Any mucilaginous exudation of a tree is considered a gum. Shellac is a distinctive product inasmuch as it is an insect secretion. True gums, as distinct from varnish gums, are soluble in water; for example, gum arabic which is used in the manufacture of adhesives. The true gums are related to sugars and carbohydrates. These products are soluble in water and insoluble in organic liquids and on heating decompose without fusion. They differ from glues in that they are soluble in cold water. Varnish gums, on the other hand, are resinous materials related to terpenes and essential oils. They are soluble in oils and organic liquids but are insoluble in water. On heating they generally melt and decompose and become more readily soluble. Although the tendency has been to decry the use of the word gum for varnish resins, the term is too well established to be eradicated. Moreover, there are certain natural products which take on the properties of both gums and varnish resins. From Indian frankincense or olibanum, a water-soluble gum has been isolated as well as terpenes and a resinlike product.

Natural varnish resins, as has been noted, can be recognized by their transparency and translucency, by their brittleness and conchoidal fracture and by their brown or yellow coloration. As a rule they possess no taste or smell in the solid state. On heating they melt and often give off a distinctive aromatic odour; on burning they yield a smoky flame. Certain of these gums will dissolve directly in various organic liquids such as alcohol or turpentine. In dispersing the more insoluble resins in oils, it is necessary to preheat the resin—a process referred to as running or sweating. No generalization can be made concerning the chemical changes which occur during the running operation, but it involves complex and deep-seated chemical rearrangements such as cracking, decarboxylation and dehydration. All of these changes are accompanied by a loss in weight; it is by such heat treatment that the resins become more readily dispersible in oil.

Solubility and hardness are the chief criteria used technically in classifying resins, and on the basis of solubility resins can be divided into the spirit-soluble and oil-soluble types. Spirit-soluble means what the word implies, solubility in commercial spirit or ethyl alcohol. Many new powerful organic solvents have been developed for the preparation of cellulose lacquers, and a number of these liquids can likewise be employed in the preparation of solutions of natural resins. Congo is substantially insoluble in all liquids. Kauri and Manila are soluble in alcohols but are insoluble in hydrocarbons. Dammar is soluble in hydrocarbons but only partly insoluble in alcohols. Accroides and sandarac are soluble in alcohol but insoluble in hydrocarbons, whereas mastic and elemi are soluble in aromatic hydrocarbons.

Spirit-Soluble Resins.—As the name balsam implies, these resins are of a fluid character and have found their chief use in healing preparations as well as for other phases of materia medica. Certain of the more aromatic varieties have been incorporated into incense. Balsams are generally considered to be solutions of resins dispersed in benzoic- or in cinnamic-acid esters, whereas oleoresins are considered to be solutions of resins in essential oils. However, it is difficult to draw a rigid distinction between balsams and oleoresins, although the latter are usually considered to be slightly more fluid. Canada balsam. which is used in cementing lenses, is not a true balsam in that it does not contain benzoic acid or its ester, but is really an oleoresin derived from *Abies canadensis*. Certain of the true balsams are the balsam of Tolú, the balsam of Peru, as well as the Sumatra and Siam benzoins and storax. The storax balsam is of particular interest from the standpoint of synthetic resins in that it was from this material that M. Bonaster in 1831 first isolated styrene, and doubtlessly this product arose through decarboxylation under heat of the cinnamic acid present in the balsam. Another variety of balsam is derived from the grass trees of Australia, and these products are referred to as the Xanthorrhoea balsams. The most important varieties are the yellow and red types, often referred to as accroides gum. This resin contains phenolic bodies which appear to possess some medicinal values, particularly for treating infections of the mucous membranes.

As stated above, oleoresins are solutions of resins dispersed in essential oils; various of these oleoresins are known as turpentines. Venice turpentine is a pale green, viscous liquid which is collected from the larch (*Pinus larix, Larix decidua*). A liquid of lemonlike odour known as Strasbourg turpentine is derived from the *Pinus picea*, whereas Bordeaux turpentine is an oleoresin derived from the *Pinus maritima* or pinaster. The chief American varieties yielding oil of turpentine are the loblolly pine. *Pinus taeda*, and the slash pine, *Pinus caribaea*. On evaporation of the oleoresin a solid resin results, together with a volatile component or spirit of turpentine. The residue from distilling Bordeaux turpentine is known as Burgundy pitch and is used in medicinal plasters.

Mastic is a soft resin melting at about 105° C. and is derived from the tree of the *Pistacia* genus which grows in the islands of the Greek archipelago. When dissolved in turpentine, it is used as a varnish for the protection of paintings; and when dispersed in bodied linseed oil, it is known as megilp and is used as a colour vehicle. Dragon's blood is a black-brown resin in bulk, but in thin films it is transparent and of a deep crimson-red colour. The resin is found on the fruits of the rattan palm growing in the East Indies. It is soluble in alcohol and benzene, but not in ether or turpentine. The resin has been used as a varnish by Italian violin makers and as a dye to colour spirit varnishes a deep red. Another resin used as a colour vehicle and in medicine is gamboge.

Dammar is one of the harder resins and is usually secured in the form of clear, pale-yellow beads, melting at about 140° C. Various other coloured varieties are obtained from the *Dammara orientalis,* which is indigenous to Malaya and the East Indies. The resin is insoluble in alcohol but dissolves in both aliphatic and aromatic hydrocarbons. Excellent varnishes can be made from these solutions, and the resulting films have a light colour and a good lustre. The resin is also readily soluble in oils without preliminary thermal processing. This resin in combination with nitrocellulose enabled the formulation of rapid-drying lacquers.

From the cypress pine, *Callistris*, which grows in Australia, North Africa and North America, one can obtain the hard resin called sandarac which is solubie in alcohol as well as in the more-powerful lacquer solvents. The resin melts at 150° C. and is used as a spirit varnish for coating paper, leather and metal. Although the initial film is somewhat brittle, it can be readily modified to yield elastic films by the addition of elemi.

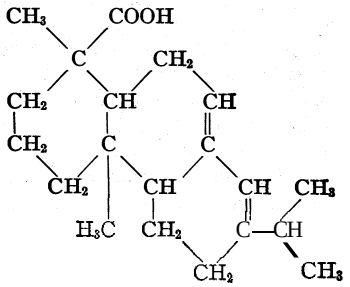
Shellac has been considered a zoochemical substance, inasmuch as it is a secretion of an insect known as *Laccifer lacca.* The word lac appears to be derived from *laksa,* an early Sanskrit word meaning 100,000. The term shellac has been used incorrectly to cover generically all of the lac products. Insects growing on certain of the trees of the genus *Acacia* produce a scaly substance known as stick-lac This material is ground, washed and filtered hot, the filtrate passing onto water-cooled drums from which it is removed in the familiar flakelike form. The button lac is a lac which has been allowed to fall on a flat surface Lac is one of the widely used resins in industry. It is also used in electric insulation as a coating for wood and metal and as a binding agent for molding composition. Certain varieties are incorporated into sealing waxes. The bulk of the shellac manufactured bears the mark T.N.

Chemically, shellac consists of a mixture of polyhydroxy acids. Two varieties have been isolated, one a hard lac and the other a softer material which appears to act as a plasticizer for the harder component. The softer portion consists primarily of uncombined acids, whereas the harder material consists of polyesters. A major portion of the hard lac was found to be a monobasic ester which could be made to undergo hydrolytic fission to aleuritic acid and lacollic lactone. Other acids which have been isolated from shellac are a tetrahydroxy'acid known as kerrolic acid, as well as shellolic acid, together with a natural yellow dyestuff known as erythrolaccin. Aleuritic acid is considered to be 9,10,16-hexadecanetriol acid ($HO-CH_2-(CH_2)_5-(CHOH)_2-(CH_2)_7-COOH$). Although the solubility of shellac is usually associated with alcohol, it is also dispersible in aqueous solutions. There appears to be some indication that on long standing alcohol may react with shellac. A white variety can be made by a bleaching process from which colourless, transparent lacquers can be made.

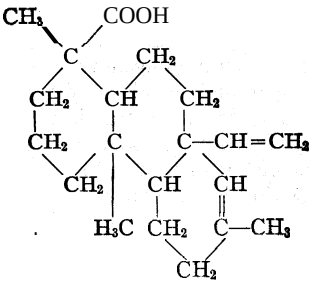
Oil-Soluble Resins.—Upon distillation of the oleoresin from the longleaf pine two materials are obtained: one a volatile component or spirit of turpentine and the other a nonvolatile, resinous residue or rosin. The word rosin is used for this product rather than resin because the latter is a term used generically to cover all of the compounds of this type. Depending on the source of the oil of turpentine, it is possible to have either gum turpentine and gum rosin or wood turpentine and wood rosin; the former variety originates from the turpentine which is secured by tapping the trees. By solvent extraction of the stumps, wood rosin is obtained, and this is generally of a darker colour. Various designations are employed to distinguish the colour of the product. The colour of French rosin is designated by the letter **A,** and the greater the number of As used the paler the grade. The U.S. designation is more arbitrary, and the better classes are known as WW (water-white) and WG (window glass). Rosin is a brittle resin which powders readily and becomes sticky when warm. Its specific gravity is about 1.070 to 1.080, and it dissolves in the usual organic liquids. Rosin is also known by the name of colophony or colophonium (from the Greek Kolophonios). The suggestion that the term was derived from two Greek words meaning sound-glue because of its use for treating violin bows does not appear satisfactory.

At one time much of the rosin was used untreated, but the trend is to subject it to chemical processing before it is offered for sale. The chief constituent of rosin is an acid known as abietic acid, and many of the uses of rosin are dependent upon its acidic properties. Combined with alkalies or with metallic oxides, soaps are obtained. The sodium soap is water dispersible and is employed in sizing paper. Sodium abietate is mixed with other alkali soaps in the manufacture of laundry soap. The lime and zinc salts find use as so-called gloss oils in the paint industry, whereas the metallic soaps derived from lead, cobalt and manganese are used as driers in paints and varnishes. When rosin is esterified with glycerol (glycerine), the resulting product is known as ester gum. Somewhat harder esterification products are made through a conjoint ester of rosin with glycerol and with phthalic anhydride. Partial decarboxylation of acid occurs when rosin is heated to elevated temperatures; such products are known as rosin oils.

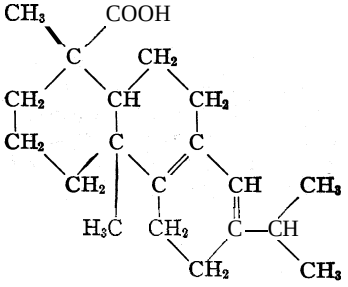
The acids isolated from rosin include abietic acid,



pimaric acid,



and laevopimaric acid,



It will be noted that certain of these acids appear to possess a system of conjugated double bonds which may account for the ease with which rosin oxidizes when it is exposed to air. By chemically combining rosin with hydrogen it is possible to obtain a product which exhibits greater stability and is less subject to discoloration on storage. The abietic acid in rosin can be made to undergo hydrogen disproportionation leading to the so-called dehydrogenated rosin. This type of chemically modified rosin, as the sodium soap, was used extensively during World War II as the emulsifying agent in the preparation of synthetic rubber. The

properties of the modified rosin were such that it could be allowed to remain in the coagulated rubber. Hydrogenation and disproportionation both cause rosin to crystallize more readily, and consequently the hydrogenation is carried only to the point where satisfactory stability can be secured without crystallization. By combining rosin chemically with certain unsaturated types of dibasic acids, such as maleic and fumaric acid, it is possible to destroy the unsaturation without inducing crystallization. It is probable that the character of the varnish which can be made from China wood oil, and rosin derivative may reside in the chemical combination that takes place between the unsaturated components of both products.

The copals form an important group of varnish resins. The word copal appears to have been derived from the Spanish or Mexican word copalli—incense. Various types of products are known—the recent varieties as well as the fossil types. Soft Manila copal is readily soluble in organic solvent liquids and in oils or, as in the case of the pontianak variety, it requires running before it can be dispersed in oil. There are several varieties which are employed in the varnish trade: kauri copal, melting at about 150° C., is derived from the New Zealand pine; Congo copal originates in the Belgian Congo; while Zanzibar copal is dug from the mainland opposite the island of Zanzibar. Some of the South American copals derived from Brazil and Colombia have attracted some attention. Copal has been esterified with glycerol in a manner similar to that employed in making ester gum. Because of the high melting point of the copal gum, it is necessary to conduct this thermal decomposition to a point much further than is customarily employed when the resin is to be dissolved in oil, and temperatures as high as 330°–340° C. are employed. Two acids have been isolated from Congo copal; one is the dibasic congocopalic acid ($C_{36}H_{58}(COOH)_2$), and the other is the monobasic congocopalolic acid ($C_{27}H_{32}(OH)COOH$).

Amber, the hardest natural resin known, finds little use in the varnish industry because of its lack of solubility. When it is incorporated in oil, so much discoloration takes place during the running operation that the resulting varnish is of a poor colour. The resin is found in the so-called blue earth, in east Prussia in the Baltic region. The fact that it is derived from a variety of *Pinus* indicates that over a sufficiently long period of time under appropriate conditions an oleoresin can be converted into a heat-infusible product.

Oriental lacquers are a distinct product derived from the Rhus *vernicifera,* a tree which is indigenous to China The process was introduced into Japan and remained secret for centuries. A milk-like emulsion secured from the tree is concentrated by evaporation to a viscous liquid which resembles a bodied oil. When this is applied as a thin film. it hardens in about a day to form a tough skin. The composition is peculiar in that it will dry only in the dark and in a moist atmosphere; exposed to light and warmth, the varnish remains tacky. The varnish contains a skin irritant, and this material may be the urishiol which is similar to a product isolated from the Rhus toxicodendron or poison ivy, which is common in the Gnited States.

Another product containing phenolic bodies is derived from the nuts of the cashew tree (*Anacardium* occidentale); the oil known as the cashew-shell-nut oil possesses materials which lead to vesicant action, but by appropriate chemical treatment the irritant is destroyed. This product has found some commercial importance in the United States.

SYNTHETIC RESINS

Synthetic resins possess most of the physical characteristics of natural resins and in addition have many unique properties of their own. Chemically there is a certain degree of resemblance between the synthetic resins of phenol-formaldehyde and the natural phenolic resins found in oriental lacquer and in accroides gum. Moreover, one can trace a certain amount of resemblance between the polyester resins known as alkyds and the polyesters found in shellac. Although it has usually been considered that the synthetic resins possess the unique characteristic of becoming insoluble and infusible on heat treatment, it is known that shellac will become insoluble on prolonged heating. and the same phenomenon has been observed with certain of the other gums. The synthetic resins are of industrial interest not only as substitutes for natural resins in the coating industry but also because they find extensive use as adhesives, textile impregnants, binders, as agents for removing ions from water solutions and as binders in the plastics molding industry (see PLASTICS).

Thermoplastic and Thermosetting Resins.—Physically it is possible to classify synthetic resins according to their solubility. There are those resins which remain permanently soluble and those which are initially soluble but become insoluble and infusible under the action of heat. The first type is known as the thermoplastic type of synthetic resin, whereas the latter is known variously as heat hardenable, thermosetting or thermocuring resins.

Linear and Three-dimensional Resins.—The permanently soluble or thermoplastic resins consist of molecules which are more or less linear in form. During solution in an organic medium, the solvent penetrates between the threadlike molecule; irrespective of the size of the resin molecule. solution will eventually occur. Under the influence of heat the threadlike molecules can be forced to move, and on cooling the impressed form is retained. On the other hand, the thermosetting resins consist of resinous molecules which are tied together three-dimensionally into a network pattern. In the initial stages where the network is small, solvent can readily penetrate the interstices of the network. but after chemical combination has taken place and a large three-dimensional network is formed, the resin becomes insoluble. Since the network is tied together rigidly, the resulting molecular structure is infusible.

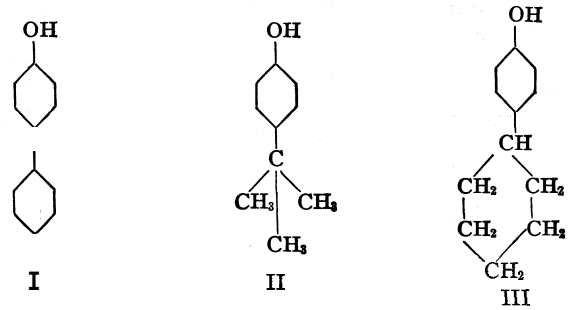
Condensation and Polymerization Resins.—Two main classes may be distinguished under chemical classification: first, the condensation resin, such as the phenol-formaldehyde or melamine-formaldehyde type, in which the molecules unite with the elimination of water; and second, the polymerization resin, in which chemical reaction takes place through loss of unsaturation, without the evolution of any low-molecular-weight material.

Coating Resins: 1. *Phenol-Formaldehyde* Resins.—The chemical combination of phenols with aldehydes was noted by many investigators in the 19th century. Among the organic chemists who had studied the reaction were C. F. Gerhardt (1853), Adolf von Baeyer (1872) and A. Michael (1883), but it was only after the advent of cheap formaldehyde in 1891 that a more extensive investigation was made toward the commercial utilization of this resin. Various investigations were made by W. Kleeberg, by A. Smith and by A. Luft, and certain of the methods employed resembled the technology which had proved successful with thermoplastic nitrocellulose plastics but which failed when such procedures were extended to thermosetting compositions. The first successful work in this field was carried out by L. H. Baekeland. Through a study of the various stages of resinification and through the utilization of a so-called bakelizer, he was able to mold many products, and in 1910 he organized the General Bakelite company. Much of the plastic entered into electrical goods. Meanwhile, the possibility of employing this condensation product to replace shellac in phonograph records was considered by J. W. Aylsworth of East Orange, N.J. On the basis of his development work, the Condensite Company of America was established at about the same time. Still another concern for the manufacture of phenolic resins was started by the Redmanol Chemical Products company, based on the studies of L. V. Redman. After much patent litigation these various companies pooled their resources.

In spite of the marked commercial success of these resins in molding, in casting and in laminating, they were not suitable for coating compositions. While it was possible to make a phenolic varnish for laminating purposes, this varnish could be dissolved only in alcohol and could not be dispersed in cheap solvents or in drying oils. The first successful attempt to use phenol-formaldehyde resins directly as substitutes for natural resins in coating composition was the result of the work of Dr. K. Albert of Germany. He found that by a preliminary heating or fluxing of the phenol-formaldehyde resin with rosin or colophony, it was possi-

ble to disperse the resulting mixture in drying oils. These products, when dispersed in China wood oil, possessed rapid drying characteristics and formed films possessing good durability.

In 1928 the first so-called oil-soluble phenolic resin appeared on the market. Through the use of appropriately substituted phenols and the combining of such substituted phenols with formaldehyde, it was possible to obtain a resin which was directly soluble in oil without preliminary fluxing with rosin. These oil-soluble phenolic resins found wide acceptance in the varnish field. Among the phenols useful for such purposes are phenyl phenol I, tertiary butylphenol II and cyclohexylphenol III, as well as certain of the



I II III

tar acids which boil in the xylenol range. The resins are incorporated into the oil by adding resin in increments at a rate at which frothing can be controlled. After addition of the resin the temperature is raised until satisfactory increase in viscosity occurs. The European procedure favours the addition of the resin to the pretreated oil, and, while it appears to yield lighter coloured and less viscous products, the resulting films appear to be less resistant chemically. Other combinations are known, certain of which consist in substituting an alkyd resin for a part of the drying oil. Durable finishes have been made from alkyd-phenol-formaldehyde oil combinations.

2. Alkyd Resins.—These resins are reaction products of polyhydric alcohols and polybasic acids, and various modifications can be made by adding monohydric alcohols or monobasic acids to the polyester composition. The derivation of the term alkyd becomes apparent when it is pointed out that the "cid" from acid was changed to "kyd" for the sake of euphony. J. J. Berzelius prepared glycerol tartrate in 1847; J. M. van Bemmelen prepared a resin by reacting succinic acid with glycerol in 1856; M. P. E. Berthelot esterified glycerol and sebacic acid in 1854; while M. A. von Lourenço prepared a resin from glycerol and citric acid in 1863. The most important dibasic acid employed in the manufacture of alkyd resins is phthalic acid. The phthalic acid (or phthalic anhydride) is obtained readily by the catalytic oxidation of naphthalene. and once this synthesis was properly worked out a ready source of this valuable commodity was available at a reasonable price. While the reaction product of glycerol and phthalic anhydride is of limited utility by itself, it is upon this structural vertebra that such ingredients as natural resin acids as well as drying and nondrying varieties of vegetable fatty-oil acids can be hung. Other dibasic acids are used where specialized properties are required. Maleic acid is obtained by the vapour-phase oxidation of benzene, while its geometrical isomer, fumaric acid. is obtained either by rearrangement of the maleic acid or by fermentation processes. Succinic acid can be prepared by the reduction of maleic acid. Sebacic acid and azelaic acids are incorporated into alkyd resins where exceptional flexibility is required. and these acids are manufactured commercially by treatment of castor oil or cottonseed oil, respectively, with caustic at elevated temperatures. Adipic acid is also available by the oxidation of cyclohexanol, which in turn can be derived from phenol. Glycerol is by far the most important polyhydric alcohol used, but ethylene glycol, diethylene glycol and pentaerythritol are used for merits of their own.

The drying-type alkyd resins first came into commercial prominence when it was demonstrated by R. H. Kienle that it was possible to form a new type of product by recombining the component parts of a drying oil. that is, the glycerol and the drying-oil acid in the presence of a saturated dibasic acid such as phthalic. Under these conditions, the cocondensation of glycerol, phthalic acid (as anhydride) and a drying-oil acid yielded a high-molecular-weight resinous condensation product in which the unsaturation of the drying-oil acid was substantially unimpaired. The result was that the resin would dry in a manner similar to the natural drying oil. Such resins in organic liquids yield solutions which resemble varnish and can be used as such Since the resins could be dispersed in relatively cheap organic liquids, these varnish solutions found wide acceptance in coating various metals, as priming paints and as enamels. They are used to finish transportation equipment such as automobiles, streetcars and railway coaches and, because of their good chemical resistance, find acceptance as enamels for coating refrigerators and washing machines. Similar resin solutions are used in ornamental hardware, to coat metal furniture. metal signs and farm equipment, and, because of good heat resistance, these resins are employed to cover radiators, smokestacks and light reflectors. They find wide acceptance as architectural enamels, traffic paints and as printing-ink ingredients.

These resins are often used alone, but they show excellent compatibility characteristics with a wide variety of other film-forming agents such as nitrocellulose, natural resins, phenolic resins and urea and melamine-formaldehyde resins With nitrocellulose it is possible to secure films possessing toughness, hardness and durability, as well as good gloss. It was this combination with nitrocellulose and alkyd resins which initially permitted the formulation of automotive finishes possessing an enamel-like quality and having excellent outdoor durability. When these resins are modified with natural resins, the melting point and hardness are increased; since such compositions release solvent very readily, they are used as rubbing and sanding vehicles. When mixed with urea-formaldehyde and melamine-formaldehyde condensation products, the alkyd resin becomes harder and more mar-resistant.

3. Polyester Resins.—While closely related to alkyd resins, the polyester materials differ from the conventional alkyd resins in that the cure is associated with a low-molecular-weight unsaturated organic liquid The polyester resins, or anhydrous thermosetting resins, usually comprise an unsaturated alkyd resin prepared from a polyhydric alcohol with an unsaturated acid such as maleic or fumaric acid. This alkyd resin is then dispersed in an organic liquid such as monomeric styrene or with diallyl phthalate. This solution, appropriately stabilized for shipping, is treated with a peroxide catalyst just before use. The catalyzed resinous material is then employed in saturating various fibrous materials such as fabric or glass fibre. The cured composite structure of resin and glass fibre found use in such widely differing applications as plastic armour, trays, radar housings, luggage and lightweight boats.

The term polyester resin has also been used for an entirely different type of product derived from terephthalic esters. Because of the high symmetry of this acid, the resulting polyesters are high-melting crystalline compositions and, when properly oriented, form a self-supporting film structure of high transparency and strength. The same resin, in oriented fibrous form, finds application both in England and in the United States as a textile fibre.

Still another polyester possessing unusual physical properties has been prepared by reacting phosgene with a phenolic substance commonly designated as bisphenol-A. In this instance the phenolic body serves as the dihydric alcohol to yield resins of outstanding toughness. Initially developed in Germany, a number of American firms are developing markets for this product.

4. *Epoxy* Resins.—When this same bisphenol-A is reacted with epichlorohydrin, one has the basis for the preparation of a curing resin where the reaction occurs without the elimination of water. Such resins have been used not only as coating materials but as potting compositions. Currently they are being utilized as textile finishes.

5. Urea-Formaldehyde Resin$.—The chemical condensation of urea and formaldehyde yields resins which are of great value both in the molding and in the coating industry. The resins are characterized by extremely light colour, and products fabricated from

such materials can be made into moldings which are colourless. The fundamental chemical investigations of Hanns John laid the foundation for the use of this resin in the plastics industry; but insofar as coating resins are concerned, it was the observation of Kurt Ripper that proved most valuable. He found that under suitable conditions the water-soluble condensation product of urea and formaldehyde could be dispersed in organic liquids. To make the resin soluble in varnish solvents for coating use, it was first necessary to conduct the condensation of urea and formaldehyde in a solvent such as alcohol and then to remove the water of condensation as an azeotrope with the alcohol. The resin thus formed in alcoholic solution could then be diluted with aromatic solvents.

By themselves, films and coatings of the unmodified urea resins are hard and marproof and possess good colour and gloss but lack distensibility. From the standpoint of their use in enamels the resins are neutral, and consequently any type of pigment can be admixed with them. When these urea resins are blended with alkyd resins, they become flexible and adhere to metal surfaces. This combination of urea-formaldehyde resins and alkyd resins is in many ways a unique combination whereby the urea resins improve certain of the deficiencies of the alkyd resins such as increasing hardness and eliminating the tendency of the oil-modified alkyd resins to wrinkle on rapid drying. The urea-formaldehyde resins under the influence of heat contribute hardness, colour and gloss to the cured film, while the alkyd resins produce flexibility, drying ability and adhesion to metal surfaces.

6. Melamine-Formaldehyde Resins.—Many of the excellent characteristics exhibited by the urea-formaldehyde resins in coatings are also shown by the melamine-formaldehyde resins. Melamine, or polymerized (trimerized) cyanamide, is a heterocyclic compound which reacts with and cures rapidly in combination with formaldehyde. Unlike urea, which is low melting and soluble in water, melamine possesses a high melting point (354° C.) and dissolves very slightly in water. It is characterized by an exceptionally stable ring system of alternate carbon and nitrogen atoms —a stability which is reflected in the resins made from it. The melamine and formaldehyde resin can be dispersed in organic solvents by procedures similar to those employed for the urea-formaldehyde condensation product. When used in admixture with alkyd resins a much faster heat cure can be secured than when urea-formaldehyde is used. The outstanding characteristics which urea resins supply to films are further enhanced with melamine resins; these are superior in resistance to various chemical reagents, outdoor durability and colour retention on exposure to both heat and light. These properties, in addition to porcelain-like appearance and resistance to abrasion, enabled such finishes to enter into automotive coatings and industrial finishes.

7. Polyethylene.—While the large majority of uses of polymerized ethylene are in moldings and in self-supporting films, there are certain newer developments whereby the thermoplastic product is converted to a thermosetting variety. When the polymer is exposed to radiation, such as the y-rays, a certain amount of hydrogen is knocked out of the system; and under appropriate conditions, depending on whether the polymer is in aerobic or anaerobic environment, the fragments will reunite to form an insoluble product. This infusible material possesses about the same electrical characteristics as the unmodified material. When this radiation is performed in the presence of polyethylene which has been milled with carbon black, one may secure an infusible, filled, molded composition.

8. Coumarone-Indene Resins.—From the light oils present in the distillation of coal tar, it is possible to secure a fraction rich in indene, coumarone and related isomers. This mixture can be polymerized by means of sulfuric acid into resins of soft or hard consistency. These synthetic resins are one of the oldest-known synthetic products and have been available from the time of the initial investigations of G. Kraemer and A. Spilker in 1890. The resins exhibit good compatibility characteristics with a wide variety of other polymeric products, both synthetic and natural, and have been used in coating of concrete, in the manufacture of antifouling ship-bottom paints, as additives to paraffin wax, in admixture with bitumens and as compounding agents in butadiene-styrene synthetic rubber.

9. Silicones.—The silicone resins are based on the silicon-oxygen skeleton rather than upon the carbon-oxygen chains or upon the carbon chain found in the conventional resins. This siloxane linkage, as the silicon-oxygen combination is called, introduces a degree of resistance to heat that is not found in those chains possessing carbon atoms exclusively. Naturally, those same reagents which can break the silicon-oxygen bridge in silicate minerals are also instrumental in causing the silicone resins to undergo cleavage; both hydrofluoric acid and strong caustic will cleave the siloxane chain in the silicone resins. Through the proper choice of ingredients, groupings can be introduced into the molecular structure whereby growth may be made to occur essentially linearly as, for example, through the introduction of saturated dialkyl-siloxy groups, or three-dimensionally through the utilization of the monoalkyl-siloxy groupings.

Various silicones can be made by changing the nature of the alkyl group, but most of the commercial production is restricted to the methyl silicones. Various polymeric structures have been made, certain of which are viscous liquids, others resinous; and even rubbery products have been produced. The liquids have found use as hydraulic oils and as instrument and transformer oils. Some of the higher-molecular-weight materials have found further application as varnishes as well as in high-temperature-resisting paints and enamels and as coatings for electrical insulation. When applied to the surfaces of glass or ceramics and baked, the silicones yield surfaces which are water repellent.

10. Fluorine Resins.—Even though elementary fluorine is a relatively reactive gas, when this element is united with carbon in the form of an unsaturated monomer and when this product is polymerized, compositions of remarkable heat and chemical resistance are formed. Compositions are commercially available where only carbon and fluorine exist in the polymer matrix, but in certain instances chloride may replace a portion of the fluorine. Two of the resins which have achieved the greatest success are tetrafluoroethylene polymer and trifluorochloroethylene derivatives. In certain instances modification has involved the use of perfluorinated propylene. While most of the applications are directed toward plastics, outstanding coatings and fibres have been prepared from these compositions. Polytetrafluoroethylene possesses an extremely low coefficient of friction, and this characteristic has been used in the fabrication of composite metal bearings. Even though only one surface is coated, the friction is reduced. Through the use of fluorinated diolefins, heat-resistant rubber compositions have been formulated.

Resin Adhesives: 1. Plywood Adhesives.—Prior to the introduction of synthetic resins for plywood construction, laminated wood was susceptible to deterioration by water and high humidity. The natural protein products such as albumin and casein could not be rendered insoluble to the same extent as later became possible with various condensation products such as phenol-formaldehyde, urea-formaldehyde and melamine-formaldehyde resins. The new resin adhesives permit the construction of plywood in which the glue line is strong, resistant to water and immune to attack by the action of fungi, molds and vermin. Such plywood can be used not only for architectural and automotive purposes but also for aeronautical and marine construction. Phenolic-resin adhesives became commercially available about 1935; urea condensation products were introduced about 1937.

Two types of synthetic glues are manufactured—cold-setting and hot-setting. Certain of the resins are supplied in powder form which requires solution prior to use, whereas other types are already dispersed in a liquid medium. Extenders such as cereal flour and wheat flour are sometimes employed where maximum strength and waterproofness are not essential. Phenolic resins yield an especially durable bond, but the resin is coloured, and the colour may bleed through thin veneers. Such colour is also a disadvantage where the glued edges are exposed. The urea resin is characterized by a rapid cure at low temperature and is widely employed in the preparation of cold-setting adhesives. The urea-resin, moreover, is colourless and will not change the colour of

the wood. Melamine resins likewise possess excellent colour characteristics, and in addition the glue line formed from this resin is resistant to cold as well as to boiling water.

Keeping pace with the development of new adhesives were new fabricating and molding techniques which allowed the construction of complicated shapes particularly necessary in aeronautics and in boat construction. Flat sheets can be "post-formed" into simple curves, but for construction of compound curved surfaces a molding procedure is preferred. This is accomplished by applying the glue to the veneers and allowing them to dry in order to permit easy handling. A mold is constructed with the exact contours needed in the finished assembly, and the coated wood veneers are placed in the mold and fastened by staples. The laminates are enclosed in a rubber bag which is evacuated in order to keep the veneers rigidly in place, and the assembly is placed in an autoclave and heated in order to render the resin insoluble and infusible. Such procedures enabled rapid construction of large aircraft parts, pontoons and motor torpedo boats.

2. *Wood Impregnation.*—Wood which has been subjected to reduced atmospheric pressure to remove occluded air can be impregnated with various resin solutions dissolved in water or in alcohol. After drying, the temperature is raised, whereupon curing of the resin occurs in the interior of the wood, rendering it harder, stronger and more resistant to water and water vapour. Through the addition of appropriate accelerators prior to impregnation the cure can be effected at a lower temperature with less damage to the structure of the wood. Phenol-formaldehyde, urea-formaldehyde and a mixture of the two resins have been employed for this purpose.

3. Other Adhesive Applications.—Many other resinous and rubbery compositions, dispersed in water or dissolved in organic liquids, are used to bind metals, plastics, glass, rubber, paper, brickwork, leather, fabrics and cork. Others are used in the manufacture of shoes, gaskets, furniture construction, lighting assemblies, sound insulation and upholstery. Certain of these adhesives have natural or synthetic rubber as a base, whereas others involve the use of synthetic thermoplastic and thermosetting resins. During World War II the reinforcement of starch by urea-resin adhesives in paperboard manufacture allowed the fabrication of paper containers which had a high resistance to water.

Resins for Textile *Applications: 1.* Continuous Coating.--One of the methods of separating electrical conductors is by means of a covering of cotton or silk, and so long as anhydrous conditions exist such insulation is satisfactory. In a humid atmosphere, the textile absorbs water, and its insulating efficiency is markedly decreased. To overcome this disadvantage, the dried fabric is treated with a varnish subsequently cured, thereby sealing the fabric. The varnish is selected in order that the water vapour transmission through the film of resin will be as small as possible. Among the resins which have been employed, the phenolic resins are the best known, although almost every type of natural and synthetic resin has been tested at some time or another for this type of insulating varnish.

2. Impregnation *of* Fabrics.—Resins are applied to fabrics for purposes other than to produce insulation; for instance, to improve the finish of cotton and rayon and to render them non-shrinking and crushproof. Resins have also been employed to bind pigments to the fabric, to minimize bleeding and crocking of dyes and as mordants for dyeing cellulosic fibres with wool dyes (animalized cellulose). Since no resin discoloration can be tolerated in uses of this type, the thermosetting resins which have enjoyed widest acceptance in this field are the urea-formaldehyde condensation products. In numerous applications, superior results can be secured only with the melamine-formaldehyde resins. Among the more notable achievements of the latter resin, the following may be mentioned: shrinkage control of cotton and wool; improvement in the crease resistance of cotton and rayon; production of durable glazes on chintz; preparation of binders to prevent thread slippage; and minimizing of gas fading of acetate colours. Many of these effects are achieved by treating textiles with low-molecular-weight water-soluble condensation products and then causing resin formation to occur on the fabric.

Quite different effects are secured by using high-molecular-weight water-insoluble thermoplastic resins which are dispersed in water. Such resins render the fabric stiff, crisp and full, and when properly formulated such properties are not destroyed by the laundering operation. Other thermoplastic resins impart good draping characteristics and improve the abrasion resistance of the textile, whereas still others are employed for upholstery finishing, raincoats, shower curtains and other waterproofing applications.

Through suitable modification of resinous ingredients, particularly through the use of phosphorous or compounds of phosphorous and halogen, it has been possible to devise finishes for cotton in which there is substantial resistance to flame. This statement does not imply that the fabric is fireproof; but when the appropriate phosphorous compounds are combined chemically with cellulose, such materials will yield water and carbon at elevated temperatures. When the flame is removed, the charred cellulose will not propagate combustion, and there is no flaming or afterglow.

Resins Possessing Ionic Charges: 1. Ion-Exchange Resins.—By the introduction of strong acid groupings such as carboxyl and sulfonic acid into a three-dimensional polymer, high-molecular-weight resins can be made up where the resin is ionic in character and where the ion is chemically bound in the resin molecule. These ionic resins in the form of sodium salt can be used as a means of softening water whereby the calcium ions of the hard water are replaced by the sodium ions from the resin. In this respect the synthetic ion-exchange resins, generally known as cation resins, behave like the natural zeolites; and, like the zeolites, the resins when used under such conditions do not change the amount of dissolved salt in the water.

Condensation products can also be prepared synthetically where basic groupings such as amino- and guanido- are bound in the resin molecule, and these so-called anion resins can replace anions. It follows that a combination of the acidic and basic resins or a cation and an anion resin can completely eliminate the mineral content of water by first allowing the cation-exchange resin in the form of a free acid to react with the salt and subsequently reacting the effluent with an anion exchanger.

Once the resins become saturated with minerals, they can be regenerated chemically and used over again as often as required. The process works most expediently where the concentration of a mineral matter is low, but the scavenging is so complete that the method has found favour not only in producing a so-called demineralized distilled water but in numerous industrial processes where the removal of ionic impurities is not possible by distillation. Ion-exchange resins have been used to remove mineral impurities from pharmaceutical preparations, dyestuffs, sugar, syrups, enzyme preparations, emulsions and glycols and formaldehyde. Other industrial uses include the recovery of valuable metals and various other inorganic and organic materials from industrial wastes. The resins have also been employed as catalysts in chemical reactions, particularly in the inversion of sugar.

Water soluble resins might most properly be designated as gums. The alternative nomenclature appears more attractive even though the definition distorts the initial distinction between resins and gums. Since the same raw materials are so closely allied with the resin industry, this terminology is useful to distinguish these synthetic products from the natural water-soluble gums. In the same way that resins may be modified, various water-dispersible functional groups may be introduced into the polymer molecule; these groups may be ionic or nonionic. By suitable adjustment a wide range of physical properties may be incorporated into the final polymer, permitting it to be more or less sensitive to accompanying ions. The carboxyl group is the preferred ionic residue, where this functional group is introduced using either acrylic and methacrylic acid or maleic anhydride. Of the nonionic residues, a much wider range of components are available such as the alcohol group, methoxides, pyrrolidone and amides. Considerable attention had been directed to various copolymers of acrylamide and acrylic acid. One of the newer outlets for these water-soluble colloids has been approved for removing the "chill haze" in beer. Polyvinylpyrrolidone will precipitate tannins and other complex proteins from beer and wine. The polymeric acids also

have applications in a number of unusual outlets such as in soil stabilization and in drilling muds. There are a number of soils which are fine powders when dry and slimy muds when wet. If, to these soils, one adds a small concentration of these polymeric acids, the mud seems to dry up yielding a friable soil permitting water to drain away without serious erosion. In drilling muds these polymeric acids allow the mud to retain water and prevent its loss of unusual formations where water loss might cause seizure of the drilling bit.

2. Resins *for* the Treatment *of* Paper.—Another resinous ion which has attracted attention is the cationic melamine-formaldehyde resin. Unlike the ion-exchange resins, the cationic melamine resin is initially dispersible in water solution. The large ion is attracted toward and adheres to the cellulose fibre. It can be incorporated into paper by adding—as an acidic dispersion to a paper-pulp suspension and after migration to the paper fibre, the resin becomes insoluble and infusible during the drying of the paper stock. The resulting product is characterized by superior fold resistance and by a nonlinting behaviour when dry, and when wet it does not disintegrate as does untreated paper. Water-dispersible urea resins with ionic properties have been developed and can be added to paper stock in a similar manner. Certain of these resins are anionic, *i.e.*, they contain sulfonic acid groups and are flocculated on the fibres through the use of aluminum sulfate while others are cationic and need no flocculation agent.

RESISTENCIA, a city of northeastern Argentina, capital of the province of Chaco (*q.v.*), is situated on the Barranqueras stream that connects with the Parana river at Barranqueras, its port. Pop. (1956 est.) 76,400. It is the administrative centre of the province and the nucleus of a zone of frontier settlement extending toward the northwest. Cotton, quebracho. leather. cattle and lead are the main industries in the area. A railroad runs west to Metán and Rosario de la Frontera, and south to Santa Fe, 348 mi. distant. (J. L. TR.)

RESONANCE, a term used in physics and related fields originally denoting a prolongation or increase of sound because of sympathetic vibration of some body capable of moving in the proper period. An example is the oscillation induced in a violin or piano string of a given pitch when a musical note of the same pitch is sung or played nearby. For resonance in acoustical theory and experiment, see SOUND; in rooms and buildings, see ACOUSTICS OF BUILDINGS; as a theory of hearing, see HEARING; in violin construction, see VIOLIN. The term has been extended by analogy to the familiar selective mechanical resonance of a springboard or bridge to certain frequencies of jumping or walking; and to the selective electrical resonance of a tuned radio circuit to the radio frequency transmitted by a single radio station. At the high frequencies used in microwaves and radar (*q.v.*), the tuned circuit is actually constructed most easily in the form of a small metal cavity resonator not unlike the cavity of an acoustical resonator such as an open-mouthed bottle. (J. R. PT.)

RESONANCE, THEORY OF, in chemistry. is an extension of the theory of valence (*q.v.*), which contributed greatly to the understanding of the structure of molecules and the structural interpretation of the chemical and physical properties of substances. The concept of resonance has been applied in chemistry in the elucidation of the nature of the covalent bond. of the partial ionic character of bonds and of other aspects of valence. Its most important chemical applications have been to aromatic molecules. molecules containing conjugated systems of double bonds, hydrocarbon free radicals, and. other molecules to which no satisfactory single structure in terms of single bonds, double bonds and triple bonds can be assigned.

For many molecules it is possible to formulate valence-bond structures which are so reasonable and which account so satisfactorily for the properties of the substances that they are generally accepted and are used as the basis for chemical reasoning. Examples of such molecules are:

hydrogen, H—H or H:H

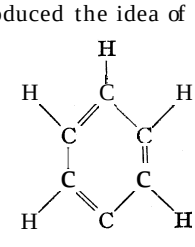
methane,  or 

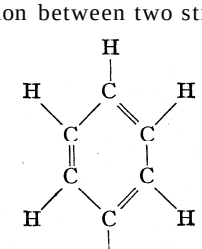
ethylene,  or 
acetylene, H—C≡C—H or H:C:::C:H

chloroform,  or 

It is sometimes found, however, that a choice cannot be made between two or more conceivable structures which are expected to be about equally stable and of which no one accounts in a completely satisfactory way for the properties of the substance. The concept of quantum-mechanical resonance provided the solution to this problem; namely, the actual normal state of such a molecule can be described as corresponding not to any one of the alternative reasonable structures but rather to a combination of them, their individual contributions being determined by their nature and stability. The molecule is then said to resonate among the several valence-bond structures or to have a structure which is a resonance hybrid of these structures. The molecule is stabilized by this resonance, its energy being less than the energy which would be expected for any one of the structures among which it resonates. This stabilization is characteristic of the phenomenon of quantum-mechanical resonance, which was discovered by Werner Heisenberg in 1926 (see below). The physical and chemical properties of the substance and the configuration of the molecule are determined by the nature of the resonating structures; these properties arc, however, not the properties averaged for the resonating structures but are instead the averaged properties as influenced also by the effects of resonance and in particular by the additional stability resulting from the resonance energy.

The aromatic substance benzene provides not only an illuminating but also the most important example of the application of the concept of the resonance of molecules among two or more valence-bond structures. The formulation of the structure of benzene as a six-membered ring of carbon atoms with attached hydrogen atoms was made by F. A. Kekulé in 1865. To make the structure compatible with the quadrivalence of carbon he introduced alternating single and double bonds in the ring, and later, in 1872, in order to account for the nonobservance of isomeric orthodisubstituted benzenes (differing in having a single bond or a double bond between the substituted carbon atoms), he introduced the idea of an oscillation between two structures:

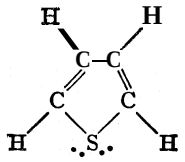




The Kekulé structure for benzene is unsatisfactory in that the substance does not show the properties of unsaturation to be expected for a molecule containing double bonds. After a period during which the centric structure of H. E. Armstrong and Adolf von Baeyer, the diagonal structure of A. Claus and the structure of J. Thiele based on his theory of partial valence were proposed, an important advance was made in the years following 1920 in the theory of intermediate stages proposed by F. Arndt and the theory of mesomerism developed by Sir Robert Robinson, C. K. Ingold and other English and U.S. chemists. The suggestion of these investigators, induced from the facts of chemistry, was that the true state of a molecule may be intermediate between those represented by several different valence-bond structures. Complete clarification of the structure of benzene was then provided in 1931 through the application of the theory of resonance and the consideration of the effect of resonance energy. According to the quantum-mechanical discussion of the structure of benzene, the normal state of this molecule can be represented as a hybrid of the two Kekulé structures  and three diagonal structures of the form  (the para bond in these structures being a weak bond, almost equivalent to a free valence on each of the para carbon atoms) and other structures which make smaller contributions. The configuration of the molecule should be a suitable average of those configurations corresponding to the individual structures. Because of the resonance the six carbon-carbon bonds are equivalent, and because of the stereochemical properties of a double bond the molecule as a whole is planar; hence the benzene molecule is predicted to be a planar hexagonal molecule, in agreement with observations made by the electron diffraction, X-ray diffraction and spectroscopic methods. Moreover, each carbon-carbon bond should be intermediate in length between a single carbon-carbon bond and a double carbon-carbon bond, the lengths of which, in molecules represented by a single valence-bond structure, are 1.54 Å and 1.33 Å, respectively. The observed value in benzene, 1.39 Å, is compatible with this prediction. Moreover, the benzene molecule is predicted from the quantum-mechanical considerations to be stabilized by resonance energy to the extent of about 40 kg.cal. per mole, relative to the value expected for one of the Kekulé structures. The amount of resonance stabilization can be estimated experimentally by measurement of the heat of combustion or heat of hydrogenation of benzene and related substances. For example, the heat of hydrogenation of cyclohexene is 28.6 kg.cal. per mole; if each of the three double bonds in benzene were the same as the double bond in cyclohexene, the heat of hydrogenation of benzene would be 85.8 kg.cal. per mole, whereas in fact the observed value is 49.8, indicating that the benzene molecule is stabilized relative to a Kekulé structure by the amount of energy 36 kg.cal. per mole, in approximate agreement with the quantum-mechanical prediction. The characteristic chemical stability and non-reactivity shown by benzene, relative to simpler unsaturated substances, may be attributed to this stabilization by resonance. It is possible, moreover, by the detailed consideration of the resonating structures to explain in a reasonably satisfactory way the other striking chemical properties of benzene, such as the influence of one substituent in determining the position of attachment of further substituents to the ring.

The structures of polynuclear aromatic hydrocarbons are similar. Naphthalene, for example, can be described as resonating among the three structures  ,  and  , with small contributions from other structures analogous to the para-bonded structures of benzene, and the resonance energy of naphthalene is found to be about 75 kg.cal. per mole.

The stabilization of the aromatic heterocyclic molecules such as thiophen results from resonance of the most important structure



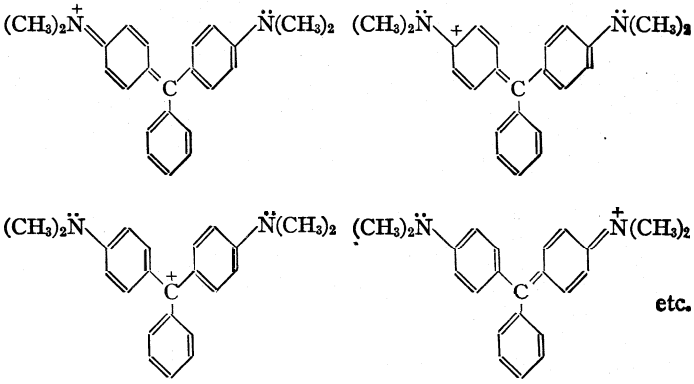
with structures such as

 and 
The resonance energy for thiophen is about 30 kg.cal. per mole.

The characteristic properties of substances which contain conjugated systems of double bonds can be readily accounted for by the theory of resonance. A molecule such as biphenyl,  , is stabilized not only by Kekulé resonance but also by the resonance energy of conjugation, resulting from the contributions of the somewhat less stable structures of type  .

For biphenyl, phenylethylene and butadiene the resonance energy of conjugation is about five kg.cal. per mole. There are two stereochemical effects of this conjugation: the carbon-carbon distance for the single bond involved in the conjugated system is decreased from the single-bond value, 1.54 Å, to about 1.48 Å, as the result of the contribution of the conjugated structures with a double bond in this position; and the double-bond character of this bond also finds expression in the tendency to hold the adjacent bonds in the planar configuration. Thrse molecules are observed to be planar or nearly planar, except when planarity is prevented by the arrangement of valence bonds or by steric effects, in which case the properties of the substance show that there is interference with the conjugation.

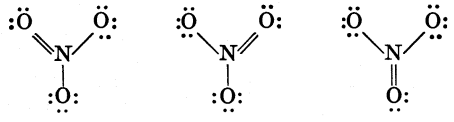
The phenomenon of resonance can be invoked in the discussion of the colour of dyes and other organic substances. The normal state of the cation of malachite green, for example, involves resonance among all structures of the sort shown below, in which the positive charge is located on different atoms within the molecule:



The excited states of the molecule are similar resonating states involving these structures. The absorption of light by the molecule, with its transition from the normal state to an excited state, occurs with great ease; the quantum-mechanical molecule can be compared with a classical oscillator in which a positive charge is resonating through a large amplitude, from one nitrogen atom across to the other, and from this comparison it can be predicted that the molecule should show intense absorption of light of suitable wave lengths.

Resonance also provides an explanation of the properties of many inorganic substances. For example, the carbon-monoxide molecule is a far more stable molecule than would be expected

from the apparent bivalence of carbon, and there was formerly discussion as to whether its structure should be written as :C=Ö:, containing a double covalent bond, or as :C≡O:, similar to the nitrogen molecule. The molecule can be assigned a hybrid structure based upon these structures, and its stability can be attributed to resonance stabilization. For carbon' dioxide the structure :Ö=C=Ö: was for many years accepted without question; later, however, evidence of interatomic distances and other properties showed that this structure is in resonance with the two structures :O≡C−O: and :O−C≡O:. Nitric oxide, which is surprisingly stable for a molecule containing an odd number of electrons, can be described as achieving this stability through resonance between the structures :N̈=Ö: and :N̈=Ö:, and may be said to have a double bond plus a three-electron bond between its two atoms. The nitrate ion, NO_3^-, resonates among the three structures



making each of the nitrogen-oxygen bonds a hybrid between a single bond and a double bond.

The general rules regarding the resonance of a molecule among alternative valence-bond structures are the following: Equivalent structures contribute equally to the normal state of the resonating molecule. The more stable structures in general make larger contributions to the normal state, and less stable structures make smaller contributions. The electronic state of the resonating molecule applies to a definite configuration of the atomic nuclei; accordingly the energy values of the individual structures to be considered in connection with the foregoing statements are those calculated for the nuclear configuration of the actual state of the molecule and not for nuclear configurations which would be the most stable for the individual structures. The strain involved in this change in configuration in some cases makes structures unimportant which otherwise might be important. All of the structures which contribute to a resonance hybrid structure must have the same number of unpaired electrons; significant resonance does not occur, for example, between a structure with no unpaired electrons (singlet state) and a structure with two unpaired electrons (triplet state).

The basis of the theory of resonance is the fundamental principle of quantum mechanics that the wave function representing a stationary state of a system can be expressed as a sum of wave functions which correspond to hypothetical structures for the system, and that, in particular, the wave function representing the normal state of a system is that sum which leads to a minimum calculated energy of the system. The concept of resonance was introduced into quantum mechanics by Werner Heisenberg in an illuminating discussion of the stationary states of the helium atom (*Z.* f. Physik, vol. 38, p. 411; vol. 39, p. 499 [1926]). Heisenberg discussed certain excited states of this two-electron atom in terms of structures in which one electron occupies an inner orbit, close to the helium nucleus, and the second electron occupies an outer orbit; and he showed that an actual stationary state can be represented by a wave function obtained by adding to or subtracting from the wave function for this structure another wave function, representing the structure in which the second electron occupies the inner orbit and the first electron the outer orbit. On the basis of analogy with the classical system of resonating coupled harmonic oscillators, he assigned the name quantum-mechanical resonance to this concept (see ATOM; QUANTUM MECHANICS; SPECTROSCOPY).

The special usefulness of the harmonic oscillator in the interpretation of quantum mechanics results from the fact that when this system is treated by the methods of classical mechanics and the old quantum theory, with the number ½ added to the integral values of the quantum number, many of the calculated properties of the system are the same as those given by quantum mechanics. The simplest system illustrating resonance consists of two equivalent harmonic oscillators with a weak Hooke's-law coupling between them. The potential energy for this system may be represented by the expression $2\pi^2 m\nu_o^2 x_1^2 + 2\pi^2 m\nu_o^2 x_2^2 + 4\pi^2 m\lambda x_1 x_2$, and the kinetic energy by $\frac{1}{2}mx_1^2 + \frac{1}{2}mx_2^2$, where m is the mass of each oscillator, x_1 and x_2 are the displacements of the oscillators from their positions of rest, ν_o is the characteristic frequency of oscillation of each oscillator when there is no coupling ($X = o$), and λ is a parameter determining the strength of the coupling. The classical equations of motion for this system can be solved in terms of the normal co-ordinates

$\xi = \frac{1}{\sqrt{2}}(x_1 + x_2)$ and $\eta = \frac{1}{\sqrt{2}}(x_1 - x_2)$. Each of these normal co-ordinates varies harmonically with the time, t, the integrated equations of motion being $\xi = \xi_o \cos(2\pi\sqrt{\nu_o^2 + \lambda}\, t + \delta_\xi)$ and $\eta = \eta_o \cos(2\pi\sqrt{\nu_o^2 - \lambda}\, t + 6_\eta)$ in which ξ_o, η_o, δ_ξ and 6, are the constants of integration. It is seen that the characteristic frequencies for ξ and η, $\sqrt{\nu_o^2 + \lambda}$ and $\sqrt{\nu_o^2 - \lambda}$ respectively, differ from ν_o. The co-ordinates x_1 and x_2 are then given by the equations

$$x_1 = \frac{\xi_o}{\sqrt{2}}\cos(2\pi\sqrt{\nu_o^2 + \lambda}\, t + \delta_\xi) + \frac{\eta_o}{\sqrt{2}}\cos(2\pi\sqrt{\nu_o^2 - \lambda}\, t + \delta_\eta)$$

and

$$x_2 = \frac{\xi_o}{\sqrt{2}}\cos(2\pi\sqrt{\nu_o^2 + \lambda}\, t + \delta_\xi) - \frac{\eta_o}{\sqrt{2}}\cos(2\pi\sqrt{\nu_o^2 - \lambda}\, t + \delta_\eta).$$

If η_o is zero, the two oscillators carry out, exactly together in phase, a simple harmonic motion with amplitude $\frac{\xi_o}{\sqrt{2}}$ and frequency $\sqrt{\nu_o^2 + A}$; and if ξ_o is zero, they carry out, with phase difference a, a similar harmonic motion with amplitude $\frac{\eta_o}{\sqrt{2}}$ and frequency $\sqrt{\nu_o^2 - \lambda}$; but if neither η_o nor ξ_o vanishes, each of the oscillators vibrates in a complex way, the amplitude changing slowly from $\frac{\xi_o + \eta_o}{\sqrt{2}}$ to $\frac{|\xi_o - \eta_o|}{\sqrt{2}}$. This is the phenomenon described as classical resonance.

The rules of the old quantum theory with zero-point energy lead to the value $(n_\xi + \frac{1}{2})\, h\sqrt{\nu_o^2 + \lambda} + (n_\eta + 3)\, h\sqrt{\nu_o^2 - \lambda}$ for the energy of this system, and to the equations

$$\xi_o = \{(n_\xi + \tfrac{1}{2})h/2\pi^2 m\sqrt{\nu_o^2 + \lambda}\}^{\frac{1}{2}}$$

and $\eta_o = \{(n, + \frac{1}{2})h/2\pi^2 m\sqrt{\nu_o^2 - \lambda}\}^{\frac{1}{2}}$

for the amplitudes. Each of the quantum numbers n_ξ and n_η can assume the values 0, 1, 2, ... Since neither ξ_o nor η_o can vanish, even when the quantum number is zero, the oscillators show the phenomenon of classical resonance in every quantized state.

The stationary states of a harmonic oscillator in quantum mechanics are described by wave functions $\psi_o(x)$, $\psi_1(x)$, $\psi_2(x)$, ..., $\psi_n(x)$, ..., corresponding to the energy values $(n + \frac{1}{2})h\nu_o$, with integral values for the quantum number n. The wave functions $\psi_n(x)$ are the successive Hermite orthogonal functions. The system of two equivalent coupled harmonic oscillators (with the same frequency) can be treated rigorously by use of the co-ordinates ξ and η, and the correct wave functions for the system are $\psi_{n\xi}(\xi)\psi_{n\eta}(\eta)$, the energy values being the same as for the old quantum theory, as given above. In this discussion of the system there is no need to mention resonance. However, the system may also be treated by a perturbation method, based on the wave functions $\psi_{n'}(x_1)\psi_{n''}(x_2)$ for the unperturbed system, with no coupling between the oscillators. For the normal state of the system, with $n' = n'' = 0$, there is only one wave function. There are, however, two independent wave functions, $\psi_o(x_1)\psi_1(x_2)$ and $\psi_1(x_1)\psi_o(x_2)$, for the next energy level; these functions correspond to states in which one oscillator has small energy, $\frac{1}{2}h\nu_o$, and the other has larger energy, $3/2h\nu_o$. It is found on treating the system of coupled oscillators that these functions are not satisfactory approximations to the correct wave func-

tions representing the two slightly different energy levels of the system, but that their normalized sum and difference, $\frac{1}{\sqrt{2}}[\psi_0(x_1)\psi_1(x_2) + \psi_1(x_1)\psi_0(x_2)]$ and $\frac{1}{\sqrt{2}}[\psi_0(x_1)\psi_1(x_2) - \psi_1(x_1)\psi_0(x_2)]$, are satisfactory; the first wave function, symmetrical in the two coordinates x_1 and x ~ reprcscnts the more stable of the two states, and the second, antisymmetrical in x_1 and x_2 (changing sign when x_1 and x_2 are interchanged), represents the less stable state. Each of these states is a hybrid of the two structures represented by $\psi_o(x_1)\psi_1(x_2)$ and $\psi_1(x_1)\psi_o(x_2)$, and, from analogy with the classical system, it has become customary to describe these hybrid states as resonance hybrids. This description is applied also to other quantum-mechanical systems which are conveniently discussed by a similar perturbation method, even though there is no close classical analogue for them.

The arbitrary nature of quantum-mechanical resonance is evident from the foregoing paragraphs. The system of coupled harmonic oscillators can be treated rigorously without mentioning resonance. It is for convenience, resulting from knowledge of the unperturbed wave functions, that these functions are used in the perturbation treatment. Quantum-mechanical resonance is not a property of a system, but of a system in relation to structures which are assumed as the basis for its discussion. In chemistry the theory of resonance is used primarily as an aid in discussing the structure and properties of complex molecules in terms of simple molecules. Simple structures similar to those which have been assigned to simple molecules are assumed as the basis for the discussion of complex molecules; and often when no one of the simple structures is satisfactory, a resonance hybrid can be formulated which represents the complex molecule in a satisfying and useful way.

The arbitrariness mentioned above is not characteristic of the theory of resonance in chemistry, but is shared by it with other branches of structural theory. It is recognized now that the structures of molecules may be correctly described by the quantum-mechanical wave functions pertaining to their normal states, and that the structural formulas assigned by chemists are symbols for the wave functions. For nearly a century chemists have written the simple valence-bond formulas H — H for molecular hydrogen, Cl — Cl for molecular chlorine and H — Cl for hydrogen chloride. The dash in the formulas H — H and Cl — Cl is a symbol for wave functions describing the normal states of these diatomic molecules formed of identical atoms. The normal state of the hydrogen chloride molecule is, of course, correctly described by its wave function, and this wave function is not rigorously related to the wave functions of the hydrogen molecule and the chlorine molecule. Nevertheless, chemists have found it convenient to assign the structural formula H — Cl to the molecule with use of a dash like that used in the formulas H — H and Cl — Cl, and to describe the hydrogen chloride molecule, like the hydrogen molecule and the chlorine molecule, as involving a single valence bond. Thus the valence-bond structural theory, which has been of great value in the development of chemistry, is an arbitrary approximate representation of the wave functions that alone correctly represent the molecules. It is conceivable that a system of symbols much different from the valence-bond dashes could be developed that would correspond just as well to the wave functions, but in fact a satisfactory alternative system of this sort has not been discovered, and chemists continue to use the valence-bond theory.

The theory of resonance in chemistry has been subjected to criticism because of its arbitrariness. The critics may not have recognized that, as mentioned above, the same criticism applies to the whole of structural theory. A structural formula for a nonresonating molecule such as ethane is a rough description of the wave function in terms of wave functions involving first a hydrogen nucleus, a carbon nucleus and a pair of electrons, and second two carbon nuclei (each with its inner shell of K electrons) and a pair of electrons. In the same way the structural formula for the resonating molecule benzene is a rough description of the wave function of benzene as a sum of valence-bond wave functions similar to the one assigned to ethane: the two Kekulé structures and other structures that are hybridized in the resonance representation of the benzene molecule do not correspond separately to states of the benzene molecule, but are symbols that. taken together, provide a rough description of the wave function of the molecule in its normal state.

The theory of resonance is of value in chemistry in the discussion not only of the configuration of molecules, interatomic distances, electric dipole moments, force constants of bonds and similar molecular-structural properties, but also of thermodynamic stability (as of aromatic substances, conjugated systems, free radicals), strengths of acids and bases, existence of tautomers. and chemical properties in general.

See L. Pauling, *The Nature of the Chenzical Bond and the Structure of Molecules and Crystals,* 3rd ed. (1959); G. W. Wheland, *Resonance in Organic Chemistry* (1955). (L. C. P.)

RESONANCE ENERGIES, also resonance potentials, are general expressions denoting energy differences between the stationary states of atoms. molecules and atomic nuclei. The term resonance was first applied because of the apparent analogy between acoustical or electrical resonance (*q.v.*) and the selective absorption or emission of certain light frequencies by these microscopic systems. Since the energy absorbed is proportional to the frequency, the microscopic system can only absorb or emit particular selected amounts of energy, which carry it from one stationary state of internal energy (or potential) to another; this holds whether the energy is the radiant energy in a particle of radiation or the kinetic energy of motion in a colliding particle of matter which hits the microscopic system.

In structural chemistry, however, the "resonance energy" of a molecule has quite a different meaning. It refers to the deviation of the energy of formation of a molecule from a hypothetical ideal energy which is conceived as the sum of the energies of its parts. Here the term resonance is supposed to be drawn from a branch of quantum theory and is only distantly related to acoustical or mechanical resonance. (J. R. Pt.)

RESORCINOL, also called resorcin, is a commercially important organic chemical. It was first obtained in 1864 by H. Hlasiwetz and L. Barth by the potash fusion of certain natural resins (galbanurn. asafetida, etc). Resorcinol. metadihydroxybenzene, $C_6H_4(OH)_2$, crystallizes in colourless rhombic prisms or plates, which dissolve readily in water, alcohol or ether. and sparingly in benzene. It melts at 110.7° C. and boils at 281° C.; its specific gravity is 1.2710. It has an unpleasant sweet taste, and its aqueous splution gives a deep-violet coloration with ferric chloride.

Resorcinol is manufactured in large quantities from benzene. The general procedure consists in sulfonating benzene with fuming sulfuric acid to benzene metadisulfonic acid and fusing the sodium salt of this acid with caustic soda.

Resorcinol is used in the manufacture of resins, plastics. adhesives, dyes, photographic-developers, explosives, cosmetics and pharmaceuticals, and as an intermediate in the synthesis of many other organic compounds. It is used medicinally as a dehydrant, antiseptic, antiferment and bactericide.

By the mid-1950s the biggest use for resorcinol was in making adhesive resins and plastics. Resorcinol-formaldehyde-type resins are used extensively as pre-dip before impregnating rayon and nylon with rubber. They are used in bonding when a cold set is necessary; *e.g.,* in bonding wooden members that are too thick to be heated.

RESPIGHI, OTTORINO (1879–1936), Italian composer, was born at Bologna on July 9. 1879, and studied at the Liceo of Bologna, at St. Petersburg (Leningrad) under Rimsky-Korsakov and in Berlin under Max Bruch. In 1913 he was made professor at the Conservatorio di S. Cecilia in Rome, and in 1923 director.

The operas *Semirama* (1910) and *La Bella addormentata* (1922) were followed by the successful *Belfagor* (1923), which reflects in the eclecticism of its style the cosmopolitan character of the composer's training. His orchestral music includes the symphonic poems *Fontane di Roma* (1917), *Pini di Roma* (1924) and *Vetrate di chiesa* (1927): in the way of chamber music he wrote a sonata for violin and pianoforte and two string quartets, while a *Concerto gregoriano* for violin and orchestra may also be mentioned.

RESPIRATION is the transfer of gases between living organisms and their environment. It goes hand in hand with metabolism. a process akin to combustion, whereby foodstuffs are oxidized. just as fuel is. with the release of energy for the needs of the organism. The gaseous exchange for man is the same basically as that for a fire, oxygen being taken out of the environment and carbon dioxide released to it. Yet biological oxidations go on at temperatures hundreds of degrees lower than those of a fire: owing to the presence of enzymes (chemical catalysts) in the tissues of animals, plants and bacteria.

Diffusion of Gases in Respiration. — Virtually every living animal. he it amoeba or whale, receives its oxygen, and gets rid of the carbon dioxide produced. by means of diffusion (*q.v.*). This process refers to the net movement of molecules, by virtue of their constant random activity, from regions of higher toward those of lower concentration. Transfer of substances by diffusion, however, is characteristically slow except over extremely short distances. This is illustrated by Fick's law of diffusion, which in simplified form is:

$$\frac{Q}{t} = \frac{D.A(C_1 - C_2)}{x}$$

where $\frac{Q}{t}$ = quantity of substance diffusing per unit time; D is the diffusion coefficient, a constant depending on the nature of the substance diffusing, on the material it is in. and on the temperature; A = the area of the surface; $(C_1 - C_2)$ refers to the concentration difference across the material; and x equals its thickness. Thus. the rate of diffusion is directly proportional to the surface area and to the concentration difference, and inversely proportional to the thickness of the substance across which diffusion is occurring.

Respiratory Adaptations in Evolution. — Sufficient gas exchange for an amoeba (diameter 0.j mm.) can be provided by diffusion across the surface membrane. With increasing size of spherical organisms, the mass of metabolizing tissue increases more rapidly than the surface area, a point being reached at a diameter of about one millimetre when the diffusing area is not large enough to meet the need. As a result, there has evolved in the majority of metazoa, or multicellular organisms, some kind of specialized respiratory system, and with it a circulatory system. These are well-suited to their function by virtue of the thin walls and large surface areas of the layers separating the circulating fluid (usually blood) from the external environment (water or air) on the one hand and from the active cells on the other.

Four chief means for respiration have appeared:

1. The first and simplest is by the way of the surface membrane, mentioned above in the case of the protozoan amoeba. Diffusion across the surface layer also suffices in certain of the more primitive metazoa, both aquatic and terrestrial. Convection often aids diffusion, by movement of sea water, as in sponges, and by the constant stirring of blood which occurs in animals with circulatory systems.

In some cases the skin shares the burden of respiration with specialized organs. Thus in cold surroundings eels and frogs can obtain most of their oxygen through the surface of the body but, when the temperature is higher, need their gills and lungs, respectively. In mammals, including man, however, the amount of oxygen received through the skin is negligible (usually less than 1%).

2. Gills represent a second chief means for respiration. Most gills are motile and are located, usually inside the body, in a moving current of water, the gas exchange being enhanced by the "countercurrent" principle, whereby the blood flows in a direction opposite to that of the water. (Purification of the blood would be much less complete were the two to go in the same direction.)

3. Third are lungs, usually aerial, though sometimes water-filled. One of the simplest forms is seen in the African pulmonate land snail, in which the lung consists of a simple air sac half a litre in volume. This is called a diffusion lung, because there is no active ventilation.

Ventilatory lungs are those in which there is a bellows function, air being moved in and out by mechanical movements. There are positive pressure lungs, in which air is pushed into the lung while the nostrils are closed, as in frogs, contractions of abdominal muscles causing expiration. Negative pressure lungs are those in which air is pulled in by expansion of a bony thoracic cage, as in man and other mammals.

With increasing demands for energy the surface area available for diffusion becomes increased by subdivision of the lung into progressively smaller and smaller air sacs. called alveoli. Thus the lung of an amphibian such as a frog contains a few hundred alveoli, whereas that of a man or a large animal contains hundreds of millions.

Greater efficiency per unit of diffusing surface exists in birds through improved ventilation. This is achieved by means of two unique anatomical features, including a tubular diffusing system (in contrast to the dead-end alveoli of mammals) and a group of air sacs located beyond the lung. An idea of this arrangement is given in fig. 1. Airways called parabronchi lead off each main bronchus and continue through the lung into one of several pairs of air sacs, located in the neck, thorax. abdomen and even inside the long bones. Each air sac is also connected to the bronchus by way of a mesobronchus. Diffusion of gases takes place in air capillaries. which, connecting adjacent parabronchi, are surrounded by a rich network of minute blood vessels.

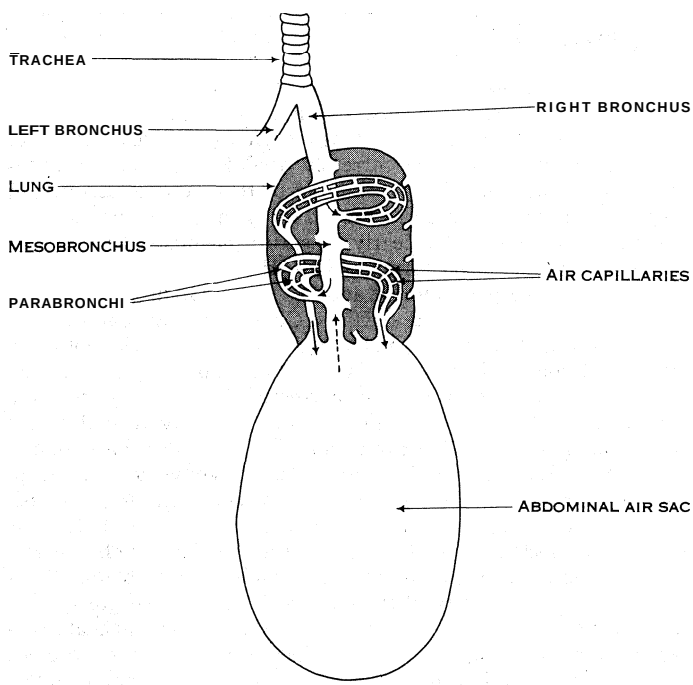

FIG. 1.— RESPIRATORY SYSTEM IN BIRDS SHOWING RIGHT LUNG AND ONE OF THE SEVERAL AIR SACS CONNECTED TO IT

Solid arrows indicate pathway of air flow during inspiration; dashed arrow, pathway during expiration

By means of rapid gas analyzers for oxygen and carbon dioxide, R. H. Shepard showed that in the chicken inspired air passes almost solely through the parabronchial diffusing system and on into the air sacs. Air leaves the lattei during expiration by way of the mesobronchus, without passing back over the respiratory surfaces, as suggested by earlier investigators. The path is therefore mouth-lung-air sacs-mouth, a process requiring a valvelike action despite the absence of anatomical valves.

4. The fourth type of respiratory mechanism consists of the tracheae of insects, narrow, air-filled, branching tubes which open

to the outside of the body by way of spiracles. A circulating fluid such as blood is of minor importance for breathing in these organisms. the air being piped directly to the tissues. Tracheal respiration has served the insects well. but because gases diffuse slowly along a narrow tube, it has limited their size, the largest apparently being the dragonfly. *(See* INSECT: *Physiology: Respiration.)*

VENTILATION OF THE LUNGS IN MAN

Distribution of Gas and Blood to the Lungs. — Incoming air is filtered by hairs in the nose. which remove larger dust particles, and is warmed and moistened as it passes down through the pharynx. becoming fully saturated with water vapour by the time it reaches the trachea (windpipe). The trachea branches into the right and left main stem bronchi. the branching continuing with the secondary bronchi. the bronchioles. and finally the respiratory bronchioles which lead into the primary lung lobule, the functional unit of the lung. The incoming air is thus distributed to the 100,000,000 or so alveoli. where exchange of oxygen and carbon dioxide between air and blood takes place. Each alveolus, 0.1–0.3 mm. in diameter. consists essentially of a bundle of capillary blood vessels suspended in air. The majority of its surface is covered by these vessels. the total length of which is about 1,500 mi.. spread out so as to provide 40 to 60 sq.m. of diffusing surface, only about 0.3 μ in thickness. The blood in each capillary is renewed each 0.9 second at rest and each 0.3 second or less during exercise. The total blood flow through the lung is about j l. per minute at rest and up to 20 to 27 l. during severe exercise. About 4 l. of air reach the alveoli each minute during rest and as much as 100 1. during exercise.

Diffusion of Oxygen and Carbon Dioxide Across the Lung. — In the closed swim bladders of the physoclist fish, a special gas gland in conjunction with a *rete mirabile* ("wonderful net" —of blood vessels) is able to secrete oxygen at concentrations up to 87% and at several atmospheres pressure. Partly because of this fact. C. Bohr and later J. S. Haldane postulated that oxygen was secreted by the lungs of human beings under certain conditions. Repeated experiments. however, have indicated that the oxygen concentration is always higher in the air of the lung than in the blood (the reverse being true for the outgoing carbon dioxide), a fact consistent with diffusion and not with secretion.

The concentration of a gas at a given temperature is expressed in terms of partial pressure. in millimetres of mercury (as indicated under *Dalton's Law of Partial Pressures and Its Application to Respiration*, below). During rest, the partial pressure of oxygen in the air of the lung is about eight to ten millimetres higher than the average partial pressure of the blood in the capillaries of the lung. This diffusion gradient increases as the oxygen consumption goes up. reaching as high as 50 mm. during severe exercise. Even with so large a mean gradient, however, the partial pressure of oxygen in the blood leaving the lung is normally only a few millimetres less than that of the air in the lung. This is because the average partial pressure of oxygen in the pulmonary capillary lies somewhere between that of venous and arterial blood.

It is customary to speak of the difiusing capacity ($D_{L_{O_2}}$) of the lung as a whole, defined as the number of millilitres of O_2 diffusing each minute, as a result of a one-millimetre difiusion gradient ior O_2. At rest. $D_{L_{O_2}}$ = approximately 2j (*i* e , 2jo ml. of O_2 diffuse across the lung per minute when the diffusion gradient equals ten millimetres). During exercise. the $D_{L_{O_2}}$ may rise to as high as 80, due presumably to enlargement of existing lung capillaries and the opening up of new ones. The $D_{L_{CO_2}}$ is about 20 times as great as the $D_{L_{O_2}}$ because CO_2 is more soluble in tissues and blood than O_2 and thereiore diffuses more readily.

Mechanics of Respiration. — Air is moved in and out of the lungs as the result of changes in the volume of the thoracic cavity, the lungs playing an entirely passive role and neither expanding. nor contracting by themselves Thus the energy required for breathing comes from muscles located entirely outside the lungs. These include. first. the powerful muscle knonn as the diaphragm. on the bottom. and, second. numerous muscles of the thoracic and abdominal walls. The lungs are nonetheless elastic sacs constantly tending to collapse. Suspended within the barrellike thoracic cape, they are prevented from doing so by the arched structure of the ribs at the sides and by the contractions of the diaphragm below.

Approximately 500 rnl. (about a pint) of air is taken in with each breath as a result of two mechanical events:

1. Impulses descending the phrenic nerve, which goes solely to the diaphragm. cause the latter to contract and move downward. Since the descent averages 1.25 cm. and the surface area equals 250 sq.cm., about 300 ml. of air (60% of the total) is taken by this means.

2. Contractions of several sets of muscles which originate at the spine and run forward and downward to the ribs elevate the latter during inspiration. causing an increase in the internal volume of the chest. About 200 ml. of air is taken in by this means. The expansion is due to the arrangement of the rihs. which are semicircular strips of bone, hinged posteriorly at the spine. the plane iormed by their circumference inclined downward and outward. Each rih may be compared to the handle of a pail. Raising the handle increases its horizontal distance from the pail. Similarly, raising the ribs increases the antero-posterior diameter of the chest. Because the rihs are hinged obliquely to the spine, the lateral dimension of the chest is also increased, the enlargement being accommodated by the flexible rib cartilages which connect the forward ends of the ribs to the sternum breastbone).

At the end of inspiration. with normal, quiet breathing (eupnea), the nervous activity originating in the respiratory centre of the brain ceases. and the chest collapses as a result of the elastic recoil of the lungs. Horn-ever. during hyperpnea — the rapid. deep breathing seen in exercise or disease — expiration becomes active. involving various thoracic muscles which pull the ribs down and abdominal muscles which push the diaphragm upward to facilitate the expulsion of air.

The mechanical factors involved in respiration have been evaluated by measuring the hydrostatic pressures in certain parts of the respiratory system, together with the volume of air breathed in or out and the rate of air flow. As a result. quantitative information is available regarding the elastic properties of the lungs. the resistance to air flow within the airways, and the mechanical work of breathing.

The significant hydrostatic pressures are: (1) Atmospheric (barometric) pressure. the reference level to which other pressures are compared. and that of the inspired air. (a) Intrapulmonic pressure, defined as the pressure inside one of the airways of the respiratory tree. The location must be specified. because as a consequence of the resistance offered by the air passages to the flow of gas (*i.e.*, air) there is a gradient of pressure in the direction of flow, just as in a river the level falls on approaching the sea. During inspiration, therefore, the pressure is lowest of all in the alveoli, rising progressively at points farther upstream to a value only slightly below atmospheric in the nostrils. (3) The intrapleural. or intrathoracic, pressure is measured within the

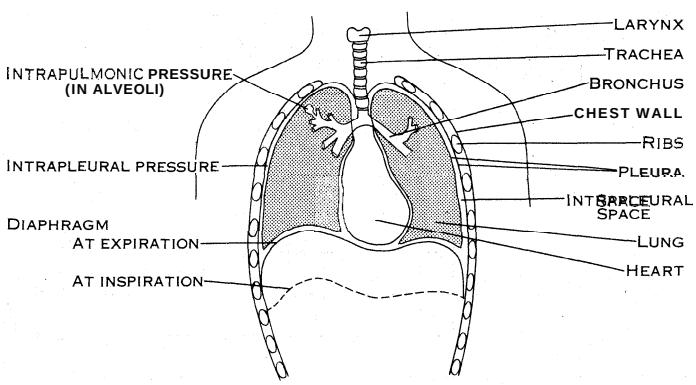

FIG. 2. — DIAGRAM OF CHEST SHOWING HOW LUNG IS ENLARGED AND AIR TAKEN IN BY DESCENT OF DIAPHRAGM DURING INSPIRATION
The process is aided by expansion (not shown) of chest wall. Intrapleural pressure and intrapulmonic pressure in alveoli are important, in the mechanics of breathing

pleural cavity. a potential space lying between the surface of the lung and the chest wall and normally filled with a layer of intrapleural lymph fluid. Thus the lungs of mammals are not attached directly to the rib cage but resemble a sac suspended within another sac (fig. 2).

If a hollow needle is inserted between adjacent ribs into the pleural cavity, the pressure is found to be subatmospheric (averaging about −3cm. of water at the end of expirationj, due to the collapsing force of the elastic tissues within the lung. If the subject now takes in a deep breath and holds it, the mouth and glottis (vocal cords) being kept open, the intrapleural pressure falls to −20 cm. of water or even lower, due to the further stretching of the pulmonary elastic tissue.

The relation of the volume of air inhaled to the change in intrapleural pressure is called the "compliance" or ease of expansion of the lung, and is expressed as litres of change in lung volume per centimetre of water. Values for normal subjects average 0.225 l./cm. (*i.e.*, after inhalation of 0.22 j l. of air the intrapleural pressure falls 1 cm. H_2O). The compliance decreases in illnesses in which fibrous tissue invades the lung.

When a given volume of air is flowing, the resulting drop in pressure is proportional to the resistance of the airways. or: $\frac{\text{pressure}}{\text{flow}}$ = resistance. (This is equivalent to Ohm's law for an electrical system.) The resistance, *R*, is expressed in centimetres of water per litre per second, and averages 2 cm./l./sec. for normal subjects. (This means that if air is being exhaled at the rate of one litre per second, the pressure in the alveoli will be 2 cm. H_2O higher than atmospheric.)

The dynamic events occurring during one respiratory cycle are shown in fig. 3. The highest air flow during inspiration and expiration = 0.5 l./sec. in this example. As predicted by the equation relating pressure to flow (assuming R = 2 cm./l./sec., as above), intra-alveolar pressure reaches peak values of ±1 cm. of water.

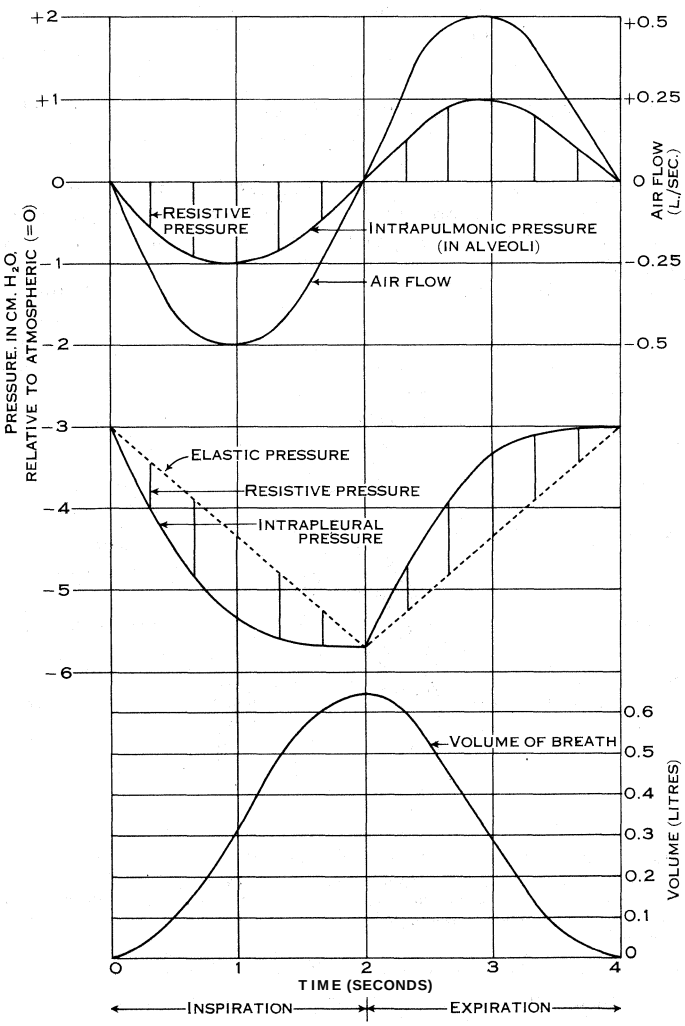

FIG 3.— INTRAPULMONICPRESSURE IN ALVEOLI, INTRAPLEURAL PRESSURE AND VOLUME OF AIR BREATHED. PLOTTED DURING ONE RESPIRATORY CYCLE. NUMERICAL VALUES SHOWN ARE FOR A NORMAL SUBJECT

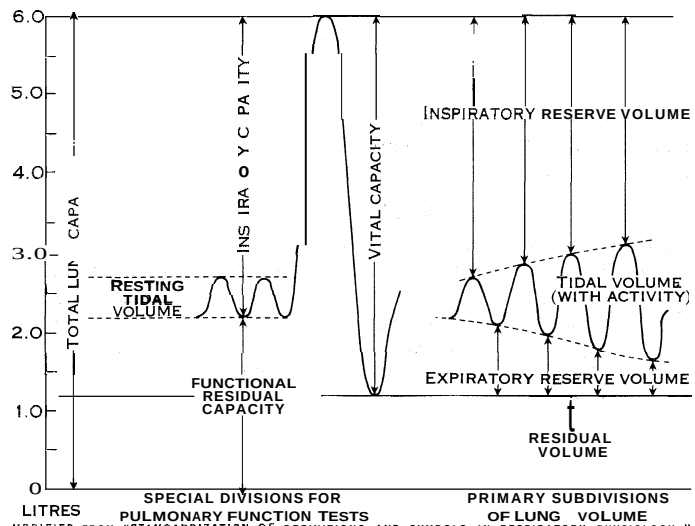

MODIFIED FROM "STANDARDIZATION OF DEFINITIONS AND SYMBOLS IN RESPIRATORY PHYSIOLOGY" FEDERATION PROCEEDINGS, VOL 9

FIG. 4.— LUNGVOLUMES AS THEY APPEAR ON THE TRACING OF A SPIROMETER (VOLUME MEASURING DEVICE)

The vital capacity is the volume of a largest single breath: the tidal volume that of a normal breath. Inspiratory capacity is the volume which can be inhaled at the end of normal expiration; expiratory reserve, the volume exhaled at the end of normal expiration; and residual volume, the air remaining even after a forced expiration. The latter volume cannot be measured by a spirometer, but by an indirect method involving collection of an inert gas such as nitrogen

The changes in intra-alveolar pressure due to resistance to the flow of air are transmitted through the lung so as to influence intrapleural pressure in the same direction. Thus, the curve for intrapleural pressure is made up of two components. elastic and resistive.

During heavy breathing accompanying exercise, the rapid flow of air causes greater swings in intra-alveolar and intrapleural pressures. The mechanical work required to inflate and deflate the lung, equal to change in intrapleural pressure times volume of air breathed, is therefore increased. It is also increased, even to the point of exhaustion. in patients with asthma, due to the wide swings in pressure needed to overcome the increased resistance to air flow which accompanies this condition.

Lung Volumes. — The lung of a man weighing 175 lb. holds about six litres of gas. called the total lung capacity. This is subdivided into components as indicated in fig. **4.** Measurement of vital capacity and of the other lung volumes is an important diagnostic procedure in pulmonary disease.

Dalton's Law of Partial Pressures and **Its** Application to Respiration. — Certain physical properties of gases in general must be considered in relation to gas exchange in the body. Whether a gas such as oxygen will combine with the hemoglobin of the blood and will diffuse from air to blood and thence to the tissues depends on the molecular concentration of the oxygen.

Chemical analysis of atmospheric air has shown that it contains the following percentages of gases, expressed as volumes of dry gas per 100 volumes of dry air: O_2. 20.94%; CO_2, 0.03%; N_2 (including the rare gases such as argon). 79.03%; totaling 100%. These percentages are surprisingly constant, not only all over the surface of the earth, but up to altitudes of approximately 2j mi.

Yet the percentage composition of a gas does not alone determine its molecular concentration. This is illustrated by the fact that a man breathing air suffers from oxygen lack at an altitude of 18,000 ft., and without an extra source of oxygen will die if he goes higher than about 25,000 ft. (*See* also HYPOXIA.j The percentage of oxygen is still 20.94, but its molecular concentration is much lower than at sea level. This is because the're is less atmosphere pressing down from above, hence the barometric pressure is less, and the molecules of oxygen and other gases are spread

farther apart.

John Dalton (1766–1844) explained this behaviour of gases by an expression which now bears his name. According to Dalton's Law of Partial Pressures. in a mixture of gases each gas behaves as if it alone occupied the total volume of the gas mixture. and exerts a pressure, its partial pressure. independent of the other gases present. The sum of the partial pressures of the individual gases equals the total pressure of the gas mixture. At a given temperature, the partial pressure provides a measure of the molecular concentration of a gas. The partial pressure, P, of a gas, G, may be calculated by Dalton's law as follows:

$$P_G = \frac{(\%\text{ concentration of G in dry gas})\ (\text{total P. of dry gases})}{100}.$$

If air at sea level were dried, then the partial pressures of its constituent gases would be:

$P_{O_2} = 20.94/100 \times 760 = 159.0$ mm. Hg
$P_{CO_2} = 0.03/100 \times 760 = 0.3$ mm. Hg
$P_{N_2} = 79.03/100 \times 760 = 600.7$ mm. Hg
Total: $P_{O_2} + P_{CO_2} + P_{N_2} = 760.0$ mm. Hg = Barometric pressure

However, air normally contains some water vapour, which exerts a partial pressure of its own. The air in all parts of the lungs is saturated with water vapour. the tension of which is related to the temperature, being equal to 47 mm. at 37° C. (= 98.6° F., body temperature). This vapour tension must be subtracted from the barometric pressure in order to get the total pressure of the dry gases in the lung. One may then calculate the partial pressures of any dry gas G. in the lung from Dalton's law (per cent concentration of each constituent gas being expressed always in terms of volumes of dry gas per 100 volumes of the dry gas mixture) as follows:

$$P_G = \frac{(\%\text{ concentration of G})\ (\text{Bar. P.} - 47)}{100}.$$

The French physiologist Paul Bert pointed out in 1878 that it was the partial pressure and not the per cent composition which determines the physiological effects of a gas. Dalton's law, he indicated, explains why it is difficult to breathe at high altitudes. The barometric pressure falls, and with it the partial pressures of all the gases. Only that of oxygen affects respiration, the P_{CO_2} in atmospheric air being negligibly low and the nitrogen gas inert. At 18,000 ft. the Po, in moist air entering the lung has fallen to only 69 mm., which is not enough to oxygenate the blood adequately. Even breathing pure oxygen, the Po, has again fallen to 69 mm. at an altitude of 44,000 ft., which is close to the "ceiling" above which a man cannot go without a pressurized cabin or flying suit.

The data in the table illustrate what happens to atmospheric air as it is breathed into the lungs. In the moistened air of the trachea the Po, is (20.94/100) (760–47) = 150 mm. However, less than this tension of O_2 is available for diffusion into the blood because the incoming air is diluted by the CO_2 leaving the alveoli, while at the same time the O, diffuses out of the air, further reducing the O, tension. Thus, there is exchanged (in almost equal quantities) O_2 for CO_2, as the incoming gas moves on down into the depths of the lung. into the alveolar ducts, the atria which open into the alveoli, and finally the alveoli themselves. The air here is called alveolar gas and is defined as gas which, in contact with the respiratory epithelium, is essentially in equilibrium with the blood leaving the lung. That is, the Po, in the gas is almost the same as in the purified blood; and similarly for the P_{CO_2}.

Thanks to the researches of Haldane, it is easy to sample alveolar gas in a normal person. The subject has only to breathe out forcefully through a long rubber tube, then the last portion of the gas exhaled is withdrawn and the percentage of carbon dioxide and oxygen present can be determined by analysis. From these data the corresponding partial pressures may be calculated by means of Dalton's law.

As indicated in the table, the P_{O_2} of alveolar gas = 100 mm., P_{CO_2} = 30 mm. These values are remarkably constant at rest at sea level and deviate only slightly during exercise. This, as will be shown below, results from the fact that the respiratory centre in the brain seems to be set to a Pco, close to 40 mm.

Respiratory Dead Space and Alveolar Ventilation. — As indicated in the table, expired gas has a higher Po, and lower Pco, than alveolar gas, because it consists of alveolar gas mixed with atmospheric air from the respiratory dead space. This term refers to that inspired air which does not come in contact with the alveolar membranes but simply fills the air passages, including the nose, pharynx, trachea, bronchi and bronchioles. At the beginning of expiration this atmospheric air is simply breathed out again, having taken no part in respiratory exchange. The dead space can be measured anatomically in a cadaver by filling the air passages with water. which presumably goes down to but does not enter the alveoli. The volume of the water is measured. and equals. on the average, 150 ml. In living subjects, the anatomical dead space may be determined by measuring the volume of gas exhaled before the tension of carbon dioxide rises sharply. Indicating the boundary between dead space and alveolar gas, this rise is detected by a rapid-acting gas analyzer nhich operates on the physical principle that carbon dioxide absorbs infrared light.

The physiological dead space is more closely related to the efficiency of ventilation because it includes not only the gas in the anatomical dead space but also that ventilating alveoli with relatively poor or no blood flow. It may be calculated from the partial pressure of carbon dioxide, as determined by chemical analysis in (1) arterial blood, (2) expired gas and (3) inspired gas (P_{CO_2} is essentially zero when breathing air), and from the tidal volume (V_T), using the so-called Bohr formula:

$$V_D = \frac{V_T\ (P_{CO_2},\ \text{arterial blood} - P_{CO_2},\ \text{expired gas})}{(P_{CO_2},\ \text{arterial blood} - P_{CO_2},\ \text{inspired gas})}.$$

For example, Pco, in arterial blood was 40 mm.. in expired gas 28, and in inspired gas 0, and tidal volume was 600 ml. Then:

$$V_D = \frac{600\ (40-28)}{(40-0)} = 180\text{ ml.} = \text{the physiological dead space.}$$

The volume of gas effectively ventilating the alveoli with each breath is equal to the difference betneen the tidal volume and the physiological dead space and when multiplied by the number of breaths per minute (f) gives the alveolar ventilation,. V_A, expressed in litres per minute. Or, in arithmetic form. $V_A = (V_T - V_D)$ f. It is V_A, rather than the total volume of gas exhaled per minute (V_E), which determines how well the-air in the lungs is being renened. With rapid, shallow breathing V_E must be larger in order to provide a given alveolar ventilation than with slow, deep breathing. This point is illustrated if we resort to a *reductio* ad *absurdum,* decreasing the tidal volume to that of the dead space. Then (V_T–V_D) = o and regardless of hon rapid the breathing is. alveolar ventilation is zero. Of course this situation is not compatible with life; no oxygen could reach the lung or carbon dioxide leave until the tidal volume was again increased. In the rapid, shallow panting of dogs. V_T is only slightly greater than V_D, the panting serving to move large volumes of air over the tongue to facilitate cooling by evaporation, without V_A being increased to the point where the lungs are overventilated and the blood carbon dioxide tension lowered below normal.

Pressures of Gases in the Respiratory Tree and in the Tissues, expressed in mm. Hg.

Sample of gas	P o	P_{CO_2}	P_{N_2}	P_{H_2O}	Total P

CARRIAGE OF OXYGEN AND CARBON DIOXIDE BY THE BLOOD

An average man at rest uses over half a pint (250 ml.) of pure oxygen per minute and gets rid of almost as much carbon dioxide, the chief by-product of the combustion of foodstuffs. These two

gases are transported in the blood largely because of the activity of hemoglobin, one of the most remarkable chemical substances produced during the course of evolution. Located inside the red blood cells, hemoglobin combines reversibly with oxygen as indicated by the reaction: $Hb + O_2 \rightleftarrows HbO_2$. Over 9j$T, of the oxygen is carried in this form; the rest being dissolved in the blood.

A much smaller fraction (about 25%) of the carbon dioxide produced is carried in direct combination. as "carbamino" hemoglobin, the majority of the CO, being transported as the result of a series of chemical reactions dependent on the special properties of hemoglobin.

Oxygen Dissociation Curve.— As the arterial blood passes through the tissues, each roo ml. gives up about 5 ml. O_2, and as it does so the Po, falls from 100 mm. to near 40, that of venous blood. This unloading of large quantities of oxygen as a result of a relatively small fall in Po, is one of the unique properties of hemoglobin. Without it. the oxygen could theoretically be carried in dissolved form, much as carbon dioxide is dissolved in soda water. But. only 0.2 ml. of O_2 would be given up under conditions comparable with those outlined above, and 25 times more blood would have to be pumped through the body, requiring an impossibly large circulatory system.

The quantity of oxygen combining with hemoglobin at various tensions of O_2 is given by an oxygen dissociation curve (fig. 5). Each point on the curve is obtained by exposing a sample of blood to a gas containing oxygen in a glass vessel. The vessel is rotated at body temperature long enough to equalize the oxygen tensions in blood and gas. The volume of oxygen in the blood sample and the Po, of the gas are then determined by chemical analysis. For example, the hemoglobin in roo ml. of blood was found to hold 14.8 ml. O_2 at a Po, of 40 mm. Another portion of the same blood was exposed to a gas with a Po_2 high enough (150 mm.) to oxygenate essentially all of the hemoglobin. The latter sample held 20 ml. O_2 per 100 ml. The oxygen saturation of the first sample was therefore 74% (14.8/20 × 100). Thus 74% of the hemoglobin molecules were combined with oxygen, the remaining 26% being reduced: *i.e.*, without oxygen. (The term oxygen saturation refers only to the oxygen combined with hemoglobin and not to dissolved oxygen.)

FIG. 5.—OXYGEN DISSOCIATION CURVES FOR WHOLE BLOOD

Increase in Pco, shifts curve to right, an illustration of the Bohr effect. Loop labeled A (arterial) and V (venous) shows approximate actual curve followed in the body

Because of the unique properties of hemoglobin, the carriage of oxygen is related to that of carbon dioxide and vice versa. Each process helps the other. This is illustrated by the fact that the position of the oxygen dissociation curve is shifted to the right by an increase in the tension of carbon dioxide (fig. 5). That is, adding CO_2 to the blood tends to drive oxygen out. This is known as the Bohr effect. It helps to deliver oxygen to the tissues. For a given fall in Po, more O_2 is released than if a dissociation curve at constant Pco, were followed. Conversely, as CO_2 is given off in the lungs, the uptake of O_2 is facilitated.

CO, Dissociation Curve and Carriage of CO_2.—There is a converse of the Bohr effect: adding oxygen to blood drives' carbon dioxide out. This. known as the Haldane effect, may be demonstrated by means of carbon dioxide dissociation curves, determined first for oxygenated and then for reduced blood. It will be noted (fig. 6) that the latter holds considerably more CO_2 at a' given Pco_2 than the former. Carriage of carbon dioxide is facilitated by the Haldane effect in much the same manner as the carriage of oxygen is facilitated by the Bohr effect. As the arterial blood gives up part of its oxygen to the tissues it is able to take up more carbon dioxide for a given increase in Pco_2 than if it remained fully oxygenated. This is shown in fig. 6 by the loop labeled "A" (arterial) "V" (venous), which describes the pathway followed by the blood as it goes from artery to vein.

FIG. 6.— CARBON DIOXIDE DISSOCIATION CURVES FOR REDUCED AND OXYGENATED BLOOD

Though the CO, dissociation curve makes it possible to predict the volume of CO_2 contained in blood at a given Pco_2, it does not describe how carbon dioxide is carried in the blood. Actually it is carried in several ways, as follows:

1. About 10% is carried in dissolved form (as carbon dioxide is in soda water).

2. About 25% is in direct combination with hemoglobin as carbamino hemoglobin.

3. About 10% is carried as carbonic acid (H_2CO_3). This splits into hydrogen ions (H^+) and bicarbonate ions (HCO_3^-). The latter, nontoxic ions, are carried inside the red blood cell and in the plasma (the clear portion of the blood). Hydrogen ions. however, which in their active state would cause damage to tissue cells, are buffered; *i.e.*, "soaked up" by the blood proteins including hemoglobin. A buffer solution (see HYDROGEN IONS), of which proteins are one example, resists change in acidity by combining with added hydrogen ions and essentially inactivating them. Because not all of the added acid can be removed from the solution, the acidity does rise slightly, but only a fraction of what it would were the buffer not present.

4. The remaining 55% or so of the carbon dioxide is also carried as carbonic acid, except that the hydrogen ions are buffered in a special way by the hemoglobin as the latter gives up its oxygen. This process is related to the Haldane effect, and depends on the fact that when hemoglobin gives up its oxygen it becomes less acid, and can therefore take up most of the hydrogen ions produced in the tissues without any change in acidity at all. This is known as the isohydric exchange.

Were carbon dioxide carried entirely in solution, no hemoglobin being present. the hydrogen ions produced from carbon dioxide would make the venous blood 800 times more acid than the arterial, the pH changing from 7.4 to 4.j. In actual fact the pH falls only 0.03 units. thanks to the two buffering mechanisms described.

The series of chemical reactions involved in the transport of oxygen and carbon dioxide by the blood are often referred to as the chloride shift (fig. 7).

The sequence of events is as follows: In the tissues, foodstuffs such as carbohydrates are oxidized, the by-products of this energy-producing reaction being carbon dioxide and water. The carbon dioxide produced immediately dissolves in the water of the blood. and 10% of it will be carried in that form to the lungs. Now, dissolved carbon dioxide reacts with water to form carbonic acid: $CO_2 + H_2O \rightleftarrows H_2CO_3$. This "hydration" of carbon dioxide takes place very slowly in water or in plasma. For this reason most of the carbon dioxide, in the form of molecular carbon dioxide. diffuses through the plasma and into the red blood cells. In the latter there is a high concentration of the enzyme carbonic anhydrase, which catalyzes (*i.e.*, speeds up) the hydration of carbon dioxide to carbonic acid inside the red cells. The car-

bonic acid ionizes slightly; that is. it splits into positively and negatively charged particles as follows: $H_2CO_3 \rightleftarrows H^+ + HCO_3^-$. The hydrogen ions are immediately taken up by the hemoglobin by the buffering mechanisms described.

A portion of the dissolved carbon dioxide combines directly with hemoglobin to form carbamino-hemoglobin. In the process. a hydrogen ion must he buffered by the hemoglobin.

More and more bicarbonate ions accumulate inside the red blood cell and are carried to the lung. A somewhat greater portion is carried as bicarbonate in the plasma. having diffused out of the red cell as a result of increasing concentration.

The plasma now contains excessive negative charges. in the form of bicarbonate ions. Unless there is an equal number of positive and negative charges in any solution, enormous electrostatic forces will be built up. Compensation for such inequality always occurs. In this case a number of negatively charged chloride ions, equal to that of the bicarbonate ions entering the plasma. are drawn by electrostatic forces into the red blood cell.

These events take place in the blood passing through the tissues. The reverse processes occur in the lungs as the blood gives off carbon dioxide and takes up oxygen.

RESPIRATORY CENTRE AND NERVOUS ORIGIN OF RESPIRATION

Since the early part of the 19th century it has been known that a small region in the medulla oblongata at the base of the brain is essential to breathing and hence to life. Occupying in a man a volume no larger than that of a good-sized grape. the respiratory centre consists of motor nerve cells imbedded in a crisscrossing matrix of nerve ,fibres. This reticular formation. as it is called. serves to co-ordinate the activity of the widely spaced respiratory muscles.

Three basic experimental approaches have been used in order to analyze in anesthetized animals the respiratory function of various parts of the medulla oblongata and a region forward of it called the pons (see BRAIN). These are: (1) effects of removal or localized destruction of discrete areas: (2) effects of stimulation by electric shocks or injected chemical solutions; and (3) recording of action potentials. the tiny electrical impulses set up by all active nerve cells. In spite of extensive studies. in the early 1960's it still was not entirely clear (*a*) how the impulses irom the respiratory neurons originate, or (b) why these bursts of impulses are rhythmically interrupted every few seconds at a rate corresponding to that of breathing.

With regard to (a) it is not surprising that reflex activity has been considered. When, for example, a person steps on a nail: nerve impulses ascend to the spinal cord and stimulate motor nerve cells there so that the foot is reflexly (*i.e.,* automatically) withdrawn.

As early as 1836 Marshall Hall stated that the medullary respiratory centre was not spontaneously active but was merely stimulated reflexly by various sensory nerves. As evidence, he cited the familiar observations that dashing cold water in the face, bathing in the cold sea or pinching certain nerves during an experiment on an animal all cause "an act of inspiration to be excited."

Subsequent inveitigation has shown, however, that reflex activity. though capable of profoundly modifying respiration. is not the prime mover. The activity of the respiratory centre is truly spontaneous, as shown by the fact that complete isolation of the medulla and the pons from all incoming nerve impulses does not abolish rhythmic breathing provided the phrenic nerves which go to the diaphragm are left intact.

Reflex activity having been eliminated. it has been suggested that the spontaneous firing of a motor neuron could be due to a steady flow of current. in the external medium. from axon (the nerve fibre) to cell body, which periodically neutralizes the normal electrical charge on the cell membranes and thus sets up nerve impulses. A similar depolarization might be caused by certain chemical substances present in the nervous system. by slowly fluctuating potentials generated by neighbouring nerve cells. or by spontaneous leaking away of the charge owing to an inherent porosity of the membrane itself.

This problem represents one of the main challenges of neurophysiology. spontaneous. repetitive activity being by no means unique to the respiratory centre. It occurs also in the neurons of the cerebral cortex. in various sensory receptors including those for touch. taste and smell. and in the sperialized muscle cells of the "pacemaker" of the heart.

More particularly the domain of the respiratory physiologist are theories concerning the manner in which rhythmicity of respiration arises. Tn·o divergent theories have been proposed and extensively evaluated. The first assumes that the medullary respiratory centre is not by itself inherently rhythmic, but produces only a steady stream of impulses. These are supposed to be periodically inhibited or turned off by influences outside the medulla, much as. in a steam erigine. the flow of steam to the moving piston is turned on and off by the valve. According to the second theory the neurons of the respiratory centre have the inherent capacity to fire in regularly repeated bursts. apart from outside influences. Such a process resembles the ticking of a watch. with the balance wheel. driven by the escapement, turning to and fro at its own natural rhythm.

Evidence for the first theory goes back to Hering and Breuer, who in 1868 discovered that inflation of the lungs with a bellows caused inspiratory activity to be inhibited, the resulting apnea or lack of breathing lasting for a considerable period. They found .that this effect was abolished when the tenth cranial nerves (the vagi) were cut. It has since been shown that receptors in the lung are stimulated by inflation. sending impulses up the vagi which cause the inhibition. The Hering-Breuer reflexes could. as their discoverers pointed out. permit a tonic (steady) inspiratory drive to be converted into a rhythmic process. Supporting evidence was obtained in 1887 by Marckwald, who discovered that, if the pons is transected in its mid-region, breathing remains normal so long as the vagi are intact. If they are then cut, the experimental animal takes a deep breath and holds it until he dies. But if the brain stem is initially severed higher up. leaving the entire pons intact, the animal continues to breathe even after the vagi are cut, though more slowly and deeply than before. Thus Marckwald had obtained evidence for a second inhibitory mechanism. in addition to the vagal one, located in the rostral (forward) part of the pons. Though either mechanism could convert the tonic inspiratory drive into a rhythmic process, it was the vagal one which was considered to be involved in normal breathing.

Much evidence in support of this periodic inhibition theory has subsequently been gathered. Lumsden in 1923 located and gave names (still used) to: (1) the pneumotaxic centre. located in the rostral pons. responsible for inhibiting the steady activity of (2) the apneustic centre, in the caudal (rearward) pons, responsible for sustained inspiration. which Lumsden called apneusis.

As a result of a comprehensive series of studies on the medullary-pontine respiratory complex. Pitts in the 1930s and '40s located by electrical stimulation a centre responsible for inspiratory activity in the reticular formation of the medulla. and a separate expiratory centre situated close to it. He obtained evidence that the

inspiratory centre was dominant to the expiratory centre. the two being interconnected by nerve fibres so that stimulation of one caused inhibition of the other, an example of reciprocal innervation as in the spinal cord.

Confirming the existence of apneusis after midpontine section and vagotomy. Pitts like Marckwald concluded that the medullary respiratory centres were not inherently rhythmic. sustained activity of the inspiratory centre being converted to periodic breathing by the vagal stretch reflexes from the lungs and, following vagotomy. by the pneumotaxic centre. This concept of the genesis of rhythmic respiration became widely accepted during the next ten years, tending almost entirely to replace the "pacemaker" theory. In the late 1940s and early '50s, however, Hoff and Breckenridge produced evidence in favour of the latter theory. They pointed out, as had some of their predecessors, that apneusis was neither permanent nor total after midpontine section and vagotomy. Superimposed on the deep. prolonged inspirations were small. rhythmic respiratory movements capable of keeping the experimental animal alive for an hour or more. More important. when they sectioned the brain stem below the pons so as to isolate the medulla. rhythmic respiration, sometimes normal. though often gasping in character, appeared. Existence of this inherent rhythmicity of the medulla was confirmed by other workers.

Hoff and Breckenridge interpreted these findings to mean that normal respiratory movements are generated by a pacemaker action. They considered the so-called apneustic and pneumotaxic centres to be simply portions of the reticular formation which serve to modify the existing spontaneous activity of the medullary respiratory centre, and similarly for the vagal afferent impulses. These did not, they believed. turn off each inspiration according to the Hering-Breuer concept.

Supporters of the periodic inhibition theory adopted the point of view that the activity of the isolated medulla is no more than the manifestation of a dormant, primitive rhythm left over from an earlier stage in the evolution of mammals.

It cannot be stated which of the two theories. periodic inhibition or pacemaker, is more nearly correct. Much research involving electrical stimulation. recording of action potentials and steady potentials. localized destruction and correlated histological examination is necessary before a clear understanding of rhythmic

REGULATION OF PULMONARY VENTILATION

Chemical Control of Breathing.— The respiratory system provides the body with oxygen and eliminates carbon dioxide. It is also one of the chief mechanisms maintaining a relatively constant internal environment, a condition essential to the survival of complex organisms, as stated by the great French physiologist Claude Bernard. Thus, it counteracts the threat of low oxygen or high carbon dioxide in the environment, and minimizes excess acidity or alkalinity of the blood caused by metabolic disorders. It performs these tasks by constantly regulating the volume of air breathed. called the pulmonary ventilation. which is the product of the rate and depth of respiration.

This process is called the chemical control of breathing because it is carried out by specialized nerve cells, sensitive to the chemical composition of the blood. which vary the activity of the medullary respiratory centre. These cells are called chemoreceptors. or sometimes chemostats. because they stabilize the internal chemical environment much as a thermostat maintains a constant temperature in a room.

Though a man will die if deprived of oxygen for only chiefly a few minutes. his pulmonary ventilation is normally regulated by the tension of carbon dioxide in the blood. rather than by that of oxygen. These facts were first discovered by Haldane and J. G. Priestley in 1905. Having developed a method for obtaining alveolar gas (which has essentially the same P_{CO_2} and P_{O_2} as arterial blood), they proceeded to analyze hundreds of samples obtained from normal subjects at various altitudes relative to sea level. and consequently at varying barometric pressures. even including that in a compressed air chamber used to treat certain respiratory disorders. In the laboratory at Oxford. at a barometric pressure (P_B) of 755 mm.. the alveolar P_{CO_2} was 42.1 mm. It remained within 1.4 mm. of that figure on a mountain 4,400 ft. high ($P_B = 646$). at the bottom of a mine ($P_B = 832$) and in the compressed air chamber ($P_B = 1.260$). Yet the corresponding alveolar oxygen tensions varied widely, being 99 in the laboratory and 79, 115 and 203 mm.. respectively, at the other locations.

These simple data, from what has come to be known as a classic experiment in respiratory physiology, indicate that the pulmonary ventilation is normally regulated by the P_{CO_2} and not by the P_{O_2}.

Confirmatory evidence was obtained by adding small quantities of carbon dioxide to the inspired air. With 3% CO_2, the alveolar ventilation was doubled, the alveolar P_{CO_2} rising only 1.5 mm.. indicating the extreme sensitivity of the respiratory centre to increases in P_{CO_2}. The increase in ventilation occurring when carbon dioxide is inhaled is compensatory, tending to minimize a rise in alveolar P_{CO_2}.

Haldane then reasoned that if a small rise in alveolar P_{CO_2} would double the ventilation, a corresponding fall might be expected to cause breathing ta cease. This was investigated by having subjects hyperventilate (*i.e.*, breathe deeply and rapidly), thereby reducing the alveolar P_{CO_2} from the normal value of 40 down to 15 or even 10 mm. Apnea (absence of breathing) invariably ensued, its duration. often of several minutes, being related to the degree oi lowering of the P_{CO_2}. That it was due to this factor was shown by keeping the P_{CO_2} essentially normal by having the hyperventilating subject breathe air containing 5% carbon dioxide. following which no apnea occurred. Nor did it occur on quietly breathing pure oxygen, thus eliminating increased P_{O_2} as a cause of posthyperventilation apnea as had been suggested by a previous investigator, who had believed that respiration was normally regulated by the oxygen tension of the blood.

That oxygen lack is at best a poor stimulus to respiration, by no means as effective as a rise in carbon dioxide, was emphasized by Haldane. Little increase in ventilation occurs until the alveolar P_{O_2} falls from its normal value of 100 mm. down to about 70 mm., equivalent to an altitude of between 6,000 and 7,000 ft. Yet the hyperpnea cannot be accounted for in terms of CO_2, since the tension of the latter falls, by ten millimetres or more. during hypoxia. It was proposed. but never proved. that lactic acid might be the stimulus. the lack of oxygen causing its production inside the medullary respiratory centre. Even in Haldane's time the latter was known to be the site where carbon dioxide exerted its influence on respiration, and it was natural to expect hypoxia to act there too.

The explanation was not forthcoming until the early 1930s, when C. Heymans and his associates demonstrated the existence of respiratory reflexes originating from the carotid arteries in the

neck. Close to uhere the latter branch into the internal and external carotid arteries lie, first. a set of pressoreceptors important in the regulation of blood pressure (*see* CIRCULATION OF BLOOD) and also influencing respiration, and, second. a set of chemoreceptors sensitive to decreases in the oxygen tension of arterial blood and to a lesser extent to rises in P_{CO_2} and acidity. Similar sets of presso- and chemoreceptors are located at the arch of the aorta The carotid and aortic bodies or glomi, as these chemoreceptors are called. consist of rounded epithelioid receptor cells. richly innervated by nerve fibres and provided with a profuse supply of arterial blood Impulses are generated in the receptor cells nhen the P_{O_2} falls sufficiently Carried by nerves to the medullary respiratory centres. these impulses increase the activity of the centre and thus increase pulmonary ventilation.

That oxygen lack stimulates respiration almost entirely by way of these peripheral chemoreceptors has been shown by the fact that after their nerves are cut the inhalation of nitrogen almost always decreases respiration. due to depression of the medullary respiratory centre. whereas normally the ventilation is more than doubled.

Though these chemoreceptors serve chiefly an emergency function, normal respiration being controlled mainly by the action of CO_2 (and probably acid also) on the medullary respiratory centre, evidence exists for a slight degree of ventilatory drive due to O_2 even at sea level.

It is of some interest to speculate what would happen were respiration controlled in man not largely by P_{CO_2}, but by P_{O_2}, as it appears to be in lizards, snakes and fishes. Assuming the alveolar P_{O_2} to be held at 100 mm., the normal value at sea level, the pulmonary ventilation would be approximately doubled on the 4,400-ft mountain referred to by Haldane, and would be reduced to less than one third in the pressure chamber. Values for alveolar Pco, would be approximately 20 and 140 mm.. respectively. Corresponding acidity of arterial blood, expressed in terms of pH, would be 7 6 (alkaline) and slightly below 7 (markedly acid). Such marked deviations from the normal Pco, of 40 and pH of 7.4 would probably lead to muscular spasms, known as tetany, in the first instance and to CO_2 narcosis and anesthesia in the second.

Nature of the Chemical Stimulus to the Respiratory Centre.——After Haldane's discovery of the importance of carbon dioxide in the control of respiration, physiologists sought to find its mode of action When, as the result of new measuring techniques, data relating rise in arterial acidity to rise in P_{CO_2} became available. Winterstein, and Haldane himself, came to believe that the pulmonary ventilation was regulated by the arterial hydrogen ion concentration rather than by the Pco, This reaction theory, as it came to be called, gained further support from the fact that in metabolic acidosis, as in diabetes. respiration was increased even though the P_{CO_2} was found to be below its normal value of 40 mm.

There were, however, experiments of a quantitative nature which cast doubt on the reaction theory. Krogh found that for a given increase in acidity produced by the acid-producing salt ammonium chloride, the hyperpnea was trifling compared to that accompanying inhalation of CO, Similarly, Hooker perfused the medulla of an anesthetized animal with blood kept at constant acidity, first by adding hydrochloric acid and second by adding carbon dioxide, the increases in pulmonary ventilation being 128 and 3,069, respectively. The inference to be drawn from these and similar experiments is that carbon dioxide has a marked stimulating effect on respiration in addition to its property of increasing the acidity of the blood.

That a special property of molecular carbon dioxide did not need to be postulated was illustrated by the experiments of Jacobs in the early 1920s. The flowers of certain carnations mere known to be blue in alkaline media and red in acid Blue flowers immersed in acid solutions remained blue for long periods, but in solutions saturated with carbon dioxide and buffered to the alkaline side with sodium bicarbonate. the flowers turned red immediately. The explanation was that dissolved carbon dioxide was able to diffuse freely into the interior of the cell, rendering it acid With the floners in acid solution, however, the acid went in very slowly, because the cell membrane was relatively impermeable to the positively charged hydrogen ions. The same effect was observed in living sea urchin eggs Jacobs' investigations made it clear that the acidity inside the cells of the respiratory centre might differ aidely from that of the arterial blood.

On the basis of these findings, Winterstein modified his original reaction theory so as to identify the acidity inside the cells of the respiratory centre, rather than that in the blood. as the unique stimulus to respiration. Gesell pursued this idea, and found evidence for disparities between the acidity of the blood and that of the cerebrospinal fluid nhich surrounds the central nervous system. including the medullary respiratory centre These differences are known to be due to the blood-brain barrier, composed of the meninges covering the brain which prevent free passage of many substances including hydrogen ions

In spite of numerous investigations, there remained two schools of thought regarding the "unique" chemical stimulus to the respiratory centre, if indeed there is one The Scandinavian group, led originally by Krogh and later by M. Nielsen, advocated P_{CO_2} as the stimulus, the hyperpnea of metabolic acidosis being explained on the basis of increased sensitivity of the respiratory centre to P_{CO_2} as a result of the acidosis. On the other hand, Winterstein, Gesell and others advocated intracellular pH.

An ingenious attempt to resolve the dilemma is provided by the multiple factor theory of J. S. Gray, according to which each chemical stimulus to respiration acts in its own right, the existing level of ventilation being the resultant of the additive effects of the known stimuli, namely P_{CO_2}, hydrogen ions (acidity) and, during hypoxia. P_{O_2}. For example, the marked response to breathing CO_2 could be due to the effect of increased P_{CO_2} plus that of the increased acidity produced by adding CO_2 to the blood. On the other hand, the much smaller response which accompanies an equal degree of acidity produced by metabolic acidosis could be due to the difference between a stimulus, increased acidity, and an antagonist, decreased P_{CO_2} (below normal in this condition). In other words, the addition is algebraic in this instance.

The concept of an antagonist—i e., a less than normal contribution of a respiratory stimulus—though implicit in the finding by Haldane of apnea following hyperventilation when the Pco, was only slightly reduced, is one of the keystones of Gray's theory. According to him, there is no unique stimulus, all three combining their effects.

Gray's theory is basically descriptive, without specifying how or where CO_2 or hydrogen ions exert their actions Each could act as a specific stimulus inside the cell, the two effects being combined. Or CO_2 could act simply as an acid inside the cell. modifying, together with acid from other sources. the intracellular pH in keeping with the Winterstein-Gesell acid theory. Clear answers to these problems probably must await development of a direct means for measuring the pH inside the cells of the respiratory centre.

Regulation of Ventilation During Physical Exercise.—Haldane proposed that carbon dioxide was responsible for the increase in breathing which accompanies exercise. The experimental data, however, have not supported him. The highest ventilation produced by increasing the P_{CO_2} is about 70 l. per minute during breathing of 7.5% CO_2, the alveolar P_{CO_2} then being 60 mm., which is 20 mm. above normal. In severe exercise, not only is the minute volume considerably higher, 100 to 120 l. per minute, but, what is more striking, the P_{CO_2} is actually below its normal value of 40 mm. Hence an elevated P_{CO_2} cannot possibly explain the great increases in ventilation observed during severe exercise, and can account only partially for the hyperpnea of moderate exercise, when the Pco, is only slightly (two to four millimetres) above normal.

No known simple factor can explain the increase in ventilation occurring during exercise. Several stimuli appear to combine their effects and in such a way that the volume of air breathed increases in direct proportion to the increase in work done and the oxygen used. It is difficult to conceive of so precise a regulation without the intervention of a chemical factor uhich, produced as a result of the exercise, acts so as to increase the ventilation. Yet no such agent has been found. It is true that an increase in blood acidity

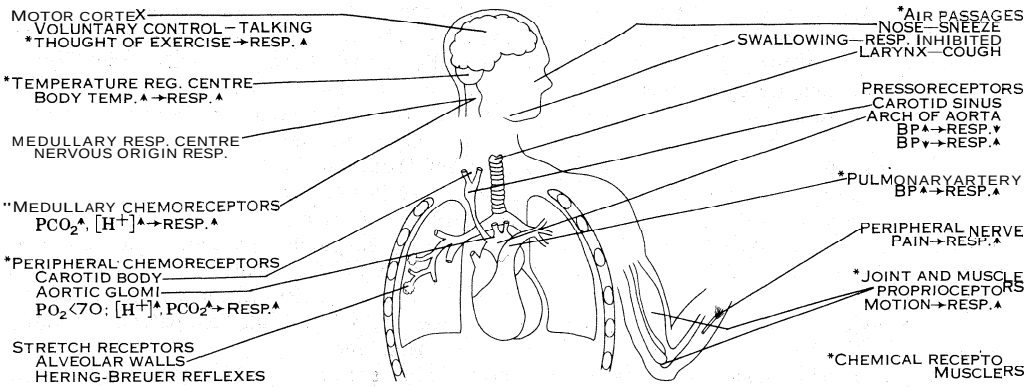

FIG. 9.—DIAGRAM SUMMARIZING PROCESSES INVOLVED IN THE NERVOUS AND CHEMICAL CONTROL OF RESPIRATION

Asterisks indicate factors probably contributing to the increased breathing of exercise. Horizontal arrows (→) denote "leads to"; vertical arrows indicate increase (↑) or decrease (↓) in the factor referred to. Bp is the symbol for blood pressure

occurs during severe exercise and could be a factor in that condition alone. An increase in sensitivity of the respiratory centre to P_{CO_2} has also been postulated. A rise in body temperature can produce such an increase. and the body temperature does 'rise 1° or 2° C. or more during severe exercise. One investigator found an 11 litre. increase in ventilation per degree rise in body temperature, due at least partly to increase in sensitivity of the medullary respiratory centre to CO_2.

Nervous reflexes also contribute their share. Passive motion of the limbs in man or animals produces an increase in ventilation. The effect is abolished n-hen the sciatic nerve to the leg is anesthetized by injection of procaine or if it is cut. The impulses responsible are known to arise in the special "position-sense" nerve endings (proprioceptors) located in joints and muscles. which permit an individual to tell whether a joint is extended or flexed and how much. The effect of such afferent impulses from moving limbs is not great, however. accounting at most for only about 20% of the increased ventilation.

Probably nerve impulses from the motor regions of the cerebral cortex which control the muscles involved in exercise also influence the respiratory muscles by a process of irradiation. or spread in the reticular substance of the midbrain. Psychic factors also serve to increase ventilation. the latter rising considerably even before the start of a competitive athletic event. Yet such factors could hardly account for the observed correlation between minute ventilation and oxygen consumption.

Other nervous and chemical factors have been proposed to help account for the hyperpnea of exercise. These include afferent impulses initiated by movement of air through the smaller air passages. nerve impulses originating as the result of a rise in the blood pressure in the pulmonary artery. impulses produced by nerves sensitive to accumulation of metabolites such as lactic acid in exercising muscles, or to rises in temperature of these muscles. Yet the experimental evidence for these other nervous and chemical reflexes is dubious at best. It is entirely possible that physiologists are at a stage in attempting to explain the hyperpnea of exercise similar to that existing before the discovery of the peripheral chemoreceptors. when many theories were proposed to account for the stimulation of ventilation by hypoxia, though none proved adequate.

Those reflexes which may contribute to the hyperpnea of exercise are marked by an asterisk in fig. 9. This diagram also gives some idea of the many other factors which influence breathing.

RESPIRATORY SYSTEM, ANATOMY OF. The respiratory tract, including all the organs concerned in the act of breathing, consists of the nasal cavities, pharynx (throat), larynx: trachea. bronchi and lungs (see fig. 1). In ordinary breathing the nasal cavities warm, moisten and filter the inspired air (*see* OLFACTORY SYSTEM). The pharynx. which lies between the nasal cavities and mouth. above. and the larynx and esophagus, below, is a transitional zone in which the pathways of swallowing and breathing cross each other (*see* THROAT). In certain mammals in which the sense of smell is all-important, breathing through the nose is made obligatory by an interlocking of the epiglottis and the uvula of the soft palate. In man there is a gap between the two; consequently food is sometimes misdirected into the larynx and windpipe.

Larynx.—When the physician looks into the throat with a laryngoscope. he is examining the mucous surfaces of the interior of the voice box. Reflected in his mirror are the structures shown in fig. 2: a lid-shaped epiglottis that can be folded backward over the larynx: the aryepiglottic folds, backward extensions of the epiglottis that help prevent spilling of food into the larynx; the pear-shaped piriform recess, through which food is guided into the esophagus; the vallecula ("little valley"). n-hich separates the epiglottis from the tongue; the ventricular folds or false vocal cords; and beneath them the glottis ("mouthpiece of a flute"). The latter consists of the vocal folds (or cords) and the slit between them, the *rima* glottidis.

The ventricular folds point downward and. when closed by action of sphincter muscles, form an exit valve that permits the building up of abdominal pressure, as in straining at stool or in expulsion of the fetus. Coughing is produced by releasing the air explosively. Between the ventricular and vocal folds of each side is a pitlike cavity. the ventricle. which is prolonged into an appendix or saccule. In the great apes these saccules become enormous accessory organs of respiration.

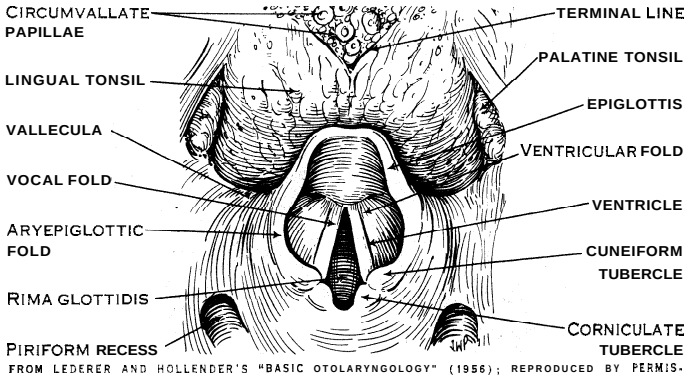
Numbers indicate the cervical vertebrae



FROM LEDERER AND HOLLENDER'S "BASIC OTOLARYNGOLOGY" (1956); REPRODUCED BY PERMISSION OF F. A. DAVIS COMPANY

FIG. 2.— LARYNGOSCOPIC VIEW OF LARYNX

The vocal iolds are whiter than the ventricular folds because their areas of contact with each other are covered by stratified scalelike epithelium. These are the hard membranes that vibrate to produce sound. In breathing. they approach each other rhythmically. When closed by the surrounding muscles they form an inlet valve that prevents the entrance oi air during fixation of the ribs for movements of the arms.

The physician examines the cords for evidence of inflammation, for the presence of tumours and ior paralysis of muscles that regulate their action. They stretch across the interior of the voice box from the shieldlike thyroid cartilage, in front. to the vocal process of the pitcher-shaped arytenoid cartilage. behind (see fig. 1–3). The arytenoids are the key to the understanding of the movements of the cords. These cartilages slide and rotate upon the signet portion of the ringlike cricoid cartilage (see fulcrum, fig. 3), abducting or adducting the cords in response to muscles that insert upon the muscular process of each arytenoid. Tensing and loosening of the cords are produced, respectively, by the crico-thyroid muscles, which tilt the thyroid cartilage forward. and by vocal muscles within the cords that shorten the distance between thyroid and arytenoid cartilages. (For action of the laryngeal muscles in the production of sounds, see VOICE.)

Injury of the recurrent laryngeal nerves, or their more central connections, results in paralysis of all laryngeal muscles except the crico-thyroids.

Trachea. — The trachea, or windpipe, is the tube that connects the larynx and the bronchi (see fig. 4); it is from 4 to 4 in. long and lies partly in the neck and partly in the thorax. It begins where the larynx ends. at the lower border of the sixth cervical vertebra (see fig. 1), and divides into its two bronchi opposite the fifth thoracic vertebra. The tube is kept open by rings of cartilage. shaped like horseshoes and embedded in an external fibroelastic membrane. Behind. where the trachea rests upon the gullet, there is a layer of smooth muscle that can draw the open ends of the rings together and so diminish the calibre of the tube.

Inside there is plentiful submucous tissue containing submucous glands and much lymphoid tissue. The whole is lined internally by columnar ciliated epithelium. These cilia form one segment of a continuous field of upward stroking lashes that carry mucus and inspired material irom the lungs to the larynx. At this upper level it can be coughed up.

The cervical part of the tube is not much more than an inch in length, but it can be lengthened by throwing back the head. This is the region in which tracheotomy is performed. At the bifurcation oi the trachea the lowest cartilage forms a carina, or keel. In birds the bifurcation is converted into a vocal organ. the syrinx, consisting of vibrating membranes controlled by special muscles. In man, the topographic relations, at this level, are of special importance (see fig. 4). If the aorta is pathologically enlarged it may compress the esophagus, causing difficulty in swallowing; or press against the left bronchus, causing difficulty in breathing; or put traction upon the left recurrent laryngeal nerve where it curves around the arch oi the aorta, thus affecting the voice.

Below the bifurcation right and left primary bronchi diverge to enter the hilum of the lung. Since the right bronchus more nearly continues the direction of the trachea than the left, foreign bodies swallowed inadvertently by children fall more commonly into the right than into the left lung.

As each primary bronchus enters the lungs it is accompanied by a large pulmonary artery, carrying venous blood to the lung, and a large pulmonary vein conveying oxygenated blood to the heart (see fig. 5). In addition there are small bronchial arteries, lymphatics and nerves.

Lungs. — These are the organs that are formed when right and left bronchial buds of the embryo push out into that portion of the body cavity that later becomes the pleural cavity (see COELOM AND SEROUS MEMBRANES). Each lung, therefore, represents the total branching of the primary bronchus plus its supporting tissue: its associated arterial and venous trees and the layer of pleura that surrounds it. Medially it is attached by a reflection of the pleura to the mediastinum, the vertical wall that divides the chest into right and left compartments.

Grossly. each lung is a somewhat conical organ having an apex, which extends into the neck; a base. which rests upon the diaphragm; and other surfaces that are costal and mediastinal. Superficially the right lung is cleft by horizontal and oblique fissures into three lobes; the left lung is cleft into two lobes. This asymmetry is characteristic of most mammals. Equally significant divisions are the bronchopulmonary segments, first recognized as such in 1932. These are polyhedral wedges of tissue separated from each other by veins and thin connective tissue membranes. They represent the zones of distribution of the larger secondary bronchi. On the right side ten such segments have been recognized. On the left the number is restricted to nine. since apical and posterior segmental bronchi have developed into a single shrublike unit. Although segments are not demarcated by surface fissures they are nevertheless surgical units that can be excised individually, thus making possible the preservation of adjacent healthy tissue that formerly was sacrificed when surgeons were compelled to remove entire lobes in order to remove small lesions.

Commonly, three techniques are available for determining the site of tumours or other lesions in lobes and segments: (1) X-rays of the chest; (2) direct examination of the orifices of the segmental bronchi by means of a bronchoscope lowered into the trachea; and (3) X-rays of the bronchial tree (bronchograms) made after the tree has been filled with a radiopaque fluid.

Bronchial Divisions. — Each of the segmental bronchi divide

FIG. 3.— CARTILAGES OF LARYNX SEEN FROM BEHIND

more or less dichotomously until there are from 20 to 25 generations of branches ending in the terminal bronchioles. The first ten generations are widely spaced divisions and occupy two-thirds to three-fourths of the way to the periphery. These are secondary bronchi, lined by ciliated, pseudostratified epithelium. In their walls are cartilage plates, to keep the air passages open; mucous glands to moisten the ducts; and a mesh of smooth muscle fibres to regulate the calibre of the tubes. These tissues are supplied by bronchial arteries of aortic origin, and by nerves; and are drained by lymphatic vessels and veins. The remaining 10 to 15 generations are bronchioles. These branches have no cartilages. are more closely spaced and have a fairly uniform diameter (3–1 mm.). They end in terminal bronchioles, which give rise to the respiratory portions of the tree.

Finer *Structure* of *Lung.*—The terminal bronchioles are small tubes, 0.6 to 0.7 mm. in diameter. They are lined by ciliated columnar epithelium and completely invested by smooth muscle. Spasms of these muscles, as in asthma, can shut off the passage of air. Each of these short tubes gives rise to several generations of respiratory bronchioles (see fig. 6), so named because they contain scattered alveoli. Each of these bronchioles gives rise to from 2 to 11 alveolar ducts, and each of these to five or six alveolar sacs lined by polyhedral alveoli. It has been estimated that there are from 300,000,000 to 400,000,000 alveoli in the lung. These are the functional units (see RESPIRATION). Each is $\frac{1}{5}$ to $\frac{1}{4}$ mm. in diameter and is lined by an extremely thin epithelial membrane, outside which is a rich capillary plexus. As seen under the electron microscope. adherent alveolar and capillary walls measure only $\frac{1}{2500}$ mm. in thickness. It was the first sight of blood corpuscles circulating through these capillaries in 1661 that led Malphigi to exclaim. "I see with my own eyes a certain great thing" (Sir Michael Foster. *Lectures* on *the* History of *Physiology*, p. 96, Cambridge University Press, 1901).

According to W. S. Miller. all the branches of an alveolar duct form a primary lobule. Other investigators start with the respiratory bronchiole. Hundreds of these primary lobules constitute a secondary lobule. The latter can be identified on the surface of the lung as one of many irregular polygons marked out by pigment and measuring from 1 to $2\frac{1}{2}$ cm. in diameter. So far, the finer structure of the lung has been presented as a pattern of aborization. However, it should be realized that these peripheral respiratory units become so crowded together that the lung appears in microscopic sections as a meshwork of thin walls separating air spaces.

FIG. 5.— SEGMENTAL BRONCHI AND PULMONARY VESSELS

Development of Lungs.—The rudiment of the tracheobronchial tree appears as early as the 25th day of intra-uterine life in the form of a laryngeotracheal groove on the ventral side of the tubular foregut just below the pharynx. A day or so later, two epithelial lung buds push out from the lower end of this groove, indenting the pleural cavities. These are the primitive lung sacs or primary bronchi. This period is a critical one. for occasionally one lung fails to appear. In rats, this condition has been produced experimentally by feeding the mother a diet deficient in vitamin A.

By the 31st day each bronchus has developed secondary buds, which become the lobar bronchi. Meanwhile the laryngeotracheal groove is being separated from the esophageal portion of the gut by a wall that moves progressively upward from the level of the bronchial buds to the larynx. As each lobar bronchus continues to grow it divides dichotomously. By the 36th day all ten segmental buds have appeared, giving the exterior of the lung a scalloped appearance. By the 40th day several additional generations of branchings have appeared. so that a model of the bronchial tree resembles great clusters of grapes.

This period of branching of epithelial tubes continues through the fourth month of fetal life and is known as the glandular period. Some 17 generations of branching are then established. The last seven of these are lined by cuboidal epithelium. Between the fourth and sixth months—the canalicular period—capillaries protrude into the lumina of the more peripheral bronchi, pushing connective tissue fibrils ahead of them to separate the cuboidal cells. Such protrusions give rise in time to the malls of alveoli. At six months there are no alveoli as yet, but the number of capillaries protruding into the lumina is sufficient to support for several hours the life of an infant born prematurely at this age. In the alveolar period—seven months to term—vascular walls have protruded far enough into the lumina to outline shallow alveoli. From this time on the premature infant is viable.

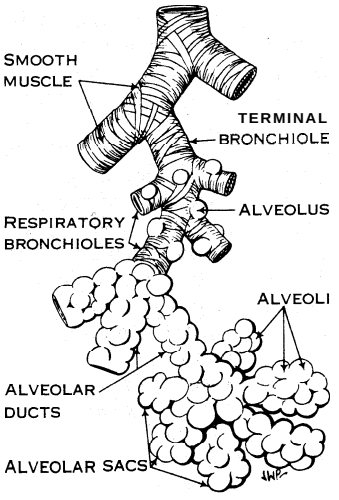

FIG 6.—TERMINAL RESPIRATORY UNITS OF BRONCHIAL TREE

Obviously, birth is another critical period. The first respira-

tions expand only a limited area. Full expansion requires several days, and sometimes weeks. Not infrequently portions of the lung never dilate (congenital atelectasis).

In premature infants, and those delivered by caesarean section, a hyaline membrane of unknown origin sometimes lines the alveoli, preventing respiration. Nor is it known whether aspiration of amniotic fluid before birth is a normal or abnormal occurrence. These and other problems dealing with respiration at birth await solution.

After birth, the lung grows rapidly, partly by lengthening and thinning of its walls and partly by increase in size of individual alveoli and in the number of branches. At maturity nonrespiratory generations of branches have increased from about 17 to 25. How this is accomplished is not known.

RESPIRATORY SYSTEM, DISEASES OF, Respiratory diseases may involve the upper respiratory tract from the nose, with its accessory sinuses, through the pharynx and larynx to the lower respiratory tract, which includes the trachea, bronchi and lungs. From beginning to end the mucous membrane of the entire tract is continuous. The anatomy and physiology of the respiratory tract are described in the articles RESPIRATORY SYSTEM, ANATOMY OF and RESPIRATION. This article is concerned mainly with diseases of the lower respiratory tract. For the upper respiratory system, see THROAT, DISEASES OF. The diseases affecting the lungs are approached somewhat differently in LUNG, DISEASES OF, and PLEURA, DISEASES OF deals with the disorders specifically affecting the pleura. An inflammation of the lung from any cause may be called pneumonia, hence see also PNEUMONIA.

Disease **Barriers.**—Normally, inspired air is warmed and moistened as it passes over the nasal turbinates, which act as baffles. This mechanism is interfered with when infection or allergy causes swelling of the mucous membrane. Particles in the inspired air are usually deposited in the nose, from which they are eliminated. A circle of lymphoid tissue surrounds the pharynx, acting as a barrier against the dissemination of infection. The mucous membrane of the trachea and bronchi is supplied with minute hairs, the cilia, which beat upward away from the lungs. This cleansing device raises to the pharynx inhaled foreign particles, which can then be expectorated. Toxic agents may slow or paralyze ciliary action; dehydration or infection may so thicken the secretions that the ciliae cannot beat freely. Some noxious particles actually reaching the air sacs or alveoli of the lungs are engulfed and disintegrated by special cells and then brought to the ciliary stream. Cough is a mechanism for forcible ejection of foreign matter and infected secretions.

Interference with any of these mechanisms predisposes to disease. In addition, there are local and general factors of resistance involving nutrition, hormones, previous experience with disease, chilling, unconsciousness due to anesthesia or inebriation, etc.

INFECTIONS

Infections can be grouped most easily by causative organisms.

Viral Diseases.—Great difficulty occurs in attempts to correlate respiratory diseases with their viral causes. One virus may be responsible for several different illnesses, and one disease may be caused by several different viruses. This is a field of active research, and new viruses are being discovered.

Influenza has a short incubation period and occurs in epidemics, usually of relatively minor significance but occasionally in pandemics of great severity, as in 1918 and 1957. The later world-wide influenza1 outbreak was caused by a substrain of type A virus named the Asian strain because the first recognized cases occurred in the orient. There is no effective treatment for pneumonia produced by the influenza virus. Total prevention as for smallpox, yellow fever and rabies, is not available, but partial control may be achieved through vaccination, provided the responsible strain has been included in the vaccine. Antibodies against one influenza virus are ineffective against another type of the same strain. One of the great medical feats of the 20th century was the world-wide co-operation that resulted in the prompt identification of the Asian strain of type A influenza virus, its incorporation into vaccines, and the use of vaccine on a mass scale so that protection was available immediately during the 1957–58 Asian- influenza epidemic. Immunity from an attack of influenza is short lived. (See also INFLUENZA.)

Another viral disease is pleurodynia, caused by the Coxsackie B virus. It occurs in small epidemics and is associated with severe chest pain made worse by deep breathing.

Primary atypical pneumonia is caused by more than one virus, is characterized by a normal white blood cell count (as are most viral infections) and by the presence of cold hemagglutinins, antibodies rarely present in other diseases. Like all viral diseases, it is resistant to treatment.

Rickettsia1 **Pneumonias.**—Bronchopneumonia may occur in louse-borne typhus (*q.v.*), a disease of world-wide distribution caused by Rickettsia *prowazeki.* Pneumonitis is a feature of many cases of Q fever (*q.v.*), a disease caused by *Coxiella* burneti and first recognized in Australia. It is transmitted mostly by inhalation through octupational exposure to infected sheep, cattle or goats, or by working with the rickettsiae in the laboratory. Many cases have been reported from California, Montana and Texas as well as from Africa, Europe, the middle east and Panamá. The rickettsia1 diseases respond well to treatment with the tetracyclines or chloramphenicol.

Bacillary Infections.—The commonest bacillary infections of the nasopharynx are due to hemolytic streptococci and staphylococci, and to pneumococci. (See also BACTERIAL AND INFECTIOUS DISEASES.)

Streptococcal sore throats are of great significance, since serious distant effects include kidney infections and flare-ups of rheumatic fever, with its possible sequel of rheumatic heart disease. Fortunately, excellent antibiotic treatment is available, penicillin being most effective. Early diagnosis is important, and for persons with a history of rheumatic fever prophylactic drug therapy during cold weather is desirable.

Staphylococcal infections occupy a major place among the pneumonias because of their rapid and often fatal course. The emergence of staphylococci resistant to many of the most potent antibiotics has presented a grave problem in treatment. Many staphylococcal infections are acquired in the hospital: resistant staphylococci have been cultured from throats and fingernails of hospital personnel, from air emerging from hospital laundry chutes and operating rooms, from blankets and from "clean" glasses and water bottles delivered to patients. Most hospitals have committees which not only review each case of staphylococcal infection but also draw up housekeeping procedures designed to prevent the transmission of such infections.

Pneumococcal pneumonias appear to be less common than they once were. It is not apparent whether this is due to a true reduction in prevalence or to the fact that cases are being successfully treated at home with the many antibiotics available. Friedländer's pneumonia, caused by Friedlander's bacillus or *Klebsiella pneumoniae,* remains a grave infection seen mostly in older men, frequently in alcoholics or grossly malnourished persons.

Tuberculosis.—This is a disease with a declining death rate—in the United States the rate fell from 202 per 100,000 population in 1900 to 8.4 in 1956, in South Australia it fell from 90 per 100,000 in 1899 to fewer than 5 in 1956. However, in many areas, including eastern Europe, Asia and the Pacific Trust Islands, the disease is still rampant. In remote or over-populated places diag-

nosis is often erroneous and statistics are inadequate, so that the true magnitude of the problem is unknown.

The number of persons suffering from active tuberculosis constitutes a better measure of the problem than the number of persons dying from the disease, particularly since modern treatment is effective. Though morbidity rates are slowly diminishing in the economically advanced countries. the problem remains of considerable magnitude. For a full discussion of this disease, see TUBERCULOSIS.

Fungus Infections. — Certain geographic areas are endemic foci of fungus diseases, many of which affect the lungs. In the U.S., portions of the south and the whole Mississippi valley have high rates of infection with *Histoplasma capsulatum.* A ten-year study of histoplasmin and tuberculin reactors among kindergarten children in Kansas City, Mo., reported by L. E. Wood and his co-workers in 1958, revealed a higher prevalence of histoplasma infection than of tuberculous infection. Histoplasmosis is a serious problem in these endemic areas. Its behaviour closely resembles that of tuberculosis. Amphotericin B gives promise of being effective in therapy. As with tuberculosis, some cases of histoplasmosis run a benign course. Miliary calcifications result from benign disseminated disease; their X-ray appearance remains unchanged over years. Localized epidemics of histoplasmosis have occurred in association with the soil of chicken houses, and the disease has been reported in association with bat dung.

In the western and southwestern United States, northern Mexico and certain areas of South America, infection with *Coccidioides immitis* is prevalent; nearly all residents are infected, many without ever having had symptoms. Coccidioidomycosis is contracted by inhaling chlamydospores (the Coccidioides reproductive organs) in dust. About half the cases exhibit respiratory symptoms. The pneumonitis which develops may clear entirely or may leave characteristic thin-walled cavities. Small cavities tend to close slowly. Larger cavities frequently give rise to expectoration of blood-stained sputum and occasionally rupture; hence surgical removal is often advised. There is no effective medication for coccidioido~nycosis. It may be prevented by avoiding endemic areas, particularly during dry. dusty seasons.

Less common fungus diseases of the respiratory tract include actinomycosis, due to *Actinomyces* bovis, a fungus harboured in the mouths of most persons; nocardiosis, due to *Nocardia asteroides*; and blastomycosis, due to *Blastomyces* dernzatitides. In actinomycosis the lesions tend to penetrate the chest wall. Effective treatment for both actinomycosis and nocardiosis consists of large doses of penicillin, either alone or with sulfadiazine. Surgical drainage is indicated for abscesses. For blastomycosis, sulfadiazine is the drug of choice. Cryptococcosis, caused by *Cryptococcus* neoformans, may begin with a mild respiratory infection and progress to involvement of the lungs and to meningitis. No satisfactory treatment is available, though amphotericin B seems promising. (See also FUNGUS INFECTIONS.)

OTHER DISEASES

Parasitic Infestations of the Lung. — Chronic pulmonary schistosomiasis (*q.v.*) has been reported from Egypt, Brazil and other countries. Infections with blood flukes are widely distributed in Japan, China, the Philippines, Africa, Brazil, Dutch Guiana and several islands of the West Indies. With the slow northern advance of the *Schistosoma,* the disease has come to be of interest in the United States. Exposure occurs through contact with water infested by snail hosts, through bathing, laundering, etc.

Amebiasis occurs all over the world, mostly in the tropics and where sanitation is poor. Prevention consists of avoiding contaminated water and raw foods which may have been washed with such water. Pulmonary abscesses occur secondary to amebic abscesses of the liver. (See also PARASITIC DISEASES.)

Allergic Diseases. — Vasomotor rhinitis, hay fever and bronchial asthma are a triad of common allergic diseases of the respiratory tract.

Vasomotor rhinitis, characterized by copious watery nasal discharge, is nonseasonal, in contradistinction to hay fever, which is seasonal and caused by pollens. Hay fever is associated with sneezing, itching of the eyes and nose, outpouring of watery secretions from the eyes and nose and an abrupt onset when the causative pollen first becomes airborne. While it is not in itself serious, it is annoying. interferes with sleep and appetite as well as with the normal functions of the nasal mucosa and thus predisposes to infection. (See also HAY FEVER.)

Bronchial asthma, the most serious of the allergic diseases of the respiratory tract, is characterized by sporadic attacks of wheezing due to spasm of the involuntary muscles in the bronchial walls. The wheezing is bilateral, intermittent and changeable, in contrast to the unilateral fixed wheeze of tumour, ulcer or scarring of a bronchus. Clear tenacious secretions are difficult to raise. Allergies include a wide variety of exogenous materials such as dust and feathers, but, especially in cases in which the onset of asthma occurs in middle age, endogenous bacteria are often causative. There are usually multiple factors. The actual attack may be precipitated by an emotional upset, a sudden marked change of temperature or a respiratory infection. During an attack air hunger is acute, the spasm of the smaller bronchi exerting a ball-valve effect by which air gets in but cannot get out because the spasm increases the normal shortening and narrowing of the bronchi on expiration. The mucoid secretions may actually plug some bronchi. Occasionally the patient goes into a serious prolonged life-threatening episode called status asthmaticus. Most attacks of asthma can be successfully treated by adrenaline or adrenalinlike drugs and can be averted by avoidance of allergens, infections, rapid changes of temperature and by the achievement of emotional tranquility. While recurrent asthmatic attacks are usually not grave, they lead over the years in many cases to a state of chronic overdistention of the lung and to emphysema. (See also ASTHMA.)

Chronic Bronchitis and Emphysema. — Repeated attacks of acute bronchitis (*q.v.*) predispose to chronic bronchitis characterized by chronic cough productive of sputum. Such persistent productive cough tends to be associated with recurrent bouts of respiratory illness, during which fever is often present and expectoration increases. Ultimately, wheezing is heard and, in an unknown but probably significant percentage of cases, overdistention of the lungs with thinning of the alveolar walls—emphysema (*q.v.*)—develops. Shortness of breath gradually increases until the slightest physical effort is followed by great difficulty in breathing. This major crippling disease of the lungs is progressive and results in total incapacitation. Death finally occurs either from heart failure or from an acute episode of infection. Drugs relieve bronchospasm, and antibiotics produce brilliant results in combating the pneumonias from which emphysema patients suffer recurrently, but there is no cure. Criteria for early diagnosis are lacking. In the absence of definitive information as to cause, measures which prevent bronchial irritation and cough may help in prevention.

Occupational Diseases of the Lungs. — The pneumoconioses are lung diseases due to inhalation and retention in the lungs of industrial dusts, with the production of fibrosis. Silicosis (*q.v.*), the most important pneumoconiosis, occurs as a result of inhalation of fine particles of quartz. Disability is due to the emphysema associated with the progressive fibrosis. Silicotics are more susceptible to tuberculosis than are nonsilicotics. Asbestosis may develop in those exposed to inhalation of asbestos fibres. Over a protracted course, it involves the pleurae and pericardium — the coverings of the lungs and heart — and causes heart failure. Prevention of inhalation of such dusts is important, since there are no successful cures once the fibroses have actually developed. Berylliosis. an acute disease associated with extreme shortness of breath, was largely caused by the inhalation of beryllium phosphors in the manufacture of fluorescent lamps; cases even occurred in persons living in the neighbourhood of such plants. The industry has changed its manufacturing process so that fewer and fewer cases are seen. Treatment with steroid hormones is suppressive. A number of other less common pneumoconioses occur due to exposure to diatomaceous earths, finely divided tin, etc.

"Farmer's lung" is an acute pneumonitis resulting from the

handling of a variety of dusty, moldy, organic materials. Repeated exposure produces recurrence. "Silo filler's disease," another uncommon disease reported among agricultural workers, is a pneumonitis apparently caused by the inhalation of certain oxides of nitrogen. Bagassosis occurs as a result of inhaling bagasse, a residue from sugar cane. (See also DANGEROUS OCCUPATIONS; PNEUMONOCONIOSIS.)

Nonoccupational Disseminated Diseases of the Lung.— Sarcoidosis, a widespread disease which often involves the lungs, is characterized frequently by dramatic bilateral chest X-ray abnormalities in the presence of few or no respiratory symptoms. The causative agent is unknown. Most of the patients have come from the southeastern United States, and the U.S. public health service has postulated a relationship to some of the pollens of pine forests in that area.

M. Bergmann and his co-workers applied the term thesaurosis to a disease they reported, implying that it resulted from the storage of macromolecules of resins used in hair spray and inhaled by the sprayer. Two cases of bilateral lung disease were found associated with the use of hair spray. Bergmann produced experimental granulomas in guinea pigs by injecting into them the residue from a well-known hair spray suspended in saline solution.

Tumours.— A dramatic rise in the incidence of lung cancer occurred after about 1930 in the United States, England and Wales, Australia, Canada, Denmark, Japan and Turkey. The rise was much more marked in men, among whom, in the United States, lung cancer became the commonest cancer. A statistical association with smoking has been pointed out by numerous British and U.S. investigators. Since lung cancer is found in urban rather than in rural areas, the possible causative role of air pollutants needs study also. As of the early 1960s the only cure for the disease was surgical removal before distant spread has occurred. Five-year survival rates reported by surgeons were less than 10%.

See CANCER; TUMOUR; LARYNGITIS; LUNG, DISEASES OF; *see* also Index references under "Respiratory System, Diseases of" in vol. 24. (K. R. B.)

RESSEL, JOSEF LUDWIG FRANZ (1793–1857), an inventor of the screw propeller for steamships, was born at Chrudim, Bohemia, June 29, 1793. He first tried a small boat fitted with a screw propeller at the bow, turned by two men (1826). Ressel obtained his Austrian patent in 1827, and a British patent, believed to have been also on his behalf, was obtained in 1828 by Charles Cummerow. Ressel tried his steamboat, the "Civetta" of 48 tons' displacement, at Trieste in 1829. The screw propeller was of copper, 5 ft. 2 in. diameter, and placed at the stern. The vessel attained a speed of six knots. Ressel died of malaria in the night of Oct. 9–10, 1857, at Laibach (now Ljubljana, Yugos.). In 1924 his native town. Chrudim. raised a monument to his memory.

See Ferdinand Thomas, *Josej Ressel, der Erfinder der Schiffsschraube* (1880). (H. P. St.)

RESTAURANT. The medieval forerunner of the modern restaurant uas the tavern, and to a lesser extent, the cookshop In London cookshops certainly existed in the 12th century, for William Fitzstephen in 1183 described one by the riverside nhere hot cooked viands of all kinds could be bought, and visiting strangers could "refresh themselves, each after his own manner" In John Lydgate's London Lickpcnny (*c.* 1450), we read how the cookshopkeepers of Westminster Gate pressed food and wine upon the ballad's hero and hastened to spread "a fayre cloth" for him, but. for lack of money he was obliged to refuse. The principal business of these shops was the sale of cooked meats which customers carried away with them, but from the foregoing references it would appear that meals were sometimes served also on the premises.

It was. however, in the taverns that the custom of providing a daily meal, or "ordinary," at a fixed hour first developed, and it was in one of these that England's earliest dining club (*see* CLUBS) normally met in the 15th century.

By the middle of the 16th century the dining-out habit was well established among townsmen of all classes. Most taverns offered a good dinner for 1*s*. or less, with wine and ale as extras Tobacco was also sold there after its introduction into England in 1565. Men resorted to taverns for companionship as well as refreshment. and some of the better houses became regular meeting places and unofficial clubhouses for particular groups. Among the more famous Tudor taverns in London were the Mermaid. frequented by William Shakespeare: Ben Jonson and their friends; the Boar's Head. traditionally associated with Falstaff; the Mitre in Bread street (not to be confused with the later house of the same name in Fleet street, frequented by Samuel Johnson and James Boswell); the Devil by Temple Bar, where the celebrated Apollo club was afterward founded: and the Falcon on Bankside, where actors and theatre managers foregathered.

In 1650 the first English coffeehouse was opened in Oxford, and two years later Pasqua Rosee opened another in St. Michael's alley. London. Thereafter similar establishments sprang up everywhere. Their principal trade was in coffee. tea and chocolate (all new drinks at this period). but many also supplied wine and ale. Horace Benedict De Saussure observed in 1726, "What attracts enormously in these coffee-houses are the gazettes and other public papers. Workmen habitually begin the day by going to coffeehouses in order to read the latest news. . . Some coffee-houses are a resort for learned scholnrs and wits; others are the resort of dandies. or of politicians. or again of professional newsmongers; and many are temples of Venus." Apparently food was sometimes served there. for we hear of Oliver Goldsmith eating his supper at the Grecian. As a rule: however. they were concerned only with light refreshments and J. Macky (*Journey Through* England, 1714) remarks that "the general way here is to make a party at a coffeehouse to go to dine at the tavern."

Macky also mentions certain "ordinaries" run by Frenchmen in Suffolk street which seem to have been nearer the modern idea of a restaurant than the contemporary taverns and coffeehouses. The word restaurant was. however. unknown until about 1765, when it was first applied to a Parisian house serving meals and light refreshments which Boulanger opened in the Rue des Poulies. The immediate success of this venture led to its imitation by others. and the use of the new name for many similar establishments in France. In England the word was not generally used until toward the end of the 19th century.

The food supplied in public eating-houses in Stuart and Hanoverian times was usually both generous and cheap. Samuel Pepys paid 10*d*. on one occasion for hot meat. bread and ale at "an ordinary hard by Temple Bar." Johnson in the following century "dined very well for *Sd."* at the Pineapple, paying 6d. for meat. 1*d*. for bread and 1*d*. to the waiter. His companions paid 1*s*., but they had wine as well. Simpson's Fish Dinner house, founded 1723, served a 2*s*. "fish ordinary" which inrluded mutton. soup and cheese as well as fish. Workmen and servants on board wages often patronized underground "dives," where they could eat adequately for as little as 2½*d*. or 3d. On the other hand, Daniel Defoe says that dinner at Pontack's normally cost 4s. or 5*s*. and might cost as much as a guinea.

By the late 19th century the long reign of tavern and chophouse was drawing to its end. In 1884 the first A.B.C. teashop was opened near London Bridge, and ten years later a similar shop mas opened by J. Lyons and Co., Ltd., in Piccadilly. These were the forerunners of a vast chain of teashops where originally teas, and later more substantial meals, were served. Their immediate popularity was largely due to women. who could not frequent taverns unless escorted and had previously had no place where they could eat alone in public. In 1873 Whiteley's store opened a restaurant for their customers and the idea rapidly spread to other shops. Six years later the Great Northern railway ran the first English restaurant car between London and Leeds.

By the beginning of Edward VII's reign: the restaurant habit was fully established in England. Restaurants of all types flourished in London and the larger towns. including the French and Italian houses for which the Soho district of London became renowned and the cafes which were beginning to supplement the humbler teashops. Most large hotels ran restaurants of an elaborate kind and grillrooms were coming into fashion. The attraction of the grillroom was that. while food and service were equal to that of the fashionable restaurants, evening dress was not obligatory.

The first London grillroom was started about 1865 by Spiers and Pond. whence the idea spread first to the Savoy hotel and afterward to most other hotels and restaurants.

A feature of the modern large restaurant faintly reminiscent of the old group gatherings in taverns and coffeehouses is the inclusion in the building of banqueting halls and smaller rooms where organizations can hold festival dinners. or meet for other purposes.

CONTINENTAL EUROPE

There are in all European capitals a number of luxury hotels where the rich and the great ones of the world are given every opportunity of enjoying all that is best, regardless of cost, and also of showing friend and foe alike how great and how rich they are. Such hotels with their international character are, however, much alike in their style of comfort and in the food they serve.

There is, happily, a greater measure of individuality in the best restaurants of Europe! This is particularly true of France. probably on account of the more general and more critical appreciation there of the happy partnership that should exist between fine fare and good wine. In Paris. the fame of such restaurants as Maxim's, La Tour d'Argent and Lapérouse is world-wide; and also among the best restaurants must be mentioned Grand Véfour.

In the French provinces. well-deserved fame belongs to the Pyramide at Vienne. below Lyons: and in Lyons itself there are half a dozen good restaurants, none better than Mère Brazier. Farther south, on the may to Monte Carlo, there is the Relais de l'Empereur, at Montélimar, a hotel with a first-class restaurant. Provided the cost matters little, superb fare may be had in the Salons privés du Casino. at Monte Carlo, and Chez Reynaud at Nice: but good restaurants abound on the Cdte d'Azur, as indeed they are to be found in all the larger towns of France, for each of the old provinces is celebrated for its gastronomic specialities and style of cooking. For remarkably fine regional cooking, partnered with the best local wines. one may dine at such restaurants as Dubern at Bordeaux; Les Trois Faisans at Dijon: La Maison des Têtes at Colmar; La Rdtisserie at Nantes; A la Sole Normande at Trouville; Lyonnais at Tours; and Hdtel de la Poste, Avallon.

In Switzerland. there are many perfectly managed hotels and restaurants but it is difficult to single out those which are really outstanding for both fine fare and an adequate choice of fine wines. The Ziirich airport restaurant may not be the most glamorous in the land but it is certainly one of the best for cuisine and Swiss wines. German food is substantial and the portions served generally are plentiful, but the cooking can also be first-class, and the fine wines of the Rhine and the light and dark beers of the country are justly famous. Throughout Germany, and particularly in the Rhineland, in small towns as well as in the cities, may be found restaurants with a specially personal, local character.

In Italy. the best restaurants. those possessing first-class chefs, a good cellar and a personality entirely their own, are mostly to be found in Venice, and after Venice, in Turin: in Venice. the Gritti and Danieli hotels, and the Taverna al La Fenice may be mentioned; in Turin. the Caval 'd Bronz. In Rome, for local colour the restaurants by Sta. Maria in Trastevere may be enjoyed, but the most fashionable is Palazzi (in the former home of Claretta Petacci). In Milan Giannini's and in Florence the Bucha di San Rufillo are noted. Among restaurants which are reputed to excel in the service of local or national dishes are the following: Amsterdam. Neth.. Die Port van Cleve and the "Five Flies"; Barcelona, Sp., Casa Agustín; Brussels, Belp.. the Astrid; Copenhagen. Den., Drachman's Kro. at Lorry's; Munich, Ger.. Schwarzwälder; Daun (Eifel. Ger.), Weier's; Jerez de la Frontera, Sp., Los Cisnes; Madrid, Sp., La Barraca. (A. L. S.; X.)

UNITED STATES

Among the earliest restaurants on record in the United States were in Philadelphia. Pa.. the Blue Anchor Tavern (1683 or 1684), Ye CoffeeHouse (1700), The London Coffee House (1701), William Bradford's second London Coffee House (1754), and the City Tavern (1773). In New Tork. the famous Fraunces' Tavern at Broad and Pearl streets still stands. Other famous early restaurants were Brown's Chop House, a favourite rendezvous of journalists, authors, actors and painters: the Old St. Denis, Fleischman's Vienna Gardens. Dorlon's. the old Hoffman House, Café Martin, the old Holland House, Delmonico's and Sherry's. In New Orleans. La.. Antoine's and Bégué's are still fashionable favourites. San Francisco. Calif.. had many renowned restaurants such as Don's. the El Dorado House (Spanish cooking); the Iron House made of sheet iron brought in a sailing vessel around the Horn, Tehama House. Marchand's and the Mint. Few of these survived the San Francisco fire of 1906.

Great economic changes brought about by World Wars I and II changed the restaurant industry drastically. Whereas originally restaurants had catered only to a fashionable society clientele?they came to serve the general public as well. Although there are still many famous fashionable restaurants, night clubs and hotel dining rooms, the largest number of restaurants have built their success by serving meals in pleasant surroundings at popular prices to the general public. In 1955 there were 186,275 commercial restaurants, cafeterias, taverns, coffeeshops, luncheonettes, sandwich shops and refreshment stands. (This total excluded dining rooms in hotels, clubs, steaniships, trains. air line terminals, hospitals. department or variety stores and institutions of various kinds.) Sixty million meals a day were served in restaurants. There was one restaurant for every 704 persons in the C.S. Its equipment cost an average of $500 per seat. Restaurants employed 1,300,000 people or one out of every six engaged in the retail trades.

The restaurant business reported sales of $8,917,000,000 in 1955, according to the U.S. Business Census, thus qualifying as the third largest retail business. A marked change was the swing from individually-owned restaurants to chains, of which there were more than 198 controlling over 900 units in the latter 1950s. These provided more than 800,000 seats and were responsible for between 11% and 15% of all restaurant sales volume. Among the chains operating in the east were Schrafft's. Longchamps, Howard Johnson's. Brass Rail. Savarin's. Child's (owners of Sherry's); bracketing the east and midwest was Stouffer's; in Washington, D.C., the S. & W's: in Cleveland, O., the Colonnade; in Chicago, Ill., and westward Fred Harvey's; in Los Angeles, Calif.. the Clinton chain. Union News restaurants and Greyhound Post houses were widespread.

F. W. Woolworth Company operated one of the largest chains comprising over 1,400 units whose sales were not included in the above figures.

Whereas originally fine American restaurants were staffed by European-trained chefs and waiters and relied upon Europe for a steady supply of trained employees, World Wars I and II modified this situation. In the latter 1950s many courses in commercial catering at both high school and college level were available in the U.S. Among the courses conducted by the universities were those at Cornell university (Ithaca. N.Y.), Michigan State university (East Lansing), University of Denver (Denver, Colo.). University of New Hampshire (Durham), The University of Chicago (Chicago, Ill.), Mississippi State college (State College. Miss.). Florida State university (Tallahassee). Oklahoma Agricultural and Mechanical college (Stillwater), Tuskegee institute (Tuskegee Institute. Xla.), State College of Washington (Pullman). City College of San Francisco (San Francisco), and at several branches of State University of New York (Albany, N.Y.), including Community college in Brooklyn. N.Y. In addition courses were offered by the Culinary Institute of America in New Haven. Conn., and Clinton's in Los Xngeles. Calif. At the high school level. the Isaac Del Gado Trade school in New Orleans: Food Trades high school in New York and Edison Technical high school in Seattle, Wash., were among those offering instruction in commercial catering. Short

courses were sponsored by various state restaurant associations, such as the ones conducted at The University of Chicago. Rutgers university (Newark, N.J.), and those conducted under the direction of the Illinois and Wisconsin State Restaurant associations. Under the bill providing funds for distributive education many high schools and trade schools offered courses for waiters and waitresses.

Research in methods for improving food and food service was also conducted by the National Restaurant association and the results were made available to all member restaurants throughout the U.S. (C. M. DL.)

RESTIF, NICOLAS EDME (1734–1806), called RESTIF DE LA BRETONNE, French novelist, son of a farmer, was born at Sacy (Yonne) on Oct. 23, 1734. He was educated by the Jansenists at Bicêtre, and on the expulsion of the Jansenists was received by one of his brothers, who mas a curé. Owing to a scandal in which he was involved, he was apprenticed to a printer at Xuxerre, and, having served his time, went to Paris. There he worked as a journeyman printer, and in 1760 he married Anne or Agnes Lebègue, a relation of his former master at Xuxerre. Restif produced about 200 volumes, many of them printed with his own hand, on almost every conceivable subject. He drew on the episodes of his own life for his books, which display an extraordinary licence in choice of subject and in treatment. They provide useful documents for the history of the underworld of the period. They include: *Le Pied de Fanchette*, a novel (1769): *Le Pornographe* (1769), a plan for regulating prostitution which is said to have been actually carried out by the Emperor Joseph II, while not a few detached hints have been adopted by continental nations; *Le Paysan perverti* (1775), a novel with a moral purpose, sufficiently horrible in detail; *La Vie de mon père* (1779); *Les Contemporaines* (42 vol., 1780–1785), a vast collection of short stories; *Ingénue Saxancour*, also a novel (1783); and, lastly, the extraordinary autobiography of *Monsieur Nicolas* (16 vol., 1794–1797; the last two are practically a separate and much less interesting work), in which at the age of 60 he has set down his remembrances, his notions on ethical and social points, his hatreds, and above all his numerous loves, real and fancied. The original editions of these, and indeed of all his books, have long been bibliographical curiosities owing to their rarity, the beautiful and curious illustrations which many of them contain, and the quaint typographic system in which most are composed.

Just before his death (Feb. 2, 1806) Napoleon gave him a place in the ministry of police.

See J. Assézat's selection from the *Contemporaines*, with excellent introductions, 3 vol (1875), and the valuable reprint of *Monsieur Nicolas*, 14 vol. (1883–84).

RESURRECTION PLANT (*Anastatica hierochuntica*), a small herb of the family Cruciferae, called also rose of Jericho, native to Arabia, Iran and Egypt.

Cpon the ripening of the seeds during the dry season, the leaves fall off and the branches curve inward so that the dry plant assumes a globular form. It then rolls about in the manner of a tumbleweed (*q.v.*) until the rainy season. When wet the branches unfold and it assumes for a time the appearance of a living plant

The name is also given to two other plants. One is the mosslike *Selaginella lepidophylla* which also dries up into a ball and expands when wet. It is called also bird's-nest moss and is found from Texas southward to Peru. The other is the resurrection fern (*Polypodium polypodioides*), the commonest epiphytic fern in Florida

RESZKE, JEAN DE (1850–1925), Polish operatic singer, who was noted for his Wagnerian roles, was born at Warsaw on Jan. 14, 1850. His father was a state official and his mother a capable amateur singer, their house being a recognized musical centre. He studied law before adopting singing as his profession and going to Italy to study.

He made his first public appearance, as a baritone, at Venice in Jan. 1874 as Alfonso in *La Favorita*, and in the folloning April he sang for the first time in London, appearing at Drury Lane theatre, and a little later in Paris He was not entirely successful and retired for a further period of study, during which his voice gained remarkably in the upper register; so that when he made his first reappearance at Madrid in 1879 it was as a tenor, in the title role of *Robert le Diable*.

Reszke's great fame as a singer, especially in Wagnerian parts, dates from this time. He appeared at the Metropolitan Opera house, New York, N.Y., from 1893 to 1899, In 1904 he retired, but he continued teaching almost to the day of his death on April 3, 1925.

RETABLE, a term of ecclesiastical art and architecture, applied in modern English usage to an altar ledge or shelf which is raised slightly above the back of the altar or communion table and on nhich are placed the cross, ceremonial candlesticks and other ornaments.

Retables may be lawfully used in the Church of England (*Liddell & Beale*, 1860, 14 P.C.).

RETAILING is the final business service that makes consumer goods and services available to ultimate consumers. It is the sale of merchandise through stores or vendors to those who buy to consume rather than to resell or to reprocess. Actual retailing establishments vary so greatly in size and in types of items of merchandise offered for sale that classifications of retail stores are not particularly useful. The peddler who sells shoelaces or handkerchiefs from a cardboard tray he carries is as clearly a retailer as is the department store.

Historical Background.— Retailing emerged as a separate business function from the fairs the bazaars and the guild-controlled shops of the middle ages, and it developed as the concept of competition grew. Yet merchants themselves have usually sought to avoid facing competition from new or larger types of stores. During the middle ages competition was virtually eliminated from retailing. Most consumer merchandise was made by master workmen under minute guild specifications and sold at prices determined by the guild. Competition between master workmen was limited by limitation of their number in each locality. Fairs were typically of short duration and offered merchandise that did not compete with the products of the guild craftsmen. The limitation on competition is indicated by the three major commercial crimes of the middle ages: forestalling, or buying before the market officially opened or from vendors before they reached the market; regrating, or reselling at a price higher than that originally paid for merchandise; and engrossing, or buying in larger than retail lots, hence implying the intention of reselling.

As long as merchandise was individually made, large-scale trade was impossible. Early textile manufacturers, for example, produced textiles in units called "cloathes," pieces of fabric of varying length and width and of varying quality. Detailed inspection of each cloathe was necessary. Other items of early trade were equally difficult to deal with in quantity. Not until goods could be manufactured to uniform specifications and sold by description could retailing develop to great importance.

Small shops and stores and often custom manufacture therefore remained the rule until the Industrial Revolution introduced a flow of machine-made products of uniform character.

In the United States, up to 1850 (to choose an arbitrary date), men's and women's clothing were made at home or by dressmakers or tailors from textiles and trimmings purchased at stores. Most furniture was custom-made at least as late as that time, with the exception of certain wardrobes and chests. Most foodstuffs were available in stores only in bulk or in the form of raw materials until nearly the start of the 20th century.

The development of retailing as a major business activity was made possible (1) by the development of mechanization, which enabled manufacturers to produce large quantities of consumer's goods; (2) by a steady increase in urbanization, which made a constantly greater proportion of the public dependent on stores for most or all goods and services needed; and (3) by increases in population, which provided mass markets for large-scale manufacturing and retailing. Moreover, the introduction in the United States of formalized consumer credit plans in the early and mid-1920s further improved markets for consumer durable goods and made possible a consequential growth in the field of retailing.

Competition. — The objection to competition that characterized the rudimentary forms of retailing during the middle ages has persisted. The department store, developing and growing during the second half of the 19th century, was widely viewed as an unfair type of institution that threatened other types of retailing. The development of mail-order firms with the introduction of parcel post service by the United States post office was expected to put rural and small-town merchants out of business. Chain stores, or multiple shops (that is, multiple retail establishments under the same ownership and management), were thought to threaten the solvency of all independent merchants, and in the United States some states actually established discriminatory taxes in the effort to prevent the operation of chain store companies within their borders. Supermarkets (large retail establishments organized around food items. but growing to include limited inventories of clothing, household hardware, electrical goods! toys, often drugs and even optical goods) have been regarded as a disrupting influence on more conventional types of retailers. After the mid-1940s the discount house, a retail establishment that has curtailed its retailing services to the point at which it is able to sell consumer durable merchandise at considerable real or apparent reductions in price, was described as a threat to retailers selling consumer durable goods.

Particularly in the United States, groups of retailers have sought to curtail competition through obtaining the enactment of one or another kind of limiting legislation. Many municipalities. particularly small towns, have adopted the so-called Green River ordinance (named for Green River. Wyo., which is said first to have enacted it), which forbids or limits the sale of merchandise by peddlers, house-to-house salesmen or other vendors who are from outside the municipality. Many localities have enacted stringent licensing laws that have the effect of limiting retail competition; such laws often affect barbers. stores selling drug sundries (as contrasted with medicines and prescription goods), plumbers and others. So-called fair-trade legislation has long been sought in the United States and has intermittently been possible, though U.S. supreme court decisions during the 1950s cast doubt on the legality of some forms of fair-trade legislation. Fair-trade legislation, as understood in the United States, allows a manufacturer to prevent "price cutting" by all retail vendors handling his merchandise if he signs and publishes a contract with one retailer or a very small number of retailers, in a particular state, agreeing to maintain certain retail prices *(see* FAIR TRADE LAWS). This type of avoidance of competition at the retail level is far commoner in Europe than in the Cnited States, but even in Europe. and particularly in France. Great Britain and West Germany. the trend in legislation is away from restrictions and toward a more open and rigorous type of competition.

Economic Aspects. — Since retailing is the business service that makes consumer goods and services available to the consuming public, it is, therefore, the last step in the chain of production by which items are brought from a state of nature to the point of consumption and is clearly a part of the process of production. It is, however, one of the more costly parts of the process of production. About half the consumer's cost is taken up in paying for marketing or distribution, and a large part of this amount is attributable to retailing.

The high cost of retailing can be explained by the requirements of seeking out goods from many sources in many locations; of providing wide ranges of choice for retail customers in sizes. colours, types and brands of merchandise; and of keeping merchandise in inventory over periods of weeks or months. In general, the proportion of gross profit or gross margin (the difference between the cost price and the selling price, usually expressed as a percentage of the selling price) varies directly with the rapidity with which merchandise can be sold. This rate is called the rate of stock turn. For some items of food the merchandise may turn weekly or oftener; whereas for some items of jewelry or of hardware the rate of stock turn may be only two or three times a year. It is obvious that retailing merchandise of the latter type is far more costly than retailing merchandise that turns rapidly.

Department stores, jewelry stores and other stores that handle merchandise with a slow rate of stock turn have a higher overall average gross margin. In the United States, department stores require from 35% to 40% of the retail price of the merchandise to pay their costs. Hardware stores also have a low rate of stock turn. On the other hand, pharmacies can do business on a much louer gross margin, and well-organized food stores can do business often on gross margins of 14% or 15%.

Gross margin constitutes a payment by the consumer for retail services. When the gross margin for a particular type of retail store increases, the consumer is very likely to respond to competitive offers and supply his needs from other types of stores. It becomes necessary, therefore, for retailers to become and to remain highly cost-conscious and to take advantage of whatever economies they can.

The net profit earned by retailers is not necessarily influenced by the size of the gross margin. Because retailers may rent their premises and their equipment, may hire delivery on a contract basis and may buy their merchandise on credit. the actual amount of investment in a retail establishment is a difficult matter to calculate and virtually impossible to compare among stores. For this reason, profits for retailing establishments are very likely to be calculated as a percentage of net sales. In general, if all costs are taken into consideration, profits are likely to vary from 0.5% of net sales to as much as 5% of net sales. The differences in rates of profit are for the most part due to different degrees of efficiency rather than to differences in gross margin or in type of merchandise handled.

In the United States, classifications of stores by volume of sales by merchandise lines is difficult because many types of stores carry varied lines of merchandise. Supermarkets, though built around food lines, distribute many other kinds of merchandise. Variety stores, which formerly sold low-priced lines of miscellaneous merchandise. have become competitors of department and hardware and furniture stores. Drugstores sell an increasingly wide variety of merchandise. Slightly more than a quarter of all retail sales in the United States, however, are made by retail outlets specializing in automobiles and automobile and petroleum supplies; this large proportion of retail trade does not take into consideration the sales of the large number of automotive repair shops. The second largest concentration of sales is in grocery stores, which account ior a little more than a fifth of all retail sales. Department stores, which formerly were among the largest volume outlets, by the early 1960s accounted for somewhere near 6% of all retail sales.

Figures ior other countries are less readily available, but insofar as they are available show a far smaller concentration on automotive goods retailing. Aside from this, the biggest difference in retailing, as betneen the United States and Europe, is in the greater reliance on co-operative stores in the Scandinavian countries, Great Britain, Germany and Switzerland. A publication (1958) of the Swiss Cooperative union shows the follouing per capita sales by co-operative retail societies (in Swiss francs): Denmark 181; West Germany, 48; Great Britain and h'orthern Ireland, 215; Finland, 744; h'orway, 194; Sweden, 321; Switzerland, 238. In the Lnited States consumer co-operative associations have made very little headway. They have been most conspicuous in food store retailing, a field in which private enterprise has been at its highest pitch of efficiency *(see* CO-OPERATIVES).

Current Trends. — Trends in retailing appear to be well established and world-wide. Although retailing has reached greater development in the western democracies than elsenhere, even in the communist countries, where sales effort is not supposed to be necessary, the same trends appear in less-advanced stages of development.

The first discernible trend is toward a constantly increasing variety of merchandise, as standards of living rise. The application of the electric motor to household appliances and of synthetic fibres and plastics to home furnishings and clothing, added to a large number of new products, and further advances in the application of chemistry and electronics have continued this process. Not only does this increased variety help to increase the volume of retail sales — and hence to stimulate the

economy—but it adds appreciably to opportunities in the field of retailing.

With improvements in manufacturing techniques, it has been possible for an increasing number of suppliers to manufacture merchandise of high quality. Consumer preference for particular brands of merchandise, therefore, is increasingly based on certain product characteristics. When competition has brought a kind of parity to competing products in a given market. the retailer's support rather than the manufacturer's brand may become the basis for selective demand. This has caused many retailers in the food, clothing, hardware and other fields to introduce their own brands, which they can sell successfully in competition with broadly distributed and widely advertised brands. Such private brands offer retailers a slightly higher margin of profit.

Partially in response to greater urbanization of consumers and partially in response to high labour costs, there has been a marked tendency toward packaging a wide variety of goods in consumer sizes. Canned foods, breakfast cereals and the like have been packaged for a number of decades, by the 1950s and 1960s fresh produce and meats also were offered in prepackaged form, and many items of clothing and household supplies were offered in separate consumer packages. Such packaging greatly reduces the cost of labour applied at the retail store and allows the packaging to be done at central points with automatic machinery at much lower cost. Moreover, the unit of purchase is often increased, thus increasing the volume of business for the retailer. A consequence of this development in packaging has been a great increase in sales by display and in self-service. Self-service is penetrating into more and more types of retail establishments, thus decreasing retail costs and often increasing the satisfaction of the retail customer.

Such consumer packaging requires a great degree of transparency of package and a considerable amount of descriptive information on the label; thus. information on the part of the retail salesperson tends to be of relatively little importance. If no particular facilities or no particularly informed sales personnel are needed to sell merchandise packaged primarily for self-service selling, then such merchandise does not need to be sold in specialized types of retail establishments. An increasing breakdown therefore occurs in the lines of demarcation between types of stores. Dentifrices, for example, may be found in the inventories of drugstores, food stores, variety stores, mail-order firms, department stores and, doubtless, other kinds of stores as well. Other items of merchandise can be found as widely distributed.

There appears to be a tendency toward seeking economies of scale by attempting to operate at large size. In the United States, Great Britain and Europe there is a strong tendency for food retailing, with the addition of accompanying lines of merchandise, to be carried on by chain store companies. Even among the cooperative societies there appears to be a tendency toward the operation of retail outlets at multiple locations. Department store and mail-order firms are tending to establish branches. The economies of central management have brought about national chains in the variety store field. Only in those fields such as furniture, where merchandise is bulky and often locally manufactured, is large size and chain or branch organization not in evidence.

With the growth in size, retailing organizations are finding it possible to introduce laboursaving mechanization. Electronic computers perform many clerical operations; scales weigh merchandise, compute price and affix price tags automatically; materials handling equipment of considerable efficiency is in wide use. In fields where personal service is highly important, nevertheless, the individual merchant can make his service of greater importance than the economies that can be introduced with large size.

See CHAIN STORE; DEPARTMENT STORE; DISCOUNT AND DISCOUNT HOUSES; MAIL-ORDER BUSINESS; SHOPPING CENTRE; see also Index references under "Retailing" in vol. 24.

(L. C. L.)

RETAINER, properly the act of retaining or keeping for oneself, or a person or object which retains or keeps; historically, a follower of a house or family and particularly used of armed followers attached to the barons of the middle ages.

Retainer of Counsel.—In the United States the term retainer is used to refer to the preliminary fee given a counsel to take or defend proceedings. In England the retainer is much more formal. When it is considered desirable by a litigant that the services of any particular counsel (barrister) should be obtained for the conduct of his case, it is necessary to deposit with counsel a form of retainer together with the necessary fee in cash, from which time counsel is bound to give the party who has thus retained him the first call on his services in the matter in which he has been retained.

Retainers are either general or special. A general retainer retains counsel for all proceedings in which the person retaining is a party. A special retainer is one which only applies to some particular cause or action.

See ADVOCATE.

Retainer of Debt.—In connection with the administration of an estate under a mill, it is the right of the personal representative —whether executor or administrator—of a deceased person to retain in respect of all assets which have come into his hands a debt due to himself in his own right whether solely or jointly with another person as against creditors of an equal degree, and this even though his debt is barred by the Statutes of Limitation.

The appointment of a receiver deprives the representative of his right except in regard to assets which came to his hands prior to the appointment of the receiver.

RETALHULEU, a department in southwestern Guatemala on the Pacific lowland. Area 717 sq.mi.; pop. (1950) 66,861. Coffee is grown on the slopes of the highlands at the northern end of the department. In the lowlands at the base of the highlands there are plantations of sugar cane, cotton, rice and cacao. Much land is devoted to the feeding of beef cattle. Retalhuleu, the departmental capital, is served by rail and highway. A railroad connects with the port of Champerico. (P. E. J.)

RETARDED CHILDREN. The phrase "retarded child" means one whose rate of development has been in any way slower than average. The retardation may be either physical, mental, educational or emotional. With earlier psychological writers, however, the phrase, when used without further qualification, usually refers to backwardness in general intelligence. In studying mental defectives in Paris, Alfred Binet noticed that in their intellectual processes they commonly resembled children three or four years younger and inferred that their condition resulted from the fact that their rate of mental growth had been retarded from birth onward. Accordingly, he suggested that a child's level of intelligence might be measured in terms of a mental age, with the difference between mental age and chronological age indicating the severity of the retardation. However, a backwardness of (say) two years would mean very different things at the age of 5 and 15; and a baby of 12 months could not be retarded by that amount. Later investigations showed that, in point of fact, the range of individual variation increases from birth to puberty in rough proportion with chronological age. Hence, it was suggested that instead of taking the difference between the mental and chronological ages it would be better to take the quotient or ratio. Expressed as a percentage, the index so obtained is known as a mental ratio or (more frequently) an intelligence quotient (I.Q.).

With later writers the term retarded child is used in a broader sense to include all those whose educational progress, from whatever cause, has been slower than that of an average child of the same chronological age. This is the definition suggested by the (British) Joint Committee on Mental Deficiency. Since the passing of the Education act of 1944, however, the designation more frequently adopted in British official publications is "educationally subnormal." Occasionally the child's educational age is compared not with his chronological but aith his mental age. In such cases an educational or achievement quotient is taken as the measure. With this interpretation a child whose innate intelligence was well above average would still be called retarded if his attainments in the chief school subjects were no more than those of the child whose intelligence was average for his age. There are many chil-

dren who in their emotional behaviour show the impulsiveness, the lack of control and the general modes of reaction distinctive of children several years younger: such children are often described as emotionally retarded, though here the term emotionally immature is more commonly employed. Finally, when a child's physical characteristics—height, weight, proportions, teeth, pubertal manifestations—are those of a younger child, he is sometimes described as physically retarded. Generally all types of retardation tend to go together.

Borderlines.—Since retardation is necessarily a matter of degree, the line between the retarded and the nonretarded must be a matter of convenience and convention. A pupil whose educational level is equivalent to that of children in the class below that which would be normal for his years needs no special treatment. Thus a child of 10, if normal, would be placed in a class containing children whose ages ranged from 9.5 to 10.5 years. Those in the class below would range in age from 8.5 to 9.5 years. If the pupil is unable to do the work even of these younger children, then, as experience shows, he requires education in a specially organized class with those who are equally subnormal. This implies that at a chronological age of 10 the borderline should be drawn at an educational age of 8.5 or generally at an educational ratio of 85%, which is the line of demarcation usually adopted for administrative purposes.

In the case of purely mental retardation (*i.e.*, retardation in innate intelligence) the upper borderline is similar. But a further classification is plainly desirable. The main division—between the milder cases and the more severe—is usually placed at an I.Q. of about 70. The figure is chosen because pupils below this level need educational provision in a special type of school. In the United Kingdom, before the Education act of 1944, they had to be certified as mentally defective before they could be removed to such a school. The act abolished the need for certification and, provided the children are in some degree educable, for official purposes they are classed with the "merely dull or backward" as belonging to the educationally subnormal, though psychiatrists retain the older nomenclature.

In the United States children whose I.Q. falls below 70 are more usually termed feeble-minded.

Causes.—Educational retardation is due to a wide variety of conditions, and in most instances several factors co-operate, although one usually stands out as the major cause. The commoner factors may be divided into two groups: extrinsic or environmental and intrinsic or personal.

Among environmental causes statistical surveys show that home conditions are more significant than school conditions. Among the lower classes poverty, together with all the handicaps it brings in its train, is one of the most frequently reported. In western countries, however, its influence has steadily diminished. The cultural conditions of the home—a low intellectual level or a lack of educative interests among the parents—appears far more important. But even in a comfortable and cultured home emotional disturbances within the family may at times so upset the child as to affect his work in the classroom. Of conditions more closely connected with the school, irregular attendance is the commonest. Almost equally frequent are inadequate organization of the classes and inefficient or inappropriate methods of teaching.

Of conditions obtaining aithin the child himself, physical defects are less important than is popularly supposed; ill health forms a major factor in only about 10% of the cases. Innate inferiority of general intelligence occurs in well over three-quarters of the cases, and in about one-half it constitutes the major cause. Of more specific disabilities the most obvious are uncorrected defects in sight and hearing. More easily missed are defects in visual and auditory perception or imagery: some children are lacking in verbal facility, others in numerical ability, but by far the commonest defect is in mechanical memory. Temperamental conditions, notably emotional instability, are found among about 7%, often conjoined with certain moral weakness: the child is lazy and ill disciplined in the classroom and prone to petty delinquencies in his life out of school.

Treatment.—The first step is to ascertain the cause. Where the educational retardation is due primarily to innate weakness in general intelligence, it is to that extent irremediable, but much may be done by suitable training in a special school or institution. With milder cases, reclassification for specific subjects, individual coaching, attendance at a special centre (*e.g.*, for speech training) or transfer to a special class may be advised. In the investigation and treatment of special disabilities, assistance commonly is needed from an educational psychologist or child guidance clinic. See also INTELLIGENCE; MENTAL DEFICIENCY.

RETFORD (officially EAST RETFORD), a market town and municipal borough in the Bassetlaw parliamentary division of Nottinghamshire, Eng., 30 mi. N.N.E. of Nottingham by road. Pop. (1951) 16,316. Area 7.3 sq.mi. Retford (Redforde in Domesday Book) owes its beginnings to its position near one of the Roman roads and on the river Idle, where there was a ford. In 1086 the archbishop of York owned a mill at Retford. It was a borough by prescription.

The earliest charter in the possession of the corporation is that of Edward II (1313) but charters were granted by Henry III (1246) and Edward I (1276). Other charters uhich have survived are those of Edward III (1329), Richard II (1378), Henry IV (1401), Elizabeth I (1562), and James I (1607). East Retford returned two members to parliament from 1315 to 1330 and again from 1571 to 1830.

The borough was joined with the hundred of Bassetlaw and two members were returned until 1885 when the representation was reduced to one member.

The town has flourishing markets and engineering, rubber, wire and dyeing and cleaning works, iron foundries and paper and corn mills. Coal is mined in the vicinity.

RETHEL, ALFRED (1816–1859), one of the few exponents of monumental painting and historical subjects of 19th-century Germany, was born at Aix-la-Chapelle (Aachen) on May 15, 1816. At 13 he entered the Dusseldorf academy, which was at that time flourishing under the direction of Wilhelm von Schadow-Godenhaus. From 1836 until 1847 he lived in Frankfurt, where artistic life centred around Philipp Veit, and occupied himself with sketches for the Charlemagne frescoes in the restored council house of Aix-la-Chapelle. Having won the competition with his sketches, he was commissioned to commence this work in 1847. From that year until 1852 Rethel used to work in Aix-la-Chapelle in summer and Dresden in winter. He died, mentally deranged, at Diisseldorf on Dec. 1, 1859.

His assistant Joseph Kehren continued Rethel's work on the half-finished series of the Charlemagne frescoes, and five of the original eight frescoes survive. Rethel is best known for his powerful series of woodcuts entitled "The Dance of Death," suggested by the Belgian insurrections of 1848, and two woodcuts, "Death as Friend" and "Death as Foe."

RETZ, JEAN FRANÇOIS PAUL DE GONDI, CARDIKAL DE (1614–1679), French churchman and agitator, was born at Montmirail in 1614. The family was one of those which had been introduced into France by Catherine de Médicis, but it acquired great estates in Brittany and became connected with the noblest houses of the kingdom. Retz himself always spelled his designation "Rais." He was the third son and was destined for the church.

He studied at the Sorbonne, and when he was scarcely 18 wrote the remarkable *Conjuration* de Fiesque, a little historical essay, of which he drew the material from the Italian of Augustino Mascardi, but which is all his own in the negligent vigour of the style and the audacious insinuation, if nothing more, of revolutionary principles.

Retz received no preferment of importance during Cardinal Richelieu's life, and even after the minister's death, though he was

presented to Louis XIII and well received, he found difficulty in attaining the coadjutorship with reversion of the archbishopric of Paris. But almost immediately after the king's death, Anne of Austria appointed him to the coveted post on All Saints' Eve, 1643.

Retz acquired great influence with the Parisians, which he gradually turned against Jules Cardinal Mazarin. No one had more to do than Retz with the outbreak of the Fronde (q v.) in Oct. 1648, and his history for the next four years is the history of that movement. Of the two parties who joined in it Retz could only depend on the bourgeoisie of Paris. But although he had some speculative tendencies in favour of popular liberties, and even perhaps of republicanism, Retz represented no real political principle, and when the breakup of the Fronde came he was left in the lurch. having more than once in the meantime been in no small danger from his own party. One stroke of luck, however, fell to him before his downfall. He was made cardinal almost by accident and under a misapprehension on the pope's part. In 1652 he was arrested and imprisoned, first at Vincennes, then at Nantes; he escaped, however, after two years' captivity, and for some time wandered about in various countries. He made his appearance at Rome more than once, and had no small influence in the election of Alexander VII. In 1662, he was received back again into favour by Louis XIV and on more than one occasion he served as envoy to Rome. Retz, however, was glad in making his peace to resign his claims to the archbishopric of Paris. In compensation he received the rich abbacy of St. Denis and restoration to his other benefices.

The last 17 years of Retz's life were passed partly in his diplomatic duties, partly at Paris, partly at his estate of Commercy. but latterly at St. Mihiel in Lorraine. His debts were enormous, and in 1675 he resolved to make over to his creditors all his income except 20.000 livres, and, as he said. to "live for" them. He died at Paris on Aug. 24, 1679.

One of the chief authorities for the last years of the life of Retz is Madame de Sévigné, whose connection he was by marriage. Retz's *Memoirs* were certainly not nritten until the last ten years of his life, and they do not go farther than the year 1655. They are addressed in the form of narrative to a lady who is not known. They display. in a rather irregular style and with some oddities of dialect and phrase. fine narrative skill and a high degree of ability in that special art of the 17th century — the drawing of verbal portraits or characters.

Besides these memoirs and the historical essay previously mentioned, Retz left diplomatic papers, sermons, Mazarinades and correspondence.

RETZIUS, the name of a family of Swedish scientists renowned for their work in natural history and medicine.

ANDERS JAHAN RETZIUS (1742–1821) was born in Kristianstad on Oct. 3, 1742. He taught at the University of Lund from 1764, was made extraordinary professor in 1777 and ordinary professor of natural history in 1781; later he taught economics and chemistry. In 1812 he transferred to the Carolinian institute in Stockholm, where he died Oct. 6, 1821. A species of plant (*retzia*) was named for him.

ANDERS ADOLF RETZIUS (1796–1860), son of Anders Jahan, was born in Lund on Oct. 13, 1796, and studied in the university of that city until the age of 19, when he transferred to the Copenhagen university. He returned to his native city to receive his medical degree in 1819 and then studied surgery at the Carolinian institute, served four years as a military surgeon and was made professor of comparative anatomy in the Veterinary school of Stockholm. In 1824 he was appointed to the chair of human anatomy and physiology in the Carolinian institute and was later made rector. He made several trips abroad, cultivating close personal friendship and scientific collaboration with Purkinje, Johannes Miiller and many other medical scientists of Europe. In 1839 he was appointed professor of anatomy in connection with painting at the Royal Academy of Fine Arts. In 1858 he was elected president of the Royal Swedish Academy of Science at Stockholm. He died April 18, 1860. Retzius is best remembered as an anthropologist, having introduced the new science of craniometry, which permitted a classification of races on the basis of cephalic measurements. The titles of his publications, dealing with a wide variety of scientific fields, fill three closely printed pages in the Swedish Biographical Lexicon. Named for him are the prevesical space (space of Retzius), dental striae (contour lines of Retzius), convolutions in the brain (gyri of Retzius), a ligament of the ankle (ligament of Retzius) and the veins of Retzius, which unite the radicles of the portal vein with the branches of the inferior vena cava.

MAGNUS CHRISTIAN RETZIUS (1795–1871), another son of Anders Jahan, was born on March 22, 1795. He was professor of obstetrics in the Carolinian institute and director of the lying-in hospital of Stockholm. He died Oct. 1, 1871.

CARL GUSTAF RETZIUS (1798–1833), also son of Anders Jahan, was born April 28, 1798. He was adjunct in chemistry at the University of Lund and professor at the Veterinary school of Stockholm. He died Feb. 23, 1833.

GUSTAF MAGNUS RETZIUS (1842–1919), son of Anders Adolf, was born Oct. 17, 1842, in Stockholm. He was an anatomist and anthropologist, best known for his studies on the histology of the nervous system. He died in Stockholm, July 21, 1919.

(HD. ST.)

REUBEN, according to Gen. xxix. 32, was the eldest son of Jacob. by his first wife. Leah. From this it may be inferred that at one time Reuben ranked as the foremost of the Hebrew tribes. But for reasons which are obscure the tribe lost this pre-eminence at an early period of the history.

In Gen. xxxv, 22 Reuben is said to have been intimate with his father's concubine, and the story. which breaks off abruptly. probably went on to record a curse pronounced upon him in consequence. This would be regarded as a sufficient explanation of the decline of the tribe (cf. Gen xlix, 4, and see I Chron. v. 1). It is possible that the story may be a personification of some aggressive move made by the tribe Reuben against the Bilhah clan. The subsequent history of the tribe is obscure. The territory which later traditions assign to it east of the Dead sea is not clearly delimited or distinguished from the territories of Gad and Moab.

A Reubenite name is found on the west of the Jordan (Josh. xv, 6; xviii, 17), and the reference to Reuben in the Song of Deborah (Judg. v, 15–17) would naturally mean that Reuben was a pastoral tribe on the west of the Jordan, since of the next tribe mentioned it is definitely stated "Gilead abode beyond Jordan."

(W. L. W.)

REUCHLIN, JOHANN (1455–1522), German humanist and Hebraist, was born on Feb. 22, 1455, at Pforzheim in the Black Forest, where his father was an official of the Dominican monastery. The name was graecized by his Italian friends into Capnion. Reuchlin constantly writes himself Phorcensis. He learned Latin at the monastery school at Pforzheim. and spent a short time in 1470 at the University of Freiburg. His fine voice gained him a place in the household of Charles I, margrave of Baden. and he was chosen to accompany to the University of Paris the young prince Frederick.

In Paris Reuchlin learned Greek, and he attached himself to the leader of the Paris realists, Jean Heynlin, or à Lapide (d. 1496), whom he followed to the vigorous young University of Basel in 1474.

At Basel Reuchlin took his master's degree (1477), and began to lecture, teaching a more classical Latin than was then common in German schools, and also explaining Aristotle in Greek. His Greek studies were continued at Basel under Andronicus Contoblacas, and he became acquainted with the bookseller, Johann Amorbach, for whom he prepared a Latin lexicon (*Vocabularius Breviloquus,* 1st ed., 1475–76).

Reuchlin soon left Basel to study under George Hieronymus at Paris. He then studied law at Orleans (1478), and at Poitiers, where he became licentiate in July 1481. On his return to Germany he was engaged as interpreter by Count Eberhard of Württemberg, for a tour in Italy. They started for Florence and Rome in February 1482.

His connection with the count became permanent,

and after his return to Stuttgart he received important posts at Eberhard's court. About this time he appears to have married, but little is known of his married life. He left no children; but in later years his sister's grandson Melanchthon was almost as a son to him till the Reformation estranged them.

In 1490 he was again in Italy. Here he saw Pico della Mirandola, to whose Cabbalistic doctrines he afterwards became heir, and also made the friendship of the pope's secretary, Jakob Questenberg. On an embassy to the emperor Frederick at Linz in 1492, he began to read Hebrew with the emperor's Jewish physician Jakob ben Jehiel Loans. In 1494 his rising reputation had been greatly enhanced by the publication of *De Verbo Mirifico*.

In 1496 Eberhard of Wiirttemberg died, and Reuchlin was glad to accept the invitation of Johann von Dalberg (1445–1503), bishop of Worms, to Heidelberg, which was then the seat of the "Rhenish Society." In this court of letters Reuchlin made translations from the Greek authors. He was during a great part of his life the real centre of all Greek teaching as well as of all Hebrew teaching in Germany. Reuchlin pronounced Greek as his native teachers had taught him to do, *i.e.*, in the modern Greek fashion. This pronunciation, which he defends in *Dialogus de Recta Lat. Graecique Serm. Pron.* (1519), came to be known, in contrast to that used by Erasmus, as the Reuchlinian.

At Heidelberg Reuchlin had many private pupils, among whom Franz von Sickingen is the best known name. With the monks he had never been liked; at Stuttgart also his great enemy was the Augustinian Conrad Holzinger. On this man he took a scholar's revenge in his first Latin comedy *Sergius*, a satire on worthless monks and false relics.

Through Dalberg, Reuchlin came into contact with Philip, elector palatine of the Rhine. who employed him to direct the studies of his sons, and in 1498 sent him on a mission to Rome. He came back laden with Hebrew books, and found when he reached Heidelberg that a change of government had opened the way for his return to Stuttgart, where his wife had remained all along. His friends had now again the upper hand, and knew Reuchlin's value. In 1500, or perhaps in 1502, he was given high judicial office in the Swabian League, which he held till 1512, when he retired to a small estate near Stuttgart.

For many years Reuchlin had been increasingly absorbed in Hebrew studies, which had for him more than a mere philological interest for as a good humanist he could not rest satisfied with the Vulgate text of the Old Testament. In 1506 appeared his epoch-making *De Rudimentis Hebraicis*—grammar and lexicon—mainly after Kimhi, yet not a mere copy of one man's teaching. The edition was costly and sold slowly. One great difficulty was that the wars of Maximilian I. in Italy prevented Hebrew Bibles coming into Germany. But for this also Reuchlin found help by printing the Penitential Psalms with grammatical explanations (1512), and other helps followed from time to time. But his Greek studies had interested him in those fantastical and mystical systems of later times with which the Cabbala has no small affinity. Reuchlin's mystico-cabbalistic ideas and objects were expounded in the *De Verbo Mirifico*, and in the *De Arte Cabbalistica* (1517).

Unhappily many of his contemporaries thought that the first step to the conversion of the Jews was to take from them their books. This view had for its chief advocate the bigoted Johann Pfefferkorn (1469–1521), who secured the ear of the emperor Maximilian. In 1510 Reuchlin was summoned in the name of the emperor to give his opinion on the suppression of the Jewish books. He proposed that the emperor should decree that for ten years there be two Hebrew chairs at every German university for which the Jews should furnish books. The other experts proposed that all books should be taken from the Jews; and, as the emperor still hesitated, the bigots threw on Reuchlin the whole blame of their ill success. Pfefferkorn circulated at the Frankfort fair of 1511 a gross libel (*Handspiegel wider und gegen die Juden*) declaring that Reuchlin had been bribed; and Reuchlin retorted as warmly in the *Augenspiegel* (1511). His adversary's next move was to declare the *Augenspiegel* a dangerous book; the Cologne theological faculty, with the inquisitor Jakob von Hochstraten (d. 1527), took up this cry, and on Oct. 7, 1512, they obtained an imperial order confiscating the *Augenspiegel*. Reuchlin was timid, but he was honesty itself. He was willing to receive corrections in theology, which was not his subject, but he could not unsay what he had said; and as his enemies tried to press him into a corner he met them with open defiance in a *Defensio contra Calumniatores* (1513). The universities were now appealed to for opinions, and were all against Reuchlin. Even Paris (August 1514) condemned the *Augenspiegel*, and called on Reuchlin to recant. Meantime a formal process had begun at Mainz before the grand inquisitor, but Reuchlin by an appeal succeeded in transferring the question to Rome. Judgment was given in July 1516; and then, though the decision was really for Reuchlin, the trial was simply quashed. The result had cost Reuchlin years of trouble and no small part of his modest fortune, but the obscurantists received a crushing blow in Germany. No party could survive the ridicule that was poured on them in the *Epistolae Obscurorum Virorum*.

Reuchlin did not long enjoy his victory in peace. In 1519 Stuttgart was visited by famine, civil war and pestilence. Reuchlin sought refuge in Ingolstadt and taught there for a year as professor of Greek and Hebrew. He was now called to Tiibingen and again spent the winter of 1521–22 teaching in his own systematic way. He died at the baths of Liebenzell on June 30, 1522, leaving in the history of the new learning a name only second to that of his younger contemporary Erasmus.

See L. Geiger, *Johann Reuchlin* (1871), which is the standard biography; also D. F. Strauss, *Ulrich von Hutten;* S. A. Hirsch, "John Reuchlin, the Father of the Study of Hebrew among the Christians," and his "John Pfefferkorn and the Battle of Books," in his Essays (London, 1905). Some interesting details about Reuchlin are given in the autobiography of Conrad Pellicanus (*q.v.*), which was not published when Geiger's book appeared. *See* also the article on Reuchlin in Herzog-Hauck, *Realencyklopadie*, and literature there cited.

RÉUNION, an island and French overseas *département* in the Indian ocean, 425 mi. S.E. of Tamatave, Madagascar, and 130 mi. S.W. of Port Louis, Mauritius. It is elliptical in form and has an area of 970 sq.mi. It lies between 20° 51′ and 21° 22′ S. and 55° 15′ and 55° 54′ E.

The coast line is little indented, high and difficult of access, and the harbours are usually sunken craters. The narrow coastlands, from $\frac{2}{3}$ to 2 mi. wide, are succeeded by hilly ground which gives place to mountain masses and tableland, occupying most of the island. The main axis and watershed runs northwest-southeast, and divides the island into windward (eastern) and leeward (western) districts. The whole relief is complex because of its volcanic nature. First was formed a mountain whose summit is approximately represented by Piton des Neiges (10,069 ft.), an immense denuded crater, and later another crater opened toward the east, piling up the mountain mass of Le Volcan. The oldest erupted rocks belong to the type of the andesites; the newest are varieties of basalt. The two massifs are united by high tablelands. In the older massif the most striking features are now three areas of subsidence--the cirques or mountain amphitheatres of Salazie, Mafatte and Cilaos—which lie northwest and south of Piton des Neiges. The first, which may be taken as typical, is surrounded by high, almost perpendicular walls of basaltic lava. Somewhat lower plateaus (the Plaine des Cafres and the Plaine des Palmistes) extend between Piton des Neiges and Le Volcan.

The second massif, Le Volcan, is cut off from the rest of the island by two "enclosures," each about 500 or 600 ft. deep. The outer enclosure runs across the island in a north and south direction; the inner forms a kind of parabola with its arms stretching east to the sea and embracing not only the volcano proper but also the great eastward slope known as the Grand Brûlé. The 30 mi. of mountain wall round the volcano is perhaps unique in its astonishing regularity. It encloses an area of about 40 sq.mi. known as the Grand Enclos. There are two principal craters, each on an elevated cone—the more westerly, now extinct (8,596 ft.), and the more easterly, called the Burning Crater or Fournaise (8,294 ft.). Eruptions, though not infrequent (30 were registered between 1735 and 1860), are seldom serious. The volcano is of Hawaiian type and its lava runs down to the sea. Following 40 years' inactivity, it reawakened in 1925 and erupted several times thereafter. Hot mineral springs are found on the flanks of Piton

des Neiges; the Source de Salazie, 2,860 ft. above sea level, has a temperature of 90° F., and discharges water impregnated with bicarbonate of soda, carbonates of magnesium, lime, iron, etc.; that of Cilaos is 3,650 ft. above the sea with a temperature of 100°; and that of Mafatte at 2.238 ft. and 87°.

Climate. — The year divides into two seasons — that of heat and rain from November to April, that of dry and more bracing weather from May to October. The prevailing wind is the south-east trade wind, which sometimes veers around to the south and more frequently to the northeast; the west winds are not so steady (307 days of east to j8 of west wind in the year). As over all the Indian ocean, cyclonic storms are frequent at the change of seasons. The relief of the land causes appreciable climatic differences, the leeward side getting much less rain than the windward. On the coast and lower zones on the windward side the mean temperature is about 73° in the "winter" and 78° in the "summer." On the leeward side the heat is somewhat greater. In the Salazie cirque the mean annual average is 66"; on the Plaine des Palmistes 62". On the mountain heights snow falls every year. Hill stations (Hellbourg, Cilaos) have been established in the cirques.

Flora and Fauna. — The heat. humidity and fertility of the volcanic soil have given Reunion an abundant and varied vegetation. In the forest region of the island there is a belt. from 4 500 to 5,000 ft. above the sea, characterized by the prevalence of dwarf bamboo (*Bambusa alpina*); and above that is a similar belt of Acacia heterophylla. Besides this last the best timber-trees are *Casuarina laterifolia, Foetida mauritiana, Elacodendron orientale, Calophyllum spurium* (red tacamahac), *Terminali borbonica, Parkia speciosa.* A species of coffee plant is indigenous. Fruits grown include banana, coconut, breadfruit and jackfruit. Forests originally covered nearly the whole island; most of the land has been cleared, but the administration in part replanted the higher districts with eucalyptus and rubber trees.

The fauna of Réunion is not very rich in variety of species. Among the mammals are several bats, a wildcat, the tenrec (*Tenrec ecaudatus*), introduced from Madagascar, rats, etc. Among the more familiar birds are the Bourbon flycatcher (*Tchitrea bourbonnensis*), the Réunion merle (*Mieroscelis borbonica*), the Bourbon manioc bird (*Malacirops borbonicus*), the cardinal (*Foudia madagascariensis*). various swallows, ducks, etc. Lizards and frogs of more than one species are common, but only one snake (*Lycodon aulicus*) is known in the island. Various species of gobies, a gray mullet that goes into fresh water, a freshwater mullet (*Agonostomus eyprinoides*), *Doules fuscus* in brackish water and *Osphronamus olfax* (introduced into the island) are among the fishes found.

History.—Réunion is usually said to have been discovered on Feb. 9, 1513, St. Apollonia's day, by the Portuguese navigator Pedro Mascarenhas, and his name is still applied to the Mascarene Islands, the archipelago of which Réunion forms a part. The island itself was at first called Santa Apollonia or Mascarenhas. The French later called it Bourbon, then, after the Revolution, "la Réunion des Patriotes." When in 1638 the island was taken possession of by Captain Goubert, of Dieppe, it was uninhabited.

The first inhabitants were a dozen mutineers deported from Madagascar by Jacques Pronis. In 1664 the Compagnie des Indes Orientales initiated a regular colonization scheme. In 1717 there were only about 2,000 inhabitants, of whom 1,100 were Malagasy and Kaffir slaves. They lived on excellent terms with the pirates who frequented Madagascar. Mocha coffee, introduced at that time, quickly made the island prosperous. At the end of the century sugar replaced it as the principal crop.

From 1810 to 1815 the island was occupied by the English. In the enthusiasm of the 1848 revolution slavery was abolished. At that time there were 105,000 inhabitants, including 60,000 slaves who now received French citizenship. Under the Second Empire Indian coolies were brought in. Réunion became an overseas *département* of France in 1946.

Réunion has been called *colonie colonisatrice* because its inhabitants were among the first French settlers in Mauritius, Rodriguez and the Seychelles (in the 18th century), Madagascar and the Austral Islands of the Indian ocean (in the 19th). People from Réunion have also gone as colonists to Cochin-China and New Caledonia. It is also called "l'île des poètes": extolled by André de Chénier, it was the birthplace of the Vicomte de Parny, Antoine de Bertin, Leconte de Lisle and Léon Dierx.

Inhabitants.—Réunion, strictly speaking, has no indigenous population. The inhabitants include Creoles, mulattoes, Negroes, Indians and other Asians. The Creole population is descended from the first French settlers, chiefly Normans and Bretons. Much of the population is of mixed descent. Three kinds of Creole are recognized — those of the towns and coasts, those of the mountains and the *petits blancs*, originally a class of small farmers living in the uplands, now reduced to a condition of poverty and dependence on the planters. The crkoles de villes, the typical inhabitants of the island, are in general of a somewhat weak physique, quick-witted and of charming manners, and very proud of their island. The Creole patois is French distorted by Malagasy and Bantu pronunciation. The population numbered 242,067 at the 1946 census (1950 est., 261.647). The density is 270 persons to the square mile or, if only the settled areas are counted, 64; to the sq.mi.; the birth rate is high. Madagascar has been a receiving country for Réunionais emigrants, but overpopulation remains a problem. Indians and Chinese together number about 30,000.

Towns and Communications. — St. Denis (pop., 1950 est., 39,057), the capital of the island, lies on the north coast. It is built in the form of an amphitheatre, and has several fine public buildings and centrally situated botanic gardens. The only anchorage for vessels is an open roadstead. St. Pierre (pop. 24,652), the chief town on the leeward side of the island, has a small artificial harbour. Between St. Pierre and St. Denis, and both on the leeward shore, are the towns of St. Louis (pop. 23,925) and St. Paul (pop. 27,585). A few miles north of St. Paul on the south side of Cap Pointe des Galets is the port of the same name, the only considerable harbour in the island. It was completed in 1886, covers 40 ac., is well protected and has 28 ft. of water. A railway serving the port goes around the coast from St. Pierre, by St. Paul, St. Denis, to St. Benoît.

A road runs around the island. Lateral roads give access to the cirques and the hill stations.

Agriculture and Industry. — Most of the coastal region is occupied by sugar-cane plantations, vanilla and cocoa. Sugar cane, introduced in 1711 by Pierre Parat, is now the staple crop. In the 18th century the first place belonged to coffee (introduced from Arabia in 1715) and to the clove tree, brought from the Netherlands Indies by Pierre Poivre at the risk of his life. Both are now cultivated on a limited scale. Vanilla, introduced in 1818, is cultivated mostly in the more humid eastern part. In the highlands, which have a Mediterranean climate, geraniums and vetiver (from which essential oils for perfumes are extracted), maize, legumes and fruit trees are cultivated.

The sugar industry suffered greatly from the competition with beet sugar, the effects of bounties and antiquated methods of manufacture. It was not until 1906 that steps were taken to set up central sugar mills and refineries. By 1954 the industry was concentrated into 13 well-equipped plants. This concentration of industry is paralleled by a concentration of property: an aristocracy of millowners and big proprietors employs a proletariat of tenant farmers and farm workers. Rum is distilled and forms an important item of export.

Administration.—Réunion is a dkpartement of France. It sends three deputies and two senators to the French legislature, and a councillor to the assembly of the French union. All nonalien inhabitants are French citizens. At the head of the local administration is a prefect who is assisted by a secretary-general, a *procureur général* and a *conseil général* elected by the suffrage of all citizens, which, after 1946, had powers no greater than those of *conseils généraux* of French metropolitan *départements*. The technical services are administered by the several metropolitan ministries, and French metropolitan legislation as a whole extends to the island. For administrative purposes the island is divided into two arrondissements, the Windward. with five cantons and nine communes, and the Leeward, with four cantons and seven communes. The towns are subject to the French municipal law.

The island's revenue and expenditure are wholly accounted for within the French metropolitan budget.

Economy.— The Banque de la Réunion issues notes valued in francs Colonies Françaises d'Afrique (1 fr. C. F. A. = 2 fr. metropolitan). Exports in 1953 mere valued at 5,354,000,000 fr. C. F. A., including 4,487,000,000 fr. C. F. A. for sugar (149,557 metric tons), 334,000,000 fr. C. F. A. for rum (41,614 hl.), 452,000,000 fr. C. F. A. for geranium and other essences (112 metric tons) and 51,000,000 fr. C. F. A for vanilla (34 metric tons). The main destinations of exports were France (3,374,000,000 fr. C. F. A.), Indochina (503,000,000 fr. C. F. A.) and Morocco. Reunion's imports cost 6,415,000,000 fr. C. F. A. in 1953. Almost all foodstuffs are imported, notably rice and meat from Madagascar (6,415,000,000 fr. C. F. A.). Nearly all manufactured goods come from France (3,984,000,000 fr. C. F. A. in 1953).

REUNION, CHURCH: *see* ECUMENICAL MOVEMENT.

REUS, a city of northeast Spain, in the province of Tarragona, on the Saragossa-Tarragona railway, 4 mi. N. of Salou, its port on the Mediterranean. Pop. (1950) 35,950 (mun.). Reus consists of two parts, the old and the new! separated by the Calle Arrabal, which occupies the site of the old city wall. The earliest records of Reus date from about the middle of the 13th century. Its modern prosperity is traced to about the year 1750, when a colony of English settled there and established a trade in woollens, leather, wine and spirits. The principal incidents in its political history arose out of the occurrences of 1843 *(see* SPAIN: *History),* in connection with which the town received the title of city, and Generals Zurbano and Prim were made counts of Reus. The city was the birthplace of General Prim (1814–70) and of the painter Mariano Fortuny (1839–74). The city has important flour, wine and fruit export houses.

REUSCH, FRANZ HEINRICH (1823–1900), German theologian, was born at Brilon, Westphalia, on Dec. 4, 1823. He studied general literature at Paderborn and theology at Bonn, Tiibingen and Munich, where he was a friend and pupil of Döllinger. In 1854, he became *Privatdozent* in the exegesis of the Old Testament in the Catholic theological faculty at Bonn; in 1858 he was made extraordinary and in 1861 ordinary professor of theology in the same university. From 1866 to 1877 he was editor of the *Bonner Theologisches Literaturblatt.* In the controversies on the infallibility of the Pope, Reusch, who had been ordained priest in 1849, attached himself to Dollinger's party, and he and his colleagues Hilgers, Knoodt and Langen were interdicted by the archbishop of Cologne in 1871 from pursuing their courses of lectures. In 1872 he was excommunicated. For many years after this he held the post of Old Catholic *cure'* of Bonn, as well as the position of vicar-general to the Old Catholic bishop Reinkens, but resigned both in 1878, when. with Dollinger, he disapproved of the permission to marry granted by the Old Catholic Church in Germany to its clergy.

He was made rector of Bonn university in 1873. In 1874 and 1875 he was official reporter of the reunion conferences held at Bonn. He produced with Döllinger the *Geschichte der Moralstreitigkeiten in der Romisch-Katholischen Kirche seit dem XVI. Jahrhundert* and the *Erorterungen über Leben und Schriften des hl. Liguori.*

Reusch died on March 3, 1900.

REUSS, EDOUARD GUILLAUME EUGENE (1804–1891), German Protestant theologian, was born at Strasbourg on July 18, 1804. He studied philology in his native town (1819–22); theology at Gottingen under J. G. Eichhorn; and oriental languages at Halle under Wilhelm Gesenius, and afterward at Paris under Silvestre de Sacy (1827–28). He taught at Strasbourg from 1828 until 1888, for 60 years, having become full professor in 1836. His most important works are: *Geschichte der heiligen Schrijten Neuen Testaments* (1842), *Histoire de la théologie chre'tienne au siècle apostolique* (1852); *L'Histoire du canon des saintes écritures dans l'église chre'tienne* (1863); *La Bible, nouvelle traduction avec commentaire* (1874, etc.); and *Geschichte der heiligen Schriften Alten Testaments,* a veritable encyclopaedia of the history of Israel from its earliest beginning till the taking of Jerusalem by Titus. He died at Strasbourg on April 15, 1891. For many years Reuss edited with A. E. Cunitz (1812–86) the *Beitrage zu den theologischen Wissenschaften.* With Cunitz and J. W. Baum (1809–78), and after their deaths alone, he edited the monumental edition of Calvin's works (38 vol., 1863 ff.). His critical edition of the Old Testament appeared a year after his death.

See the article in Herzog-Hauck, *Realenzyklopädie,* and *cf.* Otto Pfleiderer, *Development of Theology in Germany Since Kant* (1890).

REUSS, the name of two former German principalities (Reuss-Greiz and Reuss-Schleiz-Gera) which after 1918 were amalgamated into Thuringia (*q.v.*).

History.— The princes of Reuss traced their descent to Henry (d. about 1120), who was appointed by the emperor Henry IV imperial bailiff (Ger. *Vogt,* from Lat. *advocatus imperii)* of Gera and of Weida. His descendants called themselves lords of Weida. The land under their rule gradually increased in size, and it is said that the name of Reuss was applied to it because of the fact that one of its princes married a Russian princess, their son being called *der Russe,* or "the Russian." In 1564 the family was divided into three branches by the sons of Henry XVI (d. 1535). One of these died out in 1616, but those of Reuss-Greiz and Reuss-Schleiz-Gera survived as sovereign houses till the revolution of 1918. The lords of Reuss took the title of count in 1673; the head of the elder line became a prince of the empire in 1778, and the head of the younger line in 1806. In 1807 the two princes joined the confederation of the Rhine, and in 1815 the German confederation. In 1866 both principalities became members of the north German confederation.

A curious custom prevailed in the house of Reuss. The male members of both branches of the family all bore the name of Henry (Heinrich), the individuals being distinguished by numbers.

See H. von Voss, *Die Ahnen des reussischen Hauses* (Lobenstein, 1882); O. Liebmann, *Das Staatsrecht des Fürstenthums Reuss* (1884); C. F. Collmann, *Reussische Geschichte: Das Vogtland im Mittelalter* (Greiz, 1892); B. Schmidt, *Die Reussen, Genealogie des Gesamthauses Reuss* (Schleiz, 1903).

REUTER, FRITZ (1810–1874), German novelist, made Plattdeutsch a literary language. Born Nov. 7, 1810, at Stavenhagen, in Mecklenburg-Schwerin, he studied at Rostock and at Jena, where he was a member of the political students' club, or German Burschenschaft, and in 1833 was arrested in Berlin by the Prussian government. Although the only charge which could be proved against him was that he had been seen wearing the Burschenschaft colours, he was condemned to death for high treason. The sentence was commuted to imprisonment for 30 years in a Prussian fortress. In 1838, through the personal intervention of the grand duke of Mecklenburg, he was handed over to the authorities of his native state, and in 1840 was set free by a general amnesty.

In 1850 he settled as a private tutor at the little town of Treptow in Pomerania. There he married Luise Kunze, the daughter of a Mecklenburg pastor. Reuter's first publication was a collection of miscellanies, written in Plattdeutsch and entitled *Lauschen un Riemels* ("Anecdotes and Rhymes," 1853; a second collection folloued in 1858). There followed *Polterabendgedzchte* (1855) and *De Reis' nah Belligen* (1855). In 1856 Reuter left Treptow and established himself at Neubrandenburg. His next book (published in 1858) was *Kein Hüsung,* an epic in which he presents with great force and vividness some of the least attractive aspects of village life in Mecklenburg. This was followed, in 1860, by *Hanne Nüte un de liitte Pudel,* the best of his verse compositions. In 1860 he published the first series of his *Olle Kamellen* ("Old Stories of Bygone Days"), which contained *Woans ick tau'ne Fru kam* and *Ut de Franzosentid.* Later volumes were entitled *Ut*

mine Festungstid (1861); *Ut mine Stromtid* (3 vols. 1864); and *Dorchliiuchting* (1866)—all written in the Plattdeutsch dialect of the author's home. *Ut mine Stromtid* is by far the greatest of Reuter's writings. *Ut de Franzosentid* describes the deep national impulse under which Germany rose against Napoleon. Ut *mine Stromtid* deals with the revolution of 1848.

In 1863 Reuter moved to Eisenach; and here he died on July 12, 1874.

Reuter's *Sämtliche Werke,* in 13 vols., were first published in 1863–68. To these were added in 1875 two volumes of *Nachgelassene Schriften,* with a biography by A. Wilbrandt; and in 1878 two supplementary volumes to the works appeared. A popular edition in 7 vols. was published in 1877–78 (new edition, 1902); there are also editions by K. F. Muller (18 vols., 1905), and W. Seelmann (7 vols., 1905–06). See *Briefe* F. *Reuters an seinen Vater,* ed. F. Engel (2 vols., 1895); A. Romer, F. *Reuter in seinem Leben und Schaffen* (1895); *G.* Raatz, *Wahrheit und Dichtung in Reuters Werken* (1895); *E.* Brandes, *Aus* F. *Reuters Leben* (1899); *K.* F. Muller, *Der Mecklenburger Volksmund und F. Reuters Schriften* (1902). A complete bibl. will be found in the *Nzederdeutsche Jahrbuch* for 1896 and 1902.

REUTER, GABRIELE (1859–1941), German novelist, was born at Alexandria, Egypt, on Feb. 8, 1859. Her first novel, *Glück und Geld,* appeared in 1888. One of her early novels, *Aus guter Familie,* had reached its 25th edition in 1907. Among her works are *Frauenseelen* (1901); *Jugend eines Idealisten* (1916); and *Benedikta* (1923). She died at Weimar in Nov. 1941.

REUTER, PAUL JULIUS, BARON DE (1816–1899), founder of Reuters news agency, was born at Cassel, Germany. At the age of thirteen he became a clerk in his uncle's bank at Gottingen, where he met Gauss, whose experiments in telegraphy were then attracting some attention. In 1849 there was a gap between the end of the new German telegraph line at Aix-la-Chapelle and that of the French and Belgian lines at Verviers. Reuter organized a news-collecting agency at each of these places and bridged the interval by a pigeon-post. On the establishment of through telegraphic communication, Reuter endeavoured to start a news agency in Paris, but finding that the French government's restrictions would render the scheme unworkable, removed in 1851 to England and became a naturalized British subject. The first submarine cable—between Dover and Calais—had just been laid, and Reuter opened a news office in London. At first, however, his business was practically confined to the transmission of private commercial telegrams to places not connected with the new system. He appointed agents at the telegraph termini on the Continent to forward these despatches by rail or pigeon-post to the addresses. His efforts to induce the English papers to publish his foreign news telegrams were unsuccessful, until in 1858 *The Times* published the report of an important speech by Napoleon III. forwarded by Reuter's Paris agent.

Reuter now .extended his sphere of operations all over the world. He laid down a special cable from Cork to Crookhaven, Ireland. which enabled him to circulate news of the American Civil War several hours before steamers could reach Liverpool. A concession for a cable beneath the North Sea to Cuxhaven was granted him by the king of Hanover in 1865, and in the same year a concession was granted him for a cable between France and the United States, the line being worked jointly by Reuter and the Anglo-American Telegraph Company. Reuter was in 1871 given the title of baron by the duke of Saxe-Coburg and Gotha, and by a special grant of Queen Victoria he and his heirs were authorized to have the privileges of this rank in England. Reuter died at Nice on Feb. 25, 1899.

REUTERHOLM, GUSTAF ADOLF, BARON (1756–1813), Swedish statesman. After a brief military career he was appointed *Kammerherr* to Sophia Magdalena, queen consort of Gustavus III., and became intimately connected with the king's brother, Charles, then duke of Sudermania. He was imprisoned for a time in 1789 with other malcontents opposed to Gustavus III. On the death of Gustavus and the assumption of the regency by Charles he was made a member of the council of state and one of the "lords of the realm." His policy became increasingly reactionary and on the accession of Gustavus IV. he was expelled from Stockholm. He died in exile in Schleswig on Dec. 27, 1813.

See *Sveriges Historia* (Stockholm, 1877–81), vol. v.

REUTERS, the principal British and international news agency, founded in 1849 by Baron Paul Julius de Reuter (*q.v.*), who established a system of offices and correspondents throughout the world. He concentrated in London the news from these correspondents and then redistributed it. In 186 j Reuter transferred his business to a joint stock company, of which he became the governing director; he was succeeded in 1879 by his elder son, Baron Herbert de Reuter (1852–1915). Mark F. Napier was chairman of the company from 1910 to 1919, and in conjunction with him, Sir Roderick Jones, chairman and managing director, for national reasons arising out of World War I, converted the agency from a public company into a private trusteeship. This involved buying out the then existing shareholders for a sum of considerably over half a million sterling. Ten years later Sir Roderick reorganized the trusteeship in conjunction with the Press Association to ensure the passage ultimately of the complete ownership of Reuters to the newspapers of the United Kingdom. The principal news agency in every country in the world is affiliated with Reuters. Reuters' correspondents resident in the respective countries enjoy the exclusive call for Reuters' purposes upon the news of these agencies.

Where Reuters do not supply their telegrams direct to the newspapers, they deliver their service to these agencies to be disposed of by them in their territories. In addition to their services of imperial and foreign political news Reuters have greatly extended, especially to the Continent, to the East, the Far East and to the empire their services of commercial and financial prices and intelligence. (H. B. C.; X.)

REUTLINGEN, a German town, in the Swabian Alps of Wiirttemberg, Hohenzollern, on the Echatz, an affluent of the Neckar, 36 mi. by rail S. of Stuttgart. Pop. (1959 est.) 65,313. Reutlingen, which is first mentioned in 1213, became a free imperial town in the 13th century and was fortified by the emperor Frederick II. It came into the possession of Wiirttemberg in 1802. Its industries include cotton spinning and weaving, dyeing and bleaching; also the manufacture of leather and machinery.

REVAL: *see* TALLINN.

REVELATION, BOOK OF (variously called the REVELATION TO JOHN, the REVELATION OF ST. JOHN THE DIVINE and the APOCALYPSE OF ST. JOHN THE APOSTLE), last (and the only apocalyptic) book of the New Testament, is a symbolic presentation of the life of the church in a hostile world and a "prophecy" of the final end of all things.

Revelation is one of a group of Jewish and Christian books, called apocalypses. that describe, in elaborate symbols, the victory of God over an evil world. Such other apocalyptic books as Daniel in the Old Testament and II Esdras in the Apocrypha (IV Esdras in the Vulgate), and noncanonical books such as Enoch and Baruch, as well as many parts of the Dead sea scrolls from Qumran, provide an indispensable background for understanding the point of view of Revelation. (*See* also APOCALYPTIC LITERATURE.)

The apocalyptic perspective viewed the world as so decisively alienated from God that its structures of life and power (*e.g.*, structures of politics, economics, prestige and success) could not be recovered to obedience to God but would have to fall under God's judgment and be destroyed. Though created by God, the world had come under the domination of an evil power—Satan—so that its life was demonically perverted, while human decision and responsibility also contributed to the evil situation of men. In the world, though apart from it, lived a community of believers that was despised and often persecuted by the world but that was yet supported by God in all its trials. In the near future, it was believed, God would overthrow the powers of evil ("this present age"), both in their satanic dimension, which pervaded the whole physical and spiritual cosmos, and in their visible political dimension; and then God would establish a new world ("the age to come"). Such a faith is dualistic, since it views life as a struggle between two irreconcilably opposed principles—God and the demonic power of evil (*see* DUALISM). But it is not an absolute dualism, for it looks toward the speedy victory of God; and it is not a dualism of body and spirit, for in it evil is a perverted form of selfhood.

Central to the apocalyptic vision is the hope for a perfect community (a "holy city"). in which men will be free to serve God and each other. The failure of the power structures of "this world" to make possible total obedience to God and true community among men is the centre of the world's opposition to God, and the reason why this world must be destroyed to make way for a better one.

The author of Revelation uses a traditional stock of symbols. In particular he draws on the Old Testament, especially Daniel, Ezekiel and Zechariah. Perhaps ancient astrology supplied some symbols (especially in ch. xii) that came ultimately from near eastern creation myths. Jewish and Christian liturgy probably suggested many elements in the book. The author's own visions may have suggested other elements, though as they stand the visions in the book are too carefully integrated with each other and too dependent on tradition to be reports of immediate religious experience.

Since many apocalyptic books present, in symbolic form, a history of the struggles of the faithful, it has often been suggested that the symbols in Revelation represent succeeding historical events. No doubt the actual historical struggles of the church with Roman persecution are reflected in the book, especially in ch. xiii and xvii. Nonetheless, the repetitive nature of the images and the lack of concern for strict consistency suggest that the cosmic dimension of the struggle, the conflict of the powers of light and darkness, was more in the author's mind than an ordered series of historical incidents.

Outline.— An outline can only suggest the rich, interwoven texture of the book which does not have mechanical symmetry but is woven together in complex patterns of threes, sevens and other numbers. No one outline can claim to be final.

i, 1–20:	introduction
i, 1–3:	heading: a revelation of God through Christ
i, 4–20:	introductory letter: a vision of Christ
ii, 1–iii, 22:	counsel to the church: the seven letters (varied praise, warning, threat and promise)
ii, 1–7:	Ephesus
ii, 8–11:	Smyrna
ii, 12–17:	Pergamum
ii, 18–29:	Thyatira
iii, 1–6:	Sardis
iii, 7–13:	Philadelphia
iii, 14–22:	Laodicea
iv, 1–xvi, 21:	the beginnings of Judgment: God's people persecuted; God through Christ protecting his people and destrovinr his enemies
iv, 1–v, 14:	introduction: a vision-of God's world; the 24 elders and the Lamb
vi, 1–viii, 1:	the first cycle of images: the Seven Seals, the first four of which (vi, 1–8) reveal the "four horsemen of the Apocalypse" (symbolizing the lust ior conquest and its inevitable consequences of war, famine and death; traditionally identified as War, Striie, Famine and Pestilence) (*interlude* of the setting apart of the faithful and the reward of the faithful in heaven, vii, 1–17)
viii, 2–xi, 19:	the second cycle of images: the Seven Trumpets (*interlude* of the seer, x, 1–11; and the measurement of the temple, xi, 1–4 and the witnesses to God's message, xi, 4–14)
xii, 1–xv, 1:	the third cycle of images: the Seven Visions (*interlude?* of the vision of the Lamb and his worshipers, xiv, 1–5)
xv, 2–xvi, 21:	the fourth cycle of images: the Seven Plagues
xvii, 1–xix, 10:	the Judgment of this world
xvii, 1–18:	a woman sitting on a beast; explanation of the seven heads and ten horns of the beast
xviii, 1–24:	doom pronounced on "Babylon"; her friends lament her
xix, 1–10:	*interlude:* praise to God for the judgment of Babylon; proclamation of the marriage of the Lamb
xix, 11–xxii, 5:	the final purpose oi God
xix, 11–16:	the Word of God riding a white horse
xix, 17–21:	the victory of Christ
xx, 1–3:	the dragon bound for a thousand years
xx, 4–6:	the millennium
xx, 7–15:	the final deicat of Satan and final Judgment
xxi, 1–xxii, 5:	the new heaven and new earth
xxii, 6–21:	conclusion
xxii, 6–17:	concludinq words of prophecy: the end is near
xxii, 18–20:	warning not to tamper with the book
xxii, 21:	benediction

Main Themes.—*Endurance.*—The overarching practical theme of Revelation is a summons to resolute endurance in the face of coming persecution. Courageous loyalty, separation from the evil world and enduring hope for God's destruction of evil and new creation of a good world are taught through the seven letters, the interludes. the dramatic struggle and the vision of a new heaven and a new earth.

Cosmic Christ.—The vision of a struggle of cosmic dimensions is paralleled by an understanding of Christ as a pre-existent, heavenly being, capable of overcoming the most pervasive demonic opposition. Of Christ's earthly life, only his death and resurrection are mentioned, but these events reveal the eternal purpose of God (i, 18; v, 9).

God's Presence in an *Evil* World.—In Revelation, even though Christ's triumph still lies in the future, faith in Christ can span the gap between present and future and participate, even in the midst of suffering, in the joy and peace of God's presence. The "interludes" in the action are thus not an irregularity in the plan of the book but an important means by which the author communicates his faith that the movement of time can be momentarily halted, as the believer participates, by anticipation, in the end.

Roman *Empire* as *Manifestation* of Evil.—The concrete manifestation of satanic power is the government under which the author lived, the Roman empire. Rome is symbolized (though many details are obscure) by the beasts of ch. xiii and by the beast of ch. xvii. The seven heads and ten horns (xiii, 1; xvii, 3 and 9–14) represent (in a way about which there is little agreement) individual rulers of the 1st century A.D. The author's sense of the hopelessness of a constructive appeal to Rome is one reason for his view that in general the powers of evil must be destroyed rather than converted.

The *Millennium.*—The most controversial element in the Apocalypse is its prediction of a thousand years' rule of Christ on earth. The author looked forward to a real earthly kingdom, of Christ's, to come soon. That he presented it as temporary shows his conviction that this world, even perfected, could not adequately manifest the glory of God.

The *New* Jerusalem.—The vision of a true community under God. as God's ultimate purpose, is powerfully presented in the symbols of Rev. xxi, l–xxii, 5. This vision. here set in an "otherworldly" framework, has also motivated forms of Christian faith which looked for a partial realization of the hope within the structures of this world.

Literary History.—The author is John (i, 4); though most apocalyptic works were published under assumed names, this one does not seem to have been. The author regards himself as a prophet (i, 3) but does not call himself an apostle. Strong early tradition identified him with the apostle John (*e.g.*, Justin, c. A.D. 155). Yet Papias (c. A.D. 140) seems to have reported an early martyrdom for the apostle John, and some early tradition denies the apostle's authorship. Thus while Roman Catholic and some Protestant scholars support authorship by John the apostle, Protestant scholarship predominantly supports the view that some other John is the author. The differences in language between Revelation and the Gospel of John make it unlikely that the two books come from the same writer. Revelation was written for the churches in the neighbourhood of Ephesus in Asia Minor.

The Apocalypse is usually dated late in the reign of the Roman emperor Domitian (A.D. 81–96) and associated with his persecution of Christians. Since Domitian was the first to insist strongly on divine honours as a living emperor, and since Revelation opposes precisely this form of idolatry (ch, xiii), the traditional date is the most probable. Some scholars maintain an earlier date, usually by identifying the sixth head of the beast, which appears to represent the ruling emperor, with an earlier ruler (xvii. 10). But the author may have taken over and reinterpreted the symbolism of the seven heads from an earlier time, or he may have developed it in such a way that it applied to his own time. The

symbolic number 666 (xiii, 18) may refer to Nero (A.D. 54–68) but does not necessarily point to the time of Nero or even shortly afterward. since the expectation of Nero's return seems to have been a popular belief even late in the 1st century A.D.

Interpretation.— Older interpretation either "spiritualized" Revelation, applying its symbolism to general truths of the Christian religion. or looked for a literal fulfillment of its prophecies in or shortly after the time of the interpreter himself. Either path may find in the book a source of deep spiritual life but will also lead to misunderstanding of its original meaning, which is better grasped by setting the book in the context of the apocalyptic literature. Then Revelation is seen as springing from and relating to a crisis in the life of the early church. Its symbols are not descriptions of events in later history.

Once the original setting and meaning of the book are seen, the interpreter must again confront its meaning for his own time Some students have concluded that the book's lack of hope for "this world" gave it little relevance to the modern world. Others regard its message, originally focused on an ancient crisis, as a valid symbolic representation of the divine purpose. This sort of interpretation may stress the eternal truths of the book, thus standing close to the older spiritual interpretation, and it may emphasize Revelation as a portrayal of the climax of the "sacred history" of God's acts. Then the original situation of conflict with Rome is seen to typify a recurring situation in which the believing community will exist until the final end, when God's will shall be done. Still others would see the contemporary significance of the Book of Revelation in the totality of its claim for obedience. holding that the pictorial vision of the future triumph is of secondary importance and that the call to remain faithful is the enduring message. *See* also BIBLE.

REVELSTOKE, city. British Columbia, on the Columbia river, a key point on the Trans-Canada highway and a divisional station on the Canadian Pacific railway, 245 mi. N.E. of Vancouver. Pop. (1961) 3.566.

It is the supply centre for a mining and lumbering district, with railway shops, and is surrounded by rich fruit growing and ranching country. A scenic motor road leads up Mt. Revelstoke to 5.000 ft above the town

REVENTLOW, CHRISTIAN DITLEV FREDERICK, COUNT (1748–1827), Danish statesman and reformer, born on March 11, 1748, was educated at Soro and Leipzig, and made an extensive tour of western Europe to study economic conditions before he returned to Denmark in 1770. In 1774 he held a high position in the *Kammerkollegiet,* or board of trade, two years later he entered the Department of Mines, and in 1781 he was a member of the *Overskattedirectionen,* or chief taxing board.

In 1784, he was placed at the head of the *Rentekammeret,* which took cognizance of everything relating to agriculture. He appointed a small agricultural commission to better the condition of the crown serfs. and among other things enable them to turn their leaseholds into freeholds.

Reventlow induced the crown prince Frederick, in July 1786, to appoint a grand commission to take the condition of all the peasantry in the kingdom into immediate consideration. This agricultural commission resulted in a series of reforms of the highest importance. The ordinance of June 8, 1787. modified the existing leaseholds, greatly to the advantage of the peasantry; the ordinance of June 20. 1788. abolished villeinage and completely transformed the much-abused *hoveri* system whereby the feudal tenant was bound to cultivate his lord's land as well as his own; and the ordinance of Dec. 6. 1799. did away with *hoveri* altogether. Reventlow also started public credit banks enabling small cultivators to borrow money on favourable terms.

But the financial distress of Denmark. the jealousy of the duchies, the ruinous political complications of the Napoleonic period, and, above all, the crown prince Frederick's growing jealousy of his official advisers, prevented Reventlow from completing his reforms. On Dec. 7, 1813, he was dismissed, and retired to his estates in Laaland. where he died on Oct. 11, 1827.

See Adolph Frederik Bergsoe, *Grev.* C. D. *F. Rrventlows Virksomhed* (1837); Louis Theodor Alfred Bobe, *Efterl. Papirer fra den Reventlowske Familiekreds* (1895–97).

REVERE, PAUL (1735–1818), American patriot, craftsman and industrialist. best-known for his ride on the night of April 18, 1775, to warn the Massachusetts colonists of the approach of British troops, was born in Boston, Mass., on Jan. 1, 1735. His father Apollos Rivoire (later changed to Revere) was a Huguenot refugee who had come to Boston as a child and had been apprenticed to a silversmith. This craft he taught his son Paul Revere, who became one of America's greatest artists in silver. As a boy Revere received sufficient education to enable him later to read the difficult metallurgical books of his period. When Benjamin Waterhouse was brought to Massachusetts by Harvard college to teach this and allied sciences he thought Revere the only man in America with a competent knowledge in the field. It was in metal that Revere did most of his work. But his energy and skill (and the necessity of supporting an ever growing family) turned him in many directions. He not only made silver but sold spectacles, replaced missing teeth and made surgical instruments. He cut many copper plates. mostly for anti-British propaganda His "Boston Massacre." in spite of its many inaccuracies. is probably America's most famous print. He took an active interest in politics, was a leader of the Boston Tea Party in 1773 and influenced his fellow artisans toward independence.

With the outbreak of the American Revolution in 1775, Revere was called upon to construct a powder mill to supply the colonial troops. Later he and his sons East hundreds of church bells. several of them of great beauty. Although he began making copper hardware for ships soon after the Revolution it was not until 1800 that, after considerable experimentation and great expense, he set up in Canton. Mass.. a rolling mill for the manufacture of sheet copper. From this factory came the sheathing for many American ships, including the "Constitution," and for the dome of the Massachusetts state house. He worked closely with the inventor Robert Fulton on copper boilers for steamboats. With such ventures he became a connecting link between the medieval craftsman and the modern industrialist.

Revere's military career was undistinguished. In 1776, as a lieutenant colonel, he was in command of Boston harbour's principal defense. Castle William. In 1778 he was sent on the Rhode Island expedition. which proved as complete a failure as the Penobscot campaign a year later. In both of these futile attacks on the British the colonial sea and land forces were unable to work together. The retreat from the Penobscot region became such a scandal that most of the officers involved lost their reputations. Revere's good name was restored several years later after his continual demand for a court martial. Largely because of Longfellour's stirring ballad, he is remembered as the man on horseback who warned Middlesex county on "the 18th of April in '75" that the British troops were leaving Boston to seize military stores at Lexington and Concord. Although not good history the poem is still an impressive memorial to him For years Revere had been the principal express rider for Boston's Committee of Safety.

By virtue of his title of colonel, his postwar ventures as an importer, the great importance of his copper mill and the fortune he had amassed. he could have referred to himself by several prouder titles than the simple goldsmith or silversmith that he seems to have preferred to his dying day. This attitude J. S. Copley emphasized in the portrait he painted of him shortly before the Revolution, seated at his work bench, in his shirt sleeves. Gilbert Stuart's portrait of him as an old man emphasizes not only his energy but the generosity and kindness that characterized him throughout his long life. Both of these portraits along with the finest collection of his silver are in the Museum of Fine Arts, Boston. The American Antiquarian society possesses the outstanding collection of his engravings.

The house he lived in or owned for about 30 years before

his death on May 10, 1818, still stands in Boston's North Square.

See Esther Forbes, Paul Revere and the World He Lived In (1942); Clarence S. Brigham, Paul Revere's Engravings (1954). (E. Fo.)

REVERE, a city and resort in Suffolk county. Mass., U.S., on Massachusetts bay, 6 mi. N.E. of Boston. It is the "Coney Island of Boston" with three miles of beach, a dog track and night clubs. Almost from its founding (1636) as Rumney Marsh, it was a Boston resort. Subsequently the development of residential suburbs to the north made it turn almost exclusively to its beach front with its roller coaster and numerous concessions.

Because of the extensive marshes the community developed slowly. It was successively a section of Boston, part of Chelsea (1739) and reincorporated as North Chelsea (1846). The latter changed its name in 1871 in honour of Paul Revere.. Although a city since 1914, and council-manager governed since 1950, Revere is still tied to Boston through the county government. There are large colonies of Russian, Lithuanian and Italian immigrants and their descendants. The 19th-century Slade Spice mill, until 1934 a tidewater mill, is a local point of interest.

Light industry includes electrical equipment, machine parts, chemicals, spices and beverages. For comparative population figures see table in MASSACHUSETTS: Population. (R. C. Mo.)

REVERSING LAYER. It was formerly believed that the solar continuous spectrum originated in hot lower strata of the sun's atmosphere or photosphere and that the dark line spectrum was all produced in an overlying cooler stratum called the reversing layer, in accordance with Kirchhoff's third law of spectrum analysis. Early eclipse observations, especially that by C. A. Young in 1870, apparently substantiated this picture. Later work showed that the dark line and continuous spectra of the sun or stars were formed in essentially the same layers. Weak spectral lines are formed in the same layers as the continuous spectrum; stronger lines are produced predominantly in higher layers; whereas the centres of the strongest lines are formed in the chromosphere. Although the term has been used occasionally to indicate the upper layers of the photosphere where the strongest spectral lines are predominantly formed, it is now infrequently employed. See also SPECTROSCOPY. (L. H. A.)

REVERSION, in biology, an old term referring to the appearance of offspring showing resemblance to a grandparent or more remote ancestor in a character unlike that of the immediate parents. See GENETICS; HEREDITY. For reversion in law, see REMAINDER, REVERSION.

REVILLA GIGEDO, an archipelago comprising a group of rocky islands in the North Pacific, 18° N., 112° W., forming part of the state of Colima, Mex. They are about 500 mi. from the Mexican coast and comprise the large island of Socorro (San Tomás) and the three islets of San Benedicto, Roca Partida and Clarion. See COLIMA.

REVIVALISM in the broadest sense applies to any instance of renewed religious fervour within a group, church or community, whether that group be Christian or non-Christian. However, in common usage it refers primarily to concerted efforts among evangelical churches to revitalize the spiritual ardour of their members and to win new adherents. Revivalism in its modern form can be attributed to that common element in Anabaptism, Puritanism, German pietism and Methodism in the 17th and 18th centuries which stressed personal religious experience (*Herzensreligion*), the priesthood of all believers and holy living, in protest against established church systems which seemed excessively sacramental, sacerdotal and secularistic. Each of these pietistic movements contributed to the revival tradition.

Protesting against the sacramentalism and ritualism of the Church of England, the Puritans who left England carried their fervour for experiential religion and devout living to the new world in 1629. Although this fervour waned toward the end of the century, Jonathan Edwards (*q.v.*), revived Puritan zeal in New England in a period of extraordinary religious excitement from 1734 to 1742. Edwards is sometimes credited with inspiring the first Great Awakening in America (c. 1725–50), but this widespread movement of social, theological and ecclesiastical reorientation actually had its beginnings in Europe and reached America in the 1720s through the Dutch Reformed and Presbyterian churches of New Jersey and the German immigrants in Pennsylvania. While the awakening in New Jersey and Pennsylvania was in part a process of adapting European ecclesiasticism and theology to frontier conditions, it was also closely related to the pietist movement of Philipp Jakob Spener and August Hermann Francke (*qq.v.*) in Germany and to the evangelical revival in England.

Between 1670 and 1730 Spener and Francke had revitalized Lutheranism by forming within the church devout groups of believers who emphasized personal conversion, devotional prayer, asceticism and practical Christian charity. Their influence extended throughout northern Europe, affecting the Reformed churches, the Anabaptists and the revived Moravian church under Count Nikolaus Ludwig von Zinzendorf and August Gottlieb Spangenberg. The Moravian missionaries Spangenberg and Peter Boehler in turn influenced John Wesley (*q.v.*), and his religious conversion in 1738 inaugurated the evangelical revival within the Church of England. Between 1738 and 1791 Wesley traveled throughout the British Isles preaching to large crowds and laying the foundations for what became after his death the Wesleyan Methodist Church. Wesley's preaching emphasized free will and free grace, experiential conversion, the priesthood of all believers, moral perfectionism and philanthropic reform.

His associate George Whitefield (*q.v.*), the founder of Calvinistic Methodism in England, was also influenced by German pietism, and his preaching tours of the American colonies between 1739 and 1770 had a profound effect upon the first Great Awakening in America. Whitefield was welcomed to New Jersey in 1739 by Theodore J. Frelinghuysen. the pietistic leader of the revival among the Dutch Reformed churches; by Frelinghuysen's friend Gilbert Tennent (*q.v.*), the leading revivalist among the Scotch-Irish Presbyterians; and by most of the German-speaking immigrants in the middle colonies. When he toured New England in 1740, Whitefield was also endorsed by Jonathan Edwards and other influential Congregationalists. Throughout America Whitefield's preaching aroused intense religious enthusiasm; however, his emotional mass meetings and the religious disorders aroused by itinerants who imitated his flamboyant methods produced vigorous opposition to the awakening after 1742.

While the first Great Awakening created temporary schisms within almost every denomination in the American colonies, it also stimulated the churches to a vigorous new growth; it paved the way for the separation of church and state; it broke down denominational barriers and helped to unify the colonies; it produced an energetic social and intellectual ferment among the lower classes; and it instituted that emphasis upon religious activism and lay leadership that has since characterized American Protestantism. Like pietism in Germany and Wesleyan evangelicalism in England, the first Great Awakening in America promoted missionary activity. philanthropy, charity and education. Dartmouth college and Princeton and Brown universities were direct outgrowths of this awakening.

Despite the spread of deism during the 18th century the revivalistic impulse continued strong. The evangelical revival flourished in Britain, and at the end of the century a new awakening occurred in America. This second Great Awakening (c. 1795–1835) was divided into three phases: The first phase (1795–1810) was associated with the frontier camp meetings conducted by James McGready, John McGree and Barton W. Stone in Kentucky and Tennessee. The second and more conservative phase of the awakening (1810–25) centred in the Congregational churches of New England under leadership of Timothy Dwight, Lyman Beecher, Nathaniel W. Taylor and Asahel Nettleton. The third and final phase (1825–35) stemmed from the activities of Charles Grandison Finney (*q.v.*), who began his revivalism in small towns in western New York in the 1820s but eventually conducted revival meetings in the largest cities in the U.S. and Britain. During the second Great Awakening revivalistic theology in all denominations shifted from Calvinism to Arminianism as preachers emphasized the ability of sinners to make an immediate decision to save their own souls; theological differences almost disappeared among evangelical churches. Moreover, under Finney's aegis a rationale for

carefully contrived revival techniques evolved. After 1835 an irregular corps of professional revival experts traveled through the towns and cities of America and Britain organizing annual revival meetings at the invitation of local pastors who wanted to reinvigorate their churches. The second Great Awakening produced a great increase in church membership, made soul winning the primary function of the ministry and stimulated a host of moral and philanthropic reforms including temperance, antislavery and foreign missions. In 1857–58 the famous "prayer meeting revival" swept the cities of the United States following a financial panic. It indirectly instigated a revival in Northern Ireland and England in 1859–61 that rivaled the camp meetings in enthusiasm.

The preaching tour of the American lay evangelist Dwight L. Moody (*q.v.*) and his singing companion Ira D. Sankey through the British Isles in 1873–75 marked the beginning of a new outburst of Anglo-U.S. revivalism. And in his subsequent revival activity in the major cities of Britain and America Moody perfected the highly businesslike techniques that characterized the urban mass evangelistic campaigns of 20th-century professional revivalists such as Reuben A. Torrey (*q.v.*), J. Wilbur Chapman, Gypsy (Rodney) Smith and Billy (William A.) Sunday (*see* SUNDAY, WILLIAM ASHLEY). The interdenominationally supported revivalism of Moody and his imitators in 1875–1915 constituted in part a conscious co-operative effort by the Protestant churches to alleviate the unrest of urban industrial society by "evangelizing the masses," and in part an unconscious effort to counter the challenge to evangelical orthodoxy brought by higher criticism of the Bible and Darwin's *Origin of Species* (1859). In the first half of the 20th century most educated evangelical churchmen lost interest in revivalism because of its association with fundamentalism (*q.v.*) and turned their attention to social reform After World War II a renewed interest in mass evangelism appeared. symbolized by the widespread support given to the "revival crusades" of the Southern Baptist evangelist Billy (William F.) Graham (1918–), who preached on all continents and in 1962 addressed 700.000 persons in a 19-day period in Chicago.

Whether mass revivalism has been as helpful to the churches in the long run as its exponents claim is highly debatable, but there is no doubt about its ability to generate at least temporary religious enthusiasm. The best historical explanation for the recurrent nature of revivalism is based upon the inevitable need for theological and ecclesiastical reorientation from generation to generation and the concomitant religious excitement generated by such changes.

REVOLUTIONARY TRIBUNAL, THE *(le tribunal rkvolutionnaire),* a Eourt instituted in Paris by the Convention during the French Revolution for the trial of political offenders, which became one of the most powerful engines of the Terror. The news of the failure of the French arms in Belgium gave rise in Paris to popular movements on March 9 and 10, 1793, and on March 10, on the proposal of Georges Jacques Danton, the Convention decreed the establishment in Paris, in addition to the ordinary civil and criminal courts, of an "extraordinary" criminal court, which received the official name of the "revolutionary" tribunal by a decree of Oct. 29, 1793. It was composed of a paid jury, a public prosecutor and two substitutes, all nominated by the Convention, and from its judgments there was no appeal. With M. J. A. Hermann as president and Antoine Quentin Fouquier-Tinville as public prosecutor. the tribunal preserved, at first at least, the forms of a court of justice, dealing with political offenses by royalists, refractory priests and all agents of counterrevolution. The excesses of the Revolutionary tribunal increased with the growth of Robespierre's ascendancy in the Committee of Public Safety, and on June 10, 1794, was promulgated, at his instigation, the Law of *22* Prairial, which forbade prisoners to employ counsel for their defense, suppressed the hearing of witnesses and made death the sole penalty. Before *22* Prairial the Revolutionary tribunal had pronounced 1,220 death sentences in 13 months; during the 49 days between the passing of the law and the fall of Robespierre 1,376 persons were condemned, including an increasing proportion of ordinary citizens and government officials. The lists of prisoners to be sent before the tribunal were prepared by the public prosecutor and signed, after revision, by the Committee of General Security and the Committee of Public Safety jointly.

The Revolutionary tribunal was suppressed May 31, 1795. Its celebrated victims included Marie Antoinette, the Hébertists, the Dantonists and finally the Robespierrists.

REVOLVER: *see* PISTOL AND REVOLVER.

REVUE, a light form of theatrical entertainment, originally deriving from the French street fairs of the middle ages, at which events of the year were passed in review in comic song and spectacle. It differs from continental variety in its use of pointed burlesque and satire, and from musical comedy (*q.v.*) in having no plot. Revue took its present form during the early 19th century, first developed at the Paris Theatre Porte Sant Martin by the brothers Cogniard with their *Folies Marigny.*

In crossing the channel as early as 1825, revue in the London music halls *(see* MUSIC HALL AND VARIETY) took two main forms: first presented at the Adelphi theatre in London, it developed on one hand into a costume display and spectacle, reaching its peak in the Court theatre productions of the 1890s. On the other hand, revue developed into the intimate shows that resulted in the famous Andre Charlot Revues of the 1920s in London and the provinces, the handsome shows at the Hippodrome and especially the performances at Sir Charles Cochrane's Ambassador theatre, which provided continuous bills of topical sketches, monologues, songs and dances from 2 P.M. until midnight. Revues of the intimate club type played an important part in keeping up the morale of Londoners during the blitz of 1940, both at the highly regarded Gate theatre and the famous revuedeville of the Windmill.

In the United States, *The Passing Show,* produced in New York in 1894, and its second edition in 1911, led the U.S. producer Florenz Ziegfeld to initiate the 24 *Follies,* usually built around a star personality. George White and his *Scandals* put more emphasis on comedians and girls, less on spectacle for its own sake. More modest revues have been the *Music Box Revues,* the *Little Shows* of Dwight Wiman, *The Garrick Gaities,* the depression *Pins and Needles* of 1937 and the postwar G.I. show, *Call Me Mister. La Plume de Ma Tante* in 1959–60 returned the revue to its French origins. (R. N. LE.)

REWA, formerly a princely state within the Central India agency. In 1948 it became a part of the union of Vindhya Pradesh (*q.v.*), dominion (later republic) of India, the maharaja being appointed *rajpramukh,* or prince-president, of the union. In 1956 Vindhya Pradesh became part of Madhya Pradesh. Rewa division has an area of 22,870 sq.mi.; its population, mainly Hindu, was 3,410,376 in 1951. Many of the inhabitants of the hilly tracts are Gonds and Kols. More than one-third of the area is covered with forests, yielding timber and lac; the region also possesses valuable coal deposits in the Umaria field. The capital, Rewa city, is 70 mi. S.S.W. of Allahabad, Uttar Pradesh; pop. (1951) 29.623. The history of the state, until it came under British guarantee in 1812, was a record of almost continuous warfare. In the mutiny of 1857, the ruler aided the British. The maharaja's family is a Rajput of the Baghela branch of the Solianki race. The Rewa district (pop. [1961] 772,413) is 2,509 sq.mi. in area.

REWARD is money or other compensation offered orally or in writing either by the government or by an individual to the public generally or to a particular person or class of persons for the performance of a designated service, such as the return of lost property or the apprehension of a suspected criminal. The offer expires a reasonable time after it is made, unless it stipulates otherwise. Prior to substantial compliance with the offerer's terms, it may be withdrawn at any time, even if the claimant is unaware of the withdrawal. The offer may contain such terms, provided they are lawful, as the offerer wishes to prescribe. Where a reward is lawfully offered, the first one who satisfies the prescribed conditions is entitled to it. Performance of these conditions constitutes acceptance of the offer and creates a binding contract, If several persons jointly perform the stipulated act, either by concerted action or, according to some authority, by acting independently, the reward may be equitably apportioned among them. Whether a person who is unaware of the offer at the time he performs the requested act may obtain the reward is disputed. One under a moral or official duty to perform the act usually may not claim a reward unless he was required to perform acts beyond the scope of his duty for the reward. Police officers, therefore, ordinarily may not claim rewards for the apprehension of criminals or the recovery of stolen property, unless a statute provides to the contrary. (RT. K.)

REWBELL, JEAN FRANÇOIS (1747–1807), French politician, was born at Colmar (then in the department of Haut-Rhin) on Oct. 8, 1747. He sat in the constituent and legislative assemblies and in the Convention. He took part in the reactionary movement which followed the fall of Rohcspierre, and became a member of the reorganized committees of public safety and general security. His moderation caused his election by 17 departments to the Council of Five Hundred. Appointed a member of the Directory on Oct. 1, 1795, he became its president in 1796, and retired in 1799. He then entered the Council of Ancients. After the coup d'état of 18 Brumaire he retired from public liie, and died at Colmar on Nov. 23, 1807.

See L. Sciout, *Le Directoire* (1895–97).

REYKJAVIK, the capital of Iceland. is on the northern side of the Seltjarnarnes peninsula on the southeastern corner of the Faxafloi bay in the southwest of Iceland. It stood originally in a hollow between two hills, but has grown far beyond the hills. The harbour is protected on the west and on the east but is open on the north. The first Norse settler to Iceland, Ingolfur Arnarson, built his farm at Reykjavik in the 9th century, and for many centuries Reykjavik had only rural colonization. In 1786 it mas licensed by the king of Denmark with privileges of a market town.

After the restoration at Reykjavik in 1843 of the medieval Icelandic parliament, the althing, the town grew faster (pop. in 1901, 6,682), especially in the 20th century, when its main trade, the fishing industry, was developed by the use of modern vessels and equipment. By mid-20th century Reykjavik had textile, oilskin., rope, shipbuilding, fish meal, margarine, chocolate, biscuit and beer industries,.and most of the imports and exports of Iceland went through its harbour. Hot springs at Reykir make hothouse gardening possible and supply a swimming pool and the houses of Reykjavik with warm water.

In 1944 Reykjavik became the capital of the independent republic of Iceland. The residence of the president is at Bessastadir, outside the town. Reykjavik has a theatre, a museum, a library containing about 125,000 volumes and about 8,000 manuscripts, a cathedral (built in 1847), a university and a number of special schools and a state-owned general hospital. It is the seat of the Icelandic bishop. Reykjavik has regular steamship services with the United Kingdom, Norway and Denmark, and there is an airport at Keflavik, 30 mi. W. Its population, mainly Lutheran, was 56,096 in 1950. (H. LN.)

REYMONT, WLADYSLAW STANISLAW (1868–1925), Polish novelist. was born at Rohiele Wielkie in the county of Piotrkow on May 6, 1868. He spent his youth in various occupations, and his first novels were written when he was superintendent of a small railway sector. *The Comédienne* (1896; Eng. trans. 1921), *Ferments* (2 vol., 1897) and *Lily* (1899) were objective novels describing the everyday life of a troupe of provincial actors. In 1899 appeared *The Promised Land* (2 vol.; Eng. trans. 1928), modelled on Zola and describing industrialism in Lodz. Rcymont's best-known work, *The Peasants,* appeared in four volumes in 1904–09 (Eng. trans. 1925–26). He describes the iour seasons' labours of a peasant and brings to light his primitive instincts, inward dignity and almost religious attachment to the land. This great peasant epic brought Reymont the Nobel prize for literature in 1924. While *The Peasants* was being prepared, a number of novels and short stories appeared, the most important of which are *Before Dawn* (1902), *Konzurasati* (1903), *From a Diary* (1903) and *The Storm* (1907). As a historical novelist, Reymont, primarily an observer of the direct processes of liie, was less successful: the trilogy *1794 (The Last Dirt,* 1913, *Nil Desperandum,* 1916, and *The Insurrection,* 1918), though not lacking in literary merit, revealed a Iack of historical exactness. He died on Dec. 5, 1925. *(See* POLISH LITERATURE.)

See I. Matuszewski, *Tworczosci Tworcy* (Warsaw, 1904); Z. Debicki, *W. S. Reymont* (Warsaw, 192j); J. Lorentowicz, *Ladislas Reymont, prix Nobel 1924* (1925).

REYNARD THE FOX, a beast epic, current in French, Dutch and German literature. The cycle of animal stories collected round the names of Reynard the Fox and Isengrim the Wolf in the 12th century seems to have arisen on the borderland of France and Flanders. The tales, like those oi "Uncle Remus," were amusing in themselves; they were based on widely diffused follilore, and Reynard and his companions were not originally men disguised as animals. Jacob Grimm *(Reinhart Fuchs,* 18,34) maintained their popular origin.

The principal names of the Reynard cycle were German. Reynard himself (Raginohardus, strong in counsel). Bruin thk Bear, Baldwin the Ass, Tibert the Cat, Hirsent the She-Wolf, had German names, most of which were used as person names in Lorraine. But it was in France that the cycle obtained its greatest vogue. The *Roman de Renart* as printed by Méon (4 vol., 1826) runs to more than 40,000 lines. *Renart* was a popular epic parodying feudal institutions as represented in the romances of chivalry.

The early French originals are lost, the most ancient existing fragments being in Latin. The fable oi the lion's sickness and his cure by the wolf's skin occurs in the *Ecbasis cujusdam captivi per Tropologiam* (ed. by *E.* Voigt; Strasbourg, 1875), written about 940. *Ysengrimus* (ed. by E. Voigt; Halle, 1884), a clerical satire written by Nivard of Ghent about 1148. includes the story of the lion's sickness and the pilgrimages of Bertiliana the Goat. Most later versions of Reynard have been derived from the Flemish *Ban den vos Reinarde* (ed. by E. Martin, Paderborn, 1874), written about 1250 in East Flanders by Arnout and Willem. The Flemish epic is a poem of 3,476 lines. The corresponding branch of the French *Ronzan de Renart* (for which *see* FRENCH LITERATURE) is one of the earliest and best of the great French cycle.

The fable was known in England. The English poem of the *Fox and the Wolf* dates irom the 13th century; and the "Nun's Priest's Tale" of Chaucer, in which, however, the fox is Rossel and the ass Brunel, is a genuine Reynard history. A Dutch version of the Reynard poem, *Hystorie van Reynaert die Vos,* mas printed at Gouda in 1479. On this Caxton based his *Historye of Reynart the Foxe* (reprinted by *E.* Arber, 1878), which he finished on June 6, 1481. As a satire on the church, especially on monks and nuns, *Reynard* became popular with reformers, and numerous versions followed in England and Germany. The modern German version (1794) of Goethe has been often reprinted, notably in 1846, with illustrations by Wilhelm von Kaulbach.

BIBLIOGRAPHY.—The best edition of the *Ronzan de Renart* is by Ernest Martin, 3 vol. (Strasbourg and Paris, 1881–87). *See* also Jacob Grimm, *Srndschreibrn an C. Lachmann über Reinhart Fuchs* (Leipzig, 1840); Léopold Sudre, *Les Sources du roman de Renard* (Paris. 1890); Gaston Paris, "Le Roman de Renard," *Journal des savants* (Dec. 1894 and Feb. 189;); Kaarle Krohn, *Bur und Fuchs* (Helsinki, 1888); H. Gagering, *Van den Vos Reynaerde* (Münster, 1910). A modernized version of Caxton's translation appeared in 1926.

REYNAUD, PAUL (1878–), French conservative statesman, prominent in the last decade of the third republic and throughout the fourth, was born at Barcelonnette, Basses-Alpes, on Oct. 15, 1878. Educated at the Lycée Louis-le-Grand and the faculty of law in Paris, he became a barrister. Deputy for Basses-Alpes (1919–24) and then for Paris (1928–40), he made his name as a financial expert and was finance minister under André Tardieu in 1930. He was colonial minister under Pierre Laval (1931–32) and minister of justice under Tardieu (1932). He served in Édouard Daladier's government of 1938–40 first as minister of justice and then as finance minister. His budgets were austere attempts to restore the solvency of the state and at the same time pay the increasing costs of defense. He advocated firmness toward Nazi Germany, but he did not resign over the Munich agreement, and his friendship with the comtesse Hélène de Portes, associated uith pro-German political and business circles, was considered to have strengthened the cause of appeasement. He appreciated the importance of new weapons and the ideas of Charles de Gaulle. During World War II he was prime minister from March to June 1940 and, when the battle of France was being lost and the appeasers were gaining the ascendancy, he tried in vain to maintain

the British alliance and keep France in the war. After the armistice he was arrested by the Vichy government and spent the rest of the war in French and German prisons.

Re-elected a deputy in 1946, Reynaud soon returned to the fore and enjoyed considerable influence in the national assembly's finance committee and lobbies. He was finance minister in A. Marie's short-lived cabinet in 1948; he was included in H. Queuille's abortive cabinet in 1950; after being rejected by the assembly when he stood for the premiership in 1953, he was a vice-premier in J. Laniel's government of 1953–54. In these years he played an important part in the development of the movements to unite western Europe. A supporter of constitutional reform to strengthen the government, he favoured the return to power of General de Gaulle in 1958 and was appointed chairman of the advisory committee which examined the draft constitution. His efforts to make the fifth republic more parliamentary and less presidential had little success.

Besides books on earlier French history and politics (including *Les Trois glorieuses,* 1927), Reynaud published several volumes of memoirs, among them *La France a sauvé l'Europe,* 2 vol. (1946) and *Au coeur* de *la mêlée* (1951; Eng. trans. 1955). (P. W. C.)

REYNOLDS, JOHN FULTON (1820–1863), U.S. army officer, was born Sept. 20, 1820, at Lancaster, Pa., and graduated from the U.S. Military academy in 1841. During the Mexican War, Reynolds was twice promoted for gallantry in action. He took part in three expeditions into the far west and in 1859 became commandant of cadets at West Point. Soon after the beginning of the Civil War he was promoted to the rank of brigadier general of volunteers. He served as military governor of Fredericksburg and fought at Mechanicsville, Gaines's Mill and the second battle of Bull Run. After being promoted to the rank of major general in Nov. 1862, Reynolds commanded the 1st corps of the army of the Potomac and was among those considered for command of the army after Gen. Joseph Hooker's defeat at Chancellorsville. At the battle of Gettysburg (*q.v.*), Reynolds was killed in the first day's fighting (July 1, 1863) after moving up to support Buford's cavalry, which had first engaged the Confederates. The spot on the field where he fell is marked by a granite shaft erected by the state of Pennsylvania. (O. A. S.)

REYNOLDS, SIR JOSHUA (1723–1792), English painter, perhaps the dominant figure in the history of British art, was born at Plympton, Devon, on July 16, 1723. He was educated at the Plympton grammar school and was well read in classical literature. Influenced by the essays of Jonathan Richardson, Reynolds aspired to become a painter, and in 1740 he was apprenticed for four years to Thomas Hudson in London. In 1743, however, he returned to Devon and began painting at Plymouth dock portraits that reveal his inexperience and that are very much in the tradition then prevailing., Returning to London for two years in 1744, he began to acquire his independent style and his knowledge of the old masters. An outstanding picture of this period is "Capt. the Hon. John Hamilton" (owned by the duke of Abercorn), which shows Reynolds' bolder style combined with a considered use of impasto. Back in Devon in 1746 he painted his large group of the "Eliot Family," which clearly demonstrates his knowledge of the vast picture by Van Dyck at Wilton house, Wiltshire. In 1749 he sailed with his friend Augustus Keppel to Minorca, where he stayed for five months and endured the accident that permanently scarred his lip, the scar being a feature prominent in all his self-portraits. From Minorca he made his way to Rome, where he remained for over two years. There he was able to give full reign to his scholarship and to store his mind with the great masterpieces of classical and modern painting and sculpture. The impressions that he retained from this visit were to inspire his paintings and his *Discourses* for the rest of his life, for he felt that it was by allying painting with scholarship that he could best achieve his ambition of raising the status of his profession. He returned to England via Florence, Parma, Bologna and Venice, where he absorbed and noted the colour and composition of works by Titian, Tintoretto and Veronese. He was immediately seduced by Venetian colouring and, although all his life he preached the need for all young artists to study the classical forms of Michaelangelo and Raphael, his own works are redolent of the light and shade of Venetian colouring.

In 1753 Reynolds settled in London, where he was to live for the rest of his life, first in St. Martin's lane and finally, after 1760, in Leicester square. From the first his success was assured, and by 1755 he was employing studio help, notably Giuseppe Marchi. The first great work from this period is "Commodore Keppel" (in the National Maritime museum, Greenwich, London). The pose is not original, being a reversal of that of the "Apollo Belvedere" statue in the Vatican, but the subject is shown striding along the seashore in a new and vital way. It could be said that with this portrait all of English portrait painting took on a new life and vigour and the tradition of Sir Godfrey Kneller was entirely destroyed. A painter could not always hope to have such a heroic sitter, but Reynolds was equally successful with the more domestic portraits of men and women. In these first years in London his knowledge of Venetian painting is very apparent; *e.g.,* the portraits of "Lord Cathcart" (owned by Lord Cathcart) and "Lord Ludlow" (at Woburn abbey, Bedfordshire). Of his domestic portraits the most enchanting is that of "Georgiana, Countess Spencer, and Her Daughter" (owned by Lord Spencer), painted in 1760, which is one of the greatest English portraits, full of tenderness and careful observation. In the 1760s he mas more and more under the influence of the painters of the Bolognese school, and the pose and clothes of his sitters take on a more rigid, classical pattern, losing in consequence much of the sympathy and understanding he could have given them. It was from these portraits that he hoped to equate portrait painting with the "grand style," and they are indeed an illustration to much that he has to say in his *Discourses.* It has been suggested that the painting of "Garrick Between Tragedy and Comedy" (on loan from Lord Rothschild to King's college, Cambridge) is a parody of his own predicament, Comedy being painted in the softer and more domestic manner of Corregio and Tragedy in the classical manner of Guido Reni.

Reynolds was to realize his ambitions for his profession in a new and public way. Hitherto there had been no public exhibitions of contemporary artists in London, but in 1760 the Society of Artists was founded and the first of many successful exhibitions held. After some internal squabbles the patronage of King George III was sought and in 1768 the Royal Academy was founded. Although Reynolds' painting had found no favour at court, he was the obvious candidate for the presidency and the king confirmed his election and knighted him. Reynolds guided the policy of the academy with skill, and the pattern he set has been followed with little variation ever since. His yearly *Discourses* are some of the wisest words an older painter has offered to those beginning their careers, and they also clearly mirror many of his own thoughts and aspirations, as well as his own problems of line versus colour and public and private portraiture.

From 1769 nearly all of Reynolds' most important works appeared in the academy, and this undoubtedly influenced the rather more public manner of his portraits. In certain exhibitions he included historical pieces, such as "Ugolino" (at Knole house, Kent), which were perhaps his least successful contribution to painting. Many of his child studies are tender and even amusing, though now and again the sentiment tends to be excessive; two of the most enchanting are "Master Crewe as Henry VIII" (owned by Lord O'Neil) and "Lady Caroline Scott as Winter" (owned by the duke of Buccleuch). His most ambitious portrait commission was the "Family of the Duke of Marlborough" (at Blenheim palace, Oxfordshire), which was shown at the academy of 1778. Although not wholly successful it is a monumental group entirely suitable to the house that holds it: a conversation piece enlarged to the scale of a history piece. It may have been the arrival of Thomas Gainsborough in London in 1774 that caused Reynolds to revert to a more informal mood.

In 1781 Reynolds visited Flanders and Holland, where he studied the work of Rubens, and this seems to have affected his own style as from that time the texture of his picture surface becomes far richer. This is particularly true of his portrait of the "Duchess of Devonshire and Her Daughter" (at Chatsmorth house, Derby-

shire). It was this last phase of dramatic and baroque style that influenced John Hoppner and Thomas Lawrence, but they paid perhaps more attention to the painting of silks and satins and rather less to the characterization. Reynolds mas never a mere society painter or flatterer and he never forgot what James Northcote called, when writing of Allan Ramsay, the "mental part" of a portrait. It has been suggested that his deafness allowed Reynolds a clearer insight into the character of his sitters, the lack of one faculty sharpening the use of his eyes. His vast learning allowed him to vary his poses and style so often that the well-known remark of Gainsborough, "Damn him, how various he is!" is entirely understandable. In 1782 Reynolds had a paralytic stroke and about the same time he was saddened by bickerings within the Royal Academy. Seven years later his eyesight began to fail and he delivered his last *Discourse* at the academy in 1790. On Feb. 23. 1792, he died.

Reynolds preferred the company of men of letters to that of his fellow artists. Although his 14th *Discourse* is a tender and moving appreciation of Gainsborough, who stood for so much that he himself disliked in painting, it was in the company of Dr. Johnson and of Edmund Burke and Oliver Goldsmith that Reynolds was happiest. When Goldsmith died, Reynolds could not bring himself to paint for a whole day, and the moving essay he nrote on his friend showed that he could write a portrait as well as he could paint one. Reynolds and his friends were members of "The Club," which he established in 1764. He never married and his house was kept for him by his sister Frances.

Reynolds' state portraits of the king and queen were never considered a success and he seldom painted for them. but the prince of Wales patronized him extensively and there were few distinguished families or individuals who did not sit to him. None the less some of his finest portraits are those of his intimate friends and of fashionable women of a questionable way of life. Unfortunately Reynolds' technique was not always entirely sound, and many of his paintings have suffered as a result. After his visit to Italy he tried to produce the effects of Tintoretto and Titian by using transparent glazes over a monochrome underpainting, but the carmine he used for his flesh tones was not permanent and even in his lifetime began to fade, causing the overpale faces of many surviving portraits. An example of this can be seen in the "Roffey Family Group" (in Birmingham art gallery, Eng.). This paleness has been increased by injudicious cleaning in certain paintings. The most interesting picture to show how Reynolds worked is the unfinished double portrait of "Burke and Lord Rockingham" (in Fitzwilliam museum, Cambridge). In the 1760s Reynolds began to use bitumen more extensively, which mas detrimental to the paint surface. Of his later style the "Duchess of Devonshire and Her Daughter" is in almost matchless condition. Though a keen collector of old master drawings, he was never a draftsman and indeed few of his drawings have any merit, but'there is an interesting early "Self-Portrait" drawing (owned by Lord Harcourt) and a design for "Comedy" (in the Ashmolean museum, Oxford). His ledger books from 1755 to 1789, which, with a few gaps, are preserved, make it possible to date most of his sittings with reasonable accuracy.

His work is represented in most public and private collections and he is splendidly shown in the royal collection. The National gallery, London, has, among other paintings, "Capt. Tarleton," "Lord Heathfield," "The Countess of Albemarle" and "Three Graces Adorning a Term of Hymen." Among his portraits in the National Portrait gallery, London, are those of "Johnson," "Boswell" and his own early "Self-Portrait" shading his eyes. The Wallace collection, London, has "Nelly O'Brien," "Mrs. Carnac" and "Miss Bowles." Private collections particularly rich in his work include those of the duke of Bedford, duke of Devonshire, duke of Buccleuch, earl of Harewood, George Howard, earl of Ilchester, John Wyndham and Lord Spencer. An interesting portrait of Reynolds, not by his hand but by Angelica Kauffmann, belongs to Lord Morley. His work is not richly represented in the United States, although his great portrait of "Mrs. Siddons as the Tragic Muse" is in the Huntington library, San Marino, Calif.; and Washington and New York also have important examples.

REYNOLDS, OSBORNE (1842–1912), English engineer and physicist, best known for his work in the fields of hydraulics and hydrodynamics, was born at Belfast on Aug. 23, 1842. Gaining early workshop experience and graduating at Queens' college Cambridge in 1867, he became in 1868 the first professor of engineering in the Owens college, Manchester. He was elected a fellow of the Royal society in 1877 and a Royal medallist in 1888. He retired in 1905 and died at Watchet, Somerset, on Feb. 21, 1912.

Reynolds' studies of condensation and the transfer of heat between solids and fluids brought radical revision in boiler and condenser design, while his work on turbine pumps laid the foundation of their rapid development. A fundamentalist among engineers, he formulated the theory of lubrication (1886), and in his classical paper on the law of resistance in parallel channels (1883) investigated the transition from smooth, or laminar, to turbulent flow, later (1889) developing the mathematical framework which became standard in turbulence work. His name is perpetuated in the "Reynolds stress," or drag exerted between adjacent layers of fluid due to turbulent motion, and in the "Reynolds number" (see AERODYNAMICS), which provides a criterion for dynamic similarity and hence for correct modeling in many fluid flow experiments. He developed and exploited corresponding criteria for wave and tidal motions in rivers and estuaries, and made pioneering contributions to the concept of group velocity. Among his other work was the explanation of the radiometer and an early absolute determination of the mechanical equivalent of heat. Reynolds' *Scientific Papers* were published in three volumes (1900–03).

See A. H. Gibson, *Osborne Reynolds and his Work in Hydraulics and Hydrodynamics* (1946). (C. H. B. P.)

REZÁNOV, NICOLAI PETROVICH DE (1764–1807), Russian administrator under Catherine II, Paul I and Alexander I. He was the first Russian to represent his country in Japan (1804), and instigated the first attempt of Russia to circumnavigate the globe (1803), commanding the expedition himself as far as Kamchatka. But Rezánov's monument for many years after his death was the great Russian-American Fur company; and his interest to students of history centres round the policy involved in that enterprise.

Meeting (in 1788) Shelikov, chief of the Shelikov-Golikov Fur company, Rezánov became interested in the merchant's project to obtain a monopoly of the fur trade in those distant dependencies. He became a partner, and, after the death of Shelikov in 1795, the leading spirit of the company, and resolved to obtain privileges analogous to those granted by Great Britain to the East India company. He had just succeeded in persuading Catherine to sign his charter when she died, and he was obliged to begin again with the ill-balanced and intractable Paul. Rezánov's skill, subtlety and address prevailed, and shortly before the assassination of Paul he obtained his signature to the instrument which granted to the Russian-American company, for a term of 20 years, dominion over the coast of N.W. America, from latitude 55° northward; and over the chain of islands extending from Kamchatka northward and southward to Japan. This famous "trust," which crowded out all the small companies and independent traders, was a source of large revenue to Rezánov and the other shareholders, including members of the imperial family, until the first years of the 19th century, when mismanagement and scarcity of food threatened it with ruin. Rezinov, his humiliating embassy to Japan concluded, reached Kamchatka in 1805, and found commands awaiting him to remain in the Russian colonies

as imperial inspector and plenipotentiary of the company, and to correct the abuses that were ruining the great enterprise. He travelled slowly to Sitka by way of the islands.

At the end of a winter in Sitka, the headquarters of the company, he sailed for the Spanish settlements in California, purposing to trade his tempting American and Russian wares for foodstuffs, and to arrange a treaty for the provisioning of his colonies twice a year from New Spain. He cast anchor in the harbour of San Francisco early in April 1806, after a stormy voyage which had defeated his intention to take possession of the Columbia river in the name of Russia. Although he was received with courtesy, he was told that the laws of Spain forbade her colonies to trade with foreign powers, and that the governor of all the Californias was incorruptible. Rezánov, had it not been for a love affair with the daughter of the *comandante* of San Francisco, Don José Arguello, and for his personal address and diplomatic skill, with which he won over the clergy to his cause, would have failed again. As it was, when he sailed for Sitka, six weeks after his arrival, the "Juno's" hold was full of breadstuffs and dried meats, he had the promise of the perplexed governor to forward a copy of the treaty to Spain at once, and he was affianced to the most beautiful girl in California. Shortly after his arrival in Sitka he proceeded by water to Kamchatka, where he dispatched his ships to wrest the island Sakhalin of the lower Kurile group from Japan, then started overland for St. Petersburg to obtain the signature of the tsar to the treaty. He died of fever and exhaustion in Krasnoiarsk, Siberia, on March 8, 1807.

The treaty with California, the bare suggestion of which made such a commotion in New Spain, was the least of Rezbnov's projects. It was sincerely conceived, for he was deeply and humanely concerned for his employees and the wretched natives who were little more than the slaves of the company. His correspondence with the company betrays a clearly defined purpose to annex to Russia the western coast of North America, and encourage immediate emigration from the parent country on a large scale. Had he lived, he might have accomplished his object. The treaty was never signed, the reforms of Rezánov died of discouragement, the fortunes of the colonies gradually collapsed, the Spanish girl who had loved Rezánov became a nun; and one of the ablest and most ambitious men of his time was forgotten in the cemetery of a poor Siberian town.

Russell, ed., *The Rezánov Voyage to Nueva California* (1926); A. Yarmotinsky, "A Rambling Note on the Russian Columbus," *New York Public Library Bulletin,* vol. xxxi (1927). (G. At.)

RHADAMANTHUS, in Greek mythology, son of Zeus and Europa, and brother of Minos, king of Crete. Homer represents him as dwelling in the Elysian fields (*Odyssey,* iv. 564). According to later legends, on account of his inflexible integrity, he was made one of the judges of the dead in the lower world, together with Aeacus and Minos.

RHAGES: *see* RAYY.

RHAMNACEAE, the buckthorn family, a group of thorny shrubs, woody vines and trees found in the warmer parts of both hemispheres. It includes 45 genera and about 550 species of dicotyledonous plants. Large genera are *Rhamnus* with about 230 species, *Zizyphus* with 100 species and *Phylicia* with 90 species. Jujube (*q.v.*), or the Chinese date, native to Asia. is the fruit of *Zizyphus jujube* (*Z. vulgaris*), and the Indian jujube is the fruit of *Z. mauritiana.* The bark of various species of *Rhamnus* is utilized in the practice of medicine, cascara sagrada (*q.v.*) being that of the western American *R. purshiana. Ceanothus,* a genus highly developed in the western United States, is known as the California lilac. *See* also BUCKTHORN. (E. D. Mt.)

RHATICUS (RHETICUS), a surname derived from Rhaetia (Austria), the district of his birth, by GEORG JOACHIM VON LAUCHEN (1514–1576), astronomer and mathematician who, as an associate of Nicolaus Copernicus (*q.v.*), was among the first to adopt and to spread his heliocentric theory. Rhaticus was born at Feldkirch on Feb. 16, 1514. In 1537 he was appointed to a chair of mathematics and astronomy at Wittenberg. He was much attracted by news of Copernicus' heliocentric theory and in 1539 he resigned his professorship and went to Frauenburg, where he studied for two years with Copernicus. Rhaticus published the first exposition of the new heliocentric views in his *De libris revolutionum . . . Nic. Copernici . . . narratio prima. . .* (1541) and for about ten years thereafter produced ephemerides baaed on the Copernican system. He persuaded Copernicus to complete the great *De revolutionibus orbium coelestium* and to permit him to take the manuscript to Nürnberg for publication. Because of the religious objections of Luther and others, Rhäticus left Nürnberg before *De revolutionibus* was actually published in 1543, and moved to Leipzig.

From his time at Wittenberg until his death at Kassa, Hung., on Dec. 5, 1576, Rhäticus worked on his great treatise *Opus Palatinum de triangulis,* which was published posthumously in 1596 by Valentine Otto, mathematician to the electoral prince palatine. The work contains tables of sines, cosines, tangents, etc., in intervals of ten seconds of arc and calculated to ten decimal places. Rhäticus proposed to compute similar tables to 15 decimal places, but did not live to complete the task. The table of sines on this scale was published in 1613 by B. Pitiscus (1561–1613) under the title *Thesaurus mathematicus,* Pitiscus himself completing certain of the calculations. (CN. A. R.)

RHAZES (ABU-BAKR MOHAMMED IBN ZAKARIYA AR-RAZI) (*c.* 865–923 or 932), undoubtedly the greatest physician of the Islamic world, also a philosopher of remarkable independence of mind and a well-known alchemist, was a Persian Mosfem, born in the city of Rayy about 865. The tradition that he was an alchemist before he became thoroughly acquainted with medicine may be reliable. He became chief physician in a new hospital at Rayy and subsequently held a similar position in Baghdad for some time. As so many "intellectuals" in his day, he lived at different small courts enjoying the protection of minor rulers. He claimed to fulfil in his own time the function of a Socrates in philosophy and that of a Hippocrates in medicine. He died in his native city in 923 or 932.

The two most important medical works of Rhazes are the *Kitab al-Mansuri,* which he composed for Mansur ibn Ishak, the ruler of Rayy, and which became well-known in the west in Gerard of Cremona's 12th-century Latin translation; and *Al-Hawi,* the "Comprehensive Book," in which he surveys Greek, Syrian and early Arabic medicine in their entirety, as well as some Indian medical knowledge, adding his own considered judgment and his own medical experience throughout. Among his numerous minor medical treatises, *A Treatise On the Small Pox and Measles* is famous, having been translated into Latin and various modern languages and into Byzantine Greek.

The philosophical writings of Rhazes (*see* ARABIC PHILOSOPHY) were completely neglected for centuries: not until the 20th century did their importance come to be appreciated again. He claims to be a Platonist, and his views are everywhere at variance with the philosophy of such thinkers as al-Farabi, Avicenna and Averroes. He was probably acquainted with Arabic translations of Democritus and followed a similar line in his own atomic theory of matter. His *Autobiography* is rather a spirited defense of the philosophical way of life as he understood it than an account of actual events (Eng. trans. by A. J. Arberry in the *Asiatic Review,* 1949). *On Spiritual Medicine* (Eng. trans. by A. J. Arberry, *The Spiritual Physick of Rhazes,* London, 1950) is a popular ethical treatise. The main alchemical work of Rhazes is the *Secret of Secrets* (German trans. by J. Ruska, 1937).

RHEA, a Titaness, sister and consort of Cronus and mother of Zeus. For her legend, *see* CRONUS. Very litle cult of Rhea existed, but she was commonly identified in historical times with

Cybele *(see* GREAT MOTHER OF THE GODS). Hence such legends as that in Virgil *(Aen.,* iii, *111),* that Cybele originally came from Crete; and indeed the various mother goddesses of the Mediterranean, while not actually the same, closely resemble one another and are the product of the same class of ideas and practices.

RHEA, the American cousin of the African ostrich (*q.v.*), a giant flightless ratite bird confined to South America. Three species are recognized: *Rhea americana,* ranging from Paraguay to Patagonia; *R. darwini,* confined to Patagonia; and R. *macrorhyncha,* of northeast Brazil. Considerably smaller than the ostrich, about four feet tall, the rheas are further distinguished by the possession of three toes, the absence of fine plumes and the general brownish colour of the feathers, which, in R. *darwini,* are tipped with white. The feathers have a considerable market value. The rhea is polygamous, and the cock bird performs the duties of incubation. Rheas frequently associate with deer or guanacos to form "mixed herds" similar to those formed by the ostrich with zebras and antelopes.

RHEE, SYNGMAN *(1875–*), Korean statesman, first president of the Korean republic, was born on April *26, 1875,* in Whanghae province, Korea. He completed a traditional classical education and then entered a Methodist school, where he learned English and enough western thought to become a confirmed nationalist and ultimately a Christian. He joined with other Korean leaders in *1896* to form the Independence club and served briefly as a member of the privy council. When reactionary elements destroyed the club in *1897,* Rhee was arrested and imprisoned until *1904.* On his release he went immediately to the United States, where he attended George Washington university (A.B. 1907), Harvard (M.A. *1908)* and Princeton (Ph.D. *1910).* He was the first Korean to earn a doctorate degree in an American university. While a student he made frequent but unsuccessful appeals to the United States to save his country from Japan. When he returned home in *1910* he found it impossible to hide his hostility toward Japanese rule, and after short terms as a Y.M C.A. worker and high school principal he returned to the U.S. in *1912.*

For the next *30* years Rhee served as a spokesman for Korean independence, publicizing Korea's plight and trying in vain to win international support for his cause. In *1919* he was elected president of the Korean republic in exile, holding that post for *20* years. He returned to Korea in *1945* after spending the war years in trying to secure Allied promises of Korean independence. Elected president of the Republic of Korea in *1948,* he was re-elected in *1952, 1956* and *1960.*

As president of the R.O K., Rhee's great objective was the freedom and unification of his country. He used his broad powers to remove domestic opposition to his program, and even defied the United Nations when he felt that body threatened those ends (for Rhee's participation in the Korean war *see* KOREAN WAR). He purged the national assembly and outlawed the opposition Progressive party, whose leader was executed for treason. Rhee controlled the appointment of mayors, village headmen and chiefs of police, but in *1956* failed to prevent the election of an opposition vice-president. Government claims that the March *1960* elections gave Rhee over *90%* of the popuiar vote (55% in *1956)* provoked student-led demonstrations resulting in heavy casualties and demands for his resignation, supported by the unanimous vote of the national assembly. Rhee resigned April *27,* and left for exile in Hawaii. A caretaker government pledged new elections and the repudiation of the most widely criticized of Rhee's domestic and foreign policies. *See* also KOREA: *History.* (F. G. WN.)

RHEINBERGER, JOSEPH GABRIEL (1839–1901), German composer. was born at Vaduz, Liechtenstein, on March *17, 183.9* He studied at the Munich conservatorium from 1851 to 1854, and in 1859 became a professor there. He was from *1860* to *1866* organist of the Michelskirche. and then court conductor.

Rheinberger's compositions include the operas Die sieben *Raben* (Munich, 1869) and *Türmers* Tochterlein (Munich, 1873); the oratorio *Christoforus,* op 120; the well-known quartet for piano and strings in E flat, op 38; the nonet for wind and strings, op 139; and 20 organ sonatas Rheinberger's organ music is original in method, and breaks loose from the Bach tradition in many points. He died at Munich on Nov 25, 1901

RHENANUS, BEATUS (1485–1547), German humanist, was born in 1485 at Schlettstadt in Xlsace. where his father. a native of Rheinau (hence the surname *Rhenanus),* was a butcher. He was educated at the famous Latin school of Schlettstadt, and afterward (1503) went to Paris

In 1511 he removed to Basel, where he became intimate with Erasmus, and took an active share in the publishing enterprises of Joaanes Froben (*q.v.*). In 1526 he returned to Schlettstadt, and devoted himself to a life of learned leisure, enlivened with epistolary and personal intercourse with Erasmus (the printing of whose more important works he superintended) and many other scholars of his time. He died at Strasbourg on July 20, 1547.

His earliest publication was a biography of Geiler of Kaisersberg (1510). Of his subsequent works the principal are *Rerum Germanicarum* Libri *III* (1531) and editions of *Velleius Paterculus* (ed. princeps, from a manuscript discovered by himself, 1522); *Tacitus* (1519, exclusive of the Histories); Livius (1535); and *Erasmus* (with a life, 9 vol 1540–41)

RHENIUM is a very rare metallic element discovered by Ida and Walter Noddack in *1925.* The chemical symbol is Re; the atomic number is 75; and the atomic weight is *186.22.* Up to 1924, the annual world production of rhenium was conveniently estimated in kilograms. But an annual U.S. potential of about ten tons is anticipated. The metal and its alloys have found limited application as fountain-pen points. high-temperature thermocouples. catalysts, electrical contact points, instrument-bearing points and in electric components.

Rhenium is widely distributed in a variety of minerals but usually in concentrations below 0.1 part per 1,000,000. It occurs in concentrations as high as 10 to 20 parts per 1,000,000 in molybdenum sulfide ores, and to a lesser extent in sulfidic copper ores. It is probably present as its stable disulfide (ReS_2). The recovery of rhenium follows from the concentration of its volatile heptoxide in the flue dust during the smelting of molybdenite ore, or from its concentration with the platinum metals in the "anode sludge" during electrolytic copper refining. The extracted element is recrystallized as the sparingly soluble potassium perrhenate ($KReO_4$). This material is transposed to the ammonium salt and reduced in hydrogen to give black metal powder. The powder may be compressed and sintered in hydrogen at an elevated temperature to give sintered bars (density. 19). Cold working and annealing permit the fabrication of wire or foil.

The silvery massive metal has a density of *21.9* g. per cubic centimetre, melts at about 3,180° C., and is extremely hard; its near resistance is good and it is not easily corroded. The powder slowly oxidizes in air above 150° C. and rapidly at higher temperatures to form volatile Re_2O_7. This yellow, stable and relatively nontoxic oxide is the anhydride of perrhenic acid ($HReO_4$), which results from dissolution of the metal in hydrogen peroxide or nitric acid. The metal is not soluble in hydrochloric acid. and dissolves only uith difficulty in other acids. The perrhenates, the heptoxide, and perrhenic acid have been extensively studied; unlike the corresponding manganese compounds. the (VII) state of rhenium is its commonest and most stable form. Perrhenate. unlike permanganate, is only a weak oxidant, comparable in strength with ferric ion.

There is some evidence for the existence of rhenium in each of the oxidation states from (VII) through (— 1). The solution chemistry of rhenium is quite complex because of the large number of possible. acid-base sensitive, disproportionation reactions. The best characterized oxides are Re_2O_7; the insoluble red trioxide (ReO_3); and the black dioxide (ReO_2). The existence of an unstable black (possibly impure) sesquioxide (Re_2O_3) is probable, and both a monoxide and a suboxide have been reported. A number of tungsten, arsenic, silicon and other rhenium alloys are known, and the heated metal reacts more or less readily with many nonmetals such as sulfur, phosphorus or the halogens. As does tungsten. it forms numerous anhydrous halides or oxyhalides with fluorine. chlorine or bromine, which are hydrolyzed by water. The hexafluoride (ReF_6). pentachloride ($ReCl_5$) and tribromide ($ReBr_3$) exemplify the highest-state simple halides known for three of the halogens; no simple iodide has been verified. The trichloride ($ReCl_3$) is a dimeric red solid which behaves as a nonelectrolyte in solution; on heating. it emits a green vapour from which metal may be deposited by thermal decomposition. Com-

plex rhenium (IV) halides of the type K_2ReX_6 have been reported for all four of the common halogens.

There are two naturally occurring isotopes with mass numbers: 185, which is stable, and 187, which is radioactive and the more abundant; radioactive isotopes with mass numbers 182, 183, 184 and 188 have been prepared. The arrangement of electrons in the unfilled orbits (O and P) is: $5s^2$, $5p^6$, $5d^5$, $6s^2$.

RHESUS MONKEY *(Macaca mulata)*, probably the best known of all monkeys, a native of India. It is brown in colour, with long hair and a naked area on the buttocks. and is gregarious. *See* MACAQUE.

RHETORIC, the art of using language in such a way as to produce a desired impression upon the hearer or reader. Rhetoric as an art was taught in Greece by the Sophists (*q.v.*).

The power of eloquent speech is recognized in the earliest Greek writings, but the founder of rhetoric as an art was Corax of Syracuse. In 466 a democracy was established in Syracuse. One of the immediate consequences was a mass of litigation on claims to property, urged by democratic exiles who had been dispossessed by Thrasybulus, Hieron or Gelon. Such claims. going many years back, would often require that a complicated series of details should be stated and-arranged. The claimants also. in many instances, would lack documentary support, and rely chiefly on inferential reasoning. Hence the need of professional advice. The facts known as to the "art" of Corax perfectly agree with these conditions. He gave rules for arrangement, dividing the speech into five parts: proem, narrative, arguments (ἀγῶνες), subsidiary remarks (παρέκβασις) and peroration. Next he illustrated the topic of general probability (εἰκός), showing its two-edged use; *e.g*, if a puny man is accused of assaulting a stronger, he can say, "Is it likely that I should have attacked him?" If vice versa, the strong man can argue, "Is it likely that I should have committed an assault where the presumption was sure to be against me?" This topic of εἰκός, in its manifold forms, was in fact the great weapon of the earliest Greek rhetoric and it was further developed by Tisias, the pupil of Corax, as we see from Plato's *Phaedrus*. Its later developments were largely the work of Gorgias and Lysias and in a greater degree of Antiphon and Isocrates *(see* their separate biographies). But the detailed study of the art begins with Aristotle's *Rhetoric* (written 322–320 B.C.).

Aristotle's **"Rhetoric."**—Aristotle sets out from the proposition that rhetoric is properly an art. because when a speaker persuades. it is possible to find out why he succeeds in doing so. It is. in fact, the popular branch of logic. Hitherto, Aristotle says, writers on rhetoric have concerned themselves mainly with the exciting of emotions. All this is very well, but "it has nothing to do nith the matter in hand; it has regard to the judge." The true aim should be to *prove* your point, or seem to prove it.

Aristotle does not sufficiently regard the question: What. as a matter of experience, is most persuasive? Logic may be more persuasive with the more select hearers of rhetoric: but rhetoric is for the many, and with the many appeals to passion will sometimes, perhaps usually, be more effective than syllogism No formulation of rhetoric can correspond with fact which does not leave it absolutely to the genius of the speaker whether reasoning (or its phantom) is to be what Aristotle calls it, the "body of proof" (σῶμα πίστεως) or whether the stress of persuading effort should not be rather addressed to the emotions of the hearers.

His statement, that the master of logic will be the master of rhetoric, is a truism if we concede the essential primacy of the logical element in rhetoric. Otherwise it is a paradox: and it is not in accord with experience. which teaches that speakers incapable of showing even the ghost of an argument have sometimes been the most completely successful in carrying great audiences along with them. Aristotle never assumes that the hearers of his rhetorician are as οἱ χαρίεντες, the cultivated few; on the other hand. he is apt to assume tacitly—and here his individual bent comes out—that these hearers are not the great surging crowd. the ὄχλος, but a body of persons with a decided, though imperfectly developed, preference for sound logic.

What is the use of an art of rhetoric? It is fourfold, Aristotle replies. Rhetoric is useful, first of all, because truth and justice are naturally stronger than their opposites. When awards are not duly given, truth and justice must have been worsted by their own fault. This is worth correcting. Rhetoric is then (1) *corrective*. Next, it is (2) *instructive,* as a popular vehicle of persuasion for persons who could not be reached by the severer methods of strict logic. Then it is (3) *suggestive*. Logic and rhetoric are the two impartial arts; that is to say, it is a matter of indifference to them, as arts, whether the conclusion which they draw in any given case is affirmative or negative. Suppose that I am going to plead a cause, and have a sincere conviction that I am on the right side. The art of rhetoric will suggest to me what might be urged on the other side; and this will give me a stronger grasp of the whole situation. Lastly, rhetoric is (4) *defensive*. Mental effort is more distinctive of man than bodily effort; and "it would be absurd that, while incapacity for physical self-defence is a reproach." incapacity for mental defense should be no reproach. Rhetoric, then, is corrective, instructive, suggestive, defensive. But what if it be urged that this art may be abused? The objection, Aristotle answers, applies to all good things, except virtue, and especially to the most useful things. Men may abuse strength, health, wealth. generalship.

The Period from Alexander to **Augustus.**—Aristotle's method lived on in the Peripatetic school. Meanwhile the fashion of florid declamation or strained conceits prevailed in the rhetorical schools of Asia, where, amid mixed populations, the pure traditions of the best Greek taste had been dissociated from the use of the Greek language. The "Asianism" of style which thus came to be contrasted with "Atticism" found imitators at Rome. Hermagoras of Temnos in Aeolis (c. 110 B.C.) did much to revive a higher conception. Using both the practical rhetoric of'the time before Aristotle and Aristotle's philosophical rhetoric, he worked up the results of both in a new system—following the philosophers so far as to give the chief prominence to "invention." He thus became the founder of a rhetoric which may be distinguished as the scholastic. Through the influence of his school, Hermagoras did for Roman eloquence very much what Isocrates had done for Athens. Above all, he counteracted the view of Asianism, that oratory is a mere knack founded on practice, and recalled attention to the study of it as an art.

Cicero's rhetorical works are to some extent based on the technical system to which he had been introduced by Molon at Rhodes. But Cicero further made an independent use of the best among the earlier Greek writers, and he could draw, at least in the later of his treatises, on a vast fund of reflection and experience. The result is certainly to suggest how much less he owed to his studies than to his genius. Some consciousness of this is perhaps implied in the idea which pervades much of his writing on oratory, that the perfect orator is the perfect man. The same thought is present to Quintilian, in whose great work, *De Institufione Oratorin,* the scholastic rhetoric receives its most complete expression (c. A.D. 90). He treats oratory as the end to which the entire mental and moral development of the student is to be directed. Thus he devotes his first book to an early discipline which should precede the orator's first studies. and his last book to a discipline of the whole man which lies beyond them. After Quintilian, the next important name is that of Hermogenes of Tarsus. who under Marcus Aurelius made a complete digest of the scholastic rhetoric from the time of Hermagoras of Temnos (110 B.C.) in five extant treatises, remarkable for clearness and acuteness.

Hermogenes continued for nearly a century and a half to be one of the chief authorities in the schools. Longinus (*q.v.*) *(c.* A.D. 260) published an *Art oj Rhetoric* which is still extant; and the more celebrated treatise *On Sublimity* (περὶ ὕψους), if not his work, is at least of the same period. In the later half of the 4th century Aphthonius composed the "exercises" (προγυμνάσματα) which superseded the work of Hermogenes. At the revival of letters the treatise of Aphthonius once more became a standard textbook. Much popularity was enjoyed also by the ex-

ercises of Aelius Theon (of uncertain date). (See further the editions of the Rhetores *Graeci* by L. Spengel and by C. Walz.)

Rhetoric under the Empire.— During the first four centuries of the empire the practice of the art was in greater vogue than ever before or since. First, there was a general dearth of the higher intellectual interests: politics gave no scope to energy, philosophy was stagnant and literature was, as a rule, either arid or frivolous. Then the Greek schools had poured their rhetoricians into Rome. where the same tastes which revelled in coarse luxury welcomed tawdry declamation. The law courts of the Roman provinces further created a continual demand for forensic speaking. The public teacher of rhetoric was called "sophist," which was now an academic title, similar to "professor" or "doctor." In the 4th century B.C. Isocrates had taken pride in the name of σοφιστής, which, indeed, had at no time wholly lost the good, or neutral, sense which originally belonged to it.

Vespasian (A.D. 70–79), according to Suetonius, was the first emperor who gave a public endowment to the teaching of rhetoric. Under Hadrian and the Antonines (A.D. 117–180) the public chairs of rhetoric became objects of the highest ambition. The Rhetorical school (θρόνοι) had two chairs, one for sophistic, the other for political rhetoric. By "sophistic" was meant the academic teaching of rhetoric as an art, in distinction from its "political" application to the law courts. The sophistical chair was superior to the political in dignity as in emolument, and its occupant was invested with a jurisdiction over the youth of Athens similar to that of the vice-chancellor in a modern university. The Antonines further encouraged rhetoric by granting immunities to its teachers. Three sophists in each of the smaller towns, and five in the larger, were exempted from taxation (Dig. xxvii, 1, 6, §2). The wealthier sophists affected much personal splendour. The aim of the sophist was to impress the multitude. His whole stock in trade was style, and this was directed to astonishing by tours de force. The scholastic declamations were chiefly of two classes. (1) The suasoriae were usually on historical or legendary subjects, in which some course of action was commended or censured (cf. Juv. Sat.). These *suasoriae* belonged to deliberative rhetoric (the βουλευτικὸν γένος, deliberativum genus). (2) The controversiae turned especially on legal issues, and represented the forensic rhetoric (δικανικὸν γένος, *iudiciale* genus). But it was the general characteristic of this period that all subjects were treated alike in the style and spirit of that third branch which Aristotle distinguished, the rhetoric of ἐπίδειξις or "display." This academic oratory is shown under various aspects, and presumably at its best, by such writers as Dio Chrysostom at the end of the 1st century, Aelius Aristeides (see ARISTEIDES, AELIUS) in the 2nd (the chief rhetorician under the Antonines) and Themistius, Himerius and Libanius in the 4th. Amid much which is tawdry or vapid, these writings occasionally present passages of true literary beauty, while they constantly offer matter of the highest interest to the student.

The Middle Ages and the Renaissance.— In the mediaeval system of academic studies, grammar, logic and rhetoric were the subjects of the trivium, or course followed during the four years of undergraduateship. Music, arithmetic, geometry and astronomy constituted the quadrivium, or course for the three years from the B.A. to the M.A. degree. These were the seven liberal arts. In the middle ages the chief authorities on rhetoric were the latest Latin epitomists, such as Martianus Capella (5th century), Cassiodorus (5th century) or Isidorus (7th century).

After the revival of learning the better Roman and Greek writers gradually returned into use. Some new treatises were also produced. Leonard Cox (d. 1549) wrote The Art or Craft of Rhetoryke, partly compiled, partly original, which was reprinted in Latin at Cracow. The Art of Rhetorique, by Thomas Wilson (1553), afterward secretary of state, embodied rules chiefly from Aristotle, with help from Cicero and Quintilian. About the same time treatises on rhetoric were published in France by Tonquelin (1555) and Courcelles (1557). The general aim at this period was to revive the best teaching of the ancients. At Cambridge in 1570 the study of rhetoric was based on Quintilian, Hermogenes and the speeches of Cicero viewed as works of art. An Oxford statute of 1588 shows that the same books were used there. In 1620 George Herbert was delivering lectures on rhetoric at Cambridge. where he held the office of public orator. The decay of rhetoric as a formal study at the universities set in during the 18th century. The function of the rhetoric lecturer passed over into that of correcting written themes; but his title remained long after his office had lost its primary meaning. If the theory of rhetoric fell into neglect, the practice, however, was encouraged by the public exercises ("acts" and "opponencies") in the schools. The college prizes for declamations served the same purpose.

Modern Writers on Rhetoric.— The fortunes of rhetoric in the modern world, as briefly sketched above, may suflice to suggest why few modern writers of ability have given their attention to the subject. One of the most notable modern contributions to the art is the collection of commonplaces framed (in Latin) by Bacon, "to be so many spools from which the threads can be drawn out as occasion serves," a truly curious work of that acute and fertile mind, and quite in the spirit of Aristotle's treatise. The popularity enjoyed by Hugh Blair's Lectures on Rhetoric in the latter part of the 18th and the earlier part of the 19th century was merited rather by the form than by the matter. Campbell's Philosophy of Rhetoric, which found less wide acceptance than its predecessor, was superior to it in depth, though often marred by an imperfect comprehension of logic. But undoubtedly the best modem book on the subject is Richard Whately's Elements of Rhetoric. Starting from Aristotle's view, that rhetoric is "an offshoot from logic," Whately treats it as the art of "argumentative composition." He considers it under four heads: (1) the address to the understanding (=Aristotle's λογικὴ πίστις); (2) the address to the will, or persuasion (=Aristotle's ἠθικὴ and παθητικὴ πίστις); (3) style; (4) elocution, or delivery. But when it is thus urged that

> All a rhetorician's rules
> But teach him how to name his tools,

the assumption is tacitly made that an accurate nomenclature and classification of these tools must be devoid of practical use. The conditions of modern life, and especially the invention of printing, have to some extent diminished the importance which belonged in antiquity to the art of speaking, though modem democratic politics and forensic conditions still make it one which may be cultivated with advantage.

BIBLIOGRAPHY.— Among more modern works are J. Bascom, Philosophy of Rhetoric (1885), and numerous books on voice culture, gesture and elocution. For ancient rhetoric see Sir R. C. Jebb's translation of Aristotle's Rhetoric, ed. by J. E. Sandys (1909), and his Attic Orators (1876); also Spengel, Artium *Scriptores* (1828); Westermann, Gesch. der Beredtsamkeit (1833–35); Cope, in the Cambridge *Journal* of Classical and Sacred Philology (1855–57); introductions to Cicero's De *Oratore* (A. S. Wilkins) and Orator (J. E. Sandys); Volkmann, Die Rhetorik der Griechen und Romer in system. *Übersicht*, 2nd ed. (1885); Norden, Die Antike Kunstprosa (1898). (R. C. J.; X)

RHEUMATIC FEVER is a generalized disease commonest in children between the ages of 5 and 15 but occurring with considerable frequency in young adults. The manifestations, severity. duration and aftereffects are highly variable. In a small percentage of patients death may occur because of inflammation of the heart in the acute attack, but in a much larger number the acute attack subsides with a variable amount of cardiac damage. Recurrences are frequent in the absence of appropriate measures for the prevention of streptococcal infection.

Causative Factors.— The exact cause of rheumatic fever was still unknown at mid-20th century, although a close relationship to previous streptococcus infection had been well established. This is based on the high incidence of known streptococcus infection preceding attacks of acute rheumatic fever, the presence of streptococcal antibodies (particularly antistreptolysin) in the blood of patients with the disease, and the prevention of recurrent attacks of rheumatic fever by the continued use of drugs that prevent streptococcus infection. It is generally believed that the disease results from the reaction of the body to the streptococcus rather than the direct effect of streptococcal infection.

Many authorities believe that this illness represents a hypersensitivity reaction, although direct evidence for this view is lacking.

Clinical Characteristics. — The clinical recognition of rheumatic fever is made difficult by the wide variety of symptoms. The most important evidences are those that result from inflammation of the heart, and of these the commonest are certain types of murmurs and increased heartbeat rate. It is frequently difficult to determine whether a given murmur results from active rheumatic fever or a previous attack. With more serious heart involvement there may be rapid enlargement of the heart, heart failure resulting in difficulty in breathing, evidence of inflammation of the membranes overlying the heart (pericarditis) and irregularities of the heartbeat. Additional evidence of cardiac involvement is sometimes obtained on electrocardiographic tracings. The extent and duration of cardiac inflammation is extremely variable in all age groups, but in general tends to be severer in young children than in young adults. Severe cardiac involvement may result in death in a relatively short time.

Involvement of the joints is a common manifestation. This may vary from mild aches and pains to severe swelling, redness, tenderness and limitation of motion. Characteristically several joints are involved, with migration from day to day. The joint symptoms are commoner in older patients than in young children. Joint manifestations are commonest in the early stages and never result in permanent impairment of function.

Nodules may occur beneath the skin, but rarely before the third or fourth week of disease. The presence of nodules is usually associated with involvement of the heart. A variety of skin rashes may be present in acute rheumatic fever, the most characteristic of which is erythema marginatum, which is considered highly specific for the disease by most authorities.

Chorea (St. Vitus' dance; *q.v.*) represents a nervous system manifestation of rheumatic fever. It is characterized by purposeless movements of the arms and legs and inability to perform coordinated movements of muscle groups. Emotional disturbances may also be present. The severity and duration of these symptoms are highly variable.

Fever occurs early in the disease in a relatively large percentage of patients, but it is not necessarily present. A wide variety of other signs and symptoms may also occur, among them nosebleeds. weakness, abdominal pain and weight loss. Examination of the blood usually shows an increase in the rate of sedimentation of red blood cells, and frequently shows anemia and an increased number of white blood cells.

In typical cases a combination of the above symptoms makes diagnosis relatively certain. Many patients have the disease in subtler form. so that the first recognition of the previous rheumatic episode comes from the presence of structural abnormalities of the heart characteristically produced by rheumatic fever.

The length of an individual attack of acute rheumatic fever is variable and is sometimes difficult to ascertain. In certain persons symptoms may be transient, while in others the disease remains obviously active for periods of more than a year.

The degree of cardiac damage sustained during an individual attack is not related simply to the severity of the acute attack, but may be more closely related to the total duration of active disease. The interference with normal heart function, usually referred to as rheumatic heart disease, results in the main from distortion of the valve structure. Although such distortion may lead to extreme cardiac disability, patients with rheumatic heart disease may carry on relatively normal lives. The greatest threat to life is reactivation of the rheumatic process. A large percentage of people have no interference with cardiac function following recovery from acute rheumatic fever.

Pathology. — Although clinical evidences of rheumatic fever may occur in the heart, joints, skin and central nervous systems, the most characteristic pathological findings are seen in the heart. On gross examination the heart is usually dilated. and the surface may be covered by a stringy material that adheres to the membrane covering the heart (pericardium). The heart muscle is paler and softer than normal. Microscopic examination shows evidence of a peculiar type of inflammation in the connective tissue. The most characteristic microscopic lesion is the Aschoff nodule, which consists of an accumulation of large pale cells together with smaller cells surrounding degenerating connective tissue fibres. Aschoff nodules are most characteristically found in the connective tissue of various parts of the heart, but similar lesions have been identified in the connective tissue of other organs.

In later stages of the disease scar formation occurs. Such scarring results in deformity of the valves of the heart. bringing about interference with normal function. The mitral valve is most frequently involved, although the aortic valve is also commonly distorted. The tricuspid valve is rarely affected, while the pulmonary valve is almost never involved.

Treatment. — Until 1949 the usual treatment of rheumatic fever consisted of the use of salicylate drugs. There remained some difference of opinion as to whether these drugs have any specific effect on the rheumatic process. Adrenocorticotropic hormone (ACTH), cortisone and certain synthetic hormones related to cortisone have striking effects on rheumatic fever, but it is not clear whether use of these drugs prevents subsequent development of heart disease and has an advantage over salicylate treatment. Of cardinal importance in treatment is the complete eradication of any streptococcal infection, usually accomplished by large doses of penicillin.

Patients with active rheumatic fever are usually kept at bed rest for the duration of the active disease. In patients with severe cardiac failure, digitalis, mercurial diuretics, restriction of salt intake and oxygen are valuable. Adequate nutrition and good nursing care are important. The administration of prophylactic drugs (usually penicillin or sulfadiazine) has resulted in a considerable reduction in the rate of recurrences by preventing further streptococcal infection.

Surgical treatment is successfully used to relieve the narrowing of the openings of the valves of the heart. By 1958 some progress also had been made in correcting by surgical means the defect in closure of valves that occurs in rheumatic heart disease. *See* also HEART AND LUNG, SURGERY OF.

Public Health Aspects. — Rheumatic fever frequently occurs in more than one member of a family. apparently due to a hereditary susceptibility to the disease. It has been found in many parts of the world in representatives of all races. In the United States (as measured by mortality statistics) it is commoner in the northern half of the country. the highest rates occurring in the middle Atlantic and mountain states. The observed rates cannot be correlated simply with latitude, average temperature, altitude or rainfall. The disease is not confined to any socioeconomic group, but studies indicate high mortality in low-income groups.

Rheumatic fever became one of the leading causes of death of children in the U.S. as death rates from infectious diseases declined with improved measures for prevention and treatment. It is difficult to estimate the true incidence because of difficulties in diagnosis and poor reporting. but there was evidence of a decline in the death rate of children from rheumatic fever and rheumatic heart disease between 1920 and 1955.

Because of the frequently long duration of rheumatic fever, few families are able to meet the financial burden; the disease thus became an important public problem. In some large cities special hospitals are maintained for the care of children with rheumatic fever and rheumatic heart disease.

One of the earliest community attempts to meet the problem was the London County council's Rheumatism scheme, which provided for both hospital care and a follow-up program for all children with rheumatic fever. The financial difficulties in the care of rheumatic fever in Great Britain were overcome by the National Health Insurance scheme.

In the United States special programs for the care of children with rheumatic fever were developed after 1939 under the Social Security act. These programs were operated on a state basis with funds provided jointly by the states and the children's bureau of the department of health. education and welfare. By 1951, 23 states. Alaska. the District of Columbia and Hawaii had such programs. The nature of the services and of their administration varied from state to state. The American Council on Rheumatic Fever, organized in 1944 under the American Heart association, promoted public and private programs for care, research and edu-

cation. Under the National Heart act of 1948 the National Heart institute of the United States public health service began to conduct research on heart disease, including rheumatic fever. Through a program of grants-in-aid the Heart institute also supported research, training, demonstration programs and community programs for the control of rheumatic fever. Many local communities also developed programs for the control of this disease. (A. DOR.)

RHEUMATISM, a general descriptive term meaning discomfort, pain and stiffness in or around muscles and joints. It may be the result of injury, such as strain, or of the inflammatory or degenerative processes affecting the joints or ligaments, the muscles or nerves. More specifically it may refer to rheumatic fever, forms of arthritis and a variety of conditions designated by a descriptive adjective such as articular rheumatism, muscular rheumatism. etc. *See* ARTHRITIS; RHEUMATIC FEVER. (F. L. A.)

RHEUMATOID ARTHRITIS: *see* ARTHRITIS.

RHEYDT, a town in North Rhine-Westphalia, German Federal Republic, situated on the Niers, 19 mi. W. of Diisseldorf, on the main line of railway to Aachen, and at the junction of lines to Crefeld and Stolberg. Pop. (1959 est.) 94,610. Rheydt is an ancient place, but its industrial importance is of recent growth, and it only received municipal rights in 1856.

The principal products of Rheydt's numerous factories are silk, cotton, woollen and mixed fabrics, velvet, iron goods, machinery, shoes, cables, soap and cigars. It was frequently bombed in World War II.

RHIANUS, Greek poet and grammarian, a native of Crete, friend and contemporary of Eratosthenes (275–195 B.c.). Suidas says he was at first a slave and overseer of a palaestra but obtained a good education later in life and devoted himself to grammatical studies, probably in Alexandria. Of his works none has been preserved except 11 epigrams. But he was chiefly known as a writer of epics, the most celebrated of which was the *Messeniaca* in six books, dealing with the second Messenian war and the exploits of Aristomenes.

Other similar poems were the *Achaica, Eliaca, Thessalica* and *Heracleia.*

Fragments in *A.* Meineke, *Analecta Alexandrina* (1843); for Rhianus' work in connection with Homer, *see* C. Mayhoff, *De Rhiani Studiis Homericis* (Dresden, **1870);** also W. Christ, *Geschichte der griechischen Literatur* (1898).

RHIGAS, CONSTANTINE, known as Rhigas of Velestinos (Pherae), or Rhigas Pheraios (1760–1798), Greek patriot and poet. was born at Velestinos. and was educated at Zagora and at Constantinople, where he became secretary to Alexander Ypsilanti. In 1786 he entered the service of Nicholas Mavrogenes. hospodar of Wallachia, at Bucharest, and when war broke out between Turkey and Russia in 1787 he was inspector of the troops at Craiova. Rhigas later became interpreter at the French consulate at Bucharest, where he wrote the famous Greek version of the *Marseillaise,* well known in Lord Byron's paraphrase as "sons of the Greeks, arise." He founded the Hetairia, a society formed to organize Greek patriotic sentiment and to provide the Greeks with arms and money. Believing that the influence of the French Revolution would spread to the near east, he went to Vienna to organize a revolutionary movement among the exiled Greeks and their foreign supporters in 1793, or possibly earlier. There he founded a Greek press, but his chief contribution was the Collection of national songs which, passed from hand to hand in manuscript, roused patriotic sentiment throughout Greece. They were printed posthumously in 1814.

While at Vienna Rhigas communicated with Napoleon Bonaparte. to whom he sent a snuffbox made of the root of a laurel tree taken from the temple of Apollo, and eventually he set out with a view to meeting the general of the army of Italy in Venice. But before leaving Vienna he forwarded papers, among which is said to have been his correspondence with Napoleon, to a compatriot at Istria. The papers fell into the hands of the Austrian government, and Rhigas was arrested at Trieste and handed over with his accomplices to the Turkish authorities at Belgrade. Immediately on arrest he attempted suicide. His five companions were secretly drowned, but Rhigas himself offered such violent resistance that he was shot by two Turkish soldiers. Rhigas, who wrote in the popular dialect instead of in classical Greek, has been credited with arousing the patriotic fervour of his contemporaries, and his poems were a serious factor in the awakening of modem Greece.

RHINE, the most important river in Europe, both historically and commercially, has a course more than 820 mi. in length and drains an area of 76,000 sq.mi. It rises in Switzerland and later follows the Swiss-Austrian. Swiss-German and Franco-German frontiers before crossing. first northwestern Germany and then the Netherlands, to reach the North sea. Its valley has long formed part of the main highways from the North sea to the Mediterranean, across the Alps, and to the Black sea, by way of the Danube. It has always been a zone of contact between central and western Europe.

Course.—From their sources in the Glarus and Adula Alps the two main headstreams, the Vorder Rhein and Hinter Rhein, flow northeastward and unite near Chur (Coire). The river here is a typical alpine torrent, flowing rapidly in a deep, narrow valley and fed mainly by melting snow and ice on the mountains. From Lake Constance to Basle the High Rhine flows westward but still keeps its alpine character, dropping from 1,200 ft. to 800 ft. above sea level. The falls or rapids at Schaffhausen are used to develop electrical power. Midway in this section of its course it is joined by the Aar, bringing the drainage of the northern Alps and the Swiss plateau.

At Basle the river turns abruptly north again and enters the Upper Rhine valley, a tectonic depression formed in late Tertiary times and usually referred to as the Rhine rift valley or *Graben.* This depression is 25 mi. wide and extends northward for 180 mi. between the Vosges and Hardt mountains on the west and the Black Forest and Odenwald on the east. The level of the river falls about 550 ft. between Basle and Bingen. For much of the way it shares the wide valley floor with its left bank tributary, the Ill. Some of the many meanders in this part of its course have been cut across to ease navigation to Strasbourg. For 120 mi.. to near Lauterbourg, the main stream forms the boundary between France and Germany. The Neckar and the Main, both right bank tributaries. join the Rhine at Mannheim and Mainz respectively.

The Rift valley is blocked at its northern end by the Taunus range causing the river to turn westward to Bingen and enter the 80 mi. gorge characteristic of the Middle Rhine as it crosses the Rhenish plateaus. From Bingen to Bonn the river is deep and narrow, sometimes occupying the whole width of the valley, and is dominated by many castles. Channels were blasted through the rapids at Bingen to facilitate navigation. Near Coblenz the valley widens for a short distance where the Moselle and Lahn enter, the former with its tributary the Saar draining the area between the Vosges and the Xrdennes.

The Lower Rhine begins at Bonn where it enters the Cologne "gulf" and starts its course over the deltaic deposits laid down by the ancient Rhine and Maas (Meuse). Wide terraces cut in the sands and gravels mark former river levels before the marshy flood plain of the modern river is reached at Emmerich and diking becomes necessary. Throughout this section it is a wide sluggish stream. Below Cologne it receives as right bank tributaries the Ruhr and the Lippe flowing across the great industrial region of Westphalia. After the river turns west into the Netherlands it soon breaks up into two main arms of which the Waal carries about two-thirds and the Lek about one-third of its volume. The Maas (Meuse) and Waal waters mingle in the many deltaic channels and finally reach the sea by the Hollandschdiep.

The Regime.—The flow of the Rhine is remarkably regular throughout much of its course. As far downstream as Strasbourg it carries only alpine waters and the range of levels is very high. Both the alpine Rhine and the Aar are fed mainly from the snows and glaciers. Their flow is therefore at a minimum in January but reaches flood heights in June and July when the vigorous melting

is often supplemented by heavy rainstorms. At Basle the mean flow of 35,000 cusec. in January may reach 160,000 cusec. in July. The change is very apparent in the Rift valley uhere the river in winter shrinks to shallow channels through gravel banks all covered in summer. With the entry of the Neckar the regime changes. Melted snow still provides a large proportion of the river waters but, as altitudes are lower and generally continue to decrease northward, this supply is received much earlier in the year. On the Neckar and Main levels are highest in March and lowest from June to September, on the Moselle highest in January and lowest in August. All the middle and lower basins receive more rain than snow water. In this way the unbalance upstream is corrected in the middle course and the lower river has a regular flow. Minor difficulties for navigation are created for short periods from time to time in exceptional seasons. Thus a dry summer may lead to abnormally low levels in autumn and persistent heavy rains on the Rhenish plateaus may cause flooding in the diked country. Freezing occurs on slack water in most winters (at Cologne for an average period of 20 days per year) and may halt river traffic. If the frost has been long and severe, blocking of the river bridges by ice cakes may occur in the thaw period.

Navigation.—Trade from the Netherlands to the Alps has followed the Rhine since prehistoric times. By the early middle ages it mas already the scene of a flourishing civilization based on trade. mineral wealth and agriculture. In the 15th century its valley was the most important route in all western Europe. Besides draining nearly a quarter of the area of Germany it also serves Austria, Switzerland, eastern France and the Netherlands as an outlet to the North sea. Before 1939 Rotterdam handled one-fifth of Germany's overseas trade and practically all these imports and exports arrived at or left the port along the Rhine waterway.

Between the Sniss and Dutch frontiers the main river alone provides 440 mi. of navigable waterway and another 110 mi in Netherlands territory. Its tributaries, the Lippe. Ruhr, Lahn, Moselle. Main and Neckar, all have navigable stretches, some of them of considerable length and capable of carrying barge loads of about 1,000 tons. Seagoing ships pass regularly to Cologne and barge trains of 5,000 tons reach Mannheim. Strasbourg, the real head of navigation, receives barges of up to 2.000 tons. By an artificial channel 600-ton barges can reach Basle at certain times of the year.

The area from which river cargoes are drawn has been considerably extended by the construction of canals linking the Rhine with neighbouring river systems. Thus the Marne-Rhine canal makes possible aater transport from Paris and. by branch canals, from the Lorraine ore fields and the Saar basin. The Rhône-Rhine canal gives connection to southern France and Marseilles through the Belfort gap. Through traffic to the Danube is not possible as the Ludwigskanal became obsolete A new canal route up the Main and then to Regensburg was under construction in the mid-1950s. The Dortmund-Ems canal. though not suitable for the modern large barges gives an alternative route from the Ruhr to the North sea and links with the Mittelland canal, thereby giving a waterway to the Elbe and the east German rivers.

All the Rhine lands thus form a single economic unit with interdependent parts—western Germany. eastern France and the Low Countries. The Rhine with its navigable tributaries, the connecting canals and the railways folloning their valleys, provides the links which bind them together. On the east and nest flanks of the river are the greatest industrial areas of Europe based on Lorraine iron ore and Ruhr coal respectively. Before 1939 over 40,000,000 tons of shipping crossed the Dutch frontier each year. To serve this heavy traffic harbour accommodation was provided at several points and these are all rapidly recovering their former importance. The river is of course especially suitable for the carriage of bulky cargoes. Duisburg handles one-third of all the water-borne traffic of Germany, importing ore, grain and oil products and dispatching coal both up and down stream. It has separate basins equipped to handle each of these types of cargo. Mannheim-Ludwigshafen ranks second among Rhine ports, dealing aith coal for southwestern Germany as well as for its onn chemical and other industries With Strasbourg, which mainly serves the French side of the river, it shares in the landing of coal and grain for Switzerland. Mainz deals with traffic along the Main to Frankfurt-on-Main and Bamberg, while Basle collects and distributes Swiss cargoes. Down-river cargoes are relatively light—mainly timber, potash and iron ore.

RHINELAND, THE. Before Prussia's dissolution the word "Rhineland" was used to designate the Prussian province of *Rheinprovinz* as well as parts of the Prussian province of Hesse-Nassau, parts of Hesse, the Bavarian Palatinate and most of Baden.

The old Rhenish territory north of Lorraine had been annexed by France in 1801, but after the fall of Napoleon the Congress of Vienna transferred it to Prussia and Bavaria. In 1866 Napoleon III vainly tried to recover the Rhineland by diplomatic bargaining with Bismarck. After the defeat of Germany in 1918, French policy aimed at detaching the left bank of the Rhine from Germany, with the object of protecting itself against a new German attack; but since the region is German in nationality and tradition this was opposed by Great Britain and the United States, and France had to accept a compromise: (1) the left bank remained German; (2) it was to be occupied, together with the bridgeheads, by Allied troops in three zones, the northern zone (Cologne) to be evacuated after 5 years, the middle (Coblenz) after 10, the southern (Mainz) after 15 years, if Germany faithfully carried out the conditions of the peace (Art. 428–29 of the Treaty of Versailles); (3) the left bank of the Rhine and a strip of 50 km. on the right bank was to be completely and permanently demilitarized (Art. 42–44). The occupation was intended to provide both guarantees for the execution of the treaty and security to France against military aggression.

By a separate Rhineland agreement an interallied commission was established, composed of representatives of Belgium, France, Great Britain and the United States, with the right to issue ordinances for the security of the Allied forces. It was not to interfere with the German civil administration, but to erect a customs barrier in order to safeguard the economic interests of the population (Art. 270). Considerable friction developed between the commission, presided over by Paul Tirard. a Frenchman. and the Germans, particularly over the use of Negro soldiers by the French as part of their occupying troops. After the United States failed to ratify the Treaty of Versailles and made a separate peace with Germany (1921), the American troops were withdrawn from Coblenz, and that area was taken over by the French.

France accepted the compromise about the Rhineland because both Great Britain and the United States, simultaneously with the Treaty of Versailles, signed treaties of alliance with France, by which they bound themselves to come to the aid of France "in the event of any unprovoked movement of aggression against her being made by Germany." When these treaties were not ratified by the British and U.S. governments, France felt that she had been victimized, that she had lost the real fruits of victory; subsequent events were to prove the correctness of this view.

As soon as it became clear that the left bank of the Rhine would not be separated from Germany, the French military authorities began to foster separatist movements in the region An old-established anti-Prussian prejudice of the Catholic population of the Rhine province had been intensified by a fear of the spread of bolshevism, and a genuine movement for decentralization arose, which demanded the creation of a Rhineland state within the German republic. The head of this movement, Dr. Hans Dorten, entered into negotiations with General Charles-Marie Mangin, which killed the movement so far as the Germans were concerned, and since the American authorities would not cooperate, the plan collapsed.

The occupation of the Ruhr (*q.v.*) in 1923 by France and Belgium gave new life to the separatist movement. The first

manifestation was a rising in Diisseldorf on Sept. 30, which was suppressed by local authorities. Then came the proclamation on Oct. 21 of a "Rhineland republic" at Aachen (Aix-la-Chapelle). in the Belgian zone; this lasted until Nov. 2, when the Belgian government, under British pressure, disavowed the enterprise. Simultaneously, Dorten and one Matthes organized a *Putsch* at Bonn, Coblenz, Wiesbaden and Mainz, their followers being transported by the Franco-Belgian railway administration. When the two leaders quarreled, their regime collapsed, early in 1924.

More serious was the movement in the Bavarian Palatinate, where it was fathered by General de Metz. On Oct. 25, he declared that the Palatinate had ceased to be part of Bavaria, and the separatists seized the government and ejected about 19,000 German officials. The population retaliated and there was a kind of civil war. in which the separatists fared badly, 15 of them being massacred at Pirmasens.

In 1924 the new French government, under Edouard Herriot, agreed to the Dawes plan *(see* REPARATIONS) for the settlement of the reparation question and to the evacuation of the Ruhr. Germany thereupon looked forward to the evacuation of the northern zone of the Rhineland on Jan. 10. 1925. The Allied governments, however, were convinced that Germany had not carried out her obligations to disarm and postponed the evacuation until the terms of the treaty had been complied with. In order to facilitate the negotiations for evacuation and to prevent another occupation of the Ruhr, the German foreign minister, Gustav Stresemann, on Feb. 9, 1925, suggested to France a pact between the powers interested in the Rhineland which should provide a mutual guarantee of existing frontiers. The French government accepted the proposals, which were extended to include eastern Europe as well as the Rhineland, and after long negotiations between Germany, Great Britain, France, Italy, Belgium, Poland and Czechoslovakia, the Treaty of Locarno *(see* LOCARNO, PACT OF) was concluded on Oct. 16 and signed in London on Dec. 1, 1925. Reassured by the feeling of security thus created and mollified by Germany's willingness to carry out her disarmament as prescribed by the interallied commission, France now agreed to the evacuation of the northern zone.

For the next few years, Germany continually pressed for complete evacuation of the Rhineland on the ground that she was a member of the League of Nations and had fulfilled her obligations, except as regards reparation, which was the subject of another agreement (the Dawes plan); or at least for a reduction of the Allied garrisons (for the upkeep of which Germany had to pay). Shortly after Germany entered the league. Stresemann and Aristide Briand. the French foreign minister, tried, at Thoiry, to reach an understanding about reparation and the whole economic relationship between France and Germany; but nothing practical resulted, partly because Stresemann shortly afterward raised the question of "war guilt" and aroused fears in France that Germany intended to repudiate the Versailles treaty. By the time, however, that the Young committee met to revise the Dawes plan, it was generally understood that if a satisfactory financial agreement could be reached, evacuation of the Rhineland would be conceded as part of a general settlement with Germany. At the Hague conference in Aug.–Sept. 1929, the French delegates endeavoured to postpone evacuation until Germany had accepted the Young plan and to establish some kind of control in the Rhineland for making sure that the region remained demilitarized; but the new Labour government in England and the Belgian government announced their intentions to withdraw their troops before the end of the year, and France was again compelled to compromise. The British and Belgian troops were withdrawn before the end of 1929, the Young plan became effective on May 17, 1930, and on June 30 the last Allied troops left the Rhineland. The president of the Rhineland high commission, Tirard, prophetically declared: "All that remains on the Rhine is the word which Germany has given. The future depends on how that word is kept." It was significant of the future that in the November elections for the *Reichstag,* 113 Nazis were chosen, whereas they had secured only seven seats in the previous election, for the Allies had surrendered all means of pressure.

Whatever trust France may have had in Germany was shattered by the abortive attempt in 1931 to establish an Austro-German customs union. After the true character of the Nazi revolution of 1933 had begun to manifest itself, France in 1935 concluded a five-year pact of mutual guarantee with the Soviet Union. The German government protested against this pact, declaring that it was inconsistent with the Treaty of Locarno (but refusing to submit the question to arbitration, as proposed by France). Inasmuch, however, as the German foreign minister assured the British government that Germany continued to recognize the Locarno agreements the French government decided to ratify the treaty with the Soviet Union. The chamber of deputies acted on Feb. 27, 1936, but on March 7 the senate was still considering the matter.

On that day Hitler, in a speech to the *Reichstag,* repudiated the Rhineland clauses of the Treaty of Versailles and the whole of the Locarno settlement and announced the entry of German troops into the demilitarized zone, where they were uproariously received. At the same time, he declared that Germany was ready to conclude a 25-year pact of nonaggression with France and Belgium, re-enter the League of Nations, negotiate an agreement concerning disarmament and undertake a project for a Franco-German demilitarized frontier zone to be guaranteed by Great Britain and Italy.

The German action was a flagrant violation of both Versailles and Locarno, and a few years before France would certainly have sent its troops into the Rhineland. In March 1936 the French general staff, overestimating the number of German troops (35,000) and not knowing (so it is said) that Hitler had ordered his troops to withdraw if the French marched in, refused to take action unless there was a partial mobilization of the French army; the cabinet refused to sanction this, perhaps because of the cost, and only a few specialized units were moved up to the Maginot line. The French government merely asked the League of Nations and the Locarno powers to take cognizance of the situation.

The British government made clear that it would not take positive action; British public opinion regarded the Rhineland as German territory which German troops might properly enter and refused to comprehend the political or military consequences of Hitler's action. Belgium was weak and helpless. Italy was at war in Africa and secretly approved the German course. Only Poland and Czechoslovakia, among the Locarno powers, were ready to stand by France. The council of the League of Nations and the Locarno powers recorded Germany's violations of its agreements, but. since Hitler offered to make a new agreement, tried to set up a "second Locarno." Negotiations went on for several months but led to nothing.

Germany re-established its position in the Rhineland without assuming any new obligations, and soon recovered military ascendancy on the continent. The failure of Britain and France to use force against Germany on this issue proved to be a turning point, for in 1938, at the time of the Sudeten crisis, the western powers did not feel strong enough to challenge Germany on the Rhine and had to accept Hitler's terms at Munich.

The Rhineland was heavily damaged during World War II. After the conclusion of hostilities, it was occupied by British, French and U.S. troops. Thus for a second time the Rhineland was divided among three political jurisdictions until the establishment of the west German government in 1949.

After the war the northern part of the region was incorporated in the *Land* of North Rhine-Westphalia and the southern part in that of Rhineland-Palatinate (*q.v.*).

RHINELAND-PALATINATE (RHEINLAND-PFALZ), a

Land of the German Federal Republic, constituted in 1946 from the southern part of the Prussian Rhine province, the Bavarian Palatinate and part of Rhine-Hesse and of Hesse-Nassau. It is bounded north and northeast by North Rhine-Westphalia, east by Hesse and Baden-Württemberg and west and south by the Saarland and France. Area 7,656 sq.mi. Pop. (1950) 3,004,752; (1960 est.) 3,393,100. The country forms part of the Rhine massif, which here rises to the ridges of the Taunus and Westerwald. east of the Rhine, and west of the river to the Hunsriick and the bare and harsh Eifel plateau. These highlands are separated by the gorges of the Rhine, Mosel and Lahn. The Rhine constitutes the eastern border of the country for much of the way. The Mosel cuts across from west to northeast. Except for Hesse, Rhineland-Palatinate is the most wooded of all the Lander.

History. — Because it first became a political unit after World War II, Rhineland-Palatinate has no historical coherence, except in so far as this is contributed by the Rhine. The earlier history of the south and east may be followed in HESSE and PALATINATE. The largest component of the country was formerly part of the Prussian Rhine province, which stretched from the Hunsriick in the south to the Dutch frontier in the north and had an area (excluding the Saarland) of 9,451 sq.mi. Its capital was Koblenz.

The Rhinelands were of great importance from earliest times. and the valley was a land route before the river was used. The Rhine was, broadly speaking, the frontier of the Roman empire. After its decline the Franks settled on both sides of the river in the north and the Alemanni in the south, the dividing line being near Mainz. The later Rhine province was, in fact, an area of Frankish settlement. When the Carolingian empire was divided in 843 between Louis the German and Lothair, the Rhinelands were divided also, but almost all of those which were later to come to the Rhine province fell to the kingdom of Lothair. Further 9th-century agreements (see GERMANY) united the Rhinelands in the German kingdom. The Rhine was the centre of medieval German culture: some of the great universities were there and at Mainz Johann Gutenberg printed his first books. From the early middle ages the three archbishops of Cologne, Trier and Mainz possessed great strips of territory along the river and their power only ended with the secularization of the archbishoprics under Napoleon.

To make the Rhine the French frontier was traditional French policy at least from the time of Cardinal Richelieu, and the Rhinelands were a constant field of conflict in the 17th and 18th centuries. France's acquisitions on the left bank of the Rhine (treaty of Campo Formio, 1797) and the Confederation of the Rhine, which Napoleon set up east of the river, only lasted until 1815. At the Congress of Vienna Prussia mas given the whole of the Rhinelands on both sides of the river from the Dutch frontier to the Mosel, and west of the river beyond the Mosel to the Nahe. Out of these territories — the duchies of Gelderland, Jiilich. Cleves. Berg. the ecclesiastical principalities of Trier and Cologne, the free cities of Aachen and Cologne and nearly roo small lordships and abbeys — were formed the two provinces of Cleves-Berg and Lower Rhine. These were united in gne Rhine province in 1824. In 1834 the principality of Lichtenberg and in 1866 Meisenheim, both on the border of the Bavarian Palatinate, were added.

The Rhinelands mere occupied territory after World War I (see RHINELAND. THE). When at the end of World War II Prussia was abolished, the Rhineland province was divided between the new *Länder* of North Rhine-Westphalia and Rhineland-Palatinate.

Administration and Population. — The *Land* is divided into five administrative divisions. Koblenz. Trier, Montabaur, Rhinehesse and Palatinate. There were in 1960 seven towns with a population of over 50,000: Ludwigshafen (161,922); Mainz, the capital (130,915); Kaiserslautern (88,162); Trier (85,192); Koblenz (97,493); Worms (59,646); and Pirmasens (53,422). In 1955 11.6% of the population came either from the German lands east of the Oder-Neisse line or from eastern Germany and east Berlin, a proportion considerably lower than that for the Federal Republic as a whole (22.2%). In 1950 57.7% of the people were Roman Catholic and 40.8% Protestant. According to the constitution primary schools in Rhineland-Palatinate are confessional (or at least have confessional religious instruction) as are the five teachers' training colleges. Establishments for higher education include the Johann Gutenberg university at Mainz and a technical college for administration in Speyer.

Agriculture and Industry. — Forestry and farming are the staple occupations of the people. Much of the farming is arable, grain crops in particular (wheat, rye and oats) being grown, as well as potatoes, sugar beets, etc. The warmth of the river valleys allows tobacco to be grown; but far more important are the vineyards along the Rhine, and its west-bank tributaries Mosel, Nahe and the smaller rivers. In 1955 Rhineland-Palatinate had 69% of the whole area devoted to vines in the Federal Republic, and by far the greatest wine production per acre. Although it is primarily agricultural, industry plays no inconsiderable part in the economy. Ludwigshafen is a large internal port, and is especially important for chemical manufacture, as well as for metals, paper, etc. Among other industries are Pirmasens' boots and shoes and Kaiserslautern's sewing machines and bicycles. Tourists also bring in much revenue.

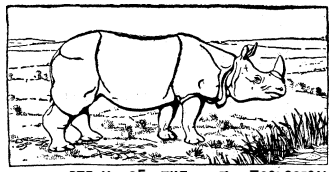
RHINE PROVINCE or RHINELAND: see RHINELAND-PALATINATE.

RHINOCEROS, the name for such perissodactyle mammals (see PERISSODACTYLA) as bear one or two median horns on the head, and for their extinct relatives. Rhinoceroses are large, massively built animals, with little intelligence and a bad temper. The horns, which are composed of modified hairs, are borne on the nose and are used as weapons. The animals are dull of sight, but their hearing and scent are very acute. They are vegetarian in diet and largely nocturnal. The skin is very thick and tough. In the Miocene and Pliocene, rhinoceroses inhabited both eastern and western hemispheres, but they are now restricted to tropical Africa and Asia. An interesting feature is that the horn appears to have been independently evolved in several separate groups of rhinoceroses. Living forms fall into four genera: (1) With a single nasal horn and the thick skin raised into folds on the shoulders and thighs. There are two species. The Indian rhinoceros (*Rhinoceros unicornis*), standing 5–5¾ ft. high at the shoulder, with a horn 1 ft. in length, is now confined to the Assam plain. The Javan rhinoceros (R. sondaicus) is smaller and in the female the horn is often absent. It inhabits Bengal, Burma, the Malay peninsula, Java, Sumatra and Borneo. It prefers hilly forests. (2) With a large nasal and a small frontal horn and the skin not thrown into folds. The only species is the Sumatran rhinoceros (Rhinoceros or Dicerorhinus *sumatrensis*), range as in the Javan species, except it does not extend into Java. It reaches a height of 4½ ft. and inhabits hilly forests. A form with hairy ears and skin is regarded as a local race. (3) With two horns, no skin folds and no lower incisors. This group is confined to Africa and comprises two species. The black rhinoceros (*Diceros bicornis*) is the smaller, weighing just over a ton, with a pointed, prehensile upper lip. It inhabits Africa south of Abyssinia, though in reduced and diminishing numbers, dwelling in the wooded, watered districts. (4) The white rhinoceros (*Ceratotherium simus*) is the largest living land mammal except the elephant and feeds largely on grass. It now inhabits only a reserve in Zululand and the Lado enclave on the Upper Nile. It may stand 5 ft. 8 in. at the shoulder and measure 15 ft. in length, but is very swift of foot. The flesh is said to be excellent to eat, especially in the autumn and winter.



BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

GREAT INDIAN RHINOCEROS (RHINOCEROS UNICORNIS)

The woolly rhinoceros (R. *antiquitatis*), which inhabited Europe, became extinct during the glacial epoch.

RHINTHON (c. 323–285 B.C.), Greek dramatist, son of a potter. He was probably a native of Syracuse and afterward settled at Tarentum. He invented the hilarotragoedia, a bur-

lesque of tragic subjects. He was the author of 38 plays, of which only a few titles (Amphitryon, Heracles, Orestes) and lines have been preserved chiefly by the grammarians, as illustrating dialectic Tarentine forms. The metre is iambic, in which the greatest licence is allowed. The *Amphitruo* of Plautus, although probably imitated from a different writer (Archippus of the Middle Comedy), may be taken as a specimen of the manner in which such subjects were treated. There is no doubt that the hilarotragoedia exercised considerable influence on Latin comedy, the *Rhinthonica* (*i.e.*, fabula) being mentioned by various authorities among other kinds of drama known to the Romans. Scenes from these travesties are probably represented in certain vase paintings from lower Italy, for which see H. Heydemann, "Die Phlyakendarstellungen auf bemalten Vasen," in Jahrbuch des *archäo*logischen *Instituts*, i (1886).

See fragments in monograph by E. Volker (1887); E. Sommerbrodt, *De Phlyacographia Graecorum* (1875); W. Christ, Geschichte der *griechischen* Literatur (1898).

RHIZOPODA, the name given by Felix Dujardin (pro *parte*, 1838) to a group of Sarcodine Protozoa. They are distinguished by their pseudopods, simple or branched, passing by nide bases into the general surface, never fine radial nor fusing into complex networks; skeleton absent or a simple shell ("test," "theca"), never (?) a calcareous shell, nor represented by a siliceous network, nor spicules. Reproduction is by binary fission; by division or abstriction of buds after the body has become multinucleate; or by the resolution of the body into numerous uninucleate zoospores (amoebulae or flagellulae) which may conjugate as gametes; plasmodium formation unknown; encystment (in "resting cysts" or "hypnocysts") common. Without a knowledge of the history it is impossible to distinguish a naked Lobose from the Amoebula (pseudopodiospore) of a Myxomycete or Proteomyxan. As to the name, Dujardin included the thecate Lobosa, the Filosa and the Reticularia or Foraminifera. For further particulars see PROTOZOA.

RHODE ISLAND, popularly known as "Little Rhody." is a North Atlantic state of the United States, belonging to the New England group. It is bounded north and east by Massachusetts, south by the Atlantic ocean and west by Connecticut. Rhode Island, official name "the State of Rhode Island and Providence Plantations" (see History, below), is the smallest state in the union, having an extreme length. north and south, of 44 mi.. an extreme width, east and west, of 35 mi. and a total area of 1.214 sq.mi., of which 156 sq.mi. are inland water area. The capital is at Providence (*q.v.*). Rhode Island was one of the original 13 states. Its state song is "Rhode Island" and the official state bird is the Rhode Island Red. The origin of the name has been variously traced to a corruption of the Dutch words for "red island," a name supposedly given to the island in Narragansett bay by the Dutch navigator Adriaen Block, and to the Florentine Giovanni da Verrazano, who is said to have called it after the Island of Rhodes.

PHYSICAL GEOGRAPHY

Physical Features. — Rhode Island lies between approximately 41° 9' and 42° 3' N. and 71° 8' and 71° 53' W. The region of which it is a part was at one time worn down to a gently rolling plain near sea level, but has since been uplifted and somewhat dissected by stream action. As a result the topography is characterized by low rounded hills but is nowhere mountainous. Since the uplift and stream dissection a slight depression has allowed the sea to invade the lower portions of the river valleys, forming bays such as Narragansett bay, Providence "river" and Sakonnet "river." Glaciation has disturbed the river systems.

The mean elevation for the entire state is 200 ft., the lowest portions occurring along the ocean and the shore of Narragansett bay. The upper bay region is composed of gently rolling lands, but about two-thirds of the state consists of higher ground nhich begins abruptly just west of Providence and rises toward the northwest where Jerimoth hill, 812 ft., is the highest point within the state. The coast line, including the shores of the bays and islands, is extensive; its western portion is only slightly indented, but its eastern portion is deeply indented by Narragansett bay, a body of water varying in width from 3 to 12 mi. and extending inland for about 28 mi. Within Narragansett bay are numerous islands characteristic of an area that has suffered comparatively recent depression, the largest being Rhode Island (or Aquidneck), Conanicut Island and Prudence Island. Of these the most important is Rhode Island, 15 mi. long and 3 mi. wide. Lying about 10 mi. off the coast and south of the central part of the state is Block Island.

The rivers are short and of no great volume, but they flow swiftly and are useful in supplying water for industry. The Providence river is really an arm of Narragansett bay, into which flow the waters of the Pawtuxet and Blackstone rivers. The latter stream has a fall of about 50 ft. at Pawtucket, and the Pawtuxet also has a number of falls along its course. Mount Hope bay is a northeastern arm of Narragansett bay and is also the estuary of the Taunton river. The Sakonnet river is a long bay separating Aquidneck or Rhode Island from the mainland on the east. The Pawcatuck river forms part of the boundary between Rhode Island and Connecticut.

Climate. — Rhode Island has a more moderate climate than that of the northern sections of New England. There are no great extremes of either heat or cold. Narragansett Pier has a mean annual temperature of 50° F., a mean summer temperature (for June, July and August) of 68° and a mean winter temperature (for December, January and February) of 30°. The mean annual temperature at Providence is 50.5°; the mean for the summer, 70.1°; and for the winter, 30.2' ; while the highest and lowest temperatures ever recorded are respectively 102° and −17°. The mean annual precipitation is about 38.68 in.

Soil.—As in most of New England, the soil in Rhode Island is for the most part sterile. Its quality improves, generally, from west to east. Almost half of the state is covered by an acidic sandy loam derived from the weathering of the underground rocks. Because of its rocky subsoil it drains very thoroughly, and in times of drought may become too dry even for pasturage. Very little of it has been cultivated and for the most part it supports a growth of stunted woodland. The best soil is found farther east on the rolling hills of the Narragansett basin: a firm, brown glacial type. Near Warwick and across the bay in East Providence a sandy loam, while loose and porous, occurs for the most part at low enough elevations to ensure sufficient moisture, and it has proved well suited to market gardening. About 8% of the state is covered by either a thin, coarse sandy soil supporting scrubby pine and grass or by swamp.

Vegetation. — The flora is surprisingly rich. About 60 species of trees are native to the state, among them ash, oak, birch, hickory, poplar, pine and maple. Where the long inlet of Narragansett bay moderates the climate more southerly species such as the tulip tree flourish, while northern types such as the paper birch and sugar maple are found in the northwest. The sand plains, rocks and tidal pools along the coast support a wide variety of seaweeds, ferns and mosses. The swamps have a particularly interesting flora, which includes the insectivorous sundew and pitcher plant and several kinds of orchids. Some of the most beautiful wildflowers occur in the wooded areas — among them violet, trillium, columbine, rhododendron and mountain laurel — and the meadows are often covered with daisies and wild carrots and, in the autumn, goldenrods and asters. Wild blackberries are abundant on the sandy soil in the western part of the state.

Animal **Life.--A** maritime state with a long and, for much of its length, protected coast line, Rhode Island boasts an extensive representation of marine invertebrates, among them the sea anemone, sea cucumber, jellyfish, several types of marine worms, crustaceans such as the barnacle, lobster and crab, and the squid, clam and oyster. The quahog, a highly-prized hard-shelled clam, is protected by law. Both the coastal waters and the inland ponds and streams contain a variety of fish. Cod, perch and alewives are common and sea bass, bluefish and swordfish are often caught off Block Island. Inland species include perch, bass, pickerel and trout. There are many types of turtles, salamanders and frogs and nearly 20 species of snakes. Rhode Island lies at the edge of the

migration route for a number of types of shore birds. In the uncultivated western portions of the state the blue jay, ruffed grouse, barred and screech owls live the year around, while the catbird, flicker and robin are common during the summer. The osprey is frequently seen in the vicinity of Touisset, and pheasants are abundant. especially in Newport county. A number of small mammals inhabit the woodlands, including foxes, rabbits, woodchucks and skunks.

State Parks and Historic Sites.—Approximately 17 state parks and beaches and 28 roadside groves are maintained by the division of parks and recreation of the state department of public works. Recreation facilities, both public and private, are liberally provided in the state, and Newport and Narragansett Pier in particular have long been noted as summer resorts.

Rhode Island's long and colourful history has left its cities and towns dotted mith monuments, buildings, ancient graveyards and other points of interest which vividly recall the past. The home of Gen. Nathanael Greene of American Revolution fame is located in Coventry and the birthplace of the painter Gilbert Stuart in North Kingstown. Bishop George Berkeley, the philosopher, lived at Whitehall in Middletown during his stay in the colony. The village of Wickford contains a number of well-preserved 18th-century houses, among them the Stephen Cooper house (1728) and the John Updike house(1 745). Other historic sites include the grave of Elizabeth Alden, daughter of John Alden and Priscilla Mullins, in Little Compton and Acote's hill in Gloucester which figured in Dorr's rebellion. *See* also NEWPORT; PROVIDENCE: *Historic Sites.*

HISTORY

Rhode Island was founded by refugees from Massachusetts who went there in search of religious and political freedom. The first settlements were made at Providence by Roger Williams (*q.v.*) in June 1636 and at Portsmouth on the island of Aquidneck by the Antinomians William Coddington (1601–78), John Clarke (1609–76) and Anne Hutchinson (1591-1643) in March–April 1638. Becoming dissatisfied with conditions at Portsmouth, Coddington and Clarke moved a few miles farther south in April 1639 and established a settlement at Newport. In a similar manner Warwick was founded in Jan. 1643 by seceders from Providence under the leadership of Samuel Gorton. The union of Portsmouth and Newport, March 12, 1640, mas followed by the consolidation of all four settlements, May 19, 1647, under a patent of March 14, 1644, issued by tht parliamentary board of commissioners for plantations. The particularistic sentiment was still strong, however, and in 1651 the union split into two confederations: one including the mainland towns, Providence and Warwick; and the other the island towns, Portsmouth and Newport. A reunion was effected in 1654 by Roger Williams and a charter secured from Charles II on July 8, 1663.

In the patent of 1644 the entire colony was called Providence Plantations. On March 13, 1644, the Portsmouth-Newport general court changed the name of the island from Aquidneck to the Isle of Rhodes or Rhode Island. The official designation for the province as a whole in the charter of 1663, therefore, was Rhode Island and Providence Plantations. The charter was suspended at the beginning of Sir Edmund Andros' regime in 1686, but was restored again after the revolution of 1689. The closing years of the 17th century were characterized by a gradual transition from agricultural to commercial activities. Newport became a centre of piracy, privateering and smuggling as well as legitimate commerce.

The passage of the Sugar act, April 5, 1764, and the steps taken by the British government to enforce the Navigation acts seriously affected Rhode Island's trade. On June 9, 1772, the "Gaspee," a British vessel sent to enforce the acts of trade and navigation, ran aground in Narragansett bay and was burned to the water's edge by a party of men from Providence. In 1776 Gen. William Howe sent a detachment of his army under Gen. Henry Clinton to seize Newport as a base of operations for reducing New England, and the city was occupied by the British on Dec. 8. To capture this British garrison, later increased to 6,000 men, a combined operation of about 10,000 men (mostly New England militia) under Maj. Gen. John Sullivan and a French fleet carrying 4,000 French regulars under Count d'Estaing, was planned in the summer of 1778. On Aug. 9 Sullivan crossed to the north end of the island of Rhode Island, but as the French were disembarking on Conanicut Island, Lord Howe arrived with the British fleet. D'Estaing hastily re-embarked his troops and sailed out to meet Howe. After two days of maneuvering the hostile fleets were dispersed by a severe storm. On the 20th D'Estaing returned to the port mith his fleet badly crippled, only to announce that he should sail to Boston to refit. The American officers protested in vain, and on the 30th the Americans, learning of the approach of Lord Howe's fleet with 5,000 troops under Clinton, decided to abandon the island. The British evacuated Newport, Oct. 25, 1779, and the French fleet was stationed there in 1780-81.

Rhode Island's association with the other colonies, particularly its New England neighbours, was characterized by individualistic tendencies. It had been one of the first colonies to advocate and to put into practice religious freedom. Throughout its early history, not only did it refuse to give up its independence by joining Massachusetts but, as noted, there was even some difficulty in keeping the colony itself united. Under the Articles of Confederation it was principally Rhode Island that defeated the proposal to authorize congress to levy an import duty of 5% to meet the debts of the central government. When the Constitutional Convention met in Philadelphia in 1787 the Rhode Island farmers and merchants, fearing that a more centralized system of government would interfere with their local privileges, 'refused to send delegates. Not until the federal government threatened to sever commercial relations between the United States and Rhode Island did the latter, in May 1790, ratify the new constitution, and then by only two votes.

At the end of the American Revolution, instead of providing itself with a new state constitution, Rhode Island continued to be governed under the charter of 1663. This charter and the franchise law of 1724 had established substantial equality of representation among the towns and also restricted the suffrage to freeholders and their eldest male heirs. Drastic changes were beginning to take place in the state's economy and population, however. Agriculture and commerce declined in relative importance as Rhode Island became one of the most completely industrialized among the states. The population, which had been increasing since 1800, began an accelerated expansion about 1840 and quadrupled between then and 1900. The bulk of this increase, which continued into the 20th century, was accounted for by successive waves of immigration, beginning with the Irish in the second quarter of the 19th century. The French Canadians arrived shortly after the Irish; the Italians around 1900; and numerous other national groups in the next two decades. In addition, the population shifted from approximately 20% urban and 80% rural in 1800 to nearly 90% urban in 1900.

Demands for a more equitable representation of the urban communities in the legislature and for an extension of the suffrage to nonproperty owners precipitated the first of a long series of struggles for constitutional reform, Dorr's rebellion of 1841–42. About 1840 Thomas W. Dorr (1805–54), a young Providence lawyer, began a systematic campaign for reform. A convention summoned without any authority from the legislature and elected on the principle of universal manhood suffrage met at Providence from Oct. 4 to Nov. 18, 1841, and drafted a document which came to be known as the People's constitution. A second convention met on the call of the legislature in Feb. 1842 and adopted the Freeman's constitution. On being submitted to popular vote (Dec. 27, 28 and 29, 1841) the former was ratified by a large majority; the latter was rejected (March 21, 22 and 23, 1842) by 676 votes. At an election held on April 18, 1842, Dorr was chosen governor. The supreme court of the state and Pres. John Tyler both refused to recognize the validity of the People's constitution, whereupon Dorr and a few of his more zealous adherents decided to organize a rebellion. They were easily repulsed in an attack upon the Providence town arsenal. Dorr, after a brief period of exile in Connecticut, was convicted of high treason, April 26, 1844, and sentenced to life imprisonment. He was released by act of the assembly in June 1845 and restored to the rights and privileges of citizenship in May 1851.

The Freeman's constitution, modified by another convention held at Newport and East Greenwich from Sept. 12 to Nov. 5, 1842, was finally adopted by popular vote, Nov. 21–23, 1842. Only a partial concession was made to the demand for reform. The suffrage was extended to nonfreeholders, but only to those of American birth, so that naturalized citizens could vote only if they held property. The charter legislature was replaced by one comprising a senate, to which each town was to send one representative, and a house of representatives of 72 members, apportioned by population. In the lower house, however, each town was to have at least one representative and no city or town more than one-sixth of the total, and the small towns were left in a dominant position.

After the American Civil War agitation for further reform was renewed. Under the leadership of Charles E. Gorman, himself naturalized, a prolonged campaign was waged to secure the same voting rights for naturalized as for native-born citizens. The constitution was finally amended in 1888 to eliminate all property restrictions but one: only property owners were allowed to vote for members of city councils. This limitation was finally removed in 1928.

It was not until 1909 that further change was made in the apportionment of legislative seats. In that year an amendment to the constitution increased the number of seats in the lower house to 100 and raised the allowable limit for any one city or town to one-quarter. The status of the senate was unchanged. Providence illustrates the inequities that remained in representation. With well over one-third of the state's population in 1910 and 1920, the city was entitled to only one-quarter of the house seats and to one seat in the senate. In 1928 a further change in legislative apportionment was made as a result of which Providence was able to return five senators and Pawtucket two, with the other cities and towns continuing to send one each.

Throughout most of its history Rhode Island has tended to cast its presidential vote for the more conservative party—the Federalists, then the Whigs and, folloning the American Civil War, the Republicans, until Alfred E. Smith carried the state in 1928. The Democrats continued to receive the state's electoral votes from 1932 through 1948. Rhode Island returned temporarily to the Republican fold in the presidential elections of 1952 and 1956, but voted Democratic again in 1960. National Republican allegiance was matched in its congressional representation as well as on the state level from the post-Civil War period until 1932 when it became predominantly Democratic.

An important result of Rhode Island's adherence first to the Republican party and then to the Democratic during their periods of national ascendancy was the prominence thus given to Rhode Island's representation in the councils of the nation—a prominence at times far out of proportion to its size and population. These long periods of one-party dominance made possible the building up of seniority in congress toward positions of national leadership. U.S. Sen. Nelson W. Aldrich (served 1881–1911), backed by a highly-disciplined Republican state organization under his lieutenant, the "blind boss" Gen. Charles R. Brayton, was one of the foremost architects of American tariff policy. Aldrich was so influential nationally that he came to be referred to as the "general manager of the United States." Democratic U.S. Sen. Theodore Francis Green. who was first elected in 1936 and served continuously until his retirement in 1960, rose to the chairmanship of the powerful senate foreign relations committee.

GOVERNMENT

The Freeman's constitution of 1842, frequently amended, remains the basic law of Rhode Island. Amendments must be passed by a majority of the legislature at two sessions and ratified by three-fifths of the voters.

Throughout much of the state's history the legislature possessed most of the governmental power. The governor did not even have the veto until 1909, and until 1935 he had little control over the administrative agencies of the state government or over appointments to these agencies. The members of the state supreme court were (and remained) removable by vote of the legislature. In 1935 Democratic Governor Green, acting with the first Democratic majority in both houses of the legislature in many years, brought about a complete reorganization of the state administration. Administrative control was centralized in the hands of the governor through the consolidation of approximately 80 independent boards and commissions into 11 departments whose heads were appointed by him. This reform, for the first time, made the governorship a full-time position and gave the governor, in effect, the major responsibility for state policy.

The executive officers of the state government are the governor, lieutenant governor, secretary of state, attorney general and general treasurer, each elected for two-year terms in even-numbered years. Each of the latter three is in charge of the department of state government corresponding to his title. Ten additional departments are responsible to the governor: executive, administration, education, social welfare, labour, public works, agriculture and conservation, health, business regulation and employment security. Two of the original 11 set up in 1935, finance and civil service, were combined in 1951 into the department of administration. The object of this merger was to bring together in one agency all the services needed to operate the other agencies of government, while at the same time keeping the total structure under the close control of the governor.

The legislative branch consists of a two-house general assembly made up of a 44-member senate, presided over by the lieutenant governor, and a 100-member house of representatives. The judicial branch is headed by a supreme court consisting of a chief justice and four associate justices, all elected by the legislature; a superior court with appellate jurisdiction and original jurisdiction in certain cases, consisting of a presiding justice and ten associate justices appointed by the governor with the consent of the senate; and 12 district courts.

Government at the local level is carried on by the 8 cities—Providence, Pawtucket, Cranston, Warwick, Woonsocket, East Providence. Newport and Central Falls (*qq.v.*)—and 31 towns into which the state is divided. The state is also divided into five counties, but the Rhode Island county is not a governmental unit as such, and it is the cities and towns which provide the usual services that are the normal responsibility of local government.

Finance.— Property taxes represent the primary source of revenue for the cities and towns. The major sources of income to the state government, in addition to federal grants, are a state sales tax and taxes on motor fuel, cigarettes and corporations. The post-World War II period saw rapidly increasing state expenditures and, hence, corresponding demands for more revenue. State expenditures almost trebled in the post-mid-century decade.

POPULATION

The population of Rhode Island in 1790 was 68,825; in 1840, 108,830; in 1880, 276,531; in 1910, 542,610; in 1950, 791,896; and in 1960, 859,488. The population per square mile in 1960 was 708 as compared with 652.3 in 1950 and with 49.6 for the U.S. in 1960.

The two most important long-term trends in the state's population have been rapid urbanization and the great impact of immigration. The urban area of the state dropped from 91.6% in 1940 to 84.3% in 1950, partly because the census definition was changed to include the suburban fringe but excluded the outlying portions of several towns formerly classed as urban under a special rule. In 1960 the urban population was 752,054, or 87.5% of the total. The state contains a portion of the Providence-Pawtucket standard metropolitan statistical area. The area within Rhode Island had a population of 733,455 or 85.3% of the total population of the state in 1960.

As elsewhere in the United States, the post-World War II years in Rhode Island brought a movement to the suburbs. This meant a flow of population out of densely settled cities such as Providence and Central Falls to residential cities and towns nearer the fringe of the urbanized areas such as Cranston, Warwick and Barrington. For example, the population of Providence fell from 253,504 in 1940 to 248,674 in 1950 and 207,498 in 1960. Warwick, on the other hand, went from 28,757 in 1940 to 43,028 in 1950 and 68,504 in 1960.

The foreign-born white population in 1880 was 73,831, or 26.7% of the total. The number of foreign born in the population reached its peak in 1910 when 178,025, or 32.8% of the total, were listed in this category. Both the number and percentage decreased from then on. In 1950, out of a total population of 791,896 the state had 538.124 inhabitants 21 years of age and older. Of these latter 425,657 were native-born citizens, 88,352 naturalized citizens and 17,810 were aliens (leaving 6,305 unaccounted for). The total population in 1950 comprised 663,751 native white, 113,264 foreign-born white and 14,881 nonwhite, practically all Negro. Of the foreign-born white population, 24,380 were born in Italy, 19,163 were French Canadian and 14.273 were born in England or Wales, with smaller groups of Irish, non-French Canadian, Portuguese, Russian, Polish and other backgrounds.

There were 97.3 males per 100 females in 1950; 8.9% of the population was 65 years of age and older; and 56% of the population 14 years of age and older was in the labour force. Of the total number of employed males, 2.1% was engaged in agriculture, 8.2% in construction, 41.3% in manufacturing and 25.8% in transportation and trade.

EDUCATION

The public-school system was established in 1800, abolished in 1803 and re-established in 1828. A state board of education (provided for in a 1951 act of the general assembly) exercises policy-making power over educational programs in the state and controls the state department of education. A commissioner of education is responsible for the administration of the department's functions under the jurisdiction of the board. Each city and town has a school committee elected by the people and independent of the town or city council.. State contributions to the support of public education in the various cities and towns reached about $8,500,000 annually in the early 1960s.

School attendance is compulsory between the ages of 7 and 16. The total public-school enrollment was approximately 125,000 in the early 1960s; about 46,000 were enrolled in private schools.

The institutions of higher education supported by the state are the University of Rhode Island at Kingston and Rhode Island College at Providence. The University of Rhode Island. a land-grant institution, was chartered in 1892 as Rhode Island College of Agriculture and Mechanic Arts. The name was changed to Rhode Island State college in 1909 and the institution became a university in 1951. It includes colleges of arts and sciences, agriculture, business administration, engineering, home economics and pharmacy and a school of nursing. The division of university extension is located at Providence. The university maintains a computation laboratory and the Narragansett marine laboratory. There is a student-operated radio station which broadcasts to the campus. A number of institutes and workshops are offered during the summer. including, among other subjects, reading and language arts, church music and elementary-school science. Also a part of the summer program is a high-school music camp. In the early 1960s the enrollment totaled approximately 2,800 full- and part-time students and there were almost 300 faculty members.

The Rhode Island College of Education mas established in 1920 as the successor of the Rhode Island Normal school which opened in 1854; the name was changed to Rhode Island college in 1960. The oldest institution of higher learning in the state is Brown university at Providence, chartered in 1764 as Rhode Island college (see also PROVIDENCE). Other colleges in the state are the Rhode Island School of Design (founded 1877; nonsectarian) and Providence college (1917; Roman Catholic), both at Providence, and Salve Regina college (1947, Roman Catholic) at Newport.

HEALTH AND WELFARE

As in most states, these functions are shared by the state and local governments in Rhode Island. Two state administrative departments are involved: the department of health and the department of social welfare. The functions of the former have been grouped under four general headings: (1) the recording of vital statistics, regulation of professions active in the health area, etc.; (2) personal health services, including chronic disease control, maternal and child care and programs for crippled children; (3) local health services, involving co-operation with the communities of the state on health problems; and (4) environmental health services, such as food and drug control and the state laboratories.

The small size of Rhode Island has made possible a high degree of centralization of the institutions relating to welfare services. The department of social welfare's division of curative services operates a state infirmary with about 700–800 beds, a state hospital for mental diseases, the Ladd school for mentally-retarded children, the Zambarano memorial hospital for tuberculosis and other related health and welfare services. The division of correctional services maintains the male and female correctional institutions, a training school for boys and one for girls. The division of community services administers programs for old-age assistance and aid to the disabled, to dependent children and the blind and general public assistance, which is handled co-operatively with local governments. The combined health and welfare services of the two departments discussed above account for one-quarter to one-third of the state's total annual expenditures.

THE ECONOMY

Agriculture. — Rhode Island ranks low in the list of agricultural states, chiefly because of its small area, density of population and the nature of its soil. As has been generally true throughout the United States, there has been a decline in farm acreage and number of farms in the state. From 1935 to 1954 acreage declined from 380,000 to 154.674, and number of farms from 4,327 to 2,004. All but a negligible number of farms are owner-operated. Nearly three-quarters of farm income represents the value of livestock and related products — dairy products, eggs, chickens and turkeys—while the remainder represents crop value. The most important crops zre hay, corn, potatoes, five principal commercial vegetables, apples and peaches.

Industry. — Throughoutits history Rhode Island has had to depend on sources of income other than agriculture. Before the gronth of manufacturing this meant reliance chiefly on the activities of merchants and shipowners. In the period preceding the American Revolution molasses was virtually the cornerstone of the colony's economy. Rhode Island ships carried cargoes of locally produced cheese, fish, lumber and similar products to ports in the West Indies and returned laden with molasses which was exchanged for English-manufactured goods or distilled into rum, a valuable item of commerce. Some idea of the significance of rum in the prerevolutionary economy of Rhode Island can be gained from the fact that in 1764 there were more than 30 distilleries in the colony. Some of the product of this early manufacturing enterprise was bartered for slaves in Africa. The acute concern felt in Rhode Island over regulation of colonial commerce by the British government and the state's later reluctance to join the newly established government under the constitution are closely related to this early growth of a commercial and mercantile economy.

The beginnings of manufacturing activity other than shipbuild-

ing and the production of rum may be said to date from the formation of a company at Providence in 1786 to spin cotton. A factory containing a spinning jenny of 28 spindles (the first machine of its kind to be used in the United States) was put into operation the following year. This factory also included a carding machine, and the fly shuttle was first introduced at Providence in 1788. In 1790 a factory was established at Pawtucket equipped with Arkwright machines constructed by Samuel Slater, an immigrant from England. These machines were operated by water power and they marked the beginning of the factory system in Rhode Island. The first power loom used in the United States was set up at Peacedale in 1814. During the rest of the 19th century and into the early 20th century textile manufacturing grew to become the major employer of labour in the state. Another industry which came to occupy an important place in the state's economy was jewelry manufacture, begun in Providence in 1784 and greatly promoted ten years later by Nehemiah Dodge's invention of the process of gold filling. Rhode Island's water power was the only natural resource in the state which contributed to this growth of manufacturing enterprise.

The most important industries in the early 1960s were textiles (including cotton and woolen worsted), metals and machinery, jewelry, rubber, apparel, food and beverage products and optical instruments. Textiles. however, had declined in both absolute and relative importance. For example, just before World War II there were 907,000 cotton spindles in the state; 15 years later this number had fallen to 475.000.

Trends at mid-20th century showed that manufacturing employment had declined steadily while government, construction, trade, finance and services increased. In the face of this trend, the Rhode Island Development council was created by law in 1953 to encourage industrial expansion and a number of financial inducements to new industry were provided.

Mining. — The only minerals of value produced in significant quantities in the state are sand and gravel, stone and graphite. Sand and gravel accounted for almost three-fourths of the value of mineral products.

Fisheries. — Whaling was early an established industry in Rhode Island. As late as 1846 about 50 whaling vessels sailed annually from Rhode Island ports; but by the close of the century the industry had become practically extinct. In the second half of the 20th century Rhode Island ranked third among the New England states in number of persons engaged, investment and yield of its fisheries. Almost half of the total value of fishery products was accounted for by shellfish.

Trade and Finance. — As already indicated, prior to the growth of industry, Rhode Island's economy was heavily dependent on trade and commerce with neighbouring states and overseas. Until the American Revolution, Newport was the primary centre of this activity. The British occupation of the city during the war, however. spelled the end of Newport's supremacy and Providence, at the head of Narragansett bay, rapidly overtook the former and has remained the commercial centre of the state and adjacent areas. During the early 19th century patterns of commerce changed. Instead of being carried on for its own sake, shipping and commercial activity became adjuncts to the burgeoning factory economy of the state. Cargoes landed at Providence were now mainly coal, cotton, lumber, cobblestones and other materials consumed directly or indirectly in manufacturing. Coal is an example: as steam supplanted water power in the mills, coal imports grew rapidly. Some 200,000 tons were landed at Providence in 1856, and by 1878 the total approached 1,000,000 tons. In the 20th century petroleum products replaced coal as a major item of seaborne commerce.

Trade in the more localized sense grew along with the population and wealth of the state. By the beginning of the 19th century wholesale and retail enterprise had become differentiated in Providence, whereas in an earlier and simpler era no such distinction was made. Retail establishments became more elaborate and numerous. The Arcade in Providence, built in 1828 to house shops fronting on a common covered thoroughfare typified this development, and is still in use by Providence merchants. In the 20th century, in Rhode Island as elsewhere, the small shop was replaced by the chain store, the department store and the suburban shopping centre, all of which owe their existence in large part to the development of more elaborate modes of organization and to new merchandising and packaging techniques.

The year 1791, which saw the chartering of the Providence bank, was a major landmark in the history of banking in the state. Until that date the state had no such institutions largely because the state government itself, through its issue of paper currency, performed many of the functions of a private banking system. Once the federal constitution, which prohibited the states from issuing paper money, had been ratified banks became essential. About 12 or more additional banks had been chartered by 1810, and 43 filed reports in 1825. In 1856–57, 98 reported, the largest number in Rhode Island history. Bank services during the 19th century were provided by numerous small local banks and failures were not uncommon. The first savings banks in the state came into existence in 1819. Around the turn of the 20th century a trend toward consolidation of many of the small banks into fewer large institutions became pronounced. This trend had progressed to the point, by mid-20th century, that the state had less than ten savings banks and only a slightly larger number of commercial banks. The latter in particular developed an ever-expanding system of branches which take the place, as it were. of the numerous independent local institutions.

Transportation. — Because of its small size and the general decline of rail transportation in relative importance by mid-20th century. Rhode Island's highway network represents by far the most important part of its transportation system. While rail mileage in the state declined from 211 in 1920 to 181 at mid-century, total highway mileage exceeded 4,000. Of this total about 1,000 mi. were unimproved and gravel-surfaced, and the remainder hard-surfaced. Approximately 20% of the over-all total comprises the state highway system, the remainder being under the jurisdiction of the cities and towns. State expenditures for highway construction and reconstruction, including federal grants, more than doubled between 1955–57 and continued to rise thereafter. Included in the highway-building program is a system of limited-access divided highways linking with similar road systems in neighbouring Connecticut and Massachusetts, plus expressways to route traffic through the congested Providence metropolitan area.

Most of the state's water-borne commerce passes through the port of Providence. By far the largest proportion of the tonnage handled there is accounted for by petroleum products. Foreign commerce amounted to more than one-sixth of the total, the remainder comprising coastwise and internal shipments.

Communications. — The first printing press was set up in Rhode Island in 1727 by James Franklin, brother of Benjamin Franklin. He published the first newspaper in the colony, the *Rhode Island Gazette,* in 1732. Other newspapers were started in the 18th century, including the *Newport Mercury* by James Franklin, Jr., and the first foreign-language paper printed in the state, which appeared in 1780, issued by the French who were in Newport with Count Jean Baptiste Rochambeau. The most famous and influential newspaper has long been the *Providence Journal,* which was started as a semiweekly in 1820 and appeared daily from 1829. The owners of the *Journal* began publishing the *Evening Bulletin* in 1863 in response to the demand for news of the American Civil War, and started the *Sunday Journal* in 1885. In the second half of the 20th century there were about two dozen newspapers published in the state: the *Journal* and *Bulletin,* which have a state-wide readership; one-half dozen other dailies in various local communities; two semiweeklies; and the rest weeklies.

Among the radio stations in operation, the oldest began broadcasting in June 1922, two others were established in the 1920s and the remaining dozen or so date from after World War II. This total includes both AM and FM outlets, with some stations combining both. A television channel began transmitting programs from Providence in 1949 and a second in 1955.

BIBLIOGRAPHY.—A recent book dealing with the history, economy, government and other aspects of the state is Paul F. Gleeson, Rhode *Island, the Development of a Democracy* (1957), which contains

numerous bibliographical references. Duane Lockard, *New England State Politics* (1959), has chapters on Rhode Island. For general physical description *see:* N. S. Shaler, J. B. Woodworth and A F. (E. E. Co.)

RHODES, CECIL JOHN (1853–1902), British-born South African statesman and financier, was one of the great empire builders of the late 19th century. It was from Rhodes that the territories of Rhodesia took their name, and it was mainly because of his efforts that Bechuanaland and the area of the present Federation of Rhodesia and Nyasaland came under British dominion.

Rhodes was born at Bishop's Stortford. Hertfordshire, Eng., on July 5. 1853, the fifth son of the vicar there. Rev. F. W. Rhodes, and was educated at the parish school, where he showed little promise of distinction beyond winning an elocution prize.

In 1869, threatened with tuberculosis, he went to Natal to join his brother Herbert. who was attempting to grow cotton in the Umkomanzi valley. Cecil landed at Durban in Sept. 1870. Their first crop failed, but they made a profit on the second and won a prize at a local agricultural show. In 1871 Cecil was left in charge while Herbert went to prospect at the newly discovered diamond fields in Griqualand West. Cecil joined Herbert at the diggings that year. and they abandoned cotton farming in 1872.

On arriving at Kimberley, Cecil managed Herbert's three claims alone, nhile his brother settled affairs in Natal. He became seriously ill, and nhen Herbert returned they took a long journey to the Transvaal interior. This helped to restore Cecil's health and made a lasting impression on him, giving him his first experience of the interior and helping to mold the future pattern of his life. After their return, Herbert Rhodes left Kimberley (1873).

Oxford.—Cecil Rhodes stayed on to gain a rapid success in the diamond mines, but in spite of his growing influence he spent much of the next few years as an undergraduate at Oxford. He matriculated in 1873, and went to Oriel college. In 1874, however, a severe chill affected his heart and lungs. Given six months to live. he went back to Kimberley. He recovered and returned to Oxford in 1876. keeping terms until 1878 and visiting Kimberley in the long vacation. He took his B.A degree in 1881.

Rhodes always retained an affectionate respect for Oxford, which he showed by founding the Rhodes scholarships in his final will. Although he was not a conventional hard-working student, what he read he thought over deeply. He became convinced that the Anglo-Saxon race was the highest point of evolution in fulfillment of a divine plan and that his aim must be to help secure its predominance. Hence his preoccupation with British expansion, particularly in Africa and with making money, not for his own comfort or security, but for power, since he felt big ideas mere useless without money to carry them out.

He wrote his first will in 1877, making the colonial secretary a trustee, and ieaving his fortune (yet unmade) to form a society to extend the British empire throughout the world, to recover the United States, to inaugurate colonial representation in the imperial parliament at Westminster and to found a power great enough to make wars impossible. These ideas, modified in his five later wills (the last made in 1899); remained the driving forces of his life.

Kimberley and Diamonds.—Even during his Oxford career, Rhodes had been building his fortune at the diamond mines. He had formed a partnership with C. D. Rudd in 1873. and they had secured a lucrative contract to pump out the flooded Kimberley, Dutoitspan and De Beers mines in 1874. Assisted by Alfred Beit (*q.v.*), a brilliant financier, they began accumulating claims, particularly in De Beers Old Rush, by purchase or amalgamation with other claim holders. In 1880 Rhodes, by then the biggest claim holder in De Beers Old Rush, floated the De Beers Mining company. By 1887 the company was sole owner of the De Beers mines, and his only significant rival for control of the diamond industry was Barney Barnato, the main owner in the Kimberley mine. Rhodes, given a £1,000,000 guarantee by Rothschilds, was victorious in the ensuing race to increase production and buy up shares. Finally Barnato acknowledged defeat in 1888 and sold his Kimberley mine for £5,338,650 to Rhodes, who formed the new De Beers Consolidated Mines, Ltd. Rhodes also acquired the Dutoitspan and Bultfontein mines in 1888 and the newly discovered Wesselton mine in 1891, thus securing control of all South African diamond production—90% of the world total. He had also invested in the newly discovered gold mines of the Transvaal after 1886 and had formed the powerful Gold Fields of South Africa company in 1887. On his insistence the terms of incorporation of both the De Beers and Consolidated Gold Fields companies were framed to allow them to finance northward expansion.

Politics and Northward Expansion.—Meanwhile, Rhodes was advancing his political career. He entered the Cape parliament in 1881 as member for Barkly West, a rural. predominantly Dutch constituency. which he kept throughout his career. He soon gained influence in parliament, and from the first he mas concerned with the north, already dreaming of British expansion to the great lakes. He urged vainly that the imperial government, not the weak Cape government, should be responsible for Basutoland. where war had broken out in 1880. While on a Basutoland commission he met General Gordon, who tried unsuccessfully to persuade Rhodes to leave South Africa and work with him.

His next concern aas Bechuanaland. of vital importance to his aims because it commanded the route to the Zambezi river via the trading road from the Cape to the interior, known as the "Missionaries' road." The establishment of two small republics, settled from the Transvaal, Stellaland and Goshen, threatened to block this route, which had been placed outside the Transvaal boundary by the Pretoria convention (1881). Rhodes succeeded in having a boundary commission to Bechuanaland set up in 1882, and he himself became a member. In Stellaland in 1882 he obtained an offer from a local chief to cede his territory to the Cape colony, and also a petition from Stellalanders for Cape annexation. But he could not persuade the Cape government to take action. despite rumours that the republics might be incorporated with the Transvaal. However, both the imperial and Cape governments saw the force of Rhodes's arguments when Germany estabiished a protectorate over Namaqualand-Damaraland (1883–84), making possible an east-west link betneen the Germans and the Transvaal which could block British expansion from the Cape. The London convention (Feb. 1884) finally excluded Stellaland and Goshen from the Transvaal, and the Cape government promised to help finance a protectorate over Bechuanaland. The imperial government sent a deputy commissioner to the area, the Rev. John Mackenzie who tactlessly offended the Boers in Stellaland and Goshen and ignored their interests Rhodes demanded that the Cape government, not the "imperial factor." should annex southern Bechuanaland and was sent to replace Mackenzie in July 1884. He successfully conciliated the Stellalanders. mainly by guaranteeing their land titles. But he was unable to prevent the Transvaal president, Paul Kruger, from declaring a protectorate over Goshen, enlarged by

systematic raiding. Rhodes could do nothing and returned to the Cape demanding imperial intervention. Both the Cape and the imperial governments protested, Sir Charles Warren was dispatched with an expeditionary force to restore order, and Kruger withdrew. At the conference at Fourteen Streams in Feb. 1885 Rhodes met Kruger for the first time but failed to establish a friendly contact, because the president distrusted Rhodes's aims. Kruger remained the greatest obstacle to Rhodes's dream of federation of south African states within the British empire.

Rhodes soon quarreled with Warren and resigned his post of deputy commissioner in March 1885. But the high commissioner, Sir Hercules Robinson, sympathized with his aims, and in Sept. 1885 southern Bechuanaland became a crown colony, and the north, up to the 22nd parallel, was declared a protectorate. It was not until 1895 that British Bechuanaland was annexed to the Cape, as Rhodes had always wished, and part of the protectorate was handed over to Rhodes's British South Africa company.

In 1887 it seemed that Rhodes's plan for northward expansion might again be jeopardized by the Transvaal, which was negotiating with Lobengula, chief of the Matabele, who controlled Mashonaland and Matabeleland. To secure British influence there, Rhodes persuaded the high commissioner to make a treaty of friendship with Lobengula, who agreed to make treaties with other powers only with British consent (Feb. 1888). But since neither the Cape nor the imperial government was prepared to take over the territory, Rhodes determined to do so himself. His agents obtained the Rudd concession from Lobengula, which gave Rhodes a prospecting monopoly in Mashonaland, rumoured to be rich in gold. This was the basis of the British South Africa company's charter, granted in 1889, after Rhodes had amalgamated with rival concessionaries and had gained widespread support in England.

The company secured control of the area of present-day Southern Rhodesia by 1893, but Rhodes's dream extended beyond the Zambezi. In 1891 he made an agreement with the imperial government whereby a British protectorate was established over Nyasaland (the company contributing £10,000 annually for its upkeep, and Rhodes privately giving a further £10,000), while the rest of central Africa north of the Zambezi to Lake Tanganyika was administered by the company. A foreign office official and friend of Rhodes, Sir Harry Johnston, was both imperial commissioner and the company's administrator in Nyasaland until 1895, when the company assumed direct administration of the area of Northern Rhodesia. Despite Rhodes's efforts to secure Nyasaland also for the company—his strong pressure on Johnston amounted almost to blackmail—the British treasury took full responsibility for Nyasaland after 1894.

Prime Minister.—Rhodes became prime minister of the Cape in 1890. His main support came from J. H. Hofmeyr (*q.v.*) and the Afrikander Bond, which had been won over to Rhodes's schemes of northward expansion under the British flag partly by the Transvaal's refusal to allow a rail link with Johannesburg until 1892, and its high duties on Cape products, partly by Rhodes's express policy of conciliating Afrikaans opinion. Rhodes's frank aim was to unite English and Dutch interests. His premiership was important in the development of local politics and education, the advancement of agriculture and the steps taken in native policy. The Franchise and Ballot act of 1892 restricted the vote to men who could write and earn a labourer's wage, removing the abuses of the tribal African "blanket" vote. In native policy Rhodes wanted to introduce measures of local self-government and education and to replace tribal land tenure by individual tenure. His policy was applied in the controversial Glen Grey act of 1894. He took a personal interest in agriculture, encouraging scientific methods of farming, and developing the railways to link the rural districts to the large towns. Rhodes also increased the Cape Colony's territory by his annexation of Pondoland in 1894.

Until 1895 Rhodes waited patiently for economic pressure and encirclement to force the Transvaal into a South African federation, led from the Cape, but President Kruger was intransigent. In Jan. 1895 he trebled the rates on the Transvaal section of the Cape-Johannesburg railway, and when Cape traders attempted to transport goods by ox wagon instead, he closed the Vaal drifts (fords). This clear infringement of the London convention stimulated protests from Rhodes and the high commissioner, and Kruger climbed down (Oct. 1895). Kruger had also infuriated Rhodes by a speech of Jan. 1895, when he had made very friendly references to Germany. Rhodes was at the height of his power. He was unopposed in the Cape and controlled the De Beers and Consolidated Gold Fields companies, with their huge resources, and the British South Africa company. Frustrated by Kruger, he decided to take a short cut to federation via revolution.

Early in 1895 he became the directing spirit in a conspiracy to overthrow the Transvaal government by an *Uitlander* rising in Johannesburg supported by a force of the British South Africa company led by his friend Dr. L. S. Jameson (*q.v.*). Rhodes arranged that his friend Sir Hercules Robinson should again be sent to South Africa as high commissioner early in 1895. He secured a strip of the Bechuanaland protectorate, ostensibly as a railway, but actually as a base for Jameson's incursion into the Transvaal. On Dec. 29, 1895, Jameson made his famous raid, despite frantic messages urging postponement and assurances that the Johannesburg rising would not take place. The fiasco of the raid was disastrous for Rhodes. Openly implicated in the scheme, he resigned the premiership in Jan. 1896. He lost the support of the Bond, which was horrified that Rhodes had conspired against a friendly neighbour while prime minister. He was censured by the committees of inquiry into the raid held by the Cape parliament (1896) and the British house of commons (1897).

The Matabele rising of March 1896 kept Rhodes from brooding on his downfall. He had temporarily lost his seat on the board of the British South Africa company, but he went to Rhodesia as a private individual and negotiated the peace terms with the Matabele (Aug.–Oct. 1896). He supervised the extension of railways in Rhodesia and arranged for a rail link from Salisbury to Lake Tanganyika to further his scheme for a Cape to Cairo railway. He also concluded arrangements for a Trans-African telegraph to pass through German East Africa to Egypt. He died at Muizenberg, Cape Colony, on March 26, 1902, and was buried in the Matopo hills, near Bulawayo, Southern Rhodesia.

Rhodes was not a great orator, but he was able to express his large ideas in popular phrases, and many of his expressions—"British dominion from the Cape to Cairo," "painting the map red," "the imperial factor," "philanthropy plus 5%"—gained common usage. He combined an almost visionary zeal for British expansion with a frank belief that money was power and that one could always deal rather than quarrel with an opponent. He gained the fervent loyalty and friendship of some of his most outstanding contemporaries, but toward the end of his career he became autocratic, imperious and surrounded by sycophants.

In his will Rhodes founded scholarships to Oxford of £250 per annum (later £300) for students of good literary attainments, a taste for outdoor sports and qualities of leadership from every self-governing British colony, the United States and Germany, so that they might appreciate the advantage of imperial unity and the union of English-speaking peoples.

(M. F. K.)

RHODES, JAMES FORD (1848–1927), U.S. historian, was born in Cleveland, O., on May 1, 1848. He studied at New York university, at The University of Chicago, and at the Collbge de France in 1867–68, and in 1868 served as occasional Paris correspondent to the Chicago Times. He then took a course in metallurgy in the School of Mines, at Berlin, Germany; subsequently he inspected iron and steel works in western Germany and in Great Britain; and in 1870 he joined his father in the iron, steel and coal business in Cleveland, becoming a member of the firm in

1874. He retired from business with an ample fortune in 1885, and after two years devoted to general reading and travel he began his *History of the United States From the Compromise of 1850,* which was published in eight volumes in 1893–1917 (rev. ed., 1920).

In 1909 he published a volume of *Historical Essays;* in 1913, *Lectures on the American Civil War;* in 1917, *History of the Civil War;* and in 1922, *The McKinley and Roosevelt Administration 1897–1909.*

The merit of his work earned him numerous honorary degrees in England and America. He died in Brookline, Mass., on Jan. 22, 1927.

RHODES (RODI), the most easterly island of the Aegean sea, about 10 mi. S. of Cape Alypo in Asia Minor (length about 45 mi. from northeast to, southwest, greatest breadth 22 mi., area 538 sq.mi.).

Rhodes was taken by Italy from the Turks in 1912 and became capital of the administration of the Dodecanese (*q.v.*). Under the Allies' peace treaty with Italy in 1947, the island of Rhodes and the other Dodecanese Islands were awarded to Greece. During World War II representatives of the people of the Dodecanese had formallv declared their union with Greece.

In 1951 the population of the island was 58,946, the population of the town was 23,599.

The island is diversified in its surface and is traversed from north to south by an elevated mountain range, the highest point of which is called Attavyros (It. Attairo; anc. Atabyris or Atabyrium) (3,986 ft.). It commands a view of the elevated coast of Asia Minor toward the north, and of the archipelago, studded with its numerous islands, on the northwest; on the southwest is seen Mt. Ida in Crete, often veiled in clouds, and on the south and southeast the vast expanse of waters which wash the African shore. The rest of the island is occupied in great part by ranges of moderately elevated hills, on which are found extensive woods of ancient pines, planted by the hand of nature. These forests were formerly very thick, but they were subsequently greatly thinned by the Turks, who cut them down and took no care to plant others in their place.

Beneath these hills the surface of the island falls lower, and several hills in the form of amphitheatres extend their bases as far as the sea. forming a series of beautiful pictures.

Rhodes has been famed at all times for its delightful climate. The wind blows from the west, often with violence, for nine months in the year; at other times it blows from the north, moderating the summer heat, except during July and August when hot winds blow from the mainland.

Rhodes, in addition to its fine climate, is blessed with a fertile soil and produces a variety of the finest fruits and vegetables. Around the villages are extensive cultivated fields and orchards containing fig, pomegranate and orange trees. On the sloping hills, carob trees and others, both useful and agreeable. grow abundantly; the vine also holds its place and produces a species of wine which was highly valued by the ancients, though it seems to have degenerated greatly in modern times; a strong red wine is still exported. The valleys afford rich pastures, and the plains produce a wide variety of grain.

Under Turkish rule Rhodes was a distributing centre for European manufactures to the neighbouring islands and mainland, receiving cattle, foodstuffs and other produce in return. Under Italian rule its commercial position changed and became uncertain. Italian, French and Greek steamships call frequently, and tourists became more numerous.

The only large town is the capital, Rhodes, at the northeast extremity, rising from the sea in the form of an amphitheatre, surrounded with walls and towers and defended by a moated castle. These are the work of the Knights of St. John, almost unimpaired. But few traces remain of the splendour of the ancient city, with its regular streets, well-ordered plan and numerous public buildings.

The modern city of Rhodes is in general the work of the Knights of St. John and has a mediaeval aspect. The picturesque fortifications by which the city is surrounded remain as they were in the 15th century, almost without alteration. Principal buildings are the church of St. John, which became the principal mosque; the hospital, transformed into a museum; the palace of the grand master; and the senate house. The picturesque Street of the Knights is perfectly straight, lined by old houses on which remain armorial bearings of members of the order, including those of royal and noble houses of Europe.

Relics of classical antiquity, inscribed altars, bases of statues and architectural fragments are found in courtyards and gardens in the suburbs, the whole of which were within the limit of the ancient city.

The foundations of the moles between the harbours are also of Hellenic works, though the superstructures were erected by the knights.

Rhodes has two harbours. The lesser lies toward the east, and admits cargo steamers, which can also anchor outside in fair weather. The larger is silted and only admits small craft. The two harbours are separated by a mole and at the eastern entrance is the fort of St. Elmo, with a lighthouse.

HISTORY

Archaeological remains of the Late Minoan age show that the early Aegean culture maintained itself in Rhodes comparatively unimpaired until the historic period. Legend also peopled primitive Rhodes with skilful workers in metal, the "Telchines," and with bold navigators, "Children of the Sun." In Homeric legend there was already a Heracleid settlement, and in historic times Rhodes was occupied by a Dorian population, mainly from Argos and subsequent to the Dorian invasion of Greece. The three Homeric cities refounded by these settlers — Lindus, Ialysus and Camirus — belonged to the League of Six Cities, by which Dorian colonists in Asia Minor protected themselves against the neighbouring mainland.

The early history of these towns records brisk commercial expansion and active colonization, illustrated by the rich tombs of Camirus. Rhodian colonies extended not only eastward along the southern coast of Asia Minor, but also to the westernmost parts of the Greek world. Examples are Phaselis in Lycia, Soli in Cilicia, Salapia on the east Italian coast, Gela in Sicily, the Lipari Islands, and Rhoda in northeast Spain. In home waters the Rhodians dominated Karpathos and other islands.

The history of Rhodes during the Persian Wars is obscure. In the 5th century B.C. the three cities were enrolled in the Delian league and were democracies. In 412 the island revolted from Athens and became the headquarters of the Peloponnesian fleet. Four years later the'inhabitants concentrated in the newly founded city of Rhodes laid out on an exceptionally fine site according to a scientific plan by the architect Hippodamus of Miletus. This town soon rose to considerable importance and attracted much Aegean and Levantine commerce which had hitherto been in Athenian hands.

In the 4th century B.C. political development was arrested by constant struggles between oligarchs and democrats, who in turn brought the city under the control of Sparta (412–395, 391–378), of Athens (395–391, 378–357) and of the Carian dynasty of Mausolus (357–340).

About 340 it was conquered for the Persian king by his Rhodian admiral, Mentor. In 332 it submitted to Alexander the Great, but on his death the people expelled the Macedonian garrison and henceforth not only maintained their independence but acquired great political influence. The expansion of Levantine trade in the Hellenistic age brought especial profit to Rhodes, whose standard of coinage and code of maritime law became widely accepted in the Mediterranean. Under modified democracy, in which the six πρυτάνεις found a powerful executive, the city long enjoyed a good administration. In foreign politics it prudently avoided the ambitious schemes of Hellenistic monarchs, but gained prestige by energetic interference against all who threatened the balance of

power or the security of the seas. Chief incidents were a memorable siege by Demetrius Poliorcetes in 304, who sought in vain to force the city into active alliance with Ring Antigonus; a severe earthquake in 227, the damages of which all Hellenistic states contributed to repair because they could not afford to see the island ruined: some vigorous campaigns against Byzantine, Pergamene and Pontic kings. who threatened the Black sea trade route (220 sqq). and against the pirates of Crete.

In accordance with their settled policy the Rhodians supported the Romans when they made war on Philip V of Macedon and Antiochus III of Syria on behalf of the minor Greek states. During the Third Macedonian War a false step deprived them of possessions in Lycia and partially diverted their trade to Delos (167). Nevertheless, during the two Mithridatic Wars they remained loyal to Rome and in 88 successfully stood a siege. The Rhodian navy did further good service for Pompey in his campaigns against the pirates and against Julius Caesar. But in 43 G. Cassius besieged and ruthlessly plundered the people for refusing to submit to his exactions and, though Rhodes continued a free town for another century. its commercial prosperity was crippled, and extensive earthquakes after A.D. 155 completed its ruin.

In the days of its greatest po er Rhodes became famous as a centre of pictorial and plastic art; it had a school of eclectic oratory whose chief representative was Apollonius Molon, the teacher of Cicero; it was the birthplace of the Stoic philosopher Panaetius; the home of the poet Apollonius Rhodius and the historian Poseidonius.

Protogenes embellished the city with his paintings. and Chares of Lindus with the celebrated colossal statue of the sun-god, which was 105 ft. high. The colossus stood for 56 years, until an earthquake prostrated it in 224 B.C. Its enormous fragments continued to excite wonder in the time of Pliny, and were not removed until AD. 653, when Rhodes was conquered by the Saracens, who sold the remains for old metal to a dealer, who employed 900 camels to carry them away. The notion that the colossus once stood astride over the entrance to the harbour is a mediaeval fiction. During the later Roman empire Rhodes was the capital of the "province of the islands."

The history of Rhodes under the Byzantine rule is uneventful except for some temporary occupations by the Saracens (6j3–658, 717–718) and the gradual encroachment of Venetian traders after 1082. In the 13th century the island stood as a rule under the control of Italian adventurers, who uere. however. at times compelled to acknowledge the overlordship of the emperors of Nicaea, and who failed to protect it against the depredations of Turkish corsairs.

In 1309 it was conquered by the Knights Hospitallers of St. John of Jerusalem at the instigation of the pope and the Genoese, and converted into a great fortress for the protection of the southern seas against the Turks. Under their mild and just rule both the native Greeks and the Italian residents were able to carry on a brisk trade. But the piratical acts of these traders, in which the knights themselves sometimes joined. and the strategic position of the island between Constantinople and the Levant necessitated its reduction by the Ottoman sultans. A siege in 1480 by Mohammed II led to the repulse of the Turks with severe losses; after a second investment. during which Sultan Suleiman (Soliman) I is said to have lost 90,000 men out of a force of 200,000, the knights evacuated Rhodes under an honourable capitulation (1522). The population henceforth dwindled in consequence of pestilence and emigration, and although the island recovered somewhat in the 18th century under a comparatively lenient rule, it was brought to a very low ebb as a result of the severity of its governor during the Greek revolution.

The sites of Lindus, Ialysus and Camirus, which in the most ancient times were the principal towns of the island, are clearly marked, and the first of the three is still occupied by a small town with a mediaeval castle, both of them dating from the time of the knights, though the castle occupies the site of the ancient acropolis. of which considerable remains were still visible. There are no ruins of any importance on the site of either Ialysus or Camirus, but excavations at both places produced valuable and interesting results in the way of ancient vases and other antiquities, which were placed in the British Museum and in the local collection at Rhodes.

In mediaeval times Rhodes's pottery, a lustreware at first imitated from Persian, developed into an independent style of fine colouring and rich variety of design. After the Italian occupation in 1912 a considerable modern quarter on European lines grew up west of the city of the knights; carriage roads were constructed and the harbours improved.

RHODESIA AND NYASALAND, FEDERATION OF. The federation consists of three British central African countries: Northern Rhodesia, a protectorate lying north of the Zambezi river; Nyasaland, also a protectorate. east of Northern Rhodesia; and Southern Rhodesia, a self-governing colony to the south of the Zambezi. It is bounded north by Tanganyika and the Republic of the Congo, south by Bechuanaland and South Africa, west by Angola and east by Mozambique (the latter two Portuguese possessions), and has an area of 477,798 sq.mi. and a population (1956) of 7,488,519. English, tribal dialects and (in Southern Rhodesia) Afrikaans are spoken. The native population is predominantly pagan, and there is a Christian minority. Salisbury. in Southern Rhodesia, is the federal capital. The federation is "exclusive" with limited powers, and those primarily affecting only Europeans, allotted to the federal government; Northern Rhodesia and Nyasaland retain their protectorate status under the aegis of the colonial office so far as African affairs are concerned, and the land rights and political prospects of the Africans are specifically safeguarded. The administration is in the hands of a governor general, a prime minister and an executive council (forming the cabinet); there is a federal assembly with speaker and elected majority, and an African Affairs board, a standing committee of the federal assembly, scrutinizes bills involving African interests before their presentation to the assembly. The three component countries retained their prefederation legislative structure. The political foundation of the federation and embryo dominion was declared to be interracial partnership based on equality of economic and political opportunity. The first governor general and prime minister of the federation were, respectively, Lord Llewellin and Sir Godfrey Huggins. The monetary unit is the Southern Rhodesian pound (= £1 sterling).

In this article the history of Rhodesia is treated first, followed by separate sections on Northern Rhodesia and on Southern Rhodesia. Nyasaland is dealt with in the separate article NYASALAND PROTECTORATE.

HISTORY

The historical records of south-central Africa before the European occupation in the closing years of the 19th century are inevitably scarce, because the African inhabitants built only with poles, grass and mud, could not write and, since they did not have the wheel, made no roads. Yet it is known that the first of them was one of the earliest of men; Rhodesian man, whose skull was discovered at Broken Hill in 1920. was comparable with Neanderthal man uho lived in Europe more than 10,000 years ago; and many palaeolithic implements of the type used by Neanderthal man have also been found. When the first wave of Bantu migrants arrived from the north, probably in the 13th century, they found, and drove before them into the southern deserts, Bushmen. These people, who still exist on the upper Zambezi and in the Kalahari desert in considerable numbers, were cave dwellers, hunters and artists. More than 400 of their lively paintings of men and animals have been discovered in the caves and on the rocks of the two Rhodesias. Of non-African culture evidence is provided by the ruins in Southern Rhodesia of at least 400 stone buildings of which Zimbabwe is the largest and most famous. Nobody really knows

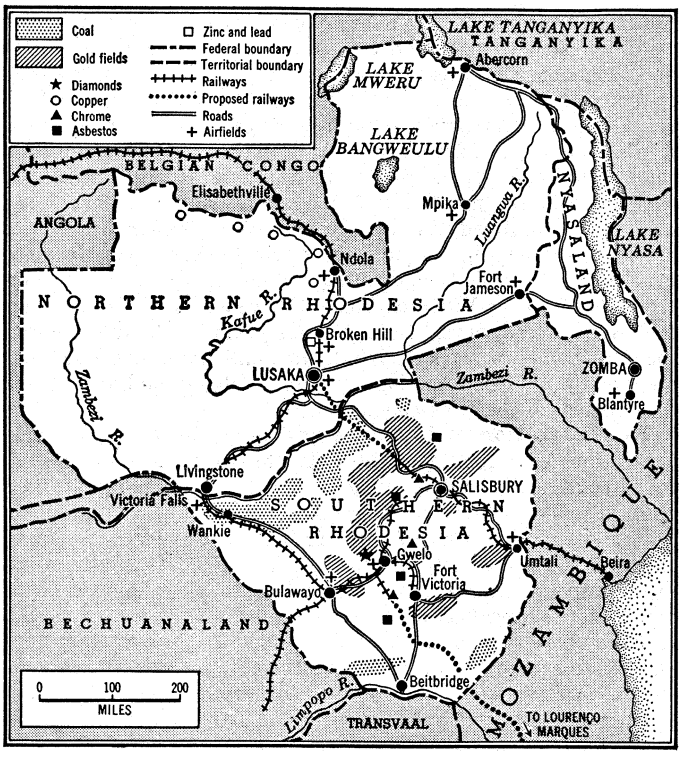
their date or origin, though theories and legends take the story back to the Sabaeo-Phoenicians and King Solomon's mines ("Ophir" was a generic term meaning any conspicuous source of natural products or merchandise, and most of the gold of those days came from southwestern Arabia), but it seems most probable that they date from the 1st millennium A.D. and that their builders either came from or at least traded with the east. In any case, by the time the Portuguese captured the east coast ports from the Arabs between 1500 and 1520, they found that this civilization had already vanished. There mas a gold industry of great size and antiquity but it was already in decay. Before this date, it is now estimated, gold to the present value of about £75,000,000 had been mined from the rocks of the Southern Rhodesian plateau, but the Portuguese bought gold only from alluvial workings, brought down to the coast in porcupine quills by the people of Monomotapa. This was the dynastic name of a series of Bantu chiefs who seem to have ruled a very considerable "kingdom" on the plateau until well into the 17th century.



COMMUNICATIONS AND MINERAL RESOURCES OF RHODESIA AND NYASALAND FEDERATION

The curtain of history lifts again in 1798 with the explorations into central Africa of Francisco de Lacerda in search of the *viagem a contracosta,* and the actual crossing of the continent from west to east by two half-castes called Pedro Baptista and A. José in 1802–11; and soon after this began the return to the north of Bantu warrior tribes from south Africa under the impact of Shaka's (Chaka's) tyranny. For one reason or another, but chiefly fear, three of these tribes fled northward during the first half of the century and themselves brought terror and conquest to much of central Africa. The Matabele conquered for themselves a kingdom south of the Zambezi, the Makololo under Sebitoane crossed that river and became the overlords of the Barotse on its upper reaches, and the Angoni went even farther north, to wander and raid and plunder as far afield as the east African hinterland. One branch of them eventually settled on the Luangwa-Lake Nyasa watershed, partly in what was later to become northeastern Rhodesia.

Meanwhile it is probable that a later wave of industrial Bantu discovered and began to mine the other great mineral belt of central Africa, the enormous copper deposits of the Congo-Zambezi watershed. It is not known when they started, but they were still mining the outcrops in the early years of the 20th century.

At about the same time, or perhaps a little later, the for the most part quite unmartial tribes north of the Zambezi began to be further afflicted by the inroads of the Arab slave trade. The slavers allied themselves with the Babemba and other warrior tribes and between them for more than a generation they decimated the population.

David Livingstone reached the upper Zambezi in 1851 and discovered the Victoria falls on Nov. 17, 1855 He died at Chitambo's village near Lake Bangweulu on May 1. 1873, during his famous last journey in fruitless quest of the source of the Nile. In the years between he discovered the whole of the Zambezi basin, Nyasaland and the plateau to the south of Lake Tanganyika. He also called the attention of the Christian world to the "open sore" of the east African slave trade, and so started the great missionary developments of the closing years of the century and, indirectly, the occupation and liberation of central Africa from 50 years of war and slavery.

This occupation came from the south. Cecil Rhodes first discussed the possibility of opening up central Africa in a conversation with (later Sir) Sidney Shippard, afterward commissioner in Bechuanaland, in 1878, but it mas not until ten years later that he was in a position to act. In 1887 Portugal laid claim to all the interior between Angola and Mozambique (to secure the *viagem* a *contracosta* which De Lacerda had tried so hard to find 100 years before). This spurred Rhodes, then in Bechuanaland, to action. J. S. Moffat was sent to make a treaty, on Feb. 11, 1888, with Lobengula, chief of the Matabele, binding him to have no dealings with any foreign power; and on Oct. 30 James Rochford Maguire and two other emissaries of Rhndes acquired from the chief a mineral concession covering the whole of the country sodth of the Zambezi. Rhodes went to London and persuaded Lord Salisbury to entrust him and his associates with the occupation of the whole of central Africa. After some negotiation the British South Africa company received its charter on Oct. 29, 1889. The stated objects of the company were: (1) to extend the railway from Kimberley northward toward the Zambezi; (2) to encourage emigration and colonization; (3) to promote trade and commerce; (4) to secure all mineral rights in return for guarantees of protection and security of rights to the tribal chiefs. Nine months later a pioneer column. led by Lieut. Col. E. G. Pennefather, guided by the great hunter F. C. Selous and consisting of about 200 settlers and 500 police, reached the site of the future capital of Southern Rhodesia and built Fort Salisbury. There was a brush with the Portuguese on the eastern border but in 1891 a treaty was concluded which was still in force in the 1950s; it delineated the frontier and included provision for the building of a railway from Beira and the recognition of the Shiré and Zambezi rivers as international waterways. By 1892 there were 1.500 settlers prospecting in Matabeleland, mostly on the ancient gold workings, and beginning to take up land, but for the next few years they were beset by trouble. In 1893 the Matabele attacked and were only defeated after severe fighting. In 1895 many of the settlers took part in the Jameson raid and were subsequently sent to England for trial; and a few months later the Matabele rose again, 10,000 of them forcing the settlers at Bulawayo to go into laager. Rhodes came out from London by way of Beira and held his famous indaba with the Matabele chiefs at the place in the Matopo hills where his grave now lies.

Meanwhile Rhodes had been energetically trying to secure the hinterland north of the Zambezi for Britain before the Germans, the Belgians or the Portuguese should forestall him. The "scramble for Africa" was on. In 1887 Chief Lewanika of the Barotse on the upper Zambezi had, under the influence of the great missionary, François Coillard, sought Queen Victoria's protection, and after much tortuous negotiation an agreement was arranged by Frank Lochner in 1890. It was followed by a treaty in 1900. This secured for the company rights which were later extended to cover the whole of what was to become northwestern Rhodesia. In the northeast Rhodes's emissaries were Alfred Sharpe and Joseph Thomson who between them, in 1890, made treaties with most of the chiefs in the country. Sharpe tried to secure also a concession from the powerful Chief Msiri in the Katanga hills, but, because of a misunderstanding, he did not succeed and in 1891 the Belgians

annexed Msiri's country and so secured the "Congo Pedicle" which contains some of the richest copper mines in the world. The warlike Babemba, south of Lake Tanganyika, refused to parley and continued. in alliance with the Arabs, to raid their weaker neighbours for slaves and ivory. The first European to penetrate their country was a missionary called Père van Oost of the White Fathers but it took several years of intermittent fighting to drive the Arabs from the plateau and to pacify the area. In the east, too, the Angoni, who had given a concession to a German which he in turn sold to the North Charterland Exploration company, rebelled. None of this fighting was very serious, but it was not until 1900 that the ***Pax Britannica*** was finally secured throughout the chartered company's vast new territories.

In 1899 the Barotseland-Northwestern Rhodesia order in council established a separate protectorate over northwestern Rhodesia with its capital at Kalomo and with Robert Coryndon as its first administrator; and two years later a similar order was made establishing the protectorate of North-Eastern Rhodesia with its capital at Fort Jameson. Robert Codrington, its administrator, and Coryndon in the west were both very remarkable men and were both under 30 years of age when given these high commands.

For the next 14 years the story of all these territories was one of peaceful progress and economic development. The railway had reached Bulawayo five months after the end of the Matabele rebellion and eight years later (two years after Rhodes's death) the Victoria falls. It halted for a while at Broken Hill and finally linked up with the Belgian system on the Katanga border in 1909. In Southern Rhodesia there were 12,506 settlers by 1904. In 1905 gold exports rose to £1,500,000 and by 1909 to £2,623,708. Agricultural development, however, got off to a slower start and it was not until 1907 that steps were taken to make the acquisition of land easier and give help and advice to the farmers. After that, progress improved and £34,810 worth of tobacco was exported in 1911. By then the white population (mainly of British stock) had risen to 23,606.

In the north settlement followed the railway and, because of the remoteness of the country, it was slow to develop. The lead-zinc-vanadium mine at Broken Hill was discovered in 1902 and by 1911 both this and the Bwana Mkubwa copper mine, the forerunner of the Northern Rhodesia copper belt, were in operation. But the prospecters had been active. The outcrops of most of the great copper mines had been discovered, including the Roan Antelope and Nkana, though they attracted little attention. The surface ores were copper oxides which were very expensive to work and the attention of the mining world was fully concentrated on the fabulous discoveries in the Katanga. In 1911 there were still only 1,500 Europeans, including officials and missionaries, in both the northern territories. In that year the two were united into the single protectorate of Northern Rhodesia, with its capital at Livingstone, near the Victoria falls.

In 1914. when the a;-year term of the company's charter was due to expire, the electors in Southern Rhodesia had the choice of either joining the Union of South Africa, supporting the continuation of the charter or pressing for self-government. They chose the middle course and the British government renewed the charter for ten years, provided that self-government should be granted earlier if the settlers showed themselves capable of administering the colony. During World War I all three territories contributed liberally of their manpower to the armed services, and local units played a prominent part in the campaign in East Africa against Gen. Paul von Lettow-Vorbeck. The armistice came at a very timely moment, when the German column, hotly pursued by Northern Rhodesian troops, was moving southward through the Bemba country in the direction of Broken Hill. The formal surrender took place at Abercorn. The Rhodesias, like most other countries, suffered severely from the influenza epidemic in 1918–19 and tens of thousands of Africans died. Meanwhile discussion about the political future of the territories had been going on and a privy council judgment was needed in 1918 to settle a dispute between the legislative council of Southern Rhodesia and the company about the ownership of unalienated land. After the war a royal commission under Lord Buxton was appointed to consider the political problem, as a result of which a referendum was held in 1922 on the choice between entry into the Union of South Africa and self-government. In spite of the offer of generous terms by Gen. Jan Christiaan Smuts 8,774 electors voted for self-government as against 5,989 for joining the Union, and on Sept. 12, 1923, on the 32nd anniversary of the arrival of the pioneers at Fort Salisbury, Southern Rhodesia was annexed to the crown and became a self-governing colony. Northern Rhodesia became a protectorate of the crown under colonial office rule in 1924. The company, which had never yet paid a dividend and had spent great sums on administration and development, received £3,750,000 in cash, retained its land rights in the north for 40 years, and all its mineral rights in both territories, from which. later, it was to reap a rich reward. At the time of the annexation there were about 34,000 whites in Southern Rhodesia and still only 4.000 in the north, but the dawn of Northern Rhodesia's prosperity was already in the sky. In 1921 Chester Beatty had become interested in the mineral possibilities of the Northern Rhodesian side of the Congo border and had formed a small syndicate called Copper Ventures Ltd. The ventures which it undertook were to lead, during the next four years, to the discovery of the great bodies of copper-sulphide ores underlying the oxide outcrops on the old Roan Antelope and Nkana claims, and to the rapid development of the great copper belt.

The Federation of Rhodesia and **Nyasaland.**—After 1924 the obvious geographical unity of the three central African territories continually bred discussion about the possibility of their political union. Royal commissions reported on the question in 1927 and 1939 but both of them recommended postponement of any such project, mainly because Southern Rhodesia. as a much more prosperous and self-governing colony, would be too weighty a partner for the two backward protectorates. Northern Rhodesia's revenues, however, leaped from £3,000,000 to £30,000,000 a year between 1945 and 1953 and, in this respect, to equality with the south. In consequence the northern settlers stepped up their agitation for closer union and in 1951 an impartial committee of civil servants from the three territories and the United Kingdom strongly recommended a federation. They rejected outright amalgamation because of the long-expressed opposition of the northern Africans to such a project. Two years of discussion and negotiation followed, marked by considerable opposition from the vocal elements of the African populations of Northern Rhodesia and Nyasaland and sharp party controversy in the British parliament; but a referendum in Southern Rhodesia supported federation; the colonial office remained convinced that it was both essential and urgent, and the necessary legislation was passed in July 1953. The federal assembly met for the first time on Feb. 2, 1954, and by the following July the government had assumed most of the responsibilities allotted to it. Oct. 23 was chosen as "Federation day."

NORTHERN RHODESIA

Northern Rhodesia is a British central African protectorate administered by the colonial office. It is 288,130 sq.mi. in area and is bounded on the north by the Belgian Congo, Lake Tanganyika and Tanganyika, on the east by Nyasaland, on the south by Portuguese East Africa and Southern Rhodesia and on the west by Angola.

Physical Features.—Most of the country consists of undulating plateaus between 3.000 and 4,500 ft. high, rising to more than 5,000 ft. on the Congo-Zambezi watershed along the Congo border, in the hills along the eastern border and in. the Muchinga escarpment southeast of Lake Bangweulu (*q.v.*). Most of it is drained by the Zambezi and its two great tributaries, the Luangwa and the Kafue. In the northeast the Chambezi river runs into Lake Bangweulu and this in turn drains into Lake Mweru (q v.) through the Luapula river. The Luangwa and lower Zambezi, below the Victoria falls, run in deep, hot valleys through broken, arid country.

The climate is tropical, with three distinct seasons: hot, August to October; wet, November to April; cool, May to July. Annual rainfall amounts vary, according to altitude, from 25 in. to 50 in.

The plateau country is of the wooded savanna type, though the

woodland is heavier along the Congo-Zambezi watershed and in the teak forests on the central Zambezi. Most of the country north of Broken Hill is infested with tsetse fly. For 100 mi. W. of Kafue township the Kafue is bordered by grassy plains about 40 mi. wide, flooded in the rains, the home of thousands of antelope and buffalo. Similar plains occur on the middle Zambezi and near Lake Bangweulu. The westward bend of the Kafue (the "Hook") was made a national park (c. 8,650 sq.mi.) in 1950 and is particularly well stocked with game. Game is fairly plentiful in most of the more thinly inhabited areas, and almost all varieties of south-central African fauna are to be found, including sitatunga, koodoo, sable and roan antelope, wildebeest, rhinoceros, hippopotamus and a few giraffe. Lions are not uncommon and elephant and buffalo abound in certain areas.

Population and Chief Towns. — There were, in 1951, 37,221 Europeans in the country, 2,529 Asiatics, 1,092 coloured people and about 1,700,577 Africans. In 1942 there were estimated to be only about 15,000 Europeens and 1,366,641 Africans. More than 20,000 Europeans are concentrated on the copper belt and most of the remainder live near the railway, with isolated planting communities at Fort Jameson and Abercorn. There are about 60 distinguishable tribes of Africans, among the largest being the Babemba, Xchewa, Barotse and Angoni.

The chief towns are Lusaka (cap.), 62,000 (1953 est., 6,000 Europeans); Kitwe 60,926 (6,300 Europeans); Luanshya, 54,127 (4,727); Ndola, 44,120 (5,120); Mufulira, 41,668 (4,247); Chingola, 34,484 (3,384); and Broken Hill 32,810 (4,050).

Education and Health. — For European children there are 22 government and 9 other schools. Seven of them offer secondary education. Education is free. In 1951 approximately 146,000 Africans were attending 1,380 schools, administered either by the government or the missions or the native authorities with government grants. Teacher training and secondary and technical education for Africans are being developed as rapidly as the output of the primary schools permits. The climate is good and, if normal precautions against tropical disease are taken, healthful. Malaria, hookworm, dysentery and similar illnesses are prevalent in rural areas only and there is much malnutrition in the villages. Sleeping sickness occurs in certain, well-defined areas. Hospitals and dispensaries serve all but the remotest districts.

Administration. — Northern Rhodesia is administered by a governor and commander in chief assisted by an executive council of seven official and four unofficial members, one of whom represents African interests. These councillors, including the unofficial members, share between them most of the administrative portfolios and answer for the departments in the legislative council. This consisted in 1953 of a speaker, nine official members, nine (European) elected members and four members nominated to represent African interests, of whom two were Africans. The latter were members of the African representative council which advises on all bills affecting African interests and which stands at the apex of a system of provincial councils and tribal local government. The franchise for the legislative council was limited to British subjects, which virtually means the European population.

Agriculture and Industries. — Copper mining employs about 6,000 European males out of a total labour force of 16,000 and about 40,000 Africans. Apart from civil servants, missionaries, traders and railway workers, most other Europeans are engaged in farming. Along the railway they produce cattle, maize, some wheat and tobacco (which is also grown around Fort Jameson in the east). Coffee is produced on the highlands south of Lake Tanganyika. Except for tobacco, which is exported, the chief market for produce is the copper belt, and after World War II many secondary industries developed, including a big, publicly owned cement factory at Chilanga near Lusaka. Lead, zinc and vanadium are mined at Broken Hill, and there is a considerable output of timber from the Zambezi teak forests. After the war production and trade expanded remarkably. Exports in 1938 were worth £5,114,428; by 1951 the figure had risen to more than £67,000,000. This prosperity was almost entirely the result of the rise in the price of copper of which 309,142 tons were exported in 1951, worth 83% of the total value of the export trade. The African population is mainly engaged in subsistence farming though maize is grown as a cash crop. mainly in the Southern province, and tobacco and cotton in the Eastern province. There is a big fishing industry on the Luapula river. About 46,000 adult males are usually away working in Southern Rhodesia and many others in South Africa, in addition to those employed on the copper belt and in the farming areas. In many tribal areas less than 30% of the men are to be found in their villages.

Communications. — The Cape to Congo railway runs northward (507 mi.) from the Victoria falls to the Katanga border with a branch-line system serving the copper belt. It provides access to the ports of Lobito Bay in Angola, Beira in Mozambique and all South African ports. Some barges operate on the upper Zambezi but otherwise the rivers are only used for local canoe transport. Mpulungu on Lake Tanganyika is served by a lake steamer operating from East Africa. Main roads (only 300 mi. with a bitumen surface) run northward from Livingstone to the copper belt and northeast to Abercorn (1,100 mi.); eastward from Lusaka, to Fort Jameson (392 mi.); westward from Lusaka and Nchanga to Mwinilunga, and from Lusaka to Mongu. and southeastward from Kafue to Chirundu and onward to Salisbury. These are all-weather roads of varying quality. District roads serve all the settled areas and the more densely populated African areas. There are 42 airfields, those at Lusaka and Livingstone being of international standard. Internal and regional air services are provided by Central African airways.

Finance. — Revenue rose from less than £3,000,000 in 1942 to £15,000,000 in 1951 and more than £23,000,000 in 1952, more than half of it being paid in income tax by the mining companies. Expenditure followed suit. A ten-year development plan was expected to cost £36,000,000 and was to be financed by £20,500,000 from revenues, £13,000,000 from loans and £2,500,000 from colonial development and welfare funds.

Customs. — The northern third of the country is in the "Congo basin" where, by international convention, no preferences can be given. Ad valorem duties do not exceed 10%. The rest of the country is covered by customs agreements with Southern Rhodesia and South Africa under which these countries admit their products. except spirits and tobacco, duty free. Goods from overseas may be consigned through to Northern Rhodesia in bond, thus, in some cases, saving the higher duties payable in South Africa.

(K. G. B.)

SOUTHERN RHODESIA

Southern Rhodesia, separated from Northern Rhodesia by the Zambezi river, is bounded on the northeast and east by Portuguese East Africa, on the south by the Transvaal and on the southwest and west by the Bechuanaland protectorate. It consists of Matabeleland and Mashonaland, covering 150,333 sq.mi. The country lies between 15° 36' and 22° 25' S. and 25° 14' and 33° 4' E.

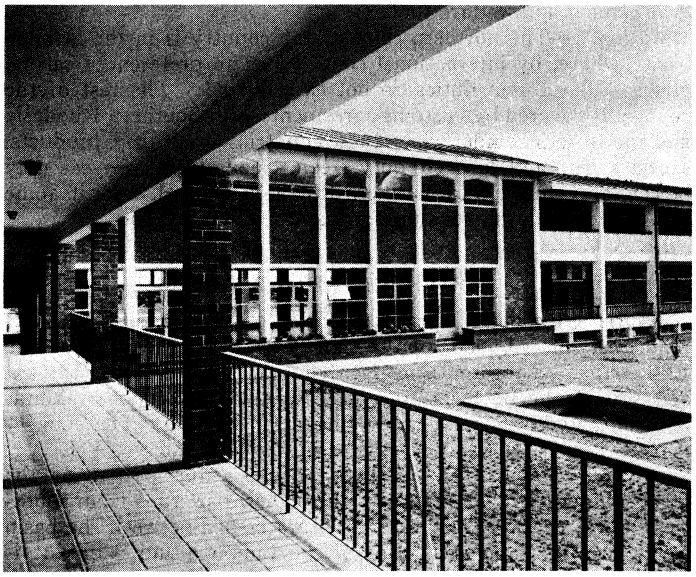
Physical Features. — Southern Rhodesia forms part of the great southern African plateau. The highest part runs from southwest to northeast and forms a broad watershed between the basin of the Zambezi and the basins of the Limpopo and Sabi. It is along this central axis that the railway runs from Plumtree through Bulawayo to Salisbury. In this central area the elevation ranges from more than 4,000 ft. to more than 5,000 ft. On each side the elevation decreases, falling to less than 2,000 ft. about the Zambezi and to less than 1,000 ft. in the southeast. About 24% of the total area lies above 4,000 ft. The surface consists for the most part of gently undulating plains, diversified by steep-sided hill ranges and isolated *kopjes*. The highest point occurs 48 mi. N. of Umtali in Mt. Inyangani, 8,251 ft. There a definite mountain range runs north and south and forms the eastern border of the country.

On the whole the considerable altitude partly compensates for the low latitude. The days are mostly hot throughout the year, the nights frequently cool, and frost is likely to occur during June, July and August. From the middle of August the temperature increases to its maximum in October, when the mean maximum is 85.2" F., taking the country as a whole. Rains and clouds usually appear about October and bring a little coolness. Sometimes the rains are

late and the high temperatures continue to be rather trying during November and December. The thermometer may rise to more than 100° F. even on the high veld. Humidity averages 65% over the year, falling to 48% in October and remaining at about 75% from December to March. The rainy season may be said to last from October to March. The annual average rainfall is 28 in.

About two-thirds of the country is covered with trees and shrubs. There are comparatively few open stretches. The prevailing plant association is savanna, forming parklike territory. At favourable spots on the mountainous eastern border, close evergreen forests occur in patches, some of the trees attaining a height of 200 ft. On the upper slopes Lussonia *umbellifera* and Eugenia species are dominant, and there they grow to heights up to 80 ft. The so-called Rhodesian teak (native igusi; Baikiaea *plurijuga*) is about 50% harder than real teak. From the bark of the baobab the natives obtain a fine fibre which they use for making nets.

The country is rich in antelopes, the most common species being the duiker, the steinbok and the reitbok. Other herbivorous animals are the buffalo, giraffe, zebra. elephant, rhinoceros and hippopotamus. The Carnivora include the lion, leopard, cheeta and various wildcats. There are crocodiles in the rivers. Beetles, butterflies and moths abound. White ants (termites) and locusts can be troublesome. Among the largest of the birds are ostriches, secretary birds, paauws, knorhaans, cranes, storks, vultures and eagles. Guinea fowl, partridge, duck, geese and teal are shot. Good shooting is to be had. but the following are royal game, and so are protected: eland, elephant, giraffe, gemsbok, hippopotamus, inyala, ostrich and rhinoceros. Animals and plants are protected in eight national parks. (See also SOUTH AFRICA, UNION OF.)



AUTHENTICATED NEWS

UNIVERSITY COLLEGE OF RHODESIA AND NYASALAND. LOCATED IN SALISBURY. SOUTHERN RHODESIA. THE COLLEGE WAS OPENED FOR CLASSES IN 1957

Population and Chief Towns. — In 1956 the population consisted of 176,000 Europeans, 2,290,000 Africans and about 13,000 Asian and coloured people. One of the first concerns of the colonial government was to augment the European element. In the first nine months of 1927, 3,574 immigrants were received. In the following year the European population was estimated to be 50,000. After World War II immigration averaged 15,000 a year. The Africans include Amandebele, Amatshangana, Basuto and numerous tribes often grouped together as "Mashona." English is the official language. A certain amount of Afrikaans, however, is spoken in the country districts.

Salisbury (cap.) and Bulawayo are described in separate articles. Umtali, the centre of a gold-mining area, has a non-African and employed African population of 21, 500 (1956). Other municipalities are Gwelo, Fort Victoria, Que Que and Gatooma.

Education. — In 1954 there were 116 European government schools and 24 private, 9 European-aided farm schools, 14 Asian and coloured government schools and more than 2,300 mission and government schools for Africans.

Administration. — In the constitution under the letters patent of 1923 legislation affecting the African population, the unalienated land. the railways and the mineral rights of the British South Africa company were subject to disallowance by the crown (there mere several important changes later), but in other respects Southern Rhodesia was endowed with the institutions of a self-governing overseas British state. Legislative power is vested in the sovereign, represented by the governor, and an executive council composed of the ministry under the presidency of the governor and responsible to the legislative assembly of 30 members. The first general election was held on April 29. 1924, and the first ministry was then formed by Sir Charles Coghlan. The franchise is extended to all British subjects. including Africans, over 21 years of age and possessing premises to the value of £500 or receiving an income of not less than £240 a year.

Agriculture and Industries. — Farming exists in several forms. from ranching to tobacco growing. Mixed farming is common and dairying is practised on the smaller farms near the towns and mines. The three major agricultural products are tobacco, cattle and maize. The acreage under crops (1953) was: maize 374,500; tobacco 178,200; green manures, legumes and fodders 240,000. Irrigation is rapidly developing. Citrus orchards are extending.

Ranching is favoured by the climate. which allows the cattle to run on the veld throughout the winter. In 1953 there were more than 3,000,000 head of cattle, generally in herds of from 600 to 1,000 African-owned cattle totalled 1,831,735. They are grass-fattened for market or are sent on to agricultural farms for final preparation.

Minerals being mined in the 1950s were gold, chrome. lead, asbestos. mica, tungsten, coal. silver, etc. In 1954 the output of gold was valued at £6,651,000. The total output of minerals was valued at £18,776,000.

The gross output of industries in 1952 was valued at £60,000,000. Exports (1952) were valued at £44,486,182, in the form of produce and manufactures. Tobacco exports were valued at £18,838.300. Imports of general merchandise totalled £88.377,915, chiefly textiles and iron and steel goods. Exports to the U.K. were £19,362,000 (1952); to the U.S.. £2,596,484.

Communications. — The railways, with a mileage of nearly 3,000, are operated by a railway commission acting for the two Rhodesias and Bechuanaland (Railaay act, 1926). The colony is well served. and is connected with Beira, the nearest port. Lourenço Marques, the Belgian Congo and the Union of South Africa. There is through communication by the Rhodesian system from Cape Town to the Congo border and, via Bulawayo and Salisbury, to Beira on the Indian ocean. The lines, as far as possible, follow the watersheds. The standard gauge is 3 ft. 6 in. More than 2,500 mi. of all-weather roads of full tarmac or on the strip principle reach in all directions from end to end of the country. The approximate mileage of existing motor roads is 15,600.

Finance. — In the budget for Southern Rhodesia for 1954–55 revenue was estimated at £12,346,000 and expenditure at £12,900,000. The national income for 1954 was estimated at £127,600,000. (See also NYASALAND PROTECTORATE.) (C. L. BK.)

RHODES SCHOLARSHIPS, founded in 1902 under the

will of Cecil Rhodes. Rhodes provided for the maintenance at Oxford university of men from specified areas overseas. The value of each scholarship eventually rose to £600 a year, for two years in the first instance, and for a third year should the trustees so decide in individual cases. The annual awards in the 1950s were distributed as follows: from Australia, 6 (1 from each state); from Canada 11 (Ontario and Quebec, 2 each; the other provinces. including Newfoundland, 1 each); from New Zealand, 2; from Rhodesia, 3; from South Africa, 8 (including boys from 4 specified schools); and from Bermuda, India, Jamaica, Malta and Pakistan, 1 each. From the United States 32 scholars are elected annually. Five annual scholarships were originally allotted to Germany (because "an understanding between the three great powers will render war impossible and educational relations make the strongest tie") but these were annulled by act of parliament in 1916. The renewed German scholarships were discontinued in 1939.

In his will Rhodes mentions the objects he had in view in founding the different scholarships.

1. *Colonial.* "I consider that the education of young colonists at one of the universities in the United Kingdom is of great advantage to them for giving breadth to their views, for their instruction in life and manners, and for instilling into their minds the advantage to the colonies as well as to the United Kingdom of the retention of the unity of the empire."

2. *United States.* "I also desire to encourage and foster an appreciation of the advantages which I implicitly believe will result from the union of the English-speaking people throughout the world, and to encourage in the students from the United States an attachment to the country from which they have sprung, but without, I hope, withdrawing them or their sympathies from the land of their adoption or birth."

He defines as follows the principles on which he wished his scholars to be selected: "My desire being that the students who shall be elected to the scholarships shall not be merely bookworms, I direct that in the election of a student to a scholarship regard shall be had to (1) his literary and scholastic attainments; (2) his fondness for and success in manly outdoor sports such as cricket, football and the like; (3) his qualities of manhood, truth, courage, devotion to duty, sympathy for and protection of the weak, kindliness, unselfishness and fellowship; and (4) his exhibition during school days of moral force of character and of instincts to lead and to take an interest in his schoolmates, for those latter attributes will be likely in after life to guide him to esteem the performance of public duties as his highest aim."

Method of Selection. — Subject to ratification by the eight trustees, the nomination of scholars is in the hands of local committees, which are appointed by the trustees, and on which former Rhodes scholars sit, but never preside. Candidates must be citizens of the country which they are to represent, with at least five years' domicile, and unmarried; and they must have passed their 19th and not have passed their 25th birthday by Oct. 1 of the year for which they are elected. Candidates are judged on their records and after a personal interview with the election committee. Save in certain exceptional cases. candidates are obliged to have attended a recognized degree-granting college or university for two years at least.

At Oxford the scholars are distributed, as Rhodes desired, among all the colleges of the university, as far as possible in accordance with their own wishes; but acceptance of any scholar is determined by the colleges themselves. More than 3,000 scholars had been elected by 1955.

The 50th anniversary of the first elections (all of which were from South African schools) and the centenary of the founder's birth were celebrated in Rhodes house, Oxford, in 1953.

(P. K.; E. T. Ws.)

RHODIUM is a chemical element which is a precious silver-white metal, one of the six platinum metals (*q.v.*). The metal has a specific gravity of 12.4 and melts at 1,980° C.; thus it is difficult to fuse or cast.

Rhodium (symbol Rh, atomic number 45, atomic weight 102.91) is fairly hard and cannot be easily worked at room temperature; but it can be forged above 800° C., a red heat. Its boiling point must be above 2,500° C.

The surface of the metal has a high reflectivity for light and is not corroded or tarnished by the atmosphere at room temperature. It is frequently electroplated onto metal objects and polished to give permanent attractive surfaces for jewelry and other decorative purposes. In particular, the black tarnish of silver is avoided by the use of rhodium plate. Rhodium also serves for the preparation of "silvered" surfaces for reflectors of searchlights and motion-picture projectors.

Rhodium added to platinum in small amounts yields alloys which are harder and lose weight at high temperatures even more slowly than does pure platinum. Therefore crucibles for heating materials in the chemical laboratory are commonly made from these alloys. In the industrial manufacture of nitric acid, gauze catalysts of the rhodium-platinum alloys are used because of their ability to withstand the flame temperature as ammonia is burned to nitric oxide.

A wire of the alloy 10% rhodium-90% platinum joined to a wire of pure platinum forms an excellent thermocouple for measuring high temperatures in an oxidizing atmosphere. The international temperature scale is defined over the region from 660° to 1,063° C. by the electromotive force of this thermocouple.

The only stable isotope for rhodium has a mass number of 103, *i.e.*, Rh^{103}. Its nuclei possess a high cross section or probability for the capture of neutrons with thermal energies. The Rh^{104} formed by neutron capture is radioactive, and consists of two nuclear isomers (half lives of 44 sec. and 4.3 min.). In nuclear physics experiments, a flux of neutrons can be conveniently and quickly measured by the determination of the amount of radioactivity induced in a thin rhodium foil, exposed for a few minutes to the neutrons.

Rhodium always accompanies platinum in minerals, but only to a minor extent. It was first isolated from crude platinum by William Wollaston. who announced its discovery in 1804. He gave it the name rhodium in consequence of the red colour of a number of its compounds.

Rhodium is almost as resistant as iridium to chemical attack by acids. The massive metal is not dissolved by hot concentrated nitric or hydrochloric acid or even by aqua regia which dissolves gold and platinum. The element dissolves in fused potassium hydrogen sulfate to yield a complex sulfate, soluble in water.

Rhodium, in all well-characterized compounds, possesses the +3 oxidation state. Possibly some compounds of lower oxidation state can form. and strong oxidizing agents yield higher oxidation states of transient stability, probably +4 and +6. All its compounds are readily reduced or decomposed by heating to yield the powdered or sponge metal.

Many rhodium compounds contain co-ordination complexes in which ammonia, water, chloride or other groups are bonded covalently to a central rhodium ion. Characteristically, the groups in these complexes are replaced slowly. A series of substituted ammine compounds is analogous to familiar compounds of cobalt (III) (see COBALT). A yellow hydrous rhodium hydroxide, soluble in acid or alkaline solutions, can be precipitated, but some conditions will cause a black precipitate to form. Rh_2O_3 is a gray compound, insoluble in acids. $RhCl_3$ can be prepared in a form which does not dissolve in water or acids. Other forms dissolve readily to give solutions whose colour may range from brown to yellow and in which some or all of the chloride is not precipitated by silver nitrate.

(D. S. MN.)

RHODOCHROSITE, one of the calcite group of carbonate minerals, consisting of manganese carbonate. It is used as a source of manganese for the ferromanganese alloys consumed in steelmaking and in the preparation of other manganese chemicals. Named from the Greek meaning "rose coloured," it sometimes is known as manganese spar.

The formula for rhodochrosite is $MnCO_3$. Extensive substitution of iron and calcium, as well as lesser amounts of magnesium, may occur in place of the manganese. It crystallizes in the rhombohedral system, and occurs commonly as compact crystalline masses and incrustations rather than as single crystals. When

pure it is usually some shade of pink or rose-red, with a specific gravity of 3.7 and a hardness of 3.5–4.

Rhodochrosite is found in sedimentary deposits, in mineral veins of silver, lead, copper and zinc minerals formed at moderate temperatures and in high-temperature metamorphic deposits. It is found in England, at a number of localities in Europe, in Siberia and in Argentina. Brazil and Peru.

In the United States it occurs abundantly at Butte, Mont.. and is found in California, Colorado, Nevada, Ctah, Arkansas. Tennessee and Maine. (D. L. G.; X.)

RHODODENDRON, of the heath family (Ericaceae), is one of the largest genera of woody plants. It comprises 800–900 species including about 70 azaleas. Azaleas, together with rhodora, were once considered as constituting a distinct genus, but are now treated as species of *Rhododendron.*

The true rhododendrons are mostly evergreen and with campanulate corollas while the azaleas are usually deciduous and with funnelform corollas. They are commonly kept distinct by gardeners but botanical characters distinguishing the two are not constant. Some azaleas are evergreen while some true rhododendrons are deciduous.

Rhododendrons are among the most popular garden plants, much planted for their beautiful showy flowers and for their

ROCHE

RHODORA (RHODODENDRON CANADENSE) **BLOSSOMS**

ornamental foliage in the evergreen species. The species are distributed throughout the colder regions of the northern hemisphere, and also on the high mountains of southern Asia, Malaysia and New Guinea. with one in northern Australia, but none in Africa and South America. The greatest development is found in the Himalayas eastuard to western and central China, in the wet monsoon zone of Asia. There are about 26 species in North America, but none extending into Mexico.

There is no wild species in Britain. although *R. ponticum* is practically naturalized in the south. but the genus is exceedingly popular for gardens and most species do extremely well there. In North America they are best cultivated along the Atlantic seaboard, in the Alleghenies and on the Pacific coast.

The rhododendrons are shrubs. rarely small trees. Some species are epiphytic. The leaves are alternately arranged, stalked and, generally, with entire margins. The flowers are large and showy, on stalks, generally several to many grouped together in terminal umbellike clusters. There is a small calyx. generally five-parted. The corolla is red blue. yellow or white, or of intermediate shades, rotate to campanulate or funnelform, usually slightly irregular, and five or rarely six to ten lobed, occasionally divided to the base. There are five to ten stamens with anthers opening with apical pores. The ovary is five to 20 celled. each cell many ovuled. There is a slender style ending in an enlarged stigma. The fruit is an ovoid or elongate capsule, splitting from top into 5 to 20 valves when mature, liberating numerous minute seeds.

The species grow only in acid soils rich in humus. They thrive best in a cool, damp atmosphere and prefer "high shade." To prepare ground for cultivation, peat moss or acid leafmold, especially from oaks, or sawdust can be used to mix with loamy soil. The roots are shallow and are without root hairs but are associated with a mycorrhizal fungus. It is important to mulch the soil to keep the roots from drying out in summer as well as in winter. The evergreen rhododendrons are generally propagated by seeds or layering. Grafting is resorted to in only the rarer and more tender kinds.

A number of American species are highly ornamental and much planted. Among these are the coast rhododendron, R. *macrophyllum,* the state flower of Washington; the catawba rhododendron, *R. catawbiense,* of the southern Alleghenies; and the rose bay rhododendron, *R. maximum,* of eastern North America. The latter two, together with the less hardy *R. arboreum* and *R. campanulatum* from the Himalayas, *R. caucasicum* from the Caucasus, R, *ponticum* from the Mediterranean region and other species have given rise by hybridization to numerous horticultural varieties now in general cultivation. (H. L. L.)

RHODONITE, a member of the silicate group of minerals, consisting of manganese metasilicate. It commonly occurs as cleavable to compact masses with a rose-red colour; hence the name, from the Greek word meaning a rose. The formula is $MnSiO_3$. It crystallizes in the triclinic system and crystals often have a thick tabular habit; there are perfect cleavages parallel to the prism faces. The hardness is 5.j–6.5, and the specific gravity 3.4–3.68.

Rhodonite is liable to alteration, and in certain cases forms the primary source of very important deposits of ores of manganese, mainly in the form of oxides, such as pyrolusite (*q.v.*); such are a considerable part of the manganese ores of India.

Rhodonite occurs as large rough crystals with franklinite and zinc ores at Franklin, N.J. Fine-grained rhodonite of clean colour is a desirable gem and ornamental stone. The finest quality is mined near Sverdlovsk, U.S.S.R., in the Urals. Good stone occurs in Siskiyou and Plumas counties in California. It has been used for beads, pendants and other ornaments.

See JADE AND OTHER HARD STONE CARVINGS: *Other* Hard *Stones.* (W. F. FG.)

RHODORA, the common name for *Rhododendron canadense* (formerly *Rhodora canadensis),* a small deciduous shrub of bogs and lox\-acid soils of the New England states and adjacent areas. It produces beautiful pale to deep rose-purple flowers in April and May.

The plant is perhaps best known from Emerson's poem concerning it.

(*See* RHODODENDRON.) (*J.* M. BL.)

RHOECUS, a Samian sculptor and architect of the 6th century B.C. He and his partner Theodorus were especially noted for their work in bronze.

Herodotus says that Rhoecus built the temple of Hera at Samos. In the temple of Artemis at Ephesus was a figure of "Night" by Rhoecus, apparently of bronze. The name has been found on a fragment of a vase dedicated to Aphrodite at Naukratis. His sons Theodorus and Telecles made a statue of the Pythian Apollo for the people of Samos.

RHONDDA, DAVID ALFRED THOMAS, 1ST VISCOUNT (1856–1918), British colliery owner and statesman. was born on March 26, 1856, in Aberdare, the son of a grocer, Samuel Thomas, who had enriched himself by colliery speculations. After an education at Clifton college and Caius college. Cambridge university, Thomas joined his father in the coal business, into which he threw himself with great energy and ability. His extraordinary commercial gifts, his insight, his foresight and the sympathy which he brought to bear on conditions of life in the mining industry soon made him a prominent, and eventually the leading, figure in the

industrial world of south Wales. His business combinations brought him great wealth: and culminated in the Cambrian supercombine, which produced about 6,000,000 tons of steam coal a year.

Though he had sat as a Liberal for Merthyr Tydfil for 22 years from 1888, and for Cardiff for a few months in 1910, Thomas achieved no political importance till the outbreak of World War I, when Lloyd George invoked his assistance in mobilizing British industrial resources. He considerably expedited U.S. munitions supplies by personal visits to the United States. on one of which he narrowly escaped with his life from the sinking of the "Lusitania." He was created a baron, as Lord Rhondda. for his services. in Jan. 1916: and took office in Lloyd George's ministry in the following December as president of the local government board. passing to the food controllership in June 1917. There, taking strong steps to put an end to speculation in the necessities of life, he gradually fixed prices and brought supplies under control.

He will be mainly remembered as the author of the system of compulsory food rationing, which was carried out with absolute fairness and impartiality. In April 1918 he tendered his resipnation; but pressure was put upon him to remain. He died on July 3 at Llanwern, Monmouthshire. Just previously he had been created a viscount. His only child. a daughter (who married Sir Humphrey Mackworth in 1908, and obtained a dissolution of their marriage in 1923), succeeded to the viscounty of Rhondda under a special remainder. In 1921 Lady Rhondda published a *Life* of her father.

RHONDDA, a municipal borough (1955) of Glamorgan, south Wales. 12 mi. long by about 4¾ mi. across at its widest part, comprising two main valleys, named after their respective rivers, Rhondda Fawr and Rhondda Fach. Pop. (1961) 100,314. Area 37.3 sq.mi. The valleys are deeply incised in the coal measures of the south Wales geological basin and their lateral boundaries are formed by hills varying from 560 ft. near Trehafod to 1,567 ft. on the northeast of Maerdy in the Rhondda Fach and 1,742 ft. on the southwest of Treherbert in Rhondda Fawr. The upper end of the latter valley rises to the Rhigos plateau where Craig-y-Llyn (1,969 ft.) is the highest point in Glamorgan. The two valleys are separated by the ridge of Cefn-y-Rhondda, which ranges from 600 ft. above Porth to 1,690 ft. There are tributary valleys where it joins the Rhigos plateau of which Cwmparc, Clydach vale and Cymmer are the chief.

Rhondda is the centre of the eastern division of the south Wales coal field. Coal exploitation there started in 180; and so it was later than that of the northern sections of the south Wales area where coal was worked early for iron smelting. It was the realization of the steam-raising properties of the Rhondda coal and the opening of the Treherbert pits in 1855 that made the region famous.

With the great demands made for steam coal by the ever-increasing railway traffic. steamship services and navies of the last half of the 19th century. Rhondda from being a purely pastoral upland region was transformed into a densely populated industrial area. No thought was given then, however, to the development of other industries which could provide alternative employment in the event of a setback in the coal-mining industry. With the rapid growth of each township provision was made for miners' libraries and institutes and numerous places of worship, and around these grew and flourished social, religious and cultural activities, particularly in music and drama, which. in turn: led to the creation of a strong community of interest and civic pride.

In 1801 the population was 542, but by 1871 it had reached 23,950; in 1881 it was jj.632 and in 1901 it was 113,735. The peak population figure was 167,900 in 1924 but during the severe industrial depression of the 1930s it fell to 121,940 by 1938 Further migration during World War II reduced the population seriously and by 1951 the figure stood at 111.389.

With the development of the coal exporting trade a number of small railway companies connected Rhondda with Cardiff, Port Talbot and Swansea but all these lines were eventually merged in the Great Western railway, and in 1947 in the Western region of British railways. The slump in world demand for Welsh coal following World War I undermined the prosperity of the area and led to mass unemployment and migration. In 1934, of Rhondda's 61.460 insured men more than 47% were without work. In an attempt to relieve this critical situation two new factories were opened in the area in 1939. After World War II the policy of redistribution of industry to help depressed areas brought 29 new industries to Rhondda. At mid-century the area had a stable and varied industrial pattern. There are two major schemes of mining reorganization at Maerdy and Treherbert. (J. C. G. J.)

RHÔNE, a *département* of southeastern France, formed in 1793 from the eastern portion of the *département* of Rhône-et-Loire, and comprising the old districts of Beaujolais, Lyonnais, Franc-Lyonnais, Forez and a small portion of Dauphiné. Pop. (1954) 966,782. Area, 1,104 sq.mi. Rhône is bounded north by the *département* of Saône-et-Loire, east by Ain and Isère and south and west by Loire. The Saône and the Rhône form its natural boundary to the east. The *département* belongs almost entirely to the basin of the Rhône, to which it sends its waters by the Saône and its tributary the Azergues, and by the Gier. The mountains which cover the surface of the *département* constitute the watershed between the Rhdne and the Loire, and from north to south form four successive groups—the Beaujolais mts., the highest peak of which is 3,320 ft.; the Tarare group; the Lyonnais mts. (nearly 3,000 ft.); and Mt. Pilat, the highest peak of which belongs to the *département* of Loire.

Good agricultural land is found in the valleys of the Saône and Rhône, but for the most part the soil is stony and only moderately fertile. Wheat, oats, rye and potatoes are widely grown. with colza on the banks of the Saône, but they are less important than the vine, the hills of the Beaujolais on the right bank of the Sadne producing excellent wines. Mines of copper pyrites and coal and quarries of marble (at Bully) are worked. The production of silk fabrics, the chief branch of manufacture of artificial silk goods, of chemicals and machinery, together with most of the other industries of the *de'partement,* are concentrated in Lyons (*q.v.*) and its vicinity. Tarare is a centre for the manufacture of velvet, muslin and embroidery. Oullins has large railway workshops belonging to the P.L.M. railway, and there are important glassworks at Lyons and at Givors. Cotton spinning and weaving are carried on in several localities.

The *de'partement* is served by the P.L.M. railway. The Rhône and the Sadne and in the extreme south the canal of Givors are its navigable waterways. Lyons, the capital. is the seat of an archbishop and of a court of appeal and centre of an educational division *(acaddmie).*

The *de'partement* is in the 14th military region. There are two *arrondissements* (Lyons and Villefranche) with 33 cantons and 269 communes. The principal places besides Lyons are Givors, Tarare and Villefranche (*q.v.*).

RHÔNE, one of the most important rivers in Europe, and the chief of those which flow directly into the Mediterranean. It rises at the eastern. extremity of the Swiss canton of the Valais, flows through Switzerland and France and enters the Mediterranean at the Gulf of Lyons. Its total length is 505 mi.. of which the Lake of Geneva, through which it flows: claims 45 mi.; and its total fall is 5.898 ft. Its course (excluding the Lake of Geneva. *q.v.*) naturally falls into three divisions: (1) from its source to the Lake of Geneva (105½ mi. and fall 4.679 ft.) *(2)* from Geneva to Lyons (124 mi. and fall 689 ft.) and (3) from Lyons to the Mediterranean (230 mi. and fall 530 ft.).

From its Source to the Lake the Rhdne is a purely Alpine river, flowing through a great trench first in a synclinal structure between the Aar and St. Gothard massifs, then along the front of the Pennine nappes. *(See* ALPS.) It issues as a torrent, at the height of 5,909 ft., from the Rhône glacier at the head of the Valais. It is almost immediately joined (left) by the Mutt torrent. coming from a small glacier and then flows past the Gletsch hotel (where the roads from the Grimsel and the Furka pass unite). About half a mile from the glacier the river descends through a wild gorge to the more level valley, to reach the first village, Oberwald. It preserves a south-westerly direction till

Martigny.

The uppermost valley of the Rhbne is named Goms, its chief villages being Miinster and Fiesch, whilst the river is swollen by mountain torrents, descending from the glaciers on either side, by the Geren (left), near Oberwald; by the Eginen (left), near Ulrichen; by the Fiesch (right), from the Fiesch glacier, at Fiesch; by the Binna (left), near Grengiols; by the Massa (right) from the Aletsch glaciers, above Brig. At Brig the RhBne has descended 3,678 ft. from its source in 28 m., and is already a considerable stream when joined (left) by the Saltine. descending from the Simplon Pass. Its course below Brig is less rapid and lies through wastes of alluvial deposits. The valley is wide and marshy, the river frequently overflowing its banks. Further mountain torrents fall into the RhBne: these are the Visp (left) from the Zermatt valley, at Visp; at Gampel, the Lonza (right) from the Lotschen valley; at Leuk, the Dala (right) from the Gemmi Pass; at Sierre, the Navizen (left) from the Einfisch or Anniviers valley; at Sion, the capital of the Valais, the Borgne (left) from the Val d' Hérens; below Sion, by the Morge (right), from the Sansetsch pass; and at Martigny by the Dranse (left) from the Great St. Bernard and the Val de Bagnes. At Martigny, the river bends sharply to the northwest toward the Lake of Geneva. Opposite Dorénaz it receives the Salanfe (left). Immediately below St. Maurice the Rhône rushes through a narrow and striking defile which commands the entrance of the Valais.

Beyond, the river enters the wide alluvial plain, formerly occupied by the south-eastern arm of the Lake of Geneva, but now marshy. It receives at Bex the Avançon (right) flowing from the glaciers of the Diablerets range, at Monthey the Vièze (left) from Champéry and the Val d' Illiez, and at the Aigle the Grande Eau (right), from the valley of Ormonts-dessus. It passes Port Valais, once on the lake, before expanding into the Lake of Geneva, between Villeneuve (right) and St. Gingolph (left). During all this portion of its course the Rhône is not navigable, but its valley forms an artery into the Alps which is followed by the railways and roads.

The Upper RhBne. being fed by glacial streams, is overladen with sediment, much or which is deposited along the course, the remainder settling down in the Lake of Geneva, in the blue waters of which it is possible to follow the whiter course of the stream for some distance before it disappears.

From Geneva to Lyons.—About ½ m. below Geneva the blueness of the water of the RhBne is again disturbed by the Arve (left), from the glaciers of the Mont Blanc range, the two currents for some distance refusing to mix. The RhBne is here forced southward by the sweep of the Jura folds through which it breaks in a number of narrow gorges or *cluses*. It continues southward until joined near Corbelin by the Guier (left), from the Grande Chartreuse mountains and it continues the direction of this tributary thus rounding the southern spur of the Juras.

About 12 m. south of Geneva the RhBne enters France. At Bellegarde the Valserine flows in (right), and then the river resumes its southerly direction, from which a great gorge has deflected it for a while. Some way below Bellegarde, between Le Parc and Pyrimont, the Rhbne becomes officially "navigable" though as far as Lyons the navigation consists almost entirely of flat-bottomed boats. Above Seyssel the Usses (left) joins the RhBne, while just below that village the Fier (left) flows in from the Lake of Annecy. Below the junction of the Fier the hills sink on either side, the channel of the river widens and it leaves the mountains for the plains. The Geneva-Paris railway follows the river as far as Culoz. The Rhône receives the waters from Lake Bourget by a canal (left). The last of the *cluses* is at the Pont du Saut or Sault, a little south of Lagnieu. The river now widens but the neighbouring country is much exposed to inundations.

It receives the Ain (right), which descends from the French slope of the Jura and is navigable for about 60 m., above its junction with the SaBne, just below Lyons. The SaBne (*q.v.*), which has received (left) the Doubs, is the real continuation of the lower RhBne, both from a geographical and a commercial point of view. and it is by the means of canals branching off from the course of the SaBne that the RhBne communicates with the basins of the Loire, the Seine, the Rhine and the Moselle.

Below Lyons, the Rhône becomes one of the great historical rivers of France. It was up its valley that various civilizations penetrated from the Mediterranean to Lyons. From Lyons downward the left bank serves as a great medium of commerce by which central France sends its products to the sea. During this half of its course it flows over an alluvium-filled valley resting on Jurassic and Cretaceous rocks, and it can boast of having on its left bank (the right bank is very poor in this respect) such historical cities as Vienne, Valence, Avignon, Tarascon and Arles, while it receives (left) the Iskre, the Drôme, the Aygues and the Durance rivers, all formed by the union of many streams from the Dauphiné Alps.

The Ardèche is the only considerable affluent from the right. Near Arles, about 25 mi. from the sea, and 175¼ mi from Lyons by rail, the river breaks up into two main branches, the Grand RhBne running southeast and the Petit Rhône southwest; they enclose between them the delta of the Camargue, which is cultivated on the banks of the river only, but elsewhere is simply a great alluvial plain, composed of scanty pasturages and of great salt marshes. Changes in sea level have taken place in the RhBne delta in recent times. R. D. Oldham (*Nature,* vol. cxvi, pp. 16, 52, 100 [1925]), shows that in Pre-Roman times the sea level was 15 ft. higher than in modern times. A rise was followed by a subsidence which occurred in about the 8th century when the river ended far inland in a shallow landlocked inlet uhich it proceeded to fill up with alluvium until in the 17th century it had regained the sea front. Even since that time it has greatly modified its form by changes of channels, etc.

The RhBne river system is dominated by two tectonic features, the Alps and the Central Plateau of France. Below Chalon-sur-Saône, the Saône-Rhône flows along the eastern side of the central plateau and most of the course is determined by a north to south fault. The remainder of the river system is determined by the structure of the Alps (*q.v.*). The greater length of the river and of its Alpine affluents is parallel to the trend of the structures, as above Martigny, between Lake Geneva and Corbelin, the Arve in the Chamonix valley and parts of the Iskre and of the Durance. On the other hand other portions flow radially to the trend, as between Martigny and Lake Geneva, parts of Iskre, the Drôme, the Aygues, the Durance and numerous other tributaries.

RHOXOLANI, a Sarmatian tribe defeated in the Crimea by Diophantus, general of Mithradates, c. 100 B.C., and by the Romans on the lower Danube *c.* A.D. 60, and also under M. Aurelius. They seem to have finally succumbed to the Goths.

RHUBARB. This name is applied both to a drug and to a vegetable.

Drug.—The drug has been used in medicine from very early times, being described in the Chinese herbal Pen-king, which is believed to date from 2700 B.C., and it is still produced in the four northern provinces of China in modern times. In England the culture of rhubarb for medicinal purposes began in 1777 at Banbury in Oxfordshire and continued to be carried on there.

Two varieties of the drug are known, viz., kiln dried and sun dried. So-called Turkey rhubarb was the Chinese drug which reached Europe from Aleppo and Smyrna, having traveled to Asia Minor by way of Persia and the Caspian.

The most important constituent of this drug, giving it its purgative properties and its yellow colour, is chrysarobin, formerly known as rhein or chrysophan. The rhubarb of commerce also contains chrysophanic acid, a dioxymethyl anthraquinone of which chrysarobin is a reduction product.

Nearly 40% of the drug consists of calcium oxalate, which gives it the characteristic grittiness. There is also present rheotannic acid, which is of some practical importance. There are numerous other constituents, such as emodin, mucilage, resins, rheumic acid, aporrhetin. etc.

Vegetable.—The vegetable rhubarb (Rheum *rhaponticum*), also called pieplant (family Polygonaceae), is a hardy Asiatic

perennial grown for its large, succulent leafstalks. The plant produces large clumps of enormous leaves, up to two feet across, on proportionately large petioles or leafstalks—an inch or more in diameter and up to two feet or more in length—that arise from a shortened underground stem. These huge leaves arise early in the spring; later in the season a large central flower stalk may appear and bear numerous small greenish-white flowers and three-angled or winged fruits containing one seed. The plant is best adapted to the cooler parts of the temperate zones; the roots are quite hardy to cold although the tops are killed in autumn.

J. HORACE MCFARLAND COMPANY

RHUBARB (RHEUM RHAPONTICUM) IN FLOWER

Rhubarb seed does not produce plants true to the variety that bears them; therefore it is propagated by dividing the perennial "crown" into pieces each consisting of a root piece and a bud. These are set in the field about four or five feet apart each way. The large crowns are sometimes moved into forcing houses in late winter for producing the leafstalks under artificial heat. and in subdued light. A greenhouse is not necessary. Only the fleshy leafstalks are eaten: they are highly acid and contain considerable amounts of oxalates. The leaves should never be eaten since they are sometimes poisonous.

(J. M. BL.)

RHUS: *see* SMOKETREE; SUMACH.

RHYL, a seaside town and urban district in the West Flintshire parliamentary division of Flintshire, north Wales. 18 mi. W.N.W. of Flint by road. Pop. (1951) 18.868. Area 2.7 sq.mi. It lies on a sandy coast near the mouth of the Clwyd and was originally a fishing village with a little coastal trade. Many people on vacation visit Rhyl in summer.

RHYME, more correctly spelled rime, from Provençal word *rim* (its customary English spelling is the result of a confusion with *rhythm*), a literary ornament or device consisting of an identity of sound in the terminal syllables of two or more words. In the art of versification it signifies the repetition of a sound at the end of tn-o or more lines in a single composition. This artifice was practically unknown to the ancients, and. n-hen it occurs, or seems to occur. in the works of classic Greek and Latin poets, it must be considered to be accidental. Conscious rhyme came later. The name given to lines with an intentional rhyme in the middle is *leonine verse,* the invention being attributed to a probably apocryphal monk Leoninus or Leonius, who is supposed to be the author of a history of the Old Testament preserved in the Bibliothèque Nationale of Paris. This '.history!' is composed in Latin verses, all of which rhyme in the centre. Modern criticism has been inclined to look upon the African church Latin of the age of Tertullian as the starting point of modern rhyme, and it is probable that the ingenuities of priests, invented to aid worshippers in hearing and singing long pieces of Latin verse in the ritual of the Catholic Church. produced the earliest conscious poems in rhyme. It is certain that by the 4th century a school of rhymed sacred poetry had come into existence, classical examples of which we still possess in the "Stabat Mater" and the "Dies Irae." In the course of the middle ages, alliteration, assonance and end-rhyme held the field without a rival in vernacular poetry. After the 14th century. in the north of Europe, and indeed everynhere except in Spain. where assonance held a powerful position. end-rhyme became universal and formed a distinctive indication of metrical construction.

It was not until the invention of blank verse (*q.v.*) that rhyme found a modern rival. Certain forms of poetry are almost inconceivable without rhyme, though efforts have been made to compose even rhymeless sonnets. In the heyday of Elizabethan literature a serious attempt was made in England to reject rhyme altogether, and to return to the quantitative measures of the ancients: The prime mover in this heresy was a pedantic grammarian of Cambridge. Gabriel Harvey (1j45?–1630). For a short time he actually seduced no less melodious a poet than Edmund Spenser to abandon rhyme and adopt a system of accented hexameters and trimeters.

From 1576 to 1579 the genius of Spenser seems to have been obscured by this error of taste. but he shook it off completely when he composed The *Shepherd's Calendar.* Thomas Campion, in a tract published in 1602, advocated the omission of rhyme from lyrical poetry. By dint of a prodigious effort, he produced some unrhymed odes, which were not without charm, but the best critics of the time, such as Daniel, repudiated the innovation.

In Germany a determined attack on rhyme was made early in the 17th century. particularly by a group of aesthetic critics in the Swiss universities. G. Lessing recalled the German poets to a sense of the beauty and value of rhyme, but the popularity of F. Klopstock and his imitators continued to exercise a great influence. Goethe and Schiller. without abandoning rhyme, permitted themselves a great liberty in the employment of unrhymed measures and in imitation of classic metres. This was carried to greater lengths by A. Platen-Hallermund and H. Heine, the rhymeless rhythm of the last of whom was imitated in English verse by Matthew Arnold and others. In France. on the other hand, the empire of rhyme has always been triumphant. and in French literature the idea of rhymeless verse could till recently scarcely be said to exist.

In Italian literature the excessive abundance and facility of rhyme has led to a rebellion against its use. It was the influence of German aesthetics which forced upon the notice of G. Leopardi the possibility of introducing rhymeless lyrical measures into Italian verse. an innovation which he carried out with remarkable hardihood and success. The rhymeless odes of G. Carducci are also worthy of admiration. At the close of the 19th century, particularly in France, where the rules of rhyme had been most rigid, an effort was made to modify and minimize the restraints of rhyme.

The laws of rhyme, like other artificial regulations. may be too severe, but there is no evidence that the natural beauty which pure rhyme introduces into poetry is losing its hold on the human ear or is in any real danger of being superseded by accent, assonance, or rhythm.

See J. B. Schutze, *Versuch einer Theorie des Reimes nach Inhalt und Form* (Magdeburg, 1802); J. Minor. *Neuhochdeutsche Metrik* (Strasbourg, *1893);* J. B. Mayer, *A Handbook of Modern English Metre* (1903); Eaerton Smith, *The Principles of English Metre* (Oxford, 1923); Henry Lanz, *The Physical Basis of Rime* (1931).

RHYMNEY, an urban district in the northwestern corner of Monmouthshire. Eng.. and in the Ebbw Vale parliamentary division. 23 mi. N.N.W. of Cardiff by road. Pop. (1951) 9,137. Area 4.1 sq.mi. It comprises Rhymney and Abertysswg. It was one of the earliest and most prosperous centres of the south Wales iron industrv.

The principal industries are now brewing, light engineering and clothing manufacture. and many of the inhabitants work in nearby collieries

RHYOLITE, the volcanic, mostly effusive, equivalent of granite, takes its name from the Greek word for torrent or stream because of the frequency and variety of its fluxional textures. The term liparite, from the Lipari Islands of Italy, originally proposed for the same rocks, was subsequently restricted to porphyritic varieties and is rarely used.

The glassy rhyolites include obsidian, pitchstone, perlite and pumice, though microscopic examination sometimes shows that pumices are actually ash flows and thus better designated as tuffs.

At atmospheric pressure granitic liquid above its melting point is exceedingly viscous. Cooled rapidly, as when extruded from a volcanic vent. it tends to chill to a glass rather than crystallize, as under plutonic conditions. The glassy or partly glassy rocks so formed are metastable, however, and devitrify into minutely crystalline, frequently spherulitic or felted aggregates, in periods of time that are relatively short by geological standards. Hence pre-Tertiary rhyolites which were originally true glasses almost invariably display one of the vitrophyric, stony or felsitic textures

characteristic of devitrification. The glasses are also especially susceptible to hydrothermal alteration and weathering.

Most rhyolites are porphyritic, indicating that crystallization had begun prior to extrusion. Indeed, intratelluric crystallization may sometimes continue until the rock consists largely of phenocrysts at the time of extrusion, and the amount of microcrystalline matrix in the final product may then be so small as to escape detection except under the microscope. Such rocks (nevadites) are easily taken for granite in hand specimens.

In most rhyolites, however, the period of intratelluric crystallization is relatively short, so that the rock consists largely of a microcrystalline or partly glassy matrix in which are set a few per cent of phenocrysts. The matrix is sometimes micropegmatitic or granophyric.

Composition. — Except for occasional gross enrichment in silica, usually due to hydrothermal alteration, the chemical composition of rhyolite is very like that of granite (*q.v.*). There can be little doubt of the equivalence, and this is perhaps the strongest single reason for supposing that at least some and probably most granites are of magmatic origin.

The phenocrysts of rhyolite may include quartz, alkali-feldspar, oligoclase, biotite, amphibole or pyroxene, and the rules governing the coexistence of the different species are similar to those obtaining in granite. Thus, if an alkali-pyroxene or alkali amphibole is the principal dark mineral, oligoclase will be rare or absent and the feldspar phenocrysts will consist largely or entirely of alkali-feldspar. Rocks of this sort. for which the names comendite and pantellerite have been proposed (the latter has priority), are the volcanic equivalents of the alkali-granites.

If both oligoclase and alkali-feldspar are prominent among the phenocrysts the dominant dark silicate will be biotite, and neither amphibole nor pyroxene, if present, will be an alkaline variety. Such lavas, the quartz porphyries or "true" rhyolites of most classifications, are the volcanic equivalents of the two-feldspar granites.

Certain differences between rhyolite and granite should not be glossed over. Muscovite, a common mineral in granite, occurs very rarely and only as an alteration product in rhyolite. In most granites the alkali-feldspar is a soda-poor microcline or microcline-perthite. In most rhyolites the alkali-feldspar is sanidine, thought to be a high-temperature form, and not infrequently rich in soda.

A great excess of potassium oxide, K_2O, over sodium oxide, Na_2O, is uncommon in granite except as a consequence of hydrothermal alteration; it is not uncommon in rhyolites, and though it sometimes seems to be produced in the same way, this is by no means always the case.

Occurrence.—Rhyolites are known from all parts of the earth and of all geologic ages, though the pre-Tertiary ones are ordinarily so devitrified or otherwise altered as to receive special names, viz., felsite, quartz-keratophyre, quartz-porphyry, etc. Obsidian is well developed in Yellowstone National park, Mont., and Mono craters, Calif. Perlite has been mined in New Mexico for lightweight cement aggregate; it also occurs in Yellowstone but the classic localities for it are in Hungary. Pitchstone, of particular interest as a rock glass containing several per cent of combined water, has been described from Meissen, Saxony; Boggabri, New South Wales, Austr.; Amba Barra, Aby.; Berufjord, Ice.; and numerous other localities, but is perhaps best known from Arran Island, Scot.

Pumice, a frozen emulsion of air and lava of rhyolitic composition, is likewise of world-wide occurrence; Mono lake, Calif., is a well-known North American locality. Porphyritic rhyolites showing every ratio of phenocrysts to matrix abound in Colorado and Nevada.

The pantellerites, essentially volcanic equivalents of the alkali-granites, are spectacularly developed on the island of Pantelleria, southwest of Sicily, but are common throughout the Mediterranean as well as in British East Africa, eastern Siberia, Indonesia and west Texas.

Plagioclase and biotite are rare or lacking as phenocrysts in these rocks and in many of them quartz phenocrysts are not common. Quartz is usually abundant in the groundmass, however, and the silica content is generally appropriate for a granite or quartz syenite. The ferromagnesians are alkali amphiboles and pyroxenes, cossyrite (evidently a titaniferous amphibole) and, occasionally, fayalite.

Fractional Crystallization Hypothesis. — It is known that granites are confined to continental areas and the association can hardly be fortuitous. Rhyolites are for the most part also confined to the continents or their immediate margins, but they are not entirely lacking elsewhere. Small quantities of rhyolite (or quartz trachyte) have been described from the Marquesas, Tonga, Hawaii, Gambier, Eastern Samoa, St. Helena and Ascension, all genuine oceanic islands remote from any continental land-mass. There seems no way to explain such occurrences except as residual liquids from the fractional crystallization of basalt, and they are the clearest kind of evidence that granitic magma may indeed form in this fashion. Furthermore, on the continents proper and on continental islands, there is often a close and quite possibly genetic association between basalt, andesite and rhyolite. Sardinia and the Lipari Islands in the Mediterranean offer excellent examples of this association, as do Steens mountain and Newberry volcano in Oregon.

If the ratio of rhyolite to basalt in the oceanic islands is any criterion of the efficiency of the fractionation process, however, the derivation of the known or reasonably inferred volume of granite in the continents by this means would require an almost unimaginably immense volume of basaltic magma. Granting that this amount of basalt was available, and that it did indeed fractionate during cooling to yield granite magma, it must yet be explained why rhyolites should be so much less abundant than granites.

The derivation of granitic and rhyolitic magma by fractional crystallization of basalt is the most reasonable working hypothesis available; it is nothing more.

For additional information respecting the special characters and the occurrences and uses of the more important rhyolites see OBSIDIAN; PERLITE; PITCHSTONE; PUMICE. More detailed discussion of fractional crystallization will be found in PETROLOGY: Plutonic Complexes. See also GEOCHEMISTRY: Geochemistry of the Lithosphere: Crystallization of Magmas and Its Products.

(F. Cs.)

RHYS, SIR JOHN (1840–1915), Welsh philologist, was born near Ponterwyd, Cardiganshire, on June 21, 1840. After attending local schools, Rhys went to the Normal school at Bangor and then became a schoolteacher at Rhos-y-b61 (Anglesey). But in 1865 he was given a scholarship to attend Oxford, where he read Classics (B.A., 1869) at Jesus college, and was elected a Fellow of Merton college. On his own initiative he studied comparative philology during the summers at the Sorbonne, and at Heidelberg, Leipzig and Gottingen.

After a few years as inspector of schools for the counties of Flint and Denbigh, he became professor of Celtic at Oxford (1877–1915) and subsequently (1895) principal of Jesus college. He played an important part in the establishment of the university colleges at Cardiff and Bangor. His best work is in Welsh antiquities and philology, that on Gaulish inscriptions less satisfactory.

Rhys died on Dec. 17, 1915, at Oxford.

See *Proceedings* of ***the*** *British* ***Academy,*** xi, pp. 187–212 (bibliography) (1924–25). (J. WH.)

RHYTHM, a certain swing or balance in bodily movement, music, verse or prose; often extended by metaphor to apply in other spheres (*e.g.,* "rhythm of life"). The early critic of prosody, Aristoxenus (c. 320 B.c.), distinguished three elements in rhythm — the speech (lexis), the melody (melos) and the bodily motion (*kinesis* somatike); but the later tendency has been to separate these elements, and to emphasize more and more the distinction between them. Precision, however, has hardly yet been reached; and there are few subjects on which opinions, even among experts, differ more widely. In a short article it will be necessary to make controversial statements without defending them by argument.

Rhythm in Verse.—The line between rhythm and metre is hard to draw. Aristotle is very vague on the question: Suidas says that rhythm is the father of metre, and Quintilian that rliythm is male and metre female. Such sayings–merely prove the difficulty of measuring a delicate instinct by rule of three. It would appear, however, that to the Greeks metre was concerned with the measurements of poetic periods, and rhythm with their effective chanting or recitation; it cannot therefore have depended largely on *ictus* or stress, and the word is therefore often applied to prose as well as to verse. It is probable that, in a quantitative language like Greek, this stress (as it is in modern French) was far less strongly marked than (*e.g.*) in English; but it is a mistake to think it entirely absent, as, conversely, it is a mistake to think that in English, though accent is, of course, predominant, quantity is unimportant.

As Schipper says, "in English long and short syllables have no constant length, no constant relation; they depend on the context. They do not *determine* rhythm, but they help to *regulate* it." No rigid laws, therefore, can be laid down as to the proper employment of rhythmic balance. A subtle *feeling* must govern the periodic progress of sounds in harmony with the emotions it is desired to express. When the ear is satisfied, we feel that the rhythm is adequate; and a very brief study will show us that the ear demands different rhythms for an expression of different emotions. The genius of the poet is, on this side, revealed by the unforced skill with which he selects the appropriate rhythm. Ecstasy, *e.g*, takes a quick, eager, rising movement; sadness is full, slow and emphatic; meditation deliberate; mystery and suspense are faint, languorous and throbbing; often, indeed, the rhythm is so intimately linked with human feeling that no analysis can disentangle them.

Pauses, again, are an almost essential element in modern rhythm. In Shakespeare and Milton, *e.g.*, a pause may take the place of a whole beat; and the right use of such pauses often lends a variety which increases the beauty of a passage. Still more important is what has been called the "free musical paragraph," of which Milton, in *Paradise Lost,* is so consummate a master. Here the balance, overstepping the limits of the verse-form, and felt over wide spaces, is perhaps the chief glory of the poet's style; and the skill with which one "paragraph" is set against another forms, so to speak, a larger rhythm containing and holding up the smaller rhythms of the single paragraphs and of the verse-form. In rhymed verse this larger rhythm is represented by the progression of the stanza in itself, and by the linking of the stanzas into harmonious wholes. Thus in the full meaning of the term, rhythm depends at least as much on the orderly arrangement of the thought as on the balance of the words.

Rhythm in Prose.—We perceive then that there is a rhythm in prose no less than in verse; and this appears not only in the balance of the sentence, but in the arrangement of the sentences in paragraphs and in the building up of paragraphs into chapters. Here, as in everything else, the art must be concealed. A mechanical, epigrammatic balance, like that of Johnson, is too obvious, and ere long tends to weary. The truly rhythmic prose-writer satisfies at once the ear and the mind as a skilled dancer satisfies at once the ear and the eye, without drawing attention to the means by which the effect is attained.

On the special laws of rhythm in the poetry of different nations—Greek, Hebrew, Old English, and the like—it is impossible to speak here; the works of scholars should be studied.

RHYTHM IN MUSIC

Like all artistic categories musical rhythm must be studied historically, to avoid Philistinism towards the rhythms of early periods. But the musical rhythms of the 18th and 19th centuries are so much more familiar to us than any others, and so radically different from speech-rhythms, that we shall do well to analyse them first. Their true relation to speech-rhythms will then become much clearer, and the study of older rhythms will be greatly simplified.

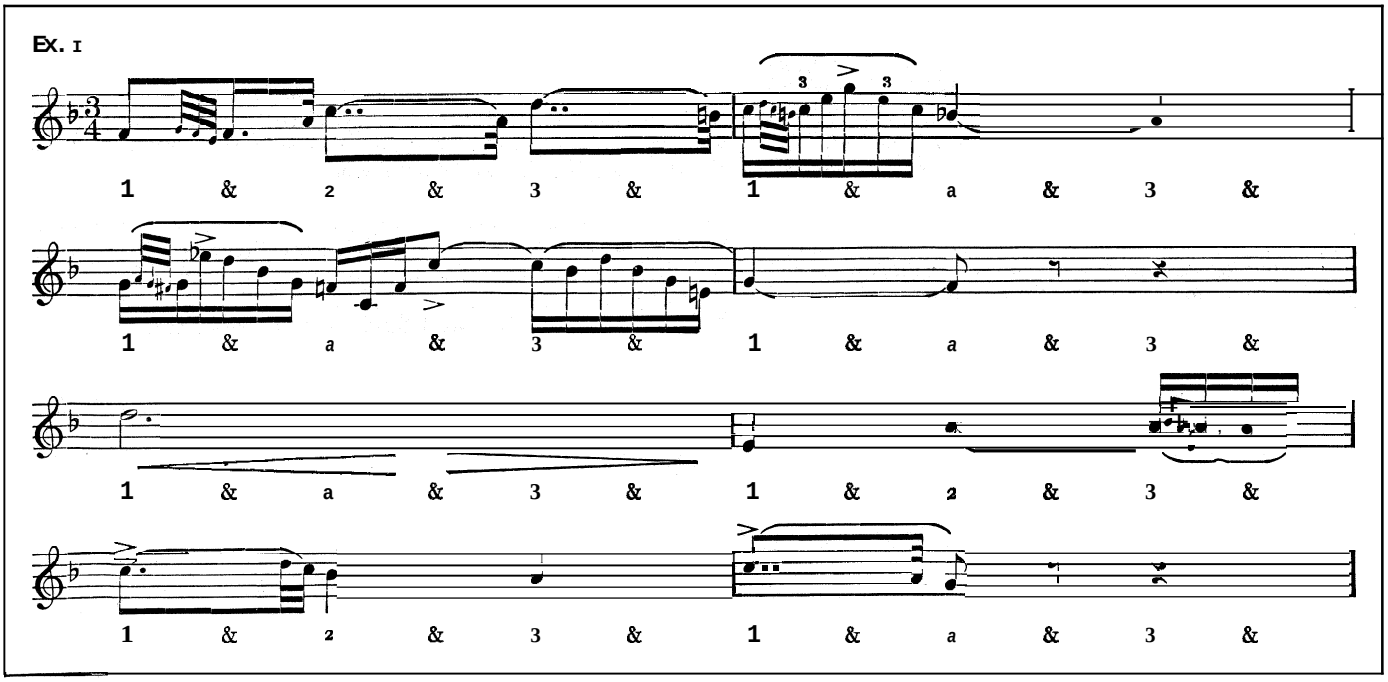
1. Body-rhythm and Speech-rhythm.— These are two prehistoric elements in musical rhythm; and in modern music they are in equipoise, though apart from music they are incompatible. Dance-rhythm is too narrow a term for the one, and speech-rhythm is a satisfactory term for the other. We may coin the term body-rhythm as giving the necessary extension to the notion of dance-rhythm. Musical body-rhythm, even in the slowest paces, is enormously stronger than anything known to prosody. It is no exaggeration to say that it is as strong as the pace of a horse. Not even Browning could have recited "How they brought the good news from Ghent to Aix" with comfort while riding a galloping horse; but Schubert's Characteristic Marches (op. 121) do not merely imitate that pace but go far to stimulate it if played to a body of cavalry. Gentler rhythms may be less immediately understood, but, once grasped, are not more easily changed. The music must brace itself up for any abrupt change of its fundamental rhythm. But that fundamental rhythm may be very slow and lie very deep.

In the example on p. 274 (Ex. 1), Haydn uses an underlying rhythm of thrice two beats. The beat is a quaver, for which one second is not too slow a tempo for this particular composition. Its whole group of six beats is invariably $3 \div 2$ and never $2 \div 3$. In this kind of music change from the one division to the other would be impossible without either violence or vagueness; unless it were a permanent change of metre. So important is the notion of $3 \div 2$ that it is not counted as 6 at all, but as 1 & 2 & 3, etc. Of these beats the first bears the chief stress, the second and third bear less, and there is no rule to give either more stress than the other. We are not, at present, considering the case of three beats quick enough to mark the rhythm without subdivision. Obviously the subdivisions (counted by "&") have no accent, except in relation to their own further subdivisions. Musical rhythms are measured from accent to accent; and of pairs of accents the first is stronger than the second. In larger groups, if the rhythm is binary the third accent will be stronger than the second, but not as strong as the first or fifth. At a very quick pace the difference of strength between the first accent and the fifth may become perceptible, but the rhythm would be inartistically stiff if such distinctions were not soon obliterated.

Triple rhythm, whether slow and subdivided or quick and undivided, also falls readily into larger binary periods with the same relative strengths of accent. There is nothing to prevent it from falling into ternary periods, but the mind ceases to apprehend a high power of three rhythmically, for we cannot know that the third period of a slow group is not the first of a new pair.

On these data it is now possible to analyse the rhythm of Ex. 1. It begins on the main accent, with no anacrusis. Between the first and second quaver beats there is a group of grace-notes. In actual time these should come on the second quaver and reduce the length of the second main note instead of that of the first, but they have no accent, and the second main note has its due stress and is not noticed to have arrived late, even if the grace-notes have been taken with some deliberation. They are like the consonants in the word *three:* it is easy to pronounce the word at a given moment, and nobody thinks of dividing it as thr-ee, though the consonants really take an appreciable time.

During the second bar of six beats the accompaniment (not given here) takes its cue from the melody and divides the quaver-beats by 3 (and the crotchets by 6). This motion thereafter pervades the whole composition, sometimes in the melody, and



always in the accompaniment, except when the whole orchestra pauses. These triplet semiquavers become equivalent to the average length of syllables in speech-rhythm, and the mind automatically measures all pauses by them. Besides the indeterminate grace-notes there are definite shorter values.

No rhythm in poetry or prose ever contemplated giving one syllable seven times the length of another, as we see in the double-dotted quavers with their complementary demisemiquavers. But in the fifth bar we have the whole six beats occupied by one sustained note, eighteen times the length of the average syllable. Yet so cogent is the body-rhythm of these long and complex bars that a deviation from the symmetry of an 8-bar period is permissible only when a change of key introduces new topics, as happens immediately after this quotation. But this will lead us to the separate topic of *phrasing.* Irregularities in the lengths of the bars themselves would be quite impossible, except in the case of a dramatic or final pause. Haydn has one opportunity for a dramatic pause in the course of the movement, yet he does not leave it at that, but expands it to two entire normal bars filled with organized rhythms.

Musical rhythm is not often as ornate as this, nor is this elaboration capable of much contrast or development, but the example at once carries us far away from the rhythms of poetry and includes all the musical principles so far mentioned. From it we can move a step nearer towards considering the simple relations between musical and poetic rhythm.

The technical terms of prosody are of no use here, with the solitary exception of the word anacrusis, which may be generalized to mean anything that happens before the first principal accent. When Rockstro tells us that "the theme of Weber's Rondo brillante in E flat (op. 62) is in Anapaestic Tetrameter Brachycatalectic, very rigidly maintained," this tells us less about the music than Weber's brilliant theme tells us about these solemn terms. A more scientific idea of Weber's theme, and of the prosodic technicalities, may be obtained from the following paradigm, to be recited *prestissimo.* Each dash at the end of the line represents a quarter of a beat.

Prestissimo.

Diddle | dum diddledum diddledurn diddledurn diddle | durn diddledum diddledum:— —
1 & 2 & I & & 2 &

Diddle | dum diddledurn diddledurn diddledurn diddle | durn diddledurn diddledum:— —
1 & 2 & I & & 2 &

After which Weber ceases to maintain his anapaestic-etcetera so rigidly, and proceeds for two lines with:—

Diddle | diddle diddle diddle diddle diddle diddle durn dum | durn durn durn durn Di do
1 & 2 & & 1 & & 2

Such rapid rhythms at once remind us of Aristophanes or Gilbert, though they can move faster than syllables can be pronounced. If they coalesce into uniformity for a long period (e.g., *diddle-diddle* for several bars without a single *durn)* they cease to resemble speech-rhythm and subside into vibration, unless melodic interest sets up larger rhythms by illuminating a peak here and there. A common defect in second-rate music is the composer's failure to know when his quick motion has settled down into mere vibration.

2. Time.—The body-rhythm underlying Weber's Rondo brillante is an unchangeable binary rhythm, counted (as the paradigm shows) in a slow two or a quick four. Classical music uses only binary and ternary times, which, so long as vertebrate anatomy continues to develop with bilateral symmetry, are the only ones that yield a strong body-rhythm naturally, the elements of triple time giving just enough resistance to be overcome by a pleasant compromise.

The kinds of time, *i.e.,* of invariable rhythmic molecules underlying each continuous piece of music, are classed not only as *duple* and *triple* but also as *simple* and *compound.* Compound time is the result of dividing simple time by three. Division by two is ignored: thus the evidently highly compound time of Ex. 1 is reckoned as simple triple time. All beats are reckoned as binary divisions and subdivisions of the modern standard note, the semibreve: the time-signature given at the beginning of a composition is a fraction, with a numerator showing the number of beats in a bar, and a denominator showing the size of the beat. Thus $\frac{3}{4}$ signifies three crotchets (quarters) in a bar. Compound time does not indicate the main beats at all, but counts the smaller beats as normal fractions of the semibreve. The main beats are written as *dotted* notes, in which the dot lengthens the note by one half. Accordingly $\frac{6}{8}$ is the compound time of two dotted crotchets divided by three quavers; $\frac{9}{8}$ is that of three dotted crotchets: $\frac{12}{8}$ of four. When the division by three is only local, *triplets* are used. Triplets are groups of three equal notes crowded into the time of two.

Binary and ternary subdivision answers every ordinary purpose of musical rhythm, being capable of expressing distinctions far more subtle than have ever been regulated in speech. It is impossible to pronounce a syllable in less than a tenth of a second; but it is easy to play 16 notes in a second on the pianoforte. In such rapid notes a single break twice in a second would have an effect directly measured by the ear. If the broken series were

levelled into an even series of fourteen notesasecond, the rhythmic effect would be appreciably different, though the actual difference of pace would be only $\frac{1}{56}$ of a second.

The special sign for triplets is readily adapted to other subdivisions. In most cases such adaptation is not meant to produce abstruse rhythms, but to secure an effect of free declamation. Freedom is as necessary in music as it is in speech; but fine playing, whether in obvious *tempo rubato* or in apparent strictness, bases this freedom on the superlative accuracy of good rhythmic notation.

3. Tempo.—The time-signature tells us nothing about the pace of the music, for the choice of the denominator is determined by a tangle of historic associations, so that $ may mean (as in Beethoven's C minor concerto) the slowest movement ever written, and $\frac{3}{4}$ may be a scherzo-tempo in which only one beat in a bar is countable.

The sense of tempo is a larger aspect of the body-rhythm, and in classical music it is very steady. A fundamental law of all musical rhythm is that a hurrying or slackening of tempo has no power to alter the rhythmic organization. If your phrase is too short a *ritardando* will not make it aesthetically any the longer; nor will an *accelerando* get rid of a redundant bar. On the contrary, it is crowded detail that will best profit by slackening, and loose-knit passages that have most to gain by an unobtrusive mending of the pace.

The genuine *tempo rubato* is, as its name implies, a rhythmic robbing of Peter to pay Paul. Chopin said that his left hand conducted in strict time while his right declaimed freely. The truth is that sound is as full of illusions as sight. One such illusion has already been illustrated by the grace-notes of Ex. 1, and other illusions are of much the same kind. The tick of metronome measures average time-intervals; and if it is set to measure a naturally rhythmic performance it will seem to hustle the player in some passages and to drag upon him in others, however carefully we select its pace.

In the classics from Bach to Brahms a movement may give more legitimate scope for *tempo rubato* than some purists care to admit, but it will not drift from one tempo to a radically different tempo, unless towards the end, or as evidence of imminent break-up. The gradual drift from one tempo to another first becomes something better than a weakness when the whole nature of musical movement becomes capable of continuity over hours, as in Wagnerian opera. Then, and not before, can we view one and the same tempo from opposite directions. Thus, in *Tristan und Isolde* the last part of the love-duet in the second act is a quick movement in $\frac{2}{2}$ time. Isolde's *Liebestod* ends the opera with an exact recapitulation of this (differing only in the voice part and absolutely unaltered in the orchestra) in rather slow $\frac{4}{4}$ time. By metronome the two tempi should be identical, though the impulse in the duet is energetic and that of the *Liebestod* reposeful. Wagner merely feels that the broader notation better suits Isolde's dying vision; and the listener, who may know and care nothing about the notation, agrees with Wagner.

Ex. 2

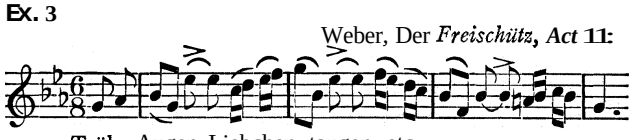
It is partly a question of accent and comes under the heading of phrasing.

4. **The** Rhythm of Classical Music in Relation to Poetry.—We can now return, furnished with new criteria, to the relation between musical and poetic rhythm. Even a simple musical setting of poetry will stretch the words in ways which speech does not normally admit. The naïve poet will unhesitatingly accept this as in the nature of singing. Only the half-baked musical *littérateur* objects, when Mozart makes Ottavio sing *Dalla sua pace la mia dipende* (Ex. 2) five times as slowly as any speaker could naturally utter the words, and then puts the top note and chief accent on the unimportant la. The poet would be glad to sing it that way if he could. It is quite good Italian prosody to give a nearly equal stress to *la* and *mia:* and the climax on *la* is more than counterbalanced by the fact that the important word *mia* falls on a harmonically sensitive note. The grammatical sense might have been clearer if a similar but slighter emphasis had been given to sua. But Ottavio is not giving instructions to a servant, but expressing his inmost feelings in solitude. Language does not base its emotional accents on logical analysis. Dr. Johnson corrected a clergyman for saying "Thou *shalt* not steal" instead of "Thou shalt *not* steal." If Johnson was right, how in the world did "shall not" ever become "shan't"?

The sensitive note on *mia* shows one of the four main degrees of freedom in musical accent. There is first the normal time-accent. Many critics of musical declamation seem to know no other forms of stress; but it can be completely eclipsed by putting the highest note of the melody elsewhere. The highest note can in its turn be eclipsed by the longest note. And in Ex. 2, both together are eclipsed by the most sensitive note. Moreover, and without recourse to anything so drastic as syncopation, the weakest note in the phrase may be given a special accent stronger than a main beat. This is beautifully shown in the third bar of Ex. 1, where the accented E♭, normally quite the weakest note in the bar, could certainly bear the chief syllable in a sentence if words for Haydn's wonderful rhythm could be found at all. Lastly, such a displaced accent may have a double meaning, the note retaining its original lightness in spite of its borrowed stress. Weber has been blamed for his bad declamation in the following famous passage:—

Ex. 3

Weber, Der *Freischütz*, Act 11:

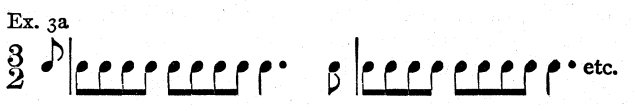


But, by your leave, this is a triumph of musical gesture. The lively Aennchen might even point a playful finger at the anxious Agathe with each false accent that Weber so explicitly marks. Meanwhile the orchestra corrects the declamation in waltz-rhythm.

By the interplay of these varieties of accent the strophic song, with the same tune to several stanzas, condemned as lazy and low by our prose critics of music, becomes, as Brahms always maintained, the highest achievement of a song-writer. The interplay does not annihilate right and wrong in declamation, nor does it prove that the classics are infallible; but it forms a musical technique as disciplined as prosody and as unlike prose. In such ways artistic factors reconcile their conflicts, and without such conflicts there is neither art nor life. Wagner and Wolf are perfect masters of a musical declamation that follows the rules of prose; but when we are told that there are no other rules, and that the classics from Bach to Brahms merely blundered insensitively, it is time to point out that musical rhythm cannot be learnt from a bell-metronome nor poetry from a pronouncing dictionary.

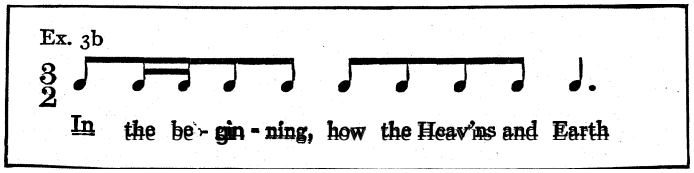
Let us now try a few experiments in setting blank verse to music. The first step will be to find a constant musical rhythm to represent the average line. This average rhythm will horrify the poetic ear if it is put forward as a specimen of blank verse, and probably if a line could be found that fitted it exactly that line would be a very ugly one. Still, the fact remains that the musician's average idea of blank verse is accurately represented by the following scheme, which represents two lines:

Ex. 3a



Now read the first paragraph of *Paradise Lost* rigidly to this scheme at the rate of two syllables to a metronome-beat of 80 to the minute. You will not satisfy the poet's ear; but you will find

that the lines accommodate themselves better to this than to any other uniformity; that extra syllables can be managed by grace-notes, and that the interval of two quavers between each line is a natural part of the scheme. We can proceed thus for eight lines, with rheumatic pains but not complete disaster. The imperative "Sing" is a heavy word to put into anacrusis, even of double length, and our three main beats must override many accents in lines that so often have four. Also the interlinear pause of two beats is irksome when the sense runs on. In the ninth line we must alter the scheme, for no anacrusis can digest any part of "In the beginning." So we must "invert" the first foot thus:—



But before we condemn the scheme let us see how far the torture is mitigated by merely adding musical rise and fall:—

Blank verse has been worse recited than this. The rigid musical timing proves uqexpectedly flexible already; and the rubato of a good singer can go far to improve it without becoming vulgar.

Now let us legalize the singer's rubato, and, without altering the two-quaver intervals between the lines, help the *enjambement* by a pianoforte accompaniment that makes the ear expect the resolution of a discord. Sensitive harmonies will further aid the rhythmic sense. The $\frac{3}{2}$ notation is now becoming troublesome; so that bars are divided into three and the lengths of the notes doubled. But the original $\frac{3}{2}$ scheme is nowhere violated. *(See* Ex. j.)

After this point any attempt to continue this literal interpretation of the metre would make the music drag hopelessly. Already the first two lines would be the better for running over the pause and doubling the pace of "that forbidden tree." But this would mean using two time-scales and would take us into free composition. The object of this illustration is not to show how these words ought to be set, nor to prove the very doubtful proposition that they are singable to any kind of music; but simply to bring out the most elementary relations between music and verse.

5. Phrasing. — The higher art of phrasing is chiefly observable in groups of very much simpler bars than those of our illustrations so far. Two facts, often ignored, must be realized before we can understand phrasing at all. First, music, being in time and not in space, is never apprehended in a *coup d'oeil,* but always in a momentary present connecting a remembered past with an imperfectly anticipated future. Consequently we miss half the aesthetic values of rhythm if we insist on knowing all about it from the first note. Rhythms have as much right to change their meaning while we listen to them as the cats of Wonderland have to grin; and "they all can and most of them do."

The second point is that the bar represents no fundamental rhythmic fact. It did not come into existence so long as music was printed only in parts. When music began to be printed with all the parts ranged legibly on one page, it was necessary to score the pile of parts with vertical strokes to range them in partitions and guide the eye. Hence the word *score,* and the French *partition* and German *Partitur.* The nascent body-rhythm grew stronger and gradually made it convenient that the bars should coincide with the groups indicated by the time-signature, and this gave rise (but only in recent times) to the delusion that the bar was the permanent unit. It is often obviously not so. When Mozart writes in moderate common time his phrasing is sure to make an odd number of half-bars somewhere so that a theme that originally lay on **1**, 2, 3, 4 now lies on 3, 4, **1**, 2. In such a case it is pedantic to say that the accent has changed and still more pedantic to blame Mozart for not either taking shorter bars throughout or changing to them according to the rhythm. If the half-bar displacement is really awkward Mozart will put it right, as when he rebarred the duet "Bei Männern welche Liebe fühlen" in *Die Zauberflöte.* But long bars imply delicate accents and these accents become no harder when the phrasing contracts.

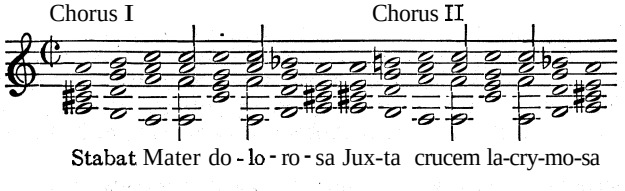
Beethoven writes his scherzos, and some very powerful other movements, in the shortest possible bars, and it is often difficult to tell whether the first of such bars is a main accent or an anacrusis. In the first movement of the C minor sonata (op. 10, No. 1) when we reach bar 22 it becomes manifest that bar g must have been in anacrusis; but we cannot have noticed that at the time, for when theorists go back to bar 1 and say that that initial bump was in anacrusis we can only smile. In three late works Beethoven helps the players by the words *Ritmo di tre battute* and *Ritmo di quattro battute.* The most famous of these passages is in the scherzo of the ninth symphony. Why did Beethoven not use there $\frac{6}{4}$ or $\frac{12}{4}$ bars so that his *ritmo di tre battute* became self-evident as a change to $? Because if you wish to ride this Pegasus you must please to rise on your stirrups once in Beethoven's bar, and not only once in 3 or 4. The change to 3-bar rhythm is obvious enough; but the return to 4 is not, as Grove said, effected by the drums, but comes where nobody can possibly detect it. And Beethoven, having helped the conductor at this point, is quite content, as in earlier works *passim,* that the listeners should gradually become aware that the 3-bar swing is no longer in being. In the trio, Beethoven wishing to indicate that 2 of its crotchets correspond to 3 of the scherzo, first wrote in $\frac{2}{4}$ time. But this made the lilt as unrecognizable as the true proportions of Iceland at the top of a map on Mercator's projection. So he changed it to alla-breve bars $\frac{2}{2}$.

The common sense of the whole matter is that hard accents and soft accents are equally liable in the long run to obliterate the distinction between the first and the third of four beats, and may go far to weaken that between the first and the second. We shall never find that Beethoven's short bars will fit any one interpretation throughout a piece, nor shall we often be able to fix the point at which the rhythmic angle is shifted. And when we have fixed everything some overlap will upset us or some extra bar make us hold our breath. Four-bar rhythm is more important to music than limericks are to literature, but the limerick is hardly more adequate or historically qualified to be taken as the fundamental basis for rhythm. And we must not take a lofty timeless view of rhythmic inequalities and changes. Farmer Giles is mistaken in the idea that the lady he finds sketching in the woods where you can't see round the corner would find a better subject on the top of a hill where you can see six counties.

Ex. 5

6. **Older Musical Rhythms.—In** measuring the distance between the musical rhythms, the most familiar to us and those of the 16th and earlier centuries, the first thing we must dismiss is our strong body-rhythm. Only the lightest ballets and fa-las of our great madrigalists have any such element. The greater part of the 16th century polyphony is held together by a time system which merely counts semibreves and settles whether the semibreve is to be *perfect* and equal to 3 minims or *imperfect* and equal to 2, and also whether three or only two semibreves are to go to a breve. The law of accent holds with pairs of minims about as strongly as in modern music, but it is already very much weakened with pairs of semibreves. Examine the first two lines of Palestrina's *Stabat Mater,* which is as wonderful in rhythm as it is in harmony.

Ex. 6

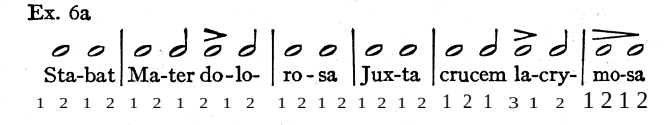


The music of the second line is identical with that of the first, and both lines are an exact quantitative rendering of the verses, with longs twice the size of shorts. The time signature tells us that the breve contains 2 semibreves and the semibreve two minims. Accordingly the modern editor draws bar strokes at regular breve-distances throughout the score. Then comes the modern choir master, warm from a rehearsal of ***Be*** Not *Afraid* in *Elijah,* and beats four in a bar, down, left, right, up, while the dutiful double choir sings

Sta-bat		Ma-ter			do	(sniff)		lo	ro	Sa	jux				
1		**1**	2	3	4	**1**		2	3 4	**1**	2	3	4		
Ta	cru	Cem	la	(sniff)	cry	mo	sa								
1	2 3 4	**1**		2	3	4	**1**	2 3 4							

But now let each singer, at a starting signal from the conductor, merely move one finger regularly up and down in minims, downward for accented beats and upward for unaccented. It will then be found perfectly easy to override these gentle accents whenever the sense dictates, and the choir will find itself declaiming the words beautifully.

Ex. 6a



If bars must be drawn let them come only where there is a normal accent. We must not put a bar line after *mater,* because this would come in the middle of a semibreve, or, as Morley calls it, a stroke.

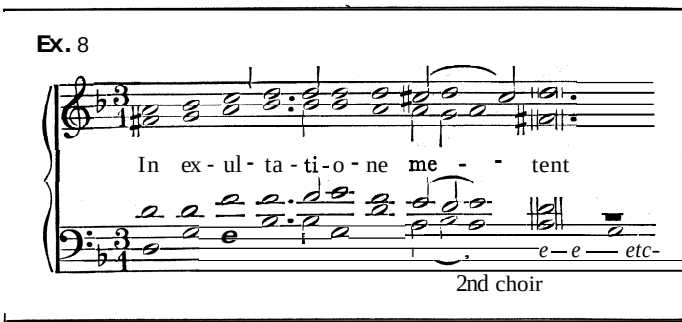
The examples of Victoria and Josquin given in the articles MASS and MUSIC are barred freely by these rules, but no such single scoring is adequate for an elaborate polyphony. Ex. 7 gives a passage from Victoria's *O quam gloriosum.*

From this we can see Victoria's Miltonic art of finishing a big paragraph.

The lower voices enjoy their own rhythms until the slow swing of the soprano draws the bass along with it. Then the alto joins. and the tenor is compelled to regard his own rhythm as a syncopation against this majority.

Little has been said so far about syncopation, and little now remains to be said. Its main point, even in the 16th century, as Ex. 7 shows, is that it requires a strong body-rhythm to contradict. A common fallacy of self-centred composers is to write syncopations that never encounter opposition at all. We must not confuse this with the legitimate case of a rhythm the meaning of which first appears later in the course of the music, nor with the case of an intentional vagueness. Nor, to return to the 16th century, must we put the unanimous speech-rhythm syncopations of Ex. 6 into the same category as those of the tenor at the end of Ex. 7.

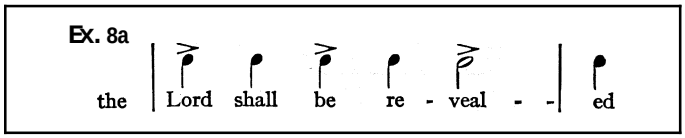
Ex. 8



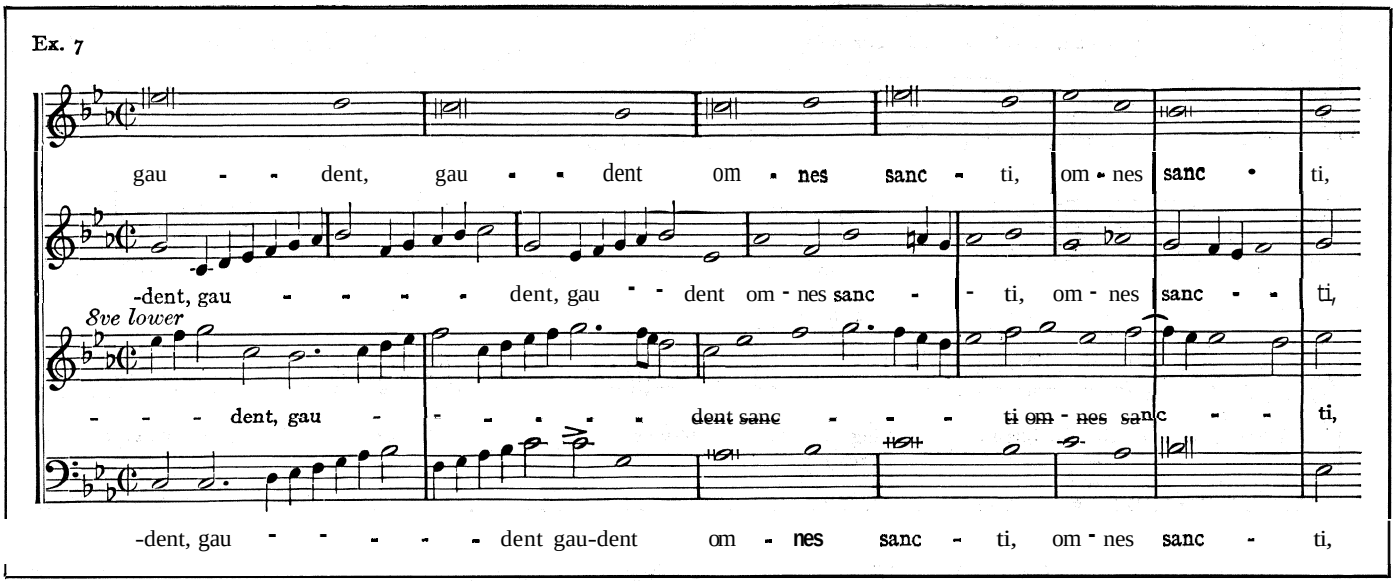
Triple time in the 16th century was very dilferent from what it is in music with a strong body-rhythm. For one thing, it continually obliterates the difference between 2÷3 and 3÷2, as in example 8 by Lasso.

This swing from 3 to a 3 twice as slow is called *hemiole* and survives as late as Bach and Handel. Thus, in the first chorus of The *Messiah* the hemiole which Handel always uses in triple time closes gives the cadential accentuation:

Ex. 8a



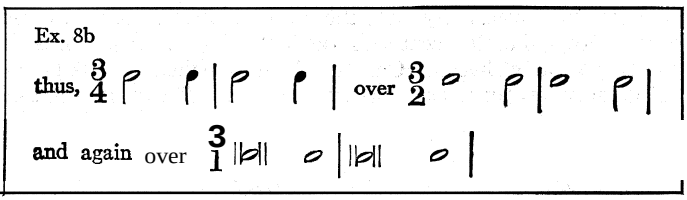
Ex. 7



The opposite swing from $ to $ with a curious bump in the last ( ) bar characterizes the French courantes of Couperin and Bach.

Before Palestrina we find in England a fairly steady slow triple time (3 divided by 2 or 4) in Tallis; but a little earlier we find Obrecht writing music which abounded in amazing complexities, such as three depths of triple rhythm:

Ex. 8b



The complexity is illusory, for the ear makes nothing of it, and the same is the case with the capacity of the ancient time system of mode, time and prolation to multiply triple rhythms up to 27 beats. The fact that the process was by multiplication shows at once that no real rhythmic effects are concerned, and that the system is only a device by which the long-suffering tenors may count out the enormous notes of some unrecognizable *canto fermo.* If we want genuine highly compound times we must leave these multiplication tables and study the last movement of Beethoven's sonata Op. 111, where the theme and first variation are in triple time divided by 3 ($\frac{9}{16}$); the second variation divides the half-beat by 3, producing &$ (which Beethoven misnames &); the

third variation divides the quarter-beats, producing $\frac{36}{64}$ (misnamed $\frac{12}{32}$); and the fourth variation returns to $\frac{9}{16}$ time and divides it by a uniform triplet vibration of 27 notes to a bar, afterwards surmounted by the unmeasured vibration of a trill. All this is sublime in its cogent clearness.

Genuine complexity was achieved by Palestrina in the second Kyrie of his *Missa* "L'homme armé," a work as beautiful as it is ingenious. But Mozart achieved something unsurpassed in the ballroom scene in *Don Giovanni,* putting his vigorous body-rhythms to the supreme test of making the characters actually dance and pass remarks in them.

7. **Recent** Rhythmic Developments. — Rhythms other than binary and ternary cannot develop a very strong ictus, though Holst manages in the ballet of *The Perfect Fool* to make some good dance-rhythms of $\frac{7}{8}$. But they tend to flow like speech-rhythms, and they are very reluctant to change their pattern. A rhythm of 5 falls into either 3+2 or 2+3. The famous 5-time movement in Tschaikowsky's *Pathetic* symphony is 2+3 and is in absolutely square 8-bar rhythm throughout. Again g-time will be some form of 4 and 3, or will suggest 8 with a beat clipped. Ravel, in his pianoforte trio, showed that it is possible to divide 8 into 3+2+3 so inveterately that no listener can possibly hear it as 4+4. The effect is excellent, and other versions of it are used in a much quicker tempo and with more variety by Holst in his Fugal Overture. But we must call things by their right names and not say that a thing is complex when it clings like grim death to its one pattern and falls into phrases of 2+2 for pages together.

The *Pantoum* of Ravel's trio blends an impish $\frac{3}{4}$ with a sanctimonious $\frac{4}{2}$ very amusingly. An early pianoforte sonata by Cyril Scott attempts to get away from all regularities. Its 13s and 3s do not always succeed in avoiding straightening out into plain 16=4×4; and when successful are conscientious rather than impulsive. The rhythms of Greek tragedy, interpreted syllabically, are suggestive, and so are many oriental rhythms. But they are not body-rhythms; and it may be doubted whether any great increase in variety of strong body-rhythms is imminent at present.

(D. F. T.)

RHYTINA: see SEA COW.

RIAL. The monetary unit of Persia (Iran), which has a paper currency mainly. There are notes of 5, 10, 20, 50, 100, 500 and 1,000 rials issued by the Bank Melli Iran and subsidiary coins of copper and bronze for 5, 10 and 50 dinars (1 rial= 100 dinars). Authority was given in Dec. 1943 for the minting of 1, 2, 5 and 10 rial coins from an alloy containing 60% silver and 40% copper. Fixed rates of exchange are maintained by virtue of the foreign exchange control law of 1936. The sterling value of the rial in 1944 was slightly under *2d.*, the rate of exchange being fixed at 128–130 in accordance with the currency law of Nov. 19, 1942, which also provided for the retention of a 60% reserve of gold and silver against the first 3,500,000,000 rials in circulation and a reserve of 100% in gold or foreign exchange convertible into gold against any circulation in excess of this figure. The circulation on April 20, 1944, was 6,035,000,000 as compared with approximately 800,000,000 in the years 1936–38. (N. E. C.)

RIAZ PASHA (c. 1835–1911), Egyptian statesman, was born about 1835. He was discovered by Ismail Pasha, who made him one of his ministers. When Ismail's financial straits compelled him to agree to a commission of inquiry, Riaz was vice-president of the commission. He filled this office with distinction, but not to the liking of Ismail.

When Ismail attempted to resume autocratic rule, Riaz fled the country. Upon the deposition of Ismail (June 1879), Riaz was sent for by the British and French controllers, and he formed the first ministry under the khedive Tewfik. His administration was overthrown by the agitation which had for its figurehead Arabi Pasha (*q.v.*).

On Sept. 9, 1881, Riaz was dismissed and went to Europe, remaining until the fall of Arabi. He then accepted office as minister of the interior under Sherif Pasha. He wanted the immediate execution of Arabi and his associates; and when the British insisted on clemency to the leaders of the revolt, he resigned (Dec. 1882).

Riaz took no further part in public affairs until 1888 when, on the dismissal of Nubar Pasha (*q.v.*), he was summoned to form a government, remaining in office until May 1891. In Feb. 1892 he again became prime minister under Abbas II. In April 1894 he finally resigned office.

Riaz died on June 18, 1911.

RIBADENEIRA, PEDRO A. (1527–1611), hagiologist, was born at Toledo on Nov. 1, 1527. In Rome on Sept. 18, 1540, he was admitted by Ignatius Loyola as one of the Society of Jesus.

He pursued his studies at Paris (1542) in philosophy and theology. Loyola, in 1555, sent him on a mission to Belgium; in pursuance of it he visited England in 1558. In 1560 he was made provincial of the Society of Jesus in Tuscany. He was transferred as provincial to Sicily in 1563, was again employed in Flanders and from 1571 served in Spain. In 1574 he settled in Madrid, where he died on Sept. 10, 1611. His most important work is the *Life of Loyola* (1572). That Ribadeneira was, though an able, a very credulous writer, is shown by his lives of Loyola's successors Diego Laynez and St. Francis Borgia; and especially by his *Flos Sanctorum* (1599–1610), a collection of saints' lives, entirely superseded by the labours of the Bollandists.

See his autobiography in his *Bibliotheca Scriptorum Societatis Jesu* (1602 and 1608, supplemented by P. Alegambe and N. Sotwell in 1676); H. F. De Puy, *An Early Account of the Establishment of Jesuit Missions in America* (1921).

RIBAULT or **RIBAUT, JEAN** (*c.* 1520–1565), French navigator, was born at Dieppe, about 1520. Appointed by Admiral

Coligny to take French Protestants to America, Ribault sailed on Feb. 18, 1562, with two vessels, and on May 1 landed at Florida at St. John's river, or. as he called it. Rivière de Mai. Having settled his colonists at Port Royal harbour (now Paris Island, S.C.), and built Fort Charles for their protection, he returned to France. In 1563 he appears to have been in England and to have issued *True and Lust Discoverye of Florida* (Hakluyt Soc., vol. vii.). In April 1564 Coligny despatched another expedition under René de Laudonnière, but meanwhile Ribault's colony. destitute of supplies. revolted against their governor and attempted to make their way back to Europe in a boat which was happily picked up by an English vessel. In 1565 Ribault was again sent out to satisfy Coligny as to Laudonnikre's management of his new settlement, Fort Caroline. on the Rivière de Mai. While he mas still there the Spaniards attacked the French ships at the mouth of the river. Ribault set out to retaliate but his vessels mere wrecked near Matanzas Inlet and he had to return to Fort Caroline by land. The Spaniards by this time had slaughtered all the colonists except a few who got off with two ships under Ribault's son. Induced to surrender by false assurances. Ribault and his men were put to the sword in Oct. 1565.

RIBBONFISH: *see* OARFISH.

RIBBONS. By this name are designated narrow webs. commonly of silk or velvet. used primarily for binding and tying in connection with dress. but also applied for innumerable useful, ornamental and symbolical purposes. Along with that of tapes, fringes and other small wares. the manufacture of ribbons forms a special department of the textile industries.

RIBEIRO, BERNARDIM (*c.* 1482–1552), the father of bucolic prose and verse in Portugal. was a native of Torrão and the son of a treasurer in the household of the duke of Viseu. The details of Ribeiro's life are very uncertain. Between 1507 and 1512 he was a student in the faculty of law at the university, which was at that time in Lisbon. He later frequented the court of King Manuel where he won the friendship of the poet Sá de Miranda and perhaps fell in love with one of the court ladies, whose identity is unknown. In 1521 he probably went to Italy; it was there. perhaps. that he wrote his chivalric and pastoral romance. *Menina e Moça,* in which. it is thought. he may have related his own love story. personifying himself under the anagram of "Binmarder" and the lady under that of "Aonia."

On his return he was appointed secretary to Ring John III (1524). About 1540 he seems to have suffered some mental derangement and he died insane in Oct. 1552 in the hospital of Todos os Santos, Lisbon.

The *Menina e Moça* was first printed at Ferrara in 1554, together with six eclogues (including the eclogue *Crisfal* which may not be his) and some minor poems. A second edition appeared in Évora in 1557, containing a much longer version of the story but it is doubtful how much of this is Ribeiro's own work.

Modern editions are *Obras de Bernardim Ribciro e Cristovam Falcão* by A. Braamcamp Freire. 2 vol. (1923); *Obras Completas de Bernardim Ribeiro* by A. Ribeiro and M. Braga, 2 vol. (1949–50); and *Histdria de Menina e Moça* by D. E. Grockenberger (1947).

See A. Salgado Júnior, *A 'Menina e Moça' e o Romance Sentimental* (1940), a valuable critical study. (N. J. L.)

RIBERA, JUSEPE (José) **DE** (Lo SPAGNOLETTO) (1591–1652), Spanish painter and engraver who worked in Naples. Italy, was born at Játiva, near Valencia, but spent most of his life in Italy. where he was known as Lo Spagnoletto. Apart from his certificate of baptism (Feb. 17, 1591), there is no record of his life in Spain, though he is said by A. Palomino to have received his first training there under Francisco Ribalta. It is not known when he went to Italy but there is evidence that he worked as a young man in Parma and Rome. In 1616 he married in Naples, then under Spanish rule. where he was established during the rest of his life. In 1626 he signed as a member of the Roman Academy

ANDERSON

"THE MARTYRDOM OF ST. BARTHOLOMEW" BY RIBERA. IN THE PRADO. MADRID

of St. Luke and in 1631 as a knight of the Papal Order of Christ. He died in Naples on Sept. 2, 1652.

The whole of Ribera's surviving work appears to belong to the period after he settled in Naples. His very large production comprises mainly religious compositions with a number of classical and genre subjects and a few portraits. He did much work for the Spanish viceroys, by whom many of his paintings were sent to Spain. He was also employed by the church and had numerous private patrons of various nationalities. Whether or not he first studied painting in Spain, he became in Italy one of the chief followers of Caravaggio, who formed the Neapolitan school, and he is often referred to as a Neapolitan artist.

Ribera's earliest known painting is probably the "Crucifixion" (Colegiata. Osuna), presumed to have been made for the duke of Osuna. viceroy in 1616–20. From 1621 onward there are numerous signed, dated and documented works; some of the more important are: etchings of "St. Peter" and "St. Jerome" (1621); "St. Jerome" (1626. Hermitage. Leningrad). "Drunken Silenus" (1626, Naples museum), his earliest dated paintings; "Martyrdom of St. Andrew" (1628, Budapest!; "Archimedes" (1630. Prado museum. Madrid); "Portrait of a Bearded Woman" (1631. Lerma collection, Toledo); "Tityus" and "Ixion" (1632, Prado museum); "Immaculate Conception" (1635, Augustinian convent, Salamanca); "Pietà" and "Prophets" (1637–38), first commissions for the monastery of S. Martino. Naples; "Venus and Adonis" (1637, Galleria Nazionale. Rome); "Clubfooted Boy" (1642, Louvre. Paris); and "Holy Family" (1648. Metropolitan museum, New York). In 1651 he completed the "Institution of the Eucharist" (S. Martino, Naples), one of his last and most important works.

The chief elements of Ribera's style, tenebrism and naturalism, derived from Caravaggio, are used to emphasize the mental and physical suffering of penitent or martyred saints or tortured gods. Realistic detail. often horrific. is accentuated by means of coarse brush marks on thick pigment to represent wrinkles, beards, flesh wounds, etc. The influence of Bolognese and Venetian artists and probably of Velázquez, who visited Naples in 1630–31 and 1649–50, contributed to the more spacious settings, lighter tones: richer colours and more pleasing subjects which appear in Ribera's works after 1630; but he never entirely abandoned detailed realism or dramatic lighting. The objective realism of his portraits relates them to the early manner of Velázquez and to the school of Seville; while his figures of ancient philosophers in picaresque

guise are typically Spanish subjects which Ribera popularized in Italy and Spain.

Ribera had many pupils and followers in Naples. In Spain his works were widely copied and imitated and were one of the chief sources of Caravaggesque naturalism. He was one of the few Spanish artists to produce numerous drawings, which were also much imitated. His etchings as well as his paintings contributed to his European fame. Like other Spanish "naturalists" he was admired and studied by 19th-century French painters.

RIBES: *see* CURRANT.

RIBOT, ALEXANDRE FELIX JOSEPH (1842–1923), French prime minister, was born at Saint-Omer on Feb. 7, 1842. He practised at the bar and first entered the chamber of deputies in 1878, where he won eminence among the right-wing republicans opposed to the Radicals and followers of Léon Gambetta. He specialized in financial matters, serving as *rapporteur* of the budget in 1882 and opposing the credits sought by Jules Ferry for the Tongking expedition. In 1890 he joined the Charles de Freycinet ministry as minister of foreign affairs and kept that office under Emile Loubet (Feb.–Nov. 1892) and in his own ministry which succeeded Loubet's until its fall in March 1893. In these years he gave a fresh direction to French policy by the *rapprochement* with Russia which ripened into formal alliance by 1895. He formed his second ministry in Jan. 1895, and took also the ministry of finance. but it fell in October. In opposition until 1914, he attacked the anticlericalist policies of Emile Combes and tried to alleviate the severities of the separation of church from state in 1905. His tenures of office in 1914–17 were all at the ministry of finance, but in March 1917 he succeeded Aristide Briand as prime minister and minister of foreign affairs, and kept the latter post under Paul Painlevé until Oct. 1917. He brought to politics undoubted talents and patriotism, but the brevity of his periods in power prevented him from achieving much financial reform. He was a member of the Académie française and of the Académie des Sciences Morales et Politiques. He died in Paris on Jan. 13, 1923.

See **A. Ribot,** *Lettres à un anzi: Souvenirs de ma vie politique,* 5th ed. (1924; Eng trans. by H. Wilson, 1921). (D. TN.)

RIBOT, THÉODULE ARMAND (1839–1916), French psychologist, best known for his studies in the pathology of the brain and mind, was born at Guingamp, Côtes-du-Nord, on Dec. 18, 1839. He studied medicine in Paris and became director of the first French psychological laboratory at the College de France. He was early impressed by the physiological and biological theories of contemporary British associationists (notably Herbert Spencer and Alexander Bain) and by the experimental researches carried out by Wilhelm Wundt at the Leipzig laboratory. He first attracted attention by his work on mental inheritance (*L'Hérédité: étude psychologique,* 1869)—a problem to which English writers had recently drawn attention—and by his survey of British psychology (*La Psyclzologie anglaise contemporaine,* 1870). His studies in psychopathology, like nearly all his later writings, were almost at once translated into English (*Diseases of Memory,* 1881; *Diseases of the Will,* 1884; *Diseases of Personality,* 1891). All such disorders he regarded as the direct outcome of cerebral disturbances, which he interpreted in terms of gross lesions rather than of a disorganization of the minuter structures (nerve cells and their connections); *i.e.,* as organic rather than functional. In later life he turned to the study of normal mental processes (*The Psychology of Attention,* 1890; *The Psyclzology of Emotions,* 1897; *The Evolution of General Ideas,* 1889; *Essay on the Creative Imagination,* 1906). His systematic analyses of emotional states provided much of the material for the theories of "primary emotions" and "sentiments" subsequently developed by such British psychologists as William McDougall and **A.** F. Shand. Ribot died in Paris on Dec. 9, 1916. (CY. B.)

RICARDO, DAVID (1772–1823), English economist who systematized and gave classical form to the rising science of economics, was born in London on April 19, 1772, of Jewish origin. His father, who was of Dutch birth, was a successful member of the stock exchange. In 1786 Ricardo entered his father's office, where he showed much aptitude for business. After 1793, upon abandoning the Jewish faith for the Unitarian and marrying a Quaker, he was separated from his family for about eight years and was thrown upon his own resources. He continued as a member of the stock exchange, however, his talents and character winning him the support of an eminent banking house. He prospered immediately, and by 1815, when he prepared to retire from business, he had accumulated a large fortune. In 1819 he entered parliament as a member for Portarlington. There he made valuable speeches on economic questions and helped bring about a change in opinion respecting freedom of trade which eventuated in the legislation of Sir Robert Peel (*q.v.*) on that subject. Ricardo died on Sept. 11, 1823, at his estate in Gloucestershire.

His first communication on an economic subject appeared in 1809, a decade after a chance reading of Adam Smith's *Wealth of Nations* had diverted his attention largely from geology and mineralogy, which, along with mathematics and chemistry, had begun to interest him about 1797. His tract, *The High Price of Bullion, a Proof of the Depreciation of Bank Notes* (1810), gave a fresh stimulus to the controversy respecting the resumption of cash payments and indirectly led to the appointment of a committee of the house of commons, commonly known as the Bullion committee, to consider the question. The report of the committee confirmed Ricardo's views and recommended the repeal of the Bank Restriction act, but the house of commons declared that paper had undergone no depreciation.

In 1815, when the corn laws were under discussion, Ricardo published his *Essay on the Influence of a Low Price of Corn on the Profits of Stock,* directed against a tract by T. R. Malthus but based upon a theory of rent already stated by Malthus and James Anderson. In this essay are set forth the essential propositions of the Ricardian system. such as that an increase of wages does not raise prices; that profits can be raised only by a fall in wages and diminished only by a rise in wages; and that profits, in the whole progress of society, are determined by the cost of the production of the food which is raised at the greatest expense. These ideas were afterward incorporated in Ricardo's chief work *Principles of Political Economy and Taxation* (1817). In the field of the theory of banking and currency some of Ricardo's best work appears. His main ideas are expressed in three pamphlets: (1) *The High Price of Bullion* (1810), in which he discussed the available means of testing the value of paper money and the power of the Bank of England to regulate the supply; (2) *Proposals for an Economical and Secure Currency* (1816), in which he elucidates the quantity theory and pronounces in favour of a monometallic standard; and (3) the *Plan for a National Bank* (1824), which was, in fact, an indictment of the methods of the existing bank, particularly in connection with its issue of paper money. In an essay on the "Funding System" (1820), written for the 6th edition of the *Encyclopaedia Britannica,* Ricardo urged that nations defray their expenses, whether ordinary or extraordinary, at the time when they are incurred instead of providing for them by loans.

In the *Principles of Political Economy and Taxation,* Ricardo undertook "to determine the laws which regulate" the distribution, under free competition, of the "produce of the earth" among the "three classes of the community," namely, the landlords, the farmers and the agricultural labourers. He applied his findings more widely, however, and elaborated various other economic principles. He found that the relative domestic values of commodities are dominated, but not wholly determined in the longer run, by the quantities of labour required in their production, rent being eliminated from the costs of production. He concluded that profits vary inversely with wages which move with the cost of necessaries; and that rent tends to increase as population grows; rising as the marginal costs of cultivation rise. He supposed, following J. B. Say, that there was little tendency to unemployment. but remained apprehensive lest population grow too rapidly, depress wages to the subsistence level, and, by extending the margin of cultivation, reduce profits and check capital formation.

He concluded that trade between countries was not dominated by relative costs of production, but by differences in internal price structures which reflected the comparative advantages of the trading countries and made exchange desirable. He treated monetary questions and especially tax incidence at length.

In his exposition Ricardo usually made use of apposite hypothetical examples rather than of empirical data. While he built in part upon the work of Smith, he defined the scope of economics more narrowly than had Smith and included little explicit social philosophy. His views early won considerable support in England despite their abstract character and the many criticisms to which they were subjected. For this support Ricardo's two principal disciples were significantly responsible. J. R. M'Culloch, a voluminous writer and skilled propagator, was chosen to fill a lectureship on political economy commemorating Ricardo. James Mill, friend and political and editorial counselor to Ricardo. made of his son, John Stuart Mill, an able expounder and influential improver of the Ricardian system. Ricardo and the theories associated with his name have continued to command the critical attention of economists ever since.

His works and correspondence, in 10 vol., were edited by Piero Straffa for the Royal Economic society (1951–55). *Principles of Political Economy and Taxation* appeared in several editions, including Everyman's Library. Several of the minor works were edited by J. H. Hollander.

RICASOLI, BETTINO, BARON (1809–1880), Italian statesman, born at Broglio, March **19, 1809.** In **1847** he founded the journal *La Patria,* and sent to the grand duke of Tuscany a memorial suggesting remedies for the difficulties of the state. In **1848** he was for a short time gonfaloniere of Florence. As Tuscan minister of the interior in **1859** he promoted the union of Tuscany with Piedmont. Elected Italian deputy in **1861,** he succeeded Cavour in the premiership. As premier he admitted the Garibaldian volunteers to the regular army, revoked the decree of exile against Mazzini, and attempted reconciliation with the Vatican; but his efforts were rendered ineffectual by the *non possumus* of the pope. He found himself obliged in **1862** to resign office, but returned to power in **1866.** On this occasion he refused Napoleon III's offer to cede Venetia to Italy, on condition that Italy should abandon the Prussian alliance, and also refused the Prussian decoration of the Black Eagle because Lamarmora, author of the alliance, was not to receive it. After the French troops left Rome in **1866** he attempted to conciliate the Vatican with a convention, in virtue of which Italy would have restored to the Church the property of the suppressed religious orders in return for the gradual payment of **£24,000,000.** He conceded the *exequatur* to **45** bishops inimical to the Italian regime. The Vatican accepted his proposal, but the Italian Chamber proved refractory, and, though dissolved by Ricasoli, returned more hostile than before. Without waiting for a vote, Ricasoli resigned office. He died at Broglio on Oct. **23,** 1880. His private life and public career were marked by a rigid austerity which earned him the name of the "iron baron."

See Tabarrini and Gotti, *Lettere e documenti del barone Bettino Ricasoli,* 10 vol. (Florence, 1886–94); Passerini, *Genealogia e storia della famiglia Ricasoli* (1861); Gotti, *Vita del barone Bettino Ricasoli* (1894).

RICCATI, JACOPO FRANCESCO, COUNT (1676–1754), Italian mathematician, whose authority on all questions of practical science was deferred to by the senate of Venice. Born at Venice on May **28, 1676,** he died at Treviso on April 15, 1754. He studied at the University of Padua, where he graduated in **1696.** He corresponded with many of the European savants of his day. and contributed largely to the *Acta Eruditorum* of Leipzig. He was offered the presidency of the academy of science of St. Petersburg (Leningrad), but declined, preferring the leisure and independence of life in Italy. Riccati's name is best known in connection with his problem called Riccati's equation, published in the *Acta Eruditorum,* Sept. 1724. A very complete account of this equation and its various transformations was given by J. W. L. Glaisher in the *Philosophical Transactions* **(1881).**

His works were collected and published by his sons **(4** vol., 1758).

RICCI, CURBASTRO GREGORIO (1853–1925), Italian mathematician, celebrated for the discovery of the absolute differential, or Ricci calculus, was born at Lugo, Romagna, on Jan. 12, 1853. From **1880** until his death on Aug. **7, 1925,** he was professor at the University of Padua. His earliest work was in the fields of mathematical physics and differential equations. In **1887** appeared his first contribution to the subject, now known as the absolute differential, or Ricci calculus. Its origins are to be found in the differential geometry of G. F. B. Riemann, where it is necessary to study the behaviour of functions of partial derivatives in which the variables undergo transformation. First steps in the development of the appropriate technique of tensors had been taken by E. B. Christoffel, while important concepts had been introduced by E. Beltrami and R. O. S. Lipschitz (*q.v.*). But the systematic theory is due to Ricci (1887–96); significant extensions were later contributed by his pupil T. Levi-Civita. For some time the new calculus found few applications; when, however, Einstein came to formulate his theory of general relativity, Ricci's methods proved to be the natural tool. The impulse given by Einstein has resulted in an intensive study of differential geometry based on the tensor calculus. (L. R.)

RICCI, MATTEO (1552–1610), Italian Jesuit missionary who with Michael Ruggieri opened China to evangelization, was born at Macerata in the march of Ancona on Oct. **6,** 1552. After some education in his native town he went to study law at Rome (1568), where in 1571 he entered the Society of Jesus. He studied mathematics and geography under Clavius at the Roman college between 1572 and 1576, and in 1577, accompanied by others, he left for the Indies via Lisbon. He arrived in **1578** in Goa, where, after finishing his religious training. he taught in the college until **1582;** he was then called to Macao to prepare himself for the task in China.

It was only after Alessandro Valignani became visitor of the Jesuit missions in the far east that the opening of China to Christianity was really taken up, although fruitless efforts had been made since Francis Xavier (*q.v.*). First Michael Ruggieri and then, in **1582,** Ricci were summoned to Macao by Valignani for the undertaking. After various disappointments they established themselves at Ch'ao-ching, Kwangtung province, in Sept. **1583.** Though never forgetting the spiritual purpose of his mission, Ricci proceeded with circumspection and contented himself with exciting the interest of the Chinese, even the more educated, with clocks, maps, European paintings and books and his own vast erudition. When in **1589** the new viceroy of Kwangtung-Kwangsi forced the missionaries to leave, Ricci obtained permission to settle elsewhere in the province in compensation for selling the mission property at a lower price. The church at Shao-chou was constructed in Chinese style and the missionaries themselves, relinquishing the costume of the despised bonzes, adopted that of the litterati.

When after various misfortunes the occasion presented itself in **1595,** Ricci, in the company of a high official, set out to realize his own fondest plan to establish himself in Peking. Upon arrival in Nanking, however, he found that, because of Toyotomi Hideyoshi's invasion of Korea, all foreigners were suspect and that it would be unwise to continue northward; he therefore established a new residence in Nan-ch'ang, Kiangsi province. His second chance to go to Peking came in **1597** when an official of the tribunal of rites, Kuang by name, invited Ricci to accompany him and help him compose the calendar. After waiting for two months before the gates of Peking he had to return south, again because of the Sino-Japanese conflict in Korea. He settled in Nanking until **1600** when, accompanied by two confreres, he traveled north once more. Their entrance into Peking was delayed by the intrigues of the eunuch Ma T'ang, who tried to take possession of the presents brought for the Wan-li emperor. The emperor, however, having already heard about Ricci, granted permission to enter and to offer the presents on Jan. **25, 1601.** This event is recorded in the history of the Ming dynasty (Ming-shih).

They obtained a settlement with an allowance for subsistence in Peking, and from this time on to the end of his life Ricci's esti-

mation among the Chinese increased. Besides the missionary and scientific work, from 1jg6 he was also superior of the mission, which in 1605 numbered 17. Ricci died on May 11, 1610, and was granted a place for burial by imperial order.

Ricci's efforts to attract and convert the Chinese intelligentsia brought him into contact with many outstanding personalities, among them Hsu Kuang-ch'i, Li Chih-tsao and Yang T'ing-yun, who later became known as the "Three Pillars of the Early Catholic Church" in China and who assisted the missionaries. especially in their literary efforts. Ricci's literary efforts include about 20 works, mostly in Chinese, ranging from religious and scientific works to treatises on friendship and local memory. Probably the most famous of his works are the "Mappamondo" and the "True Idea of God."

Ricci's "accommodation method" was the foundation of the subsequent success obtained by the Roman Catholic Church in China. The unhappy rites controversy, however: which erupted shortly afterward brought the mission near ruin. Probably the name of no European of past centuries is so well known in China as that of Li Ma-tou (Ricci Matteo).

Hummel, *Eminent Chinese of the Ch'ing Period,* vol. i (1943), vol. ii (1944); Pasquale M. D'Elia, S.J., *Fonti Ricciane,* vol. i–iii (1942–49). (J. S. Ss.)

RICCIO (ANDREA BRIOSCO) (*c.* 1470–1532), Italian sculptor, was born at Padua about 1470 and died in 1532. Trained in the workshop of B. Bellano and active principally as a bronze sculptor, he executed the great paschal candlestick for S. Antonio at Padua (1507–1j) and the Girolamo della Torre monument in S. Fermo at Verona (1516–21). The bronze reliefs from the latter are now in the Louvre, Paris. The style and imagery of both works are strongly influenced by Paduan humanism. Riccio was also a prolific maker of bronze statuettes, for the most part of subjects from classical mythology. Unlike the statuettes of his contemporary Antico at Mantua, these are romantic in treatment. with marked individuality and expressive character. Outstanding examples are the "Boy Milking a Goat" in the Museo Nazionale, Florence, the "Warrior on Horseback" in the Victoria and Albert museum, London, and the "Arion" in the Louvre.

See L. Planiscig, *Andrea Riccio* (1927). (J. W. P.-H.)

RICCIO, DOMENICO (called IL BRUSASORCI) (c. 1516–1567), Italian painter of the Veronese school. pupil of Giovanni Francesco Caroto. He was a colourist, characterized by B. Berenson as "the first purely pictorial artist in Italy." His importance in art history is mainly the result of his being the predecessor of Paolo Veronese. There are pictures by him which resemble those of his great follower, both in design and colour; among these are the altarpieces in the churches of Sta. Eufemia and S. Lorenzo, and some single, well-preserved figures in his frescoes in the archbishop's palace at Verona. His principal works are in Verona; there are very few elsewhere. In 1j51 he painted frescoes on the façade of the Casa Garavaglia in Via San Marco at Trent, representing Midas and Apollo, and a battle with Norsemen. His altarpiece at Mantua cathedral is dated 1j52.

RICCOBONI, MARIE JEANNE, LABORAS DE MÉZIÈRES (1714–1792), French novelist, was born in Paris. She married Antoine François Riccoboni, an actor and dramatist, in 1735 but separated from him soon after. She was also an actress but had no great success on the stage. Her writings are examples of the "novel of sensibility." the nearest English equivalent being the work of Henry Mackenzie. Her works include. *Lettres de Mistriss Fanny Butlerd* (1757); the remarkable *Histoire de* M. *le Marquis de Cressy* (1758); *Lettres de Milady Juliette Catesby* (1759); *Lettres d'Adelaïde de Dammartin, Comtesse de Sancerre,* 2 vol. (1767); *Lettres d'Elisabeth-Sophie de Vallikre,* 2 vol. (1772); *Lettres de Mylord Rivers,* 2 vol. (1777); and *Histoire d'Ernestine* (1783), which J. F. de La Harpe thought her masterpiece. Deprived of her small pension from the crown by the Revolution, she died in great indigence on Dec. 6. 1792.

BIBLIOGRAPHY.—The complete edition of Madame Riccoboni's *Oeuvres,* 9 vol. (1826) gives notices by J. F. de La Harpe, Baron von Grimm and Denis Diderot. *See* also J. M. Querard, *La France littéraire,* vol. vii (1835); Julia Kavanagh. *French Women of Letters,* 2 vol. (1862), which gives an account of her novels; Jean Fleury, *Marivaux et le marivaudage* (1881); and E. A. Crosby, *Cne romancière oubliée* (1924).

RICE, EDMUND IGNATIUS (1762–1844), Irish philanthropist.-founder of the "Irish Christian Brothers." was born at Westcourt, near Callan, Kilkenny, on June 1, 1762. He abandoned his provision merchant business to devote himself to education and in 1808 he and nine others, meeting at Waterford, took religious vows from their bishop, assumed a habit and adopted an additional Christian name, by which, as by the collective title "Christian Brothers," they were thenceforth known. Schools were established in Cork (1811), Dublin (1812), and Thurles and Limerick (1817). In 1820 Pope Pius VII issued a brief sanctioning the order of "Religious Brothers of the Christian Schools (Ireland)," the members of which were to be bound by vows of obedience. chastity, poverty and perseverance, and to give themselves to the free instruction, religious and literary, of male children, especially the poor. Rice held the office of superior general of the order from 1822 to 1838. He died on Aug. 29, 1844.

RICE, a well-known cereal. is the staple food of hundreds of millions of people in Asia. Cultivated rice. *Oryza sativa,* was first mentioned in history in 2800 B.C. when a Chinese emperor proclaimed the establishment of a ceremonial ordinance for the planting of rice. Other authorities have traced the origin of rice to a plant grown in India in 3000 B.C. Rice culture gradually spread westward from southeastern Asia with the passage of time and was introduced to southern Europe in medieval times by the invading Saracens. This article briefly summarizes the botanical characteristics of rice and discusses its cultivation, preparation for the market and production. For additional information *see* TROPICAL AGRICULTURE: GRAIS PRODUCTIOS AND TRADE; FOOD SUPPLY OF THE WORLD; AGRICULTURE: *World Agriculture;* CEREALS. *See* also articles on various rice-growing countries, as CHINA; INDIA; etc.

The cultivated rice plant is an annual grass with numerous varieties that differ markedly in morphological characters and in physiological behaviour. It originated from wild species which are indigenous to Africa. India and Indochina. The rice plant has linear pubescent or glabrous leaves. each provided with a pointed ligule. The spikelets are borne on a loose panicle, which is erect at blooming, but nodding as the grains develop and mature. Each spikelet contains one flower enclosed by the compressed lemma and palea. At the base of each of these organs is a small lance-shaped glume. The flower consists of six stamens and an ovary surmounted by two styles bearing a feathery stigma. The ovary, after fertilization, develops into the fruit or grain, which is enclosed by the lemma and palea, or hull. Most varieties are grown on submerged land. but others, known as upland rice, are grown on land not submerged.

RICE (ORYZA SATIVA), SHOWING GENERAL HABIT OF GROWTH

(A) Single flower with part removed to show branched stigma and 6 stamens. (B) Single stamen (Both A and B are enlarged)

Cultivation.— Rice is grown in coastal plains. tidal deltas and river basins in tropical, semi-tropical and temperate regions where fresh water is available to submerge the land. In the orient, where most of the farms are too small for the use of farm machinery. rice is generally grown by hand labour, although animals, when available, are used in preparing the land. The rice is sown broadcast on well-prepared beds. and when the seedlings are 25 to 50 days old they are transplanted to the field, or paddy, by hand. Before transplanting, the fields, which are enclosed by levees, or bunds, are submerged

two to four inches and the surface soil is thoroughly stirred. Two to five seedlings are placed in hills 3 to 6 in. apart in rows 8 to 12 in. apart. The land is submerged during most of the growing season, and the crop is harvested by hand. About 95% of the world's rice is produced in Asia and the Japanese, Philippine, Indonesian and other nearby islands.

Outside of the orient, farm machinery usually is used for preparing the land, seeding and harvesting. The crop is grown in essentially the same manner as wheat, oats and barley, except that the land is submerged during most of the growing season. The principal rice-producing countries outside of the orient are Egypt, Italy, Spain, Brazil and the United States. Rice was introduced to North America in the colony of South Carolina about 1685. By 1839 South Carolina produced 60% of the rice grown in the United States. Other rice-producing states were North Carolina and Georgia. The American Civil War and the reconstruction period adversely affected this crop but rice acreage increased along the Mississippi river in Louisiana, becoming an important crop in this state in 1887 with the introduction of mechanized farming methods. In Texas, upland or nonirrigated rice was grown to a small extent in 1863, becoming of commercial importance on irrigated land in 1899, when 8,500 ac. were grown around the Beaumont district. Commercial production of rice began in Arkansas in 1903 and in California, in the Sacramento valley, in 1912. In the second half of the 20th century, many farmers broadcast seed and fertilizer by airplane on submerged land while others seed and fertilize their fields with a grain drill.

Preparation of Rice.—The kernel of rice as it leaves the thresher is enclosed by the hull, or husk, and is known as paddy or rough rice. Rough rice is used for seed and feed for livestock, but most of it is milled for human consumption. Rice is a good energy food, and is consumed in vast quantities in the orient. In the western hemisphere, however, rice is not the staple cereal food, except in certain Caribbean and South Pacific islands. A diet limited largely to well-milled rice renders eastern people on a restricted diet liable to beriberi (*q.v.*), a deficiency disease caused by a shortage of essential thiamine (vitamin B_1) and minerals. This disease, however, can be avoided by adding legumes, fish, fruits and vegetables to the diet.

Rough rice that is parboiled and dried prior to milling retains more thiamine and minerals than untreated rice, and hence is less apt to cause beriberi. It appears that in parboiling, the thiamine, which is largely in the germ and bran layers of the kernel, diffuses into and is fixed in the starchy endosperm.

Most of the rice is milled in or near the areas in which it is produced. In modern mills, special machines are used for removing the hull from the kernel, for removing the bran layers by attrition, for polishing, for coating and for grading. The object in milling is to remove the hull and the bran layers of the kernel with as little breakage as possible, for the most valuable product is the whole kernel. Milled rice is sometimes coated with glucose and talc to give a high glossy finish. The by-products of milling—bran and rice polish (finely powdered bran and starch resulting from polishing)—are used as feed for livestock, and oil is processed from bran for edible and industrial uses. Broken rice is used in brewing, distilling and manufacturing starch and rice flour. The hulls are used for fuel, packing, poultry litter, manufacturing furfural, industrial grinding and manufacturing fertilizer. Straw is used for feed, bedding livestock, thatching roofs and for mats, garments, packing and broomstraws.

World Production.—In the second half of the 20th century the world rice crop averaged between 360,000,000,000 lb. and 460,000,000,000 lb. annually, from an average of about 250,000,000 ac. The average acre yield for the world was about 1,450 lb.

Principal producing countries included China, India, Japan, Pakistan, Indonesia, Thailand and Burma.

Annual rice production in the United States averaged about 5,000,000,000 lb. from an average of less than 2,000,000 ac. The average acre yield was more than 3,000 lb. Leading producing states were Texas, Louisiana, Arkansas, California and Mississippi.

RICE, WILD (*Zizania aquatica*), or Indian rice, water oats, also knonn locally by many other names, is an indigenous, coarse, annual grass, the grain of which has long been used as an important food by various Indian tribes and early settlers. It is commonly found on muddy bottom in fresh to brackish water along shores, streams or in lakes and swampy places from the Atlantic coast west to the Mississippi valley and is widely planted as food for waterfowl. A tall, self-sowing grass (4 to 8 ft.), it is highly variable and regionally marked by three varieties: (1) short variety of the St. Lawrence river system; (2) small northern wild rice found along the Canadian border; and (3) the large wild rice of the middle west. The fruiting panicle may be one to two feet long, the lower spreading branches of which bear male flowers whereas the upper erect branches bear female flowers. When well cooked, the slender, round, purplish black, starchy grain (nearly ¾ in. long) is delicious.

Among northern Indians "ricing" means harvesting wild rice by canoe and preparing it for winter storage. The primitive methods employed by them still yield a superior product. Unless kept in wet, cool storage, wild rice loses its viability. (T. K. J.)

RICEBIRD: *see* BOBOLINK.

RICE PAPER. The substance which has received this name in Europe, through the mistaken notion that it is made from rice, consists of the pith of a small tree, *Aralia papyrifera,* which grows in the swampy forests of Formosa. The cylindrical core of pith is rolled on a hard flat surface against a knife, by which it is cut into thin sheets of a fine ivorylike texture. Dyed in various colours, rice paper is extensively used for the preparation of artificial flowers, while the white sheets are employed by native artists for water-colour drawings.

RICH, BARNABE (1542–1617), English author and soldier whose *Farewell to Militarie Profession* was the source for *Twelfth Night,* was born in 1542. He entered military service in 1562 and fought in the Low Countries and Ireland, eventually becoming a captain and a self-styled gentleman. Later he was an informer for the crown in Ireland, under Elizabeth I, and, again, under James I. He died on Nov. 10, 1617.

Rich wrote at least 26 books, including five romances and translations, five military works, seven reports on Ireland, six commentaries on manners and morals and three miscellaneous pamphlets. *Riche His Farewell to Militarie Profession* (1581), a collection of eight tales, is the best-known because of Shakespeare's borrowings in *Twelfth Night.* Though in this he emulated the euphuistic prose of John Lyly and appealed to English gentlewomen, ordinarily Rich boasted of his self-education, his "homely style" and his freedom from the affectations of the university. Despite his fulminations against iniquities in such tracts as *The Honestie of This Age* (1614), he appropriated material from other books and exhibited many of the hack writer's tactics of exploitation.

See T. Cranfill and D. Bruce, *Barnaby Rich* (1953). (E. H. MR.)

RICH, JOHN (1682?–1761), English theatre manager and actor, was the originator of English pantomime and founder of Covent Garden theatre. He was a manager by inheritance, receiving a half share in Lincoln's Inn Fields theatre from his father, Christopher Rich (d. 1714), and after running that house successfully for 18 years he founded Covent Garden theatre (1732). At both he staged entertainments of a new type based on Italian foundations, known as "pantomime," in which, from 1717 until the year before his death, he played Harlequin (under his stage name of Lun). He has thus a claim to be the inventor of the harlequinade of English pantomime tradition. After Rich's death David Garrick paid tribute to the matchless expressiveness of his miming.

Rich has another special claim to be remembered. Some time in 1727 he was offered John Gay's Newgate pastoral *The Beggar's Opera,* which Drury Lane had refused. Rich, though not an educated man, nevertheless appreciated Gay's satire and produced the play on Jan. 29, 1728, at Lincoln's Inn Fields theatre. It ran 62 performances, the longest then known, and, as was said at the time, "made Gay rich and Rich gap." (W. A. DN.)

RICH, PENELOPE, LADY (*c.* 1562–1607), the Stella of Sir Philip Sidney's *Astrophel and Stella*, was the daughter of Walter Devereux, 1st Earl of Essex. She was a child of fourteen when Sir Philip Sidney accompanied the queen on a visit to Lady Essex in 1576, on her way from Kenilworth, and must have been frequently thrown into the society of Sidney, in consequence of the many ties between the two families. Essex died at Dublin in Sept. 1576. He had sent a message to Philip Sidney from his deathbed expressing his desire that he should marry his daughter, and later his secretary wrote to the young man's father, Sir Henry Sidney, in words which seem to point to the existence of a definite understanding. But her relative and guardian, Henry Hastings, earl of Huntingdon, secured Burghley's assent in March 1581 for her marriage with Robert Rich, 3rd Baron Rich. Penelope is said to have protested in vain against the alliance with Rich, who is represented as a rough and overbearing husband. The evidence against him is, however, chiefly derived from sources as interested as Sir Philip Sidney's violent denunciation in the twenty-fourth sonnet of *Astrophel and Stella*, "Rich fooles there be whose base and filthy hart." Sidney's serious love for Penelope appears to date from her marriage with Rich. The eighth song of *Astrophel and Stella* narrates her refusal to accept him as a lover.

Lady Rich was the mother of six children by her husband when she contracted in 1595 an open liaison with Charles Blount. 8th Lord Mountjoy, to whom she had long been attached. Rich obtained a legal separation in 1601, and Mountjoy acknowledged her five children born after 1595. Mountjoy was created earl of Devonshire on the accession of James I, and Lady Rich was in high favour at court. In 1605 they legitimized their connection by a marriage celebrated by William Laud, the earl's chaplain. This proceeding, carried out in defiance of canon law, was followed by their banishment from court. Devonshire died on April 3, 1606, and his wife within a year of that date.

See the editions of *Astrophel and Stella* by A. B. Grosart, E. Arber and A. W. Pollard; also the various lives of Sir Philip Sidney, and Mrs. Aubrey Richardson's *Famous Ladies of the English Court* (London, 1899). *See* also reierences under SIDNEY.

RICH, RICHARD, 1ST BARON RICH (*c.* 1496–1567), lord chancellor of England, was born in the parish of St. Lawrence Jewry. London. His great grandfather. a mercer, had been sheriff of London. Richard, a lawyer of the Middle Temple and M.P. for Colchester (1529), held various minor offices before becoming solicitor general in 1533. He took part in the trials of Sir Thomas More and Bishop Fisher and was one of Thomas Cromwell's agents in the dissolution of the monasteries, himself obtaining large grants of monastic property. In 1536 he was M.P. for Essex and speaker of the house of commons. That year also he was knighted and became the first chancellor of the newly established court of augmentations. By Aug. 1540 he was a privy councillor. He was one of the executors of Henry VIII's will, was created Baron Rich in Feb. 1547, and succeeded the earl of Southampton as lord chancellor in October. In Oct. 1549 he joined the earl of Wanvick and Southampton in overthrowing the duke of Somerset, the Protector, over whose trial he presided. He resigned the lord chancellorship, on grounds of ill health, in Dec. 1551, at the time of the final breach between Warwick (now duke of Northumberland) and Somerset. Like other councillors, he had to subscribe Edward VI's settlement of the succession on Northumberland's daughter-in-law. Lady Jane Grey, but after Edward VI's death he soon declared for Mary Tudor. whose religious policy he now supported, although henceforward he did not take a prominent part in public affairs. A "civil servant" rather than a politician he had never been an heroic or a very attractive figure. He died at Rochford, Essex. on June 12, 1567. and was buried in Felsted church. (R. B. WM.)

RICH, RICHARD (*fl.* 1610), English soldier and adventurer, the author of *Newes* From *Virginia*, sailed from England on June 2, 1609, for Virginia, with Capt. Christopher Newport and the three commissioners entrusted with the foundation of the new colony.

In his verse pamphlet he relates the adventures undergone by the expedition, and describes the resources of the new country with the advantages offered to colonists. The only known copy of this tract, dated 1610, is in the Huth library. A reprint edited by J. O. Halliwell-Phillips appeared in 1865.

RICHARD, ST., of Wyche (c. 1197–1253), English saint and bishop, was named after his birthplace, Droitwich in Worcestershire. Educated at Oxford, he soon began to teach in the university, of which he became chancellor, probably after he had studied in Paris and in Bologna. About 1235 he became chancellor of the diocese of Canterbury under Archbishop Edmund Rich, and he was with the archbishop during his exile in France. Having returned to England some time after Edmund's death in 1240 he became vicar of Deal and chancellor of Canterbury for the second time. In 1244 he was elected bishop of Chichester, being consecrated at Lyons by Pope Innocent IV. in March 1245, although Henry III. refused to give him the temporalities of the see, the king favouring the candidature of Robert Passelewe (d. 12 52). In 1246, however, Richard obtained the temporalities. He died at Dover in April 1253. It was generally believed that miracles were wrought at his tomb in Chichester cathedral, which was long a popular place of pilgrimage, and in 1262 he was canonized at Viterbo by Pope Urban IV.

His life by his confessor, Ralph Bocking, is published in the *Acta Sanctorum* of the Bollandists, with a later life by John Capgrave.

RICHARD (d. 1184), archbishop of Canterbury, was a Norman, who became a monk at Canterbury, where he acted as chaplain to Archbishop Theobald and was a colleague of Thomas Becket. In 1173, more than two years after the murder of Becket, it was decided to fill the vacant archbishopric of Canterbury; there were two candidates, Richard, at that time prior of St. Martin's, Dover, and Odo, prior of Canterbury, and in June Richard was chosen, although Odo was the nominee of the monks. Objections were raised against this election both in England and in Rome, but in April 1174 the new archbishop was consecrated at Anagui by Pope Alexander III., and he returned to England towards the close of the year. The ten years during which Richard was archbishop were disturbed by disputes over the respective rights of the sees of Canterbury and York. Richard died at Rochester on Feb. 16, 1184, and was buried in his cathedral.

See the article by W. Hunt in the *Dict. Nat. Biog.* vol. xlviii. (1896); and W. F. Hook, *Lives of the Archbishops of Canterbury.*

RICHARD *I.* (1157–1199), king of England, nicknamed "Coeur de Lion" and "Yea and Nay," was the third son of Henry II. by Eleanor of Aquitaine. Born in Sept. 1157, he received at the age of 11 the duchy of Aquitaine, and was formally installed in 1172. In his new position he was allowed, probably from regard to Aquitanian susceptibilities, to govern with an independence which was studiously denied to his brothers in their shares of the Angevin inheritance. Yet in 1173 Richard joined with the young Henry and Geoffrey of Brittany in their rebellion; Aquitaine was twice invaded by the old king before the unruly youth would make submission. Richard was soon pardoned and reinstated in his duchy, where he distinguished himself by crushing a formidable revolt (1175) and exacting homage from the count of Toulouse. In a short time he was so powerful that his elder brother Henry became alarmed and demanded, as heir-apparent, that Richard should do him homage for Aquitaine. Richard having scornfully rejected the demand, a fratricidal war ensued; the young Henry invaded Aquitaine and attracted to his standard many of Richard's vassals, who were exasperated by the iron rule of the duke. Henry II. marched to Richard's aid; but the war ended abruptly with the death of the elder prince (1183).

Richard, being now the heir to England and Normandy, was invited to renounce Aquitaine in favour of Prince John. The proposal led to a new civil war; and, although a temporary compromise was arranged, Richard soon sought the help of Philip Augustus, to whom he did homage for all the continental possessions in the actual presence of his father (Conference of Bonmoulins, Nov. 18, 1188). In the struggle which ensued the old king was overpowered, chased ignominiously from Le Mans to Angers, and forced to buy peace by conceding all that was demanded of him; in particular the immediate recognition of Richard as his successor.

But the death of Henry II. (1189) at once dissolved the friendship between Richard and Philip. Not only did Richard continue the continental policy of his father, but he also refused to fulfil his contract with Philip's sister, Alais, to whom he had been betrothed at the age of three. An open breach was only delayed by the desire of both kings to fulfil the crusading vows which they had recently taken. Richard, in particular, sacrificed all other interests to this scheme, and raised the necessary funds by the most reckless methods. He put up for auction the highest offices and honours; even remitting to William the Lion of Scotland, for a sum of 15,000 marks, the humiliating obligations which Henry II. had imposed at the Treaty of Falaise. By such expedients he raised and equipped a force which may be estimated at 4,000 men-at-arms and as many foot-soldiers, with a fleet of 100 transports (1191).

Richard did not return to his dominions until 1194. But his stay in Palestine was limited to 16 months. On the outward journey he wintered in Sicily, where he employed himself in quarrelling with Philip and in exacting satisfaction from the usurper Tancred for the dower of his widowed sister, Queen Joanna, and for his own share in the inheritance of William the Good. Leaving Messina in March 1191, he interrupted his voyage to conquer Cyprus, and only joined the Christian besiegers of Acre in June. The reduction of that stronghold was largely due to his energy and skill. But his arrogance gave much offence. After the fall of Acre he inflicted a gross insult upon Leopold of Austria; and his relations with Philip were so strained that the latter seized the first pretext for returning to France, and entered into negotiations with Prince John (see JOHN, king of England) for the partition of Richard's realm.

Richard also threw himself into the disputes respecting the crown of Jerusalem, and supported Guy of Lusignan against Conrad of Montferrat with so much heat that he incurred grave, though unfounded, suspicions of complicity when Conrad was assassinated by emissaries of the Old Man of the Mountain. None the less Richard, whom even the French crusaders accepted as their leader, upheld the failing cause of the Frankish Christians with valour and tenacity. He won a brilliant victory over the forces of Saladin at Arsuf (1191), and twice led the Christian host within a few miles of Jerusalem. But the dissensions of the native Franks and the crusaders made it hopeless to continue the struggle; and Richard was alarmed by the news which reached him of John's intrigues in England and Normandy. Hastily patching up a truce with Saladin, under which the Christians kept the coast-towns and received free access to the Holy Sepulchre, Richard started on his return (Oct. 9, 1192).

His voyage was delayed by storms, and he appears to have been perplexed as to the safest route. The natural route overland through Marseilles and Toulouse was held by his enemies; that through the empire from the head of the Adriatic was little safer, since Leopold of Austria was on the watch for him. Having adopted the second of these alternatives, he was captured at Vienna in a mean disguise (Dec. 20, 1192) and strictly confined in the duke's castle of Diirenstein on the Danube. His mishap was soon known to England, but the regents were for some weeks uncertain of his whereabouts. This is the foundation for the tale of his discovery by the faithful minstrel Blondel, which first occurs in a French romantic chronicle of the next century. Early in 1193 Leopold surrendered his prize, under compulsion, to the emperor Henry VI., who was aggrieved both by the support which the Plantagenets had given to the family of Henry the Lion and also by Richard's recognition of Tancred in Sicily. Although the detention of a crusader was contrary to public law, Richard was compelled to purchase his release by the payment of a heavy ransom and by doing homage to the emperor for England. The ransom demanded was 150,000 marks; though it was never discharged in full, the resources of England were taxed to the utmost for the first instalments; and to this occasion we may trace the beginning of secular taxation levied on movable property.

Richard reappeared in England in March 1194; but his stay lasted only a few weeks, and the remainder of his reign was entirely devoted to his continental interests. He left England to be governed by Hubert Walter (*q.v.*), and his personal authority was seldom asserted except by demands for new subsidies. The rule of the Plantagenets was still popular in Normandy and Aquitaine; but these provinces were unable or unwilling to pay for their own defence. Though Richard proved himself consistently the superior of Philip in the field, the difficulty of raising and paying forces to resist the French increased year by year. Richard could only stand on the defensive; the keynote of his later policy is given by the building of the famous Chdteau Gaillard at Les Andelys (1196) to protect the lower courses of the Seine against invasion from the side of France. He did not live to see the futility of such bulwarks. In 1199 a claim to treasure-trove embroiled him with the viscount of Limoges. He harried the Limousin and laid siege to the castle of Chdlus; while directing an assault he was wounded in the shoulder by a crossbow bolt, and, the wound mortifying from unskilful treatment or his own want of care, he died on April 6, 1199. He was buried by his own desire at his father's feet in the church of Fontevrault. Here his effigy may still be seen[1]. Though contemporary, it does not altogether agree with the portraits on his Great Seal, which give the impression of greater strength and even of cruelty. The Fontevrault bust is no doubt idealized.

The most accomplished and versatile representative of his gifted family, Richard was, in his lifetime and long afterwards, a favourite hero with troubadours and romancers. This was natural, as he belonged to their brotherhood and himself wrote lyrics of no mean quality. But his history shows that he by no means embodied the current ideal of chivalrous excellence. His memory is stained by one act of needless cruelty, the massacre of over two thousand Saracen prisoners at Acre; and his fury, when thwarted or humbled, was ungovernable. A brave soldier, an experienced and astute general, he was never happier than when engaged in war. As a ruler he was equally profuse and rapacious. Not one useful measure can be placed to his credit; and it was by a fortunate accident that he found, in Hubert Walter, an administrator who had the skill to mitigate the consequences of a reckless fiscal policy. Richard's wife was Berengaria, daughter of Sancho VI., king of Navarre, whom he married in Cyprus in May 1191. She was with the king at Acre later in the same year, and during his imprisonment passed her time in Sicily, in Rome and in France. Husband and wife met again in 1195, and the queen long survived the king, residing chiefly at Le Mans. She died soon after 1230. Berengaria founded a Cistercian monastery at Espau.

BIBLIOGRAPHY.—The more important of the general chronicles are: the *Gesta Henrici Secundi*, ascribed to Benedict of Peterborough (Rolls Series, 2 vols., 1867); the *Chronica* of Roger of Hoveden (Rolls Series, 4 vols., 1868–71); the *Chronica* of Gervase of Canterbury (Rolls Series, 1879); the *Imagines Historiarum* of Ralph of Diceto (Rolls Series, 2 vols., 1876); the *Historia Rerum Anglicarum* of William of Newburgh (in *Chronicles of the Reigns of Stephen*, etc., Rolls Series, 2 vols., 1884–85); the *De rebus gestis Ricardi Primi* of Richard of Devizes (in *Chronicles of the Reigns of Stephen*, etc., vol. iii., Rolls Series, 1886); the *Chronicon Anglicanum* of Ralph of Coggeshall (Rolls Series, 1875); the *Flores Historiarum* of Roger of Wendover (Rolls Series, 3 vols., 1886–89); the *Gesta Philippi Augusti* of Rigord (*Société de l'histoire de France*, Paris, 1882) and of Guillaume le Breton (*op. cit.*). A detailed narrative of Richard's crusade is given in *L'Estoire de la guerre sainte*, a rhyming French chronicle by the minstrel Ambroise (ed. Gaston Paris, Paris, 1897), and in the Latin prose version known as the *Itinerarium O. Peregrinorum et gesta Regis Ricardi;* this last, with some valuable historical letters, is printed in W. Stubbs's *Chronicles and Memorials of the Reign of Richard I.* (Rolls Series, 2 vols., 1864–65). Of modern works the following are useful: W. Stubbs's preface to vols. iii. and iv. of Hoveden; the same author's *Constitutional History of England*, vol. i. (Oxford, 1897); Miss K. Norgate's *England under the Angevin Kings*, vol. ii. (1887) and *Richard the Lion Heart* (1924); Sir J. H. Ramsay's *Angevin Empire* (1903); R. Rohricht's *Geschichte des Königreichs Jerusalem* (1898); W. B Stevenson's *Crusaders in the East* (Cambridge, 1907); A. Cartellieri's *Philipp II. August* (Leipzig, 1899, etc.). (H. W. C. D.)

RICHARD II. (1367–1400), king of England, younger son of Edward the Black Prince by Joan "the Fair Maid of Kent," was born at Bordeaux on Jan. 6, 1367. He was brought to Eng-

[1] The remains of Richard, together with those of Henry II. and his queen Eleanor, were removed in the 17th century from their tombs to another part of the church. They were rediscovered in 1910 during the restoration of the abbey undertaken by the French Government.

land in 1371, and after his father's death was, on the petition of the Commons in parliament, created prince of Wales on Nov. 20, 1376. When Edward III. died, on June 21, 1377, Richard became king. Popular opinion had credited John of Gaunt with designs on the throne. This was not justified; nevertheless, the rivalry of the boy-king's uncles added another to the troubles due to the war, the Black Death and the prospect of a long minority. At first the government was conducted by a council appointed by parliament. The council was honest, but the difficulties of the situation were too great. The ill-considered poll-tax of 1381 was the occasion, though not the real cause, of the Peasants' Revolt in that year. The ministers were quite unequal to the crisis, and when Wat Tyler and his followers got possession of London, Richard showed a precocious tact and confidence in handling it. He met and temporized with the rebels on June 13 at Mile End, and again next day at Smithfield; and with courageous presence of mind, he saved the situation when Tyler was killed, by calling on them to take him for their leader.

From this time Richard began to assert himself. His chief ministers, appointed by parliament in 1382, were the earl of Arundel and Michael de la Pole. Arundel Richard disliked, and dismissed next year, when he began his personal government. Pole, whom he retained as chancellor and made earl of Suffolk, was a well-chosen adviser. But others, and especially his youthful favourite Robert de Vere, promoted to be marquess of Dublin and duke of Ireland, were less worthy. Further, Richard made his own position difficult by lavish extravagance and by outbursts of temper. He chafed under the restraint of his relatives, and therefore encouraged John of Gaunt in his Spanish enterprise.

Thereupon, Thomas of Gloucester, supported by Arundel, attacked his nephew's ministers in the parliament of 1386, and by open hints at deposition forced Richard to submit to a council of control. When Richard, with the aid of his friends and by the advice of subservient judges, planned a reversal of the parliament, Gloucester, at the head of the so-called lords appellant, anticipated him. Richard had been premature and ill-advised. Gloucester had the advantage of posing as the head of the constitutional party. The king's friends were driven into exile or executed, and he himself forced to submit to the loss of all real power (May 1388). Richard changed his methods, and when the lords appellant had lost credit, asserted himself constitutionally by dismissing Gloucester's supporters from office, and appointing in their place well-approved men like William of Wykeham. In the next parliament of 1390 the king showed himself ready to meet and conciliate his subjects. The simultaneous return of John of Gaunt from Spain put a check on Gloucester's ambition. For seven years Richard ruled constitutionally and on the whole well.

In Jan. 1383 Richard had married Anne of Bohemia (1366–1394), daughter of the emperor Charles IV. Her death on June 7, 1394 was a great shock to Richard, and incidentally had important consequences. Richard sought distraction by an expedition to Ireland, the first visit of an English king for more than two centuries. In his policy there he showed a wise statesmanship. At the same time he was negotiating for a permanent peace with France, which was finally arranged in Oct. 1396 to include his own marriage with Isabella, daughter of Charles VI., a child of seven. Gloucester criticized the peace openly, and there was some show of opposition in the parliament of Feb. 1397.

Period of Absolute Monarchy. — But there was nothing to foreshadow the sudden stroke by which in July Richard arrested Gloucester and his chief supporters, the earls of Arundel and Warwick. The others of the five lords appellant, Henry of Bolingbroke, afterwards King Henry IV., and the earl of Nottingham, now supported the king. Richard's action was apparently in deliberate revenge for the events of 1387–88. Gloucester, after a forced confession, died in prison at Calais, smothered by his nephew's orders. Arundel, in a packed parliament, was condemned and executed; his brother Thomas archbishop of Canterbury was exiled. The king's friends, including Nottingham and Bolingbroke, made dukes of Norfolk and Hereford, were all promoted in title and estate. Richard himself was rewarded for ten years' patience by the possession of absolute power. He might perhaps have established it if he could have exercised it with moderation. But he declared that the laws of England were in his mouth, and supported his court in wanton luxury by arbitrary methods of taxation. By the exile of Norfolk and Hereford in Sept. 1398 he seemed to have removed the last persons he need fear. He was so confident that in May 1399 he paid a second visit to Ireland, taking with him all his most trusted adherents.

Rebellion and Deposition. — Thus when Henry landed at Ravenspur in July he found only half-hearted opposition, and when Richard himself returned it was too late. Ultimately Richard surrendered to Henry at Flint on Aug. 19, promising to abdicate if his life was spared. He was taken to London riding behind his rival with indignity. On Sept. 30, he signed in the Tower a deed of abdication, wherein he owned himself insufficient and useless, reading it first aloud with a cheerful mien and ending with a request that his cousin would be good lord to him. The parliament ordered that Richard should be kept close prisoner, and he was sent secretly to Pontefract. There in Feb. 1400 he died: no doubt of the rigour of his winter imprisonment, rather than by actual murder as alleged in the story adopted by Shakespeare. The mystery of Richard's death led to rumours that he had escaped, and an impostor pretending to be Richard lived during many years under the protection of the Scottish government. But no doubt it was the real Richard who was buried without state in 1400 at King's Langley, and honourably reinterred by Henry V. at Westminster in 1413.

Richard II. is a character of strange contradictions. It is difficult to reconcile the precocious boy of 1381 with the wayward and passionate youth of the next few years. Even if it be supposed that he dissembled his real opinions during the period of his constitutional rule, it is impossible to believe that the apparent indifference which he showed in his fall was the mere acting of a part. His violent outbursts of passion perhaps give the best clue to a mercurial and impulsive nature, easily elated and depressed. He had real ability, and in his Irish policy, and in the preference which he gave to it over continental adventure, showed a statesmanship in advance of his time. But this, in spite of his lofty theory of kingship, makes it all the more difficult to explain his extravagant bearing in his prosperity. In appearance Richard was tall and handsome, if effeminate. He had some literary tastes, which were shown in fitful patronage of Chaucer, Gower and Froissart. Richard's second queen, Isabella (1389–1409), was born in Paris on Nov. 9, 1389, and was married to the English king at Calais in October, or November, 1396, but on account of the bride's youth the marriage was never consummated.

When Richard lost his crown in 1399 Isabella was captured by Henry IV.'s partisans and sent to Sonning, near Reading, while her father, Charles VI., asked in vain for the restoration of his daughter and of her dowry. In 1401 she was allowed to return to France; in 1406 she became the wife of the poet, Charles, duke of Orleans, and she died on Sept. 13, 1409.

BIBLIOGRAPHY.—The best contemporary authorities are the *Chronicon Angliae* down to *1388*, Walsingham's *Historia Anglicana*, the *Annales Ricardi II.*, Knighton's *Chronicle* (all these in the Rolls Series), the *Vita Ricardi II.* by a Monk of Evesham (ed. T. Hearne), and the *Chronique* de *la traison et mort* (English Hist. Soc.). Froissart wrote from some personal knowledge. A metrical account of Richard's fall, probably written by a French knight called Creton, is printed in *Archaeologia*, xx. The chief collections of documents are the *Rolls of Parliament* and the *Calendar of Patent Rolls*. *H. A.* Wallon's *Richard II.* (Paris, *1864)* is the fullest life, though now somewhat out of date. For other modern accounts *see* W. Stubbs, *Constitutional History*, and *C.* W. C. Oman, *The Political History* of *England*, vol. iv., and *The Great Revolt of 1381.* (C. L. K.)

RICHARD III. (1452–1485), king of England, youngest son of Richard, duke of York, by Cicely Neville, was born at Fotheringhay on Oct. 2, 1452. After the second battle of St. Albans in Feb. 1461, his mother sent him with his brother George for safety to Utrecht. They returned in April, and at the coronation of Edward IV. Richard was created duke of Gloucester. As a mere child he had no importance till 1469–70, when he supported his brother against Warwick, shared his exile and took part in his triumphant return. He distinguished himself at Barnet and Tewkesbury; according to the Lancastrian story, after the latter battle

he murdered the young Edward of Wales in cold blood; this is discredited by the authority of Warkworth (Chronicle, p. 18); but Richard may have had a share in Edward's death during the fighting. He cannot be so fully cleared of complicity in the murder of Henry VI., which probably took place at the Tower on the night of May 22, when Richard was certainly present there.

Richard shared to the full in his brother's prosperity. He had large grants of lands and office, and by marrying Anne (1456–1485), the younger daughter of Warwick, secured a share in the Neville inheritance. This was distasteful to George, duke of Clarence, who was already married to the elder sister, Isabel. The rivalry of the two brothers caused a quarrel which was never appeased. Richard does not, however, seem to have been directly responsible for the death of Clarence in 1478; Sir Thomas More, who is a hostile witness, says that he resisted it openly "howbeit somewhat (as men deemed) more faintly than he that were heartily minded to his wealth." Richard's share of the Neville inheritance was chiefly in the north, and he resided usually at Middleham in Yorkshire. In May 1480 he was made the king's lieutenant-general in the north, and in 1482 commanded a successful invasion of Scotland. His administration was good, and brought him well-deserved popularity.

Protectorate.--On Edward's death he was kept informed of events in London by William, Lord Hastings, who shared his dislike of the Woodville influence. On April 29, 1483, supported by the duke of Buckingham, he intercepted his nephew at Stony Stratford and arrested Lord Rivers and Richard Grey, the little king's half-brother. It was in Richard's charge that Edward was brought to London on May 4. Richard was recognized as protector, the Woodville faction was overthrown, and the queen with her younger children took sanctuary at Westminster. For the time the government was carried on in Edward's name, and June 22 was appointed for his coronation. Richard was nevertheless gathering forces and concerting with his friends. In the council there was a party, of whom Hastings and Bishop Morton were the chief, which was loyal to the boy-king. On June 13 came the famous scene when Richard appeared suddenly in the council baring his withered arm and accusing Jane Shore and the queen of sorcery; Hastings, Morton and Stanley were arrested and the first-named at once beheaded. A few days later, probably on June 25, Rivers and Grey were executed at Pontefract. On June 22 Dr. Shaw was put up to preach at Paul's Cross against the legitimacy of the children of Edward IV. On the 25th a sort of parliament was convened at which Edward's marriage was declared invalid on the ground of his precontract with Eleanor Talbot, and Richard rightful king. Richard, who was not present, accepted the crown with feigned reluctance, and from the following day began his formal reign.

Usurpation of the Throne.--On July 6, Richard was crowned at Westminster, and immediately afterwards made a royal progress through the Midlands, on which he was well received. But in spite of its apparent success the usurpation was not popular. Richard's position could not be secure whilst his nephews lived. There seems to be no reasonable doubt that early in August Edward V. and his brother Richard (whom Elizabeth Woodville had been forced to surrender) were murdered by their uncle's orders in the Tower. Attempts have been made to clear Richard's memory. But the report of the princes' death was believed in England at the time, "for which cause king Richard lost the hearts of the people" (Chronicles of London, 191), and it was referred to as a definite fact before the French states-general in January 1484. The general, if vague, dissatisfaction found its expression in Buckingham's rebellion.

Richard, however, was fortunate, and the movement collapsed. He met his only parliament in Jan. 1484 with some show of triumph, and deserves credit for the wise intent of its legislation. He could not, however, stay the undercurrent of disaffection, and his ministers, Lovell and Catesby, were unpopular. His position was weakened by the death of his only legitimate son in April 1484. His queen died also a year later (March 16, 1485), and public opinion was scandalized by the rumour that Richard intended to marry his own niece. Elizabeth of York. Thus the feeling in favour of his rival Henry Tudor strengthened. Henry landed at Milford Haven on Aug. 7, 1485, and it was with dark forebodings that Richard met him at Bosworth on the 22nd. The defection of the Stanleys decided the day. Richard was killed fighting, courageous at all events. After the battle his body was carried to Leicester, trussed across a horse's back, and buried without honour in the church of the Greyfriars.

Richard was not the villain that his enemies depicted. He had good qualities, both as a man and a ruler, and showed a sound judgment of political needs. Still it is impossible to acquit him of the crime, the popular belief in which was the chief cause of his ruin. He was a typical man in an age of strange contradictions of character, of culture combined with cruelty, and of an emotional temper that was capable of high ends, though unscrupulous of means. Tradition represents Richard as deformed. It seems clear that he had some physical defect, though not so great as has been alleged. Extant portraits show an intellectual face characteristic of the early Renaissance, but do not indicate any deformity.

BIBLIOGRAPHY.—The chief original authorities are Sir Thomas More's *History of Richard III.*, based on information supplied by Archbishop Morton, and therefore to be accepted with caution; the more trustworthy *Continuation of the Croyland Chronicle* in Fulman's *Scriptores*, the *History* of Polydore Vergil, written in a Tudor spirit; the *Chronicle of London* (ed. *C. L.* Kingsford, 1905), and its biased expansion in Fabyan's *Chronic&. See* also *Letters and Papers Illustrative of the Reigns of Richard III. and Henry VII.*, ed. *J.* Gairdner, in Rolls Series. Of later accounts those in Stow's *Annales* (preserving some oral tradition) and George Buck's *Richard III.* ap. Kennet *History of England* deserve mention. Horace Walpole attempted a vindication in his *Historic Doubts* (1768). The best modern account is James Gairdner's *Life of Richard III.* (2nd ed., 1898). The latest and fullest defence is given in Sir Clements Markham's *Richard III., His Life and Character* (1906); *G.* B. Churchill's *Richard the Third up to Shakespeare (Palaestra* x., 1900) is a valuable digest of material. (C. L. K.)

RICHARD, earl of Cornwall and king of the Romans (1209–1272), was the second son of the English king John by Isabella of Angoulême. Born in 1209, Richard was the junior of his brother, Henry III., by fifteen months; he was educated in England and received the earldom of Cornwall in 1225. From this date to his death he was a prominent figure on the political stage. In the years 1225–27 he acted as governor of Gascony; between 1227 and 1238, owing to quarrels with his brother and dislike of the foreign favourites, he attached himself to the baronial opposition and bade fair to become a popular hero. But in 1240 he took the command of a crusade in order to escape from the troubled atmosphere of English politics. He was formally reconciled with Henry before his departure; and their amity was cemented on his return by his marriage with Sancha of Provence, the sister of Henry's queen (1243). In 1257 a bare majority of the German electors nominated Richard as king of the Romans, and he accepted their offer at Henry's desire.

In the years 1257–68 Richard paid four visits to Germany. He obtained recognition in the Rhineland, which was closely connected with England by trade relations. Otherwise, however, he was unsuccessful in securing German support. In the English troubles of the same period he endeavoured to act as a mediator. On the outbreak of civil war in 1264 he took his brother's side, and his capture in a windmill outside Lewes, after the defeat of the royalist army, is commemorated in the earliest of English vernacular satires; he remained a prisoner till the fall of Montfort. But after Evesham he exerted himself to obtain reasonable terms for those who had suffered from the vengeance of the royalist party. He died on April 2, 1272. (H. W. C. D.)

RICHARD OF ST. VICTOR (d. 1173), theologian and mystic of the 12th century. Little is known of his life; he was born in Scotland or in England, and went to Paris, where he entered the abbey of St. Victor and was a pupil of the great mystic, Hugh of St. Victor. He succeeded as prior of this house in 1162. The best known of Richard's writings are mystical treatises and two works on the Trinity. According to him, six steps lead the soul to contemplation: (1) contemplation of visible and tangible objects; (2) study of the productions of nature and of art; (3) study of character; (4) study of souls and of spirits; (5) en-

trance to the mystical region which ends in (6) ecstasy.

His theory of the Trinity is chiefly based on the arguments of Anselm of Canterbury. The influence of neo-Platonic terminology, as well as of the works of the pseudo-Dionysius, can be clearly detected in his works. In the *Paradiso* Dante placed Richard among the greatest teachers of the church His writings came into favour again in the 16th and 17th centuries, six editions of his works having been printed between 1506 and 1650.

RICHARDS, DICKINSON WOODRUFF (1895–), U.S. physician and co-winner of the Nobel prize, noted for research on the human heart, was born at Orange, S.J., on Oct. 30, 1895. He graduated from Yale university in 1917. took a master's degree at Columbia university in 1922 and received his medical degree from Columbia the next year. After study in England he began his research in heart and lung physiology at Columbia university's College of Physicians and Surgeons in 1928. In 1947 he was appointed Lambert professor of medicine there. In 1945 he also became director of the Columbia medical division at Bellevue hospital in New Pork city.

Adapting the pioneer experiments of Werner T. Forssmann, German surgeon who explored his own heart with a long, flexible tube passed through an artery (1929), Richards and André F. Cournand of Columbia university measured blood pressure and make-up inside the heart and later extended the measurements to the lungs and general circulatory system. The research of the three physicians led to important methods of diagnosis and treatment of heart disease and to discoveries concerning the behaviour of circulation in a great variety of diseases and under the influence of various drugs. Richards shared the 1956 Nobel prize in medicine and physiology with Cournand and Forssmann.

RICHARDS, THEODORE WILLIAM (1868–1928), U.S. chemist, who received the Nobel chemistry prize in 1914 for his researches on atomic weights and demonstrated the existence of isotopes (*q.v.*). He was born in Germantoun, Pa., on Jan. 31, 1868. He graduated from Haverford college (S.B., 1885) and Harvard university (A.B., 1886; Ph.D., 1888); he also studied as a Harvard traveling fellow at Gottingen, Leipzig and the Dresden Technical university, and became instructor (1891), assistant professor (1894) and professor (1901) of chemistry at Harvard. He was made director of the Wolcott Gibbs memorial laboratory and Erving professor of chemistry in 1912.

Richards greatly improved the technique of gravimetric atomic weight determinations, introducing quartz apparatus, the bottling device and the nephelometer. Although the atomic weight values of Jean Servais Stas had been regarded as standard. about 1903 physiochemical measurements showed that some were not accurate. Richards and his students revised these figures, lowering, for instance, Stas's value for silver from 107.93 to 107.88. Richard's investigations of the atomic weight of lead from different sources definitely proved the existence of isotopes. He died at Cambridge, Mass.. on April 2, 1928. (R. E. O.; X.)

RICHARDSON, DOROTHY MILLER (1873–1957), English pioneer in stream-of-consciousness fiction, was born in Abingdon, Berkshire, on May 17, 1873, and passed her childhood and youth in secluded surroundings in late-Yictorian England. After her schooling, which ended when, in her 17th year, her home broke up, she engaged in teaching, clerical work and journalism. In 1917 she married the artist Alan Elsden Odie (1888–1948). She commands attention for her sequence novel *Pilgrimage* (published in separate volumes—she preferred to call them chapters—as *Pointed Roofs,* 1915; *Backwater,* 1916; *Honeycomb,* 1917; *The Tunnel,* 1919; *Interim,* 1919; *Deadlock,* 1921; *Revolving Lights,* 1923; *The Trap,* 1925; *Oberland,* 1927; *Dawn's Left Hand,* 1931; *Clear Horizon,* 1935; the last part, *Dimple Hill,* appeared under the collective title. 4 vol., 1938).

She died June 17, 1957, at Beckenham. Kent.

Pilgrimage is the extraordinarily sensitive story, seen cinematically through her eyes, of Miriam Henderson, an attractive, spinsterish and mystical New Woman. Unfortunately, she is more new than woman, since. for a character committed to the stream-of-consciousness technique of self-revelation, her reactions to her various experiences are selected and edited with peculiarly improper reticence; while hers is entirely a woman's consciousness, it is not nearly a woman's entire consciousness. Moreover, the author too often lavishes her surpassingly delicate perceptiveness upon dull material. Nevertheless, no student of fiction can afford to overlook *Pilgrimage,* one of the significant novels of the 20th century.

RICHARDSON, HENRY HANDEL (pseudonym of ETHEL FLORENCE LINDESAY RICHARDSON ROBERTSON) (1870–1946), considered by some to be Australia's greatest novelist. Born at East Melbourne, Victoria, Jan. 3, 1870, she was educated at the Presbyterian Ladies' college, Melbourne, and in 1887 she went to Leipzig to study music. She was influenced by continental rather than English literature and thought. and apart from a short visit in 1912 to obtain material for her work, she did not return to Australia. In 1895 she married J. G. Robertson, who was appointed in 1903 to the chair of German literature in the Gniversity of London. Her first novel, *Maurice Guest* (1908), was based on her experiences in Leipzig and like much of her work was partly autobiographical. *The Fortunes of Richard Mahoney (Australia Felix,* 1917; *The* Way *Home,* 1925; *Ultima Thule,* 1929) is the story of an Irish immigrant who bears a strong resemblance to her father. Other works published during her life were: *Two Studies* (1931); *The End of a Childhood* (1934); *The Young Cosima* (1939).

She died at Hastings, Sussex, March 20, 1946, leaving an unfinished autobiography, *Myself When Young,* published in 1948.

RICHARDSON, HENRY HOBSON (1838–1886), U.S. architect, was both the initiator of the Romanesque revival and a pioneer figure in the development of an indigenous. modern American style. He was born on Sept. 29, 1838, in St. James parish, La. After graduating from Harvard college in 1859, he studied architecture at the École des Beaux-Arts, Paris, returning to the United States in 1865. Shunning the neoclassical traditions in which he had been trained, Richardson experimented briefly with Victorian Gothic and then turned to the French Romanesque style epitomized in his famous Trinity church of Boston (1872–77).

The Marshall Field Wholesale building, Chicago (1887; demolished 1930), was the masterpiece of the bold, original style that he gradually evolved: characterized by an unornamented exterior and rows of tall, arched windows, it relied for effect upon its lines and the skillful handling of material. This style survives in his Ames-Pray building. Boston. Among his other notable works are the Pittsburgh courthouse and jail; the capitol at Albany, N.Y.; Sever hall. Harvard university; and many distinctive, shingled country houses such as Stoughton house, Cambridge, Mass. His Romanesque had an integrity and grace seldom achieved by his many imitators in the latter half of the 19th century; his modern style presaged the revolutionary work of Louis Sullivan (*q.v.*). Richardson died on April 27, 1886, in Boston.

See Henry Russell Hitchcock, *The Architecture of H. H. Richardson and His Times* (1936).

RICHARDSON, LEWIS FRY (1881–1953), British mathematician and meteorologist especially remembered for his application of mathematics to weather forecasting. was born at Newcastle upon Tyne on Oct. 11, 1881, of an old Quaker family of tanners. Educated at Bootham school, York. and at King's college, Cambridge, he worked in universities, in industry, in technical colleges and in governmental scientific institutions (notably in the meteorological office). His mathematical work, marked by great originality of thought, mainly concerned the calculus of finite differences, the prediction of weather by computation, the study of diffusion and, later, the use of mathematics to elucidate the causes of war (speculations arising from religious conviction). Richardson made major contributions to numerical methods of

solving boundary-value problems in physics. and during 1913–22 applied these ideas to meteorology in a bold attempt to produce a systematic method of forecasting depending entirely on calculation. This work culminated in his classic *Weather Prediction by Numerical Process* (1922), with its scheme for "numerical" forecasting including a worked-out example. This example was a failure. The failure was caused partly by inadequate upper-air data and partly by the limitations of the mathenlatical method. but the line of thought thus pioneered and the later invention of the high-speed electronic computer together made numerical forecasts practicable. In his work on diffusion Richardson mas likewise ahead of his time, in that concepts which he advanced in 1926 were not fully recognized as valid until 20 years later, when they were rediscovered by others. His name is preserved in studies of convection by the "Richardson number." a fundamental quantity involving the gradients of temperature and velocity. He died at Kilmun, Argyll, on Sept. 30, 1953.

See E. Gold, Obituary Notices of Fellows of the Royal Society, 9 (1954); J. R. hrewman (ed.), *World of Mathematics,* vol. *2* (1956). (G. SN.)

RICHARDSON, SIR OWEN WILLANS (1879–1959), English physicist awarded the Nobel prize for physics in 1928, was one of the founders of atomic physics. He discovered the Richardson law, concerning the emission of electricity from hot bodies, on which is based the action of wireless valves; his work on valves helped to revolutionize radio communication through the development of the hard thermionic valve. Born at Dewsbury, Yorkshire, on April 26. 1879. Richardson was educated at Trinity college, Cambridge. He was professor of physics at Princeton university, 1906–13, and at King's college: London, 1914–24, Yarrow research professor of the Royal society, director of research in physics at King's college and, from 1944, emeritus professor of physics of London university. Richardson was elected fellow of the Royal society in 1913 and was knighted in 1939. He died at Alton, Hampshire, on Feb. 1 j j 1959. Among other standard works he wrote *The Emission of Electrżcżty From Hot Bodies* (1916; 2nd ed., 1921).

RICHARDSON, SAMUEL (1689–1761), English novelist, the father of the novel of sentimental analysis, was born in Derbyshire in 1689. He was apprenticed at 17 to an Aldersgate printer named John Wilde. There he became successively compositor, corrector of the press, and printer on his own account; married his master's daughter; set up newspapers and books; dabbled in literature by compiling indexes and "honest dedications," and ultimately became printer of the journals of the house of commons, master of the Stationers' company, and law printer to the king. Like all a-ell-to-do citizens, he had his city house of business and his "country box" in the suburbs; and, after a thoroughly "respectable" life, died on July 4, 1761.

The origin of his first novel *Pamela* dates back to a request from Rivington of St. Paul's Churchyard and Osborn of Paternoster Row! two book-selling friends who were aware of Richardson's epistolary gifts, to suggest that he should prepare a little model letter writer for such "country readers" as "were unable to indite for themselves." The result mas *Pamela; or Virtue Rewarded.* He completed it in a couple of months (Nov. 10, 1739, to Jan. 16, 1740). In Nov. 1740 it was issued by Messrs. Rivington and Osborn, who, a few weeks afterward (Jan. 1741), also published the model letter writer under the title of *Lettevs written to and for Particular Friends, on the most Important Occasions.* Both books were anonymous. The letter writer and *Pamela* were noticed in the *Gentleman's Magazine* for January. Such was the immediate popularity of *Pamela* that not to have read it was judged "as great a sign of want of curiosity as not to have seen the French and Italian dancers"—*i.e.*, Mme. Chateauneuf and the Fausans, who were then delighting the town. In February a second edition appeared, followed by a third in March and a fourth in May. At public gardens ladies held up the book to show they had got it; Dr. Benjamin Slocock of Southwark openly commended it from the pulpit; Pope praised it; and at Slough, when the heroine triumphed, the enraptured villagers rang the church bells for joy.

Such popularity, of course, was not without its drawbacks. That it would lead to *Anti-Pamela,* censures of *Pamela* and all the spawn of pamphlets which spring round the track of a sudden success, was to be anticipated. One of the results to which its rather sickly morality gave rise was the *Joseph Andrews* (1742) of Henry Fielding (*q.v.*). But two other works prompted by *Pamela* need brief notice: the *Apology for the Life of Mrs. Shamela Andrews,* a clever and very gross piece of raillery which appeared in April 1741, and by which Fielding is supposed to have alluded to *Joseph Andrews;* and *Pamela's Conduct in High Life* (Sept. 1741), a spurious sequel by John Kelly of the *Universal Spectator.* Richardson tried to prevent the appearance of the latter, and, having failed, set about two volumes of his own, and professed to depict his heroine "in her exalted condition." It attracted no permanent attention.

About 1744 something was heard of Richardson's second and greatest novel, *Clarissa; or the History of a Young Lady,* usually miscalled *Clarissa Harlowe.* The first edition was in seven volumes, two of which came out in Nov. 1747, two more in April 1748 and the last three in December. Upon the title-page its object was defined as showing the distresses that may attend the misconduct both of parents and children in relation to marriage. Virtue, in *Clarissa,* is not "rewarded," but hunted down and outraged. The chief drawbacks of *Clarissa* are its merciless prolixity (seven volumes, which cover only 11 months); the fact that (like *Pamela)* it is told by letters; and a certain haunting and uneasy feeling that many of the heroine's obstacles are only molehills which should have been readily surmounted.

Between *Clarissa* and Richardson's next work appeared Fielding's *Tom Jones,* a rival by no means welcome to Richardson, although a rival who generously (and perhaps penitently) acknowledged *Clarissa's* rare merits in the *Jacobite's Journal.* But even this could not console Richardson for the popularity of the "spurious brat" whom Fielding had made his hero, and Richardson's next effort was the depicting of a genuine fine gentleman. In the *History of Sir Charles Grandison,* "by the Editor of *Pamela* and *Clarissa"* (for he still preserved the fiction of anonymity). he essayed to draw a perfect model of manly character and conduct. In the pattern presented there is, however, too much buckram, too much ceremonial—in plain words, too much priggishness—to make him the desired exemplar of propriety *in excelsis.* Yet he is not entirely a failure. When Richardson delineated Sir Charles Grandison he was at his best. and his experiences and opportunities for inventing such a character were infinitely greater than they had ever been before. And he lost nothing of his gift for portraying the other sex. Harriet Byron, Clementina della Porretta and even Charlotte Grandison, are no whit behind Clnrissa and her friend Miss Howe. *Sir Charles Gmndison,* in fine, is a far better book than *Pamela.*

Grandison was published in 17j3. and by this time Richardson was 64. Although the book was welcomed as warmly as were its predecessors, he nrote no other novel, contenting himself instead with indexing his works. and compiling an anthology of the "maxims." "cautions" and "instructive sentiments" they contained. To these things, as a professed moralist, he had always attached the greatest importance. He continued to correspond relentlessly with a large circle of worshippers, mostly women. He was a nervous. highly strung little man, intensely preoccupied with his health and his feelings. hungry for praise when he had once tasted it, and afterward unable to exist without it; but apart from these things. well meaning. benevolent, honest, industrious and religious. Seven vast folio volumes of his correspondence with his lady friends, and with a few men are preserved in the Forster library at South Kensington. Parts of it only have been printed

Richardson is the father of the novel of sentimental analysis. As Sir Walter Scott has said. no one before had dived so deeply into the human heart. No one, moreover, had brought to the study of feminine character so much prolonged research, so much patience of observation. so much interested and indulgent apprehension. That he did not more materially control the course of English fiction was probably due to the new direction which was given to that fiction by Fielding and Smollett,

whose method, roughly speaking, was synthetic rather than analytic. Still, his influence is to be traced in Sterne and Henry Mackenzie, as well as in Miss Burney and Miss Austen, both of whom, it may be noted, at first adopted the epistolary form. But it was in France, where the sentimental soil was ready for the dressing, that the analytic process was most warmly welcomed. Extravagantly eulogized by the great critic, Diderot, modified with splendid variation by Rousseau, copied (unwillingly) by Voltaire, the vogue of Richardson was so great as to tempt French critics to seek his original in the *Marianne* of a contemporary analyst, Marivaux. As a matter of fact, though there is some unconscious consonance of manner, there is nothing whatever to show that the little-letter author of *Pamela,* who was also ignorant of French, had the slightest knowledge of Marivaux or *Marianne.* In Germany Richardson was even more popular than in France. Gellert, the fabulist, translated him; Wieland, Lessing, Hermes, all imitated him, and Coleridge detects him even in the *Robbers* of Schiller. What was stranger still, he returned to England again under another form. The French *comédie larmoyante,* to which he had given a fillip, crossed the channel as the sentimental comedy of Cumberland and Kelly, which, after a brief career of prosperity, received its death-blow at the hands of Goldsmith and Sheridan.

Richardson's novels were edited by Mangin (19 vols., 1811), and an edition in 12 vols. was published by Sotheran in 1883 with preface by Sir Leslie Stephen. A *Collection of the Moral and Instructive Sentiments,* etc., was published in 1755. A selection from Richardson's *Correspondence* was published by Mrs. A. L. Barbauld in 1804, in six volumes, with a valuable Memoir. Recent lives are by Miss Clara L. Thornson, 1900, and by Austin Dobson ("Men of Letters"), 1902. A convenient reprint of the novels, with copies of the old illustrations by Stothard, Edward Burney and the rest, and an introduction by Mrs. E. M. M. McKenna, was issued in 1901 in 20 volumes.

(A. Do.; X.)

RICHBOROUGH, a port on the Stour, in Kent, Eng., 15½ mi. N. of Dover by road.

Richborough castle is one of the most remarkable monuments of the Roman occupation of Britain. It marked the beginning of Watling street and guarded the channel of the Wantsum, then separating the Isle of Thanet from the mainland. The site shoas signs of occupation in the Early Iron Age but it only entered history with the invasion of Claudius in A.D. 43. A base, *Rutupiae,* was established there nhich was used throughout the occupation. The extant remains include the north mall of the Saxon Shore fort, possibly built by Carausius in the 3rd century, 460 ft. long and 22 ft high. There is a cruciform platform of concrete, 126 ft. long and 82 ft. wide. It was probably a monument to the emperor Domitian A subterranean passage runs under the foundations of the platform. In 1926 excavations revealed a double series of ditches surrounding the fortifications.

During World War I, to relieve the traffic in military stores through Dover, the old port was re-established. The Stour was widened and deepened, a canal cut across a bend, and 250 ac. of marsh were reclaimed. Nearly a mile of wharfage was built and equipped. The port eventually became derelict.

RICHELIEU, ARMAND EMMANUEL SOPHIE SEPTEMANIE DU PLESSIS, DUC DE (1766–1822), French statesman, was born in Paris on Sept. 25, 1766, the son of Louis Antoine du Plessis, duc de Fronsac and grandson of the marshal de Richelieu (1696–1788). The comte de Chinon, as the heir to the Richelieu honours was called, was married at fifteen to Rosalie de Rochechouart, a deformed child of twelve, with whom his relations were never more than formal. After two years of foreign travel he entered the Queen's dragoons and next year received a place at court, where he had a reputation for Puritan austerity. He left Paris in 1790 for Vienna, and in company with his friend Prince Charles de Ligne joined the Russian army as a volunteer, reaching the Russian headquarters at Bender on the 21st of November. By the death of his father in February 1791, he succeeded to the title of duc de Richelieu. He returned to Paris shortly afterwards on the summons of Louis XVI., but he was not sufficiently in the confidence of the court to be informed of the projected flight to Varennes. In July he obtained a passport from the National Assembly for service in Russia. In 1803 he became governor of Odessa. Two years later he became governor general of the Chersonese, of Ekaterinoslav and the Crimea, then called New Russia. In the eleven years of his administration, Odessa rose from a village to an important city. The central square is adorned with a statue of Richelieu (1826). A magnificent flight of nearly 200 granite steps leads from the Richelieu monument down to the harbours.

Richelieu returned to France in 1814; on the triumphant return of Napoleon from Elba he accompanied Louis XVIII. in his flight as far as Lille, whence he went to Vienna to join the Russian army, believing that he could best serve the interests of the monarchy and of France by attaching himself to the headquarters of the emperor Alexander. As the personal friend of the Russian emperor his influence in the councils of the Allies was likely to be of great service. He refused, indeed, Talleyrand's offer of a place in his ministry, pleading his long absence from France and ignorance of its conditions; but after Talleyrand's retirement he succeeded him as prime minister.

The events of Richelieu's tenure of office are noticed elsewhere. *(See* FRANCE: *History.)* It was mainly due to his efforts that France was so early relieved of the burden of the allied army of occupation. It was for this purpose mainly that he attended the congress of Aix-la-Chapelle in 1818. There he had been informed in confidence of the renewal by the Allies of their treaty binding them to interfere in case of a renewal of revolutionary trouble in France; and it was partly owing to this knowledge that he resigned office in December of the same year, on the refusal of his colleagues to support a reactionary modification of the electoral law. After the murder of the duc de Berry and the enforced retirement of Decazes, he again became president of the council (Feb. 21, 1821); but his position was untenable owing to the attacks of the "Ultras" on the one side and the Liberals on the other, and on Dec. 12 he resigned. He died of apoplexy on May 17, 1822.

Part of Richelieu's correspondence, his journal of his travels in Germany and the Turkish campaign, and a notice by the duchesse de Richelieu, are published by the Imperial Historical Society of Russia, vol. 54. *See* also L. de Crousaz-Crétêt, *Le Duc de Richelieu en Russie et en France* (1897); L. Rioult de Neuville in the *Revue des questions historiques* (Oct. 1897); R. de Cisternes, *Le Duc de Richelieu, son action aux conférences d'Aix-la-Chapelle* (1898).

RICHELIEU, ARMAND JEAN DU PLESSIS DE, CARDINAL (1585–1642), French statesman, was born of an ancient family of the lesser nobility of Poitou. The cardinal's father, François du Plessis, seigneur de Richelieu (d. 1590), fought through the wars of religion, first as a favourite of Henry III., and after his death under Henry IV. His mother, Susanne de La Porte, belonged to a legal family. Armand was the third son and was born in Paris, Sept. 9, 1585. In 1606, at the age of twenty-one, he was nominated bishop of Luçon by Henry IV. As he was under the canonical age, he went to Rome to obtain a dispensation and was consecrated there in April 1607. In the winter of 1608 Richelieu went to his poverty-stricken little bishopric, and for the next six years devoted himseii seriousiy to his episcopal duties. In 1614 he was elected by the clergy of Poitou to the last States-general which met before the Revolution. There he attracted the attention of Marie de' Medici, the queen-mother, and was chosen at its close to present the address of the clergy embodying its petitions and resolutions. After the States-general was dissolved he remained in Paris, and the next year he became almoner to Anne of Austria, the child-queen of Louis XIII. He was appointed in 1616 a secretary of state to the king. But he owed all to Concini, and his taste of power ended with the murder of his patron on Aug. 24, 1617.

The reign which Richelieu was to dominate so absolutely began with his exile from the court. He resigned himself to the post of chief adviser to Marie de' Medici in her exile at Rlois. Here he sought to ingratiate himself with Luynes and the king by reporting minutely the actions of Marie and by protestations of loyalty. As this ungrateful work brought no reward, Richelieu retired once more to his bishopric. But he was exiled to Avignon, with his brother and brother-in-law, on April 7, 1618. There he wrote "A Defence of the Main Principles of the Catholic Faith," but

the escape of Marie de' Medici from Blois, on Feb. 22, 1619, again opened paths for his political ambition. Luynes and the king recalled him to the post at Angoulême with the queen-mother, who allowed him to sign the treaty of Angoulême with the Cardinal de la Rochefoucauld, acting for the king. By this treaty Marie was given liberty to live wherever she wished, and the government of Anjou and of Normandy with several castles was entrusted to her. Richelieu was made a cardinal by Pope Gregory XV., on Sept. 5, 1622.

Luynes's death on Dec. 15, 1621, made possible a reconciliation a month later between the king and his mother. Richelieu seized his opportunity. He furnished Marie de' Medici with political ideas and acute criticisms of the king's ministry, especially of the Brularts. Marie zealously pushed her favourite towards office, and eventually, in 1624, the king named him a member of his council. In August he became chief minister of Louis XIII.

Home Policy. — For the next eighteen years, he worked to make the royal power — his power — absolute and supreme at home, and to crush the rival European power of the Habsburgs. At home there were two opponents to be dealt with: the Huguenots and the feudal nobility. The former were crushed by the siege of La Rochelle and the vigorous campaign against the duc de Rohan. But the religious toleration of the edict of Nantes was reaffirmed while its political privileges were destroyed, and Huguenot officers fought loyally in the foreign enterprises of the cardinal. The suppression of the independence of the feudal aristocracy was inaugurated in 1626 by an edict calling for the destruction of castles not needed for defence against invasion. There was no serious opposition to the new minister. The first serious conspiracy took place in 1626, the king's brother, Gaston of Orleans, being the centre of it. His governor, Marshal D'Ornano, was arrested by Kichelieu's orders, and then his confidant, Henri de Talleyrand, marquis de Chalais and Vendôme, the natural son of Henry IV. Chalais was executed and the marshal died in prison. The overthrow of the Huguenots in 1629 made Richelieu's position seemingly unassailable, but the next year it received its severest test. Marie de' Medici had turned against her "ungrateful" minister with a hatred intensified, it is said, by unrequited passion. In September 1630, while Louis XIII. was very ill at Lyons, the two queens, Marie and Anne of Austria, reconciled for the time, won the king's promise to dismiss Richelieu. He postponed the date until peace should be made with Spain. When the news came of the truce of Regensburg Flarie claimed the fulfilment of the promise. On Nov. 10, 1630, the king went to his mother's apartments at the Luxembourg palace. Orders were given that no one should be allowed to disturb their interview, but' Richelieu entered by the unguarded chapel door. When Marie had recovered breath from such audacity she proceeded to attack him in the strongest terms, declaring that the king must choose between him or her. Richelieu left the presence feeling that all was lost. The king gave a sign of yielding, appointing the brother of Marillac, Marie's counsellor, to the command of the army in Italy. But before taking further steps he retired to Versailles, then a hunting lodge, and there, listening to two of Richelieu's friends, Claude de Saint-Simon, father of the memoir writer, and Cardinal La Valette, sent for Richelieu in the evening, and while the salons of the Luxembourg were full of expectant courtiers the king was reassuring the cardinal of his continued favour and support. The "Day of Dupes," as this famous day was called, was the only time that Louis took so much as a step toward the dismissal of a minister who was personally distasteful to him but who was indispensable. The queen-mother followed the king and cardinal to Compiègne, but as she refused to be reconciled with Richelieu she was left there alone and forbidden to return to Paris. The next summer she fled across the frontiers into the Netherlands, and Richelieu was made a duke. Then Gaston of Orleans, who had fled to Lorraine, came back with a small troop to head a rebellion to free the king and country from "the tyrant." The only great noble who rose was Henri, duc de Montmorenci, governor of Languedoc, and his defeat at Castelnaudary on the 1st of September 1632, was followed by his speedy trial by the parlement of Toulouse, and by his execution. Richelieu had sent to the block the first noble of France, the last of a family illustrious for seven centuries, the head of the nobility of Languedoc. He knew no mercy. The only other conspiracy against him which amounted to more than intrigue was that of Cinq Mars in 1642, at the close of his life. This vain young favourite of the king was treated as though he were really a formidable traitor, and his friend, De Thou, son of the historian, whose sole guilt was not to have revealed the plot, was placed in a boat behind the stately barge of the cardinal and thus conveyed up the Rhone to his trial and death at Lyons.

Foreign Policy. — Richelieu's foreign policy was as inflexible as his home policy. To humble the Habsburgs he aided the Protestant princes of Germany against the emperor, in spite of the strong opposition of the disappointed Catholic party in France, which had looked to the cardinal as a champion of the faith. The year of Richelieu's triumph over the Huguenots (1629) was also that of the Emperor Ferdinand's triumph in Germany, marked by the Edict of Restitution, and France was threatened by a united Germany. Richelieu, however, turned against the Habsburgs young Gustavus Adolphus of Sweden, paying him a subsidy of a million livres a year by the treaty of Bärwalde of Jan. 23, 1631. The dismissal of Wallenstein was of double value to Richelieu when his Swedish ally marched south. After the treaty of Prague, in May 1635, by which the emperor was reconciled with most of the German princes, Richelieu was finally obliged to declare war, and, concluding a treaty of offensive alliance at Compiègne with Oxenstierna, and in October one at St. Germain-en-Laye with Bernard of Saxe-Weimar, he proceeded himself against Spain, both in Italy and in the Netherlands. The war opened disastrously for the French, but by 1642, when Richelieu died, his armies, — risen from 12,000 men in 1621 to 150,000 in 1638 — had conquered Roussillon from Spain; they held Catalonia, which had revolted from Philip IV. of Spain, and had taken Turin and forced Savoy to allow French troops on the borders of the Milanese. In Germany Torstensson was sweeping the imperialist forces before him through Silesia and Moravia. The lines of the treaty of Westphalia, six years later, were already laid down by Richelieu; and its epochal importance in European history is a measure of the genius who threw the balance of power from Habsburg to Bourbon.

Personality. — His own personality was his strongest ally. The king himself quailed before that stern, august presence. His pale, drawn face was set with his iron will. His frame was sickly and wasted with disease, yet when clad in his red cardinal's robes, his stately carriage and confident bearing gave him the air of a prince. His courage was mingled with a mean sort of cunning, and his ambition loved the outward trappings of power as well as its reality; yet he never swerved from his policy in order to win approbation, and the king knew that his one motive in public affairs was the welfare of the realm — that his religion, in short, was "reason of state."

No courtier was ever more assertive of his prerogatives. He claimed precedence over even princes of the blood, and one like Condé was content to draw aside the curtains for him to pass, and to sue for the hand of Richelieu's niece for his son, the "Great Condé." His pride and ambition were gratified by the foundation of a sort of dynasty of his nephews and nieces, whose hands were sought by the noblest in the realm. Like all statesmen of his time. Richelieu made money out of politics. He came to court in 1617 with an income of 25,000 livres from his ecclesiastical benefices. In the later years of his life it exceeded 3,000,000 livres. He lived in imperial state, building himself the great Palais Cardinal, now the Palais Royal. in Paris, another at Rueil near Paris, and rebuilding his ancestral château in Poitou. In January 1641 the tragedy of *Mirame,* which was said to have been his own, was produced with great magnificence. Richeliru was anxious for literary fame, and his writings are not unworthy of him. But more important than his own efforts as an author were his protection and patronage of literary men, especially of Corneille, and his creation of the French Academy

in 1635. When he died, on Dec. 4, 1642. he was buried in the chapel of the Sorbonne, which still stands as he built it. His tomb, erected in 1694, though rifled at the Revolution, still exists.

Many writings are attributed to Richelieu, although because of his habit of working with substitutes and assistants it is difficult to settle how much of what passes under his name is authentic. *Les Tuileries, La Grande Pastorale, Mirame* and the other plays have long been forgotten, hut a permanent interest attaches to his *Mémoires* and correspondence: *Mémoire d'Armand du Plessis de Richelieu, l'année 1607 à 1610,* ed. by A. Baschet (1880); *Histoire de la mère et du fils* (Marie de Medici and Louis XIII), sometimes attributed to Mézeray (Amsterdam, 1730) and, under title *Histoire de la régence de reine Marie de Medici, femme de Henry IV* (The Hague, 1743); *Mémoires sur le règne de Louis XIII,* 1610 to 1638, and of which the earlier portion is a reprint of the *Histoive de la mère et du fils,* Petitot's collection (1823, *seq.*); *Testament politique d'Armand du Plessis, cardinal de R.* (Amsterdam, 1687, *seq.); Journal de 1630–31* (1645); "Lettres, instructions diplomatiques, et papiers d'état," publ. in the *Coll. de doc. ined.* (1853–77); these, with the *Mdmoires* in J. F. Michaud and J. Poujalat's collections, are the most important sources for Richelieu's statesmanship.

RICHELIEU, LOUIS FRANÇOIS ARMAND DU PLESSIS, DUC DE (1696–1788), marshal of France, was a grandnephew of Cardinal Richelieu and was born in Paris on March 13, 1696. As ambassador to Vienna (1725–29) he settled in 1727 the preliminaries of peace; in 1733–34 he served in the Rhine campaign. He fought with distinction at Dettingen and Fontenoy; three years afterward he made a brilliant defense of Genoa: in 1756 he expelled the English from Minorca by the capture of the San Felipe fortress; and in 1757–58 he closed his military career by those pillaging campaigns in Hanover which procured him the sobriquet of *Petit Pbre de la Maraude.* In his early days he was thrice imprisoned in the Bastille: in 1711 at the instance of his stepfather. in 1716 in consequence of a duel, and in 1719 for his share in Alberoni's conspiracy against the regent Orléans. He died in Paris on Aug. 8, 1788.

RICHEPIN, JEAN (1849–1926), French writer in the tradition of Villon and the poets of low life. Born at Médéa, Algeria, Feb. 4, 1849, the son of an army doctor, he left the École Normale early and during the Franco-German War joined the *francs-tireurs.* He worked as a sailor, an actor and a docker before his first book of poems. *La Chanson des gueux* (1876), won him both instantaneous fame and a month's imprisonment for its immorality. When Zola revolutionized the French novel by introducing naturalism, Richepin did the same for poetry in *Les Caresses* (1877), *Les Blasphbmes* (1884) and *La Mer* (1886). He wrote novels himself: *Les Morts bizarres* (1876), *La Glu* (1881) and *Miarka* (1883); besides very successful plays: *Nana Sahib* (1883), in which he acted with Sarah Bernhardt, *Le Flibustier* (1888), *Par le glaive* (1892), *Les Truands* (1899) and *Le Chemineau* (1897; Eng. tr. by W. Wallace, 1910), a lyric drama with music by Xavier Leroux. To be properly appreciated he should be considered in his period, when thinkers were preoccupied with materialism and "scientism" as expounded by Ernst Haeckel and Ludwig Biichner. *Les Blasphbmes* translates this philosophy into verse of great power, and it has been said that Richepin's very defiance of God was almost a tribute to Him. He was director of the Académie Française (to which he was elected in 1908) nhen he died in Paris on Dec. 11, 1926. (R. DL.)

RICHERUS (*fl.* 10th century), monk of St. Remi at Reims and a chronicler of the 10th century, studied at Reims under Gerbert, afterward Pope Silvester II. He was still living in 998, but there is no later mention of him. His *Historiae* has a unique value as giving the only tolerably full account by a contemporary of the revolution of 987, which placed the Capets on the throne of France. From 969 Richerus had no earlier history before him, and he is the chief source for the period.

There are French translations by Guadet (1845) and Poinsignon (1855).

RICHET, CHARLES (ROBERT) (1850–1935), French physiologist, was born in Paris on Aug. 26, 1850, the son of Alfred Richet, a well-known surgeon. He obtained his M.D. in 1877, but before this he had carried out important researches on the role of conditioned reflexes in the digestive process and had discovered that the acid of gastric juice is hydrochloric acid. In 1881 he was appointed codirector of the *Revue Scientifique* and in 1887 he was nominated professor of physiology in the faculty of medicine of the University of Paris. He worked on the physiology of respiration, on epilepsy and on the treatment of tuberculosis by feeding with raw meat.

More important were his researches on immunity. He discovered that an animal can be immunized against an infection by introducing blood taken from another animal that has already been immunized against the infection in question. On Dec. 16, 1890, he gave the first serotherapeutic injection into a human being. Richet's discovery of anaphylaxis followed upon and was connected with his work on serum therapy. He found that the injection of certain protein substances, instead of producing immunity, caused the development of a state of hypersensitivity. Anaphylaxis ("without protection") was recognized as the converse of immunity. Its discovery threw new light on diseases like hay fever and asthma and on drug reactions and serum sickness; and it provided an explanation for many mysterious cases of intoxication and sudden death. For this work—which was of profound significance both for theory and practice—Richet was awarded the Nobel prize for medicine in 1913.

Richet made outstanding contributions in many other fields. He was distinguished not only as a physiologist, bacteriologist, pathologist, psychologist and medical statistician, but also won fame as a pioneer of aviation, as an earnest worker on behalf of peace, as a scientific investigator of occult phenomena and as a poet, novelist and playwright. Among his many works the most outstanding were *Physiologie: Travaux du laboratoire de C. Richet* (1882–1909); *L'Anaphylaxie* (1911; Eng. trans. 1925); *L'Homme stupide* (1919; Eng. trans. 1925); *Traitk de métapsychique* (1922; Eng. trans. 1923); *Le Savant* (1923); and *L'Intelligence de l'homme* (1927). He died in Paris on Dec. 4, 1935. (W. J. BP.)

RICHFIELD, a village of Hennepin county in southeastern Minnesota, U.S., is located immediately south of Minneapolis. It experienced rapid growth between 1950 and 1960.

Originally called Harmony and Richland, it was renamed in 1858 when the early residents of the area held their first town meeting in a schoolhouse near Richfield Mills. It was incorporated as a village in 1908; in 1950 it adopted a village-manager form of government.

Although mainly a residential suburb of Minneapolis, it has several small light-industrial establishments that manufacture metal and wood products. Agriculture was once the dominant industry and, while its importance has diminished in the economy of the community, there is still significant dairying and truck farming of small vegetables, fruits and berries.

For comparative population figures *see* table in MINNESOTA: *Population.* (R. W. F.)

RICHLAND, a planned city and atomic-industry town in Benton county, Wash., U.S., is located near the confluence of the Yakima and Columbia rivers about 50 mi. W. of Walla Walla. Once it was the home of the Wanapam, or Wanapum, Indians, a division of the Sahaptin stock. Nelson Rich, builder of a local irrigation system, laid out a town there in 1892; incorporated in 1910, its population of about 250 remained virtually static until the site became part of the 400,000-ac. reservation of the Hanford atomic energy plant.

Its population was 1,415 by 1944, grew to 13,453 the next year

and rose to 23,548 by 1960. (For comparative population figures see table in WASHINGTON: Population.)

First administered by the U.S. army corps of engineers and E. I. du Pont de Nemours & Co., the Atomic Energy commission and the General Electric company took over on Jan. 1, 1947. Transfer of real estate to its residents began in 1951, and in 1959 it became incorporated as a city with a council-manager form of government. (H. J. DE.)

RICHMOND, EARLS AND DUKES OF. The title earl of Richmond appears to have been in existence in England a considerable time before it was held in accordance with any strict legal principle. Alan III, duke of Brittany (997–1040), had a brother Eudon who at first disputed the ducal title with him and with his successor Conan II (1040–66) but was eventually satisfied with a partition of the family's lands and the style of "count of Brittany." Two of Eudon's sons. likewise "counts of Brittany," Alan Rufus (d. 1089) and Alan Niger (d. 1093), took part in William the Conqueror's invasion of England.

Alan Rufus was rewarded with grants in various parts of England, including manors formerly held by Earl Edwin in Yorkshire, on one of which he built the castle of Richmond. His possessions there were formed into the honour of Richmond. to which first Alan Niger and after him his youngest brother Stephen (d. 1135 or 1136) succeeded. Stephen, moreover. succeeded to all the Breton lands that had previously been divided among the sons of Eudon. These "counts of Brittany" are often reckoned as earls of Richmond, though they were not so in the strict and later sense. The first to style himself and to be styled earl of Richmond was Stephen's son Alan III Niger (d. 1146).

This Alan married Bertha, daughter and heiress of Conan III, the reigning duke of Brittany; and his son Conan IV (d. 1171), who married Margaret, sister of Malcolm IV of Scotland, asserted his right to Brittany and transferred it in his lifetime to his daughter Constance (d. 1201). As he left no sons the honour of Richmond and his other English possessions passed to Constance. Constance was three times married: first to Geoffrey Plantagenet (1158–1186), son of Henry II, king of England; then to Ranulf de Blundevill. earl of Chester (c. 1172–1232), the marriage with whom Constance treated as null on the ground of consanguinity; and finally to Guy, brother of the viscount of Thouars, who survived her. Geoffrey and Ranulf in turn assumed the title earl of Richmond: and Guy for a time at least acted as if he held the honour. The only son of the first marriage. Arthur of Brittany (1187–1203). was styled earl of Richmond in his mother's lifetime. On his murder at the hands of his uncle, King John, the earldom was resumed by the crown.

By her third husband Constance had two daughters, the elder of whom, Alice, was given in marriage by Philip II Augustus, king of France, to Peter of Braine (Peter of Dreux or Pierre Mauclerc) in 1212. after which date Peter was styled duke of Brittany. In 1219 he received seisin of the lands of the earldom of Richmond; but in 1235 he finally renounced his allegiance to the king of England and thereupon suffered forfeiture of his English earldom.

In 1240 Henry III granted the honour of Richmond to Peter of Savoy (c. 1203–68), uncle of Queen Eleanor. who was thereafter described as earl of Richmond by contemporary chroniclers, though never in official documents. By his will Peter left the honour of Richmond to his niece, the queen consort, who transferred it to the crown. In the same year (1268) Henry III granted the earldom specifically to John, duke of Brittany (1216–86), son of Peter of Braine. in whose family the title continued — though it frequently was forfeited or reverted to the crown and was regranted to the next heir — till 1342, when Edward III granted it to his son John of Gaunt, who surrendered it in 1372. It was then given to John de Montfort, duke of Brittany, but on his death without heirs in 1399 it was seized by the crown.

The earldom now became finally separated from the duchy of Brittany. with which it had been loosely conjoined since the Conquest. although the dukes of Brittany continued to assume the title till a much later date. From 1414 to 1435 the earldom of Richmond was held by John Plantagenet, duke of Bedford, and in 1452 it was conferred on Edmund Tudor, uterine brother to King Henry VI, whose wife, Margaret Beaufort, was the foundress of St. John's college, Cambridge, and of the Lady Margaret professorships of divinity at Oxford and Cambridge. (See BEAUFORT, MARGARET.)

When Edmund Tudor's son Henry ascended the throne as Henry VII in 1485 the earldom of Richmond merged in the crown, but in 1525 Henry Fitzroy, natural son of Henry VIII by Elizabeth Blount, was created duke of Richmond and Somerset and earl of Nottingham, all these titles becoming extinct at his death without children in 1536.

Ludovic Stuart: 2nd duke of Lennox (1574–1624), who also held other titles in the peerage of Scotland, was created earl of Richmond in 1613 and duke of Richmond in 1623. These became extinct at his death in 1624, though his Scottish honours devolved on his brother Esmé, who was already earl of March in the peerage of England. (See MARCH, EARLS OF; and LENNOX.) Esmé's son, James. 4th duke of Lennox (1612–55), was created duke of Richmond in 1641, the two dukedoms as well as the lesser English and Scottish titles thus becoming again united. In 1672, on the death of his nephew Charles, 3rd duke of Richmond and 6th duke of Lennox, whose wife was the celebrated beauty called "La Belle Stuart" at the court of Charles II (see RICHMOND AND LENNOX. FRANCES TERESA STEWART. DUCHESS OF). his titles became extinct.

In 1675 Charles II created his illegitimate son Charles duke of Richmond) earl of March and Baron Settrington. This Charles (1672–1723), on whom the king bestowed the surname of Lennox, was the son of the celebrated Louise de Kéroualle, duchess of Portsmouth. His son Charles, 2nd duke (1701–50), added .to the titles he inherited from his father that of duke of Aubigny in France, to which he succeeded in 1734 on the death of his grandmother the duchess of Portsmouth; these honours continued to be held by his descendants, the later dukes of Richmond.

The 2nd duke, by his marriage with Sarah, daughter of the 1st Earl Cadogan, was father of Lady Caroline Lennox, who eloped with Henry Fox and was the mother of Charles James Fox. Another daughter of the 2nd duke was the beautiful Lady Sarah Lennox (1745–1826) with whom George III fell in love and contemplated marriage. and who afterward married, first. Sir Thomas Bunbury, from whom she was divorced, and second; George Napier, by whom she was the mother of Generals Sir Charles and Sir William Napier.

Charles, 3rd duke of Richmond (1735–1806), was famous for his advanced views on the question of parliamentary reform. Having succeeded to the peerage in 1750 and fought at Minden (1759), he was appointed British ambassador extraordinary in Paris in 1765, and in the following year he became a secretary of state in the Rockingham administration, resigning office on the accession to power of the earl of Chatham. In the debates on the policy that led to the American War of Independence Richmond was a firm supporter of the colonists. Richmond also advocated a policy of concession in Ireland, with reference to which he originated the famous phrase "a union of hearts." In 1779 the duke brought forward a motion for retrenchment of the civil list; and in 1780 he embodied in a bill his proposals for parliamentary reform. which included manhood suffrage, annual parliaments and equal electoral areas. Richmond sat in Rockingham's second cabinet as master general of the ordnance; and from Dec. 1783 he held the same office under William Pitt. He now developed strongly Tory opinions, and his alleged desertion of the cause of reform led to a violent attack on him by Lauderdale in 1792. Richmond died in Dec. 1806 and, leaving no legitimate children, was succeeded in the peerage by his nephew Charles.

The 5th duke (1791–1860), while still known by the courtesy title of earl of March, served on Wellington's staff in the peninsula and fought at Waterloo. He was M.P. for Chichester (1812–19). He was afterward a vehement opponent in the house of lords of Catholic emancipation, and at a later date a leader of the opposition to Peel's free trade policy. In 1836, on inheriting the estates of his maternal uncle, the 5th and last duke of Gordon. he assumed the name of Gordon before that of Lennox. On his death in 1860 he was succeeded in his titles by his son Charles Henry. 6th duke of Richmond (1818–1903), a statesman who held various

cabinet offices in the Conservative administrations of Lord Derby, Disraeli and the marquess of Salisbury; and who in 1876 was created earl of Kinrara and duke of Gordon. These honours in addition to the numerous family titles of more ancient creation passed on his death to his son Charles Henry Gordon-Lennox (1845–1928) and later to his son's descendants.

RICHMOND, GEORGE (1809–1896), English portrait painter. was born at Brompton (now within Kensington, London), on March 28, 1809. In 1824 he went to study under Henry Fuseli at the Royal Academy schools, there forming friendships with Samuel Palmer and Edward Calvert. Through them, and John Linnell, he met William Blake, who profoundly affected his early life and art. After his runaway marriage in 1831, however, he turned to portraiture for a livelihood, earning a national reputation for work in water colour and crayon. He was a staunch supporter of the Oxford church reformers, and the large group of his works in the National Portrait gallery, London, includes likenesses of John Keble, J. H. Newman and Edward Pusey. Richmond was elected to the Royal Academy in 1866. He died in London, March 19, 1896.

His second son, SIR WILLIAM BLAKE RICHMOND (1842–1921), was early a disciple of John Ruskin and the Pre-Raphaelites, later a painter of antique mythological subjects and a successful portraitist He executed mosaics in the sanctuary of St. Paul's cathedral (1891 ff.) He succeeded Ruskin in the Oxford Slade professorship (1879–83); and was appointed knight commander of the Bath in 1897.

See A M W Stirling (ed.), *Richmond Papers* (1926).

RICHMOND, a municipal borough in the Richmond parliamentary division of Surrey, Eng., on the right bank of the Thames, 9 mi. S.W. of Charing Cross, London. Pop. (1951) 41,944. Area 6 4 sq mi. Richmond was the site of the royal manor house of Sheen in the 12th century. Rebuilt as a palace by Edward III, who died there in 1377, it was also the scene of the deaths of Henry VII and Elizabeth I and of Anne of Bohemia, queen of Richard II who afterward razed it. It was rebuilt by Henry V, but burned down again in 1498. Henry VII finally re-erected it in 1501, renaming village and palace after his earldom of Richmond in Yorkshire. It was a favourite home of Henry VIII, who gave it to Cardinal Wolsey after the latter had presented him with Hampton Court. During the Civil War much of the building was demolished and today only the gateway remains. The site is now occupied by gracious Georgian houses. Attached to the palace was a large park, now known as the Old Deer park, and there Henry V founded a Carthusian priory in 1416. All traces of this disappeared in the mid-18th century, and on the site stands Kew observatory, built in 1768–69 by Sir William Chambers for George III, and now an important meteorological station. To the south lies Richmond park, enclosed by Charles I in 1637 and containing White lodge, built for George II and the birthplace of Edward VIII. The main gate is on Richmond hill, which commands the famous view of the Thames valley. A theatre has existed on various sites since 1719, and the many celebrated figures associated with it include Dorothy Jordan and Edmund Kean. The latter is buried in the parish church, uhere also is the grave of James Thomson, the poet (1700–48), who lived for 12 years in a house which is now part of the Royal hospital.

Richmond was incorporated in 1890, and the borough now includes Kew. Petersham. North Sheen and Ham, where Ham house, built in 1610, contains Stuart furniture.

RICHMOND, a municipal borough in the Richmond (Yorks) parliamentary division of the North Riding of Yorkshire, Eng , 45 mi. N.N.W. of York by road. Pop. (1951) 6,166. Area 3.9 sq mi. It lies on the left bank of the Snale, where the valley is still narrow and steep-sided before the river emerges from the Pennines into the Vale of York.

The town is chiefly interesting because of the castle, which occupies the summit of a high cliff. The castle was founded about 1071 by Alan Rufus of Penthièvre in Brittany, who is said to have rebuilt the town on obtaining from William the Conqueror the estates of the Saxon earl Edwin, which embraced some 200 manors of Richmond and extended over nearly a third of the North Riding. This tract was called Richmondsbire at that time, but the date of the creation of the shire is uncertain. William the Lion of Scotland was imprisoned in the castle in the reign of Henry II; otherwise the town owes its importance chiefly to its lords. It was a valuable possession in the middle ages, and was usually in royal or semiroyal hands. The whole shire reverted to the crown on the accession of Henry VII. The original castle covered an area of 5 ac., but the only portions remaining are the Norman keep, with pinnacled tower and walls 109 ft. high by 11 ft. thick, and some smaller towers.

The French name of Richmond (Richemund) was not traced farther back than about 1100, but it is probable that there was an earlier settlement on the site. As far as is known, the earliest charter was granted in 1145 giving the burgesses the borough of Richmond to hold for ever in fee farm at an annual rent of £29. but a charter dated 1146 shows that the burgesses enjoyed some municipal liberties at an earlier period. In 1278, a yearly fair was granted and in 1329, Edward III gave the first royal charter to the town. A charter of incorporation, under the title of aldermen and burgesses, mas granted in 1576 by Queen Elizabeth I who also allowed a market each Saturday, an animal market every fortnight, and a fair each year on the vigil of Palm Sunday. In 1668, Charles II granted a charter under the title of mayor and aldermen. This charter, though superseded later, uas restored in the reign of James II, and, until the passing of the Municipal Corporations act of 1835, was regarded as the governing charter of the borough. Although Richmond received a summons as early as 1328, it was not represented in parliament until 1584, from which time it usually sent two members. From 1867 to 1885 one member was sent. In 1889, Richmond became the seat of a bishop suffragan in the diocese of Ripon, but the second and last bishop died in 1921.

The church of St. Mary is transitional Norman, Decorated and Perpendicular, and is largely restored. The church of the Holy Trinity, in the large market place, is ancient and was restored to use from ruins; only the nave and a detached tower remain. A curfew bell is tolled every evening and in the mornings the 'Prentice bell. The 16th-century tower of a Franciscan abbey, founded in 12 58, still stands. Close to the town are the ruins of Easby abbey, a Premonstratensian foundation of 1152, beautifully situated by the river. The remains include a Decorated gateway, an Early English chapel and fragments of the transepts and choir of the church, with sufficient portions of the domestic buildings to enable the complete plan to be traced. In Friar's Wynd is the Theatre Royal, a Georgian theatre (1788). In Hill house lived Frances l'Anson or Janson, "the lass of Richmond Hill," to whom her future husband, Leonard MacNally, wrote the verses of the famous song.

The free grammar school existed in 1390, and was refounded in 1567, but the present building dates from 1850.

The principal trade is in agricultural produce, and as Richmond possesses the only railway station in Swaledale, the market is still important.

See R. Gale, *Registrum Honoris de Richmund* (London, 1722); C. Clarkson, *The History and Antiquities of Richmond* (Richmond, 1821); T. D. Whitaker, *A Hzstory of Richmondshire,* 2 vol. (London. 1823); *Victoria County Hzstory of Yorkshtre: North Riding,* 2 vol. and index (London, 1914–23).

RICHMOND, a city of Contra Costa county, Calif., U.S., is situated on the eastern shore of San Francisco bay, 16 mi. N.E. of San Francisco via the San Francisco-Oakland bay bridge. The Richmond-San Rafael bridge connects it nith Marin county.

The city, which is in the San Francisco-Oakland standard metropolitan area, experienced a phenomenal growth during World War II, and the population grew from 23,642 in 1940 to 99,545 in 1950, but with removal of wartime public housing declined to 71,854 in 1960.

Development of the area dates from 1899, when the Santa Fe railway purchased a right of way to the bay shore. In 1900 Point Richmond became the western terminal of the system, and ferry service was established to San Francisco. The construction of a large oil refinery in 1902 furthered settlement. The city is an important industrial centre! and its harbour is one of the busiest on the Pacific coast. Major industries include petroleum refining, railroad shops; food processing and the manufacture of chemicals, electronic equipment, aircraft parts and plumbing fixtures.

The city was incorporated in 1905 and adopted the council-manager form of government in 1920. Richmond civic centre includes the city hall, hall of justice, a public library and an auditorium. (M. H. Mo.)

RICHMOND, a city of Indiana, U.S., is located 68 mi. E. of Indianapolis; the seat of Wayne county. Settled in 1806 by migrating North Carolina antislavery Quakers and German and Irish immigrants, Richmond has always been a centre of Quaker influence and organizations. The publications office and the general offices of the Five Years Meeting of Friends (Quakers) are located there. and the sessions of this group are regularly held in the city. Earlham college, a Quaker-controlled liberal arts co-educational institution founded in 1847 and noted for the large number of its graduates who have distinguished themselves in public life, is also located in Richmond, on a modern 120-ac. campus.

The Art association, civic theatre, symphony orchestra. Musical Arts society and Wayne County Historical museum are civic enterprises. Richmond also has several golf courses and city parks. Located in a prosperous agricultural area, early industries included grain threshers and steam engines, buggies and carriages, and lawn movers; later industries were diversified and include automotive parts, school-bus bodies and cut-flower production. It was chartered as a city in 1840.

For comparative population figures see table in INDIANA: *Population.* (WI. R.)

RICHMOND, a borough of New York city and a county of New York, U.S., the two having identical boundaries. Richmond includes all Staten Island and part or all of several smaller islands in New York harbour. It was named after the duke of Richmond, son of Charles II of England.

Indian attacks wiped out the earliest settlements. The first permanent settlement was made under Dutch authority in 1661 at Oude Dorp ("Old Town"). Three years later the British drove out the Dutch and took control. Gen. William Howe landed his forces on Staten Island in 1776, making it a base for his successful attack on Gen. George Washington's positions on Long Island and Manhattan. During the 19th century, Richmond grew more slowly than other sections of modern New York city, partly because it was cut off by water barriers and had to rely on ferries for transportation. When greater New York city was formed in 1898, Richmond county became one of its five boroughs.

Modern Richmond is linked by bridges to the New Jersey mainland. It is an important shipping and manufacturing centre and an expanding residential area. In Richmond are Wagner Lutheran college (established 1883), Notre Dame College of Staten Island (Roman Catholic, established 1931), a community college, a zoo, museums, libraries, hospitals and several historic houses. There at Billopp house in 1776 Adm. Richard Howe tried to persuade representatives of the Continental congress to reconcile their differences with England. See also NEW YORK (CITY).

(J. A. FR.)

RICHMOND, the capital of Virginia, U.S., and the seat of Henrico county, is located at the falls of the James river, 100 mi. S. of Washington, D.C. Its maximum elevation above sea level is 312 ft. The annual precipitation is 43 in. and the mean annual temperature is 57.9" F., combining to give the city a moderate and comfortable climate. In 1960 Richmond had a population of 219,958 in the city itself and 408,494 in the standard metropolitan statistical area (comprising the city of Richmond and Chesterfield and Henrico counties). For comparative population figures for the city see table in VIRGINIA: *Population.* Although the city lost population between 1950 arid 1960. the metropolitan area made a substantial gain of 23.8%. Residential suburbs have grown with great speed since World War II. Despite this rapid growth. Richmond has managed to preserve a civic personality which, in its friendliness and good humour, is usually found only in much smaller communities.

History. — The first Europeans to visit the present site of Richmond were a party of 21 men led by Christopher Newport and John Smith, who sailed up the James in 1607 a short time after the founding of Jamestown. In 1637 Thomas Stegg established a trading post at the falls of the James, and in 1644, following the Indian massacre of that year, Ft. Charles was built. Indian attacks continued to harass the settlers, and in exchange for a grant of land William Byrd I undertook to maintain 50 men at Ft. Charles to protect the frontier. In 1737 William Byrd II, who had inherited a large tract of land at the falls, allowed Maj. William Mayo to lay out a town on what is now Church hill; it was incorporated by the general assembly in 1742 and in that year had a population of 250.

In the period of the American Revolution, Richmond was the scene of the Virginia conventions of 1774 and 1775, and in 1780 was made the state capital, replacing Williamsburg. At that time the town still had less than 300 buildings and when it was occupied by the British in 1781 the capitol was so humble a structure that the invaders were unable to find and destroy it. Construction of the present capitol was begun four years later.

By the beginning of the 19th century, Richmond's population had grown to 5,735. and the city was becoming a commercial and transportation centre of increasing prominence In 1840 it was linked to Lynchburg by the James river and Kanawha canal. By 1860 there were 43 tobacco factories, several iron foundries, flour and corn mills, and establishments manufacturing carriages, textiles. nails. cutlery and paper; the census of 1860 ranked Richmond 13th among American cities in manufacturing. By that same year six railroads terminated in the city. Culturally the ante-bellum years were brightened by visits of such famous literary and stage figures as Charles Dickens, William Thackeray, Jenny Lind and Joseph Jefferson. Edgar Allan Poe edited the *Southern* Literary Messenger in Richmond from 1834 to 1837.

The coming of the American Civil War brought Richmond into a national and international prominence unparalleled in the city's history. Following the secession of Virginia in April 1861, the capital of the Confederacy was moved to Richmond from Montgomery. Ala. As the seat of government, and also because of its factories and railroads, Richmond was the major military objective of Union armies for four years.

In 1862 Gen. George B. McClellan's army of the Potomac mas within hearing of the city's church bells but was driven away in the Seven Days' battle (*q.v.*), June 26–July 2. Although threatened from time to time by cavalry raids, the city was not again closely beset until June 1864, when the siege of Richmond and Petersburg began. Finally, on April 2, 1865, Gen. U. S. Grant broke through the Coniederate defenses, and the city was abandoned that same night, a large part of the business section being destroyed by fire in the course of the evacuation. (See also PETERSBURG CAMPAIGN and WILDERNESS.)

During the difficult postwar years Richmond was more fortunate than other southern cities in having an industry with a seemingly unlimited market: tobacco, especially cigarettes. With this as an economic base, rebuilding and recovery were soon under way. Flour mills and an iron foundry were revived; railroads were reconstructed; paper and chemical factories were established. By 1890 the population was 85.000, more than twice that of 1860. The depression of the 1930s once again demonstrated the value of the tobacco industry to the municipal economy, for Richmond suffered much less than many other U S. cities. Economic revival and growth mere greatly stimulated by the advent of World War II. After the war, in 1948, the strong mayor type of government was discarded in favor of the council-manager system.

Historic Sites. — Richmond is pre-eminently a historic city, a fact in which its citizens have always taken great pride. The capitol was designed by Thomas Jefferson. after the Maison Carrée at Nîmes, France, and contains the famous Houdon statue of George Washington. St. John's church, where Patrick Henry

delivered his "Liberty or Death" address, is still a place of worship. At the corner of 9th and Marshall streets stands the house designed. built and occupied by Chief Justice John Marshall. Reminders of the American Civil War period are numerous. Richmond is, in fact, perhaps the chief repository and guardian of the Confederate legend. The Confederate White House, the Valentine museum, Battle abbey and the Virginia Historical society all contain books, paintings, relics and manuscripts from the war years. On Monument avenue stand large bronze statues portraying Jefferson Davis, Generals Lee, Jackson and Stuart and Comdr. Matthew Fontaine Maury. Remains of elaborate entrenchments that encircled the city can still be found in many places.

Commerce, Industry and Transportation. — In the economic life of the city, commerce is more significant than manufacturing. The chamber of commerce estimates that retail stores draw customers from 40 counties and 9 cities, including a population of over 1,000,000. The three leading components of this trade are general merchandise, food and automobiles. Richmond's wholesale market embraces most of the state plus the eastern half of North Carolina, with a sales volume twice that of retail trade. The most important products manufactured or processed in the Richmond area (ranked according to employment) are tobacco, chemicals, food, metals, paper products, printing, clothing, lumber and wood products. The presence of the Fifth Federal Reserve bank makes the city a financial centre for five states and the District of Columbia.

Richmond is the state's most important transportation centre and is served by several major railroads and airlines, as well as bus and truck lines. The Richmond-Petersburg turnpike allows north-south traffic to bypass both cities. At the Deepwater terminal on the James ocean-going vessels bring cargoes from the Gulf coast, Cuba, Canada and elsewhere.

Education and Cultural Activities. — Richmond has a vigorous public-school system, which absorbs one-fourth of the municipal income, and a number of excellent private and parochial schools. Among the institutions of higher learning are the University of Richmond (Baptist, founded 1830), Medical College of Virginia (state-supported), Union Theological seminary (Presbyterian, founded 1812) and Virginia Union university (Baptist, established 1865).

The Mosque, a municipal auditorium seating over 4,500, is the scene of dramatic productions, as well as concerts by the Richmond Symphony orchestra and visiting orchestras. The state's finest collection of paintings and *objets d'art,* including the works of Rubens. Murillo and Reynolds, is exhibited by the Virginia Museum of Fine Arts. Library facilities include the Virginia State library and the Richmond Public library. (L. H. J.)

RICHMOND AND LENNOX, FRANCES TERESA STEWART, DUCHESS OF (1648–1702), daughter of a physician in the household of Queen Henrietta Maria when she was in exile after 1649. was born in 1648 and was brought up in France. Henrietta Maria sent her to England, where she was appointed maid of honour to Catherine of Braganza. queen of Charles II. Charles II became infatuated with her. and it is stated that in 166; he was considering the possibility of obtaining a divorce in order to make her his uife. This was at a time when he feared to lose her as his mistress, since her hand was sought in marriage by Charles Stewart, duke of Richmond and Lennox. In March 1667 she eloped with Richmond and married him secretly; but on her return to court she retained her hold on the king's affections.

See C H. Hartmann, La Belle *Stuart* (New York, London, 1924).

RICHMOND RIVER AND BASIN, together with the basins of the Tweed and Clarence rivers, forms the largest area of coastal lowland in New South Wales, Australia (c. 125 mi. N.-S.; 20–40 mi. E.-W.). The area is subject to violent rainstorms which cause wide flooding on the lower ground. Electric power is developed on the Nymboida tributary of the Clarence. Dairying, the main feature of local farming, produces about two-thirds of the state production of butter, with large factories at Byron bay, Lismore and Grafton. The whole of the cane sugar produced in New South Wales (about 5% of Australian output) is grown in the area. Yields per ton of cane are somewhat lower than in Queensland and the growing period is nearly double (20–24 months against 12–14 months). The district is linked by rail with Sydney, and by both a through route and a coastal route to Brisbane. (T. HER.)

RICHTER, EUGEN (1839–1906), German politician, was born on July 30, 1839 at Düsseldorf. After attending the universities of Bonn, Heidelberg and Berlin, he entered the government service. In 1864 he was chosen burgomaster of Neuwied; but he was already known for his Liberal opinions, and the government refused to confirm the appointment and transferred him to Bromberg, in East Prussia. In consequence, he resigned from the public service, went to Berlin and entered journalism. A consistent advocate of the economic doctrines of the Manchester school, he was also keenly interested in the working-class co-operative movement, on which he wrote a book. In 1867 he was tried for revolutionary tendencies but acquitted. In 1867 he was elected a member of the Reichstag. and in 1869 of the Prussian parliament. A member of the Progressive party, in 1880 one of the founders, and eventually the leader, of the Freisinnige, he was always in opposition. Next to Ludwig Windthorst he was Bismarck's most dangerous opponent, and leader of the opposition to the introduction of protection, to the new colonial policy introduced after 1878, and to state socialism. He also strongly opposed all increases in the army and navy; and it was his opposition to the army measures of 1893 which finally split his party. leaving him with only a small following. In 1885 he founded the *Freisinnige Zeitung,* which he edited himself; he also wrote many political brochures and works on Prussian finances. He died at Jena, on Jan. 26. 1906.

See his reminiscences *Jugenderinnerungen* (1892) and *Im alten Reichstag* (2 vols, 1894–96).

RICHTER, HANS (1843–1916), Austro-Hungarian musical conductor, born at Gyor on April 4, 1843, was the son of the chapel master at the cathedral, whose wife, *née* Josephine Csazinsky, was an operatic singer. He studied (1860–65) at the Vienna Conservatoire and in 1866–67 he assisted Richard Wagner in Switzerland, making a fair copy of the *Meistersinger* score. In 1878 he assisted in the domestic performance of the *Szegjried Idyll.*

In 1871, after holding some minor posts, Richter was appointed conductor of the Hungarian National opera at Budapest, and in May 1875 began his long connection with the Vienna opera, which terminated only with the century. In 1876 he directed the rehearsals and performances of Wagner's *Ring* at Bayreuth. and in 1877 paid his first visit to England to conduct the Wagner concerto at the Albert Hall. In 1879 he founded the Richter concerts in London and quickly established himself as a prime favourite there. Later, in 1882, he conducted a famous series of performances of Wagner's works (including the first in England of *Die Meistersinger* and *Tristan)* at Drury Lane; special performances of German opera mere also conducted by him at Covent Garden from 1904 until his retirement. In 1897 he became conductor of the Hallé orchestra in Manchester, doing splendid service in this capacity, while previously in 1885 he had established an equally happy connection with Birmingham as conductor of the Birmingham Triennial festival. His last performance of *Die Meistersinger* nas given at Bayreuth in 1912, and his last years were spent in retirement there. He died on Dec. 5, 1916. As a conductor Richter nas supreme in the interpretation of Wagner, though hardly less great in that of Mozart. Beethoven, Brahms and other German classical masters. He took no interest in non-German composers, but made an exception of Sir Edward Elgar.

RICHTER, JOHANN PAUL FRIEDRICH (1763–1825), usually called JEAN PAUL, German author, was born at Wunsiedel, in Bavaria, on March 21, 1763. His father was a schoolmaster and organist at Wunsiedel, but in 176j he became a pastor at Joditz near Hof, and in 1776 at Schwarzenbach, where he died in 1779. After attending the gymnasium at Hof. Richter went in 1781 to the University of Leipzig. Unable to maintain himself at Leipzig he returned in 1784 to Hof, mhere he lived with his mother. From 1787 to 1789 he served as a tutor at Töpen, a village near Hof; and afterward he taught the children of several families at Schwarzenbach.

Richter's first work was *Grönländische Prozesse* and *Auswahl*

aus des Teufels Papieren, the former of which was issued in 1783–84, the latter in 1789. In later life Richter had little sympathy with their satirical tone. His next book, *Die unsichtbare Loge,* a romance. published in 1793, had all the qualities which were soon to make him famous, and its power was immediately recognized. He then produced in rapid succession *Hesperus* (1; 95), *Biographische Belustigungen unter der Gehirnschale einer Riesin* (1796), *Leben des Quintus Fixlein* (1796), *Blumen- Frucht- und Dornenstücke, oder Ehestand, Tod und Hochzeit des Armenadvokaten Siebenkäs* (1796–97), *Der Jubelsenior* (1797), and *Das Kampaner Tal* (1797). This series of writings won for Richter an assured place in German literature.

In 1797 he went to Leipzig, and in the following year to Weimar, where he had much pleasant intercourse with Herder: by whom he was warmly appreciated. He did not become intimate with Goethe and Schiller, to both of whom his literary methods were repugnant; but in Weimar, as elsewhere, his good talk and genial manners made him a favourite in general society. In 1801 he married Caroline Meyer, whom he met in Berlin in 1800. They lived first at Meiningen, then at Coburg; and finally, in 1804, they settled at Bayreuth. Here Richter spent a quiet, simple and happy life, constantly occupied with his work as a writer. in 1808 he was delivered from anxiety as to outward necessities by the prince-primate, K. T. von Dalberg, who gave him a pension of a thousand florins. Before settling at Bayreuth, Richter had published his most ambitious novel, *Titan* (1800–3); and this was followed by *Flegeljahre* (1804–5), two works which he himself regarded as his masterpieces. His later imaginative works were *Dr. Katzenbergers Badereise* (1809), *Des Feldpredigers Schmelzle Reise nach Flatz* (1809), *Leben Fibels* (1812), and *Der Komet, oder Nikolaus Marggraf* (1820–22). In *Vorschule der Aesthetik* (1804) he expounded his ideas on art; he discussed the principles of education in *Levana, oder Erziehungslehre* (1807); and the opinions suggested by current events in *Friedenspredigt* (1808), *Dämmerungen fur Deutschland* (1809), *Mars und Phöbus Thronwechsel im Jahre 1814* (1814), and *Politische Fastenpredigten* (1817). In his last years he began *Wahrheit aus Jean Pauls Leben,* to which additions from his papers and other sources were made after his death by C. Otto and E. Förster. In 1821 Richter lost his only son, and never quite recovered from the shock. He died of dropsy, at Bayreuth, on Nov. 14, 1825.

Schiller said of Richter that he would have been worthy of admiration "if he had made as good use of his riches as other men made of their poverty." And it is true that in the form of his writings he never did full justice to his great powers. In working out his conceptions he found it impossible to restrain the expression of any powerful feeling by which he might happen to be moved. He was equally unable to resist the temptation to bring in strange facts or notions which occurred to him Hence every one of his works is irregular in structure, and his style lacks directness, precision and grace. But he had an amazingly fertile imagination and a surprising power of suggesting great thoughts by means of the simplest incidents and relations Richter was a great nature-lover and deeply religious in spirit; to him visible things were but the symbols of the invisible, and in the unseen realities alone he found elements which seemed to him to give significance and dignity to human life. His humour, the most distinctive of his qualities, cannot he dissociated from the other characteristics of his writings. It determined to some extent the form in which he embodied even his most serious reflections. It is sometimes extravagant and grotesque but never harsh or vulgar, and generally it springs naturally from the perception of the incongruity between ordinary facts and ideal laws. With all his wilfulness and eccentricity Richter was a man of a pure and sensitive spirit, with a passionate scorn for pretence and an ardent enthusiasm for truth and goodness.

RICHTHOFEN, FERDINAND, BARON VON (1833–1905), German geographer and traveler, was born near Karlsruhe. Silesia, on May 5, 1833. He was educated at Breslau and Berlin, and in 1856 carried out geological investigations in the Tirol, subsequently extending them to Transylvania In 1859 he accompanied. as geologist. the Prussian diplomatic mission to the Far East under Count von Eulenburg, and visited Ceylon. Japan, Formosa, the Philippines and Java, subsequently making an overland journey from Bangkok to Moulmein and reaching Calcutta in 1862. No important work resulted from these rravels, for much of Richthofen's records and collections was lost. China was at the time inaccessible owing to the Taiping rebellion, but Richthofen was impressed with the desirability of exploring it, and after a visit to California. where he remained till 1868, he returned to the east. In a remarkable series of seven journeys he penetrated into almost every part of the Chinese empire. He returned home in 1872, and a work comprising three large volumes and an atlas, which, however, did not cover the entire field or complete the author's plan, appeared at Berlin in 1877–85 under the title of *China; Ergebnisse eigner Reisen und darauf gegründeter Studien.* In this standard work the author deals not only with geology but with every subject necessary to a general geographical treatise. Notably he paid close attention to the economic resources of the country he traversed; he wrote a valuable series of letters to the Shanghai Chamber of Commerce, and first drew attention to the importance of the coalfields of Shantung, and of Kiaochow as a port In 1875 Richthofen was elected professor of geology at Bonn. but being fully occupied with his work in China he did not take up professorial duties till 1879; in 1883 he became professor of geography at Leipzig, and in 1886 was chosen to the same office at Berlin, and held it till his death. He died Oct. 16. 1905.

Among his other works are *Natural System of Volcanic Rocks* (San Francisco, Calif, 1867); *Aufgaben und Methoden der heutzgen Geographie* (an address delivered at Leipzig, 1883); *Führer* fur *Forschungsreisende* (Berlin, 1886); *Triebkrafte und Richtungen dev Erdkunde in neunzehnten Jahrhundert* (address on his election as rector, Berlin, 1903)

RICIMER (d. 472), master of the Roman empire in the west during part oi the 5th century, was the son of a prince of the Suebi and the daughter of Wallia, king of the Visigoths. His youth mas spent at the court of Valentinian III, and he won distinction under Aetius. In 456 he defeated the Vandals in a sea fight near Corsica, and on land near Agrigentum in Sicily. He then gained the consent of the Roman senate to an expedition against the emperor Avitus. whom he defeated at Piacenza on Oct. 16, 456. Ricimer then obtained from Leo I, emperor at Constantinople, the title patrician, but in 457 set up Majorianus as his own emperor in the west. When, however, Majorianus tried to rule by himself, Ricimer forced him to abdicate and caused his assassination on Aug. 7, 461. The successor whom Ricimer placed upon the throne was Libius Severus. who proved to be more docile than Majorianus. Upon his death in 465—said to be due to the poison of Ricimer—this emperor-maker ruled the west for eighteen months without an emperor, and then accepted Leo's candidate, Anthemius. Before long. however, Ricimer moved to Milan, ready to declare war upon Anthemius. St. Epiphanius, bishop of Milan, patched up a truce, but in 472 Ricimer proclaimed as emperor, Olybrius, whom Leo had sent to pacify the two enemies, and after three months' siege captured Rome, on July 1, 472. Anthemius was massacred and Rome was a prey to Ricimer's soldiers. Ricimer died on Aug. 18, 472.

The main authorities for this period are in Mommsen's *Chron. Minora,* 3 vol. (1892–98). *See* also Gibbon ed. Bury pp. 15-49 (1907); L. M. Hartmann. *Geschichte Italiens im Mittelalter.* vol. i (1897).

RICKARD, THOMAS ARTHUR (1864–1953), U.S mining engineer and author, was born in Pertusola, Italy, on Aug. 29, 1864, of English parents. His early life was spent in Switzerland, Russia and England, and he was graduated from the Royal School of Mines, London, in 1885. Moving to the United States in that year, he began practice as a mining engineer in Colorado; subsequently he served as manager or consultant for mining operations in Australia, New Zealand, France. Mexico, Nova Scotia, Yukon Territory and Alaska. Rickard was the author of many books, both technical and nontechnical, and during the period 1903–22 he was editor, for varying periods, of *Engineering and Mining Journal,* New York, *Mining and Scientific Press,* San Francisco, and *Mining Magazine,* London. Two of Rickard's books dealt with the techniques of writing. and his stated ambition was to help improve the writing of those in the engineering profession.

We died Aug. 15, 1953, at Victoria. B.C. (C. N. S.)

RICKENBACKER, EDWARD VERNON (1890–), U.S. airline executive, was born in Columbus. O., Oct. 8, 1890. He had little formal education but very early became interested in internal combustion engines and in engine-driven vehicles of all kinds. By the time the United States entered World War I, Rickenbacker had become famous for his reckless preoccupation with speed on the race tracks. He was one of the country's top three racing drivers and had set a world speed record of 134 m.p.h. at Daytona Beach, Fla. He went overseas as an army sergeant-driver attached to Gen. John J. Pershing's staff but quickly gravitated into aviation. He proved to be a natural fighter piiot and ended the war as America's outstanding "ace." with the rank of captain. He was awarded almost every decoration attainable.

Rickenbacker returned to the automobile industry after World War I. He headed his own company, the Rickenbacker Motor Car company, for a time and on its dissolution joined Cadillac Motor Car company and then its associated aviation interest, General Aviation Mfg. Co. He transferred to the airline business in 1932, first with American Airways and then with North American Aviation, Inc. On Jan. 1, 1935, he began his career with Eastern Air Lines. rising from general manager to chairman of the board of directors. Except for a period during World War II when he toured many of the combat theatres as a special representative of the U.S. secretary of war, he applied his energies to build Eastern Air Lines into one of the leading air-transport systems of the world. (S. P. J.j

RICKETS, a deficiency disease of infancy and childhood characterized by a disturbance of the normal process of ossification of bones with resultant deformity. Rickets is a systemic disease and most commonly eccurs toward the end of the first year and during the second year of life. Rare instances of congenital rickets are caused by a deficient maternal diet, Factors predisposing to the development of rickets are rapid growth, prematurity and increased susceptibility to the disease. Negro children are singularly susceptible. Genetic factors play a minor role in infantile rickets although multiple cases have been observed in a family. usually caused by similar dietary inadequacies. Common early symptoms may include profuse sweating particularly during sleep, vomiting and diarrhea. History of an inadequate dietary intake of vitamin D is usually obtained. *(See* VITAMINS: *Vitamin D.)* Softening of the bones of the skull in the first few months of life may he an early sign. Enlargement of the ends of the long bones in the region of the epiphyses and a knobbed appearance of the ribs at their junctions with the costal cartilages are common findings. The diagnosis is easily made by X-ray examination of the ends of the long bones. If no treatment is instituted early in the disease the bones show various degrees and types of curving and deformity. the legs being more deformed than the arms so that "bow-legs" or "knock-knees" develop. Bending may occur in the legs before walking is begun although with weight-bearing the bending increases. Curvature of the spine. deformity of the pelvis and the bowing of the legs result in reduction in height. The deformity of the pelvis in the female may lead to difficulty with childbearing later in life. The head of the rachitic child appears large in its upper part, the individual bones of the cranium sometimes remaining ununited for a prolonged time. The face appears small, the teeth appear late and fall out or decay early. Commonly the disease terminates in spontaneous recovery, the bones firmly ossifying although remaining altered in shape. Complications associated with rickets include bronchitis, bronchopneumonia, gastroenteritic disturbances, muscular weakness, enlargement of the liver and spleen and anemia. *See* also BONE. DISEASES ASD INJURES OF.

Rickets is recognized to be largely, if not entirely. the result of a deficiency of vitamin D. Early treatment of rickets with vitamin D in the form of concentrates, irradiated ergosterol, fish oils, exposure to sunlight or ultraviolet light or at times merely with an adequate enriched diet can prevent all the deformities mentioned above. Rickets is observed in conjunction with, or as a complication of, other diseases such as scurvy, coeliac disease, cystinosis and renal failure. A rare form of rickets is refractory to vitamin D therapy. The cause for this is unknown. Conditions which are mistaken for rickets include chondrodystrophy (formerly known as fetal rickets). familial osseous dystrophy (Morquio's disease), osteogenesis imperfecta, congenital hypothyroidism (cretinism) and hyperparathyroidism. ***See*** also MALNUTRITION.

RICKETTS, CHARLES (1866–1931), English artist, editor and publisher. was born in Geneva. Switz., on Oct. 2, 1866, and educated in France. In 1889 he became joint editor with Charles Shannon of the *Dial.* In 1896 he founded the Yale press. the output of which was a series of beautifully designed and printed books. Of his pictures "The Plague" (1911) is in the Luxembourg at Paris and "Don Juan" (1916) in the National gallery, London. He published *The Prado and Its Masterpieces* (1903): *A Bibliography of the Books Issued by Hacon and Ricketts* (1904); *Titian* (1906); *Pages on Art* (1913).

RICKETTS, LOUIS DAVIDSON (1859–1940), U.S. mining engineer who brought more of the world's great copper-mining properties into production than perhaps any other engineer, was born in Elkton, Md., on Dec. 19, 1859. He received the degrees of B.S. and Sc.D. from Princeton university in 1881 and 1583, respectively, and then spent seven years acquiring experience in various western mining camps. He was given important assignments as consulting engineer and manager by the Phelps Dodge corporation and the Anaconda Copper Mining company chiefly in properties in which those firms were interested in Arizona and Mexico. Though he was consultant to many companies, his connection with the Inspiration company. beginning in 1912, was perhaps his most important administrative post, as he became president of the firm. His specialty was the design and construction of copper-ore concentrators. smelters and leaching plants.

He was president of the American Institute of Mining Engineers in 1916, and was designated Arizona's "most useful citizen" in 1915. He died on March 4, 1940. (E. H. R.)

RICKETTSIAE are minute microorganisms which resemble very small bacteria but which grow only within susceptible cells and occur in certain arthropods (insects, mites. ticks). Some cause important diseases in man or domestic animals. (See Q FEVER; TYPHUS FEVER; ROCKY MOUNTAIN SPOTTED FEVER AND OTHER SPOTTED FEVERS.) Numerous other organisms resembling rickettsiae occur both in vertebrates and. as symbiotes. in arthropods, but their exact relation to the human pathogens is unknown.

History. — The history of the rickettsiae is intimately associated with those forms causing human disease. Epidemic typhus, one of the great plagues of mankind. was first differentiated from typhoid fever on clinical grounds in 1837. Its nature was so catastrophic that it completely dominated the field. and sporadic occurrences of other similar diseases were hardly noticed. Late in the 19th century, however, a typhuslike disease (Rocky mountain spotted fever) was recognized in the United States and river fever (tsutsugamushi disease. or scrub typhus) was first clearly described in Japan. By 1910 association of these diseases with arthropods was being established on firm scientific grounds with the demonstration of tick transmission of spotted fever and louse transmission of typhus. Elucidation of the microbes causing these diseases began with the work of Howard Taylor Ricketts, who described the new organism of spotted fever in 1909 and who, with Wilder in 1910, also described the organism of typhus fever from the blood of patients in Mexico. Confirmatory reports appeared in rapid succession, and in 1916 the typhus-fever organism was named *Rickettsia prowazekii* in honour of Ricketts and Stanislas von Prowazek, both typhus victims themselves. For a time the etiology of typhus again became clouded because of technical diffitulties, isolation of spurious agents and the discovery of nonpathogenic rickettsialike microorganisms in lice, hut the relation between the louse-borne *Rickettsia prowazekii* and typhus fever was finally clearly settled by 1922. Another rickettsialike agent causing trench fever was discovered during World War I.

Meanwhile, productive studies continued on spotted fever in the United States; variants of spotted fever were recognized in dif-

ferent parts of the world; and scrub-typhus rickettsiae were isolated. In the 1920s and 1930s numerous symbiotic organisms resembling rickettsiae were found in various arthropods. The tick-transmitted agent of heartwater fever in ruminants was identified with the rickettsiae, as were several other agents from domestic animals.

A mild typhuslike disease (Brill-Zinsser disease) was first noted in 1898 in New York. later also in other eastern seaboard cities, in immigrants from typhus-afflicted areas of Europe; the disease existed under conditions precluding louse transmission. A very similar disease, for a time confused with Brill's disease, was recognized in the southern United States beginning about 1913. However, on epidemiological grounds Kenneth F. Maxcy (1929) brilliantly postulated that the southern disease was harboured by rodents and transmitted by a biting arthropod. Eventually, during the 1930s, murine (flea-borne) and epidemic (louse-borne) typhus were clearly differentiated. Still, the northern cases did not fit this pattern. Hans Zinsser imaginatively suggested that they were sporadic recrudescences of past epidemic typhus infections, a hypothesis later verified.

In the late 1930s Q fever (*q.v.*), recognized first independently in Australia and the United States and subsequently shown to enjoy wide geographic distribution in man and domestic animals, yielded a new rickettsial agent, Coxiella *burnetii* (or Rickettsia burneti). Finally. still another rickettsial disease, rickettsialpox, caused by R. akari, was recognized in New York city in 1946.

Morphology and Chemistry. — Rickettsiae are minute (usually under 0.5 μ in diameter), nonspore-forming, nonmotile organisms which vary in form from round to rod shaped. They stain poorly with ordinary aniline dyes, are Gram-negative but may be seen readily under the ordinary light microscope with special stains. A cell wall from which the protoplast inside readily shrinks on drying is clearly visible under the electron microscope and, at least in typhus rickettsiae, contains an antigenic polysaccharide. Like bacteria, rickettsiae of typhus and Q fever contain both ribonucleic and deoxyribonucleic acids and purified suspensions of some, unlike small viruses, display a modest array of independent metabolic activities.

Taxonomy. — Despite a long-felt and still-growing impression among many authorities that rickettsiae are closely related to bacteria, they have been placed in a separate class (Microtatobiotes) along with the viruses. Controversy has long existed about the inclusion of numerous other pathogenic and nonpathogenic morphologically similar organisms with the rickettsiae. While there is no sound biological basis for excluding nonpathogenic rickettsialike organisms from the rickettsial group, the fact remains that the human pathogens have been subjected to the greatest study. Controversy about classification will undoubtedly persist until more adequate information is at hand on all forms to provide sound taxonomic criteria.

Biological Properties. — Most rickettsiae are peculiarly adapted to arthropods. The mite- and tick-borne forms are especially well adapted, being harmless to the vector and transmitted from one generation to the next through the egg. Spotted-fever rickettsiae from overwintering ticks must undergo a unique reactivation phenomenon to gain full virulence for mammals. The association of R. prowazekii with body lice, wherein the vector itself succumbs to the infection and passage through the egg does not occur, suggests less complete and possibly more recent adaptation. From the widespread occurrence of rickettsialike symbiotes in arthropods and the prominent role of arthropods in rickettsial transmission has evolved the idea that pathogenic forms may have developed originally from symbiotes accidentally introduced into the vertebrate host by biting arthropods. Man appears only as an incidental host except in epidemic typhus, and probably trench fever, where man is the only known reservoir.

Most rickettsiae pathogenic for man (except possibly R. *quintana*) grow only within animal cells (in intact animals, embryonated eggs or tissue cultures), where they multiply by binary fission There is no confirmed growth in cell-free media. Optimal growth occurs at about 35° C., lower than the body temperature of most mammalian hosts. Outside cells, most rickettsiae perish quickly unless they are preserved by freezing (−70° C.) or lyophilization. Suspensions of some pathogenic rickettsiae exert a rapid toxic effect on the vascular systems of susceptible laboratory animals as well as a lytic action on the red blood cells of certain animal species.

Some Important Human Rickettsioses

Disease	Causative rickettsia	Main vector	Vertebrate reservoir
Typhus group			
Epidemic typhus (including Brill-Zinsser disease)	*Rickettsia prowazekii*	body louse	man
Murine typhus (endemic typhus)	*Rickettsia typhi (mooseri)*	rat flea	rats
Spotted fever group (selected examples)			
Rocky mountain spotted fever	*Rickettsia rickettsii*	ticks	probably wild rodents
Fièvre boutonneuse	*Rickettsia conorii*	ticks	dogs, rodents (?)
Rickettsialpox	*Rickettsia akari*	mites	mice
Scrub typhus (tsutsugamushi disease)	*Rickettsia tsutsugamushi*	chiggerlike mites	wild rodents
Trench fever	*Rickettsia quintana*	body louse	man
Q fever	*Coxiella burnetii*	occasionally tick; mainly air, dust, contact	cattle, sheep goats, bandicoots

Rickettsial Diseases. — Most human rickettsial diseases resemble one another remarkably. Symptoms include abrupt onset of fever, lasting one to two weeks and accompanied by headache, varying degrees of mental clouding, prostration and. after a few days, a rash. Q fever, an outstanding exception, is generally mild, produces no rash but commonly presents lung infiltrations. All are naturally transmitted by some arthropod. Q fever, however, is more often contracted by contact with infected domestic animals, their carcasses or by the inhalation of contaminated air-borne particles.

During infection the organisms are disseminated throughout the body by the blood, although some proliferate also at the site of introduction to produce a small ulcer (eschar). Except for R. quintana and *C.* burnetii, rickettsiae causing human disease tend to proliferate in, and damage, the cells lining small blood vessels. Vascular damage in the skin is often associated with rash, hemorrhage or necrosis.

The intracellular habitat is probably responsible for certain unusual features of rickettsial infections, for within some body cells rickettsiae seem to be protected from antibodies and other deleterious substances. Despite the appearance of circulating antibodies just preceding and during convalescence. some viable rickettsiae persist within lymphoid tissues for months and even years after apparent recovery from epidemic (louse-borne) typhus, Rocky mountain spotted fever and scrub typhus (tsutsugamushi disease). In most instances they persist there harmlessly, but sometimes recrudescence of the latent epidemic typhus infection at a later date gives rise to a relatively mild, recurrent, typhuslike illness (Brill-Zinsser disease). During recrudescences rickettsiae again circulate in the blood. Lice feeding upon such a patient may become infected and capable of transmitting fully virulent epidemic typhus. See also BACTERIAL AND INFECTIOUS DISEASES; BACTERIOLOGY.

RICKMAN, THOMAS (1776–1841), English architect whose work reflected the Gothic revival, was born on June *8.* 1776, at Maidenhead, Berkshire, and died at Birmingham on Jan. 4, 1841. He designed many churches, the new court of St. John's college, Cambridge, and a palace for the bishop of Carlisle. These are all in the Gothic style but show more knowledge of its outward form than real acquaintance with its spirit. Rickman played

a part in the revival of medievalism perhaps second only to A. W. N. Pugin. Rickman's *Attempt to Discriminate the Styles of Architecture in England* ran through many editions.

RICKMANSWORTH, an urban district in the South West Herts parliamentary division of Hertfordshire, Eng., lies at the confluence of the Colne, the Gade and the Chess on the borders of Buckinghamshire and Middlesex. Pop. (1951) 24,508; (1957 est.) 26,640. Area 11.9 sq.mi. Rickmansworth is an old market town which has grown since World War I into a large residential district spreading into the river valleys and the surrounding woodland. Stretches of water meadows and woods have been acquired by the council as part of London's greenbelt. In the long High street are some red-brick Georgian buildings including St. Joan of Arc's Convent school and Basing house, once the home of William Penn, the founder of Pennsylvania, and now the council offices. The Royal Masonic School for Girls was built in Rickmansworth in 1928–33 and Merchant Taylors' school was built (2 mi. E.) in 1931–33. Moor park, to the east, is a splendid 18th-century mansion built on the site of a house once belonging to Cardinal Wolsey. Designed in 1720, it has a classical front with a four-column portico, a lavishly decorated great entrance hall and gardens laid out by Lancelot ("Capability") Brown. It now belongs to the council and is used as a golf clubhouse; there are three golf courses in its 400 ac. of parkland.

RICOCHET, a military term denoting the rebound of a projectile that strikes a hard surface; it is also applied to the projectile itself In the now obsolete ricochet fire in war, the shot, after striking the ground at a small angle, described for the remainder of its course a succession of leaps and falls. The discovery of this type of fire. usually attributed to Vauban (siege of Ath in 1697), had the greatest influence both on sieges and on operations in the field. In siege warfare, ricochet. especially when combined with enfilade (*i.e.*, when directed along the enemy's line of defense), soon became the principal weapon of the besieger. Enfilade (q *v.*) fire by itself was neutralized by traverses, or banks of earth at right angles to the line of defense, but by the new method a shot could be so aimed as to skip over each successive traverse and thus to search ground that was immune from direct fire The application of ricochet fire to operations in the field came somewhat later. In the 18th century field artillery. which, before Napoleon's time, was not sufficiently mobile to close with the enemy, relied principally upon the ricochet of round shot. which. sweeping a considerable depth of ground, took effect upon several successive lines of hostile troops. But once artillery was able to gallop up to the enemy and to use its far more terrible close-range projectile, case shot, ricochet fire came to be used less and less. Finally, with the general adoption of explosive-filled shells (which usually burst at the first contact with the ground). the round shot disappeared altogether from the battlefield.

Similarly in siege warfare, as soon as high-angle fire with shells became sufficiently accurate, there was no further need of round shot and ricochet. Ricochet fire with delayed action fuzes was occasionally used in World War II to obtain air burats after initial impact

The term "ricochet" is now only applied, in modem rifle shooting, to the graze of a bullet that has struck short. A modern bullet that has ricocheted inflicts a very severe mound.

RIDGWAY, MATTHEW BUNKER (1895–), U.S. army officer uho, during World War II, wastresponsible for the planning and execution of the first major air-borne assault in the history of the U S. army aith the attack on Sicily. He was born at Fort Monroe. Va., March 3, 1895, and graduated from the Cnited States Military academy in 1917. Before World War II he served in various staff positions. As commanding general of the 82nd air-borne division, he parachuted with his troops into Normandy in 1944 and subsequently led the 18th air-borne corps in action in the Netherlands, Belgium and Germany.

Assuming command of the U.S. 8th army in Korea during the Chinese Communist offensive in late 1950, Ridgway rallied the United Nations forces and initiated a counteroffensive that drove the enemy out of South Korea. Assigned in 1951 as the over-all Allied commander in the far east. succeeding Gen. Douglas MacArthur, he continued the successful defense of the Republic of Korea and assisted in the rehabilitation of Japan. In 1952 he succeeded Gen. Dwight D. Eisenhower as supreme commander, Allied forces in Europe, and in 1953 was appointed chief of staff of the U.S. army. He retired in 1955, having reached the rank of general in 1951. Ridgway's war memoirs appeared in 1956 under the title of *Soldier*. (W. SI.)

RIDING, THRPTHING or **THRIDING,** a Scandinavian term for the third part of a shire or county, *e.g.,* the ridings of Yorkshire and of Lindsey in Lincolnshire. In Iceland the third part of a *thing* which corresponds roughly to an English county was called *thrithjungr;* in Norway, however, the *thrithjungr* seems to have been an ecclesiastical division. To the riding causes were brought which could not be determined in the wapentake, and a matter which could not be determined in the riding was brought into the court of the shire. There is abundant evidence that riding courts were held after the Norman Conquest.

Each of the ridings of Yorkshire has its own lord lieutenant and commission of the peace, and under the Local Government Act of 1888 forms a separate administrative county. They are distinguished as the north, east and west ridings, but the ancient divisions of Lindsey were known as the north, south and west ridings respectively.

RIDING: *see* HORSEMANSHIP AND RIDING.

RIDLEY, NICHOLAS (*c.* 1500–1555), English bishop and martyr, was the second son of Christopher Ridley of Unthank Hall, near Willemoteswick, Northumberland. He was sent about 1518 to Pembroke Hall, Cambridge. Having graduated M.A. in 1526 he went to study at the Sorbonne in Paris and at Louvain, and on his return to Cambridge was appointed junior treasurer of his college. In 1534 he was one of the university proctors, and signed the decree of the university against the jurisdiction of the pope in England. Ridley was now chaplain to the university and began to show leanings to the reformed faith. In 1537 he became chaplain to Thomas Cranmer, archbishop of Canterbury, and in April 1538 vicar of Herne, Kent. In 1540 he was chosen master of Pembroke Hall; in 1541 he became chaplain to Henry VIII. and canon of Canterbury. In 1543 he was accused of heretical teaching and practices but acquitted, although just after his exculpation he finally abandoned the doctrine of transubstantiation.

In September 1547 Ridley was nominated bishop of Rochester. He was one of the visitors who were appointed to establish protestantism in the University of Cambridge; in 1548 helped to compile the English prayer book, and in 1549 was one of the commissioners who examined Bishops Gardiner and Bonner. He concurred in their deprivation, and succeeded Bonner in the see of London. Having signed the letters patent settling the English crown on Lady Jane Grey, Ridley, in a sermon preached at St. Paul's cross on July 9th, 1553, affirmed that the princesses Mary and Elizabeth were illegitimate, and that the succession of the former would be disastrous to the religious interests of England. When Lady Jane's cause was lost, however, he went to Framlingham to ask Queen Mary's pardon, but was at once arrested and sent to the Tower of London. From his prison he wrote in defence of his religious opinions, and early in 1554 he, with Cranmer and Latimer, was sent to Oxford to be examined. He defended himself against a number of divines, but was declared a heretic. and excommunicated. He refused to recant, and in Oct. 1555 he was tried for heresy under the new penal laws, being degraded and sentenced to death. With Hugh Latimer he met his end at the stake in Oxford on Oct. 16, 1555.

See *Works of Nicholas Ridley D.D.* (ed. *H.* Christmas, Parker Soc., 1841). His *Life* was written *by* Dr. Gloucester Ridley in 1763, and there is a memoir of him in Moule's edition of the bishops' *Declaration* of *the Lord's Supper* (1895).

RIDOLFI or RIDOLFO, **ROBERTO DI** (1531–1612), Italian conspirator, born at Florence on Nov. 18, 1531, settled in London about 1555. In 1570 he set to work on the plot against Elizabeth which is usually associated with his name. His intention was to marry Mary, queen of Scots, to the duke of Norfolk and to place her on the English throne. In 1571 he visited the duke of Alva at Brussels, Pius V. at Rome, and Philip II. at

Madrid to explain to them his scheme and to gain their active assistance thereto. His messenger, by name Charles Baillie (1542–1625), was, however, seized at Dover; Norfolk and Lesley were arrested, the former being condemned to death in January 1572. Ridolfi, who was then in Paris, died at Florence on Feb. 18, 1612.

RIEGER, PHILIPP FRIEDRICH VON (1818–1903), Bohemian politician and publicist, was born on Dec. 18, 1818, at Semil, Bohemia. He first came into prominence as one of the Czech leaders in the revolution of 1848. In 1853 he married a daughter of the historian Palacky. In 1858 he started the *Slovnik naučny,* the Czech national encyclopaedia and also helped to found the first Czech political daily newspaper published in Prague (1861), of which he was for a while the editor. After the issue of the "October diploma" of 1860, Rieger, with Palacky, undertook the leadership of the reconstituted Czech party. In 1871 he conducted the negotiations with the Hohenenwarth ministry for a federal constitution of the empire, which broke down owing to his extreme attitude in the matter of Bohemian independence On the reappearance of the Czechs in the Bohemian diet (1878) and the Austrian *Reichsrath* (1879) Rieger, as chief of the so-called "Old Czechs," supported Count Taaffe's government. In 1891, together with the other "Old Czechs," he was defeated at the poll. In March 1897 he was created a baron (*Freiherr*) and given a seat in the Upper House, but his influence was now at an end. He died on March 3, 1903.

RIEL, LOUIS (1844–1885), Canadian agitator, son of Louis Riel and Julie de Lagemaundière, was born at St. Boniface, on Oct. 23, 1844, according to his own account, though others place his birth in 1847. Though known as a half-breed, or Métis, and though with both Indian and Irish ancestors, his blood was mainly French. From July 1866 he worked for two years at various occupations in Minnesota, returning in July 1868 to St. Vital, near St. Boniface. In 1869 the transfer of the territorial rights of the Hudson's Bay Company to the dominion of Canada gave great uneasiness to the Métis, and in October 1869 a party led by Riel turned back at the American frontier the newly appointed Canadian governor; in November they captured Fort Garry (Winnipeg), the headquarters of the Company, and called a convention which passed a bill of rights.

In December a provisional government was set up, of which on Dec. 29, Riel was made president, and which defeated two attacks made on it by the English-speaking settlers of the vicinity. So far the Métis had been within their rights, but Riel was flighty, vain and mystical, and his judicial murder on March 4, 1870. of Thomas Scott, an Orangeman from Ontario, roused against him the whole of English-speaking Canada. An expedition was sent out under Colonel Garnet, later Lord Wolseley, which captured Fort Garry on Aug. 24. 1870; Riel decamped.

Riel was not arrested and on Aug. 4. 1871, urged his countrymen to combine with the Canadians against a threatened attack from American Fenians, for which he was publicly thanked by the lieutenant governor. In 1872 for religious reasons he changed his name to Louis David Riel. In October 1873 he became a member of the dominion parliament for Provencher, came to Ottawa and took the oath but did not sit. On April 16, 1874, he was expelled from the house but in September was again elected for Provencher; on Feb. 10. 1875. he was outlawed and the seat thereby again vacated. In 1877–78 he was a patient in the Beauport asylum for the insane; from 1879 to 1884 he lived in Montana.

In 1884 in response to a deputation from the Métis, who had moved west to the forks of the Saskatchewan river, he returned to Canada to win redress for their wrongs. His own rashness and the ineptitude of Canadian politicians and officials brought on a rising, which was crushed after some hard fighting, and on May 15, 1885, Riel surrendered. He was imprisoned at Regina, was tried and on Aug. 1 found guilty of treason and on Nov. 16 was hanged at Regina, meeting his fate with courage. His death was the signal for a fierce outburst of racialism in Quebec and Ontario, which nearly overthrew the Conservative government.

See J. S Willison, *Sir Wilfrid Laurier,* vol. i; George Bryce, *History of the Hudson's Bay Company* (1900)

RIEMANN, GEORG FRIEDRICH BERNHARD (1826–1866), German mathematician, exerted a profound influence on several branches of mathematics, particularly geometry and function theory (see RIEMANNIAN GEOMETRY). He was born on Sept. 17, 1826, in the village of Breselenz in Hanover, the son of a Lutheran pastor. From 1846 to 1851 he studied at the universities of Gottingen and Berlin

In 1851 he obtained his doctorate at Göttingen with his celebrated dissertation, "Foundations for a General Theory of Functions of a Complex Variable." In it he set forth an approach to function theory based on general principles and geometrical ideas rather than on formal calculation. His probationary essay for admission to the faculty in 1853 was "On the Representation of a Function by Means of a Trigonometrical Series." His trial lecture for admission to the faculty in 1854 was "On the Hypotheses Which Form the Foundation of Geometry." In this he introduced a new approach to geometry which covered ordinary Euclidean geometry, the non-Euclidean geometry of Nikolai Lobachevski, Johann Bolyai and C. F. Gauss and other possible non-Euclidean geometries as special cases. His idea was to study the properties of a geometrical space locally rather than to insist on one over-all framework for the whole space.

He became successively a Privatdocent (official but unpaid lecturer), assistant professor (1857) and professor (1859), succeeding P. G. L. Dirichlet (who had succeeded Gauss four years earlier). Consumption began to take its toll in the early 1860s and he died on July 19, 1866, at Selasca. in northern Italy.

In addition to the work mentioned above he published equally significant papers on Abelian functions, the distribution of primes, and air waves of finite amplitude. His posthumously published papers and even the fragments published in his collected works proved to be rich in new ideas. Some idea of his influence can be obtained from the impressive list of methods. theorems and concepts that bear his name: the Riemann approach to function theory, the Riemann-Roch theorem on algebraic functions, Riemann surfaces, the Riemann mapping theorem, the Riemann integral, the Riemann-Lebesgue lemma on trigonometrical integrals, the Riemann method in the theory of trigonometrical series, Riemannian geometry, Riemann curvature, Riemann matrices in the theory of Abelian functions, the Riemann zeta function, the Riemann hypothesis, the Riemann method of solving hyperbolic partial differential equations, Riemann-Liouville integrals of fractional order and others. In fact, it has been said that he anticipated a large part of 20th-century research in geometry and analysis.

Riemann was interested in physical problems and for a time was an assistant in the Gottingen physics laboratory. His idea of defining analytic functions and geometrical spaces in terms of their local properties no doubt was motivated by physical considerations. His approach to geometry made possible the general relativity theory of Einstein.

Riemann also gave the first mathematical treatment of shock waves.

In view of the tremendous importance of Riemann in the history of mathematics, it is somewhat surprising that his collected works occupy only one moderately sized volume edited by R. Dedekind and H. Weber (1876; 2nd ed., 1892; Fr. trans., 1898; reprint of 2nd Ger. ed.. with the 1902 supplement. 1953).

RIEMANNIAN GEOMETRY. Any n independent variables x_i where i takes the values 1 to n may be thought of as the co-ordinates of an n-dimensional space, or variety V_n in the sense that each set of values of the x's defines a point of V_n. In a space as thus defined there is not an *a priori* basis for the determination of magnitude nor for the comparison of directions at two different points. Riemann proposed the study of the metric properties of a general V_n by introducing as the basis for measurement a quad-

ratic differential form

$$\sum_{i,j}^{1,\ldots,n} g_{ij}dx_i dx_j,$$

where the g's are functions of the x's, subject to the restrictions that the determinant of the g's is not zero and that for all values of the differentials the above sum is positive. By definition the distance ds between the points of co-ordinates x_i and $x_i + dx_i$, is given by

$$ds^2 = \sum_{i,j}^{1,\ldots,n} g_{ij}dx_i dx_j. \qquad (1)$$

This is a generalization of the first fundamental form of a surface (*q.v.*) in ordinary space when the surface is defined in terms of two parameters, as proposed by Gauss (see DIFFERENTIAL GEOMETRY). In this case the metric on the surface is induced by the Euclidean metric of the enveloping space. whereas in a general Riemannian space the metric is assigned.

From the hypotheses concerning (1) it can be shown that at any point

$$\sum_{i,j}^{1,\ldots,n} g_{ij}\frac{dx_i}{ds}\frac{\delta x_j}{\delta s}$$

is less than unity for two different sets of differentials dx_i and δx_i. Consequently a real angle θ is determined by the equation

$$\cos\theta = \sum_{i,j}^{1,\ldots,n} g_{ij}\frac{dx_i}{ds}\frac{\delta x_j}{\delta s}; \qquad (2)$$

by definilion it is the angle between the directions at the point determined by the two sets of differentials. This, is in keeping with the fact that the cosine of the angle between two tangents, at a point, to a surface in ordinary space uhen expressed in terms of the induced metric is given by an equation of the form (2).

When we have n independent functions ϕ_i of the x's the equations

$$x'_i = \phi_i(x_1, \cdots, x_n) \qquad (i = 1, \cdots, n)$$

define a transformation of co-ordinates of the space. If the g's in (1) are such. which is rarely the case, that by a suitable transformation the form (1) is reducible to

$$ds^2 = \sum_{i}^{1,\ldots,n} (dx'_i)^2, \qquad (3)$$

which is a generalization of the metric of ordinary space in cartesian co-ordinates, we say that the space is flat, or plane; otherwise it is *curved*. The locus of points defined by

$$x_1 = f_1(t), \cdots, x_n = f_n(t)$$

for all values of the parameter t is called a curve (*q.v.*). When these expressions are substituted in (1) we obtain an expression of the form $ds = F(t)dt$, and then the length of arc of the curve is given by integration. If the result of the integration is $s = \phi(t)$, by means of this equation the co-ordinates at points of the curve are expressible as functions of the arc s as parameter. The theory of curves involves n–I principal curvatures, which are generalizations of the curvature and torsion of a curve in ordinary space.

Using the terminology of the calculus of variations. we say that the extremals of the integral

$$\int\left(\sum_{i,j}^{1,\ldots,n} g_{ij}\frac{dx_i}{ds}\frac{dx_j}{ds}\right)^{\frac{1}{2}} ds$$

are the shortest lines, or geodesics, of the space. The geodesics are found to be the integral curves of a system of differential equations

$$\frac{d^2x_i}{ds^2} + \sum_{j,k}^{1,\ldots,n} \Gamma^i_{jk}\frac{dx_j}{ds}\frac{dx_k}{ds} = 0 \qquad (i = 1, \cdots, n), \qquad (4)$$

where the Γ's are certain functions of the g's and their first derivatives. When the space is flat and the co-ordinates are those for which the fundamental form is (3), all the functions Γ vanish identically. Consequently in the co-ordinate system the equations of the geodesics of the flat space are

$$x_i = a_i s + b_i, \qquad (i = 1, \cdots, n), \qquad (5)$$

where the a's and b's are constants. Thus the geodesics of a Riemannian space are the analogues of straight lines of a Euclidean space. Riemann showed that in a general space a co-ordinate system exists such that all the geodesics through a given point are defined by $a_i s$ (i = 1, . . . ,n) = 1, but those through other points are not given by (5). In such a co-ordinate system that Γ's vanish at the given point. but not their derivatives.

Two sets of differentials, dx_i and Ax, determine two directions at a point and adx, + $b\delta x_i$, where a and b are parameters, a linear pencil of directions at the point. The geodesics issuing from a point P in a linear pencil of directions constitute a surface; the Gaussian curvature (see DIFFERENTIAL GEOMETRY) of this surface at P was taken by Riemann as the measure of curvature of the space for the given pencil. It is expressed in terms of the directions, and the components of a tensor of the fourth order, which involves the functions Γ^i_{jk} and their first derivatives; it is now known as the *Riemannian curvature* tensor (see TENSOR ANALYSIS). Ordinarily the curvature varies with the choice of the pencil. Schur showed that if it is the same for all pencils at each point of the space then it has the same value at every point; these are the spaces of constant Riemannian curvature; when, and only when, the constant is zero the space is flat.

From time to time important contributions to Riemannian geometry were made by Bianchi, Beltrami, Christoffel, Voss and others, and Ricci co-ordinated and extended the theory simultaneously with the development of tensor calculus. These contributions include the study of a subspace of a Riemannian space analogous to that of a surface in ordinary space. Such a subspace of order r is the locus of points defined by the equations

$$x_i = \psi_i(u_1, \cdots, u_r) \qquad (i = 1, \cdots, n), \qquad (6)$$

where the u's are independent parameters. When these expressions are substituted in (1) we obtain an induced metric for the subspace—a generalization of the first fundamental differential form of a surface (see DIFFERENTIAL GEOMETRY). There is also a generalized second fundamental form, whose coefficients enter in the relations between the curvatures of a curve in the subspace relative to the latter and the curvatures of the curve as of the enveloping space. Among the curves of the subspace there are geodesics, lines of curvature. asymptotic lines and conjugate systems of curves, which are generalizations of these types of curves on a surface in ordinary space. Einstein based his theory of gravitation upon the assumptions that physical space and time constitute a four-dimensional continuum whose metrical character is determined by the presence of matter and that these spaces are of a particular kind defined in invariantive form by means of the curvature tensor; in this theory the fundamental form (1) is not positive for every choice of the differentials. This and other physical interpretations of differentia! geometry of spaces have stimulated the development of the theory.

Notable among contributions is the concept of parallelism of vectors in a general Riemannian space as introduced by Levi-Civita (1873–1942). In such a space parallelism is not absolute. as it is in Euclidean space, but is relative to the curve joining the points of application of the vectors. Thus for a curve $x_i = f_i(s)$ each set of solutions of the equations

$$\frac{d\xi^i}{ds} + \sum_{j,k}^{1,\ldots,n} \Gamma^i_{jk}\xi^i\frac{dx_k}{ds} = 0 \qquad (i = 1, \cdots, n) \qquad (7)$$

are the components of a family of vectors at the points of the curve which are parallel to one another with respect to the curves. Certain Riemannian spaces admit one or more fields of vectors such that any two of them are parallel with respect to any curve joining their points of application. When there are n independent fields of this kind the space is flat. In particular, the tangents to a geodesic are parallel with respect to the geodesic, as follows from (7) and (4), when we put $\xi^i = \frac{dx_i}{ds}$; geodesics are the straight lines of the space. This concept of parallelism is involved in many of the recent developments of Riemannian geometry and its gen-

eralizations have opened up new fields (see TENSOR ANALYSIS).

One type of generalization of Riemannian geometry is that in which there is no assigned metric, but the basic concept is a generalization of geodesic lines. These curves, called paths by Veblen and Eisenhart, are defined by equations of the form (4), in which now the quantities Γ^i_{jk} are assigned, and not derived as in the case of geodesics from the quadratic form (1). When the same interpretation is put upon the functions Γ^i_{jk} in equations (7), there is thus defined parallelism in this geometry, and the paths are straight lines, in the sense that all the tangents to a path are parallel to one another with respect to the path (see DIFFERENTIAL GEOMETRY). From this basis a geometry has been developed in many respects analogous to Riemannian geometry which Eisenhart termed Non-Riemannian geometry. This term may be applied, however, to other geometries. For example, Finsler in his Goettingen Dissertation in 1918 proposed a metric different from that of Riemann, and there has been considerable study of Finsler spaces. Also. Cartan has developed the geometry of metric spaces founded on the notion of area (Paris, 1933).

RIENZI, COLA DI (c. 1313–1354), tribune of the Roman people, was born in Rome, the son of a tavern keeper named Lorenzo Gabrini. His early years were passed at Anagni. The study of the Latin writers, historians! orators and poets filled his mind with stories of the glories and the power of ancient Rome, and he dreamed of restoring his native city to its pristine greatness. His zeal was quickened by the desire to avenge his brother. who had been killed by a noble. Rienzi became a notary and a person of some importance in the city and was sent in 1343 on a public errand to Pope Clement VI at Avignon. He won the favour and esteem of the pope. Returning to Rome about April 1344 he gathered a band of supporters, plans were drawn up and at length all was ready for the rising. On May 20. 1347, dressed in full armour and attended by the papal vicar. Cola headed a procession to the Capitol; here he addressed the assembled crowd on "the servitude and redemption of Rome." A new series of laws were adopted by acclamation, and unlimited authority was given to the author of the revolution. The nobles left the city or went into hiding, and a few days later Rienzi took the title of tribune.

The new ruler governed the city with a stern justice, in marked contrast to the recent reign of licence. In July he proclaimed the sovereignty of the Roman people over the empire, but before this he had set to work to restore the authority of Rome over the cities and provinces of Italy. He invited the cities of Italy to send representatives to an assembly on Aug. 1, at which, after elaborate and fantastic ceremonial Rienzi, as dictator, issued an edict citing the emperor Charles IV and the imperial electors to appear before him in order that he might pronounce judgment in the case. Rienzi then seized, but soon released, Stephen Colonna and other barons who had spoken disparagingly of him. But his power was waning. His extravagant pretensions excited ridicule. His government was costly, and he was obliged to lay heavy taxes upon the people. He offended both pope and emperor by his proposal to set up a new Roman empire, and in October Clement gave power to a legate to depose him and bring him to trial. The exiled barons gathered some troops, and war began. On Nov. 20 Rienzi's forces defeated the nobles in a battle outside the gates of Rome. But this victory did not save him. The pope denounced him as a criminal, a pagan and a heretic, until! terrified by a slight disturbance on Dec. 15, he abdicated and fled from Rome. He sought refuge in Naples, but soon left that city and spent over two years in a mountain monastery.

Emerging from his solitude Rienzi in July 1350 threw himself upon the protection of the emperor Charles IV. Denouncing the temporal power of the pope he implored the emperor to deliver Italy, and especially Rome, from their oppressors; but Charles kept him in prison for more than a year in the fortress of Raudnitz. and then handed him over to Clement. At Avignon, where he appeared in August 1352, Rienzi mas tried by three cardinals, and was sentenced to death, but this judgment was not carried out, and he remained in prison. In December 1352 Clement died, and his successor. Innocent VI, anxious to strike a blow at the baronial rulers of Rome, pardoned and released his prisoner. Giving him the title of senator, he sent him to Italy with the legate. Cardinal Albornoz, and Rienzi. with a few mercenaries, entered Rome in August 1354. He was received with great rejoicing, and regained his former position. A tumult broke out on Oct. 8, the building in which Rienzi stood was fired, and while trying to escape in disguise he was murdered.

Rienzi's life and fate formed the subject of a famous novel by Bulwer Lytton, of an opera by Wagner and of a tragedy by Julius Mosen. His letters, edited by A. Gabrielli, are published in vol. vi of the *Fonti per la storia d'Italia* (1890).

RIESA, a town in the district of Dresden. Germany, on the Elbe. 30 mi. N.W. of the city of Dresden. Pop. (1959 est.) 36.303. Riesa received municipal rights in 1632, and after a period of decay was again raised to the rank of a town in 1859. The town contains a castle, which is now used as a town hall. There are rolling mills and sawmills and ironworks. Other industries are the manufacture of furniture, beer, soap, marble wares. and bricks. Riesa is the lading place for goods to and from Bavaria, and a mart for herrings, petroleum. wood and grain.

RIESENER, JEAN HENRI (1734–1806), French cabinetmaker, the greatest of his time, was born at Gladbeck, Ger., on July 4, 1734. the son of a courtroom usher. Coming to Paris as a young man, he began work under Jean François Oeben, whose widow he subsequently married, thereafter taking control of the Oeben workshop. Having qualified as a master craftsman in 1768, he embarked on a long and successful career. His first great achievement was the completion, in 1769. of the celebrated *bureau du roi* (now in the Louvre, Paris) that Oeben had begun for Louis XV; and this was followed by his supplying the contents for the king's garde *meuble* or personal furniture store. In recognition of this work he mas appointed "ordinary cabinet maker to the king" (Louis XVI) in 1774; and from then onward he was the regular supplier of furniture to the queen, Marie Antoinette. He died in Paris on Jan. 6, 1806.

Riesener was a consummate craftsman. His graceful furniture is often richly finished with marquetry of exceptional delicacy and with perfectly carved bronzes. His early work naturally shows Oeben's influence in the strength and architectural quality of the design, but he gradually developed a more individual, more delicately conceived style. This was to become the pure Louis XVI style, with its rectilinear side view and harmoniously distributed ornamentation. Riesener used both European and exotic woods, with a preference for mahogany; he occasionally used lacquer and mother-of-pearl to enrich the surfaces of his works.

See Pierre Verlet, *Mobel von J H. Riesener* (1955), for a description of many exquisite pieces of furniture now in museums or private collections in Europe and America. *See* also F. de Salverte, *Les Ébénistes français du XVIIIe siècle,* new ed (1953). (S. GR.)

RIESENGEBIRGE or GIAKT MOUNTAINS (KRKONOSE, KARKONOSZE), a lofty and rugged group of the Sudetes, on the boundary between Poland and Czechoslovakia, between the upper courses of the Flbe and the Oder. They are continued toward the northwest in the Erzgebirge. the Thuringian Forest and the Harz hfountains. Adjoining the Isergebirge and the Lausitzergebirge on the west. and the Eulengebirge and the Adlergebirge on the east and southeast, the Riesengebirge proper trend southeast and northwest between the sources of the Zacken and the Bober, for a distance of 23 mi.. with a breadth of 14 miles. They cover an area of about 425 sq.mi. On its northern side this mountain group has a rugged and precipitous slope from the Hirschberg valley. but on its southern slope, a more gradual one. The southern ridge is cleft about the middle by a deep gorge through which pour the headwaters of the Elbe river, which finds its source in the Siebengriinde. The Great and Little Schneegruben—two deep rocky gorgelike valleys in which snow remains all the year round —lie to the north of the Hohes Rad.

The lower parts of the mountains are clad with forests of oak, beech, pine and fir; above 1,600 ft. only the last two kinds of

trees are found, and beyond about 3,950 ft. only the dwarf pine (*Pinus Pumilio*). Wheat is grown to an elevation of 1,800 ft. above the sea and oats as high as 2,700 ft.

The Riesengebirge is the legendary home of Number Nip (Rübezahl), a goblin of German folklore.

RIETI (anc. *Reate*), a city and episcopal see of Italy. the capital of the province of Rieti, 25½ mi. by rail and 1j mi. direct S.S.E. of Terni, which is 70 mi. by rail from Rome. Population (1957 est.) 35,216 (commune). It is 1,318 ft. above sea level on the right bank of the Velino (a torrent subtributary to the Tiber), which at this point issues from the limestone plateau; the old town occupies the declivity and the new town spreads out on the level. While with its quaint red-roofed houses, its old town walls (some Roman fragments, restored about 1250), its cathedra] (13th and 15th centuries), its episcopal palace (1283) and its various churches and convents Rieti has much medieval picturesqueness. it also displays a good deal of modern activity in corn, vine and olive growing and cattle-breeding. The fertility of the neighbourhood is celebrated both by Virgil and by Cicero.

In 1149 the town was besieged and captured by Roger I of Sicily. In the struggle between church and empire, it always held with the former and defied the forces of Frederick II and Otho IV. Pope Nicholas IV long resided at Rieti, and it was there he crowned Charles II of Anjou king of the Two Sicilies. In the 14th century Robert and afterward Joanna of Naples managed to keep possession of Rieti for many years, but it returned to the States of the Church under Gregory IX.

About the year 1500, the liberties of the town, long defended against the encroachments of the popes, were entirely abolished. An earthquake in 178j was in 1799 followed by the pillage of Rieti by the Neapolitans. Rieti suffered extensive damage during air raids in World War II.

RIEVAULX, a village in the Helmsley rural district of the North Riding of Yorkshire. Eng., about 3 mi. W.N.W. of Helmsley. Pop. (1951) 173. It stands on the Rye before it emerges from the Yorkshire moors into the Vale of Pickering. The name probably comes from Rye Vale. Rievaulx abbey, one of the most beautiful ruins in Yorkshire, was founded by the Cistercians in 1131. The principal remains, now maintained by the ministry of works, are those of a cruciform church which is mainly Early English in style and is of fine workmanship. Considerable fragments of the refectory remain; domestic buildings may be traced.

RIFIS, the name given to the Berbers of the Rif district of Morocco, the mountain region bordering the north coast from Ceuta eastward nearly to the borders of Algeria and forming part of the Atlas range. The Rif dialect changes the Arabic "l" to "r," and this supports the derivation of "Rifi" from "Libi," "b" and "f" being interchangeable.

See Morocco.

RIFLE. In the broadest sense of the term, a rifle is any firearm with a rifled bore, *i.e.*, with shallow spiral grooves cut in the surface of the bore to impart a spin to the bullet or projectile. The term is most often applied to small-bore weapons fired from the shoulder and used either for sport or for military service. (*See* SMALL ARMS, MILITARY.) In military language the term also denotes larger weapons with rifled bores, such as recoilless rifles and big naval guns. Though field guns, howitzers, and machine guns have rifled bores they are not normally reierred to as rifles.

The practice of rifling the bore of a weapon is old. dating back at least to the 15th century. As the earliest examples of rifled guns had straight rather than spiral grooves. it is thought the purpose of the grooves may have been to receive the powder residue or fouling that was an annoying problem with all early firearms. Gunmakers soon discovered that spiral grooves caused bullets to spin and that the spinning action increased their range and improved their accuracy. The spinning principle increased in importance when spherical lead balls were replaced by elongated bullet-shaped projectiles. The latter type oi bullet rotated on its longitudinal axis in the same manner that an arrow rotated due to the angle of its feathers. Over the years. gun designers experimented with a great variety of rifling forms to achieve the best results. Most military rifles of the 20th century have four grooves with a right-hand twist of one turn in something between 10 and 20 inches.

A major difficulty with early muzzle-loading rifles was the problem of loading. As the bullet had to fit tight against the grooves, it had to be rammed down the bore with a ramrod. Rifles of the muzzle-loading era could not be loaded as rapidly as smooth-bore muskets and therefore never gained wide acceptance as military arms. With the advent during the 19th century of breech-loading repeating rifles using metallic cartridges the picture changed completely; the rifle soon replaced the musket as a military weapon. The repeating rifle that held sway during World War I was succeeded during and after World War II by the semi-automatic rifle, notably the U.S. army's Garand rifle. In the 1950s improved rifles capable of both semiautomatic and full automatic fire came into common use. (H. C. T.)

RIFLEBIRD (RIFLEMAN BIRD): the name applied to birds of paradise (*q.v.*) of the genera *Ptilorrhis* and *Craspidornis*, probably because their plumage bears some resemblances to the full-dress uniform (green and black) of the British rifle regiments.

There are five species. of which one inhabits New Guinea and the others the Australian continent. The best known is *P. paradisea*.

See R. B. Sharpe, *Monograph of the Paradiseidae*.

RIGA, a seaport of Latvian S.S.R., of which it is the capital. in 57° 3' N., 24" 1' E. Pop. (1959) 580,423. It is situated at the southern extremity of the Gulf of Riga, 8 mi. above the mouth of the n-estern Dvina, which is connected by means of inland canals with the basins of the Dnieper and Volga. The Gulf of Riga is 100 mi. long and 60 mi. wide, with shallow waters of slight salinity and a greatest depth of 22 fathoms. It is frozen for an average of 12i days in the year. The sea entrance has a depth of 24½ ft. which is dredged constantly to 26 ft. The channel up to the town is 26 ft. deep, and the depth at the quays varies from 18 to 26 ft. There are vast warehouses and a large grain elevator.

The Riga Exchange committee's slip dock at Bolderaja was made capable of taking ships up to 1,000 tons. Large ships unload at Ust-Dvinsk (formerly Dünamünde). The imports ordinarily are herrings, foodstuffs, clothing, sugar, tobacco, industrial and agricultural machinery, mechanical tools, railway equipment, coal, coke and fertilizers. and the exports flax, timber, wooden goods, dairy produce and meat (pork and ham). The town manufactures paper, wood pulp, cellulose, matches, veneered goods, paints and varnishes, textiles (especially cotton and linen goods), boots and shoes, rubber goods, cement! vegetable oils, tobacco and alcoholic drinks.

Manufactures were seriously hampered by the destruction of factories and plants during World War I; Riga was occupied by German troops in Sept. 1917 and held to the end of the war and was occupied again by Germany in World War II.

Riga consists of four parts—the old town and suburbs on the right bank of the Dvina (Latvian, *Daugava*), and the Mitau suburb on the left bank. the two sides being connected by a floating bridge, which is removed in winter, and by a viaduct, 820 ft. long.

The old town still preserves its Hanseatic features—high storehouses, with spacious granaries and cellars, flanking the narrow winding streets. The only open spaces are the market place and two other squares.

The suburbs, with their broad and quiet boulevards on the site of the fortifications. grew steadily during the period of Latvian independence, 1918–39.

Few antiquities of the mediaeval town remain. The oldest church, the Dom (St. Mary's), founded in 1215, was burned in 1547, and the present building dates from the second half of the 16th century, but has been thoroughly restored since 1883. Its organ, dating from 1883, is one of the largest in the world. St. Peter's church, with a beautiful tower 412 ft. high, was erected in 1406–9. The castle was built in 1494–1515 by the master of the Knights of the Sword, Walter ron Plettenberg, a spacious building often rebuilt. The "House of the Black Heads," a corporation, or club, of foreign merchants, was founded in 1330, and subsequently became the meeting-place of the wealthier youth.

The Livlandische Ritterhaus, the former place of meeting of the Livonian nobility, still stands. Near the city are extensive summer bathing beaches, with little wooden chalets. When Dorpat (Tartu) university, which served all the Russian Baltic provinces, became Estonian property in 1919, Riga Polytechnic institute was made a university. In 1939 7,231 students were enrolled.

History.—Riga was founded in 1158, as a storehouse at the mouth of the river, by a few Bremen merchants. About 1190 the Augustinian monk Meinhard erected a monastery there, and in 1199–1201 Bishop Albert I of Livonia obtained from Pope Innocent III permission for German merchants to land at the new settlement, and chose it for his seat, exercising his power over the neighbouring district in co-operation with the Teutonic Knights. As early as the first half of the 13th century the city obtained the right of electing its own magistracy. It joined the Hanseatic League, and from 1253 refused to recognize the rights of the bishop and the knights. The bishop ruled it from 1420 to 1566, when it was abolished in the Reformation. Sigismund II, king of Poland, took Riga in 1547, and in 1558 the Russians burned its suburbs. In 1561 Gotthard Rettler abdicated his mastership of the order of the Teutonic Knights, and Riga became a Polish possession. After unsuccessful attempts to reintroduce Roman Catholicism, Stephen Bathory, king of Poland, recognized the religious freedom of the Protestant population. In 1621 Gustavus Adolphus, king of Sweden, took it from Poland, and the Swedes held it when the Poles and Russians besieged it in 1656. During the Northern War between Sweden and Russia. it was defended (1700); after the battle of Poltava the Russians took it in 1710. In 1919 it became the capital of the independent republic of Latvia.

RIGAUD, HYACINTHE (HYACINTHE FRANÇOIS HONORAT MATHIAS PIERRE MARTYR ANDRÉ JEAN RIGAU Y ROS) (1659–1743), French portrait painter, born at Perpignan on July 20. 1659, was the descendant of a line of artists. He was sent to Montpellier to study under Pezet. and afterward went to Lyons, and in 1681 to Paris. There he obtained the Grand Prix de Rome, but on the advice of Jean Le Brun he allowed it to lapse and devoted himself to painting portraits. For 62 years he did as many as 30 to 40 portraits a year. But Rigaud, although purely a portrait painter, set his heart on gaining admission to the Academy as a historical painter, and succeeded in Jan. 1700. He died on Dec. 27, 1743.

His principal portraits at the Louvre are those of himself and his mother (Marie Serre). of the sculptor Desjardins, of Mignard and Le Rrun, of Bossuet and of Louis XIV.

RIGAUDON, a lively dance of frivolous nature in 2/2 or 4/4 time. It should properly begin (although exceptions occur) with two eighth-note upbeats on the count of 4. Most authorities believe it to be truly French, specifically a Provençal sailors' dance. deriving its name from a famous Marseilles ballet master named Rigaud who brought it t~ Paris around 1630. It became very popular in England as the Rigadoon. The dance itself included much running. hopping and turning; also *balancés* done with quick little jumps. The music. the melodic structure of which closely resembles that of most English hornpipes, is only occasionally found in the suite. (L. HT.)

RIGEL, the bright star at the heel of the constellation Orion (*q.v.*). It is one of the brightest stars in the sky. Its equivalent in the alphabetical series is β Orionis. Rigel is in reality—as well as apparently—one of the brightest stars known.

Rigel is a blue supergiant located at a probable distance from the sun of about 1,100 light-years. If Rigel were as close to the sun as the bright star Sirius (nine light years)! it would shine with a brilliancy similar to that of the half-moon. (*See* STAR.) (W. W. M.)

RIGG, JAMES HARRISON (1821–1909), English Nonconformist divine, was born at Newcastle-on-Tyne on Jan. 16, 1821. In 1845 he entered the Wesleyan ministry, and during the agitation of 1849–52 wrote successfully in exposition and defence of the polity of Methodism. In 1857 he published *Modern Anglican Theology,* an acute criticism of the writings of Coleridge, Hare, Maurice, Kingsley and Jowett. In 1868 Rigg was appointed Principal of the Westminster U'esleyan Training College for day-school teachers, a post which he held for 35 years. In 1870 he was elected on the first School Board for London. In 1886 he sat on the Royal Commission of Education. In 1878 he was elected president of conference—and again in 1892. He resigned his principalship in 1903 and died at Brixton on April 17, 1909.

See *Life* by John Telford (1909). His other works include: *National Education in its Social Conditions and Aspects* (1873); *The Living Wesley* (1875, reissued as *The Centennial Life of Wesley* in 1891); *Character and Life-work of Dr. Pusey* (1893); *Oxford High Anglicanism and its chief Leader;* (1895).

RIGGING, a general term denoting the whole apparatus of masts, yards, sails and cordage of a ship. (*See* also SAILS; SEAMANSHIP; SHIP; YACHT.) The word is also used to mean cordage only. Sailing vessels are classed according to their rig; *i.e.,* the arrangement of their spars, sails and cordage. Cutter, brig and ship are really convenient abbreviations for cutter-rigged, brig-rigged and ship-rigged.

Elements of Rigging.—The basis of all rigging is the mast, which may be composed of one or many pieces of wood or steel. The mast is supported against fore and aft or athwartship strains by fore and backstays and by shrouds, known as the standing rigging, because they are made fast, and not hauled upon. The bowsprit, though it does not rise from the deck but projects from the bow, is in the nature of a mast. The masts and bowsprit support all the sails, whether they hang from yards slung across the mast: or from gaffs projecting from the mast; or. as in the case of the jibs or other triangular sails, travel on the ropes called stays. which go from the mast to the bowsprit or deck.

The bowsprit is subdivided like the masts. The bowsprit proper corresponds to the lower fore-, main- or mizzen mast. The jib boom, which is movable and projects beyond the bowsprit, corresponds to a topmast: the flying jib boom. which also is movable and projects beyond the jib boom. answers to a topgallant mast.

The ropes by which the yards, booms and sails are manipulated for trimming to the wind or for making or shortening sail are known as the running rigging. The rigging also provides the crew with the means of going aloft and for laying out on the yards to let fall or to furl the sail. The shrouds (*see* below) are utilized to form ladders, the steps of which are called ratlines. Near the heads of the lower masts are the tops—platforms on which men can stand—and in the same place on the topmasts are the crosstrees n-hose main function is to extend the topgallant shrouds. The yards are provided with ropes, extending from the middle to the extremities or yardarms, called footropes, which hang down about two or three feet and on which men can stand. The material of which the cordage is made varies greatly, Leather has been used, but the prevailing materials have been hemp or grass rope, chain and wire.

As the whole of the rigging is divided into standing and running so a rope forming part of the rigging is divided into the standing part and the fall. The standing part is that which is made fast to the mast, deck or block. The fall is the loose end or part on which the crew hauls. The block is the pulley through which the rope runs. A tackle is a combination of ropes and blocks which gives increased power at the lifting or moving end, as distinct from the end being manned. If the ship in the illustration is followed from the bow to the mizzenmast, it will be seen that a succession of stays connect the masts with the hull of the ship or with one another. All pull together to resist pressure from the front. Pressure from behind is met by the backstays, which connect the topmasts and topgallant masts with the sides of the vessel. Lateral pressure is met by the shrouds and breast backstays. A temporary or preventer backstay is used when great pressure is to be met. The bobstays hold down the bowsprit. which is likely to be lifted by the tug of the jibs and of the stays connecting it with the fore-topmast. If the bowsprit is lifted the fore-topmast loses part of its support.

The running rigging by which all spars are hoisted or lowered and sails spread or taken in may be divided into those which lift and lower—the lifts, jeers, halyards (haulyards)—and those which hold down the lower corners of the sails—the tacks and sheets. A long technical treatise would be required to name the

VARIOUS TYPES OF SAILING VESSELS AND THEIR RIGGING

1. A cutter, with gaff-mainsail and topsail
2. A yawl, with Bermuda or jib-headed rig
3. A staysail schooner, so-called because of the staysails between the masts instead of the regular foresail
4. A brigantine, or hermaphrodite brig
5. A full-rigged ship, square-rigged on all three masts
6. A barque, square-rigged on fore and main masts and fore and aft rigged on the mizen
7. A brig; two-masted ship, square-rigged on both masts
8. A barquentine; three-masted ship, square-rigged on foremast only
9. A three-masted schooner, fore-and-aft-rigged on all three masts
10. A Great Lakes schooner, with a raffee or triangular sail on the foremast

many parts of standing and running rigging and their uses. All that is attempted here is to give the main lines and general principles or divisions.

The vessel dealt with here is the fully rigged ship with three masts. But the principles of others are the same. The simplest of all forms of rigging is the dipping lug, a quadrangular sail hanging from a yard and always hoisted on the side of the mast opposite to that on which the wind is blowing (the lee side). When the boat is to be tacked so as to bring the wind on the other side, the sail is lowered and rehoisted. One rope can serve as halyard to hoist the sail and as a stay when it is made fast on the side on which the wind is blowing. The difference between such a craft and the fully rigged ship is that between a simple organism and a very complex one; but it is one of degree, not of kind. The steps in the scale are innumerable. Every sea has its own type. Some in eastern waters are of extreme antiquity, and even in Europe vessels are still to be met with which differ very little if at all from ships of the Norsemen of the 9th and 10th centuries.

Types of Rigging.— When the finer degrees of variation are neglected, the types of rigging may be reduced to comparatively few, which may be classed by the shape of their sail and the number of their masts. At the bottom of the scale is such a craft as the Norse herring boat. This boat has one quadrangular sail suspended from a yard which is hung (or slung) by the middle to a single mast which is placed (or stepped) in the middle of the boat. She is the direct representative of the ships of the Norsemen. Her one sail is a course such as is still used on the fore- and mainmasts of a fully developed ship; a topsail may be added (above the course) and then we have the beginning of a fully clothed mast. A similar craft called a Humber keel is used in the north of England.

The lug sail is an advance on the course, since it is better adapted for sailing on the wind, with the wind on the side. When the lug is not meant to be lowered, and rehoisted on the lee side, as in the dipping lug mentioned above, it is slung at a third from the end of the yard, and is called a standing lug. A good example of the lug is the junk. As the lug is a lifting sail, and does not tend to press the vessel down as the fore-and-aft sail does, it is much used by fishing vessels in the North sea.

The type of the fore-and-aft rig is the schooner. The sails on the masts have a gaff above and a boom below. These spars have a prong called the jaws, which fit to the mast and are held in place by a jaw rope on which are threaded beads called trucks. Sails of this shape are carried by fully rigged ships on the mizzen-mast, and can be spread on the fore and main. They are then called trysails and are used only in bad weather when little sail can be carried, and are hoisted on the trysail mast, a small mast above the great one. The lateen sail, a triangular sail akin to the lug, is the prevailing type of the Mediterranean.

These original types, even when unmodified by mixture with any other, permit of large variations. The number of masts of a lugger may vary from one to five, and of a schooner from two to five or even seven. A small lug may be carried above the large one, and a gaff topsail may be added to the sails of a schooner. A one-masted fore-and-aft-rigged vessel may be a cutter or sloop. But the pure types also may be combined, in topsail schooners, brigantines, barkentines and barks, when the topsail, a quadrangular sail hanging from and fastened to a yard, slung by the middle, is combined with fore-and-aft sails. The lateen rig has been combined with the square rig to make such a rigging as the xebec, a three-masted vessel square rigged on the main, and lateen on the fore and mizzen. Triangular sails of the same type as the jibs can be set on the stays between the masts of a fully rigged ship, and are then known as staysails. Studding sails (pronounced "stunsails") are lateral extensions to the courses, topsails, etc., of a square-rigged ship to increase the spread of sails.

Historical Development.— The development of the rigging of ships is a very obscure subject. It was the work of centuries and of practical men who wrote no treatises. It has never been universal, yet a comparison of a four-masted junk with the figures of shi'ps on medieval seals shows much similarity. By selecting

a few leading types of successive periods it is possible to follow the growth of the fully rigged ship in its main lines in modern times.

For a time, and after the use of spritsails had been given up, the spritsail yard continued to be used to discharge the function now given to the gaffs. The changes in the mizzen have an obscure history. About the middle of the 18th century it ceased to be a pure lateen. The yard was retained, but no sail was set on the fore part of the yard. Then the yard was given up and replaced by a gaff. The resulting new sail was called the spanker. It was, however, comparatively narrow, and when a greater spread of sail was required, a studding sail (at first called a driver) was added, with a boom at its foot. At a later date "spanker" and "driver" were used as synonymous terms, and the studding sail was called a "ringtail." The studding sails are the representatives of a class of sail once more generally used.

In modern times a sail is cut of the largest size that can be carried in fine weather, and when the wind increases in strength it is reefed; *i.e.*, part is gathered up and fastened by reef points, small cords attached to the sail. Till the 17th century at least the method was often to cut the courses small, so that they could be carried in rough weather. When a greater spread of sail was required, a piece called a bonnet was added to the foot of the sail, and a further piece called a drabbler could be added to that. An example of the tenacious conservatism of the sea is seen in the retaining of this practice by the Swedish small craft called *lodjor* in the Baltic and White seas. It will be easily understood that no innovation was universally accepted at once. Jib and sprit topsail. lateen-mizzen and spanker, and so forth, would be found for long on the sea together.

The history of the development of rigging is one of adjustment. The size of the masts had to be adapted to the ship, and it was necessary to find the proper proportion between yards and masts. As the size of the medieval ship increased, the natural course was to increase the height of the mast and of the sail it carried. Even when the mast was subdivided into lower, top and topgallant, the lower mast was too long, and the strain of the sail racked the hull. Hence the constant tendency of the ships to leak. Sir Henry Manwayring, when giving the proper proportions of the masts, says that the Flemings (*i.e.*, the Dutch) made them taller than the English but were forced to make the sails less wide.

A few words may be added concerning the tops. In the earlier form of ship the top was a species of crow's-nest placed at the head of the mast to hold a lookout, or in military operations to give a place of advantage to archers and slingers. Tops appeared occasionally as mere bags attached to one side of the mast. As a general rule they were round. In the 16th century there were frequently two tops on the fore- and mainmasts, one at the head of the lower, another at the head of the topmast, where in later times there have been only the two traverse beams which make the cross-trees. The upper top dropped out by the 17th century. The form was round, and so continued until the 18th century when the quadrangular form was introduced.

Power Ships.—Steam and motor ships still carry one or more masts for supporting derricks, for lifting heavy weights in and out of the ship, for carrying wireless antennas, for providing a platform for lookout aloft, for mounting the steaming lights and for visual signaling. In the bigger ships the masts are usually hollow steel structures, occasionally with an internal ladderway, while in some merchant ships they also act as uptake ventilators. Stays are usually provided on the same principle as in sailing days, but dead-eyes have given way to bottle screws as rope has to wire. Where masts are provided with ladderways, either internally or externally on the iron structure itself, ratlines on the rigging are dispensed with. Modern battleships, battle cruisers and light cruisers in the Royal Navy usually have a tripod foremast in which the lower mast is supported by two inclined steel struts instead of rigging. This is to give the necessary rigidity for mounting the gun director and range finder (see GUNNERY, NAVAL).

The main mast usually carries the main derrick and is stayed on the old lines. Wooden topmasts and sometimes topgallant masts are fitted for wireless and signaling, while one or more signal yards are always carried on the foremast. In light cruisers the main mast is usually a small wooden pole. Destroyers and other light craft are fitted with a light wooden foremast and usually a short main or mizzen mast.

The upper end of the standing rigging is shackled to steel bands round the lower masthead. The lower ends are secured to the deck by bottle screws and slips, the screw being locked by a check piece which prevents its easing back; together with its slip it is covered with painted canvas.

The topmast rigging, consisting of the usual shrouds, stays and backstays, is fitted with insulators to avoid interference with radio and danger from lightning. A Jacob's ladder gives access to the masthead, while above all is a lightning conductor connected by a copper strap running down the mast to the hull of the ship. Where a masthead flashing lamp is fitted, a gallows is provided for its reception. In flagships a pole 16 ft. long is clamped to the fore topmast or fore topgallant masthead to carry the admiral's flag. Clothes lines and hammock gantlines (used for drying clothes and hammocks) are of thin flexible steel rope in warships. They lead through blocks on a shroud near the fore or main lower mastheads and are set up well forward or well aft.

Dressing lines lead from the foremast awning stantion over both topmasts and down to the after awning stantion. To these are attached flags for dressing ship.

Signal halyards, made of light white line, lead through blocks on the yards and trucks for hoisting signal flags.

RIGHT ASCENSION, in astronomy, the co-ordinate on the celestial sphere analogous to longitude on the earth. It is the angle at the celestial pole reckoned eastward from the hour circle through the vernal equinox to the one through the body in question, or the arc of the celestial equator measured eastward from the vernal equinox to the foot of the object's hour circle. (Hour circle is a great circle passing through the celestial poles, perpendicular to the equator). The one through the vernal equinox, the origin for this measurement, takes the place of the Greenwich meridian in earth geography. Right ascension is expressed in time more often than in angular units, and is measured entirely around the equator, having any value from 0 hours to 24 hours, or 0° to 360° (15° is equivalent to 1 hour, and 1° to 4 minutes of time). The common abbreviation is the Greek letter, α.

(H. M. Lo.)

RIGHT-HANDEDNESS: see HANDEDNESS.

RIGHTS OF MAN AND OF THE CITIZEN, DECLARATION OF, a sort of manifesto issued in 1789, by the constituent assembly in the French Revolution, to be inscribed at the head of the constitution when it should be completed. It stated the fundamental principles which inspired the revolution. The declaration was first drafted and proposed by the marquis de Lafayette, who had returned from America full of enthusiasm for the principles proclaimed in the Declaration of Independence. The final text voted by the assembly and accepted by the king on Oct. 5, 1789, is much fuller than the American prototype. It contains a preamble and 17 articles. They proclaim and define political equality and liberty in its various manifestations.

See E. Blum, *La Dtclaration des droits de l'homme et du citoyen,* text with commentary (1902); G. Jellinck, *Die Erklarung der Menschen und Bzirgerrechte* (1895). This study was translated into English by Rudolf Tombo, and aroused considerable controversy.

RIGHT WHALE (Eubalaena) is found in the northern and southern hemispheres. The allied Greenland whale (Balaena mysticetus), also called the bowhead whale. attains a length of 60 ft. to 70 ft.. the largest and most valuable of the whalebone whales, a single specimen sometimes furnishing 3,500 lb. of whalebone It was formerly the mainstay of the whaling trade, but is now almost extinct. (See WHALE; WHALE FISHERIES)

RIGORD (*c*. 1150–c. 1209), French chronicler. was probably born near Alais in Languedoc, and became a physician. He entered the monastery of Argenteuil, and then that of St. Denis,

and described himself as *regis Francorum chronographus.* Rigord wrote the *Gesta Philippi Augusti,* covering the period 1179–1206. It was abridged and continued by William the Breton.

See Dom Bouquet's *Recueil des historiens des Gaules et de la France* (1738–1876); another ed. by H. F. Delaborde (1882–85); French trans. in tome xi of François Guizot's *Collection des mémoires relatifs à l'histoire de France jusqu'au XIII^e siècle* (1825).

RIGORISM, in general, means stern attachment to a rule, as in asceticism or monasticism (*qq.v.*). In the 18th century, however, the term was applied in particular to the practice of those moral theologians who insisted on the strictest interpretation of the laws of God and of the church in cases of conscience (*see* CASUISTRY). The Jansenists, especially, were described as rigorist in their opposition to probabilism (*q.v.*). In philosophical ethics, Kant took the term to describe a system of morality based on reason alone, without any appeal to hedonism.

RIJEKA (Ital. FIUME), a port of Croatia, Yugoslavia, on the Gulf of Quarnero (Rijecki Zaliv, Kvarner). The old town is built on a ridge of the Karst, while the newer parts are crowded into the amphitheatre between the ridge and the shore. The modern names date from the 13th century and refer to the river (in Italian called Eneo or Fiumara; in Croatian, Recina, "rivulet") which separates Rijeka from the eastern suburb of Susak.

The old town, which has a 3rd-century Roman triumphal arch, was known in ancient times as Tarsatica. Captured by Charlemagne, it long remained under the Franks. Later it was held by the bishop of Pola. The counts of Duino held it from 1139 to *c.* 1400, and in 1377 the cathedral of the Assumption was founded. Next held by the counts of Walsee, Rijeka was incorporated in Austria in 1466. It was made a free port in 1723, was united to Croatia in 1776 and was declared a *corpus separatum* of the Hungarian crown in 1779. The French held it from 1809 to 1813, when the English took it. Restored to Austria in 1814, it passed to Hungary in 1822, was Croatia's from 1848 to 1870 and was thereafter under Hungary until World War I.

Rijeka-Fiume became a matter of controversy after World War I. Although the secret treaty of London between Italy, Great Britain, France and Russia (April 26, 1915) had assigned Rijeka to Yugoslavia, the Italians claimed the port at the Paris peace conference on the principle of self-determination, because in 1910 its population had comprised 22,488 Italians as against 13,351 Yugoslavs and certain others, while Susak had been estimated to have 1,500 Italians as against 11,000 Yugoslavs.

On Sept. 12, 1919, Gabriele d'Annunzio (*q.v.*), who mustered a body of men at Ronchi near Trieste, occupied Rijeka and proclaimed himself the "commandant" of the "Reggenza Italiana del Carnaro." The Italian government, however, on concluding the treaty of Rapallo (Nov. 12, 1920) with Yugoslavia, resolved to turn D'Annunzio out of Rijeka. Giovanni Giolitti, the prime minister, ordered the battleship "Andrea Doria" to shell D'Annunzio's palace only, predicting that the surprise would cause the "commandant" to escape at once—as indeed it did. Riccardo Zanella, who then took office, representing the Autonomist party as opposed to the Italian Nationalist, supported Count Carlo Sforza's solution of the problem, namely a free state of Rijeka with an Italo-Fiuman-Yugoslav consortium for the port; and such a solution was approved by the town's electorate on April 24, 1921. But on March 3, 1922, a *coup d'état* brought the Nationalists to power in Rijeka. With Benito Mussolini as head of a new regime in Italy (Oct. 30, 1922) the Rapallo plan for a free state came to nothing. A new Italo-Yugoslav treaty, signed in Rome on Jan. 27, 1924, recognized Rijeka itself as Italian while Susak became Yugoslav. As Italy was unable to feed three Adriatic ports, Rijeka's traffic declined. The port handled only 770,000 metric tons of merchandise in 1938 as against 2,100,000 in 1913.

In Sept. 1943, Rijeka was occupied by the Germans; but on May 3, 1945, after two weeks' fighting, the Yugoslavs occupied the city, the Germans having blown up the port installations. By the treaty of Paris (Feb. 10, 1947), Fiume-Rijcka became part of Yugoslavia. The port was rebuilt, and by 1949 its sea traffic amounted to 2,179,298 tons.

In 1936 the population of Rijeka was 53,896 and that of Susak 16,111. After 1945 Rijeka and Susak merged. Pop. (1961) 100,-339; about 25,000 Italians had left by 1947. (K. SM.)

RILEY, JAMES WHITCOMB (1849–1916), U.S. poet famous for nostalgic dialect verse. was born in Greenfield, Ind., on Oct. 7, 1849. "The poet of the common people," Riley was elected to the American Academy of Arts and Letters, received the gold medal of the National Institute of Arts and Letters and was given several honorary degrees. His boyhood experience as an itinerant sign painter, entertainer and assistant to patent-medicine venders gave him the opportunity to compose songs and dramatic skits, to gain skill as an actor and to come into intimate touch with the rural folk of Indiana. His first reputation was gained by the series in Hoosier dialect ostensibly written by a farmer, "Benj. F. Johnson, of Boone," contributed to the *Indianapolis Daily Journal* and later published as *The Old Swimmin' Hole and 'Leven More Poems* (1883). Riley was briefly local editor of the *Anderson* (Ind.) *Democrat,* but his later life was spent in Indianapolis, where he died on July 22, 1916. Among Riley's numerous volumes are: *Pipes o' Pan at Zekesbury* (1888), *Old-Fashioned Roses* (1888), *The Flying Islands of the Night* (1891), *A Child-World* (1896) and *Home Folks* (1900). The best collected edition is the memorial edition of his *Complete Works,* 10 vol. (1916).

See M. Dickey, *The Youth of James Whitcomb Riley* (1919), *The Maturity of James Whitcomb Riley* (1922); J. Nolan *et al., Poet of the People; an Evaluation of James Whitcomb Riley* (1951).

RILKE, RAINER MARIA (1875–1926), the most influential German poet of his time, whose impact was felt far beyond the borders of the German-speaking countries.. He was born in Prague on Dec. 4, 1875, the only surviving child of Joseph and Sophia (Phia) Rilke. He was educated at the military academies of St. Pölten and Weisskirchen, then at a commercial institution in Linz and later at the universities of Prague, Munich and Berlin. He visited Italy and in 1899 and 1900 made two important journeys to Russia in the company of his lifelong friend Lou Andreas-Salomé. He then settled for a short time in an artists' colony at Worpswede. On April 29, 1901, he married the sculptress Clara Westhoff and settled at Westerwede. Their daughter Ruth was born on Dec. 12 of the same year. But in 1902 Rilke went to Paris to write a monograph on Auguste Rodin; and, although he remained attached to his wife and daughter, he began to drift away from family life and the tie between them slackened with the years. Returning to Paris after a sojourn in Rome and Sweden, he acted as Rodin's secretary from 1905 to 1906, when the arrangement was abruptly terminated by the irascible sculptor. From then until the outbreak of World War I, Paris was the centre to which the poet always returned for spells of concentrated creative activity; but with the failure of inspiration after 1910 his existence became increasingly disrupted and nomadic. He was in Capri in 1907 and later he traveled through Germany, Austria, Italy, Algeria, Tunis, Egypt and Spain, often staying in the castles or on the estates of his numerous aristocratic admirers.

During the first half of his life this shrinking, sensitive and delicate poet, who had suffered greatly in body and mind from the rigorous military training of his boyhood, wrote prolifically, both poetry and prose. Strong lyrical compulsion is evident in both, but verse was his natural idiom and already in *Das Buch der Bilder* (1902) individuality of expression, originality of thought and a haunting music in the metres are noticeable. But the inspiration he derived from Russia (which he regarded as his spiritual home) transformed him in *Das Stundenbuch* (1905) into a quasi-religious rhapsodist. whose mystical approach to God with its inexhaustible flow of images and its rushing rhythms revealed previously unsuspected depths and heights in the poet's thought. Another transformation then took place through the influence of Rodin. In the two parts of *Neue Gedichte* (1907 and 1908), Rilke set out to do with words what the sculptor did with marble or stone: to give the external reality of objects contemplated with the outward and the inward eye their spiritual reality as well. Essentially all these poems are *Dinggedichte* (poems of "things"), even when they evoke human beings. Cathedrals and statues, palaces and parks, fountains, pavilions and staircases; dolphins, panthers, flamingos and gazelles; hydrangeas,

heliotropes, poppies and roses; young girls and lovers, the beggars and the blind—Rilke seems to have entered into them all and to speak for them rather than of them. There is magic in the "things" presented in this manner, steeped as they are in their own atmosphere and most of them impregnated with the sense of the past. In Rilke's interpretation of the legends of Alcestis and of Orpheus and Eurydice, as well as in other poems in these collections and in the contemporary requiems, he voiced that absorption with the problem of death which was a lifelong preoccupation. It plays a major part in the prose work of the period, *Die Aufzeichnungen des Malte Laurids Brigge* (1910). This penetrating study of the dark side of existence and the night side of the mind reveals the mental and spiritual terrors which the young Danish hero undergoes in Paris, and the agonies of fear he lived through in his childhood. It is confessional in much the same way as Goethe's *Werther;* but, unlike Goethe, Rilke did not succeed in exorcising the horrors which haunted him. On the contrary the emotional exhaustion involved in the effort resulted in a prolonged period of poetical sterility which only began to yield during a solitary sojourn at Castle Duino on the Adriatic, placed at his disposal by his friend and benefactress Princess Marie von Thurn und Taxis-Hohenlohe (Nov. 1911–May 1912). Here a type of inspiration, different in kind from anything he had so far experienced, seized upon him and dictated the first two poems of the cycle which was finally completed in 1922 and called *Duineser Elegien.* During the ten years between its inception and its consummation Rilke lived in a state of suspension, waiting, working and hoping for the miracle of Duino to recur.

When war broke out he was in Germany and, strangely uplifted by the greatness of the calamity, he composed five magnificent hymns addressed to the god of war. Holderlin's influence is discernible in the apocalyptic quality of the style of these and one or two other poems of the period; but the rising tide of inspiration was checked by the mental suffering the war induced, aggravated by Rilke's short period of war service (Nov. 1915–June 1916), first for a few weeks in the infantry of the second reserve and then for a few months as a clerk in the war ministry in Vienna. This was a kind of sinecure. but it increased the poet's hopelessness and apathy, which were hardly lessened by the many friends he made in Munich where he spent most of the war years. In 1919 he accepted an invitation to Switzerland to give readings of his poems; and he remained in that country until his death, undertaking short visits to Venice and Paris, but never returning to Germany or Austria. The last five years of his life were spent in the little castle of Muzot in the Valais, first lent and then given to him by one of his devoted Swiss admirers. Here, in Feb. 1922, during about 18 days of tumultuous inspiration, he not only completed the ten *Duineser Elegien,* of which two further poems and several fragments had been written between 1912 and 1922, but he also wrote two complete sequences of *Sonette an Orpheus.* After this almost miraculous release of pent-up inspiration, there was a period of recuperation. But another curious transformation took place. Rilke, who had earlier translated Elizabeth Barrett Browning's *Sonnets from the Portuguese,* some of Michelangelo's poems and the sonnets of Louise Labé, was engaged at the time in translating Paul Valéry; and this resulted in a series of original poems in French. Nor was the German vein yet played out; and reminiscences in prose were also occupying the poet's mind. But his health was deteriorating rapidly and he died of leukemia in a sanatorium in Valmont on Dec. 29, 1926.

The international fame to which Rilke attained in his lifetime continued to increase after his death, as the innumerable memoirs, monographs, commentaries, biographies and translations in many European languages bear witness. His personality has aroused almost as much controversy as Byron's; and his voluminous correspondence constitutes both a literary and a psychological phenomenon of absorbing interest. The larger part of this is unpublished; but, in addition to the collected and selected letters in the general edition, many separate volumes to individual correspondents, mostly women, have appeared in print. Some of the most important are listed below; but they all contribute to the picture of the man and the poet and form an integral part of his work. Some read almost like literary essays of a descriptive or reflective nature; others contain first sketches or rough drafts of poems to come; passages from letters to his wife and to Lou Andreas-Salomé were later used almost *verbatim* in *Malte Laurids Brigge;* there are many confessional outpourings, and elaborate essays in self-portraiture and self-exegesis. When the whole is available, a revaluation of the facts of his life and facets of his character will doubtless result in a definitive biography.

Rilke's poetical reputation achieved its summit with *Duineser Elegien* and *Sonette an Orpheus.* For lovers of pure poetry *Neue Gedichte* will always rank high and the number of exquisite lyrics to be found in all the collections is an outstanding feature of his work. But the mysterious philosophical undertow of the elegies and the sonnets with its doctrinal implications creates that impression of something greater than art which great works of art produce. The cosmic isolation of man facing the glorious, austere, aloof and indifferent angels, the tragic nature of his attempts to transcend mortality by love as he journeys irrevocably deathwards, the summons received by the poet toward the end of the elegies to justify his existence by transforming the visible world into invisible art—all this, expressed with visionary intensity, embodies an appeal or a message to humanity which also pervades the sonnets. Some of these practice the doctrine they preach by magically transforming objects, already half-dematerialized in *Neue Gedichte,* into sound so pure that only their vibrations seem to linger in the air. In spite of obscurities and difficulties, the depth of thought in the elegies and the sonnets and the beauty of the expression justify Rilke's belief in their supreme importance in his work as a whole.

(E. M. BR.)

RIMBAUD, JEAN ARTHUR (1854–1891), French poet and adventurer, born at Charleville, in the Ardennes, on Oct. 20, 1834. He was the second son of a captain in the French army who in 1860 abandoned his wife and family. From early childhood Arthur Rimbaud, who was severely brought up by his mother, displayed rich intellectual gifts and a sullen, violent temperament. He began to write when he was 10, and some of the poems which now appear in his works belong to his 15th year.

Before he was 16, in consequence of a violent quarrel with his mother, the boy escaped from Charleville with a packet of his verse, was arrested as a vagabond, and for a fortnight was locked up in the Mazas prison, Paris. A few days after being taken home Rimbaud escaped again, into Belgium, where he lived for some time as a tramp, almost starved, but writing verses with feverish assiduity. In Feb. 1871 he left his mother for a third time and made his way to Paris, where he knew no one and whence, after very nearly dying of hunger and exposure, he begged his way back to Charleville. There he wrote in the same year the extraordinary poem of *Le Bateau ivre,* which is now hailed as the pioneer of the entire Symbolist or "decadent" movement in French literature in all its forms. He sent it to Paul Verlaine, who encouraged the boy

of 17 (whom he supposed to be a man of 30) to return to Paris. Rimbaud spent from Oct. 1871 to July 1872 in the capital. partly with Verlaine, partly as the guest of Théodore de Banville, and served in the army of the Commune. With Verlaine he traveled for 13 months, after the fall of the Commune. through England and Belgium, where in 1873 he published the only work which he ever printed, *Une Saison en Enfer,* in prose; in this he gives an allegorical account of his extravagant relations with Verlaine, which ended at Brussels by a double attempt of the latter to murder his young companion. On the second occasion Rimbaud was dangerously wounded by Verlaine's revolver. and the elder poet was imprisoned at Mons for two years.

Meanwhile Rimbaud, deeply disillusioned, determined to abandon Europe and literature, and he ceased at the age of 19 to write poetry. He settled for a while at Stuttgart. studying German, and in 1875 he disappeared. He set out on foot for Italy, and after extraordinary adventures found employment as a day labourer in the docks at Leghorn. Returning to Paris, he obtained a little money from his mother, and then definitely vanished. For 16 years nothing whatever was heard of him. but it is now known that he embarked as a Dutch soldier for the Sunda Isles, and, presently deserting. fled to Sumatra and then to Java where he lived for some time in the forest. Returning to Europe, after a vagabond life in every capital, in 1880 he obtained some menial employment in the quarries of Cyprus. and then worked his way to Aden and up into Abyssinia, where he was one of the pioneers of European commercial adventure. There he settled at Harrar as a trader in coffee and perfumes, to which he afterward added gold and ivory; for the next 11 years, during which he led many commercial expeditions into unknown parts of northern Africa, Shoa and Harrar were his headquarters, and he lived almost entirely with the natives and as one of them. From 1888 to 1891, having prospered greatly as a merchant, he became a sort of semi-independent chieftain, intriguing for France, just outside the borders of civilization. From documents which were first produced in 1902 it appears that from 1883 to 1889 Rimbaud mas in close relations with the Ras hlakonnen and with Rlenelek, then only king of Shoa. At the death of the Negus John. in 1888, he was concerned in the formation of the empire of Ethiopia. From this time Rimbaud had a palace in the town of Harrar and intrigued with the French government in favour of Menelek and against Italy.

Meanwhile. in 1886, believing Rimbaud to be dead, Verlaine had published his poems under the title of *Les Illuminations,* and they had created a great sensation in Paris. In this collection appeared the sonnet on the vowels, attributing a different colour to each: "A noir, E Blanc, I rouge, U vert. O bleu voyelles." But the author, in his Abyssinian hut of palm leaves, was, and remained. quite unconscious of the fact. In March 1891 a tumour in his knee obliged Rimbaud to leave Harrar and go to Europe for surgical advice. He reached Marseilles, but the case was hopeless; the leg had to be amputated, and Rimbaud died there on Nov. 10, 1891.

The poems of Rimbaud all belong to his earliest youth. Their violent originality, the influence which they have exercised upon younger writers. the tumultuous existence of their author and the strange veil of mystery which still hangs over his character and adventures have given to Rimbaud a remarkable fascination. His life was written by Paterne Berrichon (1897), and reminiscences by his sister, Mlle. Isabella Rimbaud. His *Oeuvres* were collected in 1898 by Berrichon and E. Delahaye, and in 1901 his statue was unveiled at Charleville. (E. G.)

RIME, a beautiful, white, friable, crystalline ice deposit formed by freezing of supercooled cloud- or fog-water droplets on objects exposed to the cloudy or foggy air. It occurs in two typical shapes: (1) growths of uniformly short, projecting, feathery branching crystal aggregates on all sides of a freely exposed object; and (2) asymmetrical growths of crystal aggregates in the form of long plumes or flags orientated into the direction held by the wind during the formation of the deposit. The latter type, which may reach a length of six feet, is common on exposed upper slopes of mountains in middle and high latitudes; the terms "frozen fog deposit" and "frost feathers" are often applied to the phenomenon in such places. The first type is less common and occurs chiefly in valleys from winter ground fogs with calm air. Under the microscope, rime appears to be a mosaic agglomeration of minute crystal accretions, almost amorphous, with spaces of entrapped air. Often wind-blown snowflakes become embedded in the deposit. giving it a greasy consistency when crushed between the fingers. When the temperature at formation is just below 32° F. the rime becomes a denser, smoother deposit which is hard and tenacious like ordinary ice. sometimes called rough frost, or hard rime. in contradistinction to the more usual types. or soft rime. Some hydrologists and glaciologists claimed that the larger part of the alimentation of the icecaps in such regions as Greenland, Norway, Iceland and Spitzbergen is provided by rime depositing on the surfaces of the mountain snowfields. Field measurements. however, cast some doubt on the general validity of this assumption. (R. G. SE.)

RIME ROYAL, the name given to a strophe or stanza form! which is of Italian extraction but is almost exclusively identified with English poetry from the 14th to the early 17th century. It appears to be formed out of the stanza called ottava rima (*q.v.*), by the omission of the fifth line, which reduces it to seven lines of three rhymes. arranged ababbcc. It was earliest employed with skill, if not invented, by Chaucer, who composed his long romantic poem of *Troilus and Cressida* in rime royal, of which the following is an example:

And as the new-abashid nightingale,
Thet stinteth first when she beginneth sing,
When that she heareth any herde tale,
Or in the hedges any wight stirring,
And, after, siker doth her voice out-ring,—
Right so Cresseyda. when her drede stint,
Opened her heart, and told all her intent.

In the 15th century this stanza was habitually used, in preference to heroic verse, by Thomas Occleve and John Lydgate, and, with more melody and grace. by the unknown writer of *The Flower and the Leaf.* In the 16th century it was regarded as the almost exclusive classical form for heroic poetry in England, and it had long been so accepted in Scotland, where *The King's Quair* of King James I. the Fables of Henryson and *The Thistle and the Rose* of Dunbar had closely followed the pattern of Chaucer. After the first decade of the 17th century rime royal went out of fashion. Since then it has been occasionally revived. but not in poems of great length or particular importance. Rime royal should always be written in iambic metre! and be formed of seven lines of equal length, each containing ten syllables.

RIMINI (anc. ARIMINUM), a town of Forli province. Italy, and the seat of a bishopric. lies on the Riviera del Sole of the northern Adriatic coast, a short distance from the foot of the Apennines where the steep Monte Titano is crowned by the republic of San Marino. Pop. (1957 est.) 81.663 (commune). Area of commune 152.49 sq.km. (59 sq.mi.).

The plan of the old Roman city is apparent in the area between the hlarecchia river, the Ausa torrent and the railway, where streets follow the ancient lines. The crumbling remains of 15th-century walls raised under the rule of the Malatesta family, when the town was extended, stretch along the left bank of the Marecchia. The town was divided into four quarters, known since the 18th century as Cittadella. Clodio. Pataso and Montecavallo. In the mid-19th century the suburbs of S. Giuliano, Mazzini and Marina grew up outside the walls and the first bathing stations on the coast were joined to the town by Principe Amedeo avenue. Since 1920 the town expanded farther south and the seaside suburbs of Marebello, Riva Azzurra and Miramare came into being,

and many fashionable houses and hotels were built. In spite of the destruction of 90% of its houses during World War II the town recovered, and its seaside resorts stretch for nearly 10 mi. from Torre Pedrera to Miramare. The centre of the town is the Piazza Giulio Cesare, the meeting point of ihe old Roman roads Via Flaminia and Via Aemilia; nearby are most of the monuments.

Monuments.— The oldest monument is the arch of Augustus. erected in 27 B.C. over the south gate of the city, but not finished until A.D. 22, by Tiberius; it was dedicated to Augustus. 'It has a single opening and a frieze added in the middle ages. The bridge built by Augustus over the Marecchia and also completed by Tiberius (A.D. 21) had a fifth arch added in 552. There are some remains of a Roman amphitheatre. Only ruins remain of the castle built by Sigismondo Pandolfo Malatesta (see History, below) in 1446. Rimini's most famous building is the Malatesta temple, designed to glorify Sigismondo's love for the beautiful Isotta degli Atti. Converted from the old Gothic church of S. Francesco, the temple was designed by Leon Battista Alberti, and the decoration of the interior was mostly the work of Agostino di Duccio, who enriched it with exquisite reliefs: figures of the liberal arts, the sybils. angels with fluttering veils, shields with the Malatesta arms. the planets and the moon, dancing children holding festoons of flowers and fruit; everywhere are repeated the intertwined initials S and I. The scheme for the temple, a monument of frankly pagan character, remained unfinished on Sigismondo's death.

Churches include S. Giovanni Evangelista (1247), with painted murals of the 13th-century Romagna school; S. Giuliano (16th century), built on the site of a Benedictine abbey. which preserves an altarpiece by Paolo Veronese; the little octagonal temple of S. Antonio on the Piazza Giulio Cesare; and the church of the Servi (14th century, rebuilt in the 16th). Other buildings include the restored Palazzo dell'Arengo (1202). The Piazza Cavour has a 15th-century fountain of Giovanni da Carrara. A bronze statue of Paolo V, begun by Niccolo Cordier and finished by Sebastiani di Recanati, was later transformed into S. Gaudenzio, patron saint of the town. The picture gallery contains Dutch arras of the 16th and 17th centuries and pictures by Giovanni Bellini, Ghirlandaio and Giuliano da Rimini. The Gambalunghiana civic library (1619), badly damaged in World War II, was afterward repaired, and preserves valuable incunabula and illuminated manuscripts.

Communications and **Commerce.**—Rimini is an important railway junction of the lines to Brindisi in the south, Venice and Trieste in the north and Bologna and Turin in the west, and is also a road centre. It has sea links with Ancona. Ravenna, Venice and Trieste, and an airport at Miramare. The district is rich in cereals and fruit and the town is equipped with processing factories and railway repair shops. The principal occupation. however, is the tourist industry. The gently sloping beaches backed by promenades and hotels are an attractive feature: and international shows. sporting events: concerts. etc., take place.

History.— The Roman city, called Ariminum from the old name of the Marecchia, Ariminus, stood on the boundary of Aemilia and Umbria. According to Strabo it belonged to the Umbro-Etruscan civilization. It was occupied in 268 B.C. by the Romans, and a Latin colony founded there. During the Second Punic War it was a base for military and naval operations. It became a Roman municipality and was later sacked by Sulla's troops. It witnessed the decisive step taken by Julius Caesar, when he crossed the Rubicon and marched on Rome.

In A.D. 359 the town was host to the Council of Rimini, which failed to resolve the Arian dispute. Rimini passed to the Byzantines and from them to the Goths, from whom it was recaptured by Narses, and then fell to the Lombards and Franks. It was for a long time governed for the pope by dukes and counts till the end of the 10th century when the imperial power became dominant. Transformed in the 13th century into an independent commune, it was the scene of struggles between the Guelphs and Ghibellines (*q.v.*). The leaders of the Guelphs were the Malatesta family who had established themselves at Verucchio and Rimini.

In 1239 Malatesta da Verucchio was made *podestà* ("mayor") of Rimini. The struggle with the Ghibellines had a respite when his son Malatesta II married Concordia Pandolfini, daughter of the Ghibelline leader. but her death broke the truce. Malatesta II's long life was filled with struggles and misfortunes, among them the tragedy when his son Gianciotto the Lame killed his own wife, Francesca da Polenta, daughter of the lord of Ravenna, and his brother Paolo the Fair, her secret lover. This episode was immortalized by Dante (*Inferno*, v, 73 ff.) and in Silvio Pellico's tragedy Francesca da *Rimini*. In 1334 the Council of Rimini recognized the family as lords of the town and for two centuries the town's history was united with that of this family.

Sigismondo Pandolfo Malatesta (1417–68), lord of Rimini, Fano and Senigallia, was the personage to whom Rimini principally owes its renown during the Renaissance. An unscrupulous tyrant but a valiant soldier who understood the science of fortification, he was a man of letters and a patron of the arts. Both his first wife, Ginevra d'Este. daughter of Lionello, duke of Ferrara, and his second, Polissena. daughter of Francesco Sforza, later duke of Milan, died. and Sigismondo was accused of having killed them in order to marry Isotta degli Atti.

The quarrels and rivalries of Sigismondo with other rulers and the papacy led to Pope Pius II's indictment of him in 1461. Sigismondo was compelled to submit and yielded most of his territory to the pope. keeping only Rimini and a few lands. After commanding an expedition for the I'enetians against the Turks in the Morea he returned to Rimini in the hope of recovering his dominions from the new pope, Paul II. Unsuccessful in this, he went to Rome with the intention of stabbing the pope; when Paul received him in the presence of his cardinals, Sigismondo lost courage and returned to Rimini where he died on Oct. 3, 1468, appointing his wife Isotta and their son Sallustio to succeed him.

Sigismondo's illegitimate son. Roberto, had assisted him in his struggle against Pius II, and on his father's death got rid of the legitimate heirs and made himself lord of Rimini. Reconciled with the pope, Roberto became commander in chief of the papal army. His son Sigismondo failed to defend his lands against Cesare Borgia.

Following the league of Cambrai in 1508, Rimini and its lands passed to the papal states. In 1815 it was occupied by Joachim Murat, king of Naples and brother-in-lax of Napoleon. whose "Rimini proclamation," promising the Italians a constitution, failed in its purpose when Murat was defeated by the Austrians at Tolentino. Rimini then returned to the papal states. The Rimini manifesto which accompanied the insurrection of Sept. 23, 1845, reflected the ideas of the moderate party and asked for political reforms in the modern sense. In 1860 Rimini was annexed to the kingdom of Italy. During World War II it suffered severe bombardment for it lay on the easiest route to the Po plains.

(M. T. A. N.)

RIMMER, WILLIAM (1816–1879), U.S. sculptor and anatomist, was born in Liverpool. Eng., on Feb. 20, 1816, of obscure parentage, his father Thomas claiming to be Louis XVIII of France, the "lost dauphin" of the Revolution. His family emigrated to Nova Scotia, then to Boston, Mass.. where he was trained as a lithographer. He informed himself deeply in gross anatomy, as a basis for instruction in painting and sculpture. He practised medicine, lectured on anatomy and design and made notable figures. of which the best known is the "Hamilton" facing the public gardens in Boston. His plaster "Gladiator" (1861) was the most important American nude to its date; it was cast in bronze after his death by Daniel Chester French, one of his grateful pupils. His *Art Anatomy* (1887) is a work of ingenuity and great beauty of draftsmanship. Rimmer died on Aug. 20, 1879.

See Truman H. Bartlett, *The Art Life of William Rimmer* (1882); Lincoln Kirstein, *William Rimmer* (1814–1879) (1946); William Rimmer, *Elements of Design,* rev. ed. (1879).

(L. E. K.)

RIMSKY-KORSAKOV, NICOLAS ANDREIEVICH (1844–1908), Russian composer, was born at Tikhvin, Novgorod,

on March 18, 1844. He spent six years (1856–62) in the Naval college at St. Petersburg, and at the end of that time received a commission and spent three years afloat. But as a cadet he had been one of the musical amateurs who, with Borodin, Cui and Moussorgsky, gathered round Balakirev in St. Petersburg in the days when Wagner was still unknown. During his cruise he had written a symphony (in E minor) which in that year was performed — the first by a Russian composer — under Balakirev's direction, and in 1873 he definitely retired from the navy, having been appointed a professor in the St. Petersburg Conservatoire. The same year witnessed his marriage to a talented pianist, Nadejda Pourgold, and the production of his first opera, *Pskovitianka*. This was followed by *May Night* (1878), *The Snow Maiden* (1880), *Mlada* (1892), *Christmas Eve* (1894), *Sadko* (1895). *Mozart and Salieri* (1898), *The Tsar's Brzde* (1899), *Tsar Saltana* (1900), *Seruilia* (1902), *Kostchei the Immortal* (1902), *The Tale of the Invisible City of Kitezh* (1905), and *Le Coq d'Or* (1910). For all of these, with the exception of *Mozart and Salieri*, he chose Russian national subjects. But his operas attracted less attention abroad than his symphonic compositions, which show a mastery of orchestral effect combined with a fine utilization of Russian folk-melody. Notable among these works are his first symphony, his second (op. 9) *Antar*, his third (op. 32), and his orchestral suites including the well known *Scheherazade* and overtures. He also wrote a number of beautiful songs, pianoforte pieces, etc., and he eventually took Balakirev's place as the leading conductor in St. Petersburg, where he died on June 20, 1908.

The influence of Rimsky-Korsakov on the Russian composers of his day was very great. His instrumentation was fresh and original; he was direct and clear, with something of a painter's vision, and he brought a wealth of learning and study to bear on his subject. Many came directly under his influence as his pupils at the Conservatoire, while many more studied his great treatise of *The Foundations of Instrumentation*. He did much also to promote the better appreciation of Moussorgsky and others of his fellow Russians. although during recent years he has been severely criticized for his alleged tampering with Moussorgsky's original text in his edition of *Boris Godounov*.

See his own *History of My Musical Life* (which has been translated into English); Stassov, *Rimsky-Korsakov* (1890); Rosa Newmarch, *The Russian Opera* (1914) and Montagu Nathan, *History of Russian Music* (1915); G. E. Abraham, *Studies in Russian Music* (1936).

RINCEAU (from the French, meaning "foliage"), in architecture and the decorative arts, is a decorative form consisting of a continuous wavy stemlike motif from which smaller leafy stems or groups of leaves branch out at more or less regular intervals. Its use is frequent in the friezes of Roman buildings, in the jamb ornament and capitals of Romanesque structures and in friezes and panels of buildings in the various Renaissance styles.

RINDERPEST. A disease, primarily of cattle, which has been known also as steppe murrain, contagious bovine typhus. peste bovine and cattle plague, rinderpest was first recognized in early Christian times. The earliest records of the disease suggest that it originated in Asia or eastern Europe, its incursions into western Europe having followed the paths of invading armies in the periodic sweeps of barbarous tribes from the east. Rinderpest reached Africa in the latter half of the 19th century and, after spreading throughout that continent with disastrous effect, was eventually cleared from the southern half but remained endemic or enzootic in the northern parts, its southernmost extension being in Tanganyika territory. The disease is also endemic in India and certain parts of southeastern Asia. In all these areas rinderpest is considered a major obstacle to development of the livestock industry, and in unmechanized sections. particularly those in which the water buffalo is used as the principal beast of burden, agriculture in general is retarded.

Characteristics. — Rinderpest is an acute, highly contagious disease of ruminants characterized by an unusually rapid course and a high mortality in areas where the disease is not endemic. The causative agent is an ultravisible virus, provisionally named *Tortor bovis*.

When infection is introduced into a herd of susceptible animals, signs of illness appear after an incubation period of three to five days. Early signs are depression, loss of appetite and a staring coat. These are accompanied by a pyrexia generally of the order of 105° to 107° F. In the midcourse of the disease, ocular and nasal discharges and salivation with buccal ulceration and a disagreeable fetid odour are characteristic. Profuse diarrhea with progressive emaciation and dehydration occur, often with dysentery and eventually marked tenesmus.

In many cases, a cutaneous, eruptive condition termed streptothricosis develops on the back and flanks. In the terminal stages of fatal cases, prostration, coma and death supervene generally after 10 to 14 days.

Autopsy of such an animal shows involvement of the mucous membrane of the entire alimentary tract. This is usually most marked in the mouth, where ulcers containing cheesy deposits are often found, and in the abomasum, ileum, cecum, colon and rectum. where deep congestion and sometimes ulceration occur. In the lower bowel the congestion is often in well-defined, dark streaks and has been referred to as zebra marking. Pneumonia frequently is seen as a complication, and often cystitis and vaginitis are present. Diagnosis is made on the clinical appearance of the disease and autopsy findings, but, since these may be similar to those found in certain other diseases, virus transmission and cross-immunity tests are necessary for confirmation.

Spread of the Disease. — The virus is generalized in the animal body and is passed out in all the secretions. It gains access to the tissues of a susceptible animal via the mucous membranes, most probably those of the nostrils. In areas where the disease is endemic, wild animals play an important part in the epidemiology. Many species of wild ruminants, together with wild pigs and warthogs in such areas as Tanganyika and Uganda, have been found to be susceptible to rinderpest. These animals, in competition with domestic animals for limited grazing and water, present great difficulties in the way of control. It is seen, therefore, that control of the disease is complicated by the maintenance of the virus in wild animals which form vast reservoirs of infection. Eradication in areas where wild animals exist in large numbers is dependent on the control of the disease in these animals or the elimination of their contact with the domestic animal populations.

Control. — Control of rinderpest has been attempted by several methods. Strict quarantine measures alone can be effective, provided the control of susceptible wild animals can be assured. However, it was early recognized that some form of immunization combined with quarantine was the most promising method of control, and efforts were made to find effective immunogens. As recovery from an attack of the disease leaves a durable immunity, early workers experimented with serum of recovered animals. Later, the bile of infected animals was tried. The former produced only a transient or passive immunity, while the latter caused a manifestation of the disease, often mild, which left an active immunity. The "serum simultaneous" method, which comprised the simultaneous inoculation of virulent virus and sufficient immune or hyperimmune serum to modify the reaction, proved the most satisfactory of the early methods of artificial immunization used. The use of this method, however, has some serious disadvantages, the major one being that an animal reacting to this treatment is virtually suffering from rinderpest and is a possible source of infection to other susceptible animals, and so the use of this method may set up new focuses of infection. Later work gave rise to the production of vaccines made from virulent tissues, principally spleens, in which the virus is inactivated by means of some chemical agent. These so-called inactivated vaccines produce a solid immunity which, however, lasts only for a matter of months; nevertheless, they were of great value in the control of rinderpest. Although still used in some regions under special circumstances at mid-20th century, they had been superseded by the use of living rinderpest virus which had been attenuated by repeated passage in a species other than the bovine. The first step in this direction was taken with the adaptation of bovine virus to goats, followed by the widespread use of the so-called caprinized virus in India and east Africa. Other workers, by adaptation of the virus to the

rabbit and to the developing chick embryo, opened the way to the possible use of new vaccines. (J.A. BR.; J. K. H. W.)

RINEHART, MARY ROBERTS (1876–1958), U.S. novelist and playwright best known for her mystery stories beginning with *The Man* in *Lower Ten* (serialized 1907) and *The Circular Staircase* (1908). her first book. Born in 1876 in Pittsburgh. Pa., she received nurse's training there and in 1896 married Stanley M. Rinehart, a physician. In 1903 the family found itself in financial difficulties as a result of a stock market crash, and Mrs. Rinehart turned to writing; her work proved to be a great popular success almost from the beginning. A long series of comic tales about the robust, redoubtable "Tish" (Miss Letitia Carberry) appeared in the *Saturday Evening Post* through many years. Of her plays (most of them written in collaboration with Avery Hopwood), the most successful was *The Bat* (1920). derived with significant changes from *The Circular Staircase.* She produced as well, always with a keen responsibility to her craft, a number of romances and several books of travel, some of the latter reflecting her experience as a correspondent during World War I. She died in New York city on Sept. 22, 1958.

Mrs. Rinehart established what has been called the "had-I-hut-known" sort of mystery, and her tales make it plain that she was mistress of a form in which few other writers excelled.

(J. S. SA.)

RING, a band of circular shape, made of any material and for various purposes. but, particularly, a circular band of gold. silver or other precious or decorative material used as an ornament, not only for the finger. but also for the ear, or even for the nose, as worn by certain races in India and Africa.

Egyptian Rings.—The earliest existing rings are those found in the tombs of ancient Egypt. The finest examples date from about the 18th to the 20th dynasty; they are of pure gold. simple in design, very heavy and massive, and have usually the name and titles of the owner deeply sunk in hieroglyphic characters on an oblong gold bezel. Rings worn in Egypt by the poorer classes were made of less costly materials. such as silver! bronze, glass or pottery covered with a siliceous glaze and coloured brilliant blue or green with various copper oxides. Some of these had hieroglyphic inscriptions impressed while the clay was moist. Other examples have been found made of ivory, amber and hard stones. such as carnelian. Another form of ring used in the 12th and subsequent dynasties of Egypt had a scarab in place of the bezel, and was mounted on a gold hoop which passed through the hole in the scarab and allowed it to revolve.

Cylinders.— In ancient Babylonia and Assyria the signet took the form of a cone seal or of a cylinder cut in crystal or other hard stone and perforated from end to end. A cord was passed through the cylinder. and it was worn on the wrist like a bracelet.

Within the limits necessarily imposed by its purpose the finger ring assumed a considerable variety of form, according to its date and place of origin.

In the Cretan and Mycenaean periods a characteristic form of ring had a broad flat bezel, not organically connected with the hoop, and having an incised design in the gold. The use of inset stones hardly occurs. but rings from Enkomi and Aegina of the late Mycenaean period have inset paste decorations.

The Phoenician type of ring was primarily intended to carry a scarab or scarabaeoid. usually in a box setting on a swivel, called for by the fact that the flat base of the scarab would be wanted for sealing purposes, but in wear would be most conveniently turned inward. Strength being necessary, the hoop became massive. A similar arrangement of the signet-scarab is found attached to a tmisted ring, which, from its shape. must have been meant to be suspended, and which is shown thus worn on some of the Cypriote terra cottas.

The Greek ring of an early period has a characteristic flattened bezel, for an intaglio design in the gold. An alternative form was a snivel ring for a scarab or scarabaeoid.

Etruscan Rings.—The Etruscans used very largely the gold swivel ring mounted with a scarab, a form of signet probably introduced from Egypt. Some found in Etruscan tombs have real Egyptian scarabs with legible hieroglyphs; others, probably the work of Phoenician or native engravers, have rude copies of hieroglyphs. either quite or partially illegible. A third and more numerous class of Etruscan signet rings have scarabs. cut usually in sard or carnelian. One from Etruria. now in the British museum, is formed by two minutely modeled lions whose bodies form the hoop. while their paws hold the bezel, a scarab engraved with a lion of heraldic. character. An alternative type of Etruscan ring has an incised design on the gold bezel: or a flat stone set in the rigid bezel.

Roman Rings.—The Romans appear to have imitated the simplicity of Lacedaemonia. Throughout the republic none but iron rings were worn by the bulk of the citizens. and even these were forbidden to slaves. Ambassadors were the first who were privileged to wear gold rings, and then only while performing some public duty. Next senators. consuls, equites and all the chief officers of state received the *ius annuli aurei.* In the Augustan age many valuable collections of antique rings were made. and were frequently offered as gifts in the temples of Rome. One of the largest and most valuable of the *dnctyliotkecae* was dedicated in the temple of Apollo Paiatinus by Augustus' nephew Marcellus (Pliny, *H.N.* xxxvii, 5).

Different laws as to the wearing of rings existed during the empire: Tiberius made a large property qualification necessary for the wearing of gold rings in the case of those who were not of free descent; Severus conceded the right to all Roman soldiers; and later still, all free citizens possessed the *ius annuli aurei,* silver rings being worn by freedmen and iron by slaves. Under Justinian even these restrictions passed away.

Early Christian Rings.—Most early Christian rings date from the 4th century onward. Generally of bronze or gold they are often engraved with acclamations and invocations and occasionally with the owner's bust or with Christian symbols.

Celtic Rings.—Large numbers of gold rings have been found in many parts of Europe in the tombs of early Celtic races. They are usually of pure gold, often penannular in form; that is, with a slight break in the hoop so as to form a spring. They are often of gold wire formed into a sort of rope, or else a simple bar twisted in an ornamental way. Some of the quite plain penannular rings were used in the place of coined money.

Throughout the middle ages the signet ring was a thing of great importance in religious. legal, commercial and private matters.

Episcopal Rings.—The episcopal ring was solemnly conferred upon the newly made bishop together with his crozier, a special formula for this being inserted in the Pontifical. In the earliest references to rings worn by bishops, there is nothing to distinguish them irom other signet rings. In A.D. 610 the first mention has been found of the episcopal ring as a well-understood symbol of dignity. It is clear that it was derived from the signet. It was only in the 12th century and onward that it was brought into mystical connection with the marriage ring. In the time of Innocent III (1194) the ring was ordered to be of pure gold mounted with a stone that was not engraved; but this rule appears not to have been strictly kept. It was the custom upon the death of a bishop for his ring to be handed over to the royal treasurer, but many rings with all the appearance oi consecration rings have been discovered in the coffins of bishops. Among the collection of rings formed by the naturalist Edmund Waterton, and now in the South Kensington museum, is a fine gold episcopal ring decorated with niello, and inscribed with the name of Alhstan, bishop of Sherborne irom 824 to 867. In many cases an antique gem was mounted in the bishop's ring, and oiten an inscription was added in the gold setting of the gem to give a Christian name to the pagan figure. The monks of Durham, for example, made an intaglio oi Jupiter Serapis into a portrait of St. Oswald by adding the legend CAPVT S. OSWALDI. In other cases the engraved gem appears to have been merely regarded as an ornament without meaning—as, for example, a magnificent gold ring iound in the coffin of Seffrid, bishop of Chichester (1125–1151), in which is mounted a Gnostic intaglio.

Papal Rings.—The papal "Ring of the Fisherman" (*annulus piscatoris*) bears the device of St. Peter in a boat, drawing a net from the water. The first mention of it, as the well-understood personal signet ring oi the pope, that has been iound occurs in a letter of Clemeni IV in 1265. After the middle of the 15th century it was no longer used as the private seal oi the popes, but mas always attached to briefs. After the death of a pope the ring is broken. A new ring with the space for the name left blank is taken into the conclave, and placed on the finger of the newly elected pontiff, who thereupon declares what narne he mill assume, and gives back the ring to be engraved. (See Waterton, *Archaeologia,* 40, p. 138.)

The so-called papal rings, of which many exist dating from the 15th to the 17th century, are very large thumb rings, usually of gilt bronze

coarsely worked, and set with a foiled piece of glass or crystal On the hoop is usually engraved the name and arms of the reigning pope, the bezel being without a device. They are sometimes described as rings of investiture and according to another hypothesis they were carried as credentials by envoys. Such cumbrous ornaments could not have been worn by the popes and cardinals themselves.

Other Varieties.— The giving of a ring to mark a betrothal was an old Roman custom. The ring was probably a mere pledge, *pignus,* that the contract would be fulfilled. In Pliny's time conservative custom still required a plain ring of iron, hut the gold ring was introduced in the course of the 2nd century. This use of the ring, which was thus of purely secular origin, received ecclesiastical sanction, and formulas of benediction of the ring exist from the 11th century. The exact stages by which the wedding ring developed from the betrothal ring can no longer be traced Gold marriage rings enriched with niello date from the 5th century though they may not have been used in the actual ceremony of marriage.

Posy rings, so called from the "poesy" or rhyme engraved on them, were specially common in the same centuries. The name "posy ring" does not occur earlier than the 16th century. A posy ring inscribed with "Love me and leave me not" is mentioned by William Shakespeare *(Mer.* of ***Ven.,*** act v, sc. 1). The custom of inscribing rings with mottoes or words of good omen dates from a very early time. Greek and Roman rings exist with words such as ZHCAIC, XAIPE, KAAH, or *votis meis Claudia vivas.* In the middle ages many rings mere inscribed with words of cabalistic power, such as *anam zapta,* or Caspar, Melchior and Balthasar, the supposed names of the Magi

In the 17th century memorial rings with a name and date of death were frequently made of very elaborate form, enamelled in black and white; a not unusual design was two skeletons bent along the hoop, and holding a coffin which formed the bezel

Cramp rings were much worn during the middle ages as a preservative against cramp They derived their virtue from being blessed by the king; a special iorm of service was used ior this, and a large number of rings were consecrated at one time, usually when the sovereign touched patients ior the king's evil.

Decade rings were not uncommon, especially in the 15th century; these were so called from their having ten knobs along the hoop oi the ring, and were used, after the manner of rosaries, to say nine Aves and a Pater Noster.

In the 15th and 16th centuries signet rings engraved with a badge or trademark were much used by merchants and others; these were not only used to form seals, but the ring itself was oiten sent by a trusty bearer as the proof of the genuineness of a bill oi demand At the same time private gentlemen used massive rings wholly of gold with their initials cut on the bezel, and a graceful knot of flowers twining round the letters. Other fine gold rings of this period have coats of arms or crests with graceful lambrequins.

Poison rings with a hollow bezel were used in classical times; as, for example, that by which Hannibal killed himself, and the poison ring of Demosthenes. Pliny records that. after Crassus had stolen the gold treasure from under the throne of Capitoline Jupiter, the guardian of the shrine, to escape torture, "broke the gem of his ring in his mouth and died immediately" The mediaeval *anello della morte,* supposed to be a Venetian invention, was actually used as an easy method of murder. Among the elaborate ornaments of the bezel a hollow point made to work with a spring was concealed; it communicated with a receptacle for poison in a cavity behind, in such a way that the murderer could- give the fatal scratch while shaking hands with his enemy. This device was probably suggested by the poison fang of a snake. *(See* also GEM; JEWELLERY; SEALS.)

(J. H. MI.; A. H. SM.; X.)

In Mathematics.— In mathematics the term "ring" is used for an important type of algebraic system. By a ring R is meant a set of elements in which two compositions, called addition (+) and multiplication (.), are defined in such a way that the following conditions obtain:

A 1	$a+b$ is in the set R.
A 2	$(a+b)+c=a+(b+c)$.
A 3	$a+b=b+a$.
A 4	There is an element O in R such that $a+O=a$ for all a in R.
A 5	For each a in R there is an element $-a$, called the negative of a, such that $a+(-a)=O$.
M 1	ab is in R.
M 2	$(ab)c=a(bc)$.
D 1	$a(b+c)=ab+ac$.
D 2	$(b+c)a=ba+ca$.

The conditions A 1 to A 5 imply that R is a commutative group *(see* GROUPS) relative to the addition operation. Conditions M 1 and M 2 imply that R is a system of the type called a semigroup relative to multiplication, and D 1 and D 2 are the distributive laws connecting the two operations of addition and multiplication.

The concept oi a ring is used in advance developments in algebra and details of such work may be found in the treatises listed in the bibliography. (N. J.)

RINGWORM OF THE SCALP (TINEA CAPITIS) is a highly contagious fungus disease of the scalp of children It is caused by a group of fungi which form small spores after invading the hair, hence the name *Microsporum.* The most common species, *Microsporum audouini,* causes the development of circular and rapidly spreading areas in which all the hairs break off close to the surface. The disease never causes serious harm but it is unpleasant because of its unsightliness and because the cure is difficult. Its public health significance is considerable because major epidemics may arise at any time to involve vast numbers of children. A spectacular feature of this infection is that with the onset of adolescence it disappears. The cause for this peculiar immunity in adults is the pubertal development of the oil glands of the scalp. These glands secrete fatty acids which have a powerful killing action on *Microsporum audouini.*

The scalp infection spreads in schools, orphanages, children's camps or wherever there are concentrations of children. Also contamination of barber shop instruments or the backs of public seats (on trains, in theatres, etc.) is a possible factor. In England and France, epidemics have been common for centuries. After World War I. the disease invaded central Europe. In the United States it never reached epidemic proportions before World War II, but after 1943 many large cities had major epidemics.

Other species of *Microsporum* are transferred to man from cats and dogs and cause similar ringworm diseases. The animal types of scalp ringworm usually run shorter courses than the epidemic type. There are many more types of ringworm of the scalp which are rare and difficult to treat. See also FAVUS; SKIN DISEASES.

(RD. B. S.)

RIOBAMBA, a city in highland Ecuador, capital of the province of Chimborazo. Pop. (1950) 29,830. It is located at an elevation of about 9,000 ft. in the basin of Riobamba, just south of Mt. Chimborazo, and about 100 mi. S. of Quito. It is reached by railroad or by the Inter-American highway from both Quito and Guayaquil. Domestic airlines serve its airport. The railroad and highway pass a short distance to the west of the city, and connection is by branch line and an all-weather road. A weekly fair held in the central plaza attracts Indian farmers from the surrounding countryside. Small-scale manufacturing industries produce cotton and woolen textiles, carpets, shoes, beer, liquor, butter and cheese. The first constitution of Ecuador was proclaimed there in 1830. **(P. E. J.)**

RIO BRANCO, one of four federal territories in Brazil. Formerly a part of the state of Amazonas, it was created by decree law in 1943. Area 89,058 sq.mi. Pop. (1950) 18,116. Located in the northernmost part of Brazil, it is bounded on the northeast by British Guiana, on the south by Amazonas, and on the northwest and north by Venezuela. It is drained from north to south by the Rio Branco, a tributary of the Rio Negro. Much of the territory is covered with rain forest or selva, but around Boa Vista, pop. (1950) 5,132, the chief city and capital, there are extensive woodland savannas which extend across the border into British Guiana (the Rupununi savanna). Along the Venezuelan border there are high tablelands, covered partly with forest, partly uith savanna. At the border of Rio Branco, British Guiana and Venezuela is the plateaulike Mt. Roraima. Rio Branco is scantily inhabited, especially along its borders. The savannas are used for cattle ranching, and some gold and diamonds are found in the streams. (P. E. J.)

RÍO CUARTO, a town of Argentina in the province of Córdoba, 140 mi. S. of the city of that name, and about 385 mi. N.W. of Buenos Aires. Pop. (1956 est.) 59,900. It stands 1,440 ft. above sea level and about halfway across the great Argentine pampas, on the banks of a river of the same name. The town is built on the open plain and is surrounded with attractive suburbs. It is the commercial centre of a big district and has a large and lucrative trade. Its geographical position gives it great strategic importance, and the government maintains there a large arsenal and a garrison of the regular army. Before 1872 this region was overrun by the Ranqueles, a warlike tribe of Indians. The surrounding country belongs to the partially arid pampas region and is devoted to stock-raising agriculture. Irrigation is employed in its immediate vicinity. There are some manufacturing industries in the town, although it is primarily an agricultural centre. The

San Martin and the Mitre railways pass through Rio Cuarto, giving railway communication with Buenos Aires, Rosario, Tucumin, Córdoba, San Luis, Mendoza and other cities.

The revolution which overthrew President Perón in 1955 began with an uprising at the Rio Cuarto military air base. (GE. P.)

RIO DE JANEIRO, one of Brazil's maritime states, is bounded by the Atlantic ocean and the states of Espirito Santo, Minas Gerais and São Paulo. Brazil's former federal district containing the city of Rio de Janeiro and fronting on the Guanabara bay forms a small enclave near the middle of the state. Area 16,443 sq.mi., pop. (1950) 2,297,194.

Historically it is closely associated with the city Rio de Janeiro. Its territory was selected by the Portuguese for some of their first settlements, and on parts of its coast the French waged their early struggles for the control of Brazil's resources. When Brazil was divided into captaincies in 1642, Rio de Janeiro was one of the original ten. The city of Rio de Janeiro was the seat of the captaincy's government and centre of its social and economic life throughout the colonial period. After independence was declared the *município* or county containing the national capital was separated from the state and made into a federal district.

The territory of the state may be divided roughly into four regions, namely: a low, narrow and irregular coastal plain; the Baixada Fluminense, a large basin surrounding Guanabara bay; the rugged chain of mountains, Serra do Mar, which traverses the state longitudinally; and the large valley through which the Paraiba river flows northeastward to the Atlantic. In the northeastern part of the state this river cuts through the mountain chain and its valley then broadens out into a rich alluvial plain on which for centuries sugar plantations were the basis for the wealth of some of Brazil's most opulent families. The climate is tropical or subtropical depending on altitude.

Agriculture long was the mainstay of the state's economy, but since World War II industrialization has proceeded rapidly. The chief crops are coffee, oranges, bananas, sugar cane, rice and corn, but many other fruits and truck crops are grown. The cattle population numbers more than 2,000,000; and the salt refineries and fisheries are among the most important in Brazil. Since 1945 the industrial belt surrounding the city of Rio de Janeiro and the iron and steel centre at Volta Redonda in the upper Paraiba valley developed tremendously. Pig iron, steel, steel products, textiles, cement and food products are the principal industrial products. Rio de Janeiro is a leading state in hydroelectric power production.

The major cities are: Niterói (*q.v.*), the state capital, on Guanabara bay opposite the city of Rio de Janeiro; Campos; Petrópolis (*qq.v.*), the nation's summer capital; Duque de Caxias, Nova Iguaçu, São João de Meriti and Nilópolis, all suburbs of Rio de Janeiro.

The state is served by road and rail networks which radiate from the great port of Rio de Janeiro. Most of the 1,663 mi. of railroads in service belong to two systems, the Central do Brasil whose main lines connect the city of Rio de Janeiro with São Paulo and with Belo Horizonte, and the Leopoldina railway which links Rio de Janeiro and Niterói with places to the north and east.

(T. L. SH.)

RIO DE JANEIRO (in full, SAO SEBASTIÃO DO RIO DE JANEIRO, colloquially shortened to RIO), a city and port of Brazil, capital of the republic until 1960, when Brasilia (*q.v.*) became the capital, on the western side of Rio de Janeiro, or Guanabara bay. The city occupies about 60 sq.mi. in the southeast angle of Guanabara state, formerly the Federal District, which was until 1960 an independent commune with an area of 524 sq.mi., detached from the province of Rio de Janeiro in 1834. The city stands in great part on an alluvial plain formed by the filling in of the western shore of the bay, which extends inland from the shore line in a northwesterly direction between a detached group of mountains on the south known as the Serra da Carioca, and the imposing wooded heights of the Serra do Mar on the north. The spurs of the Carioca range project into this plain, in some places close up to the margin of the bay, forming picturesque valleys within the limits of the city. Some of the residential quarters follow these valleys up into the mountains and extend up their slopes and over the lower spurs, which, with the hills covered with buildings rising in the midst of the city, give the city a distinctive charm. At the entrance to the bay is Sugar Loaf mountain (Pão de Açúcar), a conical rock rising 1,296 ft. above the water level and forming the terminal point of a short range between the city and the Atlantic coast. The culminating point of that part of the Carioca range which projects into and partly divides the city is the Corcovado (Hunchback), a sharp rocky peak, 2,310 ft. above the Botafogo inlet, on whose narrow summit towers the imposing statue 98½ ft. high of Christ the Redeemer, the construction of which was completed in 1931. The Corcovado, approachable either by road or inclined railway, provides a point of vantage from which the entire capital, the bay and its surrounding districts may be viewed. Considerably beyond the limits of the city on its southwest side is the huge isolated flat-topped rock known as the Gávea, 2,736 ft. high, which received its name from its resemblance to the square sail used on certain Portuguese craft. The sky line of this range of mountains, as seen by the approaching traveler several miles outside the entrance to the bay, forms the rough outline of a reclining figure called "the sleeping giant."

The entrance to the bay, between the Sugar Loaf on the west and the Pico do Papagaio (Parrot's Beak) on the east, with the fortress of Santa Cruz on one side and the fort of São João on the other, is about a mile wide. Although the entrance is free from obstructions, dangerous swells are produced by a deeply submerged bar whenever storms come out of the south or southwest. Almost midway in the channel is the little island and fort of Laje, temporary site of the first Huguenot settlement in Rio de Janeiro. On the west is the semicircular bay of Botafogo, round which are grouped the residences of one of the wealthiest suburbs; on the east, the almost landlocked bay of Jurujuba. (See NITERÓI.)

The bay extends northward about 16 mi, from the entrance channel, opening to a maximum width of about 15 mi. near its head. The irregular shore line was modified by the construction of sea walls and the filling in of shallow bays. Close to the shore are the islands of Villegaignon (occupied by the national naval academy), Cobras (occupied by fortifications, naval storehouses, hospital and dry docks), Santa Bárbara and Enxadas.

The oldest part of the city, which includes the commercial section, lies between Castle and Santo Antônio hills on the south, and São Bento, Conceição and Livramento hills on the north, and extends inland to the Praqa da República, though the defensive works in colonial times followed a line much nearer the bay. This section was extended southward along the bay shore during the 19th century and led to the development of a string of suburbs such as Catete and Botafogo, with that of Laranjeiras behind Catete in a pretty valley of the same name, Leme, Copacabana, Ipanema and Gavea, the last including Rio's famous botanical garden, nhich dates from the early 19th century. The major trend of later development was northward and westward, where are to be found the suburbs of Cidade Nova, São Cristóvão, Engenho Novo, Praia Formosa, Pedregulho, Vila Isabel, Tijuca, Rio Comprido, Cajú and others, some of which are residential, while others are essentially industrial. The outlying, poorer suburbs are reached by the Central do Brasil railway; those closer in are served by street railways and buses. The population of the former Federal District, according to the census of 1950, was 2,377,451; and of the city 2,303,063. Rio's citizens are known locally as cariocas.

Climate.—The climate of Rio de Janeiro is warm and humid, the average temperature for the year being about 74° F., with July, the coolest month, having an average temperature of 68.7". The rainfall averages about 44 in. annually, with July and August being the least rainy months. Formerly the low-lying and poorly drained areas which are marginal to the bay, plus the lack of adequate sanitary facilities, created a serious health problem in Rio de Janeiro, which was, however, in no way connected with the climate. Yellow iever, the first recorded appearance of which was in Dec. 1849, was for many years almost a regular occurrence, and the mortality from it was exceedingly high. This and other dangerous diseases disappeared as epidemics as a result of improved sanitary conditions following the notable work begun by

Oswaldo Cruz, under whose direction Rio de Janeiro was made one of the most healthful of tropical cities.

Streets and Parks.—Some of the most modern streets were laid out with Spanish-American regularity, but much the greater part seems to have sprung into existence without any plan. Most of the streets of the old city are parallel and cross at right angles, but they are narrow and enclose blocks of unequal size. Each suburb is laid out independently, with straight streets where the ground permits, and crooked ones where the shore line or mountain contour compels. From the beginning of the 20th century, large sums were expended on new avenues, the widening and straightening of old streets and the improvement of the water front between the Passeio Público and the southern extremity of the Praia de Botafogo by the construction of a grand boulevard. partly on reclaimed land. One of these improvements consists of a central avenue (Avenida Rio Branco) cut across the old city from a point on the water front near the Passeio Pitblico northward to the Saitde water front. More than a mile long from north to south. it is lined with brazilwood trees, mosaic sidewalks and has fine private and public buildings. The military, naval and jockey clubs are situated there, and also the offices of some of the principal ne spapers, besides fashionable shops, cafés and business places. The shore line boulevard, called the Avenida Beira Mar, is more than four miles long, the wider parts being filled in with gardens. Toward the south, outside the Guanabara bay, the shore along the beaches of Leme, Copacabana and Ipanema was built into one of the most fashionable resorts of the continent.

The Mangue canal, originally designed as an entrance to a central market for the boats plying the bay, is used for drainage purposes. The canal is nearly two miles long, enclosed with stone walls, crossed by a number of iron bridges and bordered by lines of royal palms. The most famous street of the old city is the Rua do Ouvidor. running westward from the market place to the church of São Francisco de Paula, and lined with retail shops, cafés and newspaper offices. It has long been a favourite promenade, and fills an important part in the social and political life of the city. The principal business section includes a number of short and narrow streets between the Rua Primeiro de Março, once called Rua Direita, which extends from the Praqa 15 de Novembro northward to São Bento hill and the Avenida Rio Branco. The widest boulevard in the city is the Avenida Presidente Vargas, which begins at the Candeliria church and, crossing the Avenida Rio Branco at right angles, extends toward the west for more than two miles. The streets and suburbs are served by lines of the Rio de Janeiro Tramway, Light and Power Co., Ltd., which also supplies electric power to the city from hydroelectric plants.

The public parks and gardens are numerous and include the Parque Azurem Furtado, the largest park in the central district; the botanical garden with its avenue of royal palms; the Passeio Publico (dating from 1783), a small garden on the water front facing the harbour entrance; the Praça Tiradentes with its magnificent equestrian statue of Dom Pedro I; the Praça 15 de Novembro on the water front, facing the old city palace; the Quinta da Boa Vista in São Cristóvão; and many smaller parks and squares.

Water Supply.—The water supply is derived from three sources: the small streams flowing down the mountainsides which serve small localities; the old Carioca aqueduct, dating from colonial times; and the modern Rio do Ouro waterworks, which bring in an abundant supply from the Serra do Tinguá, 30 mi. N.W. of the city. An extensive system of sewers was constructed and a separate system of rain-water drains.

Buildings.—There remain many public edifices and dwellings of the colonial period, severely plain in appearance, with heavy stone walls and tile roofs. The old city palace facing upon Praça 15 de Novembro, once the residence of the fugitive Portuguese sovereign Dom João VI, is a good example. The 19th century brought no important modifications until near its close, when French and Italian styles began to appear, both in exterior decoration and in architectural design. The Praqa do Comércio (merchants' exchange) and post office on Rua 1° de Março and the national printing office near the Largo da Carioca are notable examples. After that time architectural styles changed radically, and apartments, hotels, office buildings and public buildings of the most advanced modern design and construction were built. At the southern end of the Avenida Rio Branco is a group of elegant state edifices, the Municipal theatre, the Monroe palace and the National library and Academy of Fine Arts. The buildings of the ministries of finance, education and war are also among the most beautiful in the city. There are more than 200 churches in the city, including the cathedral which was built in 1761. The most noteworthy church is that of Our Lady of Candelária, in the commercial district, with twin towers and graceful dome.

Hospitals and *Asylums*.—Rio de Janeiro has a number of hospitals, asylums and benevolent institutions. Chief of these is the Misericórdia hospital, popularly known as the "Santa Casa," belonging to a religious brotherhood dating from 1591. Other public hospitals are a lepers' hospital in São Cristóvão, the military and naval hospitals, the São Sebastião hospital and the isolation and contagious diseases hospitals in Jurujuba. The government participated in a program of remodeling and improving existing institutions and of building such new ones as the Jesus, Miguel Couto and Getulio Vargas hospitals. There are also a number of private hospitals maintained by church brotherhoods and charitable associations; among them are the Portuguese hospital in Rua de Santo Amaro and the Strangers' hospital in Botafogo. Most prominent among the asylums is the Hospicio Nacional for the insane, which was erected in 1842–52.

Education.—Rio de Janeiro was always an important educational centre. A Jesuit school (*colégio*) transferred there in 1567 was a foremost institution of pre-university training for almost two centuries. The 19th century saw the creation of a "model" secondary school, the Colégio Dom Pedro II (1837), as well as military (1838), naval (1858) and engineering (1874) schools. The military school became famous as a stronghold for the positivist ideology which influenced the republican coup *d'état* of 1889. In 1920, Brazil's adoption of the university system was marked by the creation of the University of Brazil in Rio de Janeiro. An educational reform program inaugurated in the Federal District in 1928 made the city the focus for a renovation of pedagogical ideas and techniques which affected the whole country. As part of this reform, a presidential decree of 1931 created faculties of education, sciences and letters. At the same time, such pre-existing institutions as the schools of law, medicine, pharmacy, dentistry. mines and fine arts, the Polytechnic school, the National museum, the Geological and Mineralogical institute, the Oswaldo Cruz institute (medical research), the Astronomical observatory, the Institute of Chemistry, the Botanical garden, the Institute of Legal Medicine, the Central Meteorological institute and other centres of higher learning were made integral parts of the university. Considerable progress was made in the field of teacher training. which was climaxed in Rio de Janeiro by the creation in 1935 of the University of the Federal District—comprising the teachers' college, schools of letters, sciences, economics and law and an institute of arts. In 1939 this institution was merged with the University of Rio de Janeiro, as the University of Brazil had been temporarily renamed two years earlier. A Catholic university was founded in the city in 1940. In addition to its two universities, Rio de Janeiro has many other institutes of learning, including preparatory schools, vocational schools and schools for the deaf and blind.

Harbour, Communications and Commerce.—The port and harbour of Rio de Janeiro are the largest in the republic. The entrance is open to vessels of the largest draught, and there is sufficient deepwater anchorage inside for the navies of the world. The lower anchorage, where the health officers visit vessels, is below Ilha Fiscal, and the upper or commercial anchorage is in the broad part of the bay above Ilha das Cobras, the national coasting vessels occupying the shallower waters near the Saude and Gamboa districts. The customhouse occupies a considerable part of the shore line before the old city.

The newer port works consists of an improved water front for the Saúde. Gamboa and Saco do Alferes districts, in which the shipping interests are centred, and a continuation of the sea wall across the shallow São Cristóvão bay to the Ponta do Cajú, the

large reclaimed area being filled in by the removal of some small hills. The commercial quays are built in deep water and permit mooring alongside the largest vessels. The total length of the commercial quays is about 7,500 yd. Railway and streetcar connections are provided, and both electric and hydraulic power are available Special surtaxes are levied on imports to meet the Interest and redemption charges on the loans raised for the execution of these important works.

Railway communication with the interior is maintained by the Central do Brasil and the Leopoldina lines, besides which there is a short passenger line to Corcovado mountain about two and one half miles long, an electric line to Tijuca and a narrow-gauge line to the Rio do Ouro waterworks. There is communication with Petrópolis hy a branch line of the Leopoldina system, and also by a steamer to the head of the bay and thence by rail up the *serra*.

Rin de Janeiro is the seaport for a large area of the richest, most productive and most thickly settled parts of Brazil, including the states of Rio de Janeiro and Minas Grrais and a small part of eastern São Paulo. Its exports include coffee, sugar, hides, cabinet woods, tobacco and cigars, tapioca, gold, diamonds, iron ore. manganese and sundry small products.

The city is also a distributing centre in the coasting trade, and many imported products, including jerked beef (*xarque*), hay, flour and nines appear among the coastwise exports, as nell as domestic manufactures. The total exports for 1957 amounted to 838 286 metric tons; imports in the same year totaled 4,231,618 metric tons Formerly Rio de Janeiro led all other ports in Brazil in the export of coffee, but the enormous increase in production in the state of São Paulo later gave Santos the lead

Air travel is of increasing importance for the city's communication with other coastal cities and with the vast hinterland of Brazil, as well as with the rest of the world Rio de Janeiro is served by tno airports, Santos Dumont and Galeão.

Manufactures. — Inspite of Rio's leading role as a commercial port. the city is not equally important as an industrial or manufacturing centre. Manufactures consist largely of consumers' goods for the domestic market. and include such items as flour (from imported nheat), biscuits, macaroni, chocolate, fruit conserves, refined sugar, confectioneries and other foodstuffs. beer, liquors, ice mineral waters, cigars and cigarettes; soap, candles, perfumes, furniture, boots and shoes. hats, clothing, rape matches ink printing type, glass chemicals and tires. In addition there are plants which manufacture finished products from processed imports especially drugs and sundries. There are machine and repair shops, notably the shops of the Central do Brasil railway. One of the most important industrial enterprises in the city is that nf the Rio de Janeiro Tramway Light and Power Co. whose generating plants are located about 50 mi from the city In the late 1950s there were more than 4,000 industrial establishments employing nearly 200,000 persons. Promotion of trade in the city is largely a function of the chamber of commerce of Rio de Janeiro and the Federation of Brazilian Chambers of Commerce.

Government--Until it became the state of Guanabara in 1960, the Federal District. including Rio de Janeiro, was governed by a prefect representing the national government. and a municipal council, representing the people. The prefect was appointed by the president of the republic for a term of four years, subject to confirmation by the senate. There were seven *diretorias*, oi boards, under the prefect, each one assigned to a special field of work. chief among them being education, public health and social welfare public works and transportation. finance. police, archives and statistics. forestry, and game and fishing The municipal council of *intendentes* was elected by direct suffrage for a term of two years and was composed of 50 members meeting in ordinary session twice a year. In April 1960, a national law ordered the election, the following October. of a governor for the new state of Guanabara and a legislative assembly that would meet during its first four months as a constituent body.

Mistory. — It has been said that the Bay of Rio de Janeiro was discovered by André Gonçalves and Amerigo Vespucci on Jan. 1. 1502 and that Gonçalves named it "River of January." More probably it was discovered in 1504 by Gonçalo Coelho. The name "Rio de Janeiro" appeared on maps only in about 1515. Another Portuguese navigator. Martim Afonso de Sousa, visited the bay in 1531, but passed on south to São Vicente, where he established a colony. The first settlement in the bay was made by an expedition of French Huguenots under the command of Nicolas Durand de Villegaignon, who established his colony on the smail island that bears his name. The French called their colony La France Antarctique, and the island stronghold Fort Coligny. In 1560 the fort was captured and destroyed by a Portuguese expedition from Bahia under Gov. Mem de Sá, and in 1565 another expedition under Estácio de Sá, cousin of the governor, founded a Portuguese settlement in another part of the bay which was called São Sebastião do Rio de Janeiro. in honour of King Sebastian of Portugal. Two years later the French were decisively defeated by Mem de Sá, nho moved the settlement to the hill later known as the Morro do Castelo. He laid out streets and a plaza, and encouraged construction of the first houses The following governor built a sugar mill on the island that is still called the Ilha do Governador. Twice during the next hundred years Brazil mas divided for short periods into two governorships, with Rio serving as capital of the southern jurisdiction. In 1710–11 the French made two expeditions against Rio and finally withdrew after exacting a heavy ransom.

The discovery of gold in Minas Gerais at the end of the 17th century greatly increased the importance of Rio de Janeiro. During the governorship of Gomes Freire de Andrade (1733–63) the Carioca aqueduct, the governor's palace, the convent of St Teresa and other architectural landmarks were built; fortifications were strengthened; urbanism and public health received attention; intellectual life was encouraged; and Brazil's first printing press mas established. In 1763 Rio succredcd Bahia as the capital.

In 1808 the fugitive Portuguese court, under the regent Dom João VI, took refuge in Rio de Janeiro and gave a new impulse to its growth. It was thrown open to foreign commerce. foreign mercantile houses were permitted to settle there, printing was permanently established, industrial restrictions were removed and a college of medicine, a military academy and a public library were founded. Dom João VI returned to Portugal in 1821. and on Sept 7, 1822, Brazil was declared independent mith Dom Pedro I as its first emperor and Rio de Janeiro as its capital. In 1834 Rio became an autonomous municipality and was declared capital of the empire. In 1839 a steamship service along the coast was opened. but direct communication with Europe was delayed until 1850 and with the United States until 1865. These services added largely to the prosperity of the port The first section of the Dom Pedro II railway was opened in 1858, and the second or mountain section in 1864, which brought the city into closer relations with the interior. In 1874 cable communication with Europe was opened, which was soon afterward extended southward to the river Plate republics.

During the five years following the declaration of the republic in 1889 life in Rio de Janeiro was interrupted by political disorders,, particularly by a six-month blockade of the port and desultory bombardment. Under the presidency of Francisco de Paula Rodrigues Alves (1902–06), honever, the problems arising from the city's narrow, congested streets and deplorable health conditions were attacked in a co-ordinated effort led by Lauro Muller (federal minister of industry). Pereira Passos (city prefect) and the physician Dr. Oswaldo Cruz. The avenues. parks and port facilities for which Rio is famed were planned, while the diseases of yellow fever. bubonic plague and smallpox were eiiminated or greatly reduced. Until 1930 Rio was the scene of a number of political outbreaks, notably the short-lived revolt of the army officers of Fort Copacabana in 1922, but none was of great importance. Under the first regime of President Getulio Vargas (1930–45) and thereafter the rapid expansion of the government bureaucracy and the congestion and overbuilding of Rio de Janeiro gave impetus to plans. dating from even before the republican period, for moving the national capital to an inland site that would enjoy a cooler climate and be a stimulant for opening up Brazil's unexploited hinterland. President Juscelino Kubitschek (1956–61) resolved to effect the transfer during his

administration and ssnctioned a law for the construction of the new capital, Brasilia, 600 mi. N.W. of Rio. The official change of capitals took place on April 21. 1960. See also Index references under "Rio de Janeiro" in the Index volume. (R. M. M)

RÍO DE ORO, the name commonly used for all of Spanish Sahara on the northwest coast of Africa, though strictly applicable only to the southern two thirds of the territory between Capes Bojador and Blanco (Blanc). Its length is about 425 mi. and it extends inland about 150 mi from Cape Bojador in the north and about 250 mi. along its southern boundary North of Cape Bojador are the other parts of Spanish Sahara the so-called Free Zone of Occupation or Sekia el Hamara (Sp. Saguia del Hamra) extending from Cape Bojador to Cape Juby, The two districts are surrounded by Mauretania, Algeria and Morocco. Sekia el Hamara and Rio de Oro proper are administered together as the province of Spanish Sahara. The seat of the governor is at Villa Cisneros, on the peninsula of Río de Oro; in 1950 the town had a population of 1,096. including 312 Europeans. The peninsula projects about 23 mi. into the sea and is 1½ to 2 mi. broad. Rio de Oro bay, between it and the mainland, is about 5 mi, broad and affords a good anchorage.

The territory of Río de Oro proper has an area of 71,042 sqmi., and its population in 1950 nas 1,304 settled inhabitant, Most of Río de Oro is desert and there is hardly any agriculture. Camels, goats, sheep and zebus are reared; their meat and milk afford sustenance and there is some exportation of their skins. Villa Cisneros is connected with the rest of Spanish Sahara and the outside world by air, and there are tracks north to Cape Juby, and south to Tichlá and La Guera (on Cape Blanco), as well as several caravan routes. A shipping service links Villa Cisneros with La Guera, Tantan and the Canaries. The total population of the Spanish Sahara province (area 102,702 sq.mi) is 7.749 (1950).

Río de Oro takes its name from the bay enclosed by the promontory on which Villa Cisneros stands. It was discovered by the Portuguese in the mid-15th century, mistaken for a rive: and ndmed Rio de Ouro (Port "river of gold"; Sp Río de Oro) on account of gold dust obtained from the natives. The Spaniards had already begun the colonization of the Canary Islands and in 1476 established the fort of Santa Cruz de Mar Pequeña on the mainland in the northern part of the territory: it was abandoned in 1524, and the territory remained independent until the 19th century. In 1878 a British trading port was established by Donald Mackenzie on Cape Juby, but it was surrendered to the ruler of Morocco in 1895. Meanwhile French travelers had visited Sekia el Hamara: the Spaniard Benitez and others explored the coast in 1882, and Bonelli signed treaties with the natives on behalf of the Sociedad Española de Africanistas. In 1884 a Spanish protectorate was declared over the coastal zone from Cape Bojador to Cape Blanco and nominally subordinated to the captain-general of the Canaries. A factory was established at Villa Cisneros in 1885, but abandoned in the face of native attacks. Spanish claims were challenged by the French, who claimed a protectorate over the Sahara. and a Franco-Spanish convention of June 27. 1900, established the landward frontier of Rio de Oro proper, awarding the salt deposits of Vjil to the French. Other agreements betneen the two powers resulted in French recognition of Spanish rule between Capes Bojador and Juby (1906 and 1912), and between Cape Juby and the Wad Draa. By the convention of 1912 Spain bound itself not to alienate its rights in these zones. It was only in 1916 that Colonel Bens took effective possession of Cape Juby. In 1920 La Gdera was founded as an outpost facing Port Étienne. Other centres of Spanish influence are Tichli and Bir Gandus.

See Foreign Office, London, *Spanish Sahara* (1920); A Flores Morales, *El Sahara español (1945): E,* and F. Hernandez-Pechero *et al., El Sahara español* (1949). (H. V. L.)

RIO GRANDE (Rio GRANDE DO SUL), a port in the state of Rio Grande do Sul, Brazil. It is located on the western side of the Rio Grande, the name also given to the wide outlet to the Atlantic of the Lagôa dos Patos. The city is built on a low peninsula, barely 5 ft. above sea level, and about 8 mi. upstream from the mouth of the river. Pop. (1950) 63,235.

The peninsula on which Rio Grande has been built is a part of a long sand bar extending from north of Pôrto Alegre southwestward into eastern Uruguay. Cut off from the ocean by the bar are several shallow lagoons, the largest of uhich are Lagôa dos Patos and Lagôa Mirim. For hundreds of miles on either side ot Rio Grande the ocean is bordered by a smooth, sandy beach. backed by strings of live sand dunes, in many nays similar to the coast of southern Georgia The outlet of the lakes in back of the bar is located at the southern end of Lagôa dos Patos. Where the river enters the ocean it passes over a submerged bar which once limited passage to ships of 26 ft. draft or less. The bar was dredged and the channel is kept open so that ocean-going vessels of larger size can dock at Rio Grande or Pelotas, 20 mi. N N W.

Rio Grande was founded in 1737 by José da Silva Paes, who built a fort on the river near the site of the present city and called it Estreito. In 1745 the garrison and settlement were removed by Gornes Freire d'Andrade to its present site, which became a *vila* in 1751, with the name of São Pedro do Rio Grande and a *cidade* (city) in 1807 It was the capital of the captaincy until 1763, when it was occupied by a Spanish force from Buenos Aires under the command of Don Pedro Zeballos. The seat of government was then removed to Viamão at the northern end of the Lagôa dos Patos. The city was occupied by the national forces in the ten years' war of secession. nhich began in 1835, and in 1894 it was unsuccessfully besieged by a small insurgent force that attempted to overthrow the government at Rio de Janeiro.

Rio Grande competes with Pelotas as the outlet for the products of Rio Grande do Sul. As the outport for Pôrto Alegre, with nhich it is connected by shallow-draft lake boats. Rio Grande has an advantage; but for the products of the south, Pelotas is better situated. The exports, mostly to other parts of Brazil, include jerked beef (*xarque*), hides, lard, tallow, wool, rice, wheat and fish. In the city are factories processing meat products, nsh and vegetable canneries, a woolen textile mill, breweries, cigarette manufactures and a shoe factory. The city is linked with Pelotas by rail. A rail line also extends 12 mi. south to a bathing beach and casino. (P. E J.)

RIO GRANDE, the fifth longest North American river, has its sources in the snow fields and alpine meadows of the San Juan mountains of southwestern Colorado. It flows southeast and south 175 mi in Colorado, southerly some 470 mi across New Mexico, and southeasterly between Texas and the Mexican states of Chihuahua, Coahuila, Nuevo Leon and Tamaulipas, for about 1,240 mi. to the Gulf of Mexico. The total length (in compromise "river miles") is approximately 1,885 mi.

It starts as a clear Rocky mountain stream, fed by springs at an elevation of more than 12.000 ft., then flows in a canyon through forests of spruce, fir and aspen, into the broad San Luis valley in Colorado. after which it cuts the Rio Grande gorge and White Rock canyon and enters the open terrain of the basin and range and Mexican highland physiographic provinces. There declining elevation, decreasing latitude and increasing aridity and temperature produce a transition from a cold steppe climate with a vegetation of piñon, juniper and sagebrush, to a hot steppe and desert climate characterized by a vegetation of mesquite, creosote bush. cactus, yucca and other desert plants. Shortly before entering the Gulf coastal plain, the Rio Grande cuts three canyons between 1,500 and 1,700 ft. in depth across the faulted area occupied by the "big bend" where the Texas side of the river is included in the Big Bend National park. In the remainder of its course the river wanders sluggishly across the coastal plain to end in a true delta in the Gulf of Mexico.

The principal tributaries are the Pecos and Devils rivers from the left bank in the United States. and from the right bank the Chama and Puerco in the United States and the Conchos, Salado and San Juan in Mexico. The productive basin contains about 182,000 sq.mi., of uhich about 89,300 are in the United States—half of these being in New Mexico. The peak of flow may occur in any month from April to Oct., but in the upper reaches it usually is in May or June due to melting snow and occasional summer thunderstorms. while the lower portion commonly has highest water in June or Sept. due to summer rain storms. It has been estimated that the Rio Grande has an average annual yield or

more than 9,000,000 ac.ft. of which about one third reached the gulf before the building of the Falcón dam in 1953.

Irrigation has been practised in the Rio Grande basin since prehistoric times, as among the Pueblo Indians of New Mexico. Increase in population and in use of water made necessary the 1905–07 and 1944–45 water treaties between the United States and Mexico, as well as the Rio Grande compact (1939) among Colorado, New Mexico and Texas concerning the waters of the upper Rio Grande sub-basin (above Ft. Quitman, Tex.), and the Pecos river compact between New Mexico and Texas (1948) concerning the Pecos above Girvin, Tex. Essentially all of the average annual production of more than 3,000 000 ac.ft. in the upper Rio Grande (including the 60,000 ac ft allotted to Mexico by treaty) is consumed within this sub-basin. Not only below Ft. Quitman, but in many stretches of the river from the New Mexico-Colorado border to below Brownsville there has been no surface flow at various times. In some places the depth has varied from nearly 60 ft. to a bare trickle or nothing. The lower Rio Grande (below Ft. Quitman) is renewed by the Conchos and other Mexican rivers which produce about two-thirds of the available water. A number of large springs in the area between Hot Springs and Del Rio, Tex., including many in the bed of the river, are important and dependable producers of water. The total storage capacity of the reservoirs in the basin is about 13,000,000 ac ft., with a normal storage of less than 5,000,000 ac.ft., chiefly in the International Falcón reservoir on the lower Rio Grande. Lago Toronto (La Boquilla) on the Conchos. Elephant Butte on the Rio Grande in New Mexico, Marte Gómez (El Azhcar) reservoir on the San Juan and Venustiano Carranza (Don Martin) on the Salado. About 3.000 000 ac. are irrigated within the basin (about two-thirds of these are in the U.S.). The leading crops raised by irrigation vary from potatoes and alfalfa in Colorado to cotton, citrus fruits and vegetables in the valley of the deltaic lower Rio Grande in Texas and Tamaulipas.

After agriculture and animal husbandry, the leading industries are mining (petroleum, natural gas, coal, silver, lead. gold, potash, gypsum, etc.), and recreation (national and state parks and monuments, dude ranches, fishing and hunting, summer and winter resorts, etc.). More than 3,000,000 people live in the basin principally in urban communities. the largest of which are Monterrey, Mex.; Ciudad Jubrez, Mex.; El Paso, Tex.; Albuquerque, N M.; Chihuahua, Mex.; Saltillo, Mex.; Matamoros, Mex.; Nuevo Laredo, Mex ; Laredo, Tex.; and Reynosa. Mex.

During the Spanish period the middle and upper portions commonly were termed the Rio del Norte or Rio Grande del Norte and the loner course usually was called the Rio Bravo (apparently because of the turbulent flash floods). The river is officially the Rio Grande in the United States and the Rio Bravo in Mexico. The earliest European settlements were in the Conchos basin of Chihuahua in the 16th century, but many of the Pueblo Indian settlements of New Mexico date back to before the Spanish conquest. Small steamboats were used for navigation on the lower Rio Grande up to Rio Grande City, and even to Roma when the river was high, from the 1850s until the great hurricane of 1874 swept the river clean. Since then accelerated erosion, silting and sand-bar formation have precluded navigation, and have forced the U.S and Mexico to spend much money and time in adjusting the boundary to the numerous changes in the river channel. There has been considerable development of hydroelectricity within the basin.

(D. D. B.)

RIO GRANDE DO NORTE, a state in the northeast'of Brazil, bounded by the Atlantic ocean on the north and the east, by the state of Paraiba on the south, and by Cearb on the west. Area 20,490 sq.mi., pop. (1950) 967,921. The state capital is Natal (*q.v.*); the only other town of importance is Mossoró.

Except for the coastal strip from Natal southward, which receives adequate rainfall to support a forest, the state is semiarid. It was originally covered with a deciduous, thorny, scrub woodland (caatinga). The northern coast, beyond Cape São Roque, is low and sandy, but the land rises inland to some low mesas (taboleiros). Inland from Natal, along the southern border of the state, is the northern edge of the Borborema, a hilly upland with rounded slopes and steep margins. The Apodi, the Piranhas and the Potengi rivers rise in the Borborema and flow northward across the state.

The first settlement was near Natal in 1599. The Dutch held this region for 25 years in the 17th century. Because of semiarid conditions the land was useful mostly for the grazing of cattle and goats, but from Natal southward some sugar cane mas, and still is grown. Carnauba wax is produced in the western part of the state and cotton is grown in the south. The Borborema is known to contain a number of slightly exploited rare minerals —including beryl, diatomite, columbite and tantalite.

(P. E. J.)

RIO GRANDE DO SUL, the southernmost state of Brazil, is bounded on the north by Santa Catarina state, on the east by the Atlantic ocean, on the south by Uruguay, and on the west by Argentina. The Uruguay river (*q.v.*) forms the boundary on the west. Area 109,066 sq.mi., including inland waters; pop. (1950) 4,164,821.

Physical Geography. — In the north, the state occupies the southern part of the Paranb plateau. This highland which extends from southern São Paulo state to the middle part of Rio Grande do Sul and which crosses the border into Argentina and Paraguay, is made up of a succession of outpourings of dark-coloured basaltic lava now solidified into sheets of rock known as diabase. The surface of the plateau stands between 2.000 and 3,000 ft. above sea level. Along the streams it was dissected into a rolling hilly country, but because of the resistance of the diabase its margins are everywhere marked by steep cliffs or *cuestas*. In Rio Grande do Sul the diabase cliffs cap the southern extremity of the Great Escarpment (the eastern edge of the Brazilian highland) along the Atlantic coast almost as far south as Pdrto Alegre. Just north of this city, however, the diabase cliffs turn westward and form a sharply marked descent facing to the south along the northern side of the Jacui valley. The southern half of Rio Grande do Sul is much lower. The Jacui river drains a lowland along the base of the plateau. floning into the northern end of the Lagda dos Patos near Pôrto Alegre. South of the Jacui there are gently rolling hills, standing only some 1,000 to 1,500 ft. above sea level and extending across the border into Cruguay. West of Livramento the land forms are tabular rather than rounded, for here the diabase continues southward into western Uruguay, but at a much lower elevation than on the Paraná plateau to the north. The Uruguay river cuts through the diabase, its course frequently interrupted by rapids. All along the immediate Atlantic coast there are long sand bars and lagoons, the largest of which are Lagda dos Patos and Lagda Mirim.

Climate.—Rio Grande do Sul is far enough south to experience mild winters, but sometimes with freezing temperatures. At this time of the year cold air masses from the south pass by at frequent intervals, bringing heavy rains along their fronts. Occasionally colder minters bring snow to the higher elevations. In summer, the winds from the northeast prevail and there is less rain. Hot weather prevails, especially inland from the open ocean. Although the whole state has abundant rainfall, the prevailing vegetation cover is that of a tall-grass prairie. Forests occur only along the steep slopes of the Great Escarpment, along the south-facing margin of the Paraná plateau and along the deeper valleys that are cut into the plateau.

The Economy. — There are four chief agricultural regions in Rio Grande do Sul. The first is the oldest—the zone of large cattle and sheep ranches which lies south of the Jacui river and extends almost unbroken to the borders of Uruguay and Argentina. This is the domain of the Gauchos, the herdsmen whose cattle and sheep feed on the unimproved pastures. The beef produced is lean and tough, the kind chiefly required for the manufacture of *xarque* or jerked beef (sometimes called *carne* seca) which is eaten by the poorer Brazilians; it is also the beef most desired by the people of Italy who import it directly from this region. The

second region from south to north is the flood plain of the Jacui river, and of its northern tributary, the Taquari. It supports a dense population of Brazilians of Portuguese descent. The main product is rice. The properties are large, and each owner provides his own irrigation and drainage. The river floods in winter, but there is usually enough moisture left to support the rice crop during the following summer. The better estates are equipped with pumps to raise water from the river during the summer. The Jacui valley produces something like 25% of the Brazilian rice crop, a crop that is consumed partly in PBrto Alegre, but chiefly in the large cities of Rio de Janeiro and São Paulo. The third agricultural region is the zone of the German colonies, located on the terraces above the Jacui valley and on the lower slopes of the Paraná plateau. Maize, rye and wheat are raised here, and maize is fed to hogs. Around Santa Cruz is one of Brazil's chief tobacco-growing areas. The fourth region is higher up on the plateau—the Italian colonies with their vineyards. Each of the four regions is strikingly different not only in agriculture, but also in rural landscape, kinds of roads and buildings, and in traditions of the people.

On the plateau top large tracts of land are still used for pasture, but since 1940 there has been a considerable increase of wheat farming. In the forests of the Uruguay valley there is pine to be cut for timber, and also the leaves of the Yerba Maté which are collected and roasted to prepare the beverage known as maté. or Paraguay tea, widely used through south Brazil and the neighbouring countries.

Coal of an inferior quality is mined at São Jerônimo, just south of the Jacui river a short distance upstream from Pôrto Alegre to which it is shipped by river barge. The coal contains so much sulfur and other impurities that special grates must be used to burn it. In PBrto Alegre, however. the cost of bringing in better coal is so great that the local product is used to manufacture gas and to generate electricity.

The principal industries of the state are concentrated at Pôrto Alegre (*q v.*), the state capital, and the outports Rio Grande and Pelotas (*qq.v.*). Bagé, Santa Maria, Uruguaiana (*qq.v.*) and Livramento are important towns of the interior.

History.— The Rio Grande area, the so-called "Mission" country, was a zone of conflict between the Portuguese and Spanish. The open grasslands were entered both by Portuguese coming from São Paulo and by Spaniards from Buenos Aires, but neither group established settlements excepting for forts at key positions around the edge. Seven Jesuit missions were established, along the Uruguay river between 1632 and 1707 and the scanty Indian population was gathered together around these places. In 1737 the Portuguese established a fort near the present site of Rio Grande, and in 1738 a large extent of territory which included the present states of Santa Catarina and Rio Grande do Sul, and a part of Uruguay was named the captaincy of El Rei, to be administered from Rio Grande. But the Spaniards resented the proximity of Portuguese settlements to what they considered their domain and from 1763 to 1776 they occupied Rio Grande. The Portuguese moved their administration centre to the northern end of Lagôa dos Patos, first to Viamão, then to Porto dos Cazães which aas renamed PBrto Alegre.

When Brazil declared its independence in 1822, its territory extended southward to the shores of the Rio de la Plata. But the Argentines promptly invaded and were in process of pushing the Portuguese back, when, in 1828, Great Britain succeeded in getting the marring countries to agree to the existence of an independent Uruguay. The boundary between Rio Grande do Sul and both Uruguay and Argentina was then fixed. In 1865 a Paraguayan army captured Uruguaiana and held it for a month or so. To this day the Brazilian army spends much of its time training to protect this southern frontier.

In 1822 Emperor Dom Pedro I realized that if this southern territory was to be secured for Brazil colonies should be established there. In 1824 a small group of German peasants and craftsmen was settled at São Leopoldo (*q.v.*), just to the north of PBrto Alegre. By the time of independence all the open grasslands were divided into large private properties for use as cattle and mule ranches. The Portuguese were never attracted by forested country; it was German pioneers who occupied the forests. Between 1824 and 1859 more than 20,000 Germans were settled on small farms along the lower slopes of the plateau to the west of São Leopoldo. They planted rye and potatoes, and grew maize to feed to hogs—an agricultural procedure unknown to the Portuguese. The farm products were sent to PBrto Alegre by boat on the Jacui river. Between 1870 and 1890 a large group of Italian pioneers came to Rio Grande do Sul, and these settled above the German settlements. along the upper slopes of the plateau, especially around the town of Caxias. The Italians introduced vineyards and made wine.

The present progressive economy of the state is due in part to the contribution of these colonists.

Rio Grande do Sul, because of its position on the edge of the Brazilian nation, has often tried to secede. In 1835 a war of secession broke out which lasted for ten years. Rio Grande do Sul was kept a part of Brazil less by military force than by gifts from the federal treasury. Under Dom Pedro II, who ruled Brazil until 1889, even the more remote states were made to feel contented. But in 1892, during the presidency of Floriano Peixoto too much interference with the state government led again to insurrection in the south. The revolutionaries carried the war northward even as far as Curitiba, but were forced to surrender in 1894 because of the lack of munitions. In 1930, the revolt led by Getúlio Vargas against the domination of São Paulo started in Rio Grande do Sul. (P. E. J.)

RIOJA, LA: *see* LA RIOJA.

RIOM, a town of central France, capital of an *arrondissement* in the *département* of Puy-de-Dôme, 8 mi. N. by E. of Clermont-Ferrand by rail. Pop. (1954) 10,571. Riom (*Ricomagus* or *Ricomum* of the Romans) was, along with Auvergne, seized for the crown by Philip Augustus, and was the capital of this province under the dukes of Berry and Bourbon.

Riom stands on the left bank of the Ambène, on a height above the fertile plain of Limagne. The houses, some of the 15th and 16th centuries, being built of black lava, have a sombre appearance.

The church of St. Amable, restored, of Romanesque and early Gothic architecture, dates from the 12th century. The church of Notre-Dame du Marthuret (15th century) has a well-known statue of the Virgin at its western entrance. The Sainte-Chapelle of the 14th and 15th centuries is a relic of the palace of Jean de Berry, duke of Auvergne. The rest of the site of the palace is occupied by the law courts. The 16th-century belfry and a mansion of the same period known as the Maison des Consuls are notable. Riom is the seat of a subprefect and tribunal of commerce.

RÍO NEGRO, a province of Argentina lying within the windswept region generally referred to as Patagonia (*q.v.*). It was created a territory of the republic in 1884 dnd was raised to the status of a province in 1955. It stretches from the Atlantic coast to the Chilean frontier in the Andes. Pop. (1956 est.) 185,304. Area 78.383 sq.mi.

The land between the Colorado and Negro rivers is similar in formation and characteristic to the "dry pampas"; but a great dam was built on the Negro river near Neuquén, making possible the irrigation of a large district and the growing of alfalfa (lucerne) for cattle fodder and the planting of extensive fruit orchards, particularly pears and apples, which have earned fame for the province, The other important occupation is sheep breeding.

South of the Negro river most of the country consists of a series of arid tablelands, but there are several chains of lakes in the forested valleys of the Andes that are held to rival Sniss scenery. The principal lake is Nahuel Huapi, which lies partly in the province of Neuquén (*q.v.*).

The Atlantic coast line has one deep indentation, the Gulf of San Matías, in the northern bend of which is the little port of San Antonio Oeste. The provincial capital is Viedma on the right bank of the Negro river about 20 mi. from its mouth and opposite Carmen de Patagones, a port of the province of Buenos Aires.

There are numerous small settlements along the Negro river valley and on the railway that runs inland from San Antonio Oeste, but the only other town of importance is San Carlos de Bariloche. a holiday resort consisting of hotels and wooden chalets picturesquely situated among trees on the shore of Lake Nahuel Huapi. Bariloche is one of the two terminals of the railway from San Antonio. It can also be reached by road from Buenos Aires (1,200 mi.) and by air. (GE P.)

RÍO NEGRO, a riverside department, established 1880, in west Uruguay. Area 3,655 sqmi, pop. (1954 est.) 57 403 Its rich pastures are used to fatten livestock from northern Uruguay and from Argentine areas across the Uruguay river. The only industrial town is the departmental capital. Fray Bentos (*q.v*), an important meat packing and canning centre. Wheat is the principal farm crop, but sunflower seeds. flax, corn, fruits and vegetables are also grown. (M. I. V.)

RÍO PIEDRAS, a former city, mhich has been incorporated into the sprawling metropolis of San Juan (q *v.*), the capital of Puerto Rico. Pop (1950) 143,989. Rio Piedras is the home of the University of Puerto Rico and its very active commercial life is directed to the servicing of 14,000 university students It is connected with San Juan by modern throughways. and from Rio Piedras highways branch out to the coastal cities of the east and the interior towns of Caguas and-Humacao. (T G Ms.)

RÍO SAN JUAN, a department in southeastern Nicaragua, adjoining Costa Rica Pop (1959 est.) 11,925; area 2 801 sq mi San Carlos, pop. (1959 est.) 1.816, departmental capital and largest town, is at the junction of Lake Sicaragua and Rio San Juan Although San Juan del Norte (*q.v.*) is no longer an ocean port. small steamers use Rio San Juan between Lake Sicaragua and the Caribbean. The people of the department are concentrated mostly between the central highlands and Lake Nicaragua, where they are engaged chiefly in raising livestock and groning corn, rice, beans, cassava, other vegetables and tropical fruits (C. F. J.)

RIOT, in general terms, is a temporary violent outbreak of civil disorder, falling short of an attempt to overthrow the government, and thereby distinguished from insurrection or rebellion. As a legal concept, riot has a more limited meaning, it is a criminal offense against public order involving a group, however small, and the use of violence. honever slight. In some countries, the gravamen of the offense is the breach of peace occasioned by it. That is notably the case in the criminal law of England and of the United States. In other countries, such as those under the continental codes. the offense requires interference with or resistance to public authority.

At common law, there are three offenses which. in ascending order of seriousness, denounce group breaches of the peace. unlawful assembly, rout and riot. An assembly of persons is unlawful if the participants share a common illegal purpose. regardless of whether steps are taken to effect that purpose. Rout is a kind of way station between unlawful assembly and riot: it consists of an unlawful assembly which has taken some step. short of actual violence, to put its illegal purpose into operation.

Rout becomes riot when violence is used. Riot has been judicially stated to consist of the folloning elements: (1) the presence of three or more persons; (2) a common unlawful purpose; (3) the execution or inception of the common purpose; (4) an intent to help one another by force if necessary against any person nho may oppose them in the execution of their unlawful purpose; (5) force or violence not merely used in demolishing. but displayed in such a manner as to alarm at least one person of reasonable firmness and courage.

A person is guilty of riot if he shares the common unlawful purpose of the assembly and has the requisite intent to use force if necessary, regardless of uhether he himself has used force once actual force has been used or threatened by others. The concept is obviously a broad one. capable of embracing a wide range of group conduct from a bloody clash betneen picketers and strikebreakers to the antics of a street-corner gang.

At common law, riot nas an indictable misdemeanour, punishable by fine and imprisonment. In England the Riot act of 1714 made it a felony under certain circumstances of aggravation. The act was passed in response to the widespread rioting which attended the accession to the throne in that year of the first Hanoverian king, George I. Under its provisions, as subsequently modified. whenever an unlawful assembly of twelve or more persons (as contrasted with the three or more required for the common-law misdemeanour) fail to disperse within an hour after a magistrate has read or tried to read a proclamation. couched in language prescribed by the statute, directing them to disperse, those present cease to be merely misdemeanants and become guilty of a felony, punishable by life imprisonment. The procedure of reading the proclamation came to be known. inaccurately but inevitably, as "reading the riot act," a phrase nhich has enriched the language in situations far removed from its original meaning. An oddity of the law is that the proclamation must be read verbatim in the prescribed language; otherwise the prosecution fails. A conviction was quashed on this ground in 1830 because the proclamation omitted the concluding words "God save the King."

In spite of the severe penalties prescribed by the Riot act, there are several well-known instances of riots in England subsequent to 1714, including the Gordon anti-Catholic riots of 1780, the Bristol riots of 1831 and the Chartist riots of 1839.

Other provisions of English criminal law impose punishment for various harms to property committed in the course of a riotous assembly and prescribe various rights and duties arising out of the occurrence of a riot. For instance, the law imposes on magistrates the duty of assembling subjects of the realm, whether civil or military, for the purpose of quelling the riot. It is the magistrate's duty to keep the peace; if the peace is broken, honesty of intention will not avail him if he has been guilty of neglect of duty. A somewhat unsettled question is the extent of the protection afforded at common law and by the Riot act to persons acting under orders for the suppression of riots. Although, as just stated. the law of England requires everyone to aid the magistrates in the suppression of riotous assemblages, the degree of force which may be used in effecting that end depends on the nature of the riot. The use of deadly force can only be justified nhere lesser measures are inadequate to prevent the commission of violent felonies. These rather vague rules apply to soldiers and civilians alike. A matter of some importance is the availability of a civil remedy for persons whose property has been damaged by riot. Under the Riot Damage act of 1886. compensation is payable out of the taxes levied for police maintenance in the district where the riot occurred. Thus a form of public liability for riot damage is provided.

In the United States, lans relating to riot have in general followed the common-law view. at least to the extent of focusing upon the disturbance of the peace rather than the resistance to public authority as the gravamen of the offense The major difference between English and U.S. law is that the typical U.S. provision on this subject imposes comparatively mild penalties.

The old common-law distinctions among unlawful assembly, rout and riot are preserved in the laws of some states. Others have created a consolidated offense. Aggravated penalties are commonly provided for failing to disperse after having been called upon by a public authority to do so; but the formal requirements of the English Riot act are not often imposed. Inciting to riot is in some states made a separately punishable offense. Some states have adopted the English view that reparation should be made out of public funds to persons whose property has been damaged or destroyed in a riot.

Canadian law is based on the common-law concepts but departs from them in several important respects. An assembly of three or more persons is unlawful not if it has an unlawful purpose but if it causes persons in the vicinity to fear that the assembly will disturb the peace tumultuously or cause others to do so. A riot is an unlawful assembly which has begun to disturb the peace tumultuously. There is no statutory offense of rout. Provision is made for reading a proclamation directing the rioters to disperse and severe penalties are provided for interfering with its reading or failing to obey its injunction to disperse.

All legal systems make some provision for dealing with con-

duct analogous to that covered by the Anglo-American law of riot but the formal definitions vary, as the following examples will illustrate.

Under German law. there are two separately defined offenses which are analogous to the Anglo-American concept of riot. Riot itself (*Aufruhr*) is an offense against public authority. It consists of taking part in a public riotous gathering in the course of which an official engaged in the exercise of his duties is resisted or assaulted, or in the course of which an official is subjected to force or threats to compel the commission or omission of an official act. The penalty is aggravated if the accused actually performed one of the enumerated overt acts or was a ringleader (*Rädelsführer*). Breach of the public peace (*Landfriedensbruch*) consists of several persons publicly banding together and committing jointly act of violence against persons or property. Aggravated penalties are provided. as in the case of *Aufruhr,* for ringleaders and those who have committed overt acts. In general, the penalties for *Aufruhr* are more severe than those for *Landfriedensbruch.*

French law does not separately define riot but treats it as a special case of resistance to public authority under the general heading of *rebellion,* the punishment for which varies in seriousness depending upon the number of persons involved and whether or not they are armed. The breach of peace aspect of the offense. which is centra! to the Anglo-American concept of riot, is not treated as a group offense in French law. (H. L. PR.)

RIOT AND CIVIL COMMOTION INSURANCE. These policies cover all that is provided for by explosion insurance and in addition protect against losses due to riot. insurrection, civil commotion and strike. The rates are comparatively low, but in the case of strike, for example, they are substantially increased if the policy is taken out after the strike has been declared.

RÍOTINTO (MINAS DE RÍOTINTO), a mining town of southwestern Spain, in the province of Huelva; near the source of the Tinto river, and at the terminus of a light railway from the port of Huelva. Pop. (1950) mun.. 7,323.

Ríotinto is one of the greatest copper-mining centres of the world. Its modern importance dates from 1872. when a syndicate of London and Bremen capitalists purchased the mines from Spain.

RIOUW ARCHIPELAGO, five groups of islands oif the east coast of Sumatra. Indon.. extending from the Stra ts of Singapore in the north to the Straits of Berhala in the south. They comprise the Karimon group. the Batam group, the Bintang group, the Lingga group and the Singkep group, with territory on the mainland opposite known as Indragiri. Collectively they formerly comprised a residency of the Netherlands Indies; total area 12,235 sq.mi. and pop. (1930) 298.225. The islands vary in height and area, from rocky crags and small coral reefs, to Bintang, or Riouw, the largest island. area 4i5 sq.mi., with a height of 1,673 ft.; Lingga and Singkep are almost as large, and the former attains a height of 3.816 ft. and has the largest alluvial plain of the archipeiago. Coral reefs and currents make navigation difficult.

The people of the islands are Malays. Buginese and Chinese. with a few aboriginals known as Benua. The chief products of the islands are gambir, rubber. pepper and rice. There are large deposits of bauxite, of which those on Bintang were mined after 1935.

RIPLEY, a market town and urban district in the Ilkeston parliamentary division of Derbyshire, Eng.. 11 mi. N.N.E. of Derby by road. Pop. (1951) 18,192. Area 8.5 sq.mi. The charter for the market, held on Saturdays. was granted by Henry III. Heavy engineering, iron founding and coal mining are the principal industries The urban district of Heage was transferred to Ripley in 1934.

Ripley. Surrey. is a small town 5½ mi. N.E. of Guildford. Nearby are the Royal Horticultural society's gardens at Wisley.

RIPON, GEORGE FREDERICK SAMUEL ROBINSON, 1ST MARQUESS OF (1827–1909), British statesman, only son of the 1st earl of Ripon and his wife Lady Sarah, daughter of Robert Hobart. 4th earl of Buckinghamshire. was born in London on Sept. 24, 182;. Ripon began his political life as attaché to a special mission to Brussels in 1849. Cnder his courtesy title of Viscount Goderich he was returned to the house of commons for Hull in 1852 as an advanced Liberal. In 1853 he was elected for Huddersfield, and in 1857 for the West Riding of Yorkshire. In Jan. 1859 he succeeded to his father's title, and in November of the same year to that of his uncle, Earl de Grey. A few months after entering the upper house he was appointed undersecretary for war. and in Feb. 1861 undersecretary for India. Upon the death of Sir George Cornewall Lewis in April 1863 he became secretary for war, with a seat in the cabinet. In 1866 he was appointed secretary of state for India. On the formation of the Gladstone administration in Dec. 1868, Lord Ripon was appointed lord president of the council, and held that office until within a few months of the fall of the government in 1873, when he resigned on purely private grounds.

In 1871 Lord Ripon was appointed chairman of the High Joint-Commission on the Alabama claims, which arranged the treaty of Washington. In recognition of his services he was elevated to a marquessate (1871). In 1874 he became a convert to Roman Catholicism.

On the return of Gladstone to power in 1880 Lord Ripon was appointed viceroy of India, the appointment exciting a storm of controversy, the marquess being the first Roman Catholic to hold the vice-regal office. He went out to reverse the Afghan policy of Lord Lytton, and Kandahar was given up, the whole of Afghanistan being secured to Abdur Rahman. The new viceroy extended the rights of the natives, and in certain directions curtailed the privileges of Europeans. For the Ilbert bill of 1883—so named after its author Sir Courtenay Ilbert—see INDIA: History.

In 1886 he became first lord of the admiralty in the third Gladstone ministry; and on the return of the Liberals to power in 1892 he was appointed colonial secretary, which post he continued to hold until the resignation of the government in 1895. He was included in Sir Henry Campbell-Bannerman's cabinet at the close of 1905 as lord privy seal, an office which he retained in 1908 when Asquith formed his new ministry, but which he resigned later in the same year. He died at his seat, Studley Royal, near Ripon, on July 9, 1909, when his only son. Earl de Grey, treasurer of the queen's household since 1901, became the 2nd marquess.

RIPON, a cathedral city and municipal borough in the Ripon parliamentary division of the West Riding of Yorkshire, Eng., 24 mi N.W. of York and 27 mi. N. of Leeds by road. Pop. (1951) 9,480. Area 2.8 sq.mi. It lies at the foot of Wensleydale at the confluence of the Ure and its tributaries the Laver and the Skell. The Saxon village of Ripon first comes into history in the pages of Bede who describes how Abbot Eata of Melrose founded a Celtic monastery there *c.* 651. About ten years later Wilfrid founded a Benedictine monastery and became its abbot. Soon after this he was made bishop of York and became one of the leading figures in the English church. At Ripon he built a famous church, whose crypt may still be seen under the present cathedral. Wilfrid's church and monastery mere both destroyed by the Danes in the 9th century, and the monastery was never rebuilt. According to a local tradition of not very ancient date, Ripon received a charter from Alfred the Great in 886 By the time of the Norman Conquest, Ripon minster was a collegiate church with secular clergy. The archbishops of York owned large properties in the neighbourhood ("the Liberty of Ripon") and had an episcopal palace which stood on the site of the present courthouse, on the north side of the cathedral. In 1132 Archbishop Thurstan gave land in Skelldale to a band of monks from St. Mary's abbey, and escorted them from Ripon to the place where the ruins of Fountains abbey stand, 3 mi. W.

The greatest attraction for the modern visitor to Ripon is its lovely cathedral. Apart from the Saxon crypt the oldest parts are the chapter house and the Norman undercroft, the architecture of the present building belongs mainly to the Norman Transitional and Perpendicular periods. The nave (without aisles) north transept and part of the choir were built by Archbishop Roger in 1154, while the side aisles were added about 1500 when the central toner and south transept were rebuilt The central tower is of special interest because it has two round and tmo pointed arches, indicating that the Perpendicular work was left unfinished. The

twin towers of the west front are Early English (about 1216), and the Lady loft (now the library) dates from the 14th century. The chancel contains misericords, carved by the Ripon woodcarvers between 1489 and 1494, and also some fine canopies. The cathedral library, collected since c. 1608, has some exceptionally rare books and manuscripts. The 12th-century Leper chapel, within a few minutes' walk of the cathedral, contains a pre-Reformation stone altar.

Ripon has a large and beautiful market square, surrounded by a variety of houses, shops and inns of different dates. One of these buildings is a 15th-century house where Hugh Ripley, the last wakeman and the first mayor of Ripon, once lived. The name of the chief official was changed from wakeman to mayor in 1604 when James I gave the town a charter of incorporation. Another building in the square is the town hall (1798) on which these words are inscribed: "Except the Lord keep the City the Wakeman waketh but in vain." The ritual of the hornblowing, dating from before the Conquest, is of great interest. Every evening at nine o'clock curfew is rung on the cathedral bells, and the horn is blown at each corner of the market place and also outside the mayor's house. Originally this was a sign that the watch had been set and the citizens could sleep in peace. The original 9th-century Saxon horn may still be seen at the town hall.

The diocese of Ripon was re-established in 1836 by the division into two parts of the ancient diocese of York. The dioceses of Wakefield and Bradford have since been carved out of Ripon, which non includes Leeds and the country north as far as the Tees. A church training college for women teachers was founded in 1863.

Outside the town of Ripon is a race course which holds several meetings a year. (A. M. W.)

RIPPLE MARKS. The alternating parallel ridges and troughs formed on the surface of sand by waves and currents of water or air are known as ripple marks. Granular materials of little cohesion are essential for the formation of ripple marks by water waves and currents; they may be made by wind on dust as well as on sand.

Under some conditions ripple marks may be made on deposits of small pebbles.

Wave-formed or oscillation ripple marks have sharp. symmetrically sloped crests and rounded troughs. Current-formed ripple marks have rounded, asymmetrically sloped crests and troughs, the upcurrent slope being the longer and more gently inclined. Ripple marks are readily preserved when the sediments on which they are formed are transformed into rocks. Fossilized current ripple marks show the directions of the forming currents.

Although most water ripple marks are formed in relatively shallow water, they may be formed at any depth at which wave and currents are able to move sand. Wave ripple marks have been reported in the Indian ocean at a depth of 617 ft., and current ripple marks may form at depths exceeding 2,000 ft.

Since deposits made over wave ripple marks have corresponding crests and troughs on their undersurfaces. and since these are readily distinguishable from the originals, a valuable method of determining bottoms and tops of overturned strata is provided. Current ripple marks are not of great value in such investigations.

See also WAVES AND SHORE CURRENTS.

RISDON: see HOBART.

RISHANGER, WILLIAM (c. 12jo–c. 1312), English chronicler, made his profession as a Benedictine at St. Xlban's abbey in 1271, of which he perhaps became the official chronicler. The most important of his writings is the *Narratio* de *bellis apud* Lewes et *Evesham.* Though written many years afterward and drawn from other sources, it is a spirited account of the barons' war. He is so great an admirer of Simon de Montfort that this work has been called a hagiography.

Rishanger is credited with the authorship of a chronicle covering the period 1259–1306; this has been disputed, but the work is printed under his name by Riley.

RISK is present in a situation if the result or outcome of a choice, a decision or an action cannot be anticipated with certainty. For instance, the outcome of a throw of a die or of the drawing of a card cannot be anticipated with certainty and it may be said, therefore, that risk is present. Games of chance, in fact, provide us with the best examples of situations involving risk. In such games, since no single outcome is expected with certainty, we may list all the possible outcomes and then associate with each a number between o and 1 in such a manner that the sum of these numbers equals 1. These numbers are known as the probabilities associated with the various possible outcomes. For instance, in a game with two "unbiased" dice the probability that the sum of points in a single throw will be 2 is 1/36, whereas the probability that it will be 7 is 6/36 or 1/6. This is so because of the 36 possible outcomes there is only 1 for which the sum of points is 2 and there are 6 for which the sum of points is 7.

In general, the probability of any type of outcome is equal to the ratio of the number of outcomes of that type to the total number of possible outcomes.

In the light of these remarks it should be clear that to each choice, decision or action can be assigned a probability distribution of outcomes. In the special case where a probability of 1 is assigned to some one outcome risk is absent (certainty is present). In all other cases risk is present.

When we leave games of chance and attempt to deal with the multitude of decisions made every day which are shrouded in uncertainty, the question of applicability of these notions may be raised. Business decisions, military decisions, political decisions, scientific decisions—they all seem to involve uncertainty in some sense. Can we talk in terms of probability distributions of outcomes of business decisions? How are these probabilities to be calculated? In the case of the dice game these probabilities were known to us by reason of the fact that the dice were characterized as "unbiased." Somehow they were given objectively—they did not depend on the judgment of the players. More often than not in the world of decisions the term "probability." if it is to be used at all, must be given a subjective meaning—namely it must be thought of as an expression of the "degree of belief" in the mind of the decision maker.

We distinguish, therefore, between objective and subjective probabilities. The connection between the two involves a number of subtle and not completely resolved issues which will not be explored here. (See also PROBABILITY.)

We shall assume in what follows that each decision maker is in a position to assign a (subjective) probability distribution of outcomes to each decision or course of action he may choose to make or follow. Under these circumstances (and on the assumption that the probability of no outcome is equal to 1) we shall say that he is making a decision or taking an action involving risk. The term "uncertainty" should be reserved for describing situations in which the decision maker is unwilling to assign probability distributions of outcomes to the various contemplated alternative actions. If, for instance, we are unwilling to state the odds at which we would accept a bet (say, a bet that a major war will break out next year), then the situation involves uncertainty; if, in contrast, we are willing to state the odds, then the situation involves risk. This discussion is limited to situations involving risk.

Suppose that one is asked to play the following game. A coin will be tossed. If heads come up, one wins $5; if tails come up, one loses $2. Let us assume that one attaches a subjective probability of .4 to the outcome "heads." Should one play the game? The answer seems to be in the affirmative becausr the expected value of the game is positive. The expected value of a game (a lottery ticket or a decision) may be calculated as follows: Multiply the probability of each outcome by the payoff associated with the outcome and then add up the products. In this case we have $(.4 \times \$5) + (.6 \times -\$2) = \$.8$ or 80 cents. The game is "biased" in our favour and it seems, therefore, that we should accept the bet. Would we be ready to say. however, that refusing the bet is an indication of irrationality? What if one could not afford to lose $2? It is well known that people gamble when the odds are not fair—that they play games whose expected value is nega-

tive. Also, it is suspected that people refuse to engage in business ventures whose expected value (given the subjective probabilities of the persons in question) are positive. Are these people acting irrationally? Recognition of the fact that such actions need not be irrational has led to the formulation of the concept of utility—and the associated rule that people should make decisions in such a fashion as to maximize expected utility.

An example might help introduce the notion of expected utility. Suppose, for instance, that one has $2 in his pocket and that he assigns a utility of −10 to its loss. Now, if one assigns a utility of less than 15 to the gain of $5, it will not pay him to engage in the coin-tossing game described above. Whereas the expected value of the game is positive (it is exactly 80 cents), the expected utility of the game—if, say, the utility associated with winning $5 is equal to 15—will be zero. Expected utility: $(.4\times 15)+(.6\times -10)=0$. If one assigns to $5 a utility of less than 15, the expected utility will be negative. Whether one plays the game or not, therefore, depends on the relative valuations one places on the outcomes—as well as on the subjective probabilities one assigns to them.

The schema can easily be extended to a wide variety of situations. For instance, a business firm contemplating alternative investments (say types of expansion of plant capacity) could associate with each one of these investments, A, B, C, ... an expected utility—the expected utility for each one to be calculated by taking the sum of the products of the probability of the various possible outcomes (associated with that investment) multiplied by the utility of these outcomes. If we denote by $\bar{U}_A, \bar{U}_B, \bar{U}_C, \ldots$, the expected utility associated with investment decisions A, B, C, . . . , then clearly the firm will make that investment decision which yields the highest expected utility. $\bar{U}$. In the special case where the utility of an outcome equals the profit associated with that outcome, the firm will make that investment decision which maximizes expected profit.

The objection might be raised at this point that the assignment of utilities to outcomes was completely arbitrary. Interestingly enough it has been shown that. if a person is in a position to order (in terms of his preferences) probability distributions of outcomes in a complete and consistent manner. a utility function can be constructed which fully accounts for his choice behaviour. The utility "numbers" will be arbitrary only insofar as the origin and the unit of measurement are concerned—but the ratios of differences of utilities will be preserved no matter how we choose the origin and the unit of measurement.

It should be stressed. perhaps, that the concept of maximization of expected utility is normative rather than descriptive. Fundamentally it involves a statement of how a rational man should behave rather than how he does behave. Such a descriptive theory of human behaviour under risk was not available in the mid-20th century.

(A. G. PU.)

RISTIĆ, JOVAN (1831–1899), Serbian statesman, was born at Kragugevaz in 1831. He was educated at Belgrade, Heidelberg, Berlin and Paris. In 1861 he became Serbian diplomatic agent at Constantinople, and secured the withdrawal of the Turkish troops from the Serbian fortresses in 1867. On his return from Constantinople he became the recognized leader of the Liberal party. After the assassination of Prince Michael in 1868. he sat on the council of regency* and the first Serbian constitution (Jan. 2, 1869) was mainly his creation. When Prince Milan attained his majority in 1872, Ristić became foreign minister and then prime minister, but resigned in the following autumn (1873). He again became prime minister in April 1876, and conducted the two wars against Turkey (July 1876–March 1877 and Dec. 1877–March 1878). Because of the failure to realize Serb aspirations at the congress of Berlin, the Ristić government became unpopular, and resigned in 1880, In 1887 Milan recalled Ristić; a new constitution was granted in 1888, and in 1889 Ristić became head of the council of regency for the young king Alexander. On April 13, 1893, King Alexander, by a successful stratagem, imprisoned the regents and ministers in the palace, and, declaring himself of age, recalled the Radicals to office. Ristić died at Belgrade on Sept. 4. 1899.

RISTORI, ADELAIDE (1822–1906), Italian actress, born at Cividale del Friuli, Jan. 30, 1822, daughter of strolling players. As a child she appeared upon the stage. and at 14 made her first success as Francesca da Rimini in Silvio Pellico's tragedy. She was 18 when for the first time she played Mary Stuart in an Italian version of Schiller's play. She had been a member of the Sardinian company and also of the ducal company at Parma for several years before her marriage (1846) to the marchese Giuliano Capranica del Grillo (d. 1861); and after a short retirement she returned to the stage and played regularly in Turin and the provinces. In 1855 she took Paris by storm in the role of Alfieri's *Myrrha.* Furious partisanship was aroused by the appearance of a rival to the great Rachel. In 1857 she visited Madrid, playing in Spanish to enthusiastic audiences, and in 1866 she paid the first of four visits to the United States: where she had great success in Giacometti's *Elizabeth,* an Italian study of the English sovereign. She retired from professional life in 1885, and died on Oct. 9, 1906, in Rome. Her *Studies and Memoirs* (1888) contains valuable psychological explanations and interpretations of the characters of Mary Stuart, Elizabeth! Myrrha, Phaedra and Lady Macbeth.

RITCHIE, CHARLES THOMSON RITCHIE, 1ST BARON (1838–1906), English politician, was born at Dundee on Nov. 19, 1838. and educated at the City of London school. He went into business. and in 1874 was returned to parliament as Conservative member for the working-class constituency of Tower Hamlets. In 1885 he was made secretary to the admiralty and from 1886 to 1892 president of the local government board in Lord Salisbury's administration. with a seat in the cabinet after 1887, sitting as member for St. George's-in-the-East. He was responsible for the Local Government act of 1888. instituting the county councils; and a large section of the Conservative party always owed him a grudge for having originated the London County council. In Lord Salisbury's later ministries. as member for Croydon. he was president of the board of trade (1895–1900) and home secretary (1895–1900); and when Sir Michael Hicks-Beach retired in 1902, he became chancellor of the exchequer in Balfour's cabinet. Though in his earlier years he had been a "fair-trader." he was strongly opposed to Chamberlain's movement for a preferential tariff (*see* BALFOUR, ARTHCR JAMES BALFOUR; CHAMBERLAIN, JOSEPH), and he resigned office in Sept. 1903. In Dec. 1905 he was created a peer. He died at Biarritz on Jan. 9, 1906.

RITSCHL, ALBRECHT (1822–1889), German theologian, was born in Berlin on March 25, 1822. His father. Benjamin Ritschl (1783–1858), was from 1827 to 1854 general superintendent and evangelical bishop of Pomerania. Albrecht studied at Bonn, Halle, Heidelberg and Tiibingen. At Halle he came under Hegelian influences. In 1845 he was entirely captivated by the Tiibingen school, and in *Das Evangelium Marcions und das kanonische Evangelium des Lukas* (1846) he appears as a disciple of F. C. Baur. But the second edition (1857) of his most important work, on the origin of the Old Catholic Church *(Die Entsfehung der alt-kathol. Kirche),* shows considerable divergence from the first edition (1850), and reveals an entire emancipation from Baur's method. Ritschl was professor of theology at Bonn (extraordinarius. 1852; ordinarius, 1859) and Gottingen (1864; *Consistorialrath* also in 1874). his addresses on religion delivered at the latter university showing the impression made upon his mind by his study of Kant and Schleiermacher. Finally, in 1864. came the influence of Rudolf Lotze. He wrote *Die Christliche Lehre von der Rechtfertigung und Versöhnung* (1870–74) and *Die Geschiclzte des Pietismus* (1880–86). He died at Gottingen on March 20, 1889.

Ritschl claims to carry on the work of Luther and Schleiermacher. He criticizes especially the use of Aristotelianism and speculative philosophy in scholastic and Protestant theology. He holds that such philosophy is too shallow for theology. Hegelianism attempts to squeeze all life into the categories of logic; Aristotelianism deals with "things in general" and ignores the radical distinction between nature and spirit. Neither Hegelianism nor Aristotelianism is "vital" enough to sound the depths of religious life. Neither conceives "God" as correlative to human "trust" (cf. *Theologie und Metaphysik,* esp. p. 8 ff.). But Ritschl's recoil carries him so far that he is left alone with merely "practical" experience. "Faith" knows God in His active relation to the "kingdom." but not at all as "self-existent."

Ritschl's school, in which J. G. W. Herrmann, Julius Kaftan and Adolf Harnack were the chief names. diverged from his teaching in many directions; *e.g.,* Kaftan appreciated the mystical side of religion and Harnack's criticism was very different from Ritschl's arbitrary exegesis. They were united on the value of faith-knowledge as opposed to "metaphysic."

See H. Schoen, *Lcs Origines historiques de la théologie de Ritschl* (1893); G. Ecke, *Die theologische Schule, A. Ritschl's und die evangelische Kirche der Gegenwart* (1897); J. Orr, *The Ritschlian Theology and the Evangelical Faith* (1898), *Ritschlianism: Expositary and Critical Essays* (1903); A. E. Gavire, *The Ritschlian Theology* (1899); E. A. Edghill, *Faith and Fact, a Study of Ritschlianism* (1910); R. Mackintosh, *Ritschl* (1915). The chief authority for his biography is *Albrecht Ritschls Leben,* 2 vol. (Leipzig, 1896), by his son Otto Ritschl.

RITSCHL, FRIEDRICH WILHELM (1806–1876), German scholar who was best known as a student of Plautus, was born in 1806 in Thuringia. He was well taught in youth by Spitzner, a pupil of Gottfried Hermann, spent a year at Leipzig, and in 1826 went to Halle. He went to Bonn in 1839, where he controlled a philological seminary. The names of Georg Curtius, Ihne. Schleicher, Bernays. Ribbeck, Lorenz, Vahlen. Hiibner. Biicheler. Helbig, Benndorf, Riese. Windisch, who were his pupils either at Bonn or at Leipzig. attest his fame and power as a teacher. In 186j a violent quarrel arose between him and Otto Jahn. then his colleague; he resigned, went to Leipzig, and died there in 1876. His great faculty for organization is shown by his administration of the university library at Bonn, and by the eight years of labour which carried to success a work of infinite complexity. the famous *Priscae Latinitatis Monumenta Epigraphica* (Bonn: 1862). This volume presents in admirable facsimile. with prefatory notices and indexes, the Latin inscriptions from the earliest times to the end of the republic.

Ritschl's examination of the Plautine manuscripts was both laborious and brilliant, and greatly extended the knowledge of Plautus: for example, by the aid of the Xmbrosian palimpsest he recovered the name T. Maccius Plautus, for the vulgate M. Accius. and proved it correct by strong extraneous arguments.

In spite of the incompleteness, on many sides, of his work, Ritschl must be assigned a place in the history of learning among a very select few. His studies are presented principally in his *Opuscula* collected partly before and partly after his death. The *Trinummus* (twice edited) was the only specimen of his contemplated edition of Plautus which he completed.

The facts of Ritschl's life may be best learned from the elaborate biography by Otto Ribbeck (Leipzig, 1879). An interesting estimate of Ritschl's work is that by Lucian Miiller (1877).

RITTENHOUSE, DAVID (1732–1796), U.S. astronomer, who introduced in 1786 the use of spider lines in the focus of a transit instrument. He was born at Germantown, Pa.. on April 8, 1732. First a watchmaker and mechanician, he afterward was treasurer of Pennsylvania (1777–89), and from 1792 to 1795 director of the U.S. mint (Philadelphia).

He was a fellow of the Royal Society of London, and a member, and in 1791 president, of the American Philosophical society. His researches were published in the *Transactions of the American Philosophical Society* (1785–99). He died at Philadelphia on June 26, 1796.

RITTER, HEINRICH (1791–1869), German historian of philosophy, was born at Zerbst on Nov. 21, 1791, and died on Feb. 3, 1869, at Gottingen, where he had been professor of philosophy for nearly 30 years. Of his numerous works the most important are the *Geschichte der Philosophie* (12 vol., Hamburg, 1829–53), and, written with Preller, the *Historia philosophiae Graeco-Romanae* (1838; 7th ed.. 1888).

RITTER, KARL (1779–1859), German geographer, born at Quedlinburg on Aug. 7, 1779, is considered a founder of modern geography. His father, a physician, left his family in straitened circumstances, and Karl was received into the Schnepfenthal institution then just founded by Christian G. Salzmann (1744–1811) for the purpose of testing his educational theories. The Salzmann system was practically that of Rousseau; conformity to natural law and enlightenment were its watchwords; great attention was given to practical life, and the modern languages were carefully taught, to the complete exclusion of Latin and Greek. Ritter showed geographical aptitude at an early age, and when his school days were drawing to a close his future course was determined by an introduction to Bethmann Hollweg, a banker in Frankfurt. It was arranged that Ritter should become tutor to Hollweg's children, but that in the meantime he should attend the university at his patron's expense. His duties as tutor in the Hollweg family began at Frankfurt in 1798 and continued for 1 j years. The years 1814–19, which he spent at Gottingen in order to continue to watch over the welfare of his pupils, were those in which he began to devote himself exclusively to geographical inquiries. He had already traveled much when in 1817–18 he brought out his masterpiece *Die Erdkunde im Verhältnis zur Natur und zur Geschichte des Menschen* (Berlin, 2 vol., 1817–18). In 1819 he became professor of history at Frankfurt, and in 1820 professor extraordinarius of history at Berlin, where he remained till his death. The second edition of his *Erdkunde* (1822–58) was on a much larger scale than the first, but he completed only the sections on Africa and the various countries of Asia.

The service rendered to geography by Ritter was especially notable because he brought to his work a new conception of the subject. Geography was, to use his own expression, a kind of physiology and comparative anatomy of the earth: rivers, mountains, glaciers, etc., were so many distinct organs. each with its own appropriate functions; and, as his physical frame is the basis of the man, determinative to a large extent of his life. so the structure of each country is a leading element in the historic progress of the nation. Ritter, moreover, was a scientific compiler of the first rank.

Ritter died in Berlin on Sept. 28, 1859. After his death selections from his lectures were published under the titles *Geschichte der Erdkunde* (1861), *Allgemeine Erdkunde* (1862) and *Europa* (1863). Several of his works, for example the "Palestine" volumes of his *Erdkunde,* were translated into English.

(For a summary and comparison of the contributions to modern geography of Ritter and his contemporary Alexander von Humboldt, *see* GEOGRAPHY.)

BIBLIOGRAPHY.—G. Kramer, *Karl Ritter, ein Lebensbild* (Halle, *1864,* 1870; 2nd ed., 1875); W. L. Gage. *The Life of Karl Ritter* (1867); *F.* Marthe, "Was bedeutet Karl Ritter für die Geographie," *Zeitsch. der Ges. f. Erdk.* (Berlin, 1879).

RITUAL, a term of religion, which may be defined as the routine of worship. This is a "minimum definition"; "ritual" at least means so much, but may stand for more. Without some sort of ritual there could be no organized method in religious worship. Indeed, viewed in this aspect, ritual is to religion what habit is to life and its function is similar; namely, by bringing subordinate functions under an effortless rule, to permit undivided attention in regard to vital issues. The chief task of routine in religion is to organize the activities necessary to its stability and continuance as a social institution, in order that all available spontaneity and initiative may be directed into spiritual channels.

But, while ritual at least represents routine, it tends, historically speaking, to have a far deeper significance for the religious consciousness. A recurrent feature of religion, which many students of its phenomena would even consider constant and typical,

is the attribution of a more or less self-contained and automatic efficacy to the ritual procedure as such. Before proceeding to considerations of genesis, it will be convenient briefly to analyze the notion as it appears in the higher religions.

Two constituent lines of thought may be distinguished. Firstly, there is the tendency to pass beyond the purely petitionary attitude which as such can imply no more than the desire, hope or expectation of divine favour, and to take for granted the consummation sought, a deity that answers. a grace and blessing that are communicated. When such accomplishment of its end is assumed, efficacy can readily be held to attach to the act of worship as such. Secondly, there is the tendency to identify such a self-accomplishing act of worship aith its objective expression in the ritual that for purposes of mutual understanding makes the body of worshippers one.

The Formal Element in Ritual.—Exactly similar tendencies—to impute efficacy and to treat the ritual procedure as the source of that efficacy—are typically characteristic of black magic, and their reappearance in religion can hardly be treated as a coincidence, seeing that magic and religion would appear to have much in common, at any rate during the earlier stages of their development. In magic a suggestion is made orally, or by dramatic action, or most often in both ways together, that is held ipso facto to bring about its own accomplishment. A certain conditionality attaches to the magical operation, inasmuch as each magician is subject to interference on the part of other magicians who may neutralize his spell by a counterspell of equal or greater power; nevertheless, the intrinsic tone is that of a categorical assertion of binding force and efficacy. Again, in magic the self-realizing force is apt to seem to reside in the suggestional machinery rather than in the spiritual qualifications of the magician, though this is by no means invariably the case. On the whole, however, spells and ceremonies are wont to be regarded as an inheritable and transferable property containing efficacy in themselves. What is true of magic is true of much primitive religion.

Sir J. G. Frazer has pronounced the following to be marks of a primitive ritual: negatively, that there are no priests, no temples and no gods (though he holds that departmental, nonindividual "spirits" are recognized); positively, that the rites are magical rather than propitiatory (The Golden *Bough,* 2nd ed., ii. 191). If we leave it an open question whether, instead of "spirits," it would not be safer to speak of "powers" to nhich there is attributed not a soullike nature, but simply a capacity for acting with mana (*q.v.*) (which roughly is what Frazer means by "magical"), this characterization may be accepted as applying to many, if not to all, the rites of primitive religion.

As A. Lang well puts it, "Ritual is preserved because it preserves luck." Given an intrinsic sacredness, it is but a step to associate definite gods with the origin or purpose of a rite, whose interest it thereupon becomes to punish omissions or innovations by the removal of their blessing (which is little more than to say that the rite loses its efficacy), or by the active infliction of disaster on the community. In the primitive society it is hard to point to any custom to which sacredness does not in some degree attach, but, naturally, the more important and solemn the usage, the more rigid the religious conservatism. Thus there are indications that in Australia, at the highly sacred ceremony of circumcision, the fire stick was employed after stone implements were known; and we have an exact parallel at a higher level of culture, the stone implement serving for the same operation when iron is already in common use. (See B. Spencer and F. Gillen, *The Native* Tribes of Australia, 401; *cf.* E. B. Tylor, Early History *of Man*kind, 3rd ed.. 217.)

The Interpretation of Ritual.—A valuable truth insisted on by W. Robertson Smith (Religion of *the* Semites, 17 ff.) is that in primitive religion it is ritual that generates and sustains myth, and not the other way about. Sacred lore of course cannot be dispensed with; even Australian aboriginal society, which has hardly reached the stage of having priests, needs its *Oknirabata* or "great instructor" (Spencer and Gillen, ibid., 303). The function of such an expert, however, is chiefly to hand on mere rules for the performance of religious acts. If his lore includes sacred histories, it is largely, we may suspect, because the description and dramatization of the doings of divine persons enter into ritual as a means of suggestional control. Similarly, the sacred books of the religions of middle grade teem with minute prescriptions as to ritual but are almost destitute of doctrine. Even in the highest religions, where orthodoxy is the main requirement and ritual is held merely to symbolize dogma, there is a remarkable rigidity about the dogma that is doubtless in large part due to its association with ritual forms, many of them bearing the most primeval stamp.

As regards the symbolic interpretation of ritual, this is usually held not to be primitive; and it is doubtless true that an unreflective age is hardly aware of the difference between "outward sign" and "inward meaning," and thinks as it were by means of its eyes. Nevertheless. it is easier to define fetishism (*q.v.*) (a fetish "differing from an idol in that it is worshipped in its own character, not as the symbol, image or occasional residence of a deity," New Oxford Dictionary, Oxford, 1901) than it is to bring such a fetishism home to any primitive people, the west African Negroes not excluded (cj. A. B. Ellis, The Tshi-speaking Peoples of *the* Gold Coast *of* W. *Africa,* 192). It is the intrinsic mana, virtue or grace residing in, and proceeding from, the material object—a power the communicability of which constitutes the whole working hypothesis of the magico-religious performance—that is valued in those cases where native opinion can be tested. Moreover. it must be remembered that in the act of magic a symbolic method is consciously pursued, as witness the very formulas employed: "As I burn this image, so may the man be consumed," or the even more explicit, "It is not wax I am scorching; it is the liver, heart and spleen of So-and-so that I scorch" (W. W. Skeat, *Malay Magic,* 570), where appearance and reality are distinguished in order to be mystically reunited.

Now it is important to observe that from the symbol as embodying an imperative to the symbol as expressing an optative is a transition of meaning that involves no change of form whatever; and, much as theorists love to contrast the suggestional and the petitionary attitudes, it is doubtful if the individual does not move quite indifferently to and fro across the supposed frontier line between magic and religion, interspersing "bluff" with blandishment, spell with genuine prayer. Meanwhile the particular meanings of the detailed acts composing a complicated piece of ritual soon tend to lose themselves in a general sense of the efficacy of the rite, as a whole, to bring blessing and avert evil. In fact, unintelligibility is so far from invalidating a sacred practice that it positively supports it by deepening the characteristic atmosphere of mystery. Even the higher religions show a lingering predilection for cabalistic formulas.

Changes in Ritual.—While ritual displays an extraordinary stability, its nature is of course not absolutely rigid; it grows, alters and decays. As regards its growth, there is hardly a known tribe nithout its elaborate body of magico-religious rites. In the exceptional instances where this feature is relatively absent (the Masai of east Africa offer a case in point), we may suspect a disturbance of tradition due to migration or some similar cause. Thus there is always a pre-existing pattern in accordance with which such evolution or invention as occurs proceeds. Unconscious evolution is perhaps the more active factor in primitive times; imitation is never exact, and small variations amount in time to considerable changes.

On the other hand, there is also deliberate innovation. In Australia councils of the older men are held day by day during the performance of their ceremonies, at which traditions are repeated and procedure determined. the effect being mainly to preserve custom but undoubtedly in part also to alter it. Moreover, the individual religious genius exercises no small influence. A man of a more original turn of mind than his fellows will claim to have had a new ceremony imparted to him in a vision, and such a ceremony will even be adopted by another tribe which has no notion of its meaning (Spencer and Gillen, ibid., 272, 278, 281). Meanwhile, since little is dropped while so much is being added, the result is an endless complication and elaboration of ritual. Side by side with elaboration goes systematization, more especially

when local cults come to be merged in a wider unity. Thereupon assimilation is likely to take place to one or another leading type of rite — for instance. sacrifice or prayer. At these higher stages there is more need than ever for the expert in the shape of the priest, in whose hands ritual procedure becomes more and more of a conscious and studied discipline. the naive popular elements being steadily eliminated, or rather transformed. Not but what the transference of ritualistic duties to a professional class is often the signal for slack and mechanical performance. with consequent decay of ceremonial. The trouble and worry of having to comply with the endless rules of a too complex system is apt to operate more widely — namely, in the religious society at large — and to produce an endless crop of evasions.

Good examples of these on the part alike of priests and people are afforded by Toda religion, the degenerate condition of which is expressly attributed by W. H. R. Rivers to "the overdevelopment of the ritual aspect of religion" (The Todas, 454–5).

It is interesting to observe that a religion thus atrophied tends to revert to purely magical practices. the use of the word of power and so on (ibid., ch. x). It is to he noted, however, that what are known as ritual substitutions, though they lend themselves to purposes of evasion (as in the case of the Chinese use of paper money at funerals), rest ultimately on a principle that is absolutely fundamental in magico-religious theory; namely, that what suggests a thing because it is like it or a part of it becomes that thing when the mystic power is there to carry the suggestion through.

The Classification of Rites. — More than one basis of division has suggested itself. From the sociological point of view perhaps the most important distinction in use is that between public and private rites. While the former essentially belong to religion as existing to further the common weal, the latter have from the earliest times an ambiguous character and tend to split into those which are licit — "sacraments," as they may be termed — and those which are considered antisocial in tendency and are consequently put beyond the pale of religion and assigned to the "black art" of magic. Or the sociologist may prefer to correlate rites with the forms of social organization — the tribe, the phratry, the clan, the family and so on.

Another interesting contrast (seeing how primary a function of religion it is to establish a calendar of sacred seasons) is that between periodic and occasional rites — one that to a certain extent falls into line with the previous dichotomy. A less fruitful method of classing rites is that which arranges them according to their inner meaning. As we have seen, such meaning is usually acquired ex post facto, and typical forms of rite are used for many different purposes; so that attempts to differentiate are likely to beget more equivocations than they clear up. The fact is that comparative religion must be content to regard all its classifications alike as pieces of mere scaffolding serving temporary purposes of construction.

Negative **Rites.**—A word must be added on a subject dealt with elsewhere (see TABU), but strictly germane to the matter in hand. Ritual interdictions have the best, if not the sole, right to rank as taboos *(see* M. Mauss in *L'Année* sociologique, ix, 249). Taboo, as understood in Polynesia, the home of the word. is as wide as, and no wider than, religion, representing one side or aspect of the sacred (see RELIGION). The very power that can help can also blast if approached improperly and without due precautions. Taboos are such precautions, abstinences prompted, not by simple dread or dislike, but always by some sort of respect as felt toward that which in other circumstances or in other form has healing virtue. Thus the negative attitude of the observer of taboo involves a positive attitude of reverence from which it becomes in practice scarcely distinguishable. To keep a fast, for instance, is looked upon as a direct act of worship. It must be noted, too, that, whereas taboo as at first conceived belongs to the magico-religious circle of ideas, implying a quasi-physical transference of sacredness from that having it to one not fit to receive it, it is very easily reinterpreted as an obligation imposed by the deity on his worshippers.

The law observed by a primitive religious community abounds in negative precepts, and if early religion tends to be a religion of fear it is because the taboo breaker provides the most palpable objective for human and divine sanctions. In the higher religions to be pure remains among the most laudable of aspirations and, even though the ceremonial aversion of a former age has become moralized, and a purity of heart set up as the ideal, it is on "virtues of omission" that stress is apt to be laid, so that a timorous propriety is too often preferred to a forceful grappling with the problems of life. There are signs, however, that the religious consciousness has at length come to appreciate the fact that the function of routine in religion as elsewhere is to clear the way for action.

RITUAL MURDER, a general term for human sacrifice in connection with religious ceremonies. False accusations as to the practice of ritual murder by various bodies have often been made. Justin Martyr in his second apology (ch. xii) vigorously defends the Christian community against the charge; Octavius, Minucius Felix, Tertullian, Origen and other church fathers all refer to the subject and indignantly repudiate the atrocious libel that the Eucharist' involved human sacrifice. The myth was revived against the Montanists, and in the later middle ages against various dissenting sects of Christians. In modern times the accusation was leveled against "foreigners" during the disturbances in China. The chief sufferers from the libel were, however, the Jews. The earliest form of it (the first instance is the case of William of Norwich, 1144) was that they immolated a Christian child at Easter in mockery of the Passion. In the course of the next century there came about the elaboration that the blood was used in the manufacture of the unleavened bread for Passover (which generally coincided with Easter) or for other purposes. Ultimately, it was actually alleged that "the Jews of every province annually decide by lot" which congregation or town was to be the scene of the mythical murder. Almost invariably, the accusations were followed by spoliation and persecution. Among the classical instances are the "martyrdoms" of Hugh of Lincoln (1255) and Simon of Trent (1475), the Damascus affair (1840) and the Beilis case (1911–13). It is easy to understand how, in ages when the Jews mere everywhere regarded with suspicious awe, such stories would find ready credence; but the revival of the myth by the anti-Semite in modern times is a deplorable instance of degeneration. That there is no foundation whatsoever for the belief was proved in the classical treatise on the. subject by Hermann L. Strack, regius professor of theology at the University of Berlin. Many proselytes to Christianity have strenuously defended the Jews from the charge. Several of the popes issued bulls exonerating them, and temporal princes have often taken a similar step. Many Christian scholars and ecclesiastics felt it their duty to utter protests against the libel, including the most eminent Gentile students of Rabbinism of modern times. Indeed, the vast majority of the literature refuting the charge came from non-Jewish pens. That on the other side is entirely anti-Semitic, and in no case has it survived the ordeal of criticism.

1900; Eng trans., The *Jew and Human Sacrifice,* 1909); *D.* Chwolson, *Blutanklage* (1901); F. Frank, *Der Ritualmord vor den Gerichtshofen der Wahrheit und der Gerechtigkeit* (1901, 1902). *A* list of some of the most important cases is given by J. Jacobs in the *Jewish Encyclopaedia,* iii, 266–267.

RIVADAVIA, BERNARDINO (1780–1845), first president of the Argentine republic, was born at Buenos Aires on May 20, 1780. His education at the College of San Carlos was interrupted by the British invasion of 1806. In 1811 he became secretary to the revolutionary triumvirate and later was made a member of that body. To secure the recognition of an independent La Plata, and a Spanish prince to rule it, he was sent with tno other diplomats to Europe and was partly responsible for the British acceptance of the United Provinces into the family of nations. Upon his return to Buenos Aires he was appointed, under Gov. Martín Rodriguez, one of the two ministers of government (state) and used his office to introduce reforms in the civil government and courts and to found hospitals, asylums and schools, including the University of Buenos Aires. He introduced the Lancastrian system of elementary education.

Politically, he was a Unitarist, or nationalist. and in time became the party leader in opposition to the Federalists. He favoured the establishment of a monarchy with Spanish leanings. In 1826 he was elected president of the United Provinces of La Plata, which, a few months later, adopted a constitution for the Argentine republic.

From the outset the presidency proved to be an unhappy office. Not only was Argentina bitterly divided over the question of federalism versus nationalism, but it was also involved in mar against Brazil concerning the independence of Uruguay, then known as Banda Oriental. Handicapped by the internal dissension, Rivadavia accepted the offer of British mediation and a treaty of peace was drafted which recognized Brazilian hegemony of the disputed area. The people of Argentina refused to accept that arrangement. however, and Rivadavia was forced to continue the war. When the provinces declined acceptance of the proposed constitution, Rivadavia resigned his office (1827). In 1829 he went to Europe to study political and economic institutions. Five years later his political enemies brought charges against him in the courts, and without a hearing he was sentenced to exile within 24 hours. He went first to Brazil, then to Cádiz, Spain, where he died on Sept. 2, 1845. His remains were repatriated in 1857 and 23 years later his birthday was decreed a national holiday.

BIBLIOGRAPHY.—There is a wealth of material in Spanish concerning Rivadavia, among which may be noted C. Correa Luna, *Rivadaaia y la simulacidn monárquica de 1815* (Buenos Aires, 1929); A Lamas, *Rivadavia; su obra politica y cultural* (Buenos Aires, 1915) In English *see* Ricardo Levene, *A History of Argentina,* trans by W. S. Robertson (Chapel Hill, N.C., London, 1937). (R. G. RR)

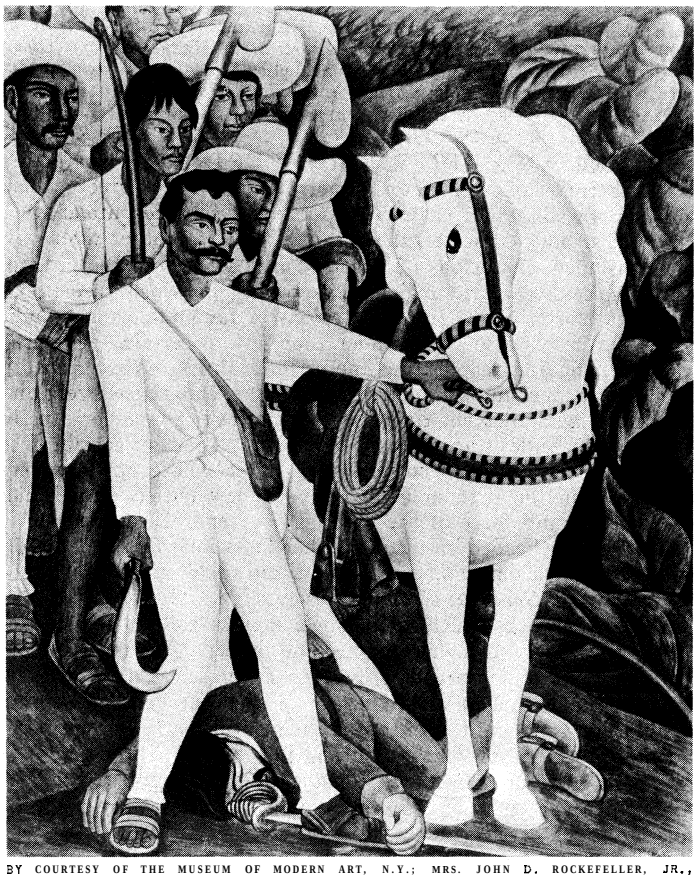
RIVAROL, ANTOINE DE (1753–1801), French writer and epigrammatist, was born at Bagnols in Languedoc on June 26, 1753, and died at Berlin on April 11, 1801. It seems that his father was an innkeeper of cultivated tastes. The son assumed the title of comte de Rivarol. and asserted his connection with a noble Italian family. After various vicissitudes he appeared in Paris in 1777. In his *Petit Almanach de nos grands hommes pour 1788,* in which he had the assistance of Richebourg de Champcenetz, he ridiculed contemporary authors. Rivarol wrote in the royalist press, in the *Journal politique* of Sabatier de Castres (1742–1817) and the *Actes des Apôtres* of Peltier (1770–1825). He emigrated in 1792, and established himself at Brussels, whence he removed successively to London, Hamburg and Berlin. Rivarol has had no rival in France in brilliant epigrams except Piron. His works include *Isman, ou le fatalisme* (1795), a novel; *Le Véridique* (1827), comedy; *Essai sur les causes de la révolution française* (1827).

See *Oeuvres,* 2nd ed., ed. by M. de Lescure (1880); G. W. Harris, *Antoine Rivarol, Journalist of the French Revolution* (Oxford, 1940).

RIVAS, ANGEL DE SAAVEDRA, DUKE OF (1791–1865), Spanish poet and politician, born at Córdova, March 19, 1791. He fought in the War of Independence, was a prominent member of the advanced Liberal party (1820–23) and in the latter year was condemned to death. He escaped to London and lived successively in Italy, Malta and France, until the amnesty of 1834, when he returned to Spain, shortly afterward succeeding his brother as duke of Rivas. In 1835 he became minister of the interior under Isturiz. and along uith his chief had again to leave the country. Returning in 1837, he joined the Moderate party became prime minister and was subsequently ambassador at Paris and Naples. He died June 22, 1865. In 1813 he published *Ensayos podticos,* and between that date and his first exile several of his tragedies (the most notable being *Alatar,* 1814, and *Lanuza,* 1822) were put upon the stage. Traces of foreign influence are observable in *El Moro Expdsito* (1834), a narrative poem dedicated to John Hookham Frere; these are still more marked in *Don Alvaro ó La Fuerza del sino* (first played March 22, 1835), a drama of historical importance inasmuch as it established the new French romanticism in Spain.

See *Obras completas del Duque de Rivas,* 7 vol. (Madrid, 1894–1904); N Gonzalez Ruiz, *El duque de Rivas* (Madrid, 1944).

RIVERA, DIEGO (1886–1957), Mexican mural painter, was one of the leaders of the revolutionary movement in public wall painting that began in Mexico in the 1920s. He was born in Guanajuato, Gto., Mex., on Dec. 8, 1886. His politically liberal father early encouraged his son's artistic bent by providing him with a studio before he mas able to read and by sending him to art classes at ten. Before 1906 Diego Rivera had studied under such Mexican masters as the romantic landscape painter José Maria Velasco and the French-trained classicist Santiago Rebull. He then went to Spain on a government scholarship, and at the beginning of the Rladero revolution in Mexico. he made an exhibition at home of his somewhat conventional Spanish canvases. Between 1911 and 1920 he lived mostly in Paris, producing hundreds of Cubist paintings and drawings in a manner largely derived from the Spanish master Picasso — though his own work retained many easily recognizable objects.



BY COURTESY OF THE MUSEUM OF MODERN ART, N.Y.; MRS. JOHN D. ROCKEFELLER, JR., PURCHASE FUND

"AGRARIAN LEADER ZAPATA" BY RIVERA IN 1931, A VARIANT OF A FRESCO IN THE CORTES PALACE. CUERNAVACA, MEX.: MUSEUM OF MODERN ART, N.Y.

After making a firsthand study of fresco painting in Italy, Rivera returned to Mexico with a newly wrought classical and didactic style, graced with lyrical elements, and began to make his famous proletarian frescoes. In the early 1930s Rivera mas the centre of wide political controversy in the United States. A mural he painted for the Detroit (Mich.) Institute of Fine Arts in 1932 was criticized as irreligious and his mural "Man at the Crossroads" (executed for Rockefeller Centre. New York city), which included a portrait of Lenin. also was the subject of strong protests. The former was defended by Institute authorities; the latter waseventually removedandreconstitutedat the Palace of Fine Arts in Mexico City.

Among Rivera's most distinguished frescoes were those painted at the National School of Agriculture, Chapingo, D.F., with its decorative studies of the nude figure: and at the Cortés palace in Cuernavaca, with its stylized and bittersweet story of the conquest of Mexico. In Mexico City he painted the lyrically landscaped staircase connecting tall frescoed corridors in the hlinistry of Education; in the National palace he portrayed Aztec history in archaistic forms and cold colours; and in the Social Security Hospital Ko. 1 he returned to his earlier lyrical style.

Rivera died Nov. 25, 1957, in Mexico City.

RIVER AND RIVER ENGINEERING. A river is any natural stream of fresh water, larger than a brook or creek, which flows in a well-defined channel. Usually it discharges into another and larger body of water, the ocean, a lake or another river. In rare instances in regions of porous soil it soaks into the ground, or, in excessively arid regions, evaporates, in which case it becomes a "lost river." In other regions of favourable rock conditions it may also run underground for certain distances, disappearing and reappearing one or more times. A river with a well-cut channel and a graded bed, usually reaching base level at its mouth, is an adolescent river. Rivers as they grow older usually widen their valleys accordingly unless prevented by certain geological formations or occurrences. A river whose upper waters sometime in the past suddenly found a new outlet, diminishing the volume and force of the original river and also its length, is known as a beheaded river. For other facts relating to the origin and subsequent development of rivers and their valleys *see* GEOLOGY: *Physical Geology: Geomorphology.*

The river works which the engineer may be called upon to execute vary widely in their character and object. The more important of these which are described in the present article may be grouped under the following heads: (1) The prevention of river inundations and the mitigation of their effects; (2) the improvement for navigation of the nontidal portions of rivers; and (3) works for the improvement of navigation in the tidal compartments of rivers, in their estuaries and at the outlets of rivers flowing into tideless seas.

Other river engineering works are dealt with under separate headings, for instance, the utilization of river waters for power production (*see* ELECTRIC POWER); works for water storage and supply for various purposes including irrigation (*q.v.*); works connected with fisheries (*q.v.*); for erosion and reclamation of land (*see* BREAKWATER; LAND RECLAMATION). *See* also the articles on MECHANICS, FLUID; WATERWAYS, INLAND; WEIR; and particular rivers; *e.g.,* MISSISSIPPI RIVER; DANUBE.

PHYSICAL CHARACTERISTICS OF RIVERS

River Basins.—In general the size of rivers above any tidal limit and their average fresh-water discharge depend upon the extent of their basins, and the amount of rain over those basins. They vary in extent according to the configuration of the country, ranging from the insignificant drainage areas of streams falling from high ground near the coast and flowing straight down to the sea to the immense parts of continents. where rivers after flowing down the slopes of mountain ranges traverse vast stretches of valleys and plains before reaching the ocean. The comparative size of the principal river systems of the world is shown in the table.

River and Location	Drainage basin in square miles	Length in miles
Nile, Africa	1,110,000	4,157
Amazon, South America	2,722,000	3,915
Missouri-Mississippi, U.S.	1,243,700	3,860
Yangtze, China	756,498	3,604
Ob, U.S.S.R.	1,131,273	3,461
Yellow, China	486,486	2,902
Congo, Africa	1,425,000	2,716
Lena, U.S.S.R.	936,293	2,653
Mackenzie, Canada	682,000	2,635
Niger Africa	580,000	2,600
Amur-Kerulen, U.S.S.R.	1,035,000	2,583
Yenisei, U.S.S.R.	1,679,535	2,349
Rio de la Plata (system), South America		
Volga, U.S.S.R.	592,000	2,200
St. Lawrence, Canada/U.S.	361,000	1,800
Brahmaputra, Asia	372,000	1,800
Indus, Pakistan	315,444	1,776
Danube, Europe		
Zambezi, Africa	513,360	1,600
Murray, Australia	350,000	1,281
Orinoco, Venezuela		

Available Rainfall, Snowfall and Snow **Melting.**—All these factors vary considerably in different localities, both in their total yearly amount and in their distribution throughout the year; also their volumes fluctuate from year to year.

Even in small river basins the variations may be considerable according to differences in elevation or distance from the sea. For instance, in the Severn basin in England and Wales. with an area of only 4,350 sq.mi., the rainfall varies from an average of less than 30 in. in the year to more than 80. The proportion, moreover: of the rain falling on a river basin which actually reaches the river, or the available rainfall in respect to its flow, depends very largely on the nature of the surface strata. the slope of the ground and the extent to which it is covered with vegetation, and varies greatly with the season of the year. The available rainfall has been found to vary from 75% of the actual rainfall on impermeable, bare, sloping, rocky strata down to about 15% on flat, permeable soils.

Slope of Rivers.—The rate of flow of rivers depends mainly upon their slope and the roughness of the channel, though where two rivers of different sizes but the same roughness have the same slope, the larger river has the quicker flow. as its retardation by friction against its bed and banks is less in proportion to its volume than that of the smaller river. The fall of a river corresponds approximately to the fall of the country it traverses, but its slope is generally more gentle because of its meandering alignment. Near the source, frequently in hilly regions, the slope of rivers is usually steep, but it gradually flattens out, with occasional irregularities, until. in traversing plains along the latter part of their course, the slope usually becomes quite gentle. Accordingly, in large basins, rivers in most cases begin as torrents with a very variable flow, and end as gently flowing rivers with a comparatively regular discharge.

Variations in the Discharge **of Rivers.**—In tropical countries, subject to periodi'cal rains, the rivers are in flood during the rainy season. Where the annual flood depends to a large extent on the melting of the snows, the rivers are in their high stages in late spring and early summer. In snowless countries sudden and, to a large extent, unpredictable floods occur frequently in winter when the rate of evaporation is relatively low and the ratio of runoff to rainfall is therefore high. Occasionally heavy rainfall may then be the cause of a sudden rise of the river level, resulting in much damage—unless duly provided for by the engineer. Mixed conditions are characteristic of rivers fed partly by snow and partly by rain: though their annual floods may be due to the melting of the snow in spring, these rivers are liable to have their flow rendered more uniform by the influx of tributaries subject to different conditions, as exemplified by the Rhdne below Lyons. Fr.

Much attention was devoted by scientists in the first half of the 20th century to deriving a reliable method for predicting the

discharges of rivers according to the available meteorological data, and successful results were reported to have been achieved by Opokine on the Dnieper, U.S.S.R.

Transportation of Materials by Rivers. — In floodtime rivers bring down a large quantity of detritus, derived mainly from the disintegration of the surface layers of the hills and slopes in the upper parts of the valleys by glaciers, frost and rain. The power of a current to transport materials depends to a large extent on its velocity, so that torrents with a rapid fall near the sources of rivers can carry down rocks, boulders and large stones. These are by degrees ground by attrition in their onward course into shingle, gravel, sand and silt which are carried forward by the main river toward the sea or partially strewn over flat alluvial plains during floods. The size of the materials forming the bed of the river or borne along by the stream becomes less as the reduction of velocity diminishes the transporting power of the current.

Since the earliest days of modern hydraulics (17th century, in Italy) progressive engineering research has attempted to solve the problem of sediment transportation. Because sediment particles are generally heavier than the amount of water they displace, the Archimedean flotation law could not be used to explain the fact that heavy sediment was capable of being lifted and transported by flowing water. Another explanation was, consequently, required, the importance of the problem being that on its solution depended the means to be taken to control soil erosion and silt deposits in the channels of rivers.

Twentieth-century research distinguishes, in this connection, between "bed load" on the one hand and "suspended sediment" on the other. The former is composed of the larger particles which are either rolled or pushed along the bed of the river, or "jump" (*i.e.*, saltate) from the crest of one ripple to another if the velocity is sufficiently great. On the other hand the smaller particles, *i.e.*, the suspended sediment, once picked up and lifted by the moving water, may remain in suspension for considerable periods of time, and thus be transported over many miles.

Bed load is capable of an easier explanation than suspended sediment because in the first case the velocity of the moving particles is less than that of the water, whereas in the second both velocities are equal. In one case, therefore, there is an impact effect due to the difference of velocities, while in the other, such effect is absent.

From among the various theories suggested to explain the phenomenon of sediment suspension the following may be quoted: (1) T. Dupuit and A. Flament believe that a rigid body transported by the flowing water tends always toward the region of maximum velocities and, as the surface velocity is usually greater than the bed velocity, a sediment particle, picked up from the bed, must of necessity rise toward the surface; (2) from numerous observations of velocities in rivers N. de Leliavsky concluded that the scour of a granular river channel and the lifting of the particles of which it is composed is due to convergent currents possessing a surplus of energy, while diverging currents have the opposite effect; *i.e.*, they cause suspended sediment to be dropped; (3) a third school of thought attributes the lifting of the particles to the rising components of the cross currents. This school is subdivided into two groups depending upon whether the cross currents are visualized as forming part of a pulsating but generally orderly flow pattern, or are believed to be a numberless multitude of instantaneous and disorderly agitations characteristic of an essentially turbulent flow.

River Channels. — A river channel eroded by the current depends obviously on the flow pattern, and the flow pattern is, in turn, affected by the form of this same channel. It may therefore appear that the problem of the river channel contains the elements of a vicious circle.

A broader approach postulates that we are faced, in this case, with a process of mutual interaction between two mediums, water and granular soil, and that the channel formation due to such an interaction is controlled by certain general laws.

Among the various authors who contributed to the discovery of these laws might be mentioned James Thomson, L. Fargue, N. de Leliavsky, R. Jasmund and others. One of the main laws is that the natural shape of a river channel eroded in an alluvial plain does not follow a straight line but shows a tendency to meander, and even if it were made straight through artificial means, it would soon begin to serpentine again. In fact, Fargue showed that water depth in a river is correlated with curvity of its channel in plan in such a manner that as the curvity increases, so does the depth.

This, and various other laws belonging to the same theory of river channels, have been much discussed and modern experimental evidence tends to bear them out. The experiments of J. F. Friedkin, of the Vicksburg experiment station of the U.S. army, as reported in *A* Laboratory Study of the Meandering of Alluvial Rivers (Vicksburg, 1945), show that "Meandering is essentially a natural trading process of sediments from banks to bars. . . Under ideal conditions of uniformity, an initial bend is perfectly transmitted downstream, thus resulting in a series of uniform bends. . . The natural process might be likened to the oscillatory course taken by a ball which has been started down a grooved incline so that it oscillates from side to side. . ."

The more uniform the configuration of the earth surface, the nearer does the river channel approach the described ideal shape. Mountains and various other natural and man-made obstructions interfere with the process of the formation of a natural river channel, causing local deviations from its ideal sinusoidal shape.

Floods of Rivers. — It will be clear that floods of rivers may be of two kinds: the annual floods which take place always during the same months of the year, and the sporadic, altogether unpredictable floods, which may not occur for several years, and then come suddenly, at an unexpected date. An outstanding example of the first class is the annual flood of the Nile, always occurring during the months of August and September, which is fed by the monsoon rains falling over the equatorial districts of central Africa; whereas the floods of the Seine at Paris are typical of the second class, for though they usually occur in winter, their dates and intensities are subject to much variation. Such floods are caused by a heavy rainfall on land already sodden by recent rains at a period of the year when evaporation is inactive, and especially by rain falling on melting snow. A fairly simultaneous rainfall over the greater part of a moderate-sized river basin is a tolerably common occurrence; and under such conditions, the floods coming from the torrential tributaries reach their maximum height and begin to subside before the floods from the gently flowing tributaries attain their greatest rise.

THE REGULATION OF NONTIDAL RIVERS

Mitigation of Floods and Protection from Inundations. — As the size of the channel of a river is generally inadequate to carry down the discharge of floods, the river overflows its banks in floodtime and inundates adjacent low-lying lands. An enlargement of the bed of a large river, principally by deepening it, in order to increase its discharging capacity, is precluded by the cost, and also, in rivers bringing down sediment, by the large deposit that would take place in the enlarged channel from the reduction in the velocity of the current when the flood begins to subside. Where, however, the depth of a smaller river has been considerably increased by dredging, the enlargement of its channel and the lowering of its low-water line facilitate the passage of the land water and consequently reduce the danger of flooding. The Glasgow quays, for instance, along the deepened Clyde are no longer subject to inundation, and the lands and quays bordering the Tyne have been relieved from flooding for 10 mi. above Newcastle by the deepening of the river from Newburn to the sea. (See fig. 10.)

In certain cases it is possible to restrict or to prevent the inundation of some riparian districts by embankments; and occasionally low-lying lands are so unfavourably situated that pumping has to be employed.

The flow of water off the slopes of a valley can be retarded by planting trees on mountain slopes, which have too often been denuded by the reckless clearing of forests.

The most efficacious way of dealing with the prbblem is to reduce the peak of the flood by withdrawing at the critical period

some part of the natural discharge from the river. This may be done in two different manners; *i.e.*, either by diverting the flow in a low-lying depression, or by building a dam across the valley of the river and storing behind it a part of the flood discharge. An example of the first arrangement is the scheme of works on the Tigris and Euphrates rivers, in Iraq, part of which was inaugurated in the early spring of 1956. The floods of these rivers have always been a major problem and have caused much damage to the town of Baghdad and the surrounding cultivated area. The Ramadi barrage and Warrar regulator were built to divert part of the flood of the Euphrates into the Habbaniya lake, some of the water to be returned into the river during the drought season through the Dhiban outlet. In more or less the same manner, the Samarra barrage and inlet regulator were planned to divert the flood of the Tigris into the Tartar depression, through a 65-km. inlet canal. On the other hand, the Aswan dam on the Nile furnishes an example of a storage reservoir in the trough of the river, which may also be used for occasional flood control. The fact that floodwater is heavily laden with silt prevents this operation being carried out systematically every year as the silt would then fill the reservoir. In 1946, during an exceptionally high flood, the Aswan reservoir was used to reduce its peak, as an exceptional measure. In the United States, during the 25-year period ending in 1952, 300 projects were constructed in the interest of flood control, 77 of which were dams, while the remainder were local protection projects. The flood control project in the lower Mississippi river valley included five reservoirs, all completed by the mid-1950s.

Methods of Increasing the Discharging Efficiency of River Channels.—The discharging efficiency of a river within the limits of its bed depends on the fall and the cross section of the channel. The only way of increasing the fall is to reduce the length of the channel by substituting shorter cuts for a winding course. In the case of a large river, however, it is very difficult to maintain a straight cut because of the tendency of the current to erode the banks and form again a sinuous channel. Cuts therefore should be in the form of one or more flat curves. Nevertheless, where the available fall is exceptionally small, as in lands originally reclaimed from the sea such as the English fen districts, straight channels have been formed for the rivers and "drains."

Prediction of Floods.—This term may be interpreted in two different manners, for it may either be meant to refer to a definite flood, the levels and dates of which must be known beforehand in order to take immediate and urgent steps for alleviating its probable effect upon the safety and welfare of the riparian population, or the same term may also be used to designate a more general problem; *i.e.*, the probabilities of the flood magnitudes and flood frequencies of a river, which are of fundamental importance in many design problems in connection with flood control.

The only generally accepted solution of the first problem consists in establishing a number of gauges for recording the water levels in the upper stretches of the river itself and in all its affluents. In order to understand how the information on the flood levels in the upper regions of the river supplied by these gauges can be used for predicting the levels for its lower course, we imagine a flood as a wave (see *abc* in fig. 1) which moves slowly downstream. The velocity of propagation of this solitary wave (celerity in U.S. terminology) is not necessarily the same as that of the water in the river, but, in practice, is frequently of the same order of magnitude. Referring again to fig. 1, it will be observed that the slope of the water surface in the downstream part of the wave, *i.e.*, in *bc*, is of necessity much steeper than in *ab*. Since the velocity of water in a river depends largely on the corresponding slope of the water surface, it follows that in *ab* the velocity is much less than in *bc*. In other words, there is less water fed into the wave on its upstream side than escapes toward its downstream end, the result being that as the flood moves slowly downstream, it gradually flattens. Thus, as it reaches the position *efg*, it is shallower than in *abc*, and in *hij* its height is still less. On the other hand, if two waves such as that shown in the drawing move in two confluents and reach the main channel simultaneously, a dangerous flood may occur. The speeds of the propagation of the waves, as well as their levels can all be calculated with remarkable precision and the floods occurring in the entire basin of the river are, consequently, capable of being predicted with enough accuracy for practical purposes. The new branch of hydraulics dealing with this particular problem is frequently referred to as flood routing.

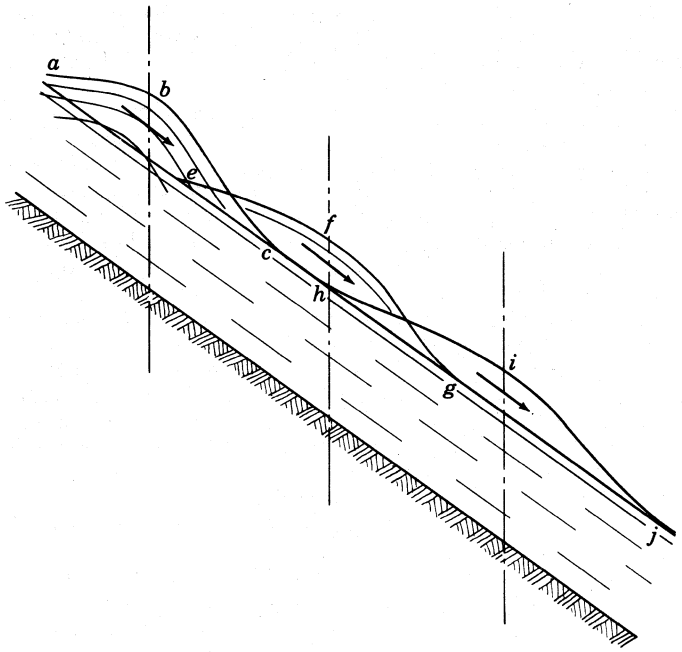

FIG. 1.—THE MOVEMENT OF A FLOOD SHOWN AS A WAVE

It remains now to consider the second, more general, problem dealing with the probability of flood levels and their incidence. Among the earliest hydraulicians who started this approach in the earlier decades of the 20th century were Allen Hazen in the United States and H. E. Hurst and P. Philips in Egypt. The bell-shaped Gaussian frequency curve, such as is represented in fig. 2, is among the best known of the popular diagrams that are used for systematizing the results of observations from which significant conclusions, capable of practical application, are derived. The numbers

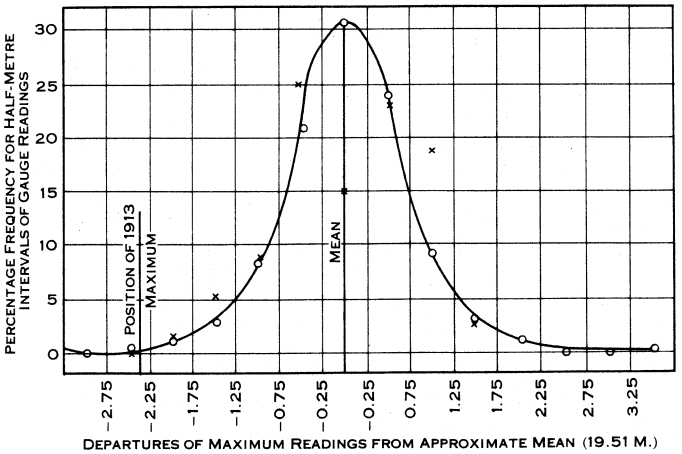

FIG. 2.—GAUSSIAN FREQUENCY CURVE, USED FOR SYSTEMATIZING FLOOD PREDICTION DATA

under the horizontal axis of the diagram are the departures of the annual Nile flood levels—measured since 640 on the Roda Nilometer at Cairo—from their mean. This mean flood level (19.51 m. above mean sea level) is, of course, the most probable, and the height of the curve above the horizontal axis gives the probabilities of the recurrence of the corresponding departures from this mean. The practical significance of such a curve is that the need for public works intended to meet conditions which may recur only once in, say, 100 or 200 years, cannot be as pressing

as in the case of a flood level recurring every 2 or 3 years. The curve may therefore be interpreted as yielding a quantitative basis for granting the yearly credits for the corresponding works.

From the standpoint of the computer the great objection against this type of diagram is that the bell-shaped curve is not so obvious as a straight line. Hazen devised, therefore, another form of computation. in which the same information is systematized in the form of a straight line—as shown, for instance, in fig. 3. It will be noted in looking at this figure that in order to convert the areas of the bell-shaped curve of fig. 2 into a straight-line representation, a special scale is used. The numbers written beneath the diagram are the figures of probabilities of lower flood levels than those indicated by the averaging straight lines drawn through the observations which appear as points. The most important conclusion derived from this diagram is that the flood levels for the period 1737–1917 are higher than for 641–1451, which means that as a result of the silt deposited by the river, the whole valley of the Nile rises gradually at a rate of about four inches per century.

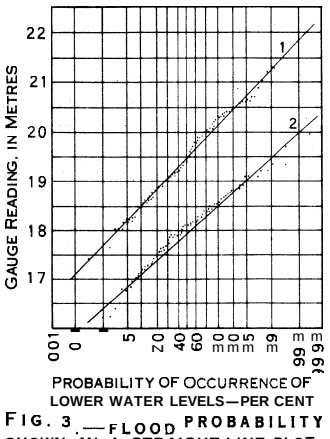

FIG. 3.—FLOOD PROBABILITY SHOWN IN A STRAIGHT-LINE PLOTTING

Fig. 2 and 3 are typical of a symmetrical frequency. Mathematical treatment of skew frequencies is somewhat more involved. This and many other problems to be solved in order to obtain in all cases an easily extrapolated straight-line diagram, involving the use of logarithmic functions and other devices, were attacked by numerous well-known mathematicians, among them Ralph W. Powell, R. D. Goodrich, E. J. Gumbel, H. Alden Foster, Ven Te Chow and many others. Both diagrams were prepared by Philips, and are reproduced here from S. Leliavsky Bey ("Underpinning and Repairing the Roda Island Nilometer," The Engineer, London, Dec. 9. 16 and 23, 1949). The gauge in question deserves mention as the oldest gauge still being used for river level measurements. It is one of the earliest masonry works erected by the Arabs after the conquest of Egypt, and is believed to be referred to by Shakespeare's Antony when he speaks about the Egyptians being particularly clever in measuring water levels (*Antony* and *Cleopatra,* act II, scene vii; the reference to the pyramid in connection with river levels would then be explained by the shape of the roof of the gauge). The maximum yearly flood levels recorded on this gauge were preserved as state documents because, according to old established routine, the yearly land tax levied from the cultivated area of the country was dependent on this level. In fact, too low a level meant insufficient irrigation, while too high a level was accompanied by inundations. Thus. the taxpaying capacity was a function of the river level, and this principle was reflected in a tradition of land-tax assessment, the origin of which dates back before the earliest recorded Egyptian history.

Embankments. — Earthen banks protecting the inhabited areas in the valley of a river against inundations during flood are possibly among the earliest types of engineering works ever created by man. For instance, in Egypt, the left-hand bank of the Nile, extending from Aswan to the Mediterranean, over a distance of more than 1,000 km., existed (partially, at least) in the time of the Pharaohs, while the right-hand bank was built somewhat later, by Arab engineers. Since the very life of the country depended on these banks during floods, legend has it that some of the earlier rulers of Egypt ordered the engineer in charge of the maintenance of a bank to be thrown into the breach in case such a breach was allowed to occur within his district. It has been suggested that, viewed in the historic perspective, the danger of inundations, forcing as it did the individual to depend for his personal safety on the construction of long and tall banks, *i.e.,* on the co-operative work of the community, must have been a strong incentive for the development of organized communal life; hence the mighty monarchies which. at the dawn of history, existed in the countries where irrigation and hydraulic engineering were practised on a large scale, such as Egypt, Mesopotamia, China, Ceylon and, possibly, Spain.

The system of embankments has been adopted in other places, also, where tracts of fertile alluvial land below flood level stretch for long distances away from the river. Thus the fens of Lincolnshire, Cambridgeshire and Norfolk in England are protected from inundations by embankments along their rivers and drains; a great portion of the Netherlands is similarly protected; and the plains of Lombardy are shut off from the floods of the Po by embankments along each side of the river for a distance of about 26j mi.

For such towns as New Orleans on the Mississippi and Szegedin on the Theiss in Hungary, which were established below the flood level of an adjoining river, the channel of the river should be improved to facilitate the passage of floods past the town. The town also should be enclosed within embankments raised above the highest possible flood level to obviate the contingency of an exceptional flood, or a gradually raised flood level leading to such a catastrophe as overwhelmed the greater part of Szegedin in March 1879 and threatened New Orleans in 1927.

The Mississippi. — A system of levee embankments has been extensively developed along the Mississippi river in its alluvial valley extending from Cape Girardeau, Mo , to the Head of Passes in the delta, a distance of 1,014 mi. by river channel. The alluvial valley has a length in latitude of 600 mi. and ranges from 20 mi. to 80 mi. in width with a total area of 35,500 sq.mi. It comprises the St. Francis, the Yazoo, the Tensas, the Lafourche, the Atchafalaya and portions of the White and Arkansas basins, as well as the alluvial lands around Lake Pontchartrain (fig. 4).

These levees, begun by the French settlers in Louisiana in the early 18th century, uere in 1735 about three feet high and had been constructed from 30 mi. above New Orleans to 12 mi. below. From this beginning the system was extended until by the mid-1950s it included 2.846 mi. of levees having an average height of 24 ft. and a content of about 1,392,000,000 cu.yd. of earth. The levees above Baton Rouge, La., are roughly parallel to the river but have a width between them of from $\frac{3}{4}$ mi. to 15 mi., thereby greatly increasing the cross-section area of the river in times of flood. Belou Baton Rouge the levees follow the bends in the river but are set back from the river bank sufficiently to prevent undercutting by the current during floods. In some parts the spacing is much greater.

The low-water discharge, measured at New Orleans, 123 mi. from the mouth of the Southwest pass, has been as low as 49,200 cu.ft. per second; this, however, was affected by tide. The lowest discharge of record at Red River Landing, La., was 75,000 cu.ft. per second. At Vicksburg, Miss., a discharge of 1,806,000 sec.-ft. was recorded in 1927 (estimated 2,278,000 sec.-ft. if flood had been confined to leveed river), which compares with the minimum of record of 93,800 sec.-ft. at that place. The levees had not been adequate during certain floods to withstand the water pressure which had (before the record flood of 1927) a maximum rise at Vicksburg of 61.65 ft. above 1940 low water at that point. In 1927 the river at Vicksburg rose 3.55 ft. higher and 6j.2 ft. above the low stage of 1940. The floods tend to increase in height due to the confinement of the river between levees. Breaches, or crevasses as they are termed in the United States, have occurred during extraordinary flood, but no crevasses occurred after 1928 in the lower Mississippi river valley. They produce a sudden rush of the floodwaters through the opening which is damaging to the land in the immediate vicinity of the breach, but the general inundation is gradual and benefits the lands with a fertilizing deposit. The velocity of the outflouing water is rapid only immediately in front of a crevasse and the water creeps over the delta lands generally, aided by the sloping down of the land on the alluvial plains for some distance away from the river.

The great floods of the Mississippi and its tributary rivers in April–June 1927 were particularly serious. They were due to the extraordinary coincidence of flood conditions in all the chief tributaries of the river. Normally the eastern floods usually culminate between January and April, while the crests of the Missouri river

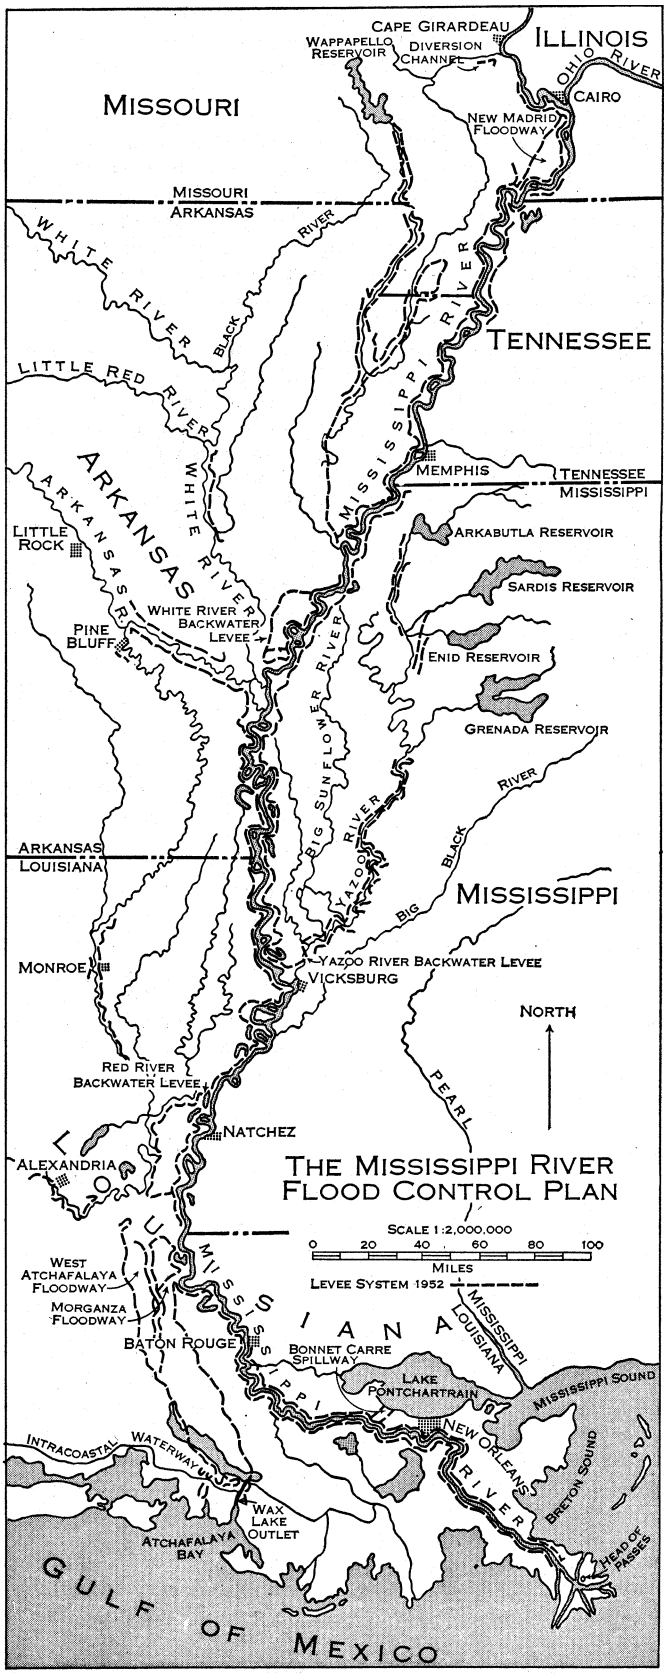

FIG. 4 — MAP OF MISSISSIPPI RIVER SHOWING AREAS SUBJECT TO OVERFLOW AND REQUIRING PROTECTIVE ENGINEERING

floods usually enter the Mississippi in June. In 1927 the levees were breached in many places and the floodwaters overflowed throughout the alluvial valley. An area of more than 23,000 sq.mi. was inundated and 700,000 people were driven from their homes, Apprehension was averted at the city of New Orleans by cutting a gap in the levees at Poydras, a few miles below the city, thus permitting a part of the floodwaters to take a short course of about 5 mi. to an arm of the sea instead of following the normal course of the river through the delta.

In Jan.–Feb. 1937, while the greatest flood of record was developing in the Ohio river, the conditions in the Mississippi river were favourable for receiving and disposing of this unprecedented discharge. The lower Mississippi was called on to carry a flood of more than 2,000,000 sec.-ft. The improved levee system successfully held the water within bounds, except in backwater areas of the tributaries, which were not protected. The Bonnet Carre spillway, 23 mi. above New Orleans, was put into operation late in January when it became apparent that the oncoming floodwaters would raise the stage at New Orleans above 20 ft. The floodway diverted a maximum of about 200,000 sec.-ft. into Lake Pontchartrain and held the crest at New Orleans to 19.3 ft. Without the relief afforded by the spillway, it is estimated that the stage at New Orleans would have been about 3 ft. higher. The Bonnet Carre floodway was also operated successfully in 1945 and in 1950. The 1950 flood, which produced the third highest stage of record at Cairo, Ill., was safely carried to the Gulf of Mexico within the levee system and control works.

In the early 1930s a system of channel cutoffs was inaugurated on the lower Mississippi river. By 1941 they had demonstrated their worth by lowering river stages more than 12 ft. at Arkansas City. Ark.. and 6 ft. at Vicksburg. Sixteen such cutoffs, combined with other channel shortenings, reduced the river distance from Memphis, Tenn., to Baton Rouge by 170 mi.

Local Protection Projects. — The above discussions are pertinent to the protection of extended continuous areas along such a river as the Mississippi. Levees and flood walls are also utilized for localized protection of municipal areas. After 1930 the United States especially developed many local protection projects of the latter type, designed to provide a higher degree of protection for highly developed industrial and residential areas than had been customary for the continuous embankment type of protection. A good example of a local protection project is that for the protection of Kansas City, Kan.. and Kansas City, Mo., located at the junction of the Missouri and the Kansas rivers, which provides for construction of a combination levee and flood wall; construction of pumping plants; construction of a river cutoff and a highway bridge across the cutoff; and alteration of 14 bridges across the Kansas river and 2 across the Missouri river.

REGULATION OF THE NONTIDAL PORTIONS OF RIVERS FOR NAVIGATION

The importance of rivers as means of communication can scarcely be overestimated. Works are, however, required in order to increase as far as practicable the navigable depth of the channel, and thus permit larger craft to navigate the river.

Since, because of its winding alignment, a naturally built river channel constitutes a succession of deeps and shoals, the removal or at least the improvement of the latter is obviously the main problem of regulation works as carried out on navigable rivers. On some rivers it is practicable to concentrate flow and fix the low-water channel by closing subsidiary low-water channels with dikes across them and narrowing the channel at the low stage by low-dipping cross dikes extended from the riverbanks down the slope, sometimes pointing slightly upstream so as to direct the water flowing over them into a central channel.

Removal of Shoals. — There are two schools of thought in connection with this problem. The first, traditional school maintains that since the flow lines in a river are generally parallel to its banks, it suffices to constrict its channel by training works in order to cause the velocity to increase and thus wash away the sand and silt forming the shoals. The second school questions these too obvious assumptions, and postulates that the nonparallelity of the flow is the main cause of the formation of shoals which. as such, can by no means be disregarded in carrying out the works intended for their removal. J. L. Van Ornum describes this second approach as the "directing control of the current of the river." Imagine a portion of a meandering river consisting of two curves with the

point of inflection, *A*, at their junction, as shown in fig. 5. The general pattern of a meandering river may be visualized as a succession of such S-shaped elements; and therefore what occurs with one of them may very well be taken as valid for the entire river.

According to Fargue's correlation law, between curvature and depth of channel the depth of water within the limits of the curved parts of the river is usually ample for the requirements of navigation. But *A*, the point of inflection, constitutes a technical design problem, for the curvature of the streamlines drops here suddenly to zero, and the water depth may be expected to be, therefore. a minimum. This, indeed. is found to be frequently the case in nature, and explains the succession of deeps and shoals; for the deeps, or pools. correspond to curves, while the shallows, or shoals. coincide with the inflection points. In this correlation between depth and curvature lies, consequently, the three-dimensional principle of alluvial river channels.

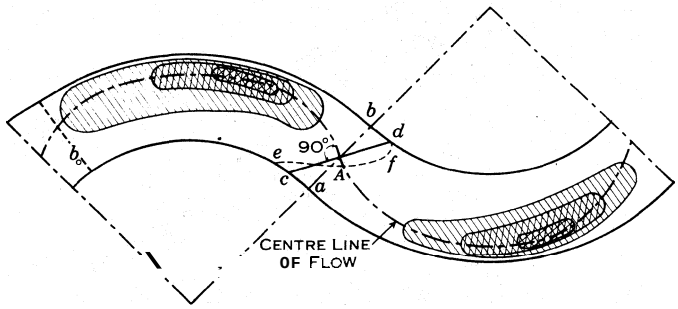

FIG. 5.— DIAGRAM OF TYPICAL MEANDER COIL. 'DEMONSTRATING THE INCONSISTENCY OF THE TRADITIONAL METHOD OF RIVER TRAINING BY CHANNEL CONTRACTION

Since the main objective in training a river is to permit larger, deeper-draft craft to ply on it, and since, in this case, the weakest link fixes the strength of the entire chain, it was only natural that the attention of training-works designers should have been concentrated on the improvement of the channel at the inflection points as the main task confronting the engineer. This point of training-works design is among the several problems, on the solution of which the parallelist and nonparallelist principles are particularly in disaccord; in fact, so long as the flow is assumed to be parallel to the banks, nature's choice of the inflection point as a locus for silting and a centre for sand deposits appears rather arbitrary. On the other hand, the physical reason of these deposits becomes quite clear if it is realized that at the inflection point the nonparallelism between flow and banks is particularly pronounced, for the main current crosses here from one concave bank to the other, and the area of waterways measured at right angles to the flow lines is not *ab (see* fig. *j),* as the parallelist school would have it, but cd (or even, as the curve *ef,* according to some observations carried out on large rivers). Since the area of waterways measured in this manner is much larger than *ab,* it follows that the velocity at the inflection point is far less than in the curve, and this explains the reason for the formation of the shoal, for as the velocity drops the sediment carried in suspension by the current is forthwith deposited. The solution advocated by the nonparallelist school consists, therefore, in dealing individually with each shoal by means of a long dike or spur protruding far into the channel of the river like a sabre in such a manner as to create a convergent, *i.e.,* scouring, type of current at the spot where it is most needed, at the inflection point. This method is recommended to replace the traditional layout of training works, consisting of a very large number of dikes and banks spread throughout the entire length of the regulated reach of the river, *i.e.,* inflection points and curves alike, as shown, for instance: in fig. 6.

Evidence on the practical results obtained by applying these two theories for the design of training works may possibly appear conflicting. But on further analysis it seems that while the traditional principle has frequently resulted in moderate general improvements of the navigation conditions. it often caused much disappointment because new shoals developed beyond the limits of the reaches trained in this manner—or even within these limits. Such local troubles could then be remedied by application of the second method. The main objection, however, against the traditional method is the very large expenditure on training works located at the spots where they are altogether unnecessary, *i.e.,* in the curves, where the natural depth of the channel is already ample for navigation.

A well-known instance of successful results obtained by this method is the regulation of the Waal river in the Netherlands, which is shown in fig. 6.

The improvement of this river was commenced about the middle of the 19th century, but the works carried out in it between 1909 and 1919 afford a most interesting example of successful results obtained by the first method, although, of course, there is nothing to prove that as good results might not have been obtained by the second method at much lower cost. The channel was deepened, throughout its length of 53 mi, from $7\frac{1}{2}$ ft. to $11\frac{1}{2}$ ft., almost entirely by training works. although no information is available on the behaviour of the river above and below the limits of this reach.

Where flood levels are a danger, training works might be objectionable because they create new obstructions to the flow and thus make this danger still greater. Such considerations lead to the development of a particular type of training works which are relatively low, as compared with the usual type, and therefore leave an almost free channel for the passage of the flood. The result of application of this type was rather indifferent on the Rhône, somewhat better on the Rhine and still better on the Mississippi above Cairo, Ill.

Much attention was devoted, at different times, to the question which of the two, training works or dredging, was the better solution for dealing with shoals. The combination of both methods seems to be the ideal solution *(see* DREDGES AND DREDGING).

On the Rhône below Lyons with its rapid current, the dikes are constructed of rubble, consolidated above low water with concrete. The dikes on the Rhine consist for the most part of earthwork mounds protected by a layer of rubble or pitching on the face, with a rubble mound forming the toe exposed to the current; but occasionally fascines are employed in conjunction with the stone or simple rubble mounds. On the Waal the newer cross dikes have a core of sand protected by a mattress weighted with stone. The dams closing subsidiary channels on the Mississippi are almost always constructed of fascine mattresses weighted with stone; but whereas the regulating dikes on the upper river are usually similar in construction, a common form for dikes in the United States consists of two parallel rows of piles filled in between with brushwood or other materials not affected by water, and protected at the sides from scour by an apron of fascines and stone.

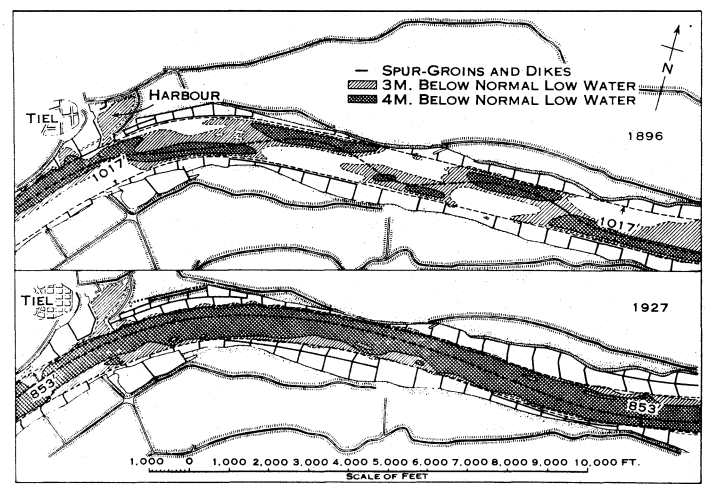

FIG. 6.— WAAL RIVER AT TIEL, NETH.. SHOWING THE CONDITION OF THE TIEL REACH IN 1896 AND 1927
The regulation works completed in this reach in 1911 effected a permanent deepening of the channel and no dredging was necessary thereafter

Protection of Vessels During Floods.—On large rivers, where vessels during high floods are exposed to injury from float-

ing debris and ice floes, shelter can be provided for them in refuge ports, formed in a recess at the side under the protection of a solid jetty or embankment constructed in the river parallel to the bank These ports are closed against floods at their upper end and have their entrance at the lower end facing downstream. There are numerous examples of such river harbours on the Danube. the Rhine and other European rivers and in the rivers of North America. Many of them. made in the vicinity of towns, as at Dusseldorf. Ger., are inland ports of considerable size.

This problem takes a particularly acute form in connection with the works carried out. after 1950, on the Don and Volga rivers in the U.S S.R.. nhere 200 mi long and 20 mi. wide internal seas have been created by building huge dams across the channels and valleys of the rivers. (See WATERWAYS, INLAND.)

SMALL RIVER OUTLETS EXPOSED TO LITTORAL DRIFT

Rivers with a small 'discharge flowing into the sea on an exposed coast are more or less obstructed at their outlet by drift of shingle or sand along the coast. When the flow falls very low in dry weather. the outlet of a river is sometimes completely closed by a continuous line of beach, any inland or tidal waters merely trickling through the obstruction; and it is only on the descent of floods that the outlet is opened out. In rivers which always have a fair fresh-water discharge, or a small fresh-water flow combined with a tidal flow and ebb, the channel sometimes has its direct outlet closed, and is deflected parallel to the shore till it reaches a weak place in the line of beach. through which a new outlet is formed; or, where the current keeps the outlet open, a bar is formed across the entrance by the littoral drift, reducing the navigable depth. (See HARBOURS; JETTY.)

Jetties at River Outlets. — The bar formed across the outlet of a river not heavily charged with sediment and flowing into a tideless sea can be lowered by carrying out solid jetties on each side of the outlet across the foreshore, so as to scour the bar by concentrating the issuing current over it. Thus by means of jetties slightly curved in plan. aided by dredging. the depth at the entrance to the Swinemunde of the Oder was increased from 7 ft. to 27 ft.. the approach channels to the Pernau river and other rivers flowing into the Baltic were deepened by jetties and the outlet channels of some of the rivers flowing into the Great Lakes of North America were improved by permanent jetties and dredging.

Where the littoral drift is powerful enough to divert the outlet of a river (as in the case of the Yare river, which at one time was driven to an outlet 4 mi. S. of its direct course into the sea at Yarmouth. Eng.. and the Adour river in France, whose outlet. because of the violent storms of the Bay of Biscay. was liable to be shifted 18 mi. from its proper position), it proved practicable to fix as well as to deepen the outlet by means of jetties. In such cases. however. where the rivers flow into tidal seas, it is important to place the jetties sufficiently apart to avoid any loss of tidal influx, since the tidal flow assists the fresh-water discharge in keeping the outlet open; whereas. with rivers flowing into tideless seas. a moderate restriction of the width between the jetties increases the scour. The tortuous and somewhat shifting outlet channel of the Scheur branch of the Maas (Meuse) river emerging onto a sandy coast where the rise of tide is small. and obstructed at its mouth by a bar, was replaced by a straight cut across the Hook of Holland. The outlet across the foreshore is fixed in position by fascine-mattress jetties (*see* JETTY). the maintenance of the depth at the mouth by the tidal and fresh waters being aided by frequent dredging (fig. 7).

DELTAIC OUTLETS OF TIDELESS RIVERS

Large rivers heavily charged with sand and silt. when their current is gradually arrested on entering a tideless or nearly tideless sea! deposit these materials as a constantly advancing fan-shaped delta through comparatively shallow diverging channels which convey the fresh-water and sediment discharge into the sea. These deltaic channels deposit their burden of sediment in front of their outlets. forming bars which advance with the delta and whose rate of progress seaward and distance in front of each outlet are proportionate to the sediment load and discharge of the several channels. A channel dredged on the bar in front of an unimproved outlet of a deltaic river retains its depth for only a moderate period

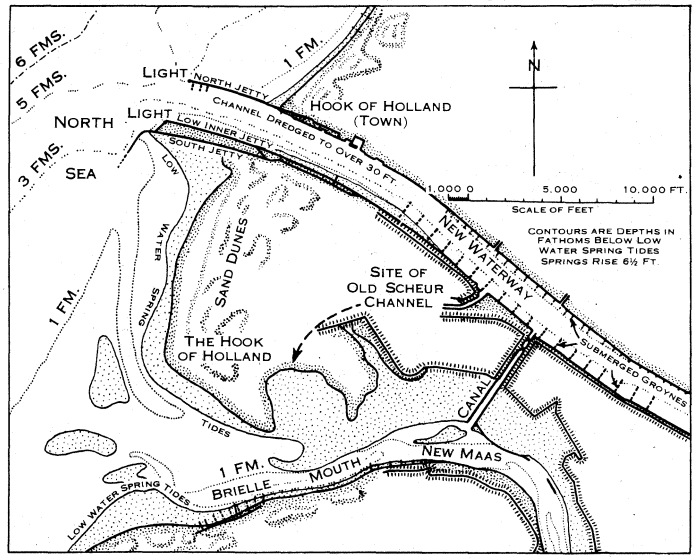

FIG 7 — JETTY OUTLET OF THE MAAS RIVER INTO THE NORTH SEA. THE ARTIFICIAL CUT FOR THE MAAS RIVER THROUGH THE HOOK OF HOLLAND WAS BEGUN IN 1864

on account of the deposit continually accumulating at the outlet.

Parallel Jetties at Delta Outlets. — The construction of parallel jetties, prolonging seaward the banks of an outlet channel, concentrates the scour of the issuing current on the bar at the outlet and under favourable conditions will procure and maintain an adequate depth for navigation. The requisite conditions for the success of this system of improvement are (1) a sufficient depth in the sea beyond the bar to allow for a considerable deposit of alluvium before the increased depth is interfered with; and (2) a littoral current carrying a portion of the alluvium away from the outlet. Both of these conditions retard the progression of the delta in front of the outlet and the inevitable eventual formation of a new bar farther out. Thus the rate of advance of the delta in front of an outlet is proportionate to the size of the channel. and the length of the jetties required is proportionate to the discharge of the channel.

The Delta of the Danube. — The Danube traverses its delta in three branches. the northern one of which. though conveying nearly two-thirds of the discharge of the river. is unsuitable for improvement due to its splitting up along portions of its course into several channels and eventually flowing into the sea through 12 mouths of a small independent delta advancing about 250 ft. annually across a shallow foreshore. The central Sulina branch was selected for improvement in 1858 in preference to the southern St. George's branch. which had a more favourable outlet and a better channel through the delta. The distance of the Sulina bar from the shore was only half that of the St. George's bar due to the much smaller discharge of. the Sulina branch. The jetties, begun provisionally in 1858 and subsequently consolidated and somewhat extended. were completed in 1877. They increased the depth over the bar from an average of about 9 ft. before 1858 up to 20½ ft. in 1873 which depth was maintained for many years. In 1894, however, the increasing draft of vessels rendered a greater depth necessary; the wide inshore portion of the jetty channel was therefore narrowed by inner parallel jetties. and a powerful suction dredger was set to work in the jetty channel and outside, whereby the depth was increased to 24 ft. in 1897 and was fairly maintained up to 1907, when a second dredger became necessary to cope with the shoaling. The depth contours gradually advanced seaward while the deepest channel was deflected northward by the action of current and waves. During World War I the decrease in depth, accelerated by the interference with dredging which occurred, was so rapid that the navigable depth was reduced at one time to 18 ft. In 1922 the seaward extension of

the jetties was commenced. leaving temporary gaps between the old heads and the new works, which mere closed after the new channel had been opened for traffic (fig. 8). This extension of the jetties for about 6.000 ft. and dredging operations restored for the time being the ruling depth of 24 ft. in the direct channel. A further extension of 2,000 ft. was made. The new jetties, like the original ones, are formed of fascine mattresses covered with stone rubble.

The Mississippi Delta.— The selection of the outlet of the

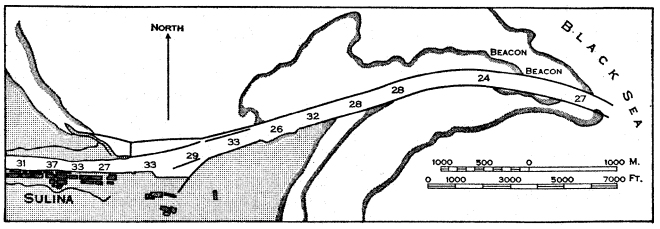

FIG. 8.— THE SULINA MOUTH OF THE DANUBE (1946)

South pass of the Mississippi delta for improvement by parallel jetties in 1876–79, in spite of the Southwest pass possessing a larger channel and a better depth over its bar, was due. as at the Danube, to motives of economy, as the bar of the Southwest pass was twice as far off from the shore as that of the South pass (fig. 9). Fascine-mattress jetties, $2\frac{1}{4}$ mi. and $1\frac{1}{2}$ mi. long, weighted with limestone, and with large concrete blocks at their exposed ends, were constructed. The jetties, which were curved slightly southward at their outer ends to direct the sediment-bearing current more directly at right angles to the westerly littoral current, increased the depth of 8 ft. over the bar in 1875 up to 31 ft. between the jetties and out to deep water. The prolonged flow of the river produced by the jetties, as at the Sulina outlet, carried the main portion of the heavier sediment into fairly deep water, so that the greatest advance of the foreshore in front of the South pass occurred in the 70-ft. line of soundings, though the shallower soundings also advanced. The shoaling, however, in the jetty channel necessitated its reduction in width by mattresses and spurs from 1.000 ft. to 600 ft., and eventually the jetties were rebuilt on lines reducing the channel width to about 6jo ft. Dredging was also required to maintain the stipulated central

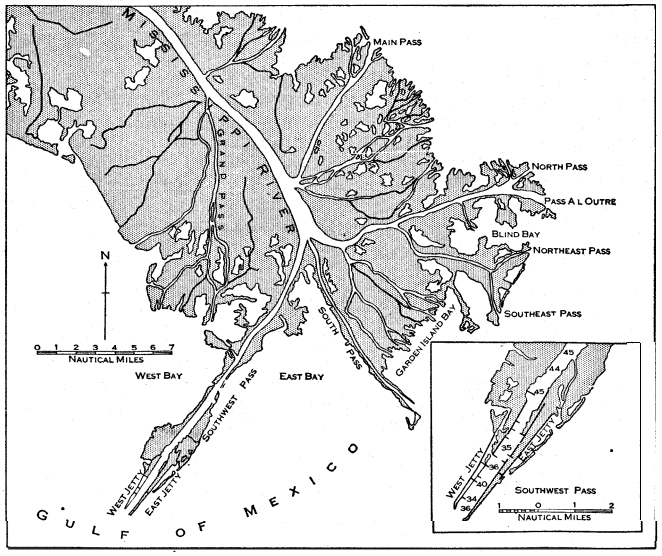

FIG. 9.— THE MISSISSIPPI DELTA (1946) SHOWING (INSET) PLAN OF SOUTHWEST PASS JETTIES

depth of 30 ft.. and 26-ft. depth for a width of 200 ft. out to deep water, while the outer channel was deflected to the east and narrowed by the alluvium carried westward by the littoral current and also deposited in front of the jetty outlet. After 1901 dredging and the increased discharge at the South pass widened the channel across the bar to about 600 ft., and gave it a minimum depth of 30 ft.

In order to provide for the increasing requirements of seagoing vessels, the formation of a channel 35 ft. deep and 1,000 ft. wide through the larger Southwest pass and its 9-ft. bar to deep water in the gulf was begun at the end of 1903. The discharge through this pass is rather more than three times that through the South pass and the bar was double the distance seaward of the outlet. Converging jetties, about 5,600 ft. apart at their land ends and about 3,000 ft. apart at the seaward outlet, were substituted for the parallel jetties constructed at the South pass, and suction dredging was relied upon to maintain the channel between the jetties and across the sea bar. The channel dredging was soon found to be excessive in quantity and in 1916 the project was modified by limiting the channel to a width of 2,400 ft between two parallel interior bulkheads and the extension of the jetties to the go-ft. contour beyond the bar. In 1923 the width was still further restricted to 1,750 ft. by building spur-dikes or groins, and by 1924 a depth of 35 ft. was secured by dredging aided by the scour of the current. The jetties are formed of fascine mattresses weighted with stone and capped with rubble and concrete (see JETTY). They were extended seaward from time to time and in 1956 the east jetty was about $4\frac{3}{4}$ mi. in length from the shore. The west jetty had a length of about $3\frac{3}{4}$ mi. The amount of dredging required to maintain the 35-ft.-deep channel through the pass and over the bar was reduced after the contraction of the width was effected. The artificial improvement and simultaneous maintenance of two entrance channels to the Mississippi river is essential to ensure the uninterrupted passage of vessels. The project was modified so that the following channel dimensions were prescribed: Southwest pass from Head of Passes to the outer end of the jetties, 40 ft. deep by 800 ft. wide; Southwest pass bar, 40 ft. deep by 600 ft. wide; South pass from Head of Passes to the outer end of the jetties, 30 ft deep by 450 ft. wide; and South pass bar, 30 ft. deep by 600 it wide. A dependable navigation channel 35 it deep is maintained via the Southwest pass. **A** study and a hydraulic model experiment were under way in the mid-1950s for the purpose of determining thc morks necessary to provide a dependable 40-ft channel.

The US congress through the River and Harbor act of Jan 21, 1927, assigned to the secretary of the army and to the chief of engineers, U.S army, the duty oi making surveys, with a view to the formulation of general plans for the most effective improvement of the U.S navigable streams and their tributaries. The Flood Control act of Mav 1j, 1928, amplified this duty with respect to the trihutaries of the Mississippi river The River and Harbor act of Aug 30, 1935, authorized the chief of engineers to make such supplemental studies as might be warranted Under these authorizations and subsequent acts of congress the corps of engineers investigated and reported on practically every river of any importance in the United States. Many of these surveys were published as congressional documents.

IMPROVEMENT OF TIDAL RIVERS FOR NAVIGATION

Whereas the size of tideless rivers depends wholly on their freshwater discharge, the condition of tidal rivers is due to the configuration of their outlets, the rise of tide at their mouths, the distance the tide can penetrate inland and the space available ior its reception. Accordingly. tidal rivers sometimes, even when possessing a comparatively small iresh-water discharge, have much better natural navigable channels at high tide than the largest deltaic rivers, as shown by a comparison of the Thames, the Humber and the Elbe with the Danube. the Nile and the Mississippi. Tidal water is, indeed. unlimited in volume; but, unlike the drainage waters, which must be discharged into the sea, it only flows up rivers where there is a channel and space available for its reception Consequently, works which exclude the tide irom a river may have injurious effects on the channel, as did the sluices which were erected long ago across the fen rivers of eastern Anglia to secure the low-lying lands irom the inroads oi the sea The tidal influx is also liable to be reduced by the accretion which may result in an estuary irom the construction of training morks. The aims of all tidal river improvement should be to facilitate to the utmost the flow of the flood tide up a river, to remove all obstructions from the channel so as to increase the scouring efficiency of the flood and ebb tides and to reduce to a minimum the period of slack tide when deposit takes place.

Tidal Flow in a River.—-The progress of the flood tide up a river and the corresponding ebb are clearly shown by a diagram giving a series oi tidal lines obtained from simultaneous observations of the height of the river. The steep form assumed by the ioremost part of the flood-tide lines on some rivers indicates the existence of a bore. This is caused by the sandbanks in the channel obstructing the advance of the flood tide, till it has risen sufficiently in height to rush up the river as a steep, breaking wave, overcoming all obstacles and producing a sudden reversal of the flow and abrupt rise of the water level. Such

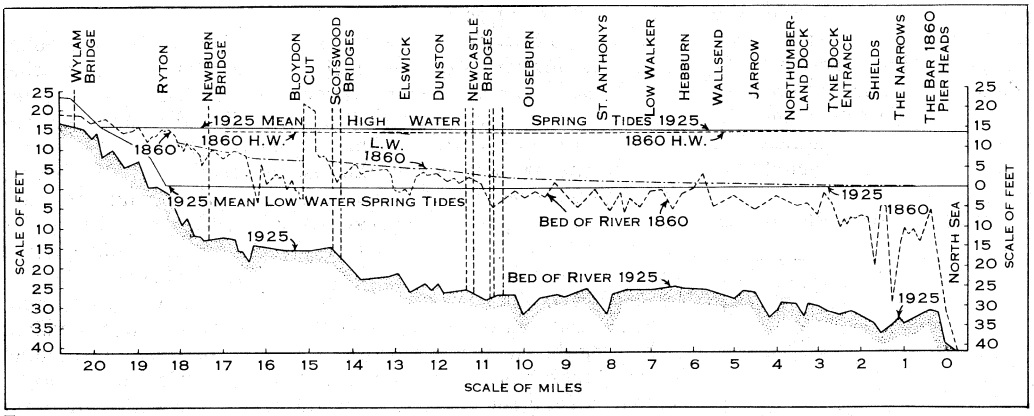

FIG. 10.—TYNE RIVER FROM THE SEA TO WYLAM: LONGITUDINAL SECTION OF THE CENTRE LINE OF THE RIVER SHOWING THE DEEPENING OF THE CHANNEL AND ALTERATION IN WATER LEVELS BETWEEN 1860 AND 1925

phenomena are observed on the Severn, the Seine, the Amazon and other rivers. A bore indicates defects in the tidal channel, which can be reduced only by lowering the obstructions and by the regulation of the river. No tidal river of even moderate length is ever completely filled by tidal water; for the tide begins to iall at its mouth before the flood tide has produced high water at the tidal limit. Every improvement of the channel, however, expedites and increases the filling of the river, while the volume of water admitted at each tide is further augmented by the additional capacity provided by the greater efflux of the ebb, as indicated by the lowering of the lorn-\eater line.

Deepening Tidal Rivers by Dredging.— The improvement of tidal rivers mainly by dredging is specially applicable to small rivers which possess a width sufficient ior navigation like the Clyde and the Tyne; for such rivers can be considerably deepened by an amount of dredging which would be quite inadequate for producing a similar increase in depth in a large, wide river with shifting channels. Both the Clyde below Glasgom and the Tyne below Newcastle were originally insignificant rivers, almost dry in places at low water of spring tides; and the earliest works on both rivers consisted mainly in regulating their flow and increasing their scour by jetties and traimng works. They were improved, after 1840 on the Clyde and after 1861 on the Tyne, by continuous systematic dredging. The Clyde was given a minimum depth of 27 ft. in the channel at low water of spring tides up to Port Glasgow; 25 ft. up to Rothesay dock and 24 ft. up to Glasgow harbour. A depth of 32 ft. at low water was provided alongside some of the quays. The Tyne was progressively deepened (fig. 10) until in 1929 the channel from the sea to the Northumberland dock (3½ mi.) had a minimum depth at low water spring tides of 30 ft.; from there to Derwenthaugh, above Newcastle, 25 ft.; and about 12 ft. on to Newburn, the rise of tide at springs increasing these depths by 15 ft.

The minimum low-water depth in the Thames river below Thames Haven in its natural state mas about 27 ft. (*see* HARBOURS). A channel at least 30 ft. deep at low water spring tides extends from the sea to King George V dock, 37 mi. above the Nore and Shoeburyness (fig. 11). Shallow portions of the channel between Shoeburyness and Purfleet were dredged and above Purfleet the river was considerably deepened throughout its course to secure this depth. Above the King George V dock the river was dredged to lesser depths at low water, decreasing to 14 ft. at London bridge.

Regulation and Dredging of Tidal Rivers.— Considerable improvements in the navigable condition of tidal rivers above their outlets or estuaries can often be effected by regulation works aided by dredging Esamples are the Kervion between Bilbao and its mouth, the Weser from Bremen to Bremerhaven at the head of its estuarv and the Whangpoo from Shanghai to Woosung uhere it enters the Yangtze estuarv These works resemble in principle the regulation works on large rivers with onlv a fresh-water discharge: hut on tidal rivers the channel should be trained with an enlarging width seaward to facilitate the tidal influx

To secure a good and fairly uniform depth on a tidal river, it is essential that the flood and ebb tides should follow the same course in order to combine their scouring efficiency and form a single, continuous, deep channel In wide, winding leaches. however, the flood tide in ascending a river follows as direct a course as practicable; and on reaching a bend, the main flood-tide current, in being deflected from its straight course, hugs the concave bank and, keeping close alongside the same bank beyond the bend, cuts into the shoal projecting irom the convex bend of the bank higher up, forming a blind shoaling channel as clearly indicated near Brul point in fig. 12. This effect is due to the flood tide losing its guidance, and consequently its concentration, at the change of curvature beyond the termination of the concave bank, where it spreads out and passes gradually over, in its direct course, to the next concave bend above along the opposite bank. The ebb tide, on the contrary, descending the river, follows the general course of the fresh-water discharge in all rivers. its main current keeping close along the concave bank and crossing over opposite Brul point to the next concave bank below. The main currents, accordingly, of the flood and ebb tides in such reaches act quite independently between the bends, forming channels on the opposite sides of the river and leaving a central intervening shoal or bar crossing.

In tidal rivers the main ebb current, being reinforced by the fresh-water discharge, generally forms the navigable channel, which is scoured out during floods. Narrowing the river between the bends to bring the two channels together would in certain cases unduly restrict the tidal flow; and in a river such as the Hooghly, dependent on the tidal flow for the maintenance oi its depth for two-thirds of the year, with channels changing with the met and dry seasons and even shifting their position from day to day, deepening by dredging can never be permanent. Hitherto, frequent redredging was relied on for maintaining the requisite depths at the bar crossings in the Hooghly.

The training and dredging works carried out in the Whangpoo after 1906 were successful in deepening the alluvial channel of the river to about 30 ft. at low water up to Shanghai including the bar crossing in a wide reach between Gough Island and Woosung where formerly the low-water depth was no more than 13 ft. to 1j ft. The problem which had to be faced differed from that of the Hooghly in that the volume of the land-water runoff is relatively small. Moreover the concave bank of the river above the crossing mas being rapidly eroded, accentuating a sharp bend below it. The condition of the lower part of the river is shown in fig. 13.

The erosion of the Taylor's bank, forming the concave side of the main sea channel oi the Mersey river: which threatened to intensify the bend to a dangerous degree. was countered by the revetting with stone of the concave face of the bank below low water (see HARBOURS).

The average rate of enlargement (of width) adopted for the trained channel of the Nervion, in proportion to its length, is 1 in 75 between Bilbao and its mouth; 1 in 71 for the Weser from Rremen to Bremerhaven; and about 1 in 73 for the Whangpoo from Shanghai to its outlet; and these ratios correspond very nearly to the enlargement of the regulated channel of the Clyde irom Glasgow to Dumbarton of 1 in 83, and of the Tyne irom Kewcastle to its mouth of 1 in 75. Accordingly a divergence comprised between 1 in 70 and 1 in 80 for the regulated or trained channel of the lower portion of a tidal river with a fairly level bed may be expected to give satisfactory results. The divergence as originally laid down for the Seine training works, 1 in 200, was found to be too small. (*See* fig. 14.) In rivers in which the channels are

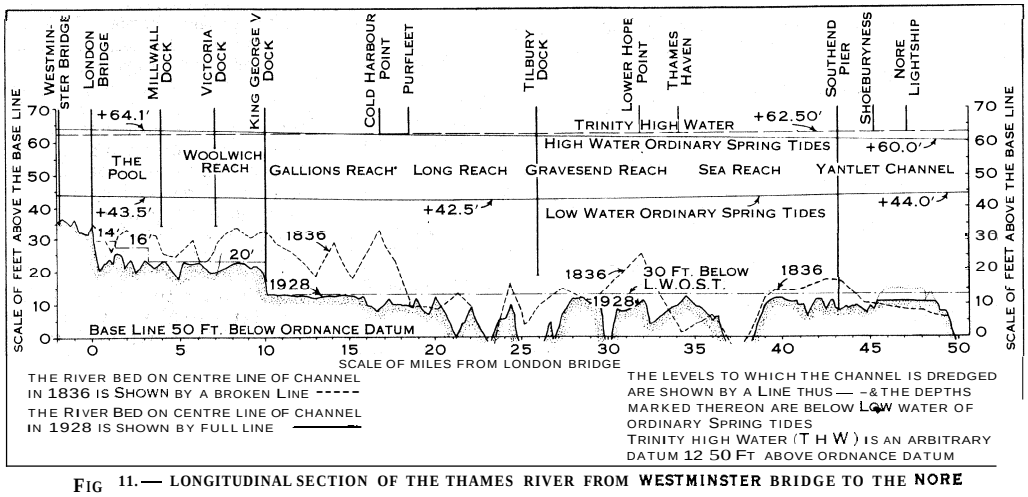

FIG 11.— LONGITUDINAL SECTION OF THE THAMES RIVER FROM WESTMINSTER BRIDGE TO THE NORE

more or less in natural condition, such as the Thames, the Humber and the Scheldt, the divergence is nearly 1 in 50.

Effect of River Deepening on Tidal Levels.—The general effect of deepening and regulating the tidal section of a river by dredging and the removal of obstructions is to facilitate the propagation of the flood tide up the channel and the efflux of the ebb. Consequently such works often result in the lowering of the low-water level and the raising of the high-water level in the upper part of the improved channel and sometimes above it. Thus the deepening of the Tyne river raised the level of mean high water spring tides at Newcastle about 1 ft. and lowered the water level by 2 ft. at Newcastle quay. In the Tyne river, the highest high water on record since 1880, 4 ft. 3 in. above high water ordinary spring tide, occurred in Dec. 1921 and again in Feb. 1943. The lowest low water recorded on the Tyne since 1880, 3 ft. 8 in. below low water ordinary spring tide, occurred March 13, 1914. The average low-water level at Glasgow fell 2 ft. after 1873 and the rise in spring tides increased by 1 ft. 8 in.

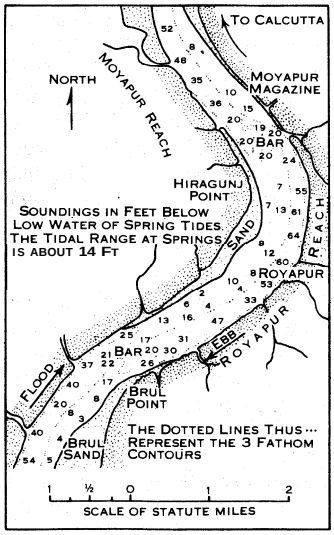

FIG. 12.—HOOGHLY RIVER SHOWING THE MOYAPUR AND ROYAPUR BAR CROSSINGS (1946)

The average high-water level in the Thames at Chelsea increased 8 in. between 1890 and 1927, a period which corresponds with the dredging carried out on a large scale in the lower reaches of the river. The maximum flood levels also increased steadily after 1874 when a tide rose 16 ft. 10 in. above ordnance datum (O.D.) at Westminster, considerably higher than any previous record. This height was exceeded on several later occasions, the highest recorded at Westminster up to the end of 1927 being 17 ft. 6 in. in 1881, the same level being reached again in 1882. These high levels were, however, far surpassed by the disastrous tidal flood of Jan. 6–7, 1928 (see *Report: Floods From the River Thames,* Cmd. 3045, 1928), when 18 ft. 3 in. above O.D. was reached at London bridge (equivalent to about 18 ft. 5 in. at Westminster).

Works at the Outlet of Tidal Rivers.—Tidal rivers flowing straight into the sea, without expanding into an estuary, are subject to the obstruction of a bar formed by the heaping-up action of the waves and drift along the coast, especially when the fresh-water discharge is small. The scour of the currents is often in such cases concentrated and extended across the beach by parallel jetties for lowering the bar, as at the outlets of the Maas and the Nervion rivers. (*See* HARBOURS; JETTY.)

Training Works Through Estuaries.—Many tidal rivers flow through bays, estuaries or arms of the sea before reaching the open sea, as, for instance, the Mersey through Liverpool bay, the Tees through its enclosed bay, the Liffey through Dublin bay, the Thames, the Ribble, the Dee, the Shannon, the Seine, the Scheldt, the Weser, the Elbe and the Yangtze through their respective estuaries, the Yorkshire Ouse and Trent through the Humber estuary, the Garonne and Dordogne through the Gironde estuary and the Clyde, the Tay, the Severn and the St. Lawrence through firths or arms of the sea. These estuaries vary greatly in their tidal range, the distance inland of the ports to which they give access and the facilities they offer for navigation Some possess a very ample depth in their outer portion, though they generally become shallow toward their upper end; but dredging often suffices to remedy their deficiencies and to extend their deepwater channel. Thus the St. Lawrence, which possesses an ample depth from the Atlantic up to Quebec, was rendered accessible for large seagoing vessels up to Montreal by a moderate amount of dredging, while dredging was resorted to in parts of the Thames and Humber estuaries and on the Elbe below Hamburg to provide for the increasing draft of vessels; and the Mersey bar in Liverpool bay, about 11 mi. seaward of the actual mouth of the river, was lowered by suction dredging from a depth of about 9 ft. down to about 26 ft. below low water of equinoctial spring tides.

A remarkable improvement was effected in the navigable condition of the upper portion of the Seine estuary by training works, begun in 1848; for in place of a shallow, intricate channel through shifting sandbanks, whose dangers were at times intensified by a bore, a stable channel was provided down to St. Sauveur, rendering access easy as far up the river as Rouen for vessels drawing up to 23 ft. at high-water neaps and up to 27 ft. at high water of spring tides. The channel itself, however, was originally made too narrow between Aizier and Berville and was subsequently enlarged, and large tracts of land were reclaimed in the upper estuary. The reduction in tidal capacity due to the reclamations, together with the fixing and undue restriction in width of the channel, occasioned large accretions at the back of the lower portions of the training walls and at the sides of the estuary beyond them, and an extension of the sandbanks seaward.

Experience proved that training works through sandy estuaries, by stopping the wanderings of the navigable channel, produce an increase in its depth and, consequently, in the tidal scour for maintaining it. This scour, however, being concentrated in the trained channel, is withdrawn from the sides of the estuary, which in its natural condition is stirred up periodically by the wandering channel and, therefore, accretion takes place in the parts of the estuary from which the tidal scour and fresh-water discharge have been permanently diverted.

This accretion reduces the tidal capacity of the estuary and, producing a diminution in the tidal volume passing through the outlet, should not be raised more above low-water level than absolutely necessary to fix the channel. Experiments with a model, molded to the configuration of the estuary under consideration and reproducing in miniature the tidal ebb and flow and fresh-water discharge over a bed of very fine sand, in which various lines of training walls can be successively inserted, are capable in some cases of furnishing valuable indications of the respective effects and comparative merits of the different schemes proposed for works which often have evoked very conflicting opinions.

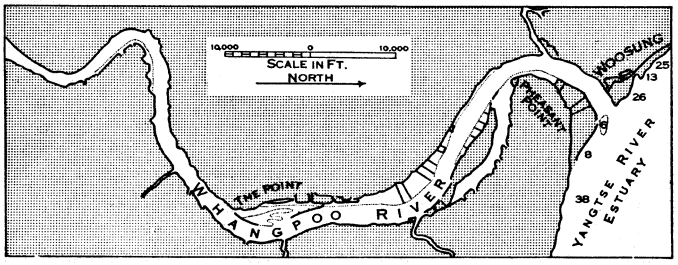

FIG. 13.—LOWER PART OF THE WHANGPOO RIVER (1946). AFTER 1907 THE CHANNEL OF THE RIVER WAS REGULATED BY BUILDING TRAINING WALLS AND GROINS

Gravity Flow.—Much attention is devoted in modern literature on river hydraulics to the phenomena known as gravity currents, which are currents of heavier liquids in currents of lighter liquids. Examples are heavily silt-laden currents in clear water lakes, and salt water currents at the estuaries of rivers moving upstream beneath the sweet water current moving downstream, as for instance in some Scottish lochs and, very probably, in the Nile.

RIVER BRETHREN: *see* BRETHREN IN CHRIST.

RIVER HOG, a name for the African wild pig. It constitutes a genus. *Potamochoerus,* allied to the typical pigs of the genus *Sus (see* SWINE). from which they are distinguishable by the presence in the males of a long horny ridge below the eye, by their thick coat of bristly and often brightly coloured hair and by tufts at the tips of the elongated ears. The red river hog. P. *porcus,* is found in typical form in west Africa. The ear tufts are especially long and the prevailing colour is brownish red; the face and legs are marked with black. while the cheeks, a ring around the eyes, the edges of the ears, the tip of the tufts and the mane are white. It inhabits the dense tropical forests. Through a number of intergrading forms this type is connected with the brownish gray brush pig of South Africa. P. *p. koiropotamus. A* small yellowish-haired representative of the genus (P. *larvatus*) occurs in Madagascar, to which island it must have come from the mainland.

RIVERINA, a district occupying the central south portion of New South Wales, Austr., bounded on the south by the Murray river and on the north by the Lachlan-Murrumbidgee from about Hillston down to the Murray confluence. The eastern boundary runs from the Lachlan above Hillston to Corowa on the Murray, but the lower slopes of the southern tableland are sometimes included in the Riverina region. Except in the east: the whole area is flat. with the rivers falling from ten inches a mile in the east to four to five inches in the west of the area. The rivers meander across vast alluvial plains, periodically flooding and forming distributaries and billabongs (lagoons); in their upper reaches in the east they offer many sites for dams. The soil is prevailingly rich.

The eastern valleys have in the past yielded considerable quantities of gold. both alluvial and reef, especially at Xdelong and Gundagai. but production is now negligible. In 1915 soft black subbituminous coal was discovered near Oaklands.

The greater part of the Riverina provides good natural fodder for sheep grazing and was originally a pastoral area, but improvements in farming (particularly in wheat breeds and in dry farming) and the development of water conservation projects led to great increases in cultivation. Along the southeastern slopes. with their cooler temperature and more reliable rain, much arable farming is carried on, with fruit growing and some dairying. Farther west mixed wheat and sheep farming is characteristic. The great wealth of the Riverina, however. lies in its irrigation farming, the bulk of irrigated land being along the Murray and Murrumbidgee. with a smaller area on the Lachlan. The Murrumbidgee irrigation area consists of 403.256 ac. served with water from Burrinjuck dam and Berembed weir, from which the irrigation channels lead. Leeton (pop. 5,148 in 1954) and Griffith (6,608), about 2.000 irrigation farms and a total population of about 26,000 people are now established in a once sparsely inhabited pastoral area. The farms are either horticultural (principal products: citrus fruits, apricots, peaches. wine grapes and vegetables) or mixed (rice, wheat, oats, meat and wool); the industry of the area is restricted to processing local products: there are wineries, canneries (including the largest in Australia), rice mills-and fruit packing houses. Smaller irrigation areas are at Hay on the Murrumbidgee (6.806 ac.) and Tullakool on the Murray (16,305 ac.); while larger areas on the Murray (Berriquin, 654,050 ac., Wakool, 486,192 ac., Denimein, 156,830 ac. and Denibooth, 303,064 ac.) and on the Murrumbidgee (Waa Waa, 583,111 ac.; Tabbita, 5.980 ac.) are farmed less intensively, water being allotted on the basis that only a portion of each holding will be irrigated. The Snowy Mountains hydroelectric scheme was begun in 1949 to make available a much larger volume of water for irrigation.

The area of the Riverina is 26,533 sq.mi., with a population in 1954 of 88,661. The chief towns are Albury (16.726). Wagga Wagga (19,235), Junee (4,064), Narrandera (4,418). Hay (3.009) and Leeton and Griffith. There were 6,787 holdings, totaling 15,-971,000 ac., with, in 1954–55. 1,003,172 ac. under cultivation (main crops: wheat. wheat hay, oats, barley, rice, lucerne, vegetables, vineyards, orchards, green fodder, grass seed, other hay pastures. sorghum, rye, maize) and over 1.000,000 ac. of sown pastures. Sheep and beef cattle are also raised. (R. M. HL.)

RIVER ROUGE, a city of Michigan, U.S., in Wayne county, bordering Detroit on the southwest, is located on the Detroit and Rouge rivers. The available rail and water transport encouraged industrialization, and manufactures include paper, ships, gypsum products and steel. Most of the residents are employed by local firms. Zug Island, a highly industrialized 400-ac. site formed by a canal dredged between the Rouge and Detroit rivers, is located in the northeast corner of the city The concentration of industry results in favourable tax rates for homeowners and, during normal periods, a solvent municipal economy. Although a site of early French settlement, the nucleus of a town did not appear until 1817 nhen a toll bridge was erected over the Rouge river at River road (Jefferson avenue). With the advent of industrialization. River Rouge was incorporated as a village in 1899. During World War I, mainly because of the construction of the Ford Motor company's River Rouge plant nearby, a population influx occurred uhich, in 1921, resulted in the incorporation of River Rouge as a city. For comparative population figures *see* table in MICHIGAN: *Population.* (E. K. R.)

RIVERS, ANTHONY WOODVILLE, or WYDEVILLE, 2ND EARL (c. 1442–1483), statesman and patron of literature, and author of the first book printed on English soil, was born probably in 1442. He was the son of Richard de Wydeville and his wife, Jacquetta de Luxemburg, duchess of Bedford. His father was raised to the peerage in his son's infancy, and was made earl of Rivers in 1466. Anthony, who was knighted before he became of age, and fought at Towton in 1461, married the daughter of Lord Scales, and became a peer *jure uxoris* in 1462, two years after the death of that nobleman. Being lord of the Isle of Wight at the time, he was in 1467 appointed one of the ambassadors to treat with the duke of Burgundy, and he exalted his office by challenging Anthony, comte de la Roche, the bastard of Burgundy, to single fight in what was one of the most famous tournaments of the age. (*See* Bentley's *Excerpta Historica,* 176–182.) In 1469 Anthony was promoted to be lieutenant of Calais and captain of the king's armada, while holding other honorary posts. His father and brother were beheaded after the battle of Edgecot, and he succeeded in August of that year to the earldom. He accompanied Edward in his temporary flight to the Continent, and on his return to England had a share in the victory of Barnet and Tewkesbury and defended London from the Lancastrians. In 1473 he became guardian and governor to the young prince of Wales. In 1475 and 1476 he went on pilgrimage to the holy places of Italy.

Caxton had in 1476 rented a shop in the Sanctuary at Westminster, and here had set up a printing-press. The first book which he undertook in London was one sent to him by "the noble and puissant lord, Lord Antone, Erle of Ryvyers," consisting of a translation "into right good and fayr Englyssh" of Jean de Teonville's French version of a Latin work, "a glorious fair mirror to all good Christian people." In 1477 Caxton brought out this book, as *Dictes and Sayengis of the Philosophers.* (*See* CAXTON, WILLIAM.) To this succeeded the *Moral Proverbs* of Christine de Pisan, in verse, in 1478, and a *Cordial,* in prose, in 1479. The original productions of Lord Rivers, and, in particular, his *Balades agaznst the Seven Deadly Sins,* are lost.

In 1478 a marriage was arranged between him and Margaret, sister of King James III of Scotland, but it was mysteriously

broken off. He was beheaded by order of Richard III at Pontefract on June 25, 1483. His protection and encouragement of Caxton were of inestimable value to English literature, and in the preface to the Dictes the printer gives an account of his own relations with the statesman which illustrates the dignity and modesty of Lord Rivers in a very agreeable way. Rivers was one of the purest writers of English prose of his time.

"Memoirs of Anthony, Earl Rivers" are comprised in the *Historical Illustrations of the Reign of Edward the Fourth* (ed. W. H. B[lack]).

RIVERS, RICHARD WOODVILLE or **WYDEVILLE,** EARL (d. 1469), served under the duke of Bedford in France, and after his master's death married his widow Jacquetta of Luxembourg. Henry VI created him Baron Rivers in 1448. His associations made him a strong Lancastrian. For some years he was lieutenant of Calais in Henry's interests. In 1459 he was taken prisoner and was sent with his son Anthony to the earl of Warwick at Calais. He was, however, released in time to fight for Henry VI at Towton. Early in the reign of Edward IV Rivers recognized that the Lancastrian cause was lost and made his peace with the new king. The marriage of his eldest daughter, Elizabeth, widow of Sir John Grey of Groby, to Edward on May 1, 1464, secured the fortunes of his family.

Rivers was appointed treasurer in 1466 and a little later was created earl. Elizabeth found great alliances for her younger brothers and sisters, and the Woodville influence became all-powerful at court. The power of this new family was very distasteful to the old baronial party, and especially so to Warwick. Early in 1468 Rivers's estates were plundered by Warwick's partisans, and the open war of the following year was aimed to destroy the Woodvilles. After the king's defeat at Edgecot, Rivers and his second son, John, were taken prisoners at Chepstow and executed at Kenilworth on Aug. 12, 1469. Rivers had a large family. His third son, Lionel (d. 1484), was bishop of Salisbury. All his daughters made great marriages: Catherine, the sixth, was wife of Henry Stafford, 2nd duke of Buckingham (*q.v.*).

For Earl Anthony's connection with Caxton consult William Blades's *Life* of *Caxton* (1861–63).

RIVERS, WILLIAM HALSE RIVERS (1864–1922), English psychologist, physiologist and anthropologist, who specialized in experimental and medical psychology, was born on March 12, 1864, at Luton, near Chatham, Kent. Completing his medical training at St. Bartholomew's hospital, London, he then devoted his attention to problems of physiological psychology—notably the nature of colour vision; and his work in this field and, later, on the influence of drugs (particularly alcohol) and on mental fatigue quickly established his reputation. In 1897 he became director of the first British laboratory for experimental psychology (opened by J. Sully at University college, London); and in the same year he was appointed lecturer on the special senses at Cambridge, where, with C. S. Myers, he was the effective founder of experimental psychology in that university.

Toward the close of 1898 he joined the Cambridge expedition to the Torres strait with A. C. Haddon, C. S. Myers and W. McDougall. With them he administered a number of tests of sensory capacity to the Melanesians, and became keenly interested in anthropological field work. In 1901–02 he made a firsthand study of the Todas, a polyandrous group in southern India, and later paid several visits to Melanesia. In 1908 he was elected fellow of the Royal society.

His two main anthropological publications—The Todas (1908) and his monumental History of *Melanesian* Society (2 vol., 1914)—are of permanent interest. His main contribution was his demonstration of the relation between kinship names and social organization. On the outbreak of World War I he became neurological consultant to the British army, and for the remainder of his life he devoted himself to medical psychology. His critical discussion of Freudian theories in his Instinct and the Unconscious (1920) did much to encourage a more sympathetic attitude toward the new psychoanalytic doctrines. But his main influence was exerted more through personality and his critical contributions at conferences and congresses than by his published writings, and in this way he perhaps did more than any other psychologist of his day toward setting up high standards of scientific rigour in the study of human behaviour. He died on June 4, 1922.

See for a biographical review *The Eagle,* vol. xliii, pp. 2–14 (1924). (CY. B.)

RIVERSIDE, a city of southern California, U.S., is situated on the Santa Ana river at the base of the San Bernardino range, about 55 mi. S.E. of Los Angeles; the seat of Riverside county. Riverside (1960 pop. 84,332) is part of the San Bernardino-Riverside-Ontario standard metropolitan statistical area (1960 pop. 809,782).

Despite nearness to Los Angeles, the city has a strongly individual character, marked by extensive planting of palm, pepper and orange trees. In the 1960s housebuilding was diminishing the orange groves, but these were still extensive.

Settlement in the area began in the 1870s, sponsored by Judge John W. North of Tennessee. Street names (Victoria, Prince Albert, Dufferin) commemorate the largely British and Canadian character of early immigration. The original idea of a silk-cultivating colony was replaced in 1878 by the successful propagation of the Washington navel orange tree; the parent tree still survives. Riverside was incorporated in 1383 and adopted the city-manager form of government in 1953.

The city is the location of a general campus of the University of California, including the citrus experiment station (founded 1907). a college of letters and science (1954) and a graduate school (1960). Other educational institutions include Riverside City college (Jr.) (1916), California Baptist college (1955) and Sherman institute (1901), a school for Indians. Its unique hotel, the Mission inn, is a show place of Spanish-style architecture.

Riverside's climate is dry and warm. Its economy, formerly based almost entirely on oranges, is diversified and includes the manufacture of aircraft motors, precision instruments, air-conditioning equipment, paints and building materials. It remains, however, an important food distribution centre with extensive citrus-fruit and vegetable packing. (A. C. TR.)

RIVES, AMÉLIE: see TROUBETZKOY, AMÉLIE.

RIVES, WILLIAM CABELL (1793–1868), U.S. political leader and diplomat, was born in Nelson county, Va., on May 4, 1793. He attended Hampden-Sydney college, Hampden Sydney, Va., and the College of William and Mary, Williamsburg, Va., was admitted to the bar and practised in Nelson and Albemarle counties. A Democrat. he served in the state constitutional convention, in the Virginia house of delegates and in the federal house of representatives. From 1820 to 1832 he was minister to France; in 1833 he entered the United States senate but resigned in the following year. From 1836 to 1845 he again served in the senate, and in 1849–53 was again minister to France. In Feb. 1861 he was a delegate to the peace conference in Washington; he opposed secession but was loyal to his state when it seceded, and was a representative in the Confederate congress during the Civil War. He died at the country estate of Castle Hill, Albemarle county, Va., on April 25, 1868. Rives was the author of Life and Times of James Madison (3 vol., 1859–68), the completion of which was prevented by his death. He was the father of ALFRED LANDON RIVES (1830–1903), an engineer of some prominence, whose daughter AMÉLIE RIVES (Princess Troubetzkoy) (1863–1945) became well known as a novelist.

RIVET is a headed pin or bolt used as a permanent fastening in metal work by forming a head on the plain end by the process of hammering or by direct pressure. Cold riveting is practicable for small sizes in copper, brass, aluminum, iron and steel, but the larger sizes have to be heated, in the cases of iron and steel, in order to secure rapid and easy closing.

Machine riveting in small sizes is done either in a power press, the ram of which works a snap and closes the tail with a blow,

or with a rotary rivet spinning machine, with hard steel rollers which spin the tail quickly and noiselessly into shape. In engineering structures, machine riveting is employed whenever practicable, portable pneumatic hammers, or fixed or portable hydraulic riveters being used.

The various shapes of rivet-heads or tails include the countersunk, beaten flush into a conical recess in the plate, the cup- or roundhead, the panhead, which has sloping sides and flat top, the conical with sloped sides ending in a point, and the thin flathead coopers' or tinmen's rivets. Bifurcated rivets for belting and harness have thin heads, but the tails are split and opened like a paper fastener. A great deal of gas or electric welding has been substituted for riveting in the case of hollowware and other sorts of sheet metal product. Electric welding is an alternate method for the connection of structural members, such as columns and beams, in building construction. See also PNEUMATIC TOOLS.

CONVENTIONAL SIGNS FOR RIVETING SHOWING HOW THE DRAFTSMAN DRAWS RIVETS IN PLAN AND ELEVATION ON ALL STRUCTURAL DRAWINGS

RIVIERA, the narrow coastland between the mountains and the sea around the Gulf of Genoa in the north of Italy, and in France from Nice on the west to Spezia on the east. The name is derived from riva (Lat. *ripa*) meaning "bank." It is usually spoken of as Riviera di Ponente ("the coast of the setting sun," the portion between Nice and Genoa), and as Riviera di Levante ("the coast of the rising sun," the portion from Genoa to Spezia). All this district, being open to the south and sheltered from the north and east winds, enjoys a remarkably mild climate (winter mean, about 49° F.); the vegetation in many places is of a subtropical character (*e.g.*, the pomegranate. agave, prickly pear, date, palm and banana). Large numbers of flowers. especially roses, violets, hyacinths, etc., are grown near Nice, Mentone, Bordighera and other towns for the London and Paris markets. The uncommon mildness of the climate, conjoined with the natural beauty of the coast scenery — the steep sea-crags, the ruined towers and the range of the Maritime Alps — attracts thousands of invalids and convalescents to spend the winter there. and these resorts are frequented for sea bathing in summer. Proceeding from west to east, the following are the places to which visitors principally resort: Nice, Monaco (an independent principality), Monte Carlo, Mentone (the last town on the French Riviera), Bordighera, Ospedaletti, San Remo, Alassio, Nervi, Santa Margherita, Rapallo, Sestri Levante, Levanto. The railway which runs close through the Riviera burrows through the many projecting headlands by means of more than 80 tunnels.

RIVIÈRE, JACQUES (1886–1925), French essayist, whose delicacy of perception and acute sense of responsibility had a profound influence on the writers associated with the *Nouvelle* Revue *française* (*N.R.F.*), was born in Bordeaux on July 1j 1886. He was secretary of the N.R.F. immediately before World War I and became editor in 1919. Among his friends were André Gide, Paul Claudel. Charles Peguy and Jacques Copeau, and he was an early admirer of Marcel Proust. He himself aspired to write an analytical novel (*Aimée,* 1922; and the unfinished Florence, published posthumously, 1935). His persona1 anxieties and aspirations are best reflected in his letters to Alain-Fournier (his brother-in-law), in his correspondence with Claudel, published after his death, and in his essay A la trace de Dieu (1925). He was brought up a Catholic, but later an oppressive awareness of "the reality of nonbeing" prevented him from accepting the Christian faith, much as he would have liked to do so. He died in Paris, on Feb. 14, 1925, before the promise of his work had been fulfilled. His other writings include *L'Allemand* (1918), *Carnet* de guerre (1929), *Études* (1912) and Nouvelles Etudes (published posthumously, 1947).

See the commemorative number of the *Nouvelle* Revue *française,* vol. 24 (1925). (A. PE.)

RIYADH, the capital of Saudi Arabia. lies 535 mi. N.E. of Jidda on the Red sea, and 250 mi. S.W. of Dammam on the Persian gulf. with which, after 1951, it was connected by a railway (350 mi long). In the mid-1950s it was planned to extend this line. via Buraida and Madina (Medina), to Jidda and Mecca (about 1,000 mi.). From Madina it was to be connected to Damascus by the Hijaz railway when repaired. Meanwhile Riyadh is linked with all parts of the kingdom and the neighbouring Arab countries by an extensive network of rough but passable roads and some lengths of macadamized road. Since soon after World War II the Saudi capital has been linked with the outside world by air services operating from Riyadh itself, Dhahran and Jidda, and by a system of wireless stations equipped uith telephones. After the 1930s the camel was discarded as the normal carrier of news, passengers and goods

The discovery of oil and the resulting institution of modern means of communication have revolutionized the life of the desert kingdom; the general tendency has been toward the development of large urban communities at the expense of what was a village and tribal economy. Riyadh best illustrates this process. The old walled town of approximately 30.000 inhabitants remained intact until the end of World War II, though a few palaces and villas made their appearance outside the perimeter toward the end of this period. It formed an irregular square of 600 yd. each way. By 1951 various minor expansions had raised the population to about 60,000. Since then the walls have gone, and most of the old houses have been destroyed to make room for modern buildings and boulevards, while the town has expanded in every direction over the uprooted palm groves into the desert. The town has become a city, covering an area of 100 sq.mi. and containing a population of more than 300,000, though exact figures are not available as no census has ever been taken. Also the character of the population, once exclusively Najdi, has changed beyond recognition; at least half of the increase must be credited to immigrants from the neighbouring Arab countries in search of employment and commercial opportunity. Most of them came from Syria. Lebanon, Egypt, the Yaman (Yemen) and the Hijaz (Hejaz). Needless to say, the old puritan way of life, the outstanding feature of the old town, became submerged by the influx of these elements.

In the centre of the old town the royal palace, which once represented "all that is best in modern Arabian architecture." has made way for a great concrete structure of cubist affinities, serving as the headquarters of the local provincial government. Opposite it. the old Wahhabi cathedral with its low minaret has disappeared in favour of a large concrete building. 200 yd. long and wide, with tao tall minarets tapering by stages to a ball point and equipped with loud speakers to relay the calls to prayer and the services. The old and famous fort df Mismak is virtually the only building of former times which survives intact; it serves as it has long done, as the local prison. The palace square is a busy crossroads from which broad Tarmac streets, lined with modern shops, run east, west, south and north into the modern suburbs of greater Riyadh. The north road, leading to the airport, is lined with palatial buildings, constructed to house the

various ministries of the central government. Beyond them are the barracks of the royal guard. the royal military college for the training of officers, with villas to house them and their families, and the military hospitals. The road ends at the government workshops and the airport. The east road. continuing ultimately to the Kharj province, the principal military centre of the country, leads to the railway station. The south road goes for a considerable distance through the old town, greatly expanded, and passes through new residential suburbs to the valley of Wadi Hanifa and the king's country palace. Finally, westward, a broad double roadway, divided in the middle by gay flower beds, as is the airport road, leads through rows of palatial mansions to the royal palace of Nasiriya, standing in its own vast grounds. The main buildings are of pink-tinted concrete in a mixture of styles ranging from pseudo-Moorish to modern European, a showy and on the whole pleasing group of buildings containing a population slightly larger than that of the Vatican City. Besides these. in the palace enclave, there are a large mosque with tall minaret; a museum still under construction in the mid-1950s; a college for the royal children (male) and the sons of courtiers; barrack accommodations for the royal guard; a zoo containing lions, rhinoceroses, elephants. baboons, bears, ostriches. oryxes and gazelles. etc.; and two imposing gates at the eastern and western extremities. with ornamental avenues and double roadways connecting them with all parts of the palace complex. The general impression is one of luxury and modernity, an epitome of the aspirations of modern Arabia.

Finally. the whole city is lavishly equipped with electric power for all purposes, and makes a brilliant display by night, as seen from the air. An ample water supply is assured to the large and ever-growing population by the harnessing of two groups of wells in Wadi Hanifa, north and south of the city, to a network of pipes circulating to every part thereof. This supply was reinforced by a deep artesian well. drilled by French experts, which raised the potential capacity of the area to about 10,000 000 gal. a day. Much of this goes to the beautification of the city with gardens and green spaces, while traffic lights and roundabouts (one-way circular systems) regulate the immense amount of motor traffic. Riyadh is in every sense a modern city. fully equipped with all the amenities of life. (H. ST. J. B. P.)

RIZAL, JOSÉ (1861–1896), Filipino patriot and inspirer of Philippine nationalism, sought to prove throughout his career that Filipinos were the intellectual and moral equals of their Spanish masters; he also worked for fundamental political and social reforms. These aims pervaded his writing, most of which was done in Europe, where, with one brief interruption. he resided betneen 1882 and 1892. His education, centring in medicine but extending to many fields, was acquired in the Philippines and Europe. His two novels. Noli Me *Tangere* (1887) and El *Filibusterismo* (1891), vividly pictured the evils of Spanish rule in the Philippines. In 1890 he published an annotated edition of Morga's Sucesos de las Islas *Filipinas,* hoping to show that the Philippines had its own history before Spanish rule. He also wrote articles for La Solidaridad, a Filipino reformist periodical published in Spain.

Rizal returned to Manila in 1892 and founded a nationalist reformist society (Liga Filipina), with the result that the Spanish exiled him to Dapitan on northwest Mindanao (1892–96). When the Philippine revolution of 1896 began, Rizal, who was on his way (via Spain) to Cuba for medical service with the Spanish army, did not take any direct part. He was, nevertheless. arrested aboard ship and brought back to Manila to stand trial for complicity in the insurrection. A military court found him guilty, and he was shot Dec. 30, 1896. His death enhanced his already great prestige among Filipinos and stimulated national sentiment.

See Rafael Palma, *The Pride* of *the Malay Race,* trans. *by* Roman Ozaeta (New York, 1949); Frank C. Laubach, *Rizal: Man and Martyr* (Manila, *1936);* W. Retana, *Vida* y *Escritos del Doctor Jose' Rizal* (Madrid, *1907).* (E. C. CN.)

RIZA SHAH PAHLAVI (1877–1944), shah of Persia (Iran) from 1925 to 1941, was born in Mazandaran, the son of an army officer. Entering the army at an early age, he showed such aptitude that promotion was rapid, and he rose at length to the command of the Cossack division. In 1921, in conjunction with Zia ad-Din, he marched on Tehran with about 4,000 men and compelled the government to resign. Zia became prime minister, while Riza Khan (as he was then known) took over the ministry of war and the command of the army. In 1923 he became prime minister and virtual ruler. Two years later, after Ahmad Shah Qajar had left the country. Riza Khan was made shah and the sovereignty was vested in the Pahlavi dynasty. Riza Shah proceeded to carry out reforms on western lines, largely on the model of Kemal Atatiirk in Turkey. He broke the power of the tribes, put down brigandage and restored the authority of the central government. His greatest achievement was the construction of the Trans-Persian railn ay, completed in 1938.

Riza Shah, who had employed many Germans in his industrialization program. rejected a joint request by Britain and the U.S.S.R. in 1941 for the expulsion of the Germans, and troops were sent into Iran to prevent Germany from seizing control. Riza Shah thereupon abdicated in favour of his son, Mohammed Riza Pahlavi, and was sent first to Mauritius and then to South Africa. He died in Johannesburg on July 26, 1944. (L. Lo.)

RIZZIO or RICCIO, **DAVID** (*c.* 1533–1566), secretary of Mary (*q.v*), queen of Scots, mas a native of Turin and went to Scotland in 1561 in the train of the Piedmontese ambassador. The queen wanted a bass singer, and he entered her service as a musician, becoming also her valet de *chambre,* and in 1564 private foreign secretary. After her marriage to Darnley in 1565 his influence with Mary became paramount. His elevation aroused the active hostility of Darnley and the other nobles, and he was suspected of being the queen's lover. On March 9, 1566, the earls of Morton and Lindsay. with armed followers. entered Mary's supper chamber at Holyrood. seized Rizzio. hacked him to death with daggers, and threw his body into the courtyard.

ROACH, JOHN (1813–1887), **U.S.** shipbuilder, who has been called "the father of iron shipbuilding in America," was born in County Cork. Ire., on Dec. 25, 1813 He emigrated to the United States at an early age, and worked at the Howell (N.J.) ironworks where he was taught the trade of iron molding Later, with other artisans he established an ironmorks in New York city. He acquired a number of marine-engine plants and in 1868 the Morgan ironnorks in New York city. After purchasing shipyards in Chester, Pa, he built many iron ships for the government and private companies. Although he was not the first to build such ships. he became a leading authority and builder. He was also a vigorous advocate of a strong U.S. merchant marine. He voluntarily closed his aorks in 1885 when the secretary of the navy, overruling the naval advisory board, rejected the "Dolphin," a dispatch boat built by Roach, and also canceled Roach's contract to build for the navy three cruisers—the "Atlanta," "Boston" and "Chicago"; construction of the cruisers had begun in 1883. Roach died on Jan. 10, 1887. at New York city.

ROACH (*Rutilus rutilus*), a cyprinid fish of England. Europe and Siberia. It is a moderately deep, silvery fish. Specimens of more than three pounds are rare. In the United States the term has been applied to various members of the carp family, and the "golden shiner" minnow has been sometimes called a roach.

ROAD RUNNER (Geococcyx *californianus*), a bird characteristic of the deserts of northnest South America, Mexico and southern U.S. It runs with head lowered and tail horizontal, stopping from time to time. when the tail assumes an almost vertical position. The road runner belongs to the cuckoo family (Cuculidae).

ROADS AND STREETS. A road system implies central government over a wide area with power to command labour and with technical experts to supervise the work The first known example of an empire larger than could be served by a single river for transport was that of Sargon, about 2600 B.C.. whose rule extended from Babylonia to the Mediterranean. About this time, or even earlier, there must have been lengthy trade routes. since tombs in this area dating back to 3000 B C. contain the blue gem lapis lazuli, mined in Afghanistan.

Any dates earlier than about 800 B.C. are usually conjectural, but there is a record of that date which claims to detail the main roads of Sargon's empire. In 800 B.C. there were in Assyria traces

of a highway system of roads, built on low embankments in the valleys and with the gradients on hills eased with cuttings. Tradition assigns all such engineering feats to the reign of Semiramis, the great Assyrian princess; all that is really known is that these roads were already of great antiquity in 800 B.C. In 1928 workers for the Field Museum of Natural History. Chicago, discovered a wheeled chariot at Kish. which they dated at about 3200 B.C. There were highly skilled stonemasons at that time. so it may well be that streets in towns began to be paved with flat stones about the time that chariots came into general use, since rammed earth is too weak to carry much wheeled traffic. There is a record, dated about 2200 B.C.. of Babylonian stonemasons laying two parallel rows of worked stones to take oxcarts whose wheels were about five feet apart, and remains of paved roads have been found in Crete which are believed to date back to 1500 B.C.

By 500 B.C there were two great roads connecting the Mediterranean with the top of the Persian gulf. One began at Sardis, near Smyrna, and passed through Ankara (Angora) eastward to Nineveh (near Mosul), crossing the Euphrates, the Tigris and the Great and Little Zab to end at Susa. Herodotus, the Greek historian (484–425 B C), travelled this road (the ancient royal road) and describes its relay stations, fortified hostels, garrisons and toll gates. The other road ran roughly parallel to it but farther south, to reach the Mediterranean near Alexandretta. There was also a road connecting Babylon with Egypt; this was built by Cyrus after his conquest of Babylon in 539 B.C. and is the "highway" mentioned in the prophetic books of the Bible (*e.g.*, Isaiah xl, 3–5).

By about A.D. 200 there were caravan routes linking the Roman empire with China for the importation of silks and jade and other articles of luxury. One route started at Chungking and passed through Burma and northern India to Delhi and thence to Tehran and Baghdad, or farther north to Samarkand and then west across the Caspian sea and through Tiflis to the Black sea. There are believed to have been at least two more northerly routes through Russia, since articles of jade are found in ancient barrows or tombs (dated 100 B.C. to A.D. 100) in the Crimea and in southern Siberia. These caravan routes were never safe and when navigators were skilled enough to cross the Indian ocean they were largely abandoned.

The growth in power of the Roman empire at this period led to the construction of an elaborate system of paved roads in western Europe. There was first the Via Appia from Rome to Brindisi, from which troops were shipped to Africa and the east. Then in the 2nd century B.C. the Via Egnatia was built from Durazzo. through northern Greece to Salonika, and later the Via Domitia was built across southern France and into Spain. Augustus (63 B.C. to A.D. 14) improved this road and drove it as far as Cadiz and also built two roads across the Alps. The first corresponds to the modern Petit St. Bernard and was suitable for wheeled vehicles; the second was a track for pack animals through Briançon. These two roads converged on Lyons, which was the centre of the Roman road system in France. From Lyons four main roads led respectively to the Baltic and the camps on the Rhine, the channel ports, Bordeaux and the Mediterranean sea. These and other main roads were planned for the imperial courier service and for the rapid movement of troops; they were furnished with posting stations with relays of horses about every 10 mi. and with lodging places (mansiones) about every 25 mi. These roads were the viae publicae regales. Where possible they took the direct line between towns, marshy ground being crossed by using piles and embankments, and cuttings and even tunnels being constructed in hilly country. A network of smaller roads (viae *vicinales*) linked up the smaller towns and there were also recognized earth tracks (viae terrenae). Drusus, the stepson of Augustus, began the building of a highway across the Alps to provide a direct route from the Adriatic to Augsburg and the Danube; it passed by Trento and over the Brenner and Reschen Scheideck passes. This road was finished by his son, the emperor Claudius, who also constructed a route over the Alps by the Great St. Bernard pass to Augst, near Basle, and from there to the permanent camps on the Rhine.

By A.D. 100 the danger of invasion from the north and east had become obvious; to meet it Trajan constructed a highway from the Rhine to the Black sea, and he and his successors built many bridges. All this was to no avail; the slow collapse of the Roman empire ushered in a thousand years of chaos and petty kingdoms whose resources were far too small for the upkeep of such roads: where dressed stone had been used in their construction they were dug up and the stones used for building. Brigandage and lawlessness prevented people from travelling, and roads and bridges fell into ruin.

Britain was a Roman colony for about 350 years (A.D. 43 to A.D. 410) and the road system was laid out to meet the strategy of the conquest, which was in stages. Thus the Fosse way running from Exeter to Lincoln through Ilchester, Bath, Cirencester and Leicester ran just behind the front line, which separated a lowland area that had been conquered and organized under a civil administration from a highland area still the scene of military operations. This line was fed by a series of roads radiating from the Roman base at London. The last of these front lines was the great wall between Carlisle and Newcastle. The principal road between London and the wall was Ermine street, via Lincoln and York. This stretched to the Tay river, but Scotland was never conquered. After A.D. 121 the wall with its mile-castles and forts was the northern boundary of the Roman occupation. Wales was also a turbulent military area with the occupation troops in forts. This area was served by Watling street, which ran through St. Albans to Towcester and thence to Wroxeter where it joined a road running from the Bristol channel through Kenchester to Chester. Other roads linked Manchester with Chester and with the Fosse way near Leicester.

In building their roads the Romans used any hard materials near at hand. Thus the Via Appia had for the most part a wearing surface of six inches or so of hard lava on a bed of gravel, which replaced the loose topsoil on the site of the road; on the outskirts of Rome it was paved with worked stone blocks. Stane street, from London to Chichester, was composed of a thickness of 12 in. or so of gravel, flints and pebbles, the larger aggregates at the bottom. Such roads were cambered; they had drainage ditches on either side and were about 15 ft. wide. The aggregates were sometimes mixed with lime mortar or with a lime-trass mortar to form concrete, the trass coming from Pozzuoli in Italy. The road was prevented from spreading by raised stone curbs and by wooden pegs driven into the bed at intervals. Where stone was plentiful, as on the Yorkshire moors, the roads were surfaced with stone slabs. Over marshy ground at Hartshill, Watling street consisted of a layer of oak logs laid diagonally and covered with moss and holly twigs. This raft carried 9 to 12 in. of sandstone with a covering layer of 6 in. of a black concrete. The "Iron way" between New Cross and Lewes, discovered in 1929 by air photography, is composed of iron slag and iron under concrete in the neighbourhood of the Roman iron mines in Sussex, but of flint pebbles and rammed chalk near the downs. In flat land liable to flooding the Roman road was carried on an embankment.

After the fall of the Roman empire there was no road or bridge-building until the custom grew up of making pilgrimages to Rome and later to the shrine of St. James of Compostella (Santiago in Spain) and to Assisi. The feudal barons levied tolls of passage on the pilgrims and some of them spent a little of this on road repairs and bridgebuilding. About 1,700 bridges were constructed in France alone between the 12th and the 16th centuries, some by bridgebuilding monks, *Frères* Pontifes, whose patron saint, St. Bénazet, according to tradition, built the bridge at Avignon in 1178–88. Road repairing and bridgebuilding were also works of piety in the middle ages.

With the beginning of the Industrial Revolution the state of the roads in the various countries of Europe was an indication of the strength of the central government. The roads were maintained largely by the forced labour of the householders, cottagers or other occupiers of land, who were required in England to give four days' labour every year and to provide carts and horses where they had them. By a rigorous application of forced labour Jean Baptiste Colbert greatly improved the roads in France in the reign of Louis XIV, but himself earned thereby almost universal detes-

tation. In other countries such work was scamped or dodged; at that time the roads in Great Britain were among the worst in Europe. In 1716 a central administration for the upkeep of roads and bridges was formed in France and a training school for young engineers was attached to it in 1747. This was one of the beginnings of the study of the science of road construction.

In Great Britain the Jacobite rebellion had collapsed in 1715, but a nervous parliament commissioned Gen. George Wade (*q.v.*) to build a series of strategic roads in Scotland for the movement of troops. From 1726 to 1737 he built 250 mi. of road and about 40 bridges. Another pioneer in road building was John ("Blind Jack") Metcalf of Knaresborough; between 1767 and 1792 he built about 180 mi. of road which were outstandingly good. This period was the beginning of the Industrial Revolution; the need to carry goods caused many canals to be built, but the large-scale building and repairing of roads came somewhat later. This was put in hand by turnpike trusts, private companies who secured acts of parliament permitting them to close a main road with gates and charge a toll to all users, part of the money being used to repair the road; at one time there were nearly 8,000 tollgates in Great Britain. These trusts employed two great engineers. The first, Thomas Telford, was apprenticed to a stonemason. The base of his roads was formed of large blocks of stone wedged together with stone chips, giving a cambered layer 9 in. thick at the edges and 15 in. thick in the middle. This was covered with 6 in. of small broken stones followed by a wearing surface of 3 in. of gravel. Between 1802 and 1834 he built many roads, the best known being between Shrewsbury and Holyhead and between Carlisle and Glasgow. The other great engineer was John Loudon MacAdam. He made the subsoil of his roads very firm and shaped to the finished camber; side ditches were also dug for draining the road bed. His road then consisted of a layer one foot thick of small broken stones as cubical as possible. able to pass through a ring $2\frac{1}{2}$ in. in diameter but not passing a 2-in. ring. No large stones, loose earth or other binding material was allowed. The wheels of the coaches ground the stones together and the dust so made filled the interstices. Most of the minor roads in Great Britain are built on this principle. They are kept in good condition by periodic surface dressings of tar or bitumen and chippings. Such roads form 58% of the total mileage of roads in Great Britain.

The delays caused by turnpikes and the burden of the tolls on merchants and travellers became so great that a mass rebellion against them broke out in Wales in 1842–43. Gates were smashed and tollhouses levelled to the ground at night by men dressed in women's nightgowns and known as Rebecca's sisters (Genesis xxiv, 60). Juries refused to convict any rioters caught and. at last, in 1864 parliament bowed to public opinion and formed a Turnpike committee to cut down the number of toll roads and bridges. A few still remain. The invention of the internal-combustion engine and the repeal of the "Red Flag" act in 1896 ushered in the modern age. (T. L.)

ADMINISTRATION: GREAT BRITAIN

Before the Highway act, 1835, responsibility for the repair of highways in England and Wales normally rested on the inhabitants of the parish in which the highway was situated. It was performed, under the supervision of the justices in special highways sessions, through the two highway surveyors appointed annually for each parish. There were two important exceptions to parochial responsibility: certain streets in towns might be the responsibility of paving commissioners under local acts; and turnpike roads were repairable by the turnpike trustees under their private acts. The act of 1835 permitted the constitution of two other bodies which might become the authority for parochial highways, namely elective highway boards and highway districts comprising two or more parishes. The act also provided that roads thereafter laid out should not become repairable by the inhabitants unless the procedure for their acceptance was complied with. This is the origin of the "private street."

The Highways and Locomotives (Amendment) act, 1878, created a new class of road called the main road. which included all roads which were no longer turnpikes after 1870 and other roads so declared by county quarter sessions, and the county was made responsible for one-half of the cost of maintaining these roads. Under the Local Government acts of 1888 and 1894, county councils became responsible for main roads and district councils for other roads. County borough councils became sole highway authorities in their respective areas. During the 20th century the central government assumed responsibility for certain roads which are main arteries of communication, known as trunk roads, and the Local Government act, 1929, reallocated certain functions between local authorities. The highway authorities in 1955 were: (1) the minister of transport and civil aviation for trunk roads; (2) county borough councils for all roads in their areas other than trunk roads; (3) county councils for main roads. all roads in rural districts and classified roads in noncounty boroughs and urban districts; (4) noncounty borough and urban district councils for unclassified roads in their areas. The council of a noncounty borough or urban district having a population exceeding 20,000 was empowered to claim to exercise the functions of repair and maintenance of any county road in its area. The minister could arrange with a highway authority to act as his agent in relation to any trunk road. (E. J. O. G.)

ROADS AND ROAD CONSTRUCTION IN THE UNITED STATES

In the mid-1950s there were approximately 3,000,000 mi. of rural roads and 350,000 mi. of municipal roads in the United States. Approximately 1,780,000 mi. or 60% of the rural mileage was surfaced and 595,000 mi. were graded and drained. Of the rural surfaced mileage about 65% was improved with low-type surfaces such as slag, sand clay, stone and gravel; 20% was improved with intermediate types of bituminous-treated or mixed-bituminous surfaces; and 15% was improved with high-type surfaces of bituminous pavements, portland cement concrete and brick or block surfaces. Highway construction, which was practically stopped during World War II, increased after the war to a rate of completion of about 60.000 mi. per year. Only a small portion of this construction resulted in an increase in highway mileage because most highway work consisted of rebuilding and modernizing existing roads. Roads are divided into three main classes—federal-aid roads, constructed with federal-aid funds and state funds under supervision of the state highway departments and the federal bureau of public roads; state roads, built with state funds under the supervision of the state highway departments; county and local roads constructed largely with county and local funds by county and local authorities.

In the various federal-aid systems there were in the mid-1950s about 665,000 mi. of road that were almost all surfaced. but additions were being made yearly. Many sections, built for a lesser and slower moving traffic, were in need of widening, straightening, resurfacing and other improvements.

The Federal-Aid Highway System.—The federal-aid highway system was designated co-operatively by the secretary of agriculture, acting through the bureau of public roads, and the officials of the several state highway departments in accordance with the Federal Highway act passed by congress, 1921. The system thus designated comprises the main interstate roads and reaches directly nearly every city of 5,000 population or greater, and the roads are so chosen that if a zone ten miles wide mere marked off on each side of them, these zones would include the homes of 90% of the population.

For improvement of the federal-aid system special appropriations were made by congress for each fiscal year from 1917, with exception of the years 1934, 1935, 1944, 1945 and 1949. These funds are required generally to be matched by the states in at least equal amount. Formerly limited to $10,000 per mile and to ex-

penditure on roads outside of cities, the federal funds may be expended without arbitrary limitation per mile and upon sections of the federal-aid system within as well as without city limits. The federal funds are appropriated from any funds in the U.S. treasury, there being no special federal tax for road construction. In addition to improvements financed with joint federal and state contributions, other improvements are made on the federal-aid system but with state funds exclusively, and the mileage improved in this way approximates that improved with federal participation.

In addition to its contribution to federal-aid roads, the federal government also assumes as a rightful obligation the duty of building those sections of the major national system which lie in the national forests and parks and other parts of the public domain. In the forest highway system in the mid-1950s were more than 75,000 mi. of road of which more than 18,000 mi. had been improved.

During the period of the depression large additional federal appropriations were made for the purpose of promoting road construction as a measure for the relief of unemployment. These appropriations were expendable upon secondary and upon feeder roads as well as upon routes of the federal-aid system, and represented the first departure by the federal government from the long-established policy of participating exclusively in the improvement of main interstate highways. Special funds were also provided for elimination of highway-railroad grade crossings. These appropriations, unlike the earlier federal grants, were not matched with state funds.

Improvement of secondary or farm-to-market roads, special urban routes and interstate highways were continued as parts of the federal-aid program. The federal government generally pays half the cost of the highway work.

State Highway Systems.—There were approximately 370,000 mi. of roads in the rural primary state highway systems in the mid-1950s. These systems include, in most states, all the roads of the federal-aid system and a number of others of important state significance. In some states the selected roads have been designated by name and description in the la s of the state; in others the designation has been left to the state highway departments.

State highway systems are constructed with state funds only and with state and county or other local funds.

Of the total state highway mileage in 1952, there were 576,918 mi. surfaced. Of the surfaced mileage, 39,131 were soil surfaced; 92,815 were of slag, gravel or stone; 150,095 were bituminous surface treated; 41,612 were of mixed bituminous (nonrigid base); 64,214 were of mixed bituminous (rigid base); 7,143 were of bituminous penetration (nonrigid base); 29,208 were of bituminous penetration (rigid base); 66,627 were of bituminous concrete and sheet asphalt; 84,093 were of portland cement concrete; 1,800 were of vitrified brick; and 180 mi. of asphalt block, wood block, stone block and miscellaneous types. The unsurfaced mileage of 59,470 included 29,974 mi. of primitive or unimproved roads and 29,496 mi. of improved roads which had been drained and had an established grade.

County and Local Roads.—There were approximately 2,320,000 mi. of county and local rural roads in the county and local road systems in the mid-1950s. All roads not included in the federal-aid and state highway systems are classified as county and local rural roads. With the exception of about 125,000 mi. transferred for administration as secondary roads by the state highway departments of six states, all local roads are built by local officials with local funds.

By far the larger part of the unimproved mileage of the country is in the county and local rodd system. There are hundreds of thousands of miles on which the traffic is so small that improvement is not justified. Of the local road mileage approximately 1,223,881 were surfaced; in large part these surfaces were of such low types as sand clay, topsoil, gravel and water-bound macadam. Great improvements have been made in methods of combining asphalt and tar with materials of a sandy or gravelly nature to make low-cost dustless surfaces. Such surfaces are particularly suited to secondary roads and a considerable mileage has been constructed.

Administration of Federal-Aid Road Construction.—Federal-aid roads are constructed under the immediate supervision of the several state highway departments subject to the approval of the department of commerce, which department delegates the details of administration to the commissioner, bureau of public roads. The bureau has established nine divisions throughout the United States, which groups act in consulting and advisory capacities on state highway programs and systems. Under these nine divisions are grouped all the states, each in charge of a district engineer representing the bureau of public roads.

When a state highway department desires federal aid in financing systems, it submits a complete program to the district engineer in its state. The district engineer examines the road and the plans proposed for its improvement and if he approves the state's proposal, he submits the program to Washington through his division office.

A formal agreement is made between the state and the federal government. Construction then proceeds with full authority of the government under the immediate supervision of the state highway engineers and subject to frequent inspection by federal engineers. The federal government has no official relations with city, county and local officials.

Administration of State Highways.—Control over the state roads is vested in the state highway departments. The highway department determines the order in which the roads of the state system are to be improved, prepares the plans for the improvement, supervises the construction and pays for it with state funds entirely under its own control and, after completion, maintains the roads also with state funds under its own control. The federal-aid system coincides with the more extensive state systems and, therefore, a considerable portion of state highway improvement is done with federal aid.

In four states in the mid-1950s the state highway department had full control over the construction and maintenance of all or most of the local roads. Until about 1930 the work of state highway departments extended only to city limits. Thereafter there was a strong trend toward state improvement of extensions of main routes into and through cities and by the mid-1950s every state highway department made expenditures on such sections of highway.

Early American Roads.—The first American roads were the narrow Indian foot trails which crisscrossed the wilderness. Many of these trails followed the well-worn paths originally formed by the movements of deer, elk or buffalo. The early American explorers and colonists used water routes whenever possible. In many cases, however, the narrow winding Indian trails offered the only course. These trails sought the high ground which offered a dry route generally kept free of leaves and snow by the wind. Among the more important Indian trails were the Old Connecticut path, which travelled from the upper Hudson valley near Albany to Boston; the Iroquois trail, which followed the Mohawk valley and terminated near Niagara falls after crossing the area south of Lake Ontario; Nemacolin's path, which was named after a Delaware chief and led northwest from the upper Potomac to Pittsburgh; and the Warrior's path, through the Cumberland gap and Kentucky to the falls of the Ohio river. In 1775 Daniel Boone widened the Warrior's path into the Wilderness road and as the colonists moved westward they followed the maps prepared by Lewis and Clark, Mackenzie, Frémont, Thompson and others who used the Indian trails as paths to open the west.

Virginia's first highway law was passed in 1632, and in 1639 the general court of Massachusetts passed a comprehensive act which ordered each town to appoint two or three men who would be responsible for building highways "where they may be most convenient." The early roads and streets were relatively local in character and were often seas of mud or clouds of dust, depending on what the previous day's weather had been. The Conestoga wagon was probably the most famous vehicle of this period. This wagon, later models of which became known as the western prairie schooner, was responsible for causing American traffic to move on the right. The early colonists introduced the English custom of keeping to the left and carriages and wagons were driven from the

right side. The Conestoga wagon had to be guided from the left side and the drivers, in order to get a clear view of the road ahead,. began to keep their vehicles to the right. Because it was much easier to follow the deep ruts formed by these heavy freight carriers, other drivers soon moved to the right, and in 1813the state of New Jersey ordered all vehicles to keep to the right.

Toward the end of the 18th century the increased demand for better roads caused many routes to be built with private capital as turnpikes. The first United States turnpike utilized existing roads to connect settlements in the Blue Ridge mountains with Alexandria, Va. The first American macadamized road was known as the Lancaster turnpike and was initiated in 1792. It was located between Lancaster. Pa., and Philadelphia.

The federal government entered the highway construction field for the first time when it appropriated funds for the completion of a road to connect the Ohio valley with the eastern seaboard. This road, known as the Cumberland road or Sational road, was originally a free road. When congressional interest lagged and no additional federal funds were appropriated, the roads reverted to the states and tolls were charged. This marked the end of federal expenditures for highways until the first Federal Aid Road act was passed in 1916. In the early 1880s road-building programs declined with the expansion of the railroads. Interest in highway, road and street construction was reborn with the development of the bicycle in about 18jo and was accelerated by the development and adoption of the automobile early in the 20th century.

STATE PARTICIPATION

Development of State Highway Departments. — In 1891 New Jersey passed a law providing for a certain measure of state participation in road building. With one exception. it mas the first instance in which any stste had undertaken to participate directly in the construction of roads. The exception nas Kentucky. which had a state highway department and a well-defined road policy from 1821 to 1837, and had completed about 340 mi of roads.

Following New Jersey's example, laws providing for establishment of state highway departments and for granting of state aid were passed in hlassachusetts in 1892, in California and Connecticut in 1895 and in Maryland, New York and Vermont in 1898.

Between 1900 and 1915, 38 other states had established highway departments and empowered them with some degree of authority. Several of these previously established departments were materially strengthened and similar agencies were created in the three remaining states uhen, in 1916, the Federal Aid Road act required the establishment of adequate state agencies as a condition of the granting of federal aid. The establishment of adequate state highway departments by all states was the most important immediate effect of the federal aid law. The first administrative act of the bureau of public roads under the federal aid law was to request all states to submit a five-year program map showing the system of roads upon which the state highway departments would request federal aid. The rapid and consistent improvement of the main highways of the United States is the result of concentration of authority in the state highway departments, the engineering control thus established and especially the correlating influence of the federal government. The several state systems were substantially welded into a national network by the designation in 1921 of the federal-aid highway system.

The purpose of the New Jersey lam was to establish a state department, employing skilled engineers, which would act in an advisory capacity to county officials for improvement of road construction The highway department developed plans and specifications. inspected and supervised the construction, but contracts nere let by the counties and the roads were to remain county roads subject to maintenance by the county. As an inducement for counties to seek state aid. funds were appropriated by the state legislature to pay one-third of the cost of road construction.

With minor modifications. the New Jersey principle of state aid was subsequently adopted by many other states. In some states joint participation of the state and county in construction of the most important roads was made mandatory. Other variations differentiated the systems as adopted by the several states.

Organization of State Highway Departments. — In most of the states the highway departments are called state highway commissions, consisting of three to five members, appointed by the governor. with the consent of the senate in some states, for a period of from two to six years. In the majority of states the executive officer of the commission is the state highway engineer, appointed by the commission. In some states the governor serves as chairman of the commission. In some. the highway departments are bureaus or divisions of highways which are part of the department of public works. The executive officer may have the title of state highway engineer. director of highways or commissioner of highways. In other states the chief executive of the highway department is a state highway commissioner, appointed by the governor, except in one state — Michigan — where he is elected by popular vote.

Construction of practically all roads of the federal-aid and state highway systems is by contract let by the state highway departments to the lowest responsible bidder. All work is advertised. Each state highway department makes its own tests of materials either in its own laboratory or in a nearby commercial laboratory. It likewise conducts its own inspections of construction work. Federal-aid highways are subject also to federal inspection.

FINANCE

Administration of Local Roads. — County roads, in general, are built and maintained by county officials with funds raised, as a rule, by taxation of real and personal property within the county. In the mid-1950s such funds were supplemented by approximately $500,000,000 from gasoline taxes and other imposts on highway users and assigned for local road improvement. The more advanced counties employ a county engineer or an engineering organization to supervise the technical details of construction, the county governing body acting only as an administrative body. In some states the lesser roads in each county are administered, constructed and maintained by a host of township and district officials, each of whom may have charge of only a few miles of road.

Sources of Highway Revenue. — For many years the property tax and poll tax were the only sources of road revenues. They were collected and expended by the local governments. Commutation of the poll tax was permitted. As an indirect source of revenue, prison labour, while not a large factor, has been used, mainly to give employment to prisoners.

The first motor vehicle fees levied by the states were nominal and were designed merely to cover cost of registration. The rapid growth in motor vehicle registration increased the demand for improved roads with the resulting issuance of state and county bonds to secure funds to speed the improvements beyond the rate possible with limited current revenues. With improved roads, special benefits resulted to operators of motor vehicles and the motor vehicle taxes have been increased in recognition of this fact.

After 1929 all states levied a gasoline tax as a source of additional revenue. The tax had been first levied in 1919 by four states: Colorado (1 cent per gallon); New Mexico (2 cents); North Dakota ($\frac{1}{4}$ cent); and Oregon(1 cent). In 1920 Kentucky joined the four and levied a gas tax of 1 cent per gallon. In 1921, 15 states levied taxes from $\frac{1}{4}$ cent to 2 cents per gallon. In 1922, four additional states levied taxes. By 1923, 35 states levied a gasoline tax. The tax rate in the mid-1950s varied from 3 cents to 7 cents per gallon in different states. In 1952 the total state motor-fuel tax earnings, inspection fees and similar receipts amounted to $1,958,182,000 and the consumption of taxed gasoline was 40,584,530,000 gal. In that year highway users also paid $1,072,501,000 for registration of vehicles and $63,367,000 as motor carrier taxes. The total contribution of highway users was $3,094,050,000. Of the amount distributed 3% went for collection costs. 71% for state highway purposes, 21% for local roads and 5% went for nonhighway purposes.

The total income to state highway departments in 1952 was $4,651,306,000, and balances on hand brought the total funds available to $6,237,700,000. The current income from state sources was $3,278,756,000, of which motor vehicle users supplied

more than **94%.** Taxes on property no longer supplied significant amounts to state highway funds. The net amount of funds received from federal sources was $485,273,000. Income from sale of bonds, transfers from local units and from miscellaneous sources brought the total income from other than current state revenue sources to $1,372,550,000.

Expenditures for state-administered highways in 1952 amounted to $2,577,363,000. The states spent $1,757,349,000 for construction of highways and $563,135,000 for maintenance. These expenditures were divided as follows: $1,650,288,000 on primary state highways, **$284,391,000** on secondary roads in **17** states, $358,820,000 on urban extensions of state highways and $26,985,000 on other state roads. The outlay for administration, equipment, highway police. safety and bond interest amounted to **$256,879,000.** In addition $103,203,000 was used for retirement of debt. The total expenditure for all purposes was $2,680,566,000. During the period 1916–52 a total of $9,010,000,000 in federal-aid funds was authorized by the federal government to aid the states in highway improvements through the fiscal year 1957. For the fiscal years **1956** and 1957 the federal-aid authorization was $315,000,000 for primary roads, **$210,000,000** for secondary roads, $175,000,000 for urban roads and $175,000,000 for interstate roads.

MODERN ROAD PRACTICE

Types of Road.—Prior to 1904 the major types of surfacing were gravel and macadam, which gave entire satisfaction under the normal traffic of relatively light horse-drawn. steel-tired vehicles, with a bicycle traffic near the cities. The outpouring of motor vehicles from the cities which began about 1904 caused the macadam roads to "ravel," and maintenance under such traffic was impossible. Tars and asphalts were substituted for the weaker binders; first as dust layers and protective surface coatings, then as binders introduced into roads of the macadam type by penetration, and finally as hot admixtures according to the bituminous concrete principle. These types were entirely satisfactory for automobile traffic.

The period from 1904 to 1914 was one of bituminous construction. In 1904 there were in the entire country only **18** mi. of bituminous rural roads, all in Massachusetts and Ohio. By 1914 there were 10,500 mi.. a mileage which was nearly three-quarters of the aggregate length of all roads of higher type than macadam. The decline in the surface-treated and penetration types of macadam began when motor trucks in considerable numbers began to appear on the rural highways. They brought a demand for rigid pavements of concrete and brick and bituminous concrete on a concrete base.

Although the first concrete road had been built in **1893,** in Bellefontaine, O., there were no more than five miles of that type on rural highways in the entire country in 1909. The first big increase occurred in **1912** when more than **250** mi. of rural highways were paved, to be followed in 1913 with 500 mi., and in 1914 with more than 1,500 mi. At the close of 1914 there were in the entire country **2,348** mi. of concrete roads. Ten years later the mileage had increased to **31,186** and construction was proceeding at the rate of more than 6,000 mi. a year, a rate approached by no other type better than gravel.

The increase of motor trucks on the highways also caused a more extensive use of brick and the bituminous pavements of the mixed type on concrete bases. In 1914 there were approximately **1,600** mi. of brick pavement; in 1924 there were 4,319 mi. In 1914 the bituminous concrete or sheet asphalt mileage on rural highways was negligible; in 1924 there were more than 9,700 mi. of these types.

Main highways thereafter were improved with high-type surfaces such as concrete and bituminous mixtures. For moderate and light traffic water-bound macadam, gravel, sand clay, selected soil mixtures and low-cost bituminous mixtures were used. Practically all surfaces that tend to become dusty in dry weather were made dustless by applying a bituminous or chemical treatment during construction or soon thereafter. Great progress was made in learning how to combine granular materials such as sand and gravel with clay and bituminous binders to form durable surfaces that are moderate in cost.

Because the type of soil below a road surface greatly influences the ability of the pavement to carry traffic loads, the data obtained from extensive soil surveys play an important part in modern highway construction. These surveys include the use of test pits, auger borings, core drillings, resistivity methods and seismic methods to obtain samples or other information for the determination of the engineering characteristics of the materials in the various horizons or layers of the soil profile. Agriculture soil survey maps, certain types of geologic maps and aerial photographs also are utilized to obtain this type of information.

The variations in designs of pavements in use in the early 1950s on some of the several turnpikes in the United States are noteworthy from the standpoint of indicating modem trends. However, some of these designs also reflect the local influence of: (1) availability of materials of construction at very low cost; **(2)** prevailing soils of a granular texture; **(3)** low rainfall; and **(4)** absence of serious frost action. The highest types of highway design can be found in the multilane freeways, expressways and toll roads being built. Rigid pavements, built of portland cement concrete, are commonly eight to ten inches thick and are placed on a granular layer a few inches thick, which in turn is placed on a well compacted earth subgrade. The original sections of the Pennsylvania turnpike were constructed with a nine-inch reinforced concrete slab which was placed directly on the subgrade without a base or subbase.

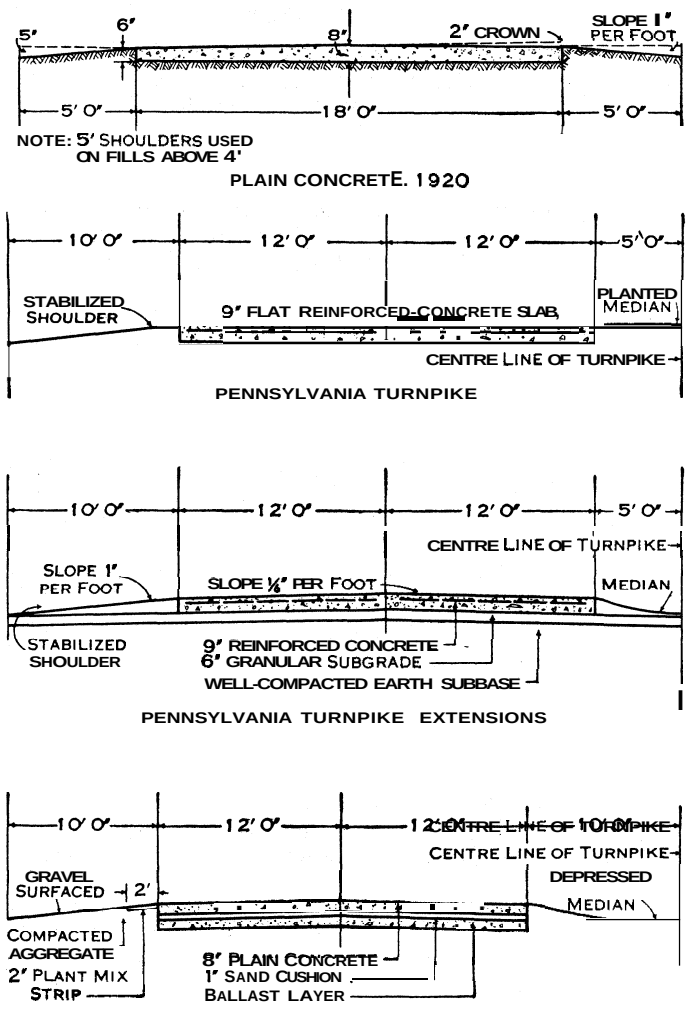

FIG. 1—CONCRETE PAVEMENTS IN THE UNITED STATES

Later extensions to the Pennsylvania turnpike had nine inches of reinforced concrete placed on a six-inch granular subbase while the Denver-Boulder (Colorado) turnpike, built in a dryer climate,

employed eight inches of plain concrete. Construction joints and longitudinal joints are generally used but expansion joints are no longer used extensively for rigid pavements for highways. Flexible or bituminous pavements consist of several layers of different materials which serve to spread the concentrated load, imposed by the wheel on the surface, over a large area of the subgrade. The New Jersey turnpike used layers of the following materials: 4.5 in. asphaltic concrete; 7.5 in. macadam base; 6.5 in. gravel subbase; and 18 in. selected subgrade material. In the drier area

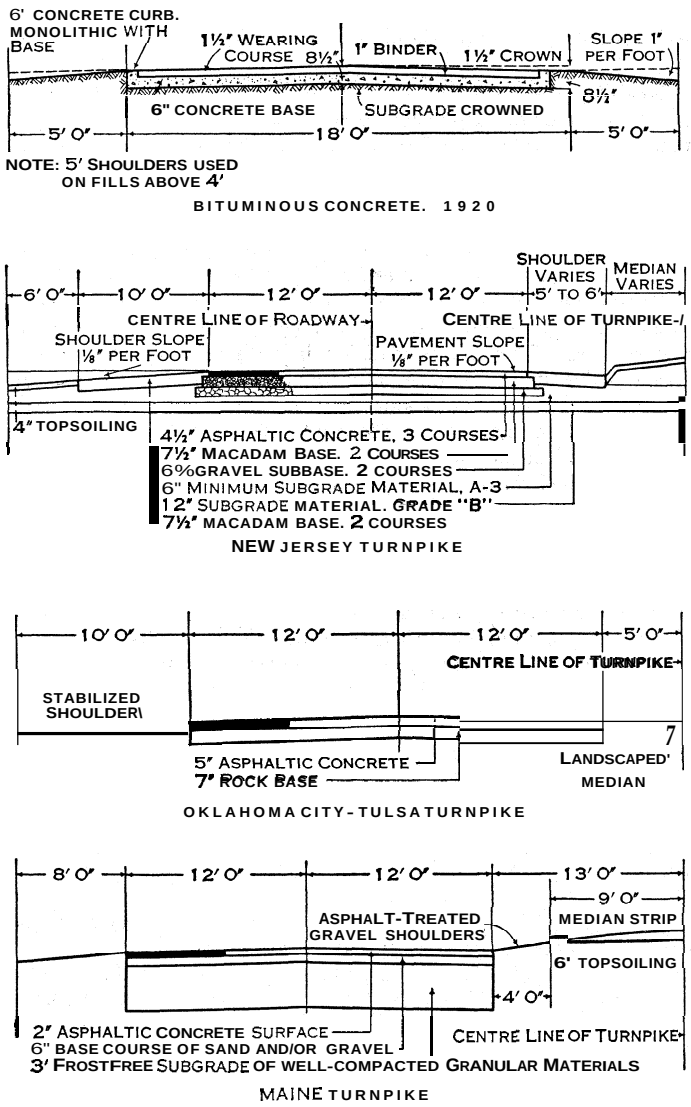

FIG. 2.—EXAMPLES OF BITUMINOUS PAVEMENTS IN THE UNITED STATES

crossed by the Oklahoma City-Tulsa turnpike, a five-inch layer of asphaltic concrete was placed on seven inches of rock base. Meanwhile in Maine, where frost is an important problem but where gravel is economically available in abundance, the Maine turnpike has a 2-in. asphaltic concrete surface and a 6-in. base course of sand or gravel placed on a 36-in. layer of frost-free, well-compacted granular material.

Until about 1930 road-building efforts were directed largely toward the extension of surfaced mileage. This early objective was reached, but the amount of needed highway improvements remained greater than ever before. The great increase in volume and speed of traffic made obsolete the highways built years before when conditions were different. Existing highways were modernized by placing better and wider surfaces, eliminating sharp curves and steep grades, eliminating railroad grade crossings and placing warning and danger signs and marks.

A great many two-lane highways mere built 20 or 22 ft. wide but soon there was a trend toward greater width. Provision of a third lane was resorted to where two lanes were not sufficient but because of the danger of using the middle lane it was not a satisfactory solution. Where two lanes were not sufficient, four lanes were provided. For great volumes of traffic the multiple-lane highway became the only satisfactory solution. Experience with four-lane highways showed that traffic flowing in opposite directions must be separated by a dividing strip if a heavy accident toll is to be avoided.

The need for express routes into and through the centres of big cities resulted in extensive construction of such routes. On these routes no roads intersect at grade and parallel roads are necessary to serve abutting property. Lanes for each direction are separated from each other by some type of dividing strip. These roads, commonly called expressways or freeways, were also built to carry heavy volumes of traffic in rural areas.

Development of the interstate system, consisting of about 40,000 mi. of the most used primary federal-aid highways, was one of the features of the highway program in the mid-1950s.

Toll Roads.—Although many early American roads were built with private funds as toll roads, they soon gave way to roads constructed and maintained by public funds. The Pennsylvania turnpike, opened in 1940, began a modern era of toll-road construction. As of Oct. 1954 there were 1,335.5 mi. open to traffic in 10 states, 1,256.3 mi. under construction in 11 states, 3,708 mi. authorized in 16 states and 2,640 mi. proposed in 9 states. A total of 28 states were active in various phases of toll-road development. The cost of the mileage in operation was in excess of $1,516,403,000.

CO-OPERATION OF INTERESTS

The United States Highway System.—Through the co-operation of all states and the federal government, effected initially through the agency of the Joint Board on Interstate Highways and continued by the American Association of State Highway Officials, a system of main transcontinental highways, known as the U.S. highway system, was designated in 1926. The standard signs adopted for this system are of two general classes. One group, the danger and caution signs, are of four different shapes representing as many degrees of danger. These have a red or yellow background with black letters and symbols. The other group includes the standard route marker in the form of a U.S. shield which contains the route number and directional and informational signs with white backgrounds and black letters.

Highway Research.—As a result of the co-operation of the bureau of public roads with state highway departments and universities in scientific research looking to the development of types of construction and methods of administration and finance adequate to meet the demands of the fast-growing traffic, there is being built up a new science of highway engineering.

The investigations conducted include studies of the characteristics of materials; determination of the forces applied to road surfaces by standing and moving vehicles; of stresses developed in the structure of roads and bridges by live loads and by temperature and other natural causes; analyses of subgrade soils and tests of methods designed for their improvement; studies of the flow of water through drainage structures; of the runoff from drainage areas; of the effect of moisture and frost on soils; analysis of human behavior as related to driver and pedestrian action; development of methods for predicting future traffic volumes; improvement of techniques to measure the adequacy of service provided by roads; and others of fundamental importance and value.

ROANNE, a town of east-central France, capital of an *arrondissement* in the *département* of Loire, on the left bank of the Loire, 54 mi. N.W. of Lyons. Pop. (1954) 45,262.

Roanne (*Rodomna* or *Roidomna)* was an ancient city of the

Segusiani and a station on the Roman road from Lyons to the sea. In 1447 the lordship of Roannais became the property of the banker Jacques Coeur, from whom it passed to the family of Gouffier. The title was raised to the rank of marquisate and in 1566 to the rank of duchy; it became extinct in the 18th century.

The industrial suburb of Le Côteau is on the right bank of the river. It is the terminus of the Roanne-Digoin canal.

ROANOKE, a city of western Virginia, U.S., on the Roanoke river, 166 mi. W.S.W. of Richmond. It was settled in 1740 but did not become important until 1882 despite its favourable location in a fertile bowl between the Blue Ridge and Allegheny mountains, easily accessible from the north, east and west. It was first called Big Lick because of its salt deposits. In 1852 it became a way station of the railroad extending across southern Virginia but in 1880 it had only 669 inhabitants. Its growth started in 1882 when a railroad from the north made a junction there with the line across southern Virginia, offering an outlet for the coal deposits of the Virginias; the town acquired huge railroad shops and offices,and in that year was renamed Roanoke. In 1884 it was chartered as a city, its population at that time being 5.000. Railroads were supplemented by various industrial activities including fabricated steel. The city grew to 21.495 by 1900. Further growth was assured by the coming of the Virginian railroad in 1908 and of a large rayon plant in 1917. Roanoke suffered a labour depression after 1957 when the Norfolk and Western Railway shifted from steam to diesel locomotives and the rayon works closed because its product was outmoded. But the city's industry was too extensive for its prosperity to be halted permanently. Its truck lines expanded and hotel accommodations were provided for tourists from the Sky Line drive and the Blue Ridge parkway. The population of the city in 1960 was 97,110; that of the standard metropolitan statistical area (Roanoke City and Roanoke county) was 158,803. (For comparative population figures *see* table in VIRGINIA: *Population.)* Roanoke has a council-manager form of government, in effect since 1918. A few miles west of the city is Salem, the county seat and home of Roanoke college (Lutheran, founded 1842), and 6 mi. N. is Hollins, a private college for women. established in 1842. (F. B. S.)

ROANOKE ISLAND, in Dare county, off the coast of North Carolina. U.S., is south of Albemarle sound between the Outer Banks and the mainland. The island, which is 12 mi. long with an average width of about 3 mi., is the site of the first attempted English settlement in America and the birthplace of the first child of English parents born in the new world (Virginia Dare, Aug. 18. 1587). In 1584 captains Philip Amadas, or Amidas, and Arthur Barlowe there claimed the North American continent for Sir Walter Raleigh under his patent from Elizabeth I. After two months exploration they returned to England with the Indians, Manteo and Wanchese. and with samples of tobacco and potatoes. Next year Sir Richard Grenville (*q.v.*) transported 108 settlers under Ralph Lane, but the whole group returned to England with Sir Francis Drake in 1586. Two weeks later Grenville arrived with supplies, leaving 15 men to hold England's claim.

In 1587 John White, artist of the Lane colony (whose 75 Indian drawings are in the British museum) and grandfather of Virginia Dare, arrived at Roanoke Island but the 15 men had vanished. He planted a new colony comprising more than 100 settlers. Later he returned to England for supplies. Upon White's return on Aug. 15, 1591, the only trace of this lost colony was the word "Croatoan" carved on one tree and "Cro" on another tree. Numerous and romantic are the conjectures as to the colony's fate. From 1937 its gallant story has been portrayed locally each summer by the outdoor drama, *The Lost Colony,* by Paul Green. The Fort Raleigh National Historic site was established in 1941 to restore this first English implantation, based on original excavations and employing authentic restorations.

Roanoke was the scene of a Civil War action in Dec. 1862 when Federal troops under Gen. Ambrose Everett Burnside took the island from the Confederates under Col. Henry M. Shaw.

Manteo, the county seat, and Wanchese, a fishing village, are added tourist attractions. (B. P. R.)

ROANOKE RIVER, of southeastern United States, rises in the Appalachian valley in southwestern Virginia and flows southeasterly in a 410-mi. long course into Albemarle sound, on the Atlantic coast of North Carolina. It drains an area of 9,580 sq.mi.

Shortly before crossing the Virginia-North Carolina state line it is joined by the Dan river, its principal tributary. The Roanoke is navigable for small craft for 112 mi. from its mouth to Weldon, N.C., which lies just below the fall line.

Ships with a draft of up to 12 ft. can reach Plymouth, N.C., 6 mi. above the mouth. In 1829 the Weldon canal, 12 mi. long, was opened to afford a passage around the falls, but it was abandoned in 1850. (F. O. A.)

ROARING FORTIES. Moderate to strong winds, unmodified by large land masses, accompany the migratory pressure systems in the middle latitudes of the southern hemisphere. Early sailors recognized this wind regime and found that, unlike the condition in the northern hemisphere, the strong westerly winds were common in summer as well as in winter. They termed the region from latitude 40° to 50° S. the "roaring forties."

See also WIND: *The Westerlies.* (J. M. AN.)

ROBBER FLY, the name given to predaceous flies of the family Asilidae of the order Diptera (*q.v.*); they are also called assassin flies. They are predaceous in both the adult and larval stages. The various groups are found in a particular type of habitat. Some occur in woods, on tree trunks and foliage, some on grass and low plants or on the tips of dead twigs, some on sand or gravel and on beaches. The head is hollowed above between the eyes, which have an area of enlarged facets that give them keen sight.

A few kinds, particularly species of *Promachus,* may be serious pests of apiaries; they feed on many kinds of bees, as well as upon almost all kinds of flying insects. Their legs are long and adapted for capturing prey in flight and holding it while it is eaten. They inject a fluid into their victims which breaks down the muscular tissues so that only the skeleton remains. There are more than 4.000 species distributed through the world, most of them rather dull coloured but some metallic. They vary in length from $\frac{1}{4}$ in. to $1\frac{1}{2}$ in. (C. H. CN.)

ROBBER SYNOD, the name given to an irregular ecclesiastical council held at Ephesus in A.D. 449. See COUNCIL.

ROBBERY, in law, is the unlawful and forcible taking of goods or money from the person of another by violence or threatened violence. Robbery is larceny (*q.v.*) with violence. *See* also CRIME: CRIMINAL LAW.

ROBBIA, DELLA, the name of a celebrated family of Florentine sculptors, mainly associated with the production of works in enameled terra cotta. The principal members of this family were LUCA DELLA ROBBIA (*c.* 1399–1482), his nephew ANDREA (1435–1525) and two of Andrea's five sons, GIOVANNI (1469–1529?) and GIROLAMO (1488–1566).

LUCA, son of Simone di Marco della Robbia, matriculated in the guild of sculptors in 1432. He is mentioned in the preface to L. B. Alberti's *Della Piftura,* along with Filippo Brunelleschi, Masaccio. Donatello and Lorenzo Ghiberti, as one of the pioneers of Florentine Renaissance style, and he must have been an established artist by 1431, when his most important work was commissioned, the *cantoria,* or "singing gallery," over the door of the north sacristy of the *duomo* ("cathedral"), on which he was engaged until 1438. The balance of evidence is that at this time he practised solely as a marble sculptor. In style Luca's marble sculptures recall the work of Nanni di Banco, to whom his early training may have been due. The *cantoria* (taken down in 1688 and now reassembled in the Museo dell'Opera del Duomo) consists of ten figurated reliefs, two at the ends of the gallery, four on the front and four beneath placed between the supporting consoles. The panels illustrate Psalm cl and show two groups of singing boys, trumpeters, choral dancers and children playing on the psaltery, cithara, organ and harp, tambourine and cymbals. Two bronze *putti* from the upper corners of the gallery are in the Musée Jacquemart-André, Paris. The architectural forms throughout are strongly influenced by Brunelleschi and the handling of the figures reveals a close study of classical originals. The panels owe their

great popularity to the innocence and lack of artifice with which the children in them are portrayed.

Shortly before the completion of the *cantoria,* Luca received the commission (1437) for five reliefs of the arts and sciences for the campanile of the cathedral, in completion of the cycle begun by Andrea Pisano a century before, and in 1439 undertook work on the altars in the chapels of St. Peter and St. Paul in the cathedral. Two marble reliefs from the predella of the St. Peter altar survive in the Bargello. The most important of Luca's other works in marble are a tabernacle at Peretola. near Florence (carved for Sta. Maria Nuova in Florence in 1441–43), and the tomb of Benozzo Federighi. bishop of Fiesole (d. 1450), completed in 1459 In all these works Luca appears as an artist of strongly classical stamp, with a predilection for static figures and rectilinear compositions which stand in marked contrast to the works of Donatello in the same period.

Both in the campanile reliefs (designed to blend with those of Andrea Pisano) and in the figures of the dead Christ, Virgin and St. John behind the Federighi monument, Luca's style represents a conscious reversion to the practice of the 14th century. The Federighi monument is surrounded by a strip of flat foliated decoration in enameled terra cotta. Intimately connected with these works is the bronze door of the north sacristy of the cathedral (1446–63). Undertaken in its early stages in collaboration with Michelozzo and the bronze sculptor Maso di Bartolommeo. the door consists of two wings, with heads of prophets in the frames and ten reliefs of the Virgin and Child, St. John the Baptist and the evangelists and doctors of the church. Though features of the design may be due to Michelozzo, it is likely that the whole figurated area is the work of Luca della Robbia.

The medium of polychrome enameled terra cotta appears for the first time in a dated work in the Peretola tabernacle, where it is used to set off the marble sculpture. The earliest documented work wholly executed in this medium is a lunette of the Resurrection over the door of the north sacristy of the cathedral (1442–45). According to Giorgio Vasari, the glaze with which Luca covered his terra-cotta sculptures consisted of a mixture of tin, litharge antimony and other minerals. Precedents are found in pottery and there is evidence that in the studio of Ghiberti experiments were made in carving terra-cotta sculptures with transparent glaze as a basis for gilding. In relation to sculpture, however, the technique adopted by Luca and developed by the later members of the Della Robbia workshop was a novel one. In the late 15th and 16th centuries works in this medium seem to have been regarded as an inexpensive substitute for marble sculpture, but analysis of the early commissions suggests that initially the medium was employed only in architectural contexts where marble sculpture would have been inapposite and that the function of the glaze was colouristic and not preservative. The resurrection lunette in the *duomo* was followed (1446–51) by a corresponding relief of the Ascension over the south sacristy door, in which a wider range of colour is employed. Of the many decorative schemes for which enameled terra cotta was employed by Luca della Robbia. the most important are the roundels of Apostles in Brunelleschi's Pazzi chapel (soon after 1443); the roof of Michelozzo's chapel of the Crucifix in S. Miniato al Monte, Florence (1447–48); a lunette over the entrance of S. Domenico at Urbino (1450); two altars at Impruneta; and the ceiling of the chapel of the Cardinal of Portugal in S. Miniato al Monte (1461–66). Luca's last major work in this medium is an altarpiece in the Palazzo Vescovile at Pescia (after 1472). Many notable works by Luca della Robbia are found outside Italy. Among these are the colossal stemma of René of Anjou and 12 roundels with the labours of the months from the Palazzo Medici in the Victoria and Albert museum, London, and the Altman and Demidoff Madonnas, respectively, in the Metropolitan museum, New York city. and the Museum of Art, Toledo. O.

After Luca's death at Florence on Feb. 20, 1482, his nephew ANDREA, who had been for many years an active member of his studio, assumed control of the Della Robbia workshop. Born on Oct. 20, 1435, Andrea appears, like his uncle. to have been trained as a marble sculptor. Neither in this medium nor in enameled terra cotta, however, was he an artist of Luca's calibre, and by the supremely high standard of Luca his work is trivial in form and deficient in sculptural quality. His best-known works are ten roundels of foundlings in swaddling clothes on the façade of the Ospedale degli Innocenti in Florence (about 1480). Andrea's interest in narrative sculpture led him to develop from the reliefs of Luca a class of large polychrome reliefs of which characteristic examples exist in Sta. Maria degli Angeli at Assisi. Sta. Maria degli Angeli at La Verna, S. Bernardino at Aquila. Sta. Chiara at Borgo San Seppolcro and Sta Croce in Florence, as well as in many museums outside Italy. Between 1475 and 1522 the development of Andrea's style can be follo ed through a sequence of dated or documented works. Many of Andrea's smaller reliefs exist in a quantity of versions turned out from the Della Robbia studio.

Andrea della Robbia died at the age of 90 on Aug. 4, 1525, and control of the workshop passed to his son GIOVANNI (b. May 19, 1469). Giovanni's early works, of which the most remarkable are a lavabo in Sta. Maria Novella, Florence (1497), and the medallions in the Loggia di S. Paolo (1490–95), were executed in collaboration with or under the strong influence of his father, but as with age Andrea's grasp relaxed, Giovanni della Robbia evolved a coarser, more pictorial style in which the poverty of modeling and composition is accompanied by vivid. often vulgar polychromy. His most ambitious work is a frieze with representations of the works of mercy on the Ospedale del Ceppo at Pistoia (1525–29), in which he was assisted by his pupils Benedetto Buglioni (1461–1521) and Santi Buglioni (b. 1494).

Giovanni's younger brother GIROLAMO (b. March 9. 1488) was trained in Andrea's studio and collaborated with his father and brother until (about 1527–28) he moved to France. where he was employed on the terra-cotta decoration of the demolished Chdteau de Madrid. After the death of Francis I (1547) Girolamo returned to Florence. but later (1559), on the appointment of F. Primaticcio as superintendent of the royal buildings. he resumed his work at the Chdteau de Madrid and at Fontainebleau and was also employed on the monuments of François II and Catherine de Médicis at St. Denis. Girolamo della Robbia died in France on Aug. 4, 1566.

ROBBINS, FREDERICK CHAPMAN (1916–), U.S. pediatrician, shared with J. F. Enders and T. H. Weller (*qq.v.*) the Nobel prize in physiology and medicine in 1954 for cultivation of the poliomyelitis viruses in tissue culture. Robbins was born on Aug. 25, 1916, in Auburn. Ala., and attended the University of Missouri and Harvard medical school (M.D., 1940). After two years at the Children's hospital, Boston, Mass., he entered the army and became chief of the virus and rickettsial section, 1 jth medical general laboratory, stationed in the Mediterranean theatre, where he investigated epidemics of infectious hepatitis, typhus and Q fever. Following the war, Robbins completed his hospital training in pediatrics and joined Enders and Weller in 1948 in the research laboratory of the Children's hospital. Boston. There they devised techniques for cultivating the viruses of poliomyelitis in tissue culture which made possible the development of poliomyelitis vaccine, new diagnostic methods and the isolation of many new viruses. In 1952 Robbins became director of the department of pediatrics and contagious diseases, Cuyahoga County hospital, and professor of pediatrics at Western Reserve university school of medicine, Cleveland, O.

(J. H. DE.)

ROBBINS, JEROME (1918–), U.S. dancer and choreographer, noted for the imaginative and original use of contemporary American themes in his ballets and for the excellent dances he devised for Broadway shows. A character dancer of distinction, Robbins appeared at the Gluck Sandor-Felicia Sorel dance centre, danced in musicals and toured with Ballet Theatre before staging his first ballet, *Fancy Free,* in 1943. His ballets include *Interplay, Pied Piper* and *Fanfare* and dances for the musicals *On the Town, The King and I* and *West Side Story.*

Robbins is associate artistic director of the New York City Ballet. (LN. ME)

ROBERT I (c. 865–923), king of France, or king of the Franks, was the younger son of Robert the Strong, count of Anjou, and the brother of Odo, or Eudes, who became king of the western Franks in 888. He did not claim the crown of France when his brother died in 898; but recognizing the supremacy of the Carolingian king, Charles III, the Simple. he continued to defend northern France from the attacks of the Normans as "duke of the Franks." About 921 Robert, supported by many of the clergy and by some of the most powerful of the Frankish nobles, took up arms, drove Charles into Lorraine, and was himself crowned king of the Franks at Reims on June 29, 922. Collecting an army, Charles marched against the usurper, and on June 1j, 923, in a stubborn and sanguinary battle near Soissons, Robert was killed, according to one tradition, in single combat with his rival. Robert left a son, Hugh the Great, duke of the Franks, and his grandson was Hugh Capet, king of France.

See F. Lot, *Les Derniers Carolingiens (1891);* and *E.* Lavisse, *Histoire de France,* tome ii. (1903).

ROBERT II. (c. 970–1031), king of France, was a son of Hugh Capet, and was born at Orleans. He was educated at Reims under Gerbert, afterwards Pope Silvester II. As the ideal of mediaeval Christianity he won his surname of "Pious" by his humility and charity, but he also possessed some of the qualities of a soldier and a statesman. His father associated him with himself in the government of France, and he was crowned in December 987, becoming sole king on Hugh's death in October 996. In 988 he had married Rosala, or Susanna, widow of Arnold II., count of Flanders. He repudiated her in 989, fixing his ,affections upon Bertha, daughter of Conrad the Peaceful, king of Burgundy, or Arles, and wife of Eudes I., count of Blois; and although the pair were related, and the king had been godfather to one of Bertha's children, they were married in 996, a year after the death of Eudes. Pope Gregory V. excommunicated the king, and a council at Rome imposed a seven years' penance upon him. For five years the king braved all anathemas, but about 1002 he gave up Bertha and married Constance, daughter of a certain Count William. Still attached to Bertha, Robert took this lady with him to Rome in 1010, but the pope refused to recognize their marriage, and the king was forced to return to Constance. By this wife Robert had four sons, and in 1017, the eldest of these, Hugh, (1007–102j), was crowned as his father's colleague and successor. After Hugh's death Robert's concluding days were troubled by a rising on the part of his younger sons, and after a short war, in which he was worsted, the king died at Melun on July 20, 1031.

His life was written by his chaplain, Helgaud, and this panegyric, *Epitoma vitae Roberti regis,* is published by J. P. Migne in the *Patrologia Latina,* tome cxli. (Paris, 1844). *See* also C. Pfister, *Études sur le rigne de Robert le Pieux* (1885); and E. Lavisse, *Histoire de France,* tome ii. (1901).

ROBERT (1275–1343), king of Naples, was the son of Charles II., duke of Anjou and king of Naples. On the death of Charles in 1309 Robert succeeded to the throne, although his nephew Caroberto (Carlo Roberto), son of his elder brother Charles Martel, who had died before his father, had a prior claim. He was crowned by Pope Clement V. at Avignon, and on the descent into Italy of the emperor Henry VII. was appointed papal vicar in Romagna to resist the imperialists; thenceforth he became the recognized leader of the Guelphs or papal faction in Italy and took part in all the wars against the Ghibellines. On various occasions he obtained for himself or his sons the suzerainty over Rome, Florence and other cities, and was regarded as the most powerful Italian prince of his day. Pope John XXII. created him papal vicar in Italy against the emperor Louis the Bavarian. In 1320 Robert summoned his kinsman Philip V. of France to Italy, and he waged war against Sicily once more from 1325 to 1341, but failed to drive out the Aragonese. He died in 1343, just as he was about to lead another expedition to the island. Robert was a man of learning, devoted to literature, and a generous patron of literary men: he befriended Petrarch. Dante described Robert as a *re da sermone* (word king).

See G. Villani, *Cronache;* M. Murena, *Vita di Roberto d'Angiò, re di Napoli* (Naples, 1770); and *Archivio storico Siciliano (1884,* viii. 511 *seq.*)

ROBERT I., "THE BRUCE" (1274–1329), king of Scotland, the son of Robert de Bruce VII., earl of Carrick by right of his wife Marjorie, was a direct descendant of a Norman baron who accompanied William I. to England. He was probably born at Turnberry, Ayrshire, on July 11, 1274, and is said to have spent his youth at the court of Edward I., where he must have watched the progress of the suit for the crown of Scotland. After the death of Margaret, the "maid of Norway," Bruce's grandfather claimed the crown by right of his descent from David I.; but John de Balliol, grandson of Margaret, being preferred by the commissioners of Edward I., he resigned his estates to Bruce's father, who assumed the title of Lord of Annandale (1295). In 1292, Bruce became earl of Carrick, by which title he is often known. Some four years later Bruce and his father swore fealty to Edward I., but when Sir William Wallace raised his standard, Bruce followed the popular leader and harried the forces of John' de Warenne, Edward's general. In July, 1297, however, he was forced to sign the capitulation of Irvine, whereby the Scottish lords were pardoned in return for their allegiance.

Bruce thus took no part in the momentary triumph and final defeat of Wallace, who continued the struggle almost unaided. Soon after Bruce again appears to have sided with his countrymen, but he was not yet regarded as an open enemy of the English, for his estates were left intact, and in 1299 he was appointed co-regent of Scotland, together with William Lamberton, bishop of St. Andrews, and John Comyn the younger. For the next four years he remained passive, and in 1304 even supported Edward I. in the capture of Stirling, but secretly he entered into a bond with Lamberton which bound him to the patriotic cause.

The second period of his life, which was occupied by the contest for the kingdom, now began. After the execution of Wallace in 1305, Edward sought to conciliate the Scottish nobles by granting a liberal constitution to Scotland. Bruce is reputed to have been one of the advisers, but his fidelity was already suspected and in 1306 he returned to Scotland secretly. In the same year he murdered his old enemy Comyn, and was thenceforward definitely committed to the Scottish cause. Collecting his adherents, Bruce marched to Scone where he was crowned on March 27, 1306, and a few days later was placed on the throne according to an ancient

Celtic ceremony, by the Macduffs, earls of Fife. He then set out to win his kingdom, but after being defeated at Methven and at Dalry in Strathfillan, he fled almost alone to the island of Rathlin. Proclaimed an outlaw, excommunicated by the pope, his wife and daughter in the hands of the English, and his brother executed, Bruce's cause seemed hopeless, but on July 7, 1307, Edward I. died, and Bruce was opposed only by his incompetent son Edward II. In the winter of 1307 and in 1308, hurrying to Aberdeenshire, he harried the lands of the earl of Buchan, whom he defeated near Inverurie on May 22, 1308, while his brother Edward reduced Galloway. He then crossed to Argyllshire, took the pass of Brander (1309), captured Dunstaffnage, and in March held his first parliament at St. Andrews.

A truce having been effected by Pope Clement V. in 1309, Bruce was recognized as king by the clergy of Scotland in Feb. 1310, in spite of his excommunication; and with this backing he set out to reduce the strongholds still held by the English. Linlithgow fell towards the end of 1310, Dumbarton in Oct. 1311, Perth in Jan. 1312, two raids into the north of England were also successful in March 1313, Roxburgh and Edinburgh were captured and in May the Isle of Man was subdued. By the end of 1313, Stirling, Bothwell and Berwick alone remained English and these Edward II. made a determined effort to save. He reached Falkirk on June 22, 1314, and two days later the battle of Bannockburn was fought, in which the defeat of the English determined the independence of Scotland and confirmed the title of Bruce. On April 26, 1315, at the parliament of Ayr, the succession was unanimously settled on Bruce and his heirs.

The last part of Bruce's life, from 1315 to 1329, began with the rising of the whole Celtic race against the English. Robert Bruce declined the offer of the Irish crown, but in 1315, Edward Bruce crossed to Ireland at the invitation of the natives, and in 1317 he was joined by Robert, who defeated the English at Slane in Louth. But although they enjoyed a temporary success, Edward was finally killed at Dundalk in Oct. 1318, having previously been proclaimed king of Ireland. In 1317, Robert Bruce had been obliged to return to protect his own borders, and in 1318 he laid siege to Berwick. Refusing all offers of mediation on the part of the pope, unless his title were recognized, Bruce continued his struggle and after the capitulation of Berwick, laid waste to the English border. In Dec. 1318, he held a parliament at Scone, where the succession was settled, and legislation for the defence and administration of the kingdom was initiated.

The king's position was now so strong that foreign countries began to recognize him, and in 1323 his title was confirmed by the pope. Hostilities against England continued, however, and on May 30, 1323, Edward was forced to make a truce of 13 years. On the accession of Edward III, 1327, the treaty of York was signed, whereby "Scotland according to its ancient bounds in the days of Alexander III, should remain to Robert, king of Scots, and his heirs free and divided from England, without any subjection, servitude, claim or demand whatsoever." This was ratified by the marriage of Edward's sister, Joanna, to David, Bruce's infant son (July 12, 1328). The chief author of Scottish independence barely survived his work. In 1327 he conducted an expedition into Ireland, but on his return, he spent his remaining years at Cardross, on the Clyde, where he died from leprosy on June 7, 1329. His body was buried at Dunfermline, his heart at Melrose.

BIBLIOGRAPHY.—The chief contemporary authorities for the life of Bruce are coloured to some extent by the nationality of the writers. On the Scottish side, *The Brus*, a poem by John Barbour, ed. by W. W. Skeat (Edinburgh, 1894), and the *Chronica gentis Scotorum* of John of Fordun, ed. by W. F. Skene (Edinburgh, 1871–72), are perhaps the most valuable. The *Chronicon de Lanercost*, ed. by J. Stevenson (Edinburgh, 1839), is also important. The English chronicles which may be consulted with advantage are those of Walter of Hemingford, ed. by H. C. Hamilton (1848–49) and of Peter Langtoft, ed. by T. Wright (1866–68), and the *Scalacronica* of Thomas Gray, ed. by J. Stevenson (Edinburgh, 1836). For the documents of the time reference should be made to the *Calendar of Documents relating to Scotland*, ed. by J. Bain (Edinburgh, 1881–88), *Documents and Records Illustrating the History of Scotland*, vol. i., ed. by F. Palgrave (1837); the *Rotuli Scotiae* (1814–19), and the *Foedera* of T. Rymer, vol. i. (1704). *See* also Sir H. Maxwell, *Robert the Bruce* (1897); A. M. Mackenzie, *Robert Bruce, King of Scots* (London, 1934).

ROBERT II. (1316–1390), called "the Steward," king of Scotland, a son of Walter, the steward of Scotland (d. 1326), and Marjorie (d. 1316), daughter of King Robert the Bruce, was born on March 2, 1316. In 1318 the Scottish parliament decreed that if King Robert died without sons the crown should pass to his grandson; but the birth of a son, afterwards King David II., to Bruce in 1324 postponed the accession of Robert for nearly 42 years. Soon after the infant David became king in 1329, the Steward began to take a prominent part in the affairs of Scotland. He was one of the leaders of the Scottish army at the battle of Halidon Hill in July 1333; and together with John Randolph, 3rd earl of Moray (d. 1346), was chosen co-regent of Scotland, while David sought safety in France. The colleagues soon quarrelled; Randolph fell into the hands of the English, and Robert became sole regent until the return of David in 1341. The Steward escaped from the battle of Neville's Cross in 1346, and was again regent while the king was a captive in England.

Soon after this event some friction arose between Robert and his royal uncle. Accused, probably without truth, of desertion at Neville's Cross, the Steward as heir-apparent was chagrined by David's recognition of Edward III. as his successor.

In 1363 he rose in rebellion, and after having made his submission was seized and imprisoned together with his three sons, being only released a short time before David's death in February 1371. By the terms of the decree of 1318 Robert now succeeded to the throne, and was crowned at Scone in March 1371. His reign was unimportant; for relations with England and France see SCOTLAND: *History*. The king died at Dundonald on May 13, 1390, and was buried at Scone.

See Andrew of Wyntoun, *The Orygynale Cronykil of Scotland*, edited by *D.* Laing (Edinburgh, 1872–79); John of Fordun, *Scotichronicon*, continued by Walter Bower, ed. T. Hearne (Oxford, 1722); John Major, *Hzstória maioris Britanntae* translated by *A.* Constable (Edinburgh, 1892); and P. F. Tytler, *History of Scotland* (Edinburgh, 1841–43).

ROBERT III. (*c.* 1340–1406), king of Scotland, was the eldest son of King Robert II. by his mistress, Elizabeth Mure, and was legitimatized when his parents were married about 1349. In 1368 he was created earl of Carrick, and he took some part in the government of the kingdom until about 1387, when he was disabled by the kick of a horse. It was probably in consequence of this accident that his brother Robert, earl of Fife, and not the crown prince himself, was made guardian of the kingdom in 1389; but the latter succeeded to the throne on his father's death in May 1390. At this time he changed his baptismal name of John, which was unpopular owing to its connection with John de Baliol, for that of Robert, being crowned at Scone in August 1390 as King Robert III. The new king was only the nominal ruler of Scotland, the real power being in the hands of his brother, the earl of Fife. In 1399, his elder son, David, duke of Rothesay, was appointed lieutenant of the kingdom; but this event was followed by an English invasion of Scotland, by serious differences between Rothesay and his uncle, Robert, now duke of Albany, and finally in March 1402 by Rothesay's mysterious death at Falkland. Early in 1406 the king's only surviving son, afterwards King James I., was captured by the English; and on April 4, 1406, Robert died, probably at Rothesay, and was buried at Paisley.

ROBERT, the name of two dukes of Normandy.

ROBERT I. (d. 1035), called Robert the Devil, was the younger son of Richard II., duke of Normandy (d. 1026), and father of William the Conqueror. In 1028 he succeeded his brother, Richard III., whom he was accused of poisoning, as duke of Normandy. Robert sheltered the exiled English princes, Edward, afterwards King Edward the Confessor, and his brother Alfred, and fitted out a fleet for the purpose of restoring them to their inheritance, but this was scattered by a storm. When returning from a pilgrimage to Jerusalem, he died at Nicaea on July 22, 1035. Robert is the subject of several poems and romances. (*See* ROBERT THE DEVIL.)

ROBERT II. (c. 1054–1134), called Robert Curthose, was the eldest son of William the Conquerer. Although recognized in boyhood as his father's successor in Normandy, he twice revolted

against his father. (*See* WILLIAM I.) When the Conqueror died in Sept. 1087, Robert became duke of Normandy, but not king of England; although he received offers of help, he took no serious steps to displace his younger brother, King William II. In Normandy his rule was weak and irresolute. In 1089 his duchy was invaded by William II, who soon made peace with Robert, the two agreeing to dispossess their brother Henry of his lands in Normandy. This peace lasted until 1094, when occasions of difference again arose and another struggle began, Robert being aided by King Philip I of France.

This warfare ended in 1096, when Robert set out on the first crusade. He returned to Normandy in Sept. 1100.

William Rufus died while Robert was on his homeward way, and in Italy the Norman duke was greeted as king of England; but when he reached Normandy he learned that the English throne was already in the possession of Henry I. In July 1101 he crossed over to England, intending to contest his brother's title, but Henry met him near Alton, in Hampshire, and an amicable arrangement was made between them. But there was no lasting peace. In 1106 the English king crossed over to Normandy, and at the battle of Tinchebrai (Sept. 28, 1106), Henry took his brother prisoner and carried him to England. For 28 years Robert was a captive. He died Feb. 10, 1134.

ROBERT OF AUXERRE (*c.* 1156–1212), French chronicler, was an inmate of the monastery of St. Marien at Auxerre. At the request of Milo de Trainel (1155–1202), abbot of this house, he wrote a *Chronicon* or universal history, which covers the period between the creation of the world and 1211. Robert is an original authority for the period from 1181 to 1211. Two continuators took the work down to 1228 and it was extensively used by later chroniclers.

ROBERT OF COURTENAY (d. 1228), emperor of Rumania or Constantinople, was a younger son of the emperor Peter of Courtenay. When it became known in France that Peter of Courtenay was dead, his eldest son, Philip, renounced the succession in favour of his brother Robert, who set out to take possession of his distracted inheritance. Crowned emperor on March 25, 1221, Robert appealed for help to the pope and to the king of France; but meanwhile his lands were falling into the hands of the Greeks. Some little aid was sent from western Europe, but soon Robert was compelled to make peace with his chief foe, John Ducas Vatatzes, emperor of Nicaea, who was confirmed in all his conquests. Robert died in Achaia in 1228.

ROBERT THE DEVIL, legendary son of a duke of Normandy, who, at 20, uses his immense strength only for outrage and crime. His mother informs him, in explanation of his evil impulses, that he was born in answer to prayers addressed to the devil; and a hermit, to whom the pope directs him, requires him as a penance to maintain absolute silence, feign madness, take his food from the mouth of a dog and provoke ill-treatment from the common people without retaliating. Later, while the emperor's court fool, he appears as an unknown knight at the bidding of a celestial messenger and delivers Rome from Saracen attacks in three successive years; his disguise is pierced by the emperor's dumb daughter, who recovers speech to identify him, but he refuses her hand and withdraws to end his days with the hermit.

This legend is found in a late 12th-century romance, *Robert Le Diable,* ed. by E. Löseth for the Société des Anciens Textes Français (1903). Another version, in which Robert is a bandit who, in penitence, kills his accomplices, feigns madness, is recognized as son of the duke of Normandy and is married by the pope to the emperor's daughter, forms the subject of the 14th-century *Mystère de Robert le Diable* ed. by E. Fournier, 1879. For another 14th-century version, in alexandrine quatrains, *see* K. Breul, *Le dit de Robert le Diable,* in *Abhandlungen Prof. A. Tobler dargebracht* (1895). The legend, distorted, also provides the Eugène Scribe libretto for Meyerbeer's opera, *Robert le Diable* (1831).

ROBERT OF GLOUCESTER (fl. 1260–1300), English chronicler known only through his connection with the work which bears his name, probably written *c.* 1300. This is a vernacular history of England, from the days of the legendary Brut to the year 1270, written in rhymed couplets. The lines are of 14 syllables, with a break after the eighth syllable. In some manuscripts the early part (up to 1135) is followed by a brief continuation by an anonymous versifier, and in these slight deviations from the version generally accepted as Robert's are also discernible. The authorities employed for the earlier part were Geoffrey of Monmouth, Henry of Huntingdon, William of Malmesbury, the English chronicles and some minor sources; Robert, in making his recension of it, also used the *Brut* of Layamon. From 1135 to 1236 Robert is still a compiler, although references to oral tradition become more frequent as he approaches his own time. From 1256 to 1270 he has the value of a contemporary authority, but he is more important to the philologist than to the historian.

Robert's chronicle was first edited by T. Hearne, 2 vol. (1724), but this text was superseded by that of W. Aldis Wright, 2 vol., Rolls series (1887). Extracts (1192–1270) were edited by F. Liebermann in *Monumenta Germaniae Historica, Scriptores,* xxviii, pp. 663–669 (1888).

Brossman, *Über die Quellen der mittelenglischen Chronik des Robert von Gloucester* (1887); W. Ellmer, *Anglia,* x, pp. 1–37, 291–322 (1888); H. Strohmeyer, *Der Styl der Reimchronik Roberts von Gloucester* (1891), "Das Verhältnis der Handschriften der Reimchronik Roberts von Gloucester," *Archiv für das Studium der neueren Sprachen,* lxxxvii, pp. 217–232 (1891).

(X.; D. WK.)

ROBERT OF JUMIÈGES (d. *c.* 1055), archbishop of Canterbury, was a Norman monk who became prior of St. Ouen and in 1037 abbot of the Benedictine abbey of Jumièges, near Rouen. He was taken to England by his friend Edward the Confessor in 1042 and made bishop of London in 1044. He became Edward's leading adviser and head of the Norman party, and was appointed archbishop of Canterbury in 1051. Although Robert was instrumental in bringing about the exile of Earl Godwine in 1051, on the native leader's return in 1052 the archbishop himself was forced to flee to the continent. Deposed and outlawed by the Witenagemot, Robert died at Jumièges, possibly in 1055. The uncanonical usurpation of the primatial see by Stigand enabled William of Normandy to champion the ecclesiastical cause and obtain papal support for his invasion of 1066. (D. D. McG.)

ROBERT THE STRONG (LE FORT) (d. 866), count of Anjou and of Blois, appears as rector of the abbey of Marmoutier in 852, and as one of Charles the Bald's *missi dominici,* in 853; but soon afterward he was among those who rebelled against Charles, and invited the king's half-brother, Louis the German, to invade West Francia.

In 860 Robert came to terms with Charles, who made him count of Anjou and of Blois and entrusted him with the defense of that part of his kingdom which lay between the Seine and the Loire, a district which had suffered greatly from the ravages of the Normans and the Bretons. He was killed in battle at Brissarthe in Oct. 866, leaving two sons, Odo or Eudes and Robert, both of whom became kings of the Franks. Robert was the ancestor of the Capetian kings of France.

See K. von Kalekstein, *Robert der Tapfere* (1871); E. Favre, *Eudes, comte de Paris et roi de France* (1893).

ROBERT OF TORIGNI (*c.* 1110–1186), medieval chronicler, was prior of Bec in 1149, and in 1154 became abbot of Mont St. Michel, whence he is also sometimes called Robertus de Monte. He died, according to Potthast, on May 29, 1186.

Robert wrote additions and appendices to the chronicle of Sigebert of Gembloux, covering the period A.D. 385–1100, and a chronicle in continuation of Sigebert, extending from 1100 to 1186, of great value for Anglo-Norman history. It is for continental affairs between 1154 and 1170 that his information is valuable.

ROBERT, HUBERT (1733–1808), French painter, sometimes called "Robert des Ruines" because of his paintings of Roman ruins, was born in Paris on May 22, 1733. His first teacher was the sculptor Michel Ange Slodtz. He went to Rome in 1754, where he had to pay a small fee for his keep at the French academy before receiving a formal appointment. French travelers to Italy began to purchase his views of Rome. In 1759 the abbé de Saint-Non and the painter Jean Honoré Fragonard, his elder, joined him

and they traveled to Tivoli and Naples. Living at the Villa d'Este, they produced a quantity of drawings in red chalk of ancient buildings in ruined parks, animated with small figures. After his 11-year stay in Italy, Robert left the country in 1765, and became a member of the Paris academy the next year.

Robert was a born decorator and his paintings looked well on the gray wainscoting then much used. His popularity was enhanced by exhibitions at the Salons from 1767 on. In addition to his Italian landscapes, he painted scenes of Ermenonville, Marly and Versailles, near Paris, and of the south of France, with ruined monuments of the Roman era. During the Revolution he was imprisoned but continued his work; the fall of Robespierre saved him from the guillotine. He worked with Fragonard on a commission for the Musée Français, then a national museum in the old palace of the Louvre. He died in Paris on April 1j, 1808, entirely forgotten. He is represented by works at the Louvre, Paris, the Versailles palace and many French museums, the Metropolitan museum, New York city, the Institute of Fine Arts, Detroit, Mich., and the Art Institute of Chicago.

ROBERT GUISCARD (*i.e.*, "the resourceful") (*c.* 1015–108j), the most remarkable of the Norman adventurers who conquered southern Italy. Those who first came in 1016 to seek their fortune in Apulia and Calabria seem to have had no political ambitions. They arrived in small groups and lacked organization and experienced leadership. They were prepared to live as mercenaries in the service of Greeks or of Lombards. It was not until 1030 that Sergius of Naples, by installing the leader Rainulf in the fortress of Aversa, gave them their first *pied-à-terre* and that they began an organized conquest of the land. Foremost in this work were the sons of Tancred de Hauteville, whose lands near Coutances were too modest to support his large family. William "Iron Arm" and Drogo were successively leaders of those Normans who from 1040 were extending their possessions in Apulia and Calabria, and among their brothers who joined them were Humphrey in 1044 and Robert Guiscard in 1046. At first, Robert was not made welcome and was forced, as were many of his compatriots, to live like a brigand, terrorizing and laying waste the countrvside. Because of the distress so caused. Leo IX attempted to-subdue the Normans by force; but their principal leaders, among them Robert, combined in 1053 to defeat the pope at Civitate. Thereafter Robert prospered. In 1057 he succeeded Humphrey as recognized leader of the Normans in Apulia. In 1059 Pope Nicholas II, seeking independence from the German king Henry IV and the Roman nobility, turned to the Normans as allies. On Aug. 23, 1059, Robert became a vassal of the pope, promising tribute and help when needed. In return he became "by grace of God and St. Peter duke of Calabria and Apulia and future lord of Sicily." It was a master stroke. Robert's dominion was legitimized by solemn papal investiture.

In the next 20 years Guiscard made an amazing series of conquests at the expense of Moslems, Greeks and Lombards. Invading Sicily with his brother Roger, he captured Messina (1061) and Palermo (1072). Bari was reduced (April 1071) and the Greeks were finally ousted from southern Italy. The territory of Salerno was already Robert's; in Dec. 1076 he took the city, expelling its Lombard prince Gisulf, whose sister Sicelgaeta he had married.

The Norman attacks on Benevento, a papal fief, alarmed Gregory VII but, pressed by Henry IV, he turned again to the Normans and at Ceprano (June 1080) reinvested Robert, securing him also in the southern Abruzzi, but reserving Salerno. Guiscard's last enterprise was his attack on the eastern empire, a rallying ground for his rebel vassals. He contemplated seizing the imperial throne and took up the cause of Michael VII, who had been deposed in 1078 and to whose son his daughter had been betrothed. He sailed against the empire in May 1081 and had occupied Corfu and Durazzo by Feb. 1082. He was, however, recalled to the aid of Gregory VII, who was besieged in San Angelo by Henry IV (June 1083). Marching north, he entered Rome and forced Henry to retire, but an *émeute* of the citizens led to a three days' sack of the city (May 1084), after which Guiscard escorted the pope to Salerno. His son Bohemund (*q.v.*), for a time master of Thessaly, had now lost the Greek conquests. Robert, returning to restore them, occupied Corfu and Cephalonia, but died of fever on July 17, 1085. (E. CU.; R. C. SMA.)

ROBERTS, SIR CHARLES GEORGE DOUGLAS (1860–1943), Canadian poet and prose writer, is often referred to as the father of Canadian literature. He was the first poet to express the new national feeling aroused in Canada by the Confederation of 1867, and his example and counsel inspired a whole school of late 19th-century Canadian poets.

Roberts was born near Fredericton, N.B., Jan. 10, 1860. After graduation from the University of New Brunswick in 1879, he taught school. edited the influential Toronto magazine *The Week*, and was for ten years professor of English at King's college, Windsor, N.S. In 1897 he moved to New York city where he worked as a journalist, and in 1907 he went to London. Upon his return to Canada in 1925, he was enthusiastically received on a cross-Canada lecture tour and later settled in Toronto as the acknowledged dean of Canadian letters. He was knighted by King George V in 1935. He died in Toronto on Nov. 26. 1943. and was buried in Fredericton.

Roberts was almost equally adept at prose and poetry. His prose included a pioneer *History of Canada* (1897), several novels dealing with the past and present of the maritime provinces, and many volumes of the animal stories that were his chief source of fame as a prose writer. In such books as *Earth's Enigmas* (1896), *The Kindred of the Wild* (1902) and *Neighbours Unknown* (1911) he displayed his intimate knowledge of the woods and their animal inhabitants.

Later criticism, however, tended to value Roberts' poetry rather more highly than his prose. Beginning with *Orion* (1880), he published about 12 volumes of verse, of which the best were *In Divers Tones* (1887), *Songs of the Common Day* (1893), *The Vagrant of Time* (1927) and *The Iceberg and Other Poems* (1934). *Selected Poems*, edited by Desmond Pacey, was published in 1956. Roberts wrote of nature, love, nationalism and philosophy, but his best poems by general consent were his simple descriptive lyrics about the scenery and rural life of New Brunswick and Nova Scotia.

ROBERTS, FREDERICK SLEIGH ROBERTS, 1ST EARL (1832–1914), British soldier, whose successful campaigns principally in India, Afghanistan and South Africa culminated in his appointment as commander in chief of the British army, was born at Cawnpore, India, Sept. 30, 1832. Educated at Eton, Sandhurst and Addiscombe, he obtained a commission in the Bengal artillery on Dec. 12, 1851. In 1852 he was posted to a field battery at Peshawar, where he also acted as aide-de-camp to his father, who commanded the Peshawar division. In 1856 Roberts was appointed to the quartermaster general's department of the staff. in which he remained for 22 years, passing from one grade to another until he became quartermaster general in India. On the outbreak of the mutiny in 1857, Roberts, at first, was staff officer to the movable column operating against the mutineers in the Punjab but, toward the end of June, he joined the Delhi field force and was deputy assistant quartermaster general with the artillery during the operations against Delhi. He served under Sir Colin Campbell at the second relief of Lucknow in November, at the battle of Cawnpore on Dec. 6 and the subsequent pursuit and defeat of the Gwalior contingent near Shinrajpur.

Roberts distinguished himself at the engagement of Khudaganj on Jan. 2, 1858. He was present at the reoccupation of Fatehgarh on Jan. 6, the storm of Mianganj in February, the siege and capture of Lucknow in March, and the action at Kursi on March 22, after which he went home on sick leave. On his return to India he was entrusted with'the organization of the viceroy's camps during the progresses through Oudh, the North-West Provinces, the Punjab and Central India, in 1860 and 1861. In Dec. 1863

he took part, under Maj. Gen. John Garvock, in the Ambela campaign against the Hindustani fanatics among the mountains to the north of Peshawar, and was present at the storm of Lalu, the capture of Ambela and the destruction of Malka.

In 1867 Roberts was appointed assistant quartermaster general to Sir Donald Stewart's Bengal brigade for Abyssinia. He arrived at Zula, Annesley Bay. in the Red Sea, the base of the expedition, on Feb. 3, 1868, and remained there as senior base staff officer during the four months' campaign. At its close he superintended the re-embarkation of the whole army. He returned to India the following year as first assistant quartermaster general. In the autumn of 1871 he made the arrangements for the expedition against the tribes of the Lushai hills, between southeast Bengal and Burma. On his return in March 1872, he became deputy quartermaster general in Bengal, and in 1875 quartermaster general and colonel. He settled the details of the great camp of exercise at Delhi on the occasion of the visit of the prince of Wales in Jan. 1876, and attended him at the maneuvers. He also superintended the arrangements for the great durbar (ceremonial gathering) at Delhi on Jan. 1, 1877, when Queen Victoria was proclaimed empress of India.

In 1878 Roberts was appointed to the command of the Frontier field force at Abbottabad, in Hazara; but in the autumn, on the repulse of Sir Neville Bowles Chamberlain's mission by the Afghans at Ali Masjid, and the formation of three columns to advance into Afghanistan by the Khyber, the Bolan and the Kurram passes, he was given command of the Kurram field force, with the rank of major general. Concentrating his column at Thal, he advanced to Kurram toward the end of November and, having formed an advanced base there, moved on to Habib Kila. Under cover of preparations for a front attack on the Peiwar Kotal, he reconnoitred that formidable position and, on the night of Dec. 1, moved part of his force to attack the Spingawi Kotal. in order to turn the Afghan left flank, leaving the remainder of the force to feign a front attack on the Peiwar and to guard the camp. After a very difficult night march the Spingawi Kotal was carried at daybreak on Dec. 2 and, later, the Afghans on the Peiwar Kotal, threatened in the rear, abandoned the position.

At the end of January he returned to Hagir Pir, in Kurram, where his force remained in occupation. In July Maj. Louis Cavagnari, the British envoy to the new amir, Yakub Khan, passed through Kurram on his way to Kabul, and, shortly afterward, Roberts left his Kurram command and went to Simla to take his seat on the army commission.

While Roberts was at Simla, news arrived on Sept. 5 of the murder of Cavagnari and his companions at Kabul. By Sept. 19 a brigade was entrenched on the Shutargardan and, as Roberts advanced. Amir Yakub Khan came into his camp. On Oct. 6 the enemy was severely defeated.

Yakub Khan abdicated on Oct. 12 and was eventually deported to India. The troops occupied the Sherpur cantonments; but in November a religious war was proclaimed by the Mullahs and, early in December, in order to prevent a threatening combination of Afghan tribes against him, Roberts moved out two columns to attack them in detail. After considerable fighting near Kabul, the numbers of the enemy became so great that he was forced to concentrate his troops again at Sherpur, the defenses of which had been greatly improved and strengthened. Sherpur was invested by the enemy, and early on Dec. 23, was attacked by over 100,000 Afghans. They were driven off with great loss and, on making a second attempt to storm the place, were met by Roberts, who moved out, attacked them in flank, and defeated them.

Roberts now recommended the political dismemberment of Afghanistan, and negotiations were carried on mith the northern tribes for the appointment of an amir for the Kabul district only. On May 5, Sir Donald Stewart arrived with his column from Kandahar and assumed the supreme command in Afghanistan. Roberts retained, under Stewart. the command of the two Kabul divisions, and organized an efficient transport corps under Col. R. Low, which was soon to be of inestimable value. On July 22, Abdur Rahman was proclaimed Amir of Kabul. Roberts was preparing to withdraw his troops to India by the Kurram route, when news arrived that a British brigade had been totally defeated at Maiwand on July 27, and that Lieut. Gen. James Primrose was besieged in Kandahar.

Roberts was ordered to proceed thither at once with a specially selected column of 10.000 troops and his ne transport corps. He started on his famous march on Aug. 9 and arrived at Kandahar on the morning of the 31st, having covered 313 miles in 22 days. The ease mith which Roberts effected his famous march is partly explained by the fact that Abdur Rahman wrote to the tribal chiefs between Kabul and Kandahar asking them not to contest the advance of the British forces. On the following day he fought the battle of Kandahar and gained a complete victory. Roberts was now created K.C.B., G.C.B. and a baronet, and was given the command of the Madras army.

Before proceeding to Madras, Roberts went home on furlough, and when the news of the disaster at Majuba Hill in South Africa arrived in London at the end of Feb. 1881, he was appointed governor of Natal and commander in chief in South Africa. He arrived at Cape Town to find that peace had been made with the Boers, and that instructions awaited him to return home. He returned to India in November. The following year he visited Burma with the viceroy, and in 1885 attended the meeting between Abdur Rahman and Lord Dufferin at Rawalpindi at the time of the Panjdeh incident. In July he succeeded Sir Donald Stewart as commander in chief in India. At the end of 1886, at the request of the viceroy, he took personal command for a time of the forces in Burma, and organized measures for the suppression of dacoity. In 1893 he left India for good.

After the disastrous actions in the Boer war in South Africa in Dec. 1899 at Magersfontein, Stormberg and Colenso, where his only son was killed, Lord Roberts was sent out as commander in chief. He arrived at Cape Town on Jan. 10, 1900, and, after organizing his force, advanced with sound strategy on Bloemfontein, the capital of the Orange Free State, and soon changed the aspect of affairs. The sieges of Kimberley and Ladysmith were raised, and the Boer general, Piet Cronje, fleeing toward the capital, was overtaken at Paardeberg and, after a fine defense, was compelled to surrender.

Roberts entered Bloemfontein on March 13 and, after six weeks' preparation, advanced on Pretoria, the capital of the Transvaal. Mafeking was relieved on May 17 and Pretoria occupied on June 5. The two Boer states were annexed and, the war gradually assuming a guerrilla character, Roberts handed over the command to Lord Kitchener and returned to England to fill the office of commander in chief of the army in succession to Lord Wolseley.

On the outbreak of World War I he was a frequent visitor at the war office, and shortly after the arrival of the two Indian divisions in France he crossed the channel to visit them in the trenches. He was attacked by pneumonia while at the front and died at St. Omeron Nov. 14, 1914.

BIBLIOGRAPHY.—Lord Roberts works included: *The Rise of Wellington* (1895); *Forty-one Years in India,* 2 vol. (1897); *Letters Written During the Indian Mutiny* (1924). *See* also H Hensman, *The Afghan War of* 1879–1880 (1881); *The Anglo-Ajghan War,* official account (1881); Sir T. E. Maurice and M. H. Grant, *History of the War in South Africa* 1899–1902 (1906–10); Sir G. W. Forrest, *The Life of Lord Roberts* (1914); David James, *Lord Roberts* (1954).

ROBERTS-AUSTEN, SIR WILLIAM CHANDLER *(1843–1902)*, English metallurgist noted for his researches into the physical properties of metals, was born in Kennington, Surrey, March 3, 1843. At the wish of his uncle, Maj. Nathaniel L. Austen, he later adopted the name commemorated in the term austenite, used for the solid solution of carbon in gamma-iron (see IRON AND STEEL: *Austenite*). Educated at the Royal School of Mines, he became private assistant to the master of the mint (1865) and chemist to the mint (1870), chemist and assayer (1882) and acting deputy master (1902). He also became professor of metallurgy at the School of Mines in 1880. An outstanding teacher, Roberts-Austen won renown for his work in the new field of physical metallurgy, much of which formed the basis of the alloys research reports of the Institution of Mechanical Engineers. He served on the treasury committee entrusted with the establishment of the National Physical laboratory (1897) and

was an original member of the war office explosives committee (1899). Among the many honours bestowed upon him was fellowship of the Royal society (1875). He died in London on Nov. 22, 1902. (C. W. D.)

ROBERTSON, FREDERICK WILLIAM (1816–1853), English clergyman, known as Robertson of Brighton, was born in London on Feb. 3, 1816. He studied at Edinburgh university, and at Brasenose college, Oxford. He had intended to go into the army, but Oxford changed the bent of his mind, and he was ordained in 1840, and served in curacies at Winchester and Cheltenham. He entered in 1847 on his famous ministry at Trinity chapel, Brighton, where his church was thronged with thoughtful men of all types.

Robertson was not a scientific theologian; but his insight into the principles of the spiritual life was unrivaled. As his biographer says, thousands found in his sermons "a living source of impulse, a practical direction of thought, a key to many of the problems of theology, and above all a path to spiritual freedom." His closing years were full of suffering, arising mainly from the opposition aroused by his sympathy with the revolutionary ideas of the 1848 epoch. He died on Aug. 15, 1853.

Robertson's works include five volumes of sermons, two volumes of expository lectures. on Genesis and on the epistles to the Corinthians, a volume of miscellaneous addresses, and an *Analysis of "In Memoriam."*

See Stopford *A.* Brooke, *Life and Letters* (1865).

ROBERTSON, THOMAS WILLIAM (1829–1871), English actor and dramatist, was born at Newark on Jan. 9, 1829. Robertson was familiar with the stage from his childhood; he was the eldest of a large family, the actress Margaret (Madge) Robertson (Mrs. Kendal) was the youngest. A farcical comedy by him, *A Night's Adventure,* was produced, without great success, at the Olympic, under Farren's management as early as 1851. He remained for some years longer in the provinces, varying his work as an actor with miscellaneous contributions to newspapers. In 1860 he went to London, and edited a mining journal. He was at one time prompter at the Olympic under the management of Charles Mathews. He wrote a farce entitled *A Cantab,* which was played at the Strand theatre in 1861. This brought him a reputation in a Bohemian clique, but so little practical assistance that he thought of abandoning the profession to become a tobacconist. Then, in 1864, came *David Garrick,* produced at the Haymarket with Edward Sothern in the principal character, which has kept the stage ever since.

But his name was made by the production of *Society* at the Prince of Wales theatre in 1865, under the management of Miss Marie Wilton, afterward Mrs. Bancroft. Playwriter and company were exactly suited one to another; the plays and the acting together—the small size of the playhouse being also in their favour—were at once recognized as a new thing. Although some critics sneered at the "cup-and-saucer comedy," voted it absurdly realistic, said there was nothing in it but commonplace life represented without a trace of Sheridanian wit and sparkle, all London flocked to the little house in Tottenham street, and the stage was at once inundated with imitations of the new style of acting and the new kind of play. All Robertson's best-known plays (except *David Garrick*) were written for the old Prince of Wales's under the Bancrofts, and that régime is now an historical incident in the progress of the English stage. *Ours* was produced in 1866, *Caste* in 1867. *Play* in 1868, *School* in 1869, *M.P.* in 1870. Robertson died in London on Feb. 3, 1871.

See *Principal Dramatic Works of Robertson; with Memoir by his son* (1889) ; and *T.* E. Pemberton, *Life and Writings of Robertson* (1893).

ROBERTSON, WILLIAM (1721–1793), Scottish historian and Presbyterian minister, whose writings were the earliest popular histories within their respective fields and were highly esteemed by his contemporaries. He was born at Borthwick, Midlothian, on Sept. 19, 1721. After being educated at Dalkeith grammar school and Edinburgh university, he was presented to the living of Gladsmuir, near Edinburgh, in 1743. A member of the General Assembly from 1746 he was elected moderator in 1762 and for many years his influence as leader of the "moderate" party was supreme. *(See* PRESBYTERIAN.)

Robertson's career as historian began with the publication of *History of Scotland during the Reigns of Queen Mary and of James VI until his Accession to the Crown of England,* 2 vol. (1759), which brought immediate fame and was eulogized by, among others, David Hume and Edward Gibbon. It also gained the favour of Lord Bute, who secured Robertson's appointment as principal of Edinburgh university in 1762 and revived the office of historiographer royal for him in 1763. Robertson's next work was *History of the Reign of the Emperor Charles the Fifth,* 3 vol. (1769). and this was followed by *History of America,* 3 vol. (5th ed , 1788). Robertson's reputation has not stood the test of time. His concern for the "dignity of history" often seems mere pomposity and his straightforward prose is often dull. He had the virtue of adhering closely to his sources, but. as a corollary, held that those early periods of history which were poorly documented deserved to be forgotten. Of his three major works, the *History of America* (in effect, Spanish America) was the most outstanding and for this Robertson would undoubtedly be more widely remembered were he not unfortunate in having been followed by W. H. Prescott.

See J B. Black, *The Art of History* (1926) ; *R.* A. Humphreys, *William Robertson and his "History of America"* (1954).

ROBERTSON, SIR WILLIAM ROBERT (1860–1933), British field marshal, was born at Welbourn, Lincs., on Sept. 14, 1860. He enlisted as a private in the 16th Lancers in 1877, and served in the ranks of that regiment until 1888, when he won a commission in the 3rd Dragoon Guards, then in India. He eagerly studied his profession in all its branches and he learned the native languages. He was railway staff officer in the Miranzai and Black Mountain operations of 1891, and in the following year joined the intelligence department at Simla; while on its staff he carried out a reconnaissance to the Pamirs, and in 1895 served with the Chitral Relief Force, being wounded and receiving the D.S.O. He passed through the Staff College in 1897–8—the first officer risen from the ranks to do so—and then, after a few months at the War Office, went out to South Africa on the Intelligence Staff; he accompanied Lord Roberts on his advance from Cape Colony into the Transvaal, and was promoted brevet lieutenant-colonel for his services. He spent the period from 1901 to 1907 at the War Office, being promoted colonel in 1903, and he then went to the staff at Aldershot, where he spent three years. In 1910 he was appointed commandant of the Staff College, was shortly afterwards promoted major-general and in 1913 became director of military training at the War Office.

On the mobilization of the army for the World War, Robertson became quartermaster-genera1 of the Expeditionary Force, and in Jan. 1915 chief of the general staff to Sir John French. In the following December he was brought back to the War Office as chief of the imperial general staff and immediately introduced great improvements in the office organization. Convinced that the Western Front represented the decisive theatre of war, and fully aware how mischievous was dispersion of force in principle, he saw to it that, where operations in distant regions were unavoidable, the commanders on the spot were furnished with what was deemed essential to achieve success—with the result that the position of affairs in Mesopotamia, on the Suez frontier and in East Africa was completely transformed within a very few months. His services were recognized by promotion to general in 1916 and by the G.C B. in 1917.

In the later months of 1917 he found it more and more difficult, in view of the disappointing results of Allied offensives in France and Flanders, to persuade the War Cabinet that diversion of fighting resources to other theatres of war endangered prospects of victory at the decisive point and might lead to disaster near home. His anxieties were increased by the manner in which the problem of man-power was treated. He moreover foresaw that the Supreme War Council, introduced towards the end of the year, would not provide effective means for combining the operations of the Allies. In Feb. 1918 he was transferred by the Government to the charge of the eastern command in England—just one month be-

fore the success that attended the great German offensive of March proved how correct had been his appreciation of the situation. Three months later he succeeded French as commander-in-chief in Great Britain. After the War he received a baronetcy, a grant of £10,000, and in 1919, the G.C.M.G. From April 1919 to March 1920 he commanded the British troops on the Rhine, and, after relinquishing that appointment on the force being reduced, was promoted field-marshal. Robertson received many English and foreign honours, including the G.C.V.O. (1931).

See his *From Private to Field-marshal* (1921); and *Soldiers and Statesmen 1914–1918* (1926).

ROBERVAL, GILLES PERSONNE (PERSONIER) **DE** (1602–1675), French mathematician, whose most important work was done on curves, was born at Roberval, near Beauvais, on Aug. 8. 1602. In 1632 he became professor of mathematics in the Collège de France and maintained this position until his death in Paris on Oct. 27, 1675.

Roberval studied the quadrature of surfaces and the cubature of solids, which he accomplished, in some of the simpler cases by an original method which he called the "method of indivisibles." He discovered a general method of drawing tangents, by considering a curve as described by a moving point whose motion is the resultant of several simpler motions.

He also discovered a method of deriving one curve from another. by means of which finite areas can be obtained equal to the areas between certain curves and their asymptotes. To these curves. which were also applied to effect some quadratures, Evangelista Torricelli gave the name of "Robervallian lines." Roberval was an irascible person who indulged in scientific feuds with several of his contemporaries, among them Descartes. He invented the balance which goes by his name.

His works were published in 1693 by the Abbé Gallois, in the *Recueil* of the *Mémoires* de *l'Académie* des Sciences.

See E. Walker, *a Study of the Traité des indivisibles of G. P, de Roberval* (1932). (O. OE)

ROBES, the name generally given to a class of official dress, especially as worn by certain persons or classes on occasions of particular solemnity. The word robe (toga) was earliest used, in the sense of a garment, of those given by popes and princes to the members of their household or their great officers. It would be going too far to assume that, for example, peers' robes were originally the king's livery, but in most early cases where robes are mentioned. if not of cloth of gold, etc., they are of scarlet, furred. A robe is properly a long garment (toga talaris), and the term "robes" is now applied only in those cases where a long garment forms part of the official dress, though in ordinary usage it is taken to include all the other articles of clothing proper to the full dress in question. The term "robes" moreover, connotes a certain degree of dignity or honour in the wearer. It is proper to speak of the sovereign's robes of state. of peers' robes, of the robes of the clergy. of academical robes, judicial robes, municipal or civic robes. In the case of the official dress of the clergy, too, a distinction must be drawn. The sacerdotal vestments are not spoken of as "robes"; a priest is not "robed" but "vested" for Mass; yet the rochet and chimere of an English bishop. even in church, are more properly referred to as robes than as vestments, and, while the cope he wears in church is a vestment rather than a robe, the scarlet habit which is part of his parliamentary full dress is a robe, not a vestment. This habit is a doctor's convocation robe (supertunica, "the sleveless cote" of the act of 24 Henry VIII, 1533, *caput* 13) and non-doctor bishops and suffragans should not wear it. It is faced and partly lined uith the silk of the doctorate held. The chimere (*supertunica*) of the Anglican prelate is of black corded ottoman silk: the scarlet chimere is a preaching, court and parliamentary robe. The bishop's rochet is not a liturgical vestment but is a kind of outdoor traveling shirt. But the priest's surplice is a liturgical vestment (*superpellicium*). The full-dress doctors' robes worn by bishops on non-ecclesiastical occasions are post-Reformation, lay and purely academical robes (sleeved tabards). authorized at the Hampton Court conference, 1603. The official.non-liturgical dress of the clergy is dealt with in the article VESTMENTS.

The coronation robes reflect the requirements of royal ceremonial and the sacerdotal significance of Christian kingship. The robes of the British sovereign consist of a crimson surcoat, parliamentary robe and cap of estate worn before the service. During the ceremony, the sovereign is invested with the *Colobium Sindonis,* a loose linen garment. the dalmatic or cloth of gold surcoat with girdle of the same, surmounted by the *Pallium* Regale or cloth of gold mantle and *armilla* or stole. Leaving Westminster abbey, the purple surcoat is worn under the purple robe of estate, with the imperial state crown. Queen Elizabeth II wore these traditional robes in 1953, omitting the crimson and purple surcoats for a coronation dress, and the cap of estate. The sovereign's coronation robes are described in "The King's Coronation Ornaments," by William H. St. John Hope, in The Ancestor, vols. i and ii (1902), also by L. Wickham Legg (ed.), English Coronation Records (1901).

All countries which boast an ancient civilization have some sort of official robes, and the modern tendency has been to multiply rather than to diminish their number. In the United States few save judges of the higher courts wear robes. The scarlet judicial robes were discarded at the Revolution. Those of black silk now worn are slightly modified academical gowns. John Jay, first chief justice of the supreme court (1789), set the fashion by sitting in the LL.D. robe granted him by Columbia university.

Peers' **Robes.**—As early as the end of the 14th century peers seem to have uorn at their creation some kind of robe of honour. An illumination on the foundation charter of King's college, Cambridge, represents the peers in 1446 wearing gowns, mantles and hoods of scarlet, furred with miniver, the mantle opening on the right shoulder and guarded with two, three or four bars of miniver. in the form of short stripes high up on the shoulder. The origin of these is as yet unknown, though it is highly probable that these scarlet and miniver (or ermine) robes approximate to those of the medieval doctors, after they had adopted scarlet about 1340: it is not certain precisely when the peers' velvet robe of estate was first used. During the reign of Henry VIII, references are found to the "parliament robes" of peers. By the time of James II's coronation, the baron and viscount had the velvet robes of estate. The colour of these seems to have been crimson at first, sometimes varying to purple. They consisted of a long gown or surcoat with girdle, a mantle lined with ermine, a hood and a cape of ermine, the rows being as follows: for a duke 4, a marquess $3\frac{1}{2}$, an earl 3, a viscount $2\frac{1}{2}$ and a baron 2.

Till late in the 18th century peers continued to attend the house of lords in parliamentary robes, with the stars and ribands of their orders, but robes now are worn only in the house of lords, *e.g.,* at the opening of parliament, on occasions when the sovereign gives his (or her) assent to bills by "royal commission" (when five or six peers on the government side appear in robes and the lord chancellor also wears his peer's robe of scarlet ermine) and at the introduction of a newly created peer or peeress, when the new peer or peeress and his or her two introducers wear their parliamentary robes (over morning dress) during the ceremony of introduction only. The mover and seconder of the Address no longer wear robes, but uniform. On all the above occasions, and when the peers as a body attend church or some other ceremony, the parliamentary robe of scarlet cloth is worn; in the present day it takes the form of a mantle opening on the right shoulder, with a collar of ermine, and guarded with rows of ermine and gold lace round the right shoulder, varying in number according to the rank of the wearer. The modern coronation robes consist of a crimson velvet surcoat and a mantle with a cape of ermine and with rows of ermine as in the parliamentary robes. The surcoat is no longer a gown, but a short sleeveless garment.

As regards peeresses' robes, the order of the earl-marshal for the regulation of these at the coronation of James II shows that by then all peeresses wore the robes of state of crimson velvet and minutely regulates all details, such as shape, powderings, length of train and width of the fur edging of the mantle. They have changed very little up to the present day. Peeresses created for life when introduced into the house of lords for the first time in October 1958 wore normal parliamentary robes with a hat of

tricorn pattern.

House of Commons.—The speaker of the house of commons wears on state occasions a black damask robe with gold lace and a full-bottomed wig; in the house itself he wears a black silk robe with train and a full-bottomed wig. The clerks at the table wear barristers' gowns and wigs.

Robes of the Orders of Knighthood.—The robes of the Garter mere originally of blue woollen stuff, the surcoat and hood being powdered with garters embroidered in silk and gold. The surcoat varied in colour from year to year; the hood was made of the same material as the surcoat and, when hats began to be worn. was carried hanging over the shoulder. Robes were sometimes granted to ladies in the early days. The last lady to receive the robes was Margaret, countess of Richmond, in 1488. At the present day the mantle is of dark blue velvet, of the same colour as the riband, lined with taffeta, and with the star embroidered on the left shoulder, the hood and surcoat of crimson velvet lined with white taffeta, and with these are worn a doublet and trunk-hose of white satin and a plumed hat.

The robes worn by the knights of the Bath created at the coronation of Henry IV were green with furred hoods and a white silk cord hanging from the left shoulder. The mantle in the present day is of crimson velvet lined with white over a white satin undercoat and trunk-hose, and a plumed hat and white boots with red tops are worn. The mantle of the Thistle is of dark green velvet over surcoat, etc., of cloth of silver; that of St. Patrick azure, with doublet and trunk-hose of white satin; that of St. Michael and St. George of Saxon blue satin lined with scarlet; and that of the Star of India of light blue satin lined with white.

Judicial and Forensic Robes.—It is frequently stated that judicial robes had their origin in the dress of ecclesiastics But though ecclesiastics in early days frequently acted as judges and though, as Sir John Fortescue says. the serjeant's long robe was "after the fashion of a priest," judicial robes more probably arose from the ordinary civilian dress of the early 14th century. The chief argument for the ecclesiastical origin has been found in the coif, a cap of white linen or silk, tied under the chin, and described by Fortescue as "the principal or chief insignment and habit wherewith serjeants-at-law at their creation are decked," which is said to have been used by ecclesiastics to hide the tonsure when in court. More probably the coif was a head-dress in common use in the 13th century, which survived as the distinguishing mark of men of law. The scarlet judicial robe trimmed with white fur (ermine or miniver) together with a hood of scarlet cloth lined with white fur undoubtedly represent the survival for specialized use of the robes of the pre-Reformation doctors in canon law (*decretorum* doctor). About 1340 the doctors in theology and in canon law adopted scarlet robes and hoods, lined nith miniver, and silk linings were adopted for summer use about a century later. An ecclesiastical origin is correct in as much as, prior to the Reformation, all the members of the two ancient universities were in holy orders, or at least were tonsured, belonging to one of the lower orders of the clericature.

About the time of Queen Elizabeth I the square cap (*pileus* quadratus). otherwise known as the cornered, black or sentence cap (the last from the fact of its being put on by the judge nhen pronouncing sentence of death), began to appear. Sometimes it nas norn over the coif only, sometimes over the coif and skullcap. Sometimes it had ear flaps, sometimes, as in its present form, it had not.

Toward the end of the 17th century the judges took to wearing wigs and they have continued to wear them ever since. The nearing of wigs naturally concealed the coif and velvet skullcap. so a device had to be invented by which they could still be displayed. The expedient aas hit upon of putting a round patch of nhite stuff, aith a black spot in the middle of it, on the crown of the wig of certain of the judges, to represent the coif and skullcap. Serjeants being appointed no longer, this round patch has now disappeared, the only trace of it left being the circular depression on the crown of the aig Minute details of court and levee dress, judicial and legal, of the present day, will be found in *Dress Worn* at Court (pp. 60–61), issued with the authority of the lord chamberlain—also details of mourning costume.

Municipal and Civic Robes.—The word "livery," the use of which is now practically confined to the official dress of the "livery companies." the dress of menservants, etc., originally meant an allowance of food or clothing granted to certain persons. It is still used of the allowances of food made to the fellows of certain colleges. As early as the 13th century, the citizens of London used to assume a uniform dress to do honour to some great occasion, as when 600 citizens rode out to meet Queen Margaret of France, second wife of Edward I, "in one livery of red and white, with the cognizances of their misteries embroidered upon their sleeves." By the 14th century there is evidence of the adoption of liveries by the trades and fraternities, and when the livery companies were incorporated they took care to have their liveries authorized by their charters. As to the dress of the mayor, alderman, sheriffs, etc., the scarlet, violet and black robes, still worn by them, were early in use. The provincial mayors and aldermen at quite an early date followed the fashion of London, wearing what are virtually sleeved tabards. An account of the robes of modern provincial mayors will be found in William H. St. John Hope (ed.), Covporation Plate . . . of the cities . . . of England and *Wales* (1895).

At the present day the lord mayor has several sets of robes: a special coronation robe, a crimson velvet robe of state like that of an earl, worn with the chain and jewel, *e.g.*, in the presence of the sovereign when in the city; a black robe of state trimmed with gold, which is worn with the chain and jewel, e g., at the Guildhall on lord mayor's day; the scarlet robes, which are worn, with or without the chain. on most public occasions, such as the service at St. Paul's on the first day of the Easter law term, audiences of the sovereign, the election of the lord mayor. the opening of the central criminal court, etc.; a violet gown, which is worn, *e.g.*, when the lord mayor elect is presented to the king, when he is sworn in, at the election of sheriffs. etc., and a black gown worn in church on Good Friday, etc. The aldermen wear scarlet on most occasions of ceremony, former mayors "having the Cap of Dignity attached to their gown. and being entitled to introduce a snord and mace into their badges." Violet robes are also worn on certain occasions marked in the almanac of the *Alderman's Pocket*-Book, and black gowns when the lord mayor wears his. The sheriffs and recorders have scarlet, violet and black gowns, and the members of the common council have deep mazarine blue gowns, which seem to have been first prescribed in 1761. (X.)

Academical Dress.—Like judicial robes, academical dress has been considered to be of ecclesiastical origin. The medieval scholar was, of course, a clerk and had to wear the clerkly gown and the tonsure. The ecclesiastical dress that he wore had itself probably developed out of the ordinary civilian dress at an earlier period. The robes worn in the earliest times at Oxford and Cambridge, at least in part, were monastic or ecclesiastical in origin, but the hood was certainly derived from a lay garment, at one time commcn to all classes and both sexes, as Herbert Norris pointed out (see *Bibliography*). This lay hood was adopted by monks, clergy and all university students, and eventually mas retained in a specialized form by the various faculties, as an academical distinction. The statutes of certain colleges required of the scholars as early as the 14th century the tonsure and a "decent habit" suitable to a clerk; *i.e.*, a long gown, which it is stipulated in some cases must be closed in front like the Benedictine habit. Some colleges had liveries. prescribed perhaps by the founder of the college and laid down by the statutes. The differences of colour and shape in the undergraduate gowns of most of the Cambridge colleges are supposed to be a survival of this, but in fact the Cambridge college undergraduate gonns all date from the period 1805–40; *i.e.*, are late Guelphic (that is, Hanoverian) in origin and thus quite modern.

The gown was norn by all grades as befitting clerks. It is hard to determine whether there was at first any difference between the gowns of the senior nongraduates and the bachelors of arts and that of the masters and doctors and the bachelors in the superior faculties, but it seems improbable. It was frequently fur-lined, or at least trimmed with fur, but the use of the more costly furs was

forbidden, especially in the period between 1350–1500, to all below the degree of master, except sons of noblemen, or those possessing a certain income, bachelors using budge (common fur or black lamb's wool); students and even doctors in theology were also, at one time, restricted to budge, lamb's wool and to sombre habits. The robes of masters had to be flowing and reach to the ankles (toga talaris), and it was the masters who had the earliest distinctive dress that could be called truly academical.

The cope (*i.e.*, the *capa* or *cappa* clausa, the closed and essentially ecclesiastical cope or cape, not to be confused with the open and purely decorative cope of the clergy) probably originated in the ordinary everyday mantle of the clergy. Its wear in England was made obligatory by Cardinal Archbishop Stephen Langton, 1222, at the provincial synod held at Oseney abbey, near Oxford. All bishops, deans, archdeacons, rural deans, priests and all church dignitaries were ordered to wear it. This kind of cope, closed in front, was originally black; it sometimes, for the sake of convenience, had a slit in front to allow of the passage of the hands, this type of opening being the form or variation adopted by the doctors in theology and retained by them until the present day, although later on the slit was extended to the ground. Another variation was to make two side slits, one for each arm, a variation (the pallium or *chimaera*) adopted by the doctors in law and in physic and by the superior bachelors; *i.e.*, the bachelors in canon law, physic and possible in theology. This type is the forerunner of the convocation habit and ecclesiastico-academical chimere.

About 1330–40 doctors began to adopt scarlet for their hoods and later for their robes; at any rate by about 1500, probably long before, all doctors wore scarlet and had discarded their black *cappae* clausae for scarlet ones, the original sombre, black form being retained by the M.A.s and B.D.s. The wearing of robes of scarlet, violet or murrey, and also the "sleveless cote" (*i.e.*, convocation habits and chimeres), *supertunica*, of these colours, mas formally ratified by an act of 24 Henry VIII (1533, *caput* 13) entitled "an Act for the Reformation of Excess in Apparel." The cope still survives at Cambridge as the dress worn by the vice-chancellor and by regius professors of divinity, law and medicine when presenting for degrees; it is lined with white fur.

The hood was originally worn by all scholars, as by everybody, and had evidently no academical significance. Sometimes a cap was worn also, the hood being thrown back. There were evidently hoods of two kinds for masters from about 1432, when masters and doctors were allowed to use silk in their linings during the summer months, so that there were silk-lined and miniver-lined hoods. These two types of hood survived, at least in Oxford, until as late as 1657, or even a little later, in the time of Dr. John Fell, dean of Christ Church and vice-chancellor, and Anthony à Wood, M.A., the antiquary. Eventually (from about 1674–75, in the time of George Edwards and David Loggan) the silk-lined hood was the type principally retained by masters and doctors, the miniver-lined hood being preserved as a proctorial insignia only. At a later date, at Cambridge, a distinction was made between the hoods of nonregent masters, which were lined with silk, and those of regents which were lined with miniver. Later again, the regents wore their hoods in such a way as to show the white lining, while the nonregents wore theirs "squared," so that the white did not show. Hence the name "white hoods" and "black hoods" given to the upper and lower houses of the old senate respectively. It is not settled when the modern colouring of hoods arose; they probably followed those of the robes of the faculties, but about these there is equal uncertainty. The Oxford proctor still wears a miniver hood. The modern Oxford doctors' and B.D., and the Cambridge hoods have preserved the original shape more closely than the Oxford M.A. type, being a hood and cape combined, the cape having at Cambridge now, incorrectly, square corners: the cape, being semi-circular, should be rounded.

There seem to have been in Tudor times at least three varieties of academical headdress; one, the round cap of velvet for graduates in the secular faculties, survives as part of the full dress of doctors (except doctors in theology) to the present day. The square cap was adopted at the universities, according to N. F. Robinson, after 1520, in imitation of the University of Paris. In this connection should be mentioned the term "tufthunting" (*i.e.*, attempting to thrust oneself into the society of one's social superiors), derived from the gold tufts or tassel worn by noblemen and fellow commoners on their college caps. Originally, in the two ancient English universities, no one wore a cap except doctors in the superior faculties of theology, canon law and physic. The type of cap they wore was a tight round skullcap type, with a little point at the crown: it was called the "pileus," and was thus a cap of dignity. All other graduates and nongraduates had their hoods, which were thus a shoulder cape and a covering for the head. It appears that in Paris caps were made by sewing four pieces of cloth together, and the seams produced little raised ridges, and had a squaring effect. From this particular cap (squarish in effect), two types of cap evolved: (1) the biretta or priest's cap, simply a stiffened, rather taller *pileus*, made of the four pieces of cloth, and (2) the academical or doctor's cap (*pileus* quadratus), a velvet cap of dignity for doctors in theology. Doctors in the secular faculties adopted in the early Tudor period a soft round lay cap of velvet (*pileus* rotundus). Foundation choristers and scholars were permitted square caps in 1549. Between 1549 and 1580 there were frequent rulings and fresh statutes issued on the subject of caps. B.A.s and other junior graduates were not authorized to wear caps until between 1575 and 1580, and then only "humbly and submissively in the Schools." By 1580 a cap had been established for all members of the two ancient English universities, and the restriction to doctors and senior graduates had broken down. The beautiful series of illustrations of the academical dress in the Bodleian library at Oxford, by George Edwards and by David Loggan, 1674 and 1675, respectively, show the caps then in use.

Academical dress underwent much inquiry and some revision at the time of the Reformation, chiefly in the direction of sobriety, uniformity and laicization, "excess of apparel" being repressed as severely as ever, but not with much more effect. There have been few far-reaching changes since the Laudian code of 1636. Cambridge in the 20th century inquired into and revised its regulations as to dress. and in the Ordinances clear rules are laid down; the Oxford regulations have not been revised since 1770, and have now fallen into chaos. Some of them are dead letters: at Oxford one hood (the pale blue B.Litt. hood of 1895) by 1946 had come to be worn for four degrees, B.C.L., B.M., B.Sc. and B.Litt. The dark blue hood, lined with white fur, proper to the B.C.L. and B.M. degrees, was no longer to be seen at Oxford. The modern robe makers sell the pale blue silk B.Litt. hood, lined with white fur; for all four degrees and for the B.Phil. In 1957–58 a new hood was invented for the B.Phil. degree. This is of the debased Oxford M.A. pattern, of dark blue ribbed rayon lined with white silk: the white silk takes the place of the white fur. It is, in fact, a freak hood. The B. Mus. hood, originally dark blue as B.C.L. and B.M., was, before World War I, of dark purple: by 1945 or so it had become a brilliant lilac.

In the absence of any official regulations, the Oxford branch of the National Federation of Merchant Tailors drew up in 1957 an illustrated catalogue of what they described as the correct colours and materials of the various robes. ,This catalogue is said to have been approved by Congregation and it was deposited in the Bodleian. But some of the colours are still incorrect. Congregation never appointed a subcommittee to thresh out the whole subject, as did Cambridge in 1932–34, and thus, at Oxford, the tailors have prescribed for the university.

Doctors of both universities have three sets of robes: first, the full-dress robe of scarlet cloth; second, the scarlet, murrey or violet convocation habit and hood of scarlet (now at Cambridge a cope, at Oxford the so-called *cappa clausa*); third, the black gown or undress. The first is worn by all doctors except the doctor in music, and is accompanied by the round cap of velvet except in the case of the D.D., who continues to wear the square cap (or ecclesiastical cap) with all three forms of dress; strictly, the D.D. square cap should be soft, of black velvet and with a tuft or plain without tuft or tassel. The Oxford D.D. also wears a cassock, sash and scarf. The scarlet robe is of a different, some-

what more of a Tudor lay (or civic) shape than the M.A. and B.A. gowns. As now worn, it is faced with silk of the same colour as the hood silk lining of the faculty, except in the case of the Oxford D.D. full-dress robe, which is faced with and has bell-shaped sleeves of black velvet. The second or Cambridge cope has now gone almost out of use, but is still worn when presenting for degrees, etc., but only actually in Cambridge. It is sometimes worn over the black gown. There are several types of black gown, but the tufted gown of David Loggan's day has now gone out of use. The M.D. and Mus.D. black gowns at Cambridge are non made after the pattern of the LL.D. gown, with a square-ended sleeve and flap collar, trimmed with black lace, but the D.D.. Sc.D. and Litt.D. wear the M.A. silk gown, the former with the scarf. the two latter with lace on the sleeve, placed horizontally for Sc D. and vertically for Litt.D. Some doctors in divinity wear the full-sleeved gown with scarf. At Cambridge the headdress of a D D is the square cap, of secular doctors the velvet bonnet with gold cords. The doctors in music wear, as they have done since about 1600, a full-dress robe of white or cream damask brocaded silk. lined with pink satin at Oxford and with cherry-coloured satin at Cambridge. Formerly (1550 period) doctors in music at Cambridge wore the M.D. robes *(Cambridge Grace Book* Δ 1545).

The Oxford sleeveless commoner's gown, though still by statute *toga talaris,* now reaches little below the waist, the full-sleeved or bell-sleeved scholar's gown to the knee. The tufted silk gown of the gentleman commoner and the nobleman's gold-lace gown are not yet abolished by statute, but have fallen into disuse. The University of Oxford act, 1854, brought in and passed by Gladstone, abolished these class distinctions at Oxford, although they lingered on until about 1869 at Christ Church, so that King Edward VII as prince of Wales. wore a gentleman commoner's bell-shaped sleeved gown when up in 1860–62. Vice-chancellors have no official dress, but wear the robes of their degree. The chancellors of the older universities wear a black damask silk robe with gold lace and a black velvet square cap with gold tassel and band: those of the newer universities have had robes "created" by experts or by the robe makers, who are nowadays to a large extent the arbiters of academical dress. but based on Oxford and Cambridge customs largely. The Hull chancellor's and vice-chancellor's robes are of blue: these robes at Southampton are of black figured damask silk with gold ornamentation.

United States.—An intercollegiate commission in 1893 drafted a uniform code for academical caps, gowns and hoods which has since been accepted by 700 to 800 degree-granting colleges and universities in the United States. Three types of gown and three types of hood have been devised for bachelors, masters and doctors, respectively. The square caps remain the same except that the doctor's may be made of velvet and have a tassel of gold. The bachelor's gown is made of black worsted material and may be distinguished by its pointed sleeves of the B.A. Oxford type, though hanging only to the knee. The master's gown, made of silk, has closed sleeves of M.A. type (the arm coming through a slit at the elbow), which are square at the end and extend well below the knee.

The doctor's gown is also made of silk, and, like a judge's robe, has full round open bell-shaped sleeves, is faced with velvet and has three bars of velvet on each sleeve. The hoods are lined with silk with the colour or colours of the college or university granting the degree and trimmed with velvet of the colour that represents the department of learning in which the degree was obtained. The velvet trimming of the doctor's gown may also be of the departmental colour or it may be black if preferred. Colours of the more common departments of learning are as follows: arts and letters, white; theology and divinity, scarlet; laws, purple; philosophy, blue; science, golden yellow; medicine, green; dentistry, lilac; music, pink; engineering, orange.

A few institutions, notably Harvard. retain an individual code for their hoods. The U.S. system of hoods is. therefore, progressive and enables anyone conversant with the system to pick out the university (by the colour or colours in the lining). the faculty (by the edging on the cowl or hood portion proper) and the grade (by the size and shape, bachelors and masters having silk hoods of Oxford M.A. shape, masters' being made considerably longer than bachelors', doctors' being of cloth (rayon or silk) of the Cambridge M.A. type but with rounded corners to the cape portion). Obviously, only a very few universities, such as Harvard, Yale and Princeton, can have a single distinguishing colour as a hood lining; other universities and colleges have to have two colours, the second or subsidiary colour being sewn inside as a chevron. This system. although distinctive and advantageous in some respects, produces a somewhat patchy result in effect. But obviously it would be impossible to distinguish the degree hoods of 700 to 800 degree-granting colleges or universities without some such device.

The U.S. intercollegiate code has also devised a similar set of hoods for holders of continental and other foreign degrees.

ROBESON, PAUL (1898–), U.S. Negro actor and singer, was born at Princeton, N.J., April 9, 1898. He graduated from Rutgers college, New Brunswick, N.J., with an extraordinarily distinguished scholastic and athletic record, and in 1923 completed the law course at Columbia university. His first stage appearance was in *Taboo* (1922), but he made his reputation in *All God's Chillun's Got Wings* and in the title roles in *Emperor Jones* (1923) and *Black Boy* (1926). After appearing in *Show Boat* in England. he toured the U.S., Europe and the U.S.S.R. with recitals of Negro spirituals. Robeson entered films in 1933, playing in *The Emperor Jones, Sanders of the River* and *Showboat.* In 1943 he appeared in a New York production af *Othello,* which established the longest Shakespearean run in America.

In 1950 the U.S. state department voided his passport, charging that he had supported various Communist causes and "peace" movements. (M. S. BY.)

ROBESPIERRE, MAXIMILIEN FRANCOIS MARIE ISIDORE DE (1758–1794), French revolutionist, the son of an advocate, was born at Arras on May 6, 1758. His family, according to tradition, was of Irish descent. Maximilien was one of four orphan children who were left in the care of relatives when their father left Arras. His direct ancestors in the male line had been notaries at the village of Carvin, near Arras, from the beginning of the 17th century. His grandfather, being more ambitious, established himself at Arras as an advocate, and his father followed the same profession, marrying Jacqueline Marguerite Carraut, daughter of a brewer in the same city, in 1757. Of this marriage four children were born. two sons and two daughters, of whom Maximilien was the eldest; but in 1767 Madame Derobespierre, as the name was then spelled, died, and the disconsolate widower at once left Arras and wandered about Europe until his death at Munich in 1769. Maximilien was sent to the college of Arras and the college of Louis-le-Grand at Paris. Here he had for fellow pupils Camille Desmoulins and Stanislas Fréron. Admitted an advocate in 1781, Robespierre returned to his native city to seek for practice. His reputation had already preceded him, and the bishop of Arras, De Conzié, appointed him criminal judge in the diocese of Arras in March 1782. This appointment, which he soon resigned to avoid pronouncing a sentence of death, did not prevent his practising at the bar, and he speedily became a successful advocate. He now turned to literature and society and came to be esteemed as one of the best writers and most popular dandies of Arras. He was a member of an Arras literary and musical society known as the "Rosati," of which L. N. M. Carnot was a member. The sympathetic quality of his voice won for his

verses recited before this society applause not justified by their merits. In 1788 he took part in the discussion as to the way in which the states-general should be elected, showing clearly and forcibly in his *Adresse à la nation artésienne* that, if the former mode of election by the members of the provincial estates were again adopted, the new states-general would not represent the people of France. By the *Avis aux habitants de campagne* (Arras, 1789), which is almost certainly by him, he secured the support of the country electors, and, though but 30 years of age, poor and without influence, he was elected fifth deputy of the *tiers état* of Artois to the states-general. This election opened the way to his public career.

The Constituent Assembly.—When the states-general met at Versailles on May 5, 1789, the young deputy of Arfois already possessed the one faculty which was to lead him to supremacy: he was a fanatic. Robespierre believed in the doctrines of Rousseau with all his heart, and would have gone to death for them; and in the belief that they would eventually succeed and regenerate France and mankind, he was ready to work with unwearied patience. While the constituent assembly occupied itself in drawing up a constitution, Robespierre turned from the assembly of provincial lawyers and wealthy *bourgeois* to the people of Paris. However, he spoke frequently in the constituent assembly, and often with great success. and was eventuallv recognized as second only to Jerôme Pétion de Villeneuve—if second to him—as a leader of the small body of the extreme left—the 30 voices, as Mirabeau contemptuously called them. When he instinctively felt that his doctrines would have no success in the assembly, he turned to the Society of the Friends of the Constitution, known later as the Jacobin club. The death of Mirabeau strengthened Robespierre's influence in the assembly, but on May 15, 1791, he showed his jealous suspicion of his colleagues by proposing and carrying the motion that no deputies who sat in the constituent could sit in the succeeding assembly. The flight of the king on June 20 and his arrest at Varennes made Robespierre declare himself at the Jacobin club to be *ni monarchiste ni républicain.* After the "massacre" of the Champ de Mars (on July 17, 1791) he established himself, in order to be nearer to the assembly and the Jacobins, in the house of Duplay, a cabinetmaker in the Rue St. Honoré and an ardent admirer of his, where he lived (with but two short intervals) till his death. At last came his day of triumph, when on Sept. 30, on the dissolution of the constituent assembly, the people of Paris crowned Pétion and himself as the two incorruptible patriots.

On the dissolution of the assembly he returned for a short visit to Arras, where he met with a triumphant reception. In November he returned to Paris and on Dec. 18 made a speech which marks a new epoch in his life. Jacques Pierre Brissot, the *âme politique* of the Girondin party which had been formed in the legislative assembly, urged vehemently that war should be declared against Austria, and the queen was equally urgent, in the hope that a victorious army might restore the old absolutism of the Bourbons. Two men opposed the projects of the queen and the Girondins—Jean Paul Marat and Robespierre. Robespierre feared a development of militarism, which might be turned to the advantage of the reaction. From that moment began the struggle which ended in the coups d'état of May 31 and June 2, 1793. Robespierre persisted in his opposition to the war; the Girondins, especially Brissot, attacked him violently, and in April 1792 he resigned the post of public prosecutor at the tribunal of Paris, which he had held since February, and started a journal, *Le Dkfenseur de la Constitution,* in his own defense. It is noteworthy that during the summer months of 1792 in which the fate of the Bourbon dynasty was being sealed, neither the Girondins in the legislative, assembly nor Robespierre took any active part in overthrowing it. But Robespierre, though shocked at the shedding of blood, was willing to take his seat on the commune of Paris, which had overthrown Louis XVI, and might check the Girondins. The strong men of the commune were glad to have Robespierre's assistance, not because they cared for him or believed in him but because of the help got from his popularity, his reputation for virtue which had won for him the surname of "the Incorruptible," and his influence over the Jacobin club and its branches, which spread all over France. He therefore presented the petition of the commune of Paris on Aug. 16 to the legislative assembly, demanding the establishment of a revolutionary tribunal and the summoning of a convention. The massacres of September in the prisons, which Robespierre in vain attempted to stop, showed that the commune had more confidence in J. N. Billaud-Varenne than in him. Yet, as a proof of his personal popularity, he was a few days later elected first deputy for Paris to the national convention.

The Convention.—On the meeting of the convention the Girondins immediately attacked Robespierre; they were jealous of his influence in Paris, and knew that his single-hearted fanaticism would never forgive their intrigues with the king at the end of July. All personal disputes, however, gave way in December 1792 before the question of the king's trial, and here Robespierre took up a position which is at least easily understood. These are his words spoken on Dec. 3:

> This is no trial; Louis is not a prisoner at the bar; you are not judges; you are—you cannot but be—statesmen, and the representatives of the nation. You have not to pass sentence for or against a single man, but you have to take a resolution on a question of the public safety, and to decide a question of national foresight. It is with regret that I pronounce the fatal truth: Louis ought to perish rather than a hundred thousand virtuous citizens; Louis must die, that the country may live.

This great question settled by the king's execution, the impracticable plans of the Girondins drove G. J. Danton, Carnot, Robert Lindet and even Billaud-Varenne to the side of Robespierre, whom, it is apparent, they thoroughly understood. In the month of May 1793 Camille Desmoulins, acting under the inspiration of Robespierre and Danton, published his *Histoire des Brissotins* and *Brissot démasqué;* Maximin Isnard declared that Paris must be destroyed if it pronounced itself against the provincial deputies; Robespierre preached insurrection at the Jacobin club; and on May 31 and June 2 the commune of Paris destroyed the Girondin party.

Committee of Public Safety.—On July 27, 1793, when the struggle was practically decided, the convention elected Robespierre to the new Committee of Public Safety. Robespierre was always in a minority in the committee of 12, at least 7 of whom, Carnot, Billaud-Varenne, J. M. Collot d'Herbois, Comte Prieur-Duvernois, Prieur de la Marne, A. J. Saint André and Lindet, were men of action and not under his personal influence. Robespierre was not the inventor of the Terror or its machinery, the revolutionary tribunal and the representatives of the committee on mission in the provinces. He served it by his gift of eloquence. He had a fanatical following among the Jacobins and was one of the most popular orators in the convention, on which his carefully prepared addresses made a deep impression. His panegyrics on the system of revolutionary government and his praise of virtue led his hearers to believe that the system of the Terror, instead of being monstrous, was absolutely laudable; his pure life and admitted incorruptibility threw a lustre on the committee of which he was a member; and his colleagues were glad to avail themselves of these advantages so long as he did not interfere with their work. Moreover, he alone never left Paris, while all the others, except Bertrand Barère de Vieuzac, were constantly engaged on missions to the armies, the navy and the provinces. It has been asserted that Robespierre, Georges Couthon and Saint-Just took upon themselves the direction of "la haute politique," while the other members acted only in subordinate capacities; undoubtedly it would have suited Robespierre to have had this believed, but as a matter of fact he was in no way especially trusted in matters of supreme importance.

It is clear, therefore, that Robespierre was not the sole author of the overthrow of the Dantonists and the Hébertists, though he thoroughly agreed with the majority and had no desire to save them, the Hébertist principle of decentralization and the Dantonist moderatism being equally obnoxious to him.

Fall of **Danton.**—Both parties must be crushed. Before the blows at the leaders of those two parties were struck, Robespierre retired for a month (Feb. 13–March 13, 1794) from active business in the convention and the committee, apparently to con-

sider his position; but he came to the conclusion that the cessation of the Reign of Terror would mean the loss of that supremacy by which he hoped to establish the ideal of Rousseau; for Danton, he knew, was essentially a practical statesman and laughed at his ideas and especially his politico-religious projects. He must have considered, too, that the result of his siding with Danton would probably have been fatal to himself. The result of his deliberations was that he abandoned Danton and co-operated in the attacks of the committee on the two parties. On March 15 he reappeared in the convention; on March 19 J. R. Hébert and his friends were arrested. and on March 24 they were guillotined. On March 30 Danton, Camille Desmoulins and their friends were arrested, and on April 5 they, too, were guillotined.

It was not until after the execution of Danton that Robespierre began to develop a policy distinct from that of his colleagues in the committee, an opposition which ended in his downfall. He began by using his influence over the Jacobin club to dominate the commune of Paris through his devoted adherents, two of whom, J. B. E. Fleuriot-Lescot and C. F. de Payan, were elected respectively mayor and *procureur* of the commune. He also attempted to usurp the influence of the other members of the committee over the armies by getting his young adherent, Saint-Just, sent on a mission to the frontier. In Paris Robespierre determined to increase the pressure of the Terror: no one should accuse him of moderatism; through the increased efficiency of the revolutionary tribunal Paris should tremble before him as the chief member of the committee, and the convention should pass whatever measures he might dictate. To secure his aims, Couthon, his other ally in the committee, proposed and carried on June 10 the outrageous law of 22nd Prairial, by which even the appearance of justice was taken from the tribunal, which, as no witnesses were allowed, became a simple court of condemnation. The result of this law was that between June 12 and July 28, the day of Robespierre's death, no fewer than 1,285 victims perished by the guillotine in Paris. It was the bloodiest and the least justifiable period of the Terror. But before this there had taken place in Robespierre's life an episode of supreme importance, as illustrating his character and his political aims; on May 7 he secured a decree from the convention recognizing the existence of the Supreme Being. This worship of the Supreme Being was based upon the ideas of Rousseau in the *Social Contract,* and was opposed by Robespierre to Catholicism on the one hand and the Hébertist atheism on the other. In honour of the Supreme Being a great fete was held on June 8; Robespierre, as president of the convention, walked first and delivered his harangue, and as he looked around him he may well have believed that his position was secured and that he was at last within reach of a supreme power which should enable him to impose his belief on all France, and so ensure its happiness. The devotion of Robespierre's adherents was further excited by the news that a half-witted girl, named Cécile Renault. had been found wandering near his house with a knife in her possession, intending to play the part of Charlotte Corday. She was executed on June 17, on the very day that M. G. A. Vadier raised a laugh at Robespierre's expense in the convention by his report on the conspiracy of Catherine Théot, a madwoman, who had asserted that Robespierre was a divinity.

The 9th Thermidor.—Robespierre felt that he must strike his blow now or never. Yet he was not sufficiently audacious to strike at once, as Payan and Jean Baptiste Coffinhal, the ablest of his adherents, would have had him do, but retired from the convention for several weeks. as he had done before the overthrow of the Hébertists and the Dantonists, to prepare his plan of action. These weeks, the last of his life, Robespierre passed very peacefully. He continued to live with the Duplays, with whose daughter Éléonore he had fallen in love, and used to wander with her in the Champs Élysées during the long summer evenings. At last, on July 26, Robespierre appeared, for the first time for more than four weeks, in the convention and delivered a carefully studied harangue, which lasted for more than four hours, in which he declared that the Terror ought to be ended, that certain deputies who had acted unjustly and exceeded their powers ought to be punished and that the Committees of Public Safety and General Security ought to be renewed. The majority of the Committee of Public Safety determined to act promptly. The convention, moved by Robespierre's eloquence, at first passed his motions; but he was replied to by Joseph Cambon the financier, Billaud-Varenne, J. B. A. Amar and Vadier, and the convention rescinded their decrees and referred Robespierre's question to their committees. On the following day, July 27, or in the revolutionary calendar the 9th Thermidor, Saint-Just began to speak on behalf of the motions of Robespierre, when violent interruptions showed the temper of the convention. Jean Lambert Tallien, Billaud-Varenne and Vadier again attacked Robespierre; cries of "Down with the tyrant!" were raised; and, when Robespierre hesitated in his speech in answer to these attacks, the words "C'est le sang de Danton qui t'étouffe" showed what was uppermost in the minds of the Mountain. Robespierre tried in vain to gain a hearing, the excitement increased and at five in the afternoon Robespierre, Couthon and Saint-Just, with two young deputies, Augustin Robespierre (younger brother of Maximilien) and Philippe François Joseph Lebas, the only men in all the convention who supported them, were ordered to be arrested. Robespierre was speedily rescued from his prison, with the other deputies, by the troops of the commune and brought to the *hôtel de ville.* There he was surrounded by his faithful adherents, led by Payan and Coffinbal. But the day was past when the commune could overawe the convention, for now the men of action were hostile to the commune and its chief was not a master of coups d'état. On the news of the release of Robespierre, the convention had again met and declared the members of the commune and the released deputies outlawed. The national guards under the command of vicomte de Barras made their way to the *hôtel de ville;* Robespierre was shot in the lower jaw by a young gendarme named Meda while signing an appeal to one of the sections of Paris to take up arms for him, though the wound was afterward believed to have been inflicted by himself; and all the released deputies were again arrested After a night of agony, Robespierre was the next day taken before the tribunal, where his identity as an outlaw was proved, and without further trial he was executed with Couthon and Saint-Just and 19 others of his adherents on the Place de la Révolution on the 10th Thermidor (July 28), 1794.

Character.—The character of Robespierre, when looked upon simply in the light of his actions and his authenticated speeches, and apart from the innumerable legends which have grown up about it, is comparatively simple. A well-educated and accomplished young lawyer, he might have acquired a good provincial practice and lived a happy provincial life had it not been for the Revolution. Like thousands of other young Frenchmen, he had read the works of Rousseau and taken them as gospel. Just at the very time in life when this illusion had not been destroyed by the realities of life, and without the experience which might have taught the futility of idle dreams and theories, he was elected to the states-general. At Paris he was not understood till he met with his audience of fellow disciples of Rousseau at the Jacobin club His fanaticism won him supporters; his singularly sweet and sympathetic voice gained him hearers; and his upright life attracted the admiration of all As matters approached nearer and nearer to the terrible crisis, he failed, except in the two instances of the question of war and of the king's trial, to show himself a statesman, for he had not the liberal views and practical instincts which made Mirabeau and Danton great men. His admission to the Committee of Public Safety gave him power, which he hoped to use for the establishment of his favourite theories, and for the same purpose he acquiesced in and even heightened the horrors of the Reign of Terror. It is here that the fatal mistake of allowing a theorist to have power appeared: Billaud-Varenne systematized the Terror because he believed it necessary for the safety of the country; Robespierre intensified it in order to carry out his own ideas and theories. Robespierre's private life was always respectable; he was always emphatically a gentleman and man of culture, and even a little bit of a dandy, scrupulously honest, truthful and charitable. In his habits and manner of life he was simple and laborious; not gifted with flashes of genius, he had to think much before he could come to a decision; he worked hard all his life.

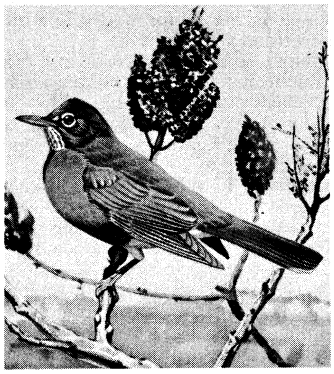
On the family of Robespierre *see* A. J. Paris in the *Mémoires,* 2nd series, vol. iii, of the Academy of Arras; the *Oeuvres de Maximilien Robespierre,* 3 vol. (1840), published by Laponneraye with preface by Armand Carrel, contain some of his speeches and the memoirs of Charlotte Robespierre on her brothers. An edition of the *Oeuvres,* 2 vol. (1913) was edited by A. Lesueur. The standard work on Robespierre's career is Ernest Hamel, *Histoire de Robespierre d'après des papiers de famille, les sources originales et des documents entièrement inédits,* 3 vol. (1865–67). After the appearance of the first volume, the publisher refused to proceed for fear of prosecution until compelled to do so by the author. Another edition with a different title appeared in 1878. *See* also C. d'Hericault, *La Re'volution de Thermidor,* 2nd ed. (1878); Karl Brunnemann, *Maximilien Robespierre* (1880); F. A. Aulard, *Les Orateurs de l'Assemblée Constituante* (1882); M. de Lescure, "Le Roman de Robespierre," in *La Société française pendant la Terreur* (1882); E. Hamel, *La Maison de Robespierre* (1895); Hilaire Belloc, *Robespierre* (1901); C. F. Warwick, *Robespierre and the French Revolution* (1909); A. Mathiez, *Études Robespierristes,* 2 vol. (1897, 1918), and *Autour de Robespierre* (1925). Many of the books which have been written about Robespierre are most untrustworthy, and the picture of him given by Thomas Carlyle

in his *French Revolution* is unjust.

ROBIN, a large North American thrush (*Turdus migratorius*), one of the most familiar songbirds in the eastern U.S. Its name was derived from its resemblance to another bird, the smaller European robin (*Erithacus rubecula*), called also redbreast or robin redbreast.

American Robin.—The American robin is about 10 in. long, with brick-red breast, blackish-gray upper parts and a yellow bill. It has bold white markings around the eye, under the chin and on the tips of the outer tail feathers. Females are slightly paler, and the young have spotted breasts as in other thrushes. Most robins are highly migratory, spending the winter in flocks in the southern U.S., but a few winter as far north as southern Canada. The robin is a shy woodland bird in northern forests, but elsewhere it has adjusted so completely to man that to see a robin pull an earthworm from the ground is a sight familiar to everyone.

The nest, of vegetation and trash, with a firm molded inner layer of mud, is built in trees, open sheds, bridges, etc. Three to five bluish-green eggs are incubated by the female for 12 days. Both parents tend the young, which fly in 14–16 days. There are two to three broods per season.



ALBERT E. GILBERT

AMERICAN ROBIN (TURDUS MIGRATORIUS)

Its song consists of caroling phrases, differing in pitch, with pauses between them—a cheerful, bubbling air. There are various call notes, harsh and scolding. Earthworms, insects, berries and some grains are taken for food. The arrival of the first robins, usually males, is looked forward to in the early spring.

European Robin.—The robin of the old world is about 5½ in. long, with brownish-orange breast and forehead, brownish-olive upper parts and a white abdomen. The young have a mottled dark brown-and-buff breast. It is a woodland bird primarily but is notably confiding toward man. Everywhere it is well known for its cocky, jaunty attitudes. It is migratory in northern Europe, but only partially so or sedentary farther south. The nest is in holes and crannies in walls, banks, trees and the like. The five to six whitish eggs are incubated 13–14 days by the female, who is fed by the male. The young fly in 12–14 days and then a second brood is reared. The bird sings almost all year, uttering high-pitched warbling phrases, and has various call notes. Food is mainly insects.

There is considerable folklore about the robin; the old-world lore that it is bad luck to kill one has been applied also to the American robin.

See David Lack, *The Life of the Robin,* rev. ed. (1947), *Robin Redbreast (1950).* (R. S. PR.)

ROBIN HOOD, English legendary hero. The oldest datable mention of Robin Hood known at present occurs in the second edition of *Piers Plowman,* the date of which is about 1377. In that poem the figure of Sloth is represented as saying:

> "I can nou3te perfitly my pater-noster, as
> the prest it syngeth:
> But I can rymes of Robyn Hood and Randolf
> Erle of Chestre."

He is next mentioned by Andrew of Wyntoun in his *Original Chronicle of Scotland,* written about 1420. Of his popularity in the latter half of the 15th and in the 16th centuries there are many signs. In the Elizabethan era and afterward mentions abound. Of the ballads themselves, *Robin Hood and the Monk* is possibly as old as the reign of Edward II *(see* Thomas Wright's *Essays on England in the Middle Ages,* ii, 174); *Robin Hood and the Potter* and *Robyn and Gandelyn* are certainly not later than the 15th century. Most important of all is *A Lytell Geste of Robyn Hode,* which was first printed about 1510 *(see* A. W. Pollard's *Fifteenth Century Prose and Verse* [1903]). This is evidently founded on older ballads; we read in *The Seconde Fytte,* II, 176 and 177:

> "He wente hym forthe full mery syngynge,
> As men have told in tale."

In fact, it does for the Robin Hood cycle what a few years before Sir Thomas Malory had done for the Arthurian romances.

These are the facts about him and his balladry. Of conjectures there is no end. He has been represented as the last of the Saxons—as a Saxon holding out against the Norman conquerors as late as the end of the 12th century *(see* Augustin Thierry's *Norman Conquest,* and compare Sir Walter Scott's *Ivanhoe).* J. M. Gutch maintains that he was a follower of Simon de Montfort. The Robin Hood story has probably some historical basis. Sloth in Langland's poem couples him with Randle, earl of Chester. whom we believe to have been the third Randle *(see* Bishop Thomas Percy's folio manuscript, ed. Hales and Furnivall, i, 260 [1867–68]); and, possibly enough. Hood was contemporary with that earl, who flourished in the reigns of Richard I, John and Henry III. His myth was, as is evident from what we have already said, full grown in the first half of the 14th century.

That the Robin Hood story attracted to it and appropriated other elements is illustrated by its subsequent history. Thus later on we find it connected with the Morris dance; but the Morris dance mas not known in England before the 16th century or late in the 15th. The Maid Marian (*q.v.*) element has been thought to have been introduced for the purpose of these performances, which were held on May day and were immensely popular *(see* Hugh Latimer's *Frutefull Sermons* [1571], p. 75; also *Paston Letters,* ed. J. Gairdner, iii, 89). After 1615, the date of the pageant prepared for the mayoralty of Sir John Jolles, draper, by Anthony hlunday and entitled *Metropolis Coronata,* the yeoman of the older version was metamorphosed into the earl of Huntingdon. for whom in the following century William Stukeley discovered a satisfactory pedigree. The earl of Huntingdon was probably a nickname for a hunter. The rise, development and decay of the myth deserve thorough study.

What perhaps is its greatest interest is its expression of the popular mind about the close of the middle ages. Robin Hood was at that time the people's ideal, as Arthur is that of the upper classes. He is the ideal yeoman, as Arthur is the ideal knight. He readjusts the distribution of property; he robs the rich and endows the poor. He is an earnest worshiper of the Virgin, but a vigorous hater of monks and abbots. He is the great sportsman, the incomparable archer, the lover of the greenwood and of a free life, brave, adventurous, jocular, openhanded. a protector of women. The story is localized in Barnsdale and Sherwood; *i.e.,* between Doncaster and Nottingham. In Yorkshire, Nottinghamshire and Lincolnshire a host of place names testify to the popularity of the Robin Hood legend—Robin Hood's Bay, Robin Hood's cave, Robin Hood's chase. Robin Hood's cup (a well), Robin Hood's chair and many more.

ROBINSON, BOARDMAN (1876–1952), Canadian-U.S. political cartoonist and painter, was born in Somerset. Nova Scotia, on Sept. 6, 1876. As a student in Paris in 1898, he was influenced by the great tradition of French political cartooning begun by Honoré Daumier. In New York city his trenchant cartoons later appeared in many newspapers and periodicals, and he affected a whole school of political cartoonists. including artists such as H. Glintenkamp, Robert Minor, William Gropper, Daniel Fitzpatrick and Edmund Duffy. As a teacher at the Art Students league, New York city, 1919–30, and as founder and head of the Colorado Springs (Colo.) Fine Arts centre, 1936–47, he taught many outstanding artists. Robinson also made illustrations for *Spoon River Anthology, The Brothers Karamazov, Moby Dick* and *Leaves of Grass* and created the murals in the Department of Justice building in Washington, D.C. His remarkable gift was his calligraphic line; its searching quality inspired a new kind of political cartooning in the United States. He died in Stamford,

Conn., on Sept. 5, 1952.

See Albert Christ-Janer, *Boardman Robinson* **(1946).**

(A. W. C.-J.)

ROBINSON, EDWARD (1794–1863), U.S. biblical scholar, who is considered the father of biblical geography, was born in Southington, Conn., on April 10, 1794. In **1837** he became professor of biblical literature in Union Theological seminary, and left the U.S. for three years of study in Palestine and Germany, the fruit of which, his *Biblical Researches* (published simultaneously in England. Germany and the U.S. in 1841), brought him the gold medal of the Royal Geographical society in **1842.**

Later Biblical Researches appeared in 1856. His plans to sum up his important topographical studies in a work on biblical geography were cut short by cataract in **1861** and by his death in New York city on Jan. 27, **1863.** His *Biblical Researches,* supplemented by the *Physical Geography of the Holy Land* (1865), mere based on careful personal exploration and tempered by a thoroughly critical spirit, which was possibly at times too skeptical of local tradition.

Of scarcely less value in their day were Robinson's *Greek Harmony of the Gospels* **(1845)** and his *Greek and English Lexicon of the New Testament* (1836).

ROBINSON, EDWIN ARLINGTON (1869–1935), U.S. poet whose main emphasis was on the psychological, was born in Head Tide, Me.. Dec. 22. **1869.** He grew up in Gardiner. Me., the "Tilbury Town" of his poetry, where he attended the public schools. In **1891** he enrolled at Harvard as a special student. but withdrew after two years because of family financial difficulties. Most of his life after **1898** he lived in New York city, but he spent his summers writing at the MacDowell colony in New Hampshire. In **1896** he privately printed *The Torrent and The Night Before,* which was incorporated in *The Children of the Night* **(1897).** Robinson worked at various odd jobs, including that of subway time checker, until his poetry was brought to the attention of Pres. Theodore Roosevelt, who, in 1904, offered him a position in the New York customhouse. This he held until he resigned in 1909. *The Man Against the Sky* **(1916)** firmly established him in the first rank of U.S. poets of his day and he subsequently had few financial worries. He won three Pulitzer prizes for poetry *(Collected Poems,* **1921;** *The Man Who Died Twice,* 1924; and *Tristram,* 1927). His work after **1928** showed a decline in strength and became rather repetitious. He died in New York city on April **6,** 1935.

He used traditional verse forms, particularly the sonnet, with new vigour, and was a master of blank verse. Often bleak and sombre in tone. straightforward but condensed, his verse reveals the author's sharp psychological insight, restless quest for moral values and intellectual honesty, Robinson's principal volumes include three long poems on Arthurian themes: *Merlin* (1917), *Lancelot* (1920) and *Tristram* (1927); and psychological studies with a psychoanalytical bent, *Avon's Harvest* **(1921);** *Roman Bartholow* (1923); *Dionysus in Doubt* **(1925);** *Cavender's House* (1929); *Matthias at the Door* (1931); and *Amaranth* (1934). His letters, compiled by Ridgeley Torrence, were published in 1940.

Hogan, *A Bibliography of Edwin Arlington Robinson* **(1936);** *R* **P** T Coffin, *The New Poetry of New England: Frost and Robinson* **(1938);** *H.* Hagedorn, *Edwin Arlington Robinson* **(1938);** Yvor Winters, *Edwin Arlington Robinson* **(1946);** *E.* Barnard, *Edwin Arlington Robinson,* **a** *Critical Study* (1952).

ROBINSON, HENRY CRABB (1775–1867), English journalist and diarist. who is remembered chiefly as the friend of Charles Lamb, Samuel Coleridge. William Wordsworth and Robert Southey, was born at Bury St. Edmunds on March **13,** 1775. He traveled much on the continent of Europe. and acted as special war correspondent for the *Times,* 1807–08. From **1813** to **1828** he practised at the bar. He was a great conversationalist, and his breakfast parties rivaled those of Samuel Rogers. He died at London on Feb. 5, **1867.**

His *Diary* of **35** vol., his *Journals* of **30** vol, and his *Letters and Reminiscences* in **36** vol. contain vivid pictures of contemporary celebrities. Thomas Sadler edited *The Diary, Reminiscences, and Correspondence of H. Crabb Robinson,* **3** vol. **(1869)** and E. J. Morley edited the *Correspondence of Henry Crabb Robinson with the Wordsworth Circle,* **2** vol. (1927).

ROBINSON, JOHN (1575–1625), English Nonconformist clergyman, settled in Amsterdam, Neth., in **1608,** but in the following year moved, with a large contingent, to Leyden, where he ministered to a community whose numbers gradually grew from 100 to 300. In **1620** a considerable minority of these sailed for England in the "Speedwell." and ultimately crossed the Atlantic in the "Mayflower"; Robinson intended to join his flock later, but he died on March 1, **162;.** His *Works* were reprinted by R. Ashton in 3 vol. in **1851.** *See* also **CONGREGATIONALISM.**

ROBINSON, JOSEPH TAYLOR (1872–1937), U.S. political official, was born near Lonoke, Ark., Aug. **26, 1872.** After graduating from the University of Arkansas and receiving his law degree at the University of Virginia, he returned to Lonoke in **1895** to practise. He became interested in politics at once. was elected a member of the state legislature, 189**5-97,** and served as delegate to the Democratic national convention in 1900. In 1902 he was elected U.S. representative, in which office he was continued until he was elected governor of Arkansas in **1912.** He was governor only a few weeks when he was elected by the state legislature to fill the position of U.S. senator left vacant by the death of Sen. Jefferson Davis. Robinson was re-elected senator in **1918** and in 1924. In 1923 he was chosen to succeed Sen. O. W. Underwood as chairman of the minority conference and Democratic floor leader. He possessed an unusual kno ledge of parliamentary procedure, was a ready debater and an influential legislator. He was the Democratic party's candidate for vice-president in **1928.**

ROBINSON, LENNOX (1886–1958), Irish dramatist, was born at Douglas, County Cork, on Oct. **4, 1886,** and educated at Bandon grammar school. His first play, *The Clancy Name,* was produced in 1908 at the Abbey theatre, Dublin, of which he was manager from 1910 to 1914. **In** 1915 he was appointed organizing librarian to the Carnegie trust, a post which he held until **1925.** From **1919** to 1923 he was again manager of the Abbey theatre, and in 1923 became director. Robinson's plays *The Lost Leader* **(1918)** and *The Whiteheaded Boy* **(1916)** were both produced in London and in the United States. In addition to numerous plays, he wrote a novel. *A Young Man From the South* (1917), *Ireland's Abbey Theatre* (1951) and the autobiographies. *Three Homes* (1938) and *Curtain Up* (1941). He died in Dublin on Oct. 14, 1958.

Other plays include *The Cross Roads* (1909); *Patriots* **(1912);** *The Dreamers* (1915); *The Round Table* (1924); *Birds' Nest* (1938): *Pictures in a Theatre* (1947); *The Lucky Finger* (1949).

ROBINSON, SIR ROBERT (1886-), British chemist, who was awarded the Nobel prize for chemistry for his research on the alkaloids in 1947, was born at Bufford, near Chesterfield, Derbyshire, on Sept. **13, 1886,** and educated at Fulneck school, Leeds, and the University of Manchester, where he obtained the degree of D.Sc. in **1910.** He was professor of pure and applied organic chemistry in the University of Sydney. New South Wales (1912–1**j),** and then occupied chairs of chemistry successively in the universities of Liverpool (1915–**21**), St. Andrews (1921–22), Manchester (1922–28) and at University college, London (1928–**30).** He was appointed to the Waynflete chair of chemistry in the University of Oxford in 1930 and retired in 1955. His extensive researches in organic chemistry dealt not only with the structure, including the syntheses, of many complicated organic bodies, but also with the electrochemical (electronic) mechanism of organic reactions. His studies of the structure of the plant pigments or anthocyanins led him to extend his investigations to another group of vegetable bodies, the alkaloids, the whole series of researches being remarkable for Robinson's brilliant syntheses. His discoveries of the detail of the structure of alkaloid molecules led to the successful production of certain antimalarial drugs. Many honours were conferred on him, including the Copley medal of the Royal society in 1942. He mas knighted in 1939 and received the Order of Merit in 1949. He was president of the Royal society, 1945–50 and of the British Association for the Advancement of Science. 19**j**5.

(D. McK.)

ROBOT. This term has long been in use in many languages.

Derived from the Czech word *robota* ("work"), it passed into popular use after 1923 to describe either mechanical devices so ingenious as to be almost human, or workers whom mechanical and repetitive work was making almost into machines. Its popular usage is based on the play R.U.R. (Rossum's Universal Robots), written by the Czechoslovakian writer. Karel Capek, in which society is described as depending on mechanical workers, called robots, which can do any kind of mental or physical work and which when worn out are scrapped and replaced by new. In the play the robots develop intelligence and a spirit of revolt, turn upon their employers and exterminate their creators.

The construction of a mechanical man has captivated the imagination of men since antiquity and early literature contains many schemes for the construction of some device that would require no human effort. It is not improbable that this idea has had a marked influence upon the development of mechanics and other branches of physics. In the Icelandic saga, Frithiof's ship needed no helmsman; she understood what was said to her and obeyed. Modern "robots" automatically hold ships true to the compass course (see GYROCOMPASS; NAVIGATION). In a medieval romance a great brazen head in the castle of a giant would tell those who inquired whatever they wished to know about the past, present or future. Modern robots also answer questions about the future, predicting, for example, ocean tides for every port in the world for years ahead with great precision. (See MATHEMATICAL INSTRUMENTS.) Mythical manlike monsters permeate the folklore of all peoples. Albertus Magnus in the middle ages, Roger Bacon, Descartes and other philosophers built androids or automatons in human form. which could open doors and play musical instruments. Anthropoid figures which apparently perform actions which call for independent thought are still to be seen and are often accepted with credulity by the public. On the other hand modern mechanical men have been constructed and placed at the disposal of industry, that have sensitive fingers and ears, talk with a predetermined conversation, that are able to test by "a sense of taste" chemicals, and with some equivalent of the sense of smell and balance. By the use of photo-electric cells, the partial equivalent of the sense of sight has been accomplished. (See the articles SELENIUM CELLS, PHOTOELECTRICITY, AUTOMATIC MACHINES.)

Perhaps the most valuable outcome of these endeavours will be the development of mechanisms capable of taking over those tasks that men and women find too monotonous or otherwise burdensome. One such device is the Televox, invented in 1927 by R. J. Wensley of the Westinghouse Electric and Manufacturing Co. This device permits the use of the network of the telephone system for the distant control of an electrical mechanism by means of certain sounds. The mechanism is arranged to answer the telephone and execute orders in a manner peculiarly similar to that of a human being. It was developed for the use of public utility companies to, supplement the use of supervisory control systems of electrical sub-stations, reservoir systems, gas regulators, etc.

The Televox can transmit electric meter readings, heights of water, gas pressures, position of valves and switches, and can execute actual mechanical operations at the direction of a distant operator. In using the Televox a call is put through exactly as though there were a human operator on the other end of the phone. The person making the call uses certain tones of the desired pitch to transmit the message. It is essential that a consistency of pitch be maintained. These tones are ordinarily delivered by electrically driven tuning forks. The telephone transmitter converts the tones into electrical vibrations, which at the distant station are caused to actuate steel reeds, which in turn actuate the selecting and operating relays. The responses are obtained from an instrument placed near the transmitter which sounds certain combinations of long and short notes, to form a code understandable by the operator at the other phone. The machine "hangs up" the receiver when the order has been executed, thereby ending the "conversation."

There are a number of processing machines which control all processes in a given industry, including temperature and humidity control during the process, starting, stopping, and varying the different materials which enter into the process in accordance with a time schedule, and independent of an outlet. If anything goes wrong, the machine stops and shows a red light until the operator has made the necessary changes. At the conclusion of the operation the machine shows a green light until the operator has removed the material in process.

The Tagliabue Automatic Flue-Gas Analyzing Machine which makes an analysis for CO_2 and for CO every minute, and records the results. is such a robot.

The Product Integraph is a robot ahich solves almost any second-order differential equation. It performs, by a combination of electrical and mechanical means. certain computations which are actually beyond the power of the human brain, so far demonstrated

Other processes, which if performed by mathematics would require from a week to a year to solve, are solved by the integraph in a fen minutes or hours.

ROB ROY (1671–1734), the designation of a Highland outlaw whose prowess is the theme of one of Sir Walter Scott's novels, and who was by descent a Macgregor. He received the name Roy from his red hair, and latterly adopted Campbell as his surname on account of the acts proscribing the name of his own clan. At first he devoted himself to rearing cattle on his estates on the Braes of Balquhidder, but having formed a band of clansmen, he obtained, after the accession of William III, a commission from James II to levy war on all who refused to acknoaledge him as king. Shortly afterwards he married Helen Mary, daughter of Macgregor of Comar. On the death of Gregor hfacgregor, the chief of the clan, in 1693 he was acknowledged chief, obtaining control of the lands stretching from the Braes of Balquhidder to the shores of Loch Lomond, and situated between the possessions of Argyll and those of Montrose. To assist in carrying on his trade as cattle-dealer he borrowed money from the 1st duke of Montrose, and, being unable to repay it, was in 1712 evicted and declared an outlaw. Taking refuge in the Highlands, Rob Roy supported himself by depredations on the duke and his tenants, all attempts to capture him being unsuccessful. During the rebellion of 1715, though nominally siding with the Pretender, he took no part in the battle of Sheriffmuir except in plundering the dead on both sides. He was included in the Act of Attainder; but through the influence of the duke of Argyll, he obtained, on making his submission at Inveraray, a promise of protection. He established his residence at Craigroyston, near Loch Lomond, whence he levied blackmail as formerly upon Montrose. Through the mediation of Argyll, he was reconciled to Montrose, and in 1722 he made submission to General Wade; he was carried off, and imprisoned in Newgate, and in 1727 was pardoned just as he was to be transported to Barbados. He died at Balquhidder on Dec. 28, 1734, and was buried in Balquhidder churchyard.

The best lives are K. Macleay, *Historical Memoirs of Rob Roy* (1818; new ed., 1881); A. H. Millar, *Story of Rob Roy* (1883). See also Sir W. Scott's introduction to the novel *Rob Roy*. An early account, *The Highland Rogue, etc.* (1723), is ascribed to Defoe.

ROBSART, AMY, first name of LADY AMY DUDLEY (1532–1560), wife of Lord Robert Dudley, afterwards earl of Leicester. She was the daughter of Sir John Robsart of Norfolk, and was married to Lord Robert on June 4, 1550. When Elizabeth became queen in 1559 Lord Robert was soon known to be her favourite, and it was believed that she would marry him if he were free. His wife never came to court and was never in his company. In 1560 she went by her husband's directions to Cumnor Place, a house near Oxford, rented by his agent Anthony Forster or Forrester, member of parliament for Abingdon. Here she was found lying dead on the floor of the hall on Sept. 8, 1560, by her servants. The circumstances of her death were never, cleared up.

See G. Adlard, *Amy Robsart and Leycester* (London, 1870), and W. Rye, *The Murder of Amy Robsart* (London, 1885); Sir B. H. T. Frere, *Amy Robsart of Wymondham; the Story of her Life and the Mystery of her Death* (Norwich, 1937).

ROC, or more correctly RUKH, a fabulous bird of enormous size which carries off elephants to feed its young. The legend of the roc, familiar from the *Arabian* Nights, was widely spread in

the east; and later the home of the monster was sought in Madagascar, when gigantic fronds of the *Raphia* palm very like a quill in form appear to have been brought under the name of roc's feathers *(see* Yule's *Marco Polo,* bk. iii, ch. 33). Such a feather was brought to the Great Khan, and we read also of a gigantic stump of a roc's quill being brought to Spain by a merchant from the China seas.

The roc is hardly different from the Arabian *'ankā (see* PHOENIX) ; it is also identified with the Persian *simurgh.*

Jayakar (1906).

ROCAMADOUR, a village of southwestern France, in the *département* of Lot. 36 mi. N.K.E. of Cahors by road. Pop. (1954) 204. Rocamadour owes its origin to St. Amadour or Amateur, who, according to tradition, chose the place as a hermitage for his devotions to the Virgin Mary. The renown of Rocamadour as a place of pilgrimage dates from the early middle ages. Rocamadour is most strikingly situated. Its buildings rise in stages up the side of a cliff on the right slope of the gorge of the Alzou. Flights of steps ascend from the lower town to the churches halfway up the cliff. The chief of them is the church of Notre-Dame (1479), containing the wooden figure of the Madonna reputed to have been carved by St. Amadour. The interior walls of the church of St. Sauveur are covered with paintings and inscriptions recalling the pilgrimages of celebrated persons. The subterranean church of St. Amadour (1166) extends beneath St. Sauveur and contains relics of the saint. On the summit of the cliff stands the medieval château built to defend the sanctuaries.

ROCAMBOLE *(Allium scorodoprasum,* family Liliaceae), a hardy bulbous perennial plant occurring in a wild state in sandy pastures and waste places throughout Europe and Asia Minor (often called giant garlic) but not common in the south; in Great Britain it is rare, and found only in the north of England and the south of Scotland. It is practically unknown in the United States.

The plant is grown for its bulbs, which are smaller and milder than those of garlic, and consist of several cloves chiefly produced at the roots. The cloves are planted about the end of February or in March, and treated like shallot.

ROCH, ST. (Lat. ROCHUS; Ital. Rocco; Span. ROQUE; Fr. ROCH) (d. 1327), a confessor whose death is commemorated on Aug. 16; he is specially invoked against the plague. According to his *Acta,* he was born at Montpellier, France. about 1295. On the death of his parents in his 20th year he gave all his substance to the poor.

During an epidemic of plague in Italy, he tended the sick at Aquapendente, Cesena and Rome, and effected miraculous cures by prayer and simple contact. After similar ministries at Piacenza he himself fell ill. He was expelled from the town and withdrew into the forest, where he would have perished had not a dog belonging to a nobleman named Gothardus supplied him nith bread.

On his return to Montpellier he was arrested as a spy and thronn into prison, where he died Aug. 16. 1327, having previously obtained from God this favour — that all plague-stricken persons invoking him be healed. His cult spread through Spain, France. Germany, Belgium and Italy. A magnificent temple was raised to him at Venice. (H. DE.)

ROCHAMBEAU, JEAN BAPTISTE DONATIEN DE VIMEUR, COMTE DE (1725–1807). French soldier, was born at Vendbme (Loir-et-Cher) on July 1, 1725. He was brought up at the Jesuit college at Blois, but entered a cavalry regiment. He served in Bohemia and Bavaria and on the Rhine. and in 1747 had attained the rank of colonel. He became governor of Vendôme in 1749, and after distinguishing himself in 1756 in the Minorca expedition was promoted brigadier of infantry. In 1757 and 1758 he fought in Germany. notably at Crefeld, received several wounds in the battle of Clostercamp (1760) and was appointed *maréchal de camp* in 1761 and inspector of cavalry. In 1780 he was sent, with the rank of lieutenant general. in command of 6,000 French troops to help the American colonists under Washington against the English. He landed at Newport, R.I., on July 10, but was held there inactive for a year, because of his reluctance to abandon the French fleet, blockaded by the British in Narragansett bay. At last, in July 1781, Rochambeau's force was able to leave Rhode Island and joined Washington on the Hudson. Then followed the celebrated march of the combined forces to Yorktown, where on Sept. 22 they joined the troops of Lafayette; Cornwallis was forced to surrender on Oct. 19. Congress voted Rochambeau and his troops the thanks of the nation and presented him with two cannon taken from the English. These guns, which Rochambeau took back to Vendôme, were requisitioned in 1792. On his return to France he was loaded with favours by Louis XVI and was made governor of Picardy.

During the Revolution he commanded the army of the north in 1790, but resigned in 1792. He was arrested during the Terror, and narrowly escaped the guillotine. He was subsequently pensioned by Bonaparte, and died at Thoré (Loir-et-Cher) on May 10, 1807.

A statue of Rochambeau by Ferdinand Hamar, the gift of France to the United States, was unveiled in Lafayette square, Washington. by Pres. Theodore Roosevelt on May 26, 1902.

BIBLIOGRAPHY.—The *Mémoires militaires, historiques et politiques, de Rochambeau* were published by Luce de Lancival in 1809. Of the first volume a part, translated into English by M. W. E. Wright, was published in 1838 under the title of *Mentoirs of the Marshal Count de R. Relative to the War oj Independence in the United States.* Rochambeau's correspondence during the American campaign is published in H. Doniol, *Histoire de la participation de la France à l'établissement des États Unis d'Amérique,* vol. v (1892). *See* J. J. Jusserand, "Rochambeau and the French in America" in *With Americans of Past and Present Days* (1916).

ROCHDALE, a county and parliamentary borough, Lancashire, Eng., 11 mi. N.N.E. of Manchester by road. Pop. (1961) 85,785. Area 14.9 sq.mi. The town lies at the foot of a western spur of the Pennines and at the junction of the Spodden with the Roch, which latter flows through the town (the central part has been covered in). The moribund Rochdale canal also passes through the town. The manufacture of cotton, woollen and rayon materials are the main industries, and there are engineering, asbestos, rubber, electrical and other works. Rochdale has an art gallery, a museum, a repertory theatre and five parks in addition to Hollingworth lake (117 ac.) 3½ mi. S.E.

Rochdale was the birthplace of the co-operative movement, the Rochdale Pioneers' Equitable society having been founded there ip 1844. The first shop, in Toad lane, has been restored to its original appearance. A statue of John Bright (1811–89) recalls the connection of the statesman's family with Rochdale.

Rochdale was incorporated in 18j6, but the parliamentary borough has returned one member since 1832. The county borough was created in 1888 and extended in 1933.

Rochdale (Recedham, Rachedam, Rachedal) takes its name from the river on which it stands. A Roman road passed the site, and a Saxon castle stood in Castleton. During Edward the Confessor's reign most of the land was held by Gamel the Thane, but after the Conquest the manor came into the hands of Roger de Poictou, from whom it passed to the Lacys and became merged in the duchy of Lancaster. From 1462 to 1625 the crown leased it to the Byron family. In 1625 Charles I conveyed the manor in trust, and in 1638 it was sold to Sir John Byron, afterward Baron Byron of Rochdale, whose descendants held it till 1823 when it was sold to the Deardens. Henry III (1240–41) granted to Edmund de Lacy the right to hold a weekly market on Wednesday and an annual fair on the feast of SS. Simon and Jude (Oct. 28).

ROCHDALE PIONEERS: *see* CO-OPERATIVES.

ROCHEFORT, HENRI VICTOR, MARQUIS DE ROCHEFORT-LUÇAY (1830–1913), one of the most effective polemical writers ever known in France. He was born at Paris on Jan. 31, 1830. He made a name as a successful journalist and writer of vaudevilles during the second empire, and began his turbulent career as an abusive political journalist when in May 1868 he founded and edited *La Lanterne.* It was suppressed on its 11th appearance, and Rochefort was fined and imprisoned. But the paper was then published in Brussels, Belg., and smuggled into

France. It circulated throughout Europe because it was printed in English, Spanish, Italian and German as well as in French. He also contributed to Victor Hugo's newspaper *Le Rappel,* founded in 1869. and in that year founded yet another opposition journal, *La Marseillaise.* As a leader of the republican opposition to the rule of Napoleon III, he was elected in 1869 to the *Corps le'gislatif* for a Paris constituency. Imprisoned again, he was released when the empire fell in Sept. 1870 and became a member of the provisional government of national defense. His open support for the Paris Commune of 1871 led to his resignation from the national assembly and his condemnation under military law. Though transported to New Caledonia he escaped after three months to the United States and lived abroad in London and Geneva, Switz., until the general amnesty of 1880 permitted him to return to France.

Hitherto the brilliant invective of his journalism had served the cause of the left, and now in *L'Intransigeant* he championed the more extreme Radicals and Socialists against Léon Gambetta, Jules Ferry, and the moderate Republicans. But he rashly backed Gen. Georges Boulanger against them, and in 1889 found himself again sentenced to prison for his activities. After the collapse of Boulangism he returned temporarily to the support of Socialism, but again swung over to the right in the Dreyfus case and belaboured the leaders of the Dreyfusards. He left *L'Intransigeant* in 1907, and wrote until his death for the national and conservative *La Patrie.* He wrote also many plays and novels, and had a genius for satire. He died at Aix-les-Bains in July 1913.

See his *Les Aventures de ma vie,* 5 vol. (Paris, 1896–98), partly in Eng. trans, by E. W. Smith, 2 vol. (London, 1896); A. Zévaès, *Henri Rochejort le pamphlétaire* (Paris, 1946). (*D* TN.)

ROCHEFORT, a small town of Belgium, on the Lomme, a tributary of the Lesse, in the southeast of the province of Namur close to the Ardenne. Population (1955 est.) 3.796. It has ruins of the old castle, which gave the place its name and a title to a long line of counts who had the right of coining their own money. This castle underwent many sieges and suffered much in the earlier wars, especially at the hands of Marshal de Chatillon in 1636.

Rochefort is noted for its healthfulness, and is a favourite place of residence and resort.

There are many grottoes, one of which. in the town itself, contains six halls or chambers; the largest, called the Sabbat, is remarkable for its great height. But the most famous are the grottoes of Han, 3 mi. from Rochefort where the Lesse river passes by a subterranean and undiscovered passage under the hillcalled Boème or Boine. The endedvour to trace the course of the river led to the discovery of the grottoes, which consist of 1 j separate halls, connected by passages more or less short and emerging on the river in a dark and extensive cavern forming a sort of side creek or bay. Near Rochefort are the famous red marble quarries of St. Remy, and the old Cistercian abbey of that name is now a Trappist seminary.

ROCHEFORT, a town of western France, capital of an *arrondissement* in the *de'partement* of Charente-Maritime, 20 mi. S.S.E. of La Rochelle on the state railway from Nantes to Bordeaux. Pop. (1954) 23,753.

The lordship of Rochefort. held by powerful nobles in the 11th century, was united to the French crown by Philip the Fair early in the 14th century; but it was alternately seized during the Hundred Years' War by the English and the French and in the Wars of Religion by the Catholics and Protestants. Colbert in 1665 chose Rochefort as the seat of a repairing port between Brest and the Gironde, so the town rapidly increased in importance, and the Dutch admiral Cornelius Tromp with his fleet failed to destroy the new arsenal. The naval school, afterward transferred to Brest, was originally founded at Rochefort. Its fleet, under Adm. Roland Michel de la Galissonnière, a native of the place, defeated Admiral Byng in 1755 and did good service in the wars of the republic. But the destruction of the French fleet by the English in 1809 in the roadstead of Ile d'Aix and the preference accorded to Brest and Toulon and the unhealthfulness of its climate diminished its prosperity. It was from the Ile d'Aix that Napoleon embarked on the "Bellerophon" in 181 j.

Rochefort is capital of the fourth maritime *arrondissement.* The commercial harbour, higher up the river than the naval harbour, has two small basins, a third basin with a depth at neap tide of 24 ft. and at spring tide of 30 ft., and a dry dock. Trade is in wood. cereals, salt and coal.

ROCHESTER, JOHN WILMOT, 2ND EARL OF (1647–1680), English poet and wit, the son of Henry Wilmot, the 1st earl, was born at Ditchley in Oxfordshire on April 10, 1647, and succeeded his father as 2nd earl in 1658. He was educated at Wadham college, Oxford, and in 1661, although he was only 14 years of age, received the degree of M.A. On leaving Oxford he traveled in France and Italy with a tutor. He returned in 1664, and at once made his way to Charles II's court, where his youth, good looks and wit assured him of a welcome. In 1665 he joined the fleet serving against the Dutch as a volunteer. He became gentleman of the bedchamber to Charles II. John Dryden had dedicated to Rochester his *Marriage-d-la-Mode* (1672); but Dryden's *Aurengzebe* (1675) was dedicated to Lord Mulgrave, who was Rochester's enemy. Consequently Rochester thwarted Dryden at every turn, and in 1679 a band of roughs set on the poet in Rose alley, Covent Garden, and beat him. Rochester obviously felt no shame for this infamous attack, for in his "Imitation of the First Satire of Juvenal" he says, "Who'd be a wit in Dryden's cudgelled skin?" His health was already undermined, and in the spring of 1680 he retired to High lodge, Woodstock park. He began to show signs of a more serious temper, and at his own request was visited (July 20 to July 24) by Bishop Burnet, who attested the sincerity of his repentance. He died, however, two days after the bishop left him.

When his son Charles, the 3rd earl, died on Nov. 12, 1681, Rochester's titles became extinct.

As a poet Rochester was a follower of Abraham Cowley and of Boileau, to both of whom he was considerably indebted. His love lyrics are often happy. but his real vigour and ability are best shown in his critical poems and satires.

The political satires are notable for their fierce exposure of Charles II's weakness.

BIBLIOGRAPHY. — *Poems on Several Occasions by the Right Honourable the Earl of Rochester . . .* (Antwerp, 1680) was really printed in London Other issues, slightly varying in title and contents, appeared in 1685, 1691 and 1696 *Valentinian, a Tragedy,* adapted from Beaumont and Fletcher, was printed in 1685; a scurrilous attack on Charles II in the shape of a play in heroic couplets, *Sodonz,* was printed in 1684, and is supposed, in spite of Rochester's denial, to have been chiefly his work. No copy of this is known, but there are two manuscripts extant. The completest edition of his works is *The Poetical Works oj the Earl of Rochester* (1731–32). Expurgated collections are to be found in Johnson's, Anderson's and Chalmers' editions of the *British Poets.* His *Familiar Letters* were printed in 1686, 1697 and 1699. His political satires are available in the *Bibliotheca Curiosa, Some Political Satires of the Seventeenth Century,* vol. i (Edinburgh, 1885).

ROCHESTER, LAWRENCE HYDE, EARL OF (1642–1711), English statesman, second son of Edward Hyde, earl of Clarendon, was born in March 1642. After the restoration of Charles II he sat as member of parliament, first for Newport in Cornwall and afterward for the University of Oxford, from 1660 to 1679. In 1661 he was sent on a complimentary embassy to Louis XIV of France, while he held the court post of master of the robes from 1662 to 1675. In 1665 he married Henrietta (d. 1687), daughter of Richard Boyle, earl of Burlington and Cork. When his father was impeached in 1667, Lawrence joined with his elder brother, Henry, in defending him in parliament, but the fall of Clarendon did not injuriously affect the fortunes of his sons. They were connected with the royal family through the marriage of their sister, Anne, with the duke of York, afterward James II, and were both able and zealous royalists. In 1681 Lawrence Hyde, who had been made first lord of the treasury and a privy councillor in 1679, was made Viscount Hyde of Kenilworth, and in November following earl of Rochester.

He was compelled to join in arranging the treaty of 1681, by which Louis XIV agreed to pay a subsidy to Charles, at the very moment when he was imploring William, prince of Orange, to save Europe from the ambitions of the French monarch. In Aug. 1684

he was removed from the treasury to the post of lord president of the council. He was still president of the council when James II became king in Feb. 1685, and he was at once appointed lord treasurer. But in spite of their family relationship and their long friendship, James and his treasurer did not agree. In Jan. 1687 he was removed from his office of treasurer.

After the revolution of 1688 Rochester, after a brief protest, accepted the new regime. From Dec. 1700 until Feb. 1703 he was lord lieutenant of Ireland, and in 1710 he was again made lord president of the council.

Rochester died on May 2, 1711, and was succeeded by his only son, Henry (1672–1753), who in 1723 inherited the earldom of Clarendon. When Henry died without issue on Dec. 10, 1753, all his titles became extinct.

The correspondence of Rochester with his brother the earl of Clarendon, together with other letters written by him, was published with notes by S. W. Singer, 2 vol. (London, 1828).

ROCHESTER, a city and municipal and parliamentary borough of Kent, Eng., on the Medway river, 31½ mi. E.S.E. of Hyde Park corner, London; it adjoins Chatham. Pop. (1951) 43,934. Area 5.9 sq.mi. Its situation on the Roman way from the Kentish ports to London, as well as at a Medway crossing, gave Rochester (Durobrivae; Hrofaecaestrae and Hrofi c. 730) an early importance. It was a walled Romano-British town, and the original bridge across the Medway (Durobrivae, an old British word probably meaning "stronghold bridge") probably dated from that period. The church of St. Andrew was founded by King Aethelbert, who also made Rochester a bishop's see. It was a royal borough in the time of William I, who built a castle there, probably on Boley hill. Richard I granted the citizens quittance of pas-*sagium* from crusaders in the town of Rochester in 1189. In 122 j Henry III granted them the city, a guild merchant, the right to be impleaded only within the city walls and other liberties. These charters were confirmed by subsequent sovereigns down to Henry VI, who in 1446 incorporated the city and granted it the power of admiralty and many privileges. Charters were granted in later reigns down to Charles I, whose charter of 1629 remained the governing charter until 1835. Rochester returned two members to parliament from Edward I's time until 1885, one from then until 1918. two from 1918 to 1950; one from then on.

The cathedral church of St. Andrew was originally founded by St. Augustine in 604, for whom Aethelbert built the church. It was partly destroyed by the Danes, but was rebuilt by Bishop Gundulph. the second Norman bishop (1077–1108). Gundulph or Gundulf established (1082 or 1083) Benedictine monks there. Bishop Ernulf (1115–24) completed and also renovated the church, lengthening it by two bays eastward; the old chapter house remains. The Norman west front was built about 1125–30, and in 1130 the new cathedral was consecrated. The work included an extended choir by William de Hoo (122 j), enlargement of the main transepts, the building of piers for a central tower and treatment of the nave to the third bay. About 1352 a low central tower was built, to which a spire was added in the next century. Toward the end of the 15th century St. Mary's chapel was added. The ruins of Gundulph's tower stand detached from and are earlier than the church; it was built by Bishop Gundulph probably as a defensive work for the eastern boundary of the city. The crypt beneath the choir is Early Norman in the western part. The remainder is Early English, and there are traces of mural painting. The library attached to the modern chapter house contains, among various relics, the *Textus Roffensis,* being records of the cathedral compiled in the time of Bishop Ernulf.

On the eminence overlooking the right bank of the river are the remains of the Norman castle, part of which was built by Bishop Gundulph at the order of William Rufus in the 11th century. The castle was besieged by King John, by Simon de Montfort in the reign of Henry III and by the followers of Wat Tyler. It was repaired by Edward IV, but soon afterward fell into decay, although the massive keep still stands. This is the work of William de Corbeil or Corbeuil, archbishop of Canterbury, to whom the castle was granted in 1123. It is a quadrangular four-storied structure, flanked by turrets, with a height of 113 ft. Remains of the 13th-century walls which once surrounded the city also exist. Charles Dickens lived at Gad's hill. above Strood, to the northwest. At Borstal, southwest of Rochester, was a large convict prison where early experiments on the educational treatment of delinquent boys between the ages of 16 and 21 were carried out, which resulted in the Borstal system (*q.v.*).

Among the principal buildings in the city are the guildhall (1687), the Richard Watts' almshouses (founded in 1579) and the almshouse of St. Catherine (built 1805), which originated in 1316 as a leper's hospital. An Elizabethan mansion was acquired by the corporation for a museum as a memorial of Queen Victoria's diamond jubilee. The principal schools are the cathedral grammar school or King's school, founded in 1544, and the Sir Joseph Williamson's Mathematical school (1701), formerly for sons of freemen but now open to all. St. Bartholomew's hospital (1708) occupies modern buildings, though the ancient chapel remains. A municipal airport has been provided by the corporation.

The Medway is navigable to Rochester bridge and vessels drawing 26 ft. can reach it. Since the 1850s Rochester has become increasingly industrialized with cement, engineering and other works. The towns of Rochester, Chatham and Gillingham form one great conurbation sometimes known as the Medway Boroughs,

ROCHESTER, a city of Minnesota, U.S., in Olmsted county, home of the world-famous Mayo clinic, is located about 80 mi S.E. of Minneapolis-St. Paul in the rich diversified agricultural plains region of southeastern Minnesota. It has one of the largest hatchery-breeding farm operations in the country as well as a large dairy processing plant. The establishment of an electronic data processing centre there has added to the growing industrial pattern of the city.

The site at the confluence of three tributaries of the Zumbro river was chosen by settlers in 1854 and named for Rochester. N.Y., by George Head. The city was incorporated in 1858 with a population of about 1,500.

Long famed as a health centre, Rochester houses the Mayo Foundation for Medical Education and Research, which is one of the world's largest graduate medical schools, and a branch of the University of Minnesota. There is a large privately operated hospital, and the Mayo clinic which is actually a combination of hospitals and hotels. The clinic operates with the co-operation of the largest voluntary association of physicians, surgeons, medical technicians and researchers in the world engaged in private practice. It was established in 1889 by William U'0rrall Mayo and his sons Charles Horace (*q.v.*) and William James Mayo (*q.v.*) and greatly stimulated Rochester's growth. The total number of hospital beds in the city, including the state mental hospital immediately east of the city, is more than 3,300.

As these medical services attract patients from all over the U.S. and the world, a cosmopolitan atmosphere is apparent. Because of a fairly constant transient population of 6,000–9,000 at any given time, the 1960 census return of 40,663 and earlier population figures are misleading. (For comparative population figures *see* table in MINNESOTA: *Population.)* Along with excellent public education facilities, the town has five parochial schools, two schools of nursing, a school of music and an evening community college. (JE. C. T.)

ROCHESTER, a city of northwestern New York, U.S., and seat of Monroe county, is located 70 mi. E. of Buffalo and 90 mi. W. of Syracuse, and is bisected by the Genesee river, which flows into Lake Ontario. The area is a prosperous manufacturing centre of quality photographic, optical and precision instruments; it is in the heart of a fruit and truck farming belt; and the gateway to the Finger Lakes resort area to the south. The climate is characterized by short pleasant summers and long, harsh winters.

History and Industrial Growth. — Rochester's first settlement dates from 1789. In 1788 Oliver Phelps obtained from the Seneca Indians land on the west side of the Genesee river to establish grist mills which would utilize the natural water power of the river falls. In 1789 Ebenezer "Indian" Allen was deeded 100 ac. of this land for the construction of a sawmill and grist mill. Allen's venture was a failure, and further settlement was impeded by the malarial conditions known as Genesee fever.

Col. Nathaniel Rochester. Revolutionary War soldier and Maryland aristocrat, laid out the town in 1811 and named it Rochesterville, shortened in 1822 to Rochester. In 1812 the first dwelling unit. a log cabin, was occupied by Hamlet Scrantom and his family and marked the beginning of permanent settlement. Rochester was incorporated as a village in 1817 and chartered as a city in 1834.

The early economy was built upon the extensive wheat production of the Genesee valley region. Rochester's cheap natural water power and the city's connection with the eastern section of the Erie canal in 1822 assured its economic development as a milling centre. By 1840 the city, one of the early boom towns of the "west," had 20,000 residents. By the 1860s the clothing and shoe industries, given impetus by the American Civil War and the arrival of skilled immigrants, thrived; Rochester had also become the flour milling capital of America. But by 1878 this latter industry had passed its peak and was moving westward to Minnesota. In 1942 the last flour mill was closed. After the Civil War, Rochester was transformed from the "flour city" to the "flower city." Large nursery and seed enterprises were developed with James Vick pioneering the mail order approach to seeds and shrubs. Although the business aspects of horticulture declined by the beginning of the 20th century, the influence of this industry is still manifested in the residents' concern with flowers, gardens and shrubs. Rochester's lilac collection in Highland park is widely known.

By the latter part of the 19th century the area was developing into a quality manufacturing centre with emphasis upon photographic, optical and precision instrument products. The major industries with few exceptions were founded by Rochester men utilizing local capital. Notable among these was George Eastman (*q.v.*), who was interested in photography and scientific experimentation. He developed a machine which coated dry photographic plates and began business in 1880 with six employees, becoming a major film and camera manufacturer.

Two industrialists, John Jacob Bausch and Henry Lomb, who perfected better techniques for grinding lenses, established their optical company there. Other entrepreneurs built successful manufacturing firms specializing in thermometers, machine tools, check protectors, mail chutes, glass-lined enameled steel tanks and dental equipment.

Aside from photographic, optical and precision equipment, the chief modern manufactures are electrical goods, clothing and textiles. shoes, machine tools and fabricated metal products. Lithography. printing and food processing are also important.

Organized labour has never been strong. Photographic instrument workers are relatively unorganized. Men's clothing workers are strongly organized as are the workers in the metal and printing trades, transportation and building trades.

Frederick Douglass, the Negro abolitionist and runaway slave, published his anti-slavery paper, *The North Star,* in Rochester when the community was an important terminus for the Underground Railroad (*q.v.*) to Canada. The area is regarded as a cradle of modern Spiritualism because of Margaret and Katharine Fox's numerous seances (the "Rochester Rappings") in the late 1840s which attracted world attention. Susan Brownell Anthony, a leading advocate of woman's suffrage, aided Clara Barton (*q.v.*) in establishing the second American Red Cross chapter in 1881 in Rochester. Lewis Henry Morgan (*q.v.*) an early ethnologist and the area's greatest intellect, wrote *Ancient Society* and *The League of the Iroquois.* A noted social reformer was the theologian, Walter Rauschenbusch (*q.v.*) who expounded. prior to World War I. the social gospel philosophy of Christianizing the social order of America.

Population. — Rochester with a population of 318,611 in 1960 is the central city of a standard metropolitan statistical area comprising Monroe county which had a population of 586,387. Although the city's population decreased by 4.2% between 1950 and 1960, the population of the metropolitan area increased by 20.3%. (For comparative population figures *see* table in NEW YORK: *Population.)* In the metropolitan area Irondequoit. Greece and Brighton are the largest suburban towns. These towns along with Gates, Chili, Pittsford, Perinton, Henrietta, Penfield and Webster, are predominantly residential in character, although industrial parks have been created in the last three. The fringe metropolitan area towns of Hamlin, Clarkston, Sweeden, Ogden, Riga, Wheatland, Rush and Mendon are predominantly rural in character, although limited suburbanization has occurred.

The area's earliest settlers were of northern European ancestry who migrated chiefly from New England. Prior to the American Civil War, significant numbers of Irish and Germans became residents. Before World War I, large numbers of Italian immigrants arrived, and they represent the largest foreign-born group in the area. At least 15% of the population is of Italian extraction. There are smaller numbers of Polish, Ukrainians, Dutch. Lithuanians and Jewish immigrants from Germany and eastern Europe and their descendants.

Administration. — The Republican party has dominated the political affairs of the area, with few interruptions, since the Civil War. In 1925 Rochester adopted the city-manager form of government. The governing body, the city council, is composed of five councilmen-at-large and four district councilmen elected for four-year terms. The council selects one of its members as mayor. In the other 19 metropolitan towns the chief official, the supervisor, is elected for a two-year term.

Education, Culture and Recreation. — George Eastman's philanthropy supported or helped to establish a number of cultural and public facilities including the Eastman theatre, the city's university, the Dental dispensary and Durand-Eastman park.

The two major educational institutions are the University of Rochester (founded 1850) which includes the well-known Eastman school of music and school of medicine and dentistry, and the Rochester Institute of Technology (1829). Undergraduate collegiate education is provided by Nazareth (1924; Roman Catholic) St. John Fisher (1951; Roman Catholic) and Roberts Wesleyan (1866) colleges, and theological education by St. Bernard's seminary (1893; Roman Catholic) and Colgate-Rochester Divinity school (1819; Baptist). The Rochester Philharmonic orchestra provides musical concerts during the winter season. The area has an excellent system of parks and recreational facilities including Hamlin State park on Lake Ontario, Genesee Valley park, the yacht basin in Irondequoit bay, the ski jump at Powder Mill park and Highland park, with its floral displays, in Rochester.

ROCK, in geology a mass of the mineral matter of which the crust of the earth is composed. *See* GEOCHEMISTRY; GEOLOGY; PETROLOGY.

ROCKEFELLER, the name of a U.S. family founded by JOHN DAVISON ROCKEFELLER (1839–1937), industrialist. founder of the Standard Oil enterprise and of the first great American oil fortune. He was born in Richford, N.Y., on July 8. 1839, the son of a small trader. In 1853 the family settled in Cleveland, O. In 1859 Rockefeller formed a partnership with M. B. Clark in the produce and commission business. The first U.S. oil well was drilled that summer in Titusville, Pa., and in 1863 Rockefeller organized the firm of Andrews, Clark and company to enter the oil refining business as a sideline. Two years later the firm was reorganized as Rockefeller and Andrews. His brother WILLIAM ROCKEFELLER (1841–1922) joined him in the organization of William Rockefeller and company for the operation of a second refinery in Cleveland. In 1867 the two Cleveland refineries were consolidated into the partnership of Rockefeller, Andrews, Flagler and company, and three years later this firm was replaced by a joint stock company, the Standard Oil Company of Ohio, with John D. Rockefeller as president. Under his direction, this company obtained control of the oil industry by means of mergers, favourable railroad rates. rebates and other devices which at that time were not illegal. In 1882 was organized the Standard Oil trust, which controlled 95% of the oil refining business in the country and had in addition substantial interests in iron ore mines, lumber tracts, manufacturing plants, transportation and other

businesses. In 1899 the supreme court of Ohio held this trust to be a violation of the Sherman Anti-Trust act, and the trust was replaced by the holding company device, Standard Oil of New Jersey, which existed until 1911 when the United States supreme court declared it also to be illegal. By this time John D. Rockefeller had retired from active business and was devoting his time to giving away a large part of his fortune. For this purpose he established charitable corporations governed by trustees and operated by officers devoted to a continuous study of opportunities for public service. It is estimated that by this means Rockefeller's benevolences mounted to nearly $600,000,000. His first large benefaction was to The University of Chicago (*q.v.*), which received from him a total of $35,000,000. He died at his home in Ormond Beach, Fla., on May 23, 1937.

JOHN DAVISON ROCKEFELLER, JR. (1874–1960), the only son of John D. Rockefeller and Laura Spelman Rockefeller, was born in Cleveland, O., on Jan. 29, 1874. After graduation from Brown university in 1897, he entered his father's office, working closely with him in the business, philanthropic and civic enterprises of the family. His life was devoted primarily to philanthropic and civic activities. He was associated with his father in the creation and development of the Rockefeller Institute for Medical Research, the General Education board, the Rockefeller foundation and the Laura Spelman Rockefeller memorial. In 1923 he founded the International Education board, which operated in the fields of the natural sciences, the humanities and agriculture until it was terminated in 1937, its capital fund of more than $21,000,000 having been expended. Deeply interested in the conservation of natural resources and in preserving historic places, the younger John D. Rockefeller made many contributions for these purposes, including among them the restoration of Williamsburg, Va. His contributions from Jan. 1, 1917, to Dec. 31, 1955, amounted to about $400,000,000. He died in Tucson, Ariz., on May 11, 1960.

NELSON ALDRICH ROCKEFELLER (1908–), second son of John D. Rockefeller, Jr., was born at Bar Harbor, Me., on July 8, 1908. He graduated from Dartmouth and was associated with the family interests thereafter. In addition, he served during World War II as co-ordinator of inter-American affairs and as assistant secretary of state (1944–45). In 1958 he was elected governor of New York.

Other of the five sons of John D. Rockefeller, Jr., have been associated with the various Rockefeller benevolent corporations, New York city banks and other businesses: JOHN DAVISON ROCKEFELLER III (1906–); LAURANCE S. ROCKEFELLER (1910–); WINTHROP ROCKEFELLER (1912–); and DAVID ROCKEFELLER (1915–). *See* also STANDARD OIL COMPANIES.

ROCKETS. This article is divided into the following sections:

I. INTRODUCTION

Rocket is the generic term for a wide variety of jet-propelled missiles, research vehicles, thrust devices and fireworks. Forward motion results from reaction to a rearward high-speed flow of hot gases generated in the rocket motor. Either solid or liquid propellants may be used to provide combustion gases.

A rocket motor. or engine, is one of the family of jet-propulsion devices whose other members include turbojet, pulse-jet and ramjet engines. The rocket engine is unique, however, in that the elements of the propulsive jet. fuel and oxidizer, are self-contained within the vehicle. The thrust produced is independent of the atmosphere or medium through which the vehicle travels. Other kinds of jet-propulsion engines carry their fuel only. This fuel is burned with the oxygen content of the air, scooped into the engine as the vehicle flies along. Thus these other varieties of jet engines are called air-breathing and are limited to operation within the blanket of atmosphere which surrounds the earth. Seventy-five thousand feet is about the upper limit of travel for air-breathing jet engines.

Rocket power is used for both military and peaceful purposes—and has been for hundreds of years. Rockets can be used to hurl explosives against targets thousands of miles away, or to lift data-gathering instruments—and man—into interplanetary space for scientific research and exploration.

The recorded history of rockets dates from the 13th century, but interest in them has risen and fallen as various other devices, such as the mortar and artillery, became competitive. Since World War II, however, rocket technology has reached such a level that it is doubtful that they will ever disappear again from the scene. As matters stand now, there is no technical competitor for rocket-propulsion systems for many missions. For instance, a rocket-powered ballistic missile can be fired against targets 6,000 mi. or more away. The speed at which it travels may be as high as 15,000 m.p.h. At the same time, as the recognized power plant for space flight, the rocket is the key to exploration of nature in a new dimension. In fact, the same basic vehicle used to carry an explosive warhead over intercontinental distances may be used instead to place man or a ton or more of scientific instruments in satellite orbit around the earth.

Launchings of earth satellites and of lunar and interplanetary research probes are but the prelude to an era of space exploration. Until 1955 man was a passive observer of laws of celestial mechanics. Since then he has begun to apply these laws through the use of rocket power. *See* also MISSILES; SPACE EXPLORATION.

II. HISTORY TO WORLD WAR II

1. Early History.— NO one knows when or by whom rockets were invented. In all probability the rocket was not suddenly "invented" but gradually developed over a long period of time, perhaps in different parts of the world at the same time. Some historians of rocketry, notably Willy Ley, trace the development of rockets to 13th century China, a land noted in ancient times for its fireworks display. In the year 1232 A.D. when the Mongols laid siege to the city of Kai-feng Fu (K'ai-feng), capital of Honan province, the Chinese defenders used weapons that were described as "arrows of flying fire." There is no explicit statement that these arrows were rockets, but some students have concluded that they were because the record does not mention bows or other means of shooting the arrows. In the same battle, we read, the defenders dropped from the walls of the city a kind of bomb described as

"heaven-shaking thunder." From these meagre references some students have concluded that the Chinese by the year 1232 had discovered gunpowder and had learned to use it to make explosive bombs as well as rockets.

In the same century rockets appeared in Europe. There is indication that the first use was by the Tatars against the Polish duke Henry in the battle of Liegnitz in 1241. The Arabs used rockets on the Iberian peninsula in 1249; and in 1288 Valencia was attacked with rockets. The Italian historian L. A. Muratori writes that a lucky hit of a rocket was decisive in a battle for Chioggia in 1379.

Around 1248 Roger Bacon (*q.v.*), an English Franciscan monk, wrote formulas for gunpowder in his *Epistola,* with great secrecy and the use of ciphers. He evidently experimented with various proportions of the three classic ingredients, saltpetre, charcoal and sulfur, raising the amount of saltpetre to 41%. The Chinese had used rather less saltpetre, which resulted in slower-burning mixtures. In Germany, a counterpart of Bacon, Albertus Magnus, was writing of powder charge formulas for rockets in his book *De mirabilis mundi.* About 1325 the first firearms were invented, utilizing a closed tube and gunpowder to propel a ball charge somewhat erratically over varying distances. Military engineers then began to invent and refine designs for guns and rockets, on a parallel basis. *(See* ARTILLERY.)

The French historian Jean Froissart (*q.v.*) suggested that rockets fired from tubes would give them better direction. In his book *Bellifortes* (1405), Konrad Kyeser von Eichstadt wrote of several designs of rockets. In Italy Joanes de Fontana conceived a number of novel war weapons based on rocket propulsion. One was a rocket-driven car designed to breach walls or gates. Another was a naval torpedo, designed to skim across water and ram its spiked nose into ships. Many other ideas were suggested in print, such as Count Reinhart von Solm's rockets with parachutes; or the count of Nassau's underwater explosive rocket. The extent to which many of these designs were reduced to working models or weapons is not known. By now rockets were used also for signaling and, especially by pirates, for setting fire to the tarred rigging of ships at sea. They had many names, such as "flying fire" or "wild fire."

The tale of Wan-Hu, presumably legendary, is an interesting milestone in the early history of the rocket. As the story goes, about the year 1500 a Chinese, Wan-Hu, made what must have been the first attempt at rocket flight, constructing a vehicle utilizing two large kites to which were attached some sort of seat. Forty-seven rockets were attached and fired simultaneously. Wan-Hu and his contrivance simply disappeared in the loud explosion which followed!

FIG. 1.—HISTORICAL EXAMPLES OF ROCKETS

(A) conventional stick-guided war rocket or fireworks skyrocket, and the earliest known concepts of (B) a step rocket, (C) a clustered rocket and (D) a fin-stabilized glide rocket. Drawings by Kazimierz Siemienowicz from *Artis magnae artilleriae,* pars prima (1650)

Of considerable historical interest are the work and writings of a Polish artillery expert, Kazimierz Siemienowicz. His monograph on military weapons, *Artis magnae artilleriae,* is noteworthy for three reasons. It contains the earliest known drawings of the step (or staged) rocket, the clustered rocket and the winged rocket. All of these concepts were to prove important several hundred years later. (See *Fundamental Principles of Rocket Propulsion,* below). Siemienowicz' book was published (in Latin) in Amsterdam in 1650. Translation of this document into French (1651), German (1676), English and Dutch (1729) gives eloquent testimony to the importance of this work. More than 200 figures were drawn on copperplate by Siemienowicz himself. Design characteristics of rockets, such as length-to-diameter ratios are given, as well as such constructional details as how to shape properly dimensioned holes for rocket nozzles. Siemienowicz died shortly after the publication of this book. His contributions to rocket technology are seldom recognized.

By 1668 military rockets, hard-pressed by development of guns and cannons, had increased in size and performance. In that year, a German. Col. Christoph Friedrich von Geissler, designed a rocket weighing 132 lb., constructed of wood, wrapped in glue-soaked sailcloth. It carried a gunpowder explosive charge weighing 16 lb.

Although the art of constructing rockets had now become quite widely known there was little appreciation or understanding of exactly how and why a rocket operated; *i.e.,* the physical principles involved. It was not until the last quarter of the 17th century that Isaac Newton formulated his famous laws of motion laying the basis for modern mechanics. Prior to this time Aristotelian theories of motion—philosophical in nature and unsupported by physical fact—had persisted for 20 centuries. Newton stated in his third law that every action is accompanied by an equal reaction in the opposite direction. The thrust of a rocket is derived from the reaction, in the opposite direction, to the expelled jet of combustion gases.

Despite the hard work of individual European enthusiasts, the use of rockets in military campaigns was sporadic. A revival of interest occurred after a series of battles in India late in the 18th century. Haidar Ali, prince of Mysore, developed rockets as weapons. The rockets had metal tubes, permitting higher internal pressures. They weighed 6–12 lb. and were flight-stabilized by a 10-ft. bamboo stick. The range of these rockets was a startling 1–14 mi. Although not individually accurate, dispersion errors of individual rockets became unimportant when large numbers were fired in mass attacks. These rockets were particularly effective against cavalry. Haidar Ali's son, Tipu Sahib, continued to develop and expand the use of rocket weapons increasing the number of rocket gunners from 1,200 to a corps of 5,000. The British suffered heavily, particularly in battles at Seringapatam in 1792 and 1799.

2. 19th-Century Developments.— The news of the successful use of rockets in these engagements spread through Europe. A British colonel, William Congreve, began to experiment privately. Within a few years he was able to match and exceed the range of the Indian rockets. In 1806 British rockets caused great fires during an attack on Boulogne. In 1807 a massed attack, using about 25,000 rockets, burned most of Copenhagen to the ground. In the decisive battle of Leipzig (1813) Congreve rockets are credited with playing an important role. Later the same year Danzig was subjected to a series of massed rocket bombardments in three successive months. The last attack caused the surrender of the city.

In the United States, the British used their rocket corps in two important engagements during the War of 1812. One was the battle of Bladensburg (Aug. 24, 1814) when their use drove back the American troops. As a result, the British were able to advance on Washington, D.C., capturing and burning the city. In September the British forces attempted to capture Ft. McHenry,

which guarded Baltimore harbour. They were unsuccessful but on that occasion Francis Scott Key, inspired by the sight of the night engagement, wrote the stirring words of the *Star Spangled Banner,* later adopted as the U.S. national anthem. "The rockets' red glare" and "bombs bursting in air" ever since have continued to memorialize Congreve's rockets.

Back in Europe, the Dutch army bought some Congreve rockets. A Captain de Boer conducted some experiments and arrived at a proposal to eliminate the heavy, stabilizing guide stick and substitute three metal vanes. Despite the fact that this lighter design should have worked, it was apparently not adopted. The stick-stabilized rocket was used until William Hale's invention several years later.

Congreve's rockets were successful for several reasons. He experimented with a number of black powder formulas and set down standard specifications. In the production of hundreds of thousands of rockets over two decades apparently a number of small refinements in design were made. Although none of these modifications materially improved performance, the sum total of the improvements resulted in a fairly reliable and potent weapon in the hands of a skilled rocket brigade. Congreve rockets ranged in weight from 25 to 60 lb. Some warheads were bombs, some steel ball charges for antipersonnel use. Extreme ranges increased to nearly three miles. They were competitive in weight and performance with the ponderous ten-inch mortar and were much more mobile. In appearance they resembled large skyrockets, the guide stick being 12–16 ft. long. Being recoilless, their launching equipment was simple and lightweight, and they could be fired from small boats. Thin copper tubes were used for initial directional guidance or, for massed bombardment, collapsible A-frames were employed. The success of Congreve's rockets caused the addition of rocket batteries to artillery units or the formation of independent rocket corps in most armies of Europe, as far east as Russia.

The next significant development in rocketry occurred about the middle of the 19th century. William Hale, a British subject, contrived a way of eliminating the dead weight of the stabilizing stick. When he placed a series of canted and curved vanes at the rear of the rocket, the exhaust gases imparted a spin to the rocket. Spin-stabilized rockets were a real improvement in performance and ease of handling. But by this time black powder rockets could no longer compete with artillery. The rocket corps of most European armies had been dissolved. Firearms and heavy field-pieces with rifled bores were outclassing rockets except on rare occasions. These exceptions were usually in mountainous terrain. On such ground, rockets could move into choice firing locations while the much heavier mortars were confined to roads or flat ground. Thus we find that the Austrian rocket corps, using Hale rockets, won a long series of engagements in such terrain against Hungary and Italy. Other successful uses were by the Dutch colonial services against natives in the Celebes and by Russia in a series of engagements in the Turkestan War.

Two thousand Hale rockets were produced by the U.S. army for the Mexican War, but from the little that has been recorded they were not particularly successful. Although the U.S. *Ordnance Manual* of 1862 listed 16-lb. Hale-type rockets with a maximum range of about $1\frac{1}{4}$ mi. their use in the U.S. Civil War is not known. There is a story that President Lincoln was interested in rocket development and was narrowly missed by an explosion in a test at the naval gun factory in Washington.

The extensive use of Congreve and Hale rockets lasted less than a century though they had appeared widely and were well known. Various applications of rocket power for other than military purposes began to appear. One of the best known was the use of a rocket to carry a lifeline to sailing ships in distress or stranded near shore. A thin line was first carried to the ship by the rocket. Then the crew would haul a heavier line out and use a breeches buoy to transfer the men, one at a time, to safety. In the 19th century hundreds of lives were saved in this way, using line-throwing mortars and rockets. Another application of rockets was in aiding lifeboats to negotiate a heavy surf. Rockets were used to throw a small grappling anchor with a light line over the surf onto the beach. By this technique, the boat could be kept straight as the occupants pulled themselves toward shore through the surf.

A line-carrying rocket was designed by Colonel Boxer about 1855 which achieved increased range by firing two rocket motors, one after the other, tandem fashion. This was the first known application of a concept sketched by Siemienowicz 200 years earlier. It differed from the modern two-staged rocket since the container of the first motor did not drop off but was carried along empty.

Signal flares also were carried aloft by rockets. One design of such a rocket by Congreve utilized a parachute to keep the flare visible for a longer period of time. A Captain Scoresby hunted whales by rocket-propelled harpoon in 1821. A woodcut from an 1865 newspaper, advertising the sale of such devices, shows a seaman launching a rocket harpoon from a shoulder-held tube equipped with a circular blast shield. The launcher appears quite similar to the bazooka of World War II.

One interesting 19th-century development was the concept of a rocket-propelled torpedo. Both the U.S. army and the British navy conducted experiments with such devices in the period 1860–80 and several ingenious devices were designed. Nevertheless, none of this work led to a real weapon. One of the fundamental problems of the rocket torpedo, as pointed out by William Hale, was that as the powder in the rocket motor was consumed, the torpedo grew lighter, making it difficult to hold the torpedo at constant level below the surface.

On the sidelines during the development of military rockets there were individual enthusiasts and inventors in nearly every country. Largely unknown, and sometimes considered a dangerous nuisance, they achieved varied success and recognition. In the early 19th century Claude Ruggieri, an Italian rocket maker, staged a number of shots in Paris in which rats and mice were sent aloft by rockets and returned by parachute. Ruggieri even planned to send up a small boy using a rocket cluster, but the police intervened.

During the 1880s and 1890s, inventors in all countries began to consider reaction propulsion. There were designs of flying devices propelled by steam jets (Charles Golightly), rocket-propelled airplanes (Werner von Siemens) and airships (Gen. Russell Thayer, Nicholas Petersen, Sumter B. Battey). There was even a helicopter design (Phillips) utilizing reaction propelled, counterrotating blades.

In the light of the times, many of these concepts were ingenious and prophetic in nature. It should be remembered that at that time the only existing mechanical prime movers were the steam engine and clockwork. Steam boilers were too heavy and clockwork mechanisms too limited in power to be of value in airborne devices. It was logical, therefore, to turn to reaction jets of steam or rocket gases. Models of some of these inventions, such as Phillips' helicopter, actually flew. But technology had not advanced sufficiently for any of these aerial, reaction-powered devices to be practical, despite the fact that, in theory, the principles involved in many cases were sound. What was lacking was sufficient power. But sufficient power was coming. In 1845 the German chemist Christian Friedrich Schonbein accidentally discovered guncotton (nitrocellulose). Fifteen years later Nobel was commercially producing nitroglycerin. Use was made of these and other combustible materials in firearms and artillery but it was about 50 years or so before their value was to be demonstrated for rockets. *(See* PROPELLANTS.)

The schemers and dreamers continued, however. In 1881 a Russian explosives maker, Nikolai Ivanovich Kibalchich, was arrested for his part in an assassination attempt on Tsar Alexander II. While in prison he conceived of a rocket airplane which functioned by successive explosions of compressed powder candles. Kibalchich's writings were doomed to lie in prison archives after his execution until the overthrow of the government in 1917.

About 1891 a most ingenious German inventor, Herman Ganswindt, conceived of a propulsion system, rather similar to that of Kibalchich but employing steel cartridges loaded with dynamite. But Ganswindt went further. He wanted to give his vehicle sufficient speed to attain escape velocity (see *Fundamental Principles of Rocket Propulsion,* below), *i.e.,* to leave the earth. Apparently,

Ganswindt was the first to connect the potentiality of rocket propulsion to space flight. In other countries the same dream was about to occur.

In Russia in 1895, a young mathematics teacher in Borovsk (District of Kaluga) published his first article on space travel. Konstantin Eduardovich Tsiolkovski was among the first to grasp the importance of exhaust velocity and the reason rockets had been limited by black powder formulas. He recognized that by using liquid fuels, *e.g.,* liquefied hydrogen and oxygen, much greater efficiencies would result. Tsiolkovski continued to make important contributions to the theory of space vehicle design but the language barrier, combined with his modesty and retiring nature, caused him to be little known for many years.

3. 20th Century to World War **II.**—In Sweden about the turn of the century, inventor Baron von Unge interested Alfred Nobel in a device described as an "aerial torpedo." Based upon the stickless Hale rocket, a number of design improvements were incorporated. Velocity and range were increased and about 1909 the Krupp armament firm purchased the von Unge patents and a number of rockets for further experimentation. But these rockets still used black powder as the propelling charge and their capabilities were limited. Von Unge, however, believed that his aerial torpedoes nould be valuable as air-to-air weapons between slow-moving dirigibles.

In the U.S., meanwhile, Robert H. Goddard (*q.v.*) was conducting theoretical and experimental research on rocket motors at Worcester, Mass; He utilized high-pressure steel motors with a tapered nozzle. In this way Goddard achieved much greater thrust and efficiency. Another of Goddard's concepts was a long-range bombardment rocket whose motor was fired in pulses. Somewhat similar to the pulsed momentum principle suggested by Kibalchich and Ganswindt, the impulses were to have derived from charges of solid fuel injected into the combustion chamber in rapid succession.

During World War I Goddard developed a number of designs of military rockets weighing $1\frac{1}{2}$ to 17 lb. to be launched from a lightweight hand launcher. By switching from black powder to double-base powder (40% nitroglycerin, 60% nitrocellulose), a far more potent propulsion charge was obtained. These rockets, forerunners of the bazooka of World War II, were proving successful under tests at the U.S. army Aberdeen proving ground when the armistice was signed. But Goddard's main interest as a physicist was in utilizing the new potential of rockets to reach high altitudes. His notebooks, after his death, revealed interest in a circumlunar rocket (carrying a camera to photograph the far side of the moon) and also in ion rockets.

Using Smithsonian institution funds, Goddard continued his research at Worcester. Switching from solid to liquid propellants he launched the first liquid-propellant rocket March 16, 1926. Liquid oxygen and gasoline powered this test vehicle, which contained turbine-driven pumps. The altitude was only 184 ft., but the significance was as great as the few feet the Wright brothers flew on their initial flights at Kitty Hawk. Later, under Guggenheim foundation funds, Goddard developed further research rockets at Roswell, N.M., in the 1930s. Although he never achieved the altitudes or velocities he knew were possible, Goddard proved himself a brilliant inventor. His later designs utilized both turbopumps and gyrostabilizers. Carbon vanes were used to deflect the rocket exhaust to correct deviations in the flight path. In 1919 the Smithsonian published a historic paper by Goddard entitled, *A Method of Reaching Extreme Altitudes.* At the end of the paper he extrapolated his calculations and discussed the possibility of a rocket reaching the moon with a payload of flash powder to signal its arrival to astronomers. The significance of this work, like Tsiolkovski's, was that the suggestions were made not by an exuberant inventor or enthusiast but a thoughtful scientist with sound academic background.

World War I saw very little use of rocket weapons. Artillery development far outclassed existing rocket designs which had changed little in the previous decades. The French, however, did successfully use incendiary rockets against hydrogen-filled dirigibles. Some French airplanes were equipped with wing-launched rockets for successfully attacking captive balloons, used for observation. German units devised a technique for dealing with barbed wire entanglements in trench warfare: a heavy rocket was used to lob a grappling hook with a trailing line across the wire; the hook would be wound back by means of a winch, pulling down the wire.

In 1923. while Goddard mas working in Worcester, an obscure German mathematics teacher, Hermann Oberth, published *Die Rakete zu den Planetenraumen* ("The Rocket Into Interplanetary Space"). In this thin pamphlet was set forth, with a grasp remarkable for his time, the potentialities of rockets to achieve great velocity. Oberth pointed out that science and technology had reached a level where the realization of manned space vehicles might be achieved in several decades. A later, major work, *Wege zur Raumschiffahrt* ("Way to Space Travel") (1929), not only set forth design concepts for immense interplanetary space vehicles utilizing clustered liquid-propellant motors, but also contained a chapter on electric propulsion and the ion rocket, predating actual development work on electrostatic propulsion by 30 years.

The decade which followed was an exciting one. Germans such as Walter Hohmann, Hermann Noordung and Austrian Baron Guido von Pirquet published technical studies on rocket power and space vehicles. In France, the famous aviator and test pilot Robert Esnault-Pelterie lectured and wrote on high-altitude rockets and interplanetary flight. It was Esnault-Pelterie who coined the term astronautics for the science of space flight. In 1929 Esnault-Pelterie and the French banker André Hirsch established an annual astronautics award for the experimenter who had done most to further space flight. In Russia, Jakov I. Perelman and Nikolai A. Rynin were interpreting and expanding Tsiolkovski's work.

This was also the period of the promotional use of rockets—to propel cars and sleds as carried out by the German engineer, Max Valier. Although Valier was a competent designer of both solid and liquid rocket motors, such applications of rocket power tended to mislead the public by deflecting attention from those fields where rockets had no competition; *i.e.,* in high-altitude, high-speed flight.

In the period 1927–33 rocket and space flight societies were formed in Germany, Austria, the U.S.S.R., the U.S. and Great Britain. These groups provided a meeting place for discussion and experimentation and their journals became a means of disseminating information. Willy Ley, a founding member of the German space flight society, related the story of these formative years of modern rocket experimentation in his book *Rockets, Missiles and Space Travel* (rev. ed., 1957).

III. HISTORY DURING WORLD WAR II

1. Germany.— The work of the German society, *Verein fur Raumschiffahrt,* attracted the attention of German army Capt. Walter Dornberger. In 1932 he hired young Wernher von Braun, who had been active in the experimental work of the German rocket society, and a few others and began experimenting at the artillery proving ground south of Berlin. Eventually, the vast rocket test, development and production site at Peenemiinde arose under the military leadership of Major General Dornberger and the technical direction of Von Braun. The fascinating story of the intensive development and engineering of the A-4 (popularly known as the V-2) is recorded in Dornberger's book, *V-2* (1954).

The V-2 rocket was nearly 47 ft. long, had a cylindrical diameter of $5\frac{1}{2}$ ft. and weighed about 27,000 lb. at takeoff. The one-ton warhead contained 1,654 lb. of high explosive. Propellants were liquid oxygen and a 75% ethyl alcohol-water mixture. Approximately 8,400 lb. of alcohol and 10,800 lb. of oxygen were burned at a rate of 300 lb. per second. The rocket motor produced 55,000 lb. thrust for about one minute at which time the engine was shut off by an integrating gyro system. Propellant supply was by turbopump, driven by high-strength hydrogen peroxide decomposed by a catalyst. Yaw and pitch control was accomplished by two pairs of graphite carbon vanes in the rocket exhaust. Ignition of the alcohol-liquid oxygen propellants was effected by a pyrotechnic pinwheel inserted in the motor. Estimated maximum range was about 200 mi.

ROCKETS

MISSILES AND A SPACE BOOSTER

BY COURTESY OF (TOP LEFT) U.S NAVY (TOP RIGHT) N A S A , (OTHERS) U S. ARMY

The first operational V-2 was fired late in the war against Paris on Sept. 6, 1944. Two days later the first of over 1,000 missiles was fired against London. The missile traveled on a ballistic arc trajectory, reaching a maximum speed of more than 1 mi. per second and an altitude of 60 to 70 mi. Since the warhead approached the target faster than the speed of sound, there was no warning of the approach of the bomb.

Although the V-2 did not become a decisive weapon, it was nevertheless a monumental engineering achievement. Large rocket motor developments after World War II, in both the U.S. and the U.S.S.R., were outgrowths of the V-2 engine design. The term V-2 stands for *Vergeltungswaffe zwei* ("vengeance weapon two"). The V-1 was not a rocket, but a pulse-jet-powered pilotless aerial bomb.

In addition to the V-2 the Germans developed a wide variety of other rocket-powered guided missiles of many categories which reached varied stages of completion before the end of the war. The Hs-293 was a rocket-powered, winged-bomb launched by long-range bombers against Allied shipping. The bomb was guided in flight by remote control radio. The X-4 was an ingenious air-to-air missile, guided by fine wires. The Wasserfall was a refined supersonic surface-to-air (antiaircraft) guided missile which was almost ready for production. Other guided missiles in this category were the Rheintochter, Schmetterling and Enzian. An interesting intermediate step between the guided missile and the piloted interceptor was the Natter, designed by Erich Bachem. This vehicle, carrying a pilot, was designed to be launched vertically toward attacking bomber formations. The Natter was designed to have a maximum horizontal flight speed of 620 m.p.h.

There were many other German rocket developments in unguided weapons. The best known were the Nebelwerfer and Wurfgerat rocket launchers used extensively on the Russian front. Projectiles ranged from 5 to 17 in. in diameter; smokeless powder served as the propellant. They carried incendiary or high-explosive charges in the warhead. In addition, there was a small unguided rocket, the Taifun, under development. The Taifun was designed to be launched in ripple fire against aircraft. Both solid- and liquid-propellant designs were under investigation.

The Rheinbote was a four-stage, solid-propellant rocket. It weighed nearly two tons, was about 40 ft. long, and had an impressive range—125 mi. However, the payload of 88 lb. of high explosive could not compete with other weapons such as aircraft bombardment and the V-2. The Rheinbote was significant, however, in that practical recognition was made of the value of the step principle suggested by Siemienowicz nearly 300 years before.

Other German rocket weapons included the Fritz-X (a bomb which utilized a rocket motor to increase target penetration); various aircraft rockets, including the excellent R-4M; and the X-7, a short range, wire-guided rocket designed for antitank use. Two versions of a rocket-powered airplane, the Messerschmitt Me-163B, and Me-163C appeared too late in the war to be important. But their flight speeds, 560–590 m.p.h., would have made them extremely effective against long-range bomber formations. The Austrian Eugen Sanger and his brilliant co-worker Irène Bredt (later Mrs. Sanger) headed the air force rocket test station at Trauen. It was here that the experimental work was conducted which laid the basis for the significant report, *A Rocket Drive for Long Range Rocket Bombers* by Sanger and Bredt, published privately by Robert Cornog (1952).

2. Great Britain.— In Great Britain, development of rockets was considered by the war office in 1934. In 1935 a program was under way headed by A. D. Crow (later Sir Alwyn). Initial effort was aimed at achieving the equivalent destructive power of the 3-in. and later the 3.7-in. antiaircraft gun. More than 2,500 rounds of an accepted 3-in. design were fired in the winter of 1938–39. The results of these trials indicated an accuracy less than the competitive 3.7-in. gun and priority accorded the work was reduced. After the outbreak of the war, however, the 3-in. rocket was accepted for production since antiaircraft units were required around hundreds of prime industrial and transportation targets. Single, double and then multiple, projectors were produced. Massed batteries of projectors fired salvos of as many as 128 rounds.

Two important innovations were developed by the British in connection with the 3-in. rocket. Both devices were directed against the German dive bombers—a serious menace in 1940. One was a rocket-propelled aerial defense system. A parachute and wire device was rocketed aloft, trailing a wire which unwound at high speed from a bobbin on the ground. Altitudes as high as 20,000 ft. were attained. Several versions of this device were used, quite successfully, from ships. The other device was a type of proximity fuze utilizing a photoelectric cell and thermionic amplifier. Change in emission of light from a nearby airplane (projected on the cell by means of a lens) triggered a thyratron and the detonating train of the shell.

A 5-in. rocket, capable of projecting a 30-lb. bomb to ranges of 2–4 mi., was developed for heavy coastal bombardment prior to landings. Automatic ripple fire in successive groups reduced the chance of mutual interference between rockets. With this weapon a tremendous rate of firepower was possible. For example, a single rocket ship was able to launch 1,000 lb. per second of high explosive for nearly a full minute.

3. United States.— The United States did not commence active development of rockets until mid-1940. At that time, the National Defense Research committee (NDRC) authorized a program under the direction of C. N. Hickman at Indian Head, Md. Hickman had worked with Goddard on the hand-launched rocket tests at Aberdeen in 1918. Aided by army Capt. L. A. Skinner, Hickman supervised the development of a refined design, known as the bazooka. About 22 in. long, $2\frac{1}{2}$ in. in diameter and weighing 3.4 lb. the rocket was fired from a $4\frac{1}{2}$-ft. shoulder launcher which weighed 14.5 lb. The bazooka was used extensively against tanks. Its maximum range was short (600 yd.) and it traveled slowly but it carried a particularly potent warhead weighing 1.8 lb. This warhead contained a conelike shaped charge which utilized the Munroe effect. This important application of explosive to achieve deep penetration was discovered by a U.S. professor, Charles E. Munroe in 1887. It was the characteristics of the shaped charge, not the use of rocket power to achieve high velocity, that made the bazooka so effective. In fact, the shaped charge is not effective if impacted at high speeds. The bazooka was the only U.S. rocket in World War II which utilized this type of warhead. (*See* BAZOOKA.)

Another U.S. army development was the Calliope, a 60-tube launching projector for 43-in. rockets mounted on Sherman-type tanks. The launcher was mounted on the tank's gun turret and both azimuth and elevation were controllable. Ripple fire was used to eliminate interference of rockets in salvo firing. Other launchers were developed for trucks and jeeps.

Close liaison was established between the U.S. NDRC and similar research groups in Great Britain. Advantage was taken of earlier rocket developments of the British. A $3\frac{1}{4}$-in British rocket was redesigned to utilize U.S. ballistite propellant in place of slower burning cordite. An antisubmarine rocket known as Mousetrap was developed along the lines of the British Hedgehog.

Other conventional rockets developed in the U.S. included a 43-in. barrage rocket with a range of 1,100 yd. and a 5-in. rocket of longer range. This latter rocket was extensively used in the Pacific theatre from type LSM-R launching barges against shore installations, particularly just before landing operations. Firing rates of these flat bottom boats was 500 per minute. The largest rocket developed by the U.S. was Tiny Tim. Ten ft. long, $11\frac{3}{4}$ in. in diameter, and weighing 1,284 lb., the rocket's warhead held 150 lb. of TNT. Tiny Tim was an airborne rocket. To eliminate wind drag resulting from exterior mounting, the rocket was carried internally in the bomb bay. Firing was effected by a lanyard which ignited the rocket motor at a safe distance below the airplane.

Significant research and development was conducted in the U.S. on solid rocket propellants. Not only were formulas and production techniques of double-base propellants refined but the composite (cast) class of propellants (see *Rocket Propellants*, below) were investigated extensively and developed at the Guggenheim

Aeronautical laboratory at California Institute of Technology (GALCIT) and elsewhere.

The GALCIT laboratory, under the direction of Theodor von Kármán developed, in addition, solid- and liquid-propellant rocket units for jet-assisted take-off (jato) for aircraft. Use of such jato units permitted aircraft, particularly seaplanes, to take off in a much shorter distance or to take off with increased loads. The U.S. navy conducted similar jato development at Annapolis, Md., concentrating on liquid propellants.

Because the U.S. had great industrial capacity, unhampered by air raids, and urgent needs for its own forces as well as for allies, its production of solid-propellant rockets increased to a high rate by the end of the war. At the close, rockets of all sizes were being manufactured at the rate of 1,000,000,000 per year. Weights of different designs ranged from 3 to 1,300 lb.; diameters, 2 to 12 in.; lengths, 1 to 10 ft.; velocities, 650 to 1,500 ft. per second; maximum ranges (ground firing), 40 to 10,000 yd.; and accuracies (angular dispersion), $\frac{1}{16}°$ to 3°.

4. **U.S.S.R.**—As far as is known, Russian rocket development activity during World War II was limited. Extensive use was made of barrage, rippfe-fired rockets against the Germans. Both A-frame and truck-mounted launchers were used. According to Ley (see *Bibliography)* much of the rocket material came from the U.S. Later, however, the Russians mass-produced a 3.2 in. rocket known as Katyusha. From 16 to 60 Katyushas were fired from a boxlike launcher known as the Stalin Organ, mounted on a gun carriage. Rocket-propelled bombs of high penetration were used by fighter aircraft, especially against tanks. Weights of these bombs ranged from 13 to 220 lb.

5. Other Countries. — Rocket development in other countries during World War II was on a lesser scale. In Japan 12 types of rocket ordnance were identified by postwar intelligence interrogation teams. Rocket development had been conducted for ten years, but at a slow rate. Uses of rockets included infantry combat, antitank, antiaircraft, antisubmarine and heavy bombardment rockets weighing 815 lb. The best known Japanese rocket development was the Ohka (kamikaze) piloted glide bomb used against warships. Air-launched from a maximum altitude of 27,000 ft. from a bomber, the 20-ft.-long Ohka carried 1,135 lb. of high explosive in the warhead. Three solid-propellant rocket motors provided thrust for maneuvering and to increase speed in final dive on target ships. Maximum range was about 55 mi.; a final speed of 535 m.p.h. was possible. The dramatic aspect of this weapon was the suicide of the kamikaze pilot, for no escape was possible.

In Italy, despite the early experimental work of army Gen. G. A. Crocco, virtually no rocket weapons were developed during the war. There was some work on antitank rockets and rocket-accelerated bombs, but no accomplishments of note are recorded. Likewise in France, no rocket ordnance of operational importance appeared. Esnault-Pelterie, however, supervised development of a liquid oxygen-gasoline motor with a thrust of 660 lb. Little is known of this work since it ceased when the Germans marched into Paris in 1940.

IV. POST-WORLD WAR II DEVELOPMENTS

When World War II came to a close in Aug. 1945, development and production of rockets was a massive enterprise in the United States and Great Britain. Despite a few ingenious uses of rocket power, however, the major effort was conservative and on conventional lines, adapting technical improvements to existing weapons. Nowhere was there the depth of appreciation and scope of plans for guided missiles or long-range ballistic rockets that there was in Germany. Recognition of the potential of rocket power by the Allied powers came too late in the war to catch up with German developments in rocket technology. And, anyway, the war was being won without dependence on these concepts.

Appreciation of the potential importance of German technical efforts was evidenced by the speed with which technical intelligence teams followed close behind front-line troops as they moved across Germany. Intensive and intelligent work on the part of these teams resulted not only in obtaining masses of technical data, design drawings and missiles, but also an opportunity for interrogation of key scientists and missile engineers. The top planning and technical staff of Peenemunde, headed by Maj. Gen. Walter Dornberger and Wernher von Braun, fled south in the last few days of the war in order to surrender to U.S. troops. Thus the priceless experience of the German rocket effort and the knowledge of about 150 rocket experts became available to the Allies. The Russian troops which captured Peenemunde found mostly wreckage and had orders to destroy what was left. However, the Russians took many German technicians to the U.S.S.R. and the exchange of technical and scientific data continued until a few years later. Thus the U.S.. France, Great Britain and the U.S.S.R. all had the benefit of information on guided missiles captured in Germany.

In general, early postwar development of rockets followed most of the lines suggested by German work with two important additions: rockets for scientific study of the upper atmosphere and to power supersonic research aircraft. Rockets were used to propel all varieties of guided missiles, competing successfully in these missions with air-breathing jet engines. Refinement of all components of these systems and improved technology based upon extensive research programs have resulted in rocket-powered weapons of immense capabilities.

1. United States. — Not only did the U.S. obtain the services of top German rocket experts but also, from the underground V-2 factory at Niedersachswerfen, 300 boxcar loads of components of V-2 missiles — enough for about 100 complete vehicles. About 70 V-2's were fired during the period 1946–51 at White Sands (N.M.) proving ground. These firings provided much experience in handling and launching large rockets. Important data were obtained in upper atmosphere research conducted by the Naval Research laboratory. Such research rockets are known as sounding rockets. The ability of the V-2 to carry a ton of research instruments to about 100 mi. eclipsed the capability of the WAC Corporal research rocket, whose payload capacity was 25 lb. to about 40 mi. One series of interesting tests in the V-2 program at White Sands was the Bumper-WAC program in which the WAC Corporal was mounted as a second stage on the V-2. An altitude of 250 mi. was achieved with this combination in Feb. 1949.

In anticipation of the end of supply of V-2 rockets, a program was undertaken by the office of naval research for a high-altitude rocket designed specifically for research. This rocket was the single-stage Viking. As with the V-2, liquid oxygen and alcohol were used as propellants. Because of the need to achieve maximum results on minimum budgets, development was slow. Improvements were made in nearly all the 14 Vikings fired, to correct deficiencies uncovered in previous launchings.

FIG. 2. — TESTING THE U.S. NAVY TERRIER

A ship-launched guided missile, powered by solid-propellant rocket booster and sustainer motors, it can intercept aircraft at a 20-mi. range and 60,000-ft. altitude

TABLE I.——Solid-Propellant Research Rockets (U.S.)

Rocket	No. of stages	Payload (lb.)	Altitude (mi.)
Arcas	1	12	40
Nike-Cajun	2	20	100
Arcon	1	40	70
Iris	2	100	200
Terrapin	2	8	80
Rockoon (balloon-Deacon)	1	20–30	50–70
Rockaire (aircraft-Deacon)	1	40	40
Farside (balloon-clusteredrocketsj	4	10	4,000
Asp	1	25	40
Aerobee	1–3	40–250	75–250
Hasp	1	6	20
Deacon	1	30	20
Dan (Deacon-Nike)	2	30	60
Exos	3	40	300
Scout	4	50	8,000

More than half of the Vikings carried research instruments to peak altitudes greater than 100 mi. in the period 1949–57. The highest flight took a payload of 825 lb. to 158 mi. in 1954. The story of the Viking program is related in *The* ***Viking*** Rocket Story (1955) by the project director. Milton W. Rosen.

Another important liquid-propellant research rocket was the Aerobee series initiated by the navy bureau of ordnance. About half the size of the Viking, the Aerobee could carry a 150-lb. payload to about 70 mi. altitude, or larger payloads to lesser heights. Like the WAC Corporal, the Aerobee used red fuming acid and aniline-furfuryl alcohol mixtures as propellants. A solid-propellant booster rocket was used in launching. A later version of this rocket, known as Aerobee-Hi, carried a 65-lb. payload to an altitude of 260 mi. in 1958.

A wide variety of smaller solid-propellant rockets were developed for research purposes. The development of miniaturized instruments greatly extended the usefulness of such small rockets, and resulted in greater ease of launching and reduction in cost of each firing. The development of large plastic balloons to carry rockets to high altitudes before launching is another technique for improving performance of research rockets. Aircraft, too, have been used to launch rockets with the resulting benefit of altitude and initial velocity of several hundred miles per hour. (See Table I.)

Sounding rockets have been used to obtain a great wealth of data about the upper atmosphere. Measurements have been made of wind velocity, and pressure, temperature and density of the upper atmosphere. The composition of the atmosphere at high altitudes, its molecular and atomic structure have been examined. The earth's magnetic field and the ionosphere—the layer of electrified particles which reflect radio waves back to the earth—have been measured. Other observations have included the aurora and cosmic rays, and X-ray and ultraviolet portions of spectra from the sun and the stars. Photographs of cloud patterns above the earth's surface from altitudes above 100 mi. give indications of weather movement of importance to meteorology. The impact and erosion effects of micrometeorites have been measured. The significance of such studies is that the sounding rocket is a scientific research tool enabling measurements to be made which heretofore have not been possible. From such raw scientific data come new theories and understanding of man and his environment.

The concept of a rocket-powered airplane for high-speed research studies originated in the U.S. at the time the Germans were developing their Me-163 rocket-powered interceptor. After the war this work continued under air force sponsorship in co-operation with the National Advisory Committee for Aeronautics (NACA). The 6.000 lb. liquid oxygen-alcohol rocket engine was a navy bureau of aeronautics development. This engine consisted of four 1,500-1b.-thrust combustion chambers which could be fired independently or in combination.

Initial flights of the Bell Aircraft Corp. airplane, the X-1, were made in 1946. Because of the rapid rate of burning of the rocket propellants—almost one ton per minute, with all four motors—powered flight lasted only a few minutes. All landings were without power, gliding down to the desert floor at Edwards air force base, Calif. For the same reason, the X-1 was carried aloft and launched from a specially modified B-29 bomber. Supersonic speed was achieved for the first time in 1947. In 1948 a new altitude record was set at 70,140 ft.

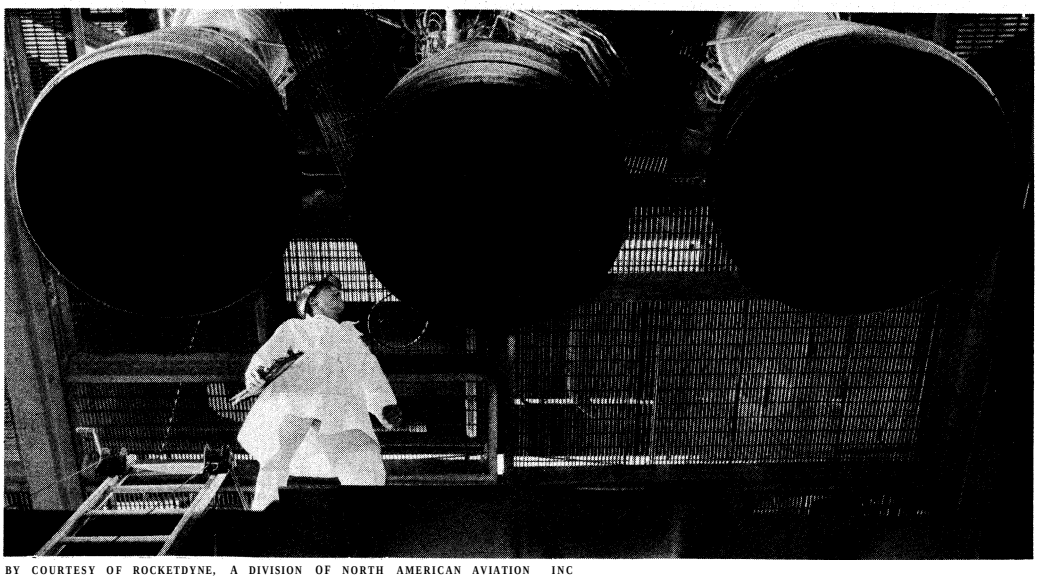
Another version of this airplane, the X-1A, used a turbopump propellant supply system instead of the heavier, nitrogen pressure feed method. The X-1A reached a speed of 1,650 m.p.h. at 90,000 ft. in 1953. Meanwhile the navy in co-operation with NACA had developed another rocket research airplane built by Douglas Aircraft Co.. Inc. Known as the D-558 this airplane, which also carried a turbojet engine, was first to fly at Mach 2 (twice the speed of sound).

The Bell X-2 was a rocket-powered research aircraft designed for even higher speeds. The rocket engine developed 12,000-lb. thrust—twice as much as the X-1. Mach 3.3 (2,200 m.p.h.) and 126,000 ft. altitude records were made in the X-2.

In 1958 another rocket research airplane. the X-15, was revealed to the public. Built by North American Aviation. Inc., the X-15 was powered by a rocket engine estimated at 50,000-lb. thrust. It was designed to be launched at 40.000 ft. from a B-52 bomber and to reach altitudes of more than 100 mi. Flight speeds greater than 3,000 m.p.h. (Mach 6–7) were attained in 1961.

The long-range ballistic missile was not a major development in the U.S. until 1954. Until that time air-breathing subsonic missile developments such as the Snark and Navaho were counted upon by military planners to supplement and supersede long-range strategic bomber aircraft.

In 1954 two developments put the intercontinental ballistic missile (ICBM) in a new light. One of these developments was the thermonuclear bomb with destructive power measured in megatons (millions of pounds of TNT equivalent). The other was the miniaturization and refinement of inertial guidance systems which were sufficiently accurate to place the warhead of the ICBM close



BY COURTESY OF ROCKETDYNE, A DIVISION OF NORTH AMERICAN AVIATION INC

FIG 3 — POWER PLANT OF THE ATLAS ICBM

The outer booster engines each deliver 165,000-lb. thrust and later drop off; the centre engine produces 60,000-lb. thrust and continues to power the rocket. The diameter of the nozzle exit of the sustainer engine is nearly as great as the larger-thrust booster engines, providing high efficiency at low atmospheric pressure of high altitudes

TABLE II.—*Significant U.S. Guided Missiles Using Rocket Propulsion*

Name	Cognizant service	Propellant	Remarks
Air-to-air category			
Falcon	Air force	Solid	Operational, homing capability
Genie	Air force	Solid	Operational, nuclear warhead
Sidewinder	Navy	Solid	Operational, infrared homing
Sparrow	Navy	Solid	Operational, radar homing
Air-to-surface category			
Bullpup	Navy	Solid	Operational, command guidance, Bulldog is later version
Antisubmarine category			
Asroc	Navy	Solid	Launched from surface ships, Asroc is a rocket-propelled acoustic homing torpedo
Weapon Alfa	Navy	Solid	Operational, ship-launched
Subroc	Navy	Solid	Submarine-launched, nuclear warhead, also for surface targets
Surface-to-air category			
Hawk	Army	Solid	Complements Nike, for low-flying aircraft
Nike-Hercules	Army	Solid booster and sustainer	Operational, replacement for similar, lower performance Nike-Ajax
Nike-Zeus	Army	Solid	Antimissile defense
Tartar	Navy	Solid	Ship-launched, lighter, smaller weapon than Terrier
Terrier	Navy	Solid	Operational, ship-launched
Surface-to-surface category			
Atlas	Air force	Liquid	ICBM (5,500 nautical miles), 1%-stage, take-off thrust 360,000 lb.
Corporal	Army	Liquid	Operational, deployed in Europe, 75–100-mi. range, 20,000-lb. thrust, acid-aniline engine
Jupiter	Army	Liquid	IRBM (1,500 nautical miles), 150,000-lh. thrust, liquid oxygen-hydrocarbon fuel engine
Lacrosse	Army	Solid	Close tactical support use, as against pillboxes
Minuteman	Air force	Solid	ICBM
Pershing	Army	Solid	Replacement for lesser range, liquid-propelled Redstone
Polaris	Navy	Solid	Launched from nuclear submarine; 2-stage
Redstone	Army	Liquid	200-mi. range, 75,000-lb. thrust, liquid oxygen-alcohol engine
Sergeant	Army	Solid	100–200-mi. range (depending on warhead), 50,000-lb. thrust, replacement for Corporal
Thor	Air force	Liquid	IRBM, 150,000-lb. thrust, liquid oxygen-hydrocarbon fuel engine
Titan	Air force	Liquid	ICBM, 2-stage, 2–190,000-lh. thrust engines first stage, 1–60,000-lb.thrust (sea-level rating) second stage, liquid oxygen-hydrocarbon fuel

to a target 5,000 or more miles around the world.

The first ICBM authorized was the Atlas, followed later by the Titan. The Atlas, built by the Astronautics division of General Dynamics Corp., was a 1%-stage vehicle. Whereas a two-stage vehicle drops both first-stage rocket engine and tankage, the 1½-stage vehicle drops only the rocket engine and the second stage continues to use the original tankage. The first Atlas was fired full range from Cape Canaveral, Fla., missile range in Nov. 1958.

The Titan, built by the Martin Co., was a conventional two-stage vehicle. The first successful tests of the Titan were not made until 1959. Both the Atlas and Titan burned liquid oxygen and hydrocarbon fuel (similar to kerosene).

A major logistic problem in ballistic missiles using cryogenic propellants, such as liquid oxygen, is the necessity for fueling just prior to launching. This weakness, which means delay in retaliatory fire, could be eliminated by the use of solid propellants. Development of solid propellants to near-competitive performance with liquids reached a point by 1958 that a solid-fueled ICBM, the Minuteman, was authorized. This ICBM would be launched from underground "silos" in so-called "hard" launching sites, relatively impervious to attack.

Three intermediate range ballistic missiles (IRBM) capable of 1,500-nautical-mile range were in production in the late 1950s in the United States. The air force Thor and the army Jupiter used the same liquid propellants as the Atlas and Titan. The navy solid-fueled Polaris missile was designed to be launched from submarines, either surfaced or submerged.

By 1961 the U.S. had, in all categories, more than 40 operational missiles, most of them rocket, powered. Of those which utilized other means of jet propulsion, such as the Matador or Snark, most were launched by solid-propellant booster rockets. Nearly all aircraft firms were engaged in missile development and production. Rocket-engine manufacturers had grown from small wartime beginnings to major industries. The largest liquid-propellant rocket engines developed more than 150,000-lb. thrust. Three of these motors were clustered in a 360.000-lb. thrust launching booster developed for the Navaho. before the cancellation of this missile. Solid-propellant motors producing 405,000-lb. thrust had been successfully fired.

Two developments were under way to obtain rocket boosters of 1,000,000- to 1,500,000-lb. thrust. One of these was a clustered rocket engine of eight units. The other was a single-chamber motor. Both of these large units were under development for space flight applications. A 1,-000,000-lb. thrust booster fitted with one or more appropriate upper stages has the potential capability of placing 20.000 lb. in low satellite orbit or sending about 5,000 lb. to nearby planets.

Significant Rocket Vehicles.—So many different rocket-powered vehicles are operational or under development that space does not permit more than a few details of the better known missiles. See Table II.

Unguided Rockets.—By 1960 the U.S. army had two unguided artillery rockets in field use. The Honest John carried a 1,500-lb. warhead to a range of about 15 mi. A smaller version, Little John, was more mobile but had less capability. Both were single-stage, solid-propellant rockets.

The U.S. navy 5-in. World War II air-to-surface rocket, known as Holy Moses, was produced extensively until 1955. It was replaced by a lighter-weight version known as Zuni. As many as 48 Zunis could be carried by a single carrier-based aircraft.

Other military uses of rockets include boosters for long-range, cruise-type, turbojet-powered missiles such as Matador. Mace, Regulus and Snark. Ram-jet-powered surface-to-air missiles, such as Bomarc and Talos, also require booster rockets. The Bomarc has a liquid-propellant booster, the Talos, solid propellant.

Various combinations of solid-propellant rockets have been used as test vehicles in research programs. One, the HTV (hypersonic test vehicle), utilizes clusters in two stages (seven and four) and

TABLE III.—*U.S. Satellite and Space-Probe Launching Vehicles*

Name	Cognizant organization	Propellant	Remarks
Atlas-Agena B	NASA	Liquid	Similar to Thor-Agena B but employs Atlas ICBM booster; capable of orbiting 5,000 lb. at 300 nautical miles or 750 lb. to escape velocity
Centaur	NASA	Liquid	Based upon Atlas ICBM; upper stage powered by 2-15,000-lb. thrust liquid hydrogen-oxygen engines; capable of orbiting 8,500-lb. payload at 300 nautical miles or 1,300 lb. to escape velocity
Delta	NASA	Liquid-solid	Three stages based upon Thor ICBM: second stage liquid, third stage solid; capable of orbiting 500 lb. at 300 nautical miles. 60-lb. payload to escape velocity
Saturn	NASA	Liquid	Two versions under development. Saturn C-I employs cluster of 8 improved Atlas engines in S-I first stage and a cluster of 6 Centaur liquid hydrogen-oxygen engines in S-IV second stage, capable of orbiting 15,000 - 20,000 lb. at 300 nautical miles. Advanced Saturn employs cluster of 5-1,500,000-lb. thrust, liquid oxygen-keroseoeenginesin S–IC first stage, plus S-II and S-IVB upper stages using 5- and 1-200 000-lb thrust, liquid hydrogen-oxygen engines, respectively.
Scout	NASA	Solid	Capable of orbiting 150 lh. at 300 nautical miles; 50 lb. payload to 8,000 mi. as sounding rocket
Thor-Agena B	NASA	Liquid	Two stages, based upon Thor IRBM; Agena B engine develops 15,000 lb. thrust using inhibited red fuminng itric acid (IRFNA) and unsymmetrical dimethyl hydrazine (UDMH); capable of orbiting 1,600 lb. at 300 nautical miles.

carries a small payload to Mach 10. A larger test vehicle, the X-17, is a three-stage vehicle for ballistic missile re-entry research. Two stages are fired to reach altitude and the third stage fires on the way down. Velocities greater than Mach 15 are achieved in this manner. Another use of rocket propulsion by the military is for target drones.

2. U.S.S.R.—As noted above, after World War II hundreds of German rocket engineers and scientists were taken to Russia. Although the senior members of the Peenemunde staff went to the United States, a considerable body of rocket knowledge and experience became available to the U.S S.R. By 1955 most of these men and their families had returned to Germany. Their apparent use was to pass along their knowledge to native Russian engineers and scientists whose programs were kept completely secret and separate. It is known that V-2's were produced in the U.S.S.R. with modifications and improved performance.

The Soviet Union evidently placed major effort on two categories. surface-to-air missiles for defense against aircraft and long-range ballistic missiles. The first proof of the successful development of reliable large-thrust rocket engines was the launching of the first earth satellite sputnik 1, on Oct. 4, 1957. Subsequent launchings of sputniks 2 (Nov. 3, 1957) and 3 (May 15. 1958) and the planetoid Mechta (1959) proved conclusively that the U.S S R. had ICBM launching capability. Take-off thrust of the launching vehicles was estimated in the 600,000- to 800,000-lb. range; propellants used were reported to be liquid oxygen and hydrocarbon fuel. similar to the large U.S. engines but possibly using a propellant additive.

Russian rockets were publicly shown for the first time in the Revolution anniversary parade in Nov. 1957. One was a two-stage surface-to-air missile, somewhat smaller than the Nike-Ajax. Four others were ballistic missiles of different sizes. One of these four weapons had an estimated range of perhaps 500 mi. The other three appeared to match roughly the capabilities of the U.S. army missiles, Corporal, Honest John and Little John. The largest missile was referred to generally as T-1 or M-101. This medium-range ballistic missile (MRBM) of a reported 600–800 mi. range was apparently an outgrowth of the German V-2. The take-off thrust was estimated at about 75,000 1b.—the same performance rating as the U.S. Redstone engine.

Little was known about the Russian IRBM (T-2) and ICBM (T-3). It was reported that the T-2 rocket engine had a take-off thrust rating of 220,000 lb., operated at high chamber pressure (900 p.s.i.) and burned liquid oxygen and hydrocarbon fuel. The T-3 ICBM was reported to be a three-stage missile with a take-off thrust of more than 600,000 lb.

In general, it was conceded that the U.S.S.R. took greater advantage of the heritage of German World War II rocket development than did its allies. It was reported, for example, that the German Wasserfall, supersonic, surface-to-air missile was put into production shortly after the war and was defending major cities by 1952.

In the field of sounding rockets the U.S.S.R. developed a number of vehicles. One of these was the POL II, capable of lifting a 100-lb. payload to 100 mi. Space medical research was conducted with dogs in such rockets. Recovery was effected by drag flaps followed by deployment of parachute.

3. Great Britain.— Immediately after the war, Great Britain test fired two German V-2 rockets at Cuxhaven, utilizing German crews. The handling and launching operations were documented in film and technical reports. But postwar Britain proceeded at a slow rate in rocket development.

In the surface-to-air category the ram-jet-powered Bloodhound was the first missile to become operational. Four solid-propellant boosters were used to launch the missile to speeds abeve the minimum for ram-jet operation. The Bloodhound was in use by both the British army and air force. The Thunderbird was the standard army antiaircraft missile. Four equally spaced, solid-propellant boosters were used for launching; the sustainer motor was also of the solid propellant type. A similar weapon was the British navy Seaslug. Although differing in external configuration, the Seaslug also used four wrap-around solid-propellant boosters and sustainer motors. Test versions of both the Thunderbird and Seaslug utilized liquid-propellant motors.

In the air-to-air category, the Fireflash was the first British guided missile development to be publicly revealed, in 1953. Four wrap-around solid-propellant boosters accelerate the centre vehicle, known as a dart, toward the target. The dart had no sustainer motor. The Firestreak was a single-stage, solid-propellant rocket-powered missile in operational use in the Royal Air Force and Navy. Twice as heavy as the U.S. Sidewinder, the Firestreak similarly used infrared heat homing on target.

In the ballistic missile field, a number of British squadrons utilized the U.S. Thor IRBM. In the meantime, the Blue Streak was under development as a 2,800 nautical-mile range weapon. This distance resulted in another missile designation, the long-range ballistic missile (LRBM). The Blue Streak utilized the 150,000-lb. thrust liquid-propellant engine of the U.S. Thor and Jupiter. Although the development program was successful, the far greater rate of development of ballistic missiles in the United States caused cancellation of the Blue Streak. The Black Knight was the re-entry research vehicle used for Blue Streak development. The power plant of the Black Knight was four liquid-propellant, hydrogen peroxide-kerosene, motors of 5,000-lb. thrust each. The possible use of the combination of these two vehicles for orbiting a 2,000-lb. satellite was suggested.

The Blue Steel was an air-to-surface missile which used two hydrogen peroxide-kerosene rocket motors developing a total thrust of 16,500 lb. A range of at least 400 mi. was anticipated. Two rocket-powered antitank missiles under development were the V. 891 and the Pye P.V. Another larger. but similar, command guided missile was the Malkara developed by the Australian commonwealth. The British used the missile range at Woomera, Austr., for major test purposes.

Hydrogen peroxide jato units and liquid-propellant rocket engines for interceptor aircraft have been successfully produced in Great Britain. A most significant development was the 8,000-lb. variable thrust peroxide-kerosene aircraft motor, Spectre, under the direction of A. V. Cleaver at De Havilland Aircraft Co. Ltd.

The best-known British research rocket was the Skylark. Powered by a solid-propellant, 11,500-lb. thrust motor, it was designed to carry a 100–150 lb. payload to 95 mi. altitude. The Skylark was used during the International Geophysical year, 1957–58, to measure high altitude pressures, temperatures, winds and ionospheric electron densities.

Elsewhere in the British commonwealth, Canada has developed a rocket-powered air-to-air missile, Velvet Glove, reported to use solid propellant. In 1959 Canada announced that a solid-propellant sounding rocket capable of carrying a 100-lb. payload to 100 mi, altitude had been developed.

4. France.— After the war France obtained the services of a small number of German rocket engineers and scientists. Several dozen designs of various type missiles are known to have been studied but few emerged for operational use. No rocket-powered surface-to-surface missiles are known other than small, wire-guided antitank weapons, S.S. 10 and an improved version, S.S. 11. The S.S. 10 has been purchased by armed forces of the U.S., Israel, Sweden and west Germany.

Surface-to-air rocket-powered missiles were the Parca and the R. 422. Two air force air-to-air missiles were the M. 510 (two stage solid propellant, optical homing) and the AA. 20 (also known as the 5103). Two sounding rockets, Veronique and Monique, have been developed. The Veronique was a single-stage liquid-propellant (acid oxidizer) rocket engine, developing 8,250-lb. thrust at take off. Research payload capability was 130 lb to 84 mi. The Monique was a smaller solid-propellant rocket, early versions of which were capable of carrying a 33-lb. payload to 25 mi.

Other French rocket developments worthy of mention include liquid-propellant (nitric acid-furaline) engines for aircraft. The Trident fighter was powered by two 6,615-lb. thrust rocket engines. Other fighter and interceptor aircraft (Durandal and Mirage 111-A) carried liquid-propellant engines for burst speed in addition to turbojet power plants.

5. Other Countries.— In Switzerland, rocket development cen-

tred around Zurich. There the Contraves A. G. and the Armament division of Oerlikon Machine and Tool works evolved a rocket-powered, single-stage surface-to-air missile. The 2,200-lb. thrust rocket engine used nitric acid and kerosene propellants. Development of this supersonic (Mach 2.4) weapon was a private venture. Extensive trial firings were carried out in Switzerland and France as early as 1950–51. In 1952, the U.S. evaluated 25 of an early model, known as Type 51. Range of the 1958 model, RSD-58, was about 19 mi. to altitudes over 65,000 ft. A training version was delivered to the Italian air force and Japanese defense agency. Other Contraves-Oerlikon rocket developments included excellent 5 cm. and 8 cm. aircraft rockets.

Postwar Germany produced a wire-controlled antitank rocket carrying a shaped charge warhead. With a range of over ½ mi the Cobra weighed only 20 lb. Under Eugen Sanger theoretical studies of photon rocket propulsion and practical development of steam rocket propulsion for jato were conducted.

In Sweden a number of smaller rocket-powered weapons were known to have been developed but almost no information has been released. One surface-to-air design. with tandem solid-propellant booster, had a liquid-propellant sustainer rocket motor. The Robot 321A was the designation of a ground-launched test vehicle used in the development of an air-to-air missile. SAAB and Bofors were the major firms engaged in this work.

Italy had a number of small-scale rocket developments under way since the war. An Italian subsidiary of Contraves produced Swiss design Oerlikon rockets. The Contraves C. 7 was an air-to-air rocket with infrared homing.

In Spain, Hispano Suiza produced a multipurpose 3.15-in. solid-propellant rocket. With air-to-air, surface-to-air and air-to-surface application, it carried a 2.2-lb. warhead.

Japan carried out an intensive small-scale sounding rocket development program utilizing solid propellants. This work conducted at the University of Tokyo under Hideo Itokawa, produced a number of two-staged research rockets designed to carry a 15-lb. payload to 80 mi. Air-to-air missiles. MM-1 and TMA-1, had solid-propellant rocket motors developed by Fuji Precision industries.

Minor efforts in rocket development were known to exist in Argentina (A-3F antitank missile) and Norway.

V. FUNDAMENTAL PRINCIPLES OF ROCKET PROPULSION

Jet propulsion—of which the rocket is one type—is based upon reaction of a body to the rearward thrust of a jet of gas. The physical principle involved was set forth in Sir Isaac Newton's *Principia Mathematica* published in 1687. In this work are stated three laws of motion. The third law states. in its simplest form, that for every action there is an equal and opposite reaction.

A simple example of reaction propulsion is the brief flight of a toy balloon after it has been filled with air and released. The forward motion of the balloon results from the rearward expulsion of air from the balloon. The thrust does not result, as sometimes erroneously presumed, from the jet pushing against the surrounding air. The force imparted by the jet is equivalent to the product of the mass flow of the air and the velocity of the jet. In the case of a chemical propellant rocket, the jet is composed of the gaseous combustion products of the propellant mixture which is burned inside a thrust chamber and ejected at supersonic velocity through a nozzle. The gas velocity in a properly designed converging-diverging nozzle is sonic at the throat (most narrow) portion of the nozzle and becomes supersonic as it travels through the diverging (exhaust) end of the nozzle.

In mathematical terms, the propulsive force derives from the momentum of the gas and is expressed as

$$F = \frac{\dot{W}}{g} \times V_e \qquad (1)$$

where F represents thrust in pounds, $\dot{W}$ the propellant flow rate, in pounds per second, g the acceleration of gravity in feet per second per second and V_e the nozzle exhaust velocity in feet per second. More precisely, another term must be added to the expression

$$F = \frac{\dot{W}}{g} \times V_e + (P_e - P_o) A, \qquad (2)$$

where P_e is the exit pressure, P_o ambient pressure and A, the nozzle exit area. Since P_o would be equal to zero in a perfect vacuum, it may be seen that rocket engine performance increases with altitude. Thrust ratings of upper-stage rocket engines are often given both at sea level and at operating altitudes; the latter rating is always higher. Effective exhaust velocity c may be expressed

$$c = \frac{Fg}{\dot{W}} = v_e + \frac{P_e - P_o}{W} A_e g \qquad (3)$$

Inspection of equation (1) shows that thrust can be increased by increasing the jet velocity and/or the mass flow of propellant gases. Jet velocity is related to the heat of combustion of the particular propellants burned. This is expressed

$$V_e = \sqrt{2g J \Delta H} \qquad (4)$$

in which J is Joule's mechanical equivalent of heat (778 ft. lb. per B.T.U.) and ΔH is the thermochemical energy of the propellant in B.T.U. per pound.

Limitations on mass flow of propellant gases arise from such design considerations as maximum temperatures and pressures feasible within permissible engine weights.

Since the kinetic energy in a rocket jet is derived from conversion of the chemical energy of combustion to directed kinetic energy, high thermochemical energy per unit weight of propellant is desired. In practice, the kinetic energy of the rocket exhaust jet may be only 40% to 70% of the theoretical heat energy from combustion of the propellant. Minor losses arise from incomplete combustion and heat lost to the thrust chamber walls. Larger efficiency losses come from unavailable thermal energy which leaves the exhaust nozzle as residual enthalpy.

An important rocket term is specific impulse, I_{sp}, which is the thrust per pound per second of propellant burned

$$I_{sp} = \frac{F}{\dot{W}} \quad \frac{\text{lb.}}{\text{lb./sec.}} \qquad (5)$$

Since the pound units cancel out, I_{sp} is given in units of seconds. Specific impulse is related to the energy content of combustion in the following general equation

$$I_{sp} = \sqrt{\frac{2J}{g}(h_c - h_e)} \qquad (6)$$

where h_c is the enthalpy of combustion products before expansion (B.T.U. per pound), h_e is the enthalpy of combustion products after expansion (expansion at constant entropy and chemical equilibrium maintained). Calculations performed with equation (6) are called shifting equilibrium calculations.

A more convenient expression, generally accurate to within a few per cent, assumes that specific heat of the gas is constant and utilizes ideal gas relationships; *i.e.*, frozen composition calculation

$$I_{sp} = \sqrt{\frac{2R}{g} \cdot \frac{k}{k-1} \cdot \frac{T_c}{M} \left[1 - \left(\frac{P_e}{P_c}\right)^{\frac{k-1}{k}}\right]} \qquad (7)$$

where R is the universal gas constant (foot-pounds per °R. per mole). k is the ratio of specific heats C_p/C_v, T, is the combustion chamber temperature (°R.). M is the average molecular weight of the combustion products (pounds per mole). P_e is the pressure of the gas at the exit plane of the nozzle (pounds per square inch absolute), P, is the combustion chamber pressure. This relationship is for a fully expanded exhaust nozzle; *i.e.*, P_e = ambient pressure. From inspection of equation (7) it may be seen that specific impulse is increased by increased chamber pressure and combustion chamber temperature and lowering of molecular weight of exhaust gases.

As a rocket-powered vehicle moves, the weight (mass) of the vehicle continuously decreases as the propellant is consumed and

disappears to the rear as exhaust jet. The velocity of a rocket vehicle may be calculated approximately

$$V = c \log, \frac{M_i}{M_f} \quad (8)$$

where c is effective exhaust velocity, M_i is initial mass and M_f is final mass, after all propellants have been burned. The expression M_i/M_f is known as the mass ratio. The true velocity will be somewhat less in practice due to air drag and energy lost in overcoming gravity. In the design of efficient long-range rockets every effort is made to reduce structural weight to a minimum and increase to a maximum the percentage weight of propellant. In the case of the V-2, 69% of the take-off weight was propellants. Take-off acceleration may vary from several g's to a few tenths of a g in large rockets taking off vertically.

The final velocity of a rocket-powered vehicle can be increased, theoretically, to any desired value by the technique of staging; *i.e.*, setting a series of rockets, one on top of the other, and firing them successively. Thus each successive stage is smaller and commences firing at a higher initial velocity. In practice, however, the complications of duplicating mechanical items. cost and reduction in reliability set a practical limit to the number of stages that are employed. An example of the benefit of staging may be obtained from the Bumper-WAC program conducted in the U.S. in 1948–50. A WAC Corporal rocket, placed on top of the V-2, was fired after burnout of the V-2. Whereas a V-2 alone achieves a maximum altitude of about 100 mi. and a maximum velocity of 3,500 m.p.h., the Bumper-WAC sent the WAC Corporal to a velocity of 5,000 m.p.h. and a peak altitude of 250 mi. Although 1,500-mi. intermediate-range ballistic missiles (IRBM) can achieve the necessary velocity to reach these distances with one stage (Jupiter. Thor), ICBM's are multistaged. Likewise, satellite launching vehicles, that must reach speeds of at least 18,000 m.p.h. are multistaged (Jupiter-C, Vanguard j. For lunar and interplanetary flights a minimum escape velocity of 25,000 m.p.h. must be achieved.

The efficiency of a rocket-propelled vehicle increases from zero at rest to a maximum when the velocity of the jet is reached. Thus rocket systems are inefficient at low speeds.

VI. ROCKET MOTORS, ENGINES AND POWER PLANTS

A rocket motor or thrust chamber assembly is composed of a combustion chamber and nozzle. The injector head is considered a part also in the case of a liquid-propellant motor. The term rocket engine (liquid propellant only) refers to the motor plus associated turbopump assembly nith gas generator, propellant lines. valves, regulators. mounting lugs, igniter. etc. A rocket power plant refers to the complete propulsion system including propellant tankage, gimbal mounting (or jetevators. vanes, etc), tankage-level sensing devices and associated computers. etc.

The best known rocket motors burn chemical propellants, either solid or liquid. Combustion of the propellants provides the hot gas which is exhausted in a jet through a nozzle to the rear Other types of rocket motors employ hybrid systems (liquid propellant burned in a solid-propellant core) and air-turborockets which utilize some ram air for part of the combustion process. Two nonchemical types of rocket propulsion systems are nuclear and electrical. These systems have received serious attention only since World War II and have particular application for space flight missions.

1. Solid-Propellant Rocket Motors.—The outstanding feature of solid-propellant motors is their relative simplicity in design All of the propellant is contained in the combustion (or thrust) chamber, usually cylindrical. to which is attached an exhaust nozzle. An electrical or pyrotechnic igniter fires the propellant charge.

Major advantages of solid rockets result from their condition of readiness and their reliability which results from simplicity. Disadvantages arise from a somewhat lower specific impulse range **(I,,** of 175–250 sec.) compared to liquid-propellant motors **(I,,** of 230–270 sec.) and performance variation caused by storage temperature.

The design configuration and chemical composition of solid-propellant charges vary widely. The charge (or grain) may burn from one end only, cigarette fashion. Or, the grain may be a hollow cylinder or have a star-shaped, interior burning surface. Important parameters of solid-propellant charge design are surface area and burning rate of particular propellant mixtures.

2. Liquid-Propellant Rocket Motors.—In this class of rocket motors, the liquid combustibles are contained in tanks and fed into the thrust chamber through an injector head by a propellant supply system. Most liquid-propellant rockets use two combustibles (bipropellant system) such as liquid oxygen and kerosene. Monopropellant systems which depend upon exothermic decomposition of a substance, such as high-strength (90%–95%) hydrogen peroxide, also exist. Such systems usually have loner performance but are simpler to design.

3. Combustion Chambers.—As in the case of all components of a rocket vehicle, a premium is placed on reduction of weight to the minimum adequate to perform the necessary function reliably. Combustion chambers are usually made of metal for strength and are cylindrical or bell-shaped in configuration. Thrust chambers for solid-propellant rockets are uncooled. Burning time is usually short and the walls of the chamber are not exposed to high temperature combustion if the grain burns outward from an interior core. In the case of liquid motors. the thrust chamber volume is designed to provide sufficient time for mixing and burning of the propellants before passing through the exhaust nozzle. Closely associated with combustion chamber design for liquid motors are cooling techniques and injector design.

4. Cooling Techniques.—The wall of a combustion chamber may be uncooled if the duration of operation of the motor is short. In such a case the metal wall acts as a heat sponge or sink. absorbing heat for a short time. At least one liquid-propellant booster rocket has been designed to operate for a few seconds with uncooled walls. But liquid rockets operate usually for longer periods of time, 15 seconds to 2 or more minutes. To accommodate chamber temperatures of 4,000° to 5,000° F. a number of techniques have evolved. Molded ceramic liners of low thermal conductivity and high melting point have been used; but such materials are

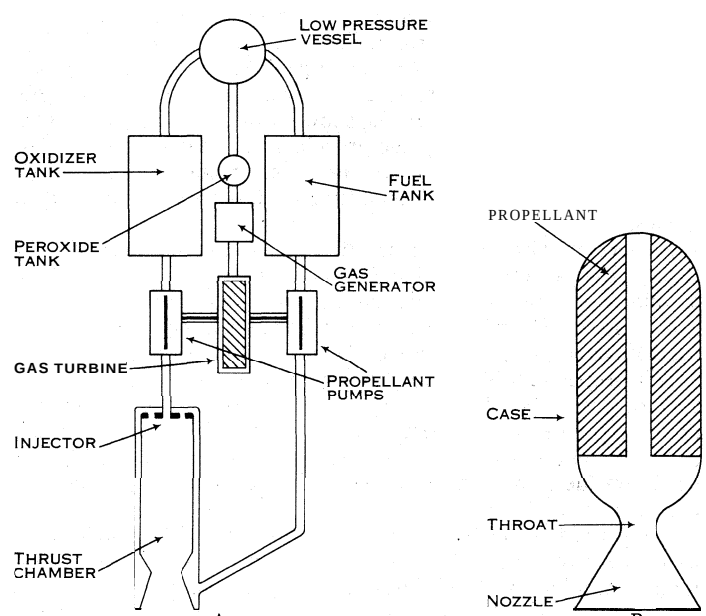


FIG. 4.— (A) LIQUID-PROPELLANT. REGENERATIVELY COOLED. -AND (B) SOLID-PROPELLANT ROCKET MOTORS

Gas pressure from the storage vessel, in a typical liquid-propellant rocket, forces high-strength hydrogen peroxide into the gas generator where a catalyst causes decomposition. Gaseous products (steam and oxygen) drive the turbine wheel which rotates centrifugal propellant pumps. Light gas pressure on propellant tanks prevents cavitation of high-performance pumps. One propellant flows directly to the rocket motor injector head; the other flows through a jacket around the combustion chamber, cooling the motor, and then through the injector. Propellants are sprayed into the combustion chamber where they burn smoothly and uniformly, exhausting in a jet through a supersonic nozzle. The solid propellant contains both the fuel and oxidizer within it. This type burns from the internal axial slot outward to the case, or from the rear toward the front **end**

often subject to cracking from high thermal stresses occurring at start. Another method is film cooling wherein water or a propellant is admitted through holes in the chamber and the liquid flows along the wall and absorbs heat. The most used method is regenerative cooling. In this technique, one of the propellants flows along the outside of the nozzle and thrust chamber wall before it is injected into the motor. The heat which the propellant thus absorbs is not lost but is added to the heat of combustion in the thrust chamber. Design of the cooling flow passages is critical since it is necessary to prevent boiling of the propellant and yet obtain a light weight structure and low pressure drop. A high pressure drop results in greater design weight and higher pressure flow systems. Because the heat transfer rates to the walls are greatest in the narrow neck of the nozzle, the coolant flow rate is usually highest at this point.

5. Design Criteria. — In the design of combustion chambers for liquid rockets the following parameters are significant: thrust, pressure and temperature of combustion gases, average molecular weight and ratio of specific heats of products of reacting propellants, velocity of flow of propellants (stay time), rates of chamber length to diameter (aspect ratio), nozzle entrance half angle, duration of continuous operation and chemical characteristics of propellants.

In the design of exhaust nozzles the combustion gases are expanded nearly isentropically to ambient pressure. In the case of a sounding or ballistic rocket the ambient pressure decreases with altitude. For high altitude or operation in the vacuum of space the diameter of the nozzle exit becomes very large and the construction weight prohibitively high. Thus nozzle design is usually subject to compromise and certain reductions in efficiency (nozzle losses) are accepted.

The function of the injector head is to meter the propellants at a predetermined rate and mixture-ratio and to atomize and combine the mixture within the combustion chamber so that burning takes place smoothly and completely. The pressure drop across the injector must not be too great or an excessive burden is placed upon the propellant supply system and the weight of construction increased unnecessarily. Good injector design reduces to a minimum the volume and length of a combustion chamber. A number of types of injector design have evolved. In the impinging spray type. propellant streams in pairs or clusters are injected to intersect at high velocity so that they break up into small droplets, evaporate and burn. In the showerhead type, a series of concentric rows of holes spray the propellant into the chamber. The rows of sprays may or may not impinge. Sometimes concentric slots are used to produce intersecting conical sheets of propellant sprays.

A German (Enzian) design utilized a splash plate within the thrust chamber on which liquid-propellant streams played. Good mixing is obtained in this design but hot spots may occur on the splash plate. Premix injectors have been tried wherein mixing is accomplished just prior to injection into the thrust chamber. Since rocket propellants by their nature are high energy substances. this type of design is subject to explosion. Swirl-type sprays are another approach to injection configuration. Shop producibility, critical tolerances and cost are factors which enter into injector head considerations and some compromises in performances are usually accepted.

Often related to injector head dynamics is the phenomenon of oscillatory combustion in the combustion chamber. Often exhibiting audible effects of chugging and screaming, these high-speed pressure differentials can destroy a rocket motor in a few seconds. Because the mixture ratios of different propellants vary widely. a rocket motor is tailored for specific propellants and it is not generally possible to operate an engine efficiently on different propellants than those for which it was designed.

Valves for rocket engines offer design problems from the nature of the propellants and requirements of high reliability and precise operation. Many rocket fights have aborted because of sticking valves. Valves are usually operated by electric solenoids or are pneumatically and/or hydraulically actuated.

Design of tankage for propellants has evolved in recent years to integral systems wherein the thin wall of the tank is the skin of the rocket vehicle itself. In addition to the weight of the propellant, rocket tankage must withstand some gas pressure head for turbopump systems and several hundred pounds pressure for gas pressurized propellant supply systems.

6. Propellant Supply Systems. — The simplest method of forcing liquid propellants into the combustion chamber is by gas pressure. An inert gas is used, such as helium or nitrogen. Because the combustion chamber pressure is usually 300 lb. or more. the pressurizing gas must be higher to overcome frictional losses in propellant lines: valves, thrust chamber cooling jacket and injector head. This high pressure necessitates heavy tanks affecting adversely the mass ratio of the vehicle. Gas pressurization is a simple and reliable system, however. It was used successfully in the U.S. V-1 supersonic research airplane. In this case liquid nitrogen was converted in a heat exchanger to high-pressure gas. For small vehicles helium gas at several thousand pounds pressure may be used with operating pressure being reduced through a regulating valve. Another source of pressurizing gas is the reaction of small quantities of the propellants themselves in a specially designed gas generator or even within the propellant tanks. In turbopump systems a source of high-velocity gas drives a turbine wheel which, in turn, drives centrifugal pumps between the propellant tanks and the rocket motor. High-strength hydrogen peroxide (95%–98%) is commonly decomposed by a catalyst bed within a gas generator. The decomposition products, oxygen and steam, are led through a nozzle and impinge on the turbine blades. The propellant pumps are centrifugal. They may be located on opposite ends of the turbine shaft or, in cases of large pumps, driven by a gear train. A certain pressure head is necessary to prevent cavitation. This is supplied from a lightweight high-pressure storage bottle.

7. Ignition. — Liquid-propellant combinations which ignite spontaneously are called hypergolic. Because ignition rates may be low when propellants such as acid and aniline are sprayed into a cold thrust chamber, a slug of another more highly reactive propellant may be injected initially. If ignition does not take place rapidly, the accumulation of unburned propellants may build up quickly to a point where chamber pressure limitations are exceeded when combustion does occur, resulting in an explosion. In the case of nonhypergolic propellants, such as liquid oxygen and gasoline. a source of flame, hot wire, spark or pyrotechnic (squib) igniter must be provided. The V-2 used a swastika-shaped, pyrotechnic pin wheel mounted on a light frame within the combustion chamber.

8. Ground Testing. — Many tests are required in the development of a rocket motor design. The term static test is used to describe rocket motor operations wherein the motor is bolted to a test stand and fired. Static test stands provide for measurements of thrust, propellant flows and a variety of significant temperatures and pressures. Control is maintained from within a reinforced concrete bunker or blockhouse. The rocket firing is viewed by means of mirrors or periscopes or at a distance through bulletproof glass. Closed-circuit television may also be used in the case of large motors. In liquid motor development. so-called battleship (heavyweight) propellant tankage is employed and gas pressure often used to force the propellants into the thrust chamber. In initial-chamber design tests water cooling provides a large safety factor over regenerative cooling. Flow measurement tests of injector heads and gas generator and turbine pump development usually proceed separately. Eventually all components are married for system tests. When missiles are in final stages of development the entire vehicle is mounted in other test stands and fired. These are known as captive tests. The cost of rocket test facilities, with associated plumbing. tankage, propellant storage and necessary safety provisions of reinforced concrete and large safety distances, is naturally great.

Scaling of successful rocket motor designs is not simple. The requirements for very large thrust engines for space flight operations can be met in two ways — manifolding (or clustering) a number of existing engines or designing one new and larger engine. The first technique is simpler. In the United States, the require-

ment for a rocket engine of over 1,000,000-lb. thrust was approached by both methods. In the one case, eight 150,000-lb. thrust engines were specified to be clustered and at the same time a single-barrel engine of 1,000,000-lb. thrust class was ordered. The time for completion of the second approach was estimated to be three to four times as long but held promise of eventual higher mass ratio advantages.

9. Nuclear Rockets. — The development of reliable nuclear fission reactors has led to the possibility of utilizing nuclear energy as a source of power for rockets. In this case the energy does not derive from the heat of combustion of a chemical reaction but from fission of nuclear particles. Although the amount of energy potentially available is very much greater, the conversion to kinetic energy in a rocket exhaust jet is more complicated. Two nuclear rocket systems were under study and development in the United States in the early 1960s. One was the rather audacious notion, suggested shortly after World War II, of obtaining impulse by a series of small nuclear explosions. In theory, these explosions behind a sturdy structure would propel it upward. The more conventional approach to a nuclear rocket is to use the heat of a fission reactor to heat a working fluid and expel the hot gas through a nozzle. Since the nuclear products are in a closed cycle, no radioactive particles are in the exhaust. The most obvious working fluid would be low-molecular-weight hydrogen. The working fluid or propellant in this system would not be burned but simply heated and ejected. Some of the major problems associated with the design of a nuclear reactor are related to the design of an efficient heat exchange to transfer heat energy from the reactor to the propellant and in cooling the thrust chamber walls. The range of specific impulse (*i.e.*, pounds thrust per pound per second of propellant flow) achievable with nuclear rockets is estimated in the order of 700–1,000 sec. Chemical propellants have a limitation of about 430 sec.

10. Electrical Propulsion Systems. — Whereas chemical-propellant rockets are characterized by high thrust for short durations, a number of electrical systems have been proposed which would yield a low thrust over a long period of time. Specific impulses of such systems range from about 1,000 to 10,000 sec. acd more. Several approaches to electrical thrust systems are under development. All such systems, because of low thrust, must be carried to the altitude of a low earth satellite orbit. From this orbit these devices will operate in pulsed fashion or continuously for weeks, months or even years in the case of distant interplanetary flight. Electric power to operate these thrust devices would be obtained from direct conversion of solar energy (solar batteries) or from nuclear electrical generators, as in a plasma thermocouple. It can be shown that specific impulses of 1,500 to 5,000 sec. are optimum for space missions from low-altitude earth satellite orbit to lunar orbits. In unmanned space journeys, such as placement of communications satellites in the 24-hour, stationary orbit (22,300 mi.), additional flight time (of extra days) is not necessarily important. The advantages of using electrical propulsion of 1,500 to 5,000 sec. are, however, truly significant. Earth take-off weights may be reduced as much as one-half to accomplish the same mission using chemical rocket propulsion throughout. In the particular case of a communications satellite payload, which could utilize the electrical power supply of the propulsion system, earth take-off weight might be reduced to one-third. In other words, an Atlas launching vehicle could accomplish the same task in conjunction with electrical propulsion that would require 1,000,000-lb. thrust booster utilizing chemical propulsion throughout the mission. Among the electrical thrust devices under development is the electrothermal arc jet. This device utilizes an electric arc to heat the propellant, or working fluid, which is expelled through a rocket nozzle to the rear. Another device under development accelerates the plasma, produced by the electric arc, by means of a magnetic field. Still other electric thrust devices operate in a pulsed fashion and utilize magnetohydrodynamics (MHD) to accelerate high-temperature gases as in the MHD shock tube.

Best known of the electrical thrust devices is the ion rocket. In this system electrostatic fields rather than electromagnetic fields are used to accelerate dust particles or positively-charged ions such as metallic cesium. Specific impulse ranges of this device are estimated at 5,000 to 100,000 sec. Of even higher specific impulse is the photon rocket — wholly theoretical — wherein energy is converted to light and expelled as such.

11. Other Systems. — One final low-thrust device for space propulsion is the so-called hydrogen heater in which solar energy is concentrated by hemispherical reflectors onto a heat exchanger, which in turn heats hydrogen to high temperature, whereupon it is accelerated through a rocket nozzle to the rear. Although the above low-thrust propulsion schemes for space missions appear exotic compared to conventional rocket systems, the inherent advantages of these high-specific-impulse propulsion devices make their development not only desirable but likely for interplanetary exploration.

VII. ROCKET PROPELLANTS

Rocket propellants, by the chemical process of combustion. provide the hot gases which produce reaction force (thrust) when ejected to the rear. These chemical propellants are divided classically into solid and liquid categories. Some studies have been conducted on solid-liquid systems. In many space flight propulsion systems such as the nuclear rocket. plasma jet or hydrogen heaters, the propellant is not a combustible but serves as a working fluid, its purpose being to transform heat and other forms of energy into kinetic energy.

1. Solid Propellants. — Various formulations of black powder (gunpowder) were the only source of propellant for rockets until late in the 19th century when nitroglycerin was discovered. Saltpetre was the oxidizer in this classic mixture, while the sulfur and charcoal served as fuel. This exothermic reaction may be written approximately

$$2KNO_3 + S + 3C \rightarrow K_2S + 3CO_2 + N_2 + 550 \text{ cal. per gram of mixture reacting}$$

In a rocket motor black powder yields a specific impulse **(I,,)** of 50–70 sec., depending upon chamber pressure and formulation (typical. by weight: 75% KNO,, 15% C and 10% S). The flame temperature of gunpowder is about 1,500"–3,000" F. and the mixture burns smoothly even below combustion chamber pressures of 100 lb, per square inch (p.s.i.). The volume of gas produced is about 400 times the original volume of the charge.

By shifting from potassium to sodium nitrate, 60 cal. per gram more heat is generated. Moreover, since the average molecular weight of the combustion products is reduced slightly, the exhaust jet velocity is increased.

With the advent of nitro explosives new possibilities opened up for obtaining high-temperature gases smoothly and reproducibly. Motor design changes were required to accommodate the higher combustion temperatures and pressures. Rocket propellants based upon nitrocellulose (guncotton) are known as single-base propellants. Mixtures of nitrocellulose and nitroglycerin are known as double-base propellants. These double-base mixtures are similar to smokeless powders for firearms. To improve the physical and chemical properties of double-base propellants, additives of a few per cent are usually present as stabilizers in order to prevent decomposition in storage or to improve combustion characteristics and to bond the propellant to the motor casing.

Double-base propellants require a minimum operating chamber pressure of about 500 p.s.i. for smooth burning. Lower pressure results in irregular burning and oscillatory combustion. Flame temperature is in the order of 5,000" F. Heat yield is in the order of 850–1,200 cal. per gram. Specific impulse is about 180–210 sec. The volume of gases produced from double-base propellants is about 1,500 times initial propellant volume.

Solid propellants are divided into two main classes : homogeneous and composite. The term homogeneous is applied to solid-propellant mixtures in which the propellant or mixture of propellants are intimately associated in a colloidal state. Single- and double-base propellants are examples of homogeneous propellants. In composite (or heterogeneous) propellants, the substances, although finely ground, are in distinctly separate phases. An example of composite propellant is gunpowder.

Nitrocellulose or nitroglycerin are different than gunpowder with respect to the process of chemical combustion. The molecules of saltpetre (KNO_3), sulfur (S) and carbon (C) in gunpowder must be intimately mixed in order to react. Nitrocellulose contains within each molecule sufficient fuel and oxidizer for complete reaction without the addition of other substances. In this regard. nitrocellulose may be considered a monopropellant.

In World War II both single- and double-base propellants were used extensively. In an important German double-base mixture, WASAG R-61, diethylene glycol dinitrate was substituted for nitroglycerin.

In the U.S., a number of new important composite propellants were produced. One of these was the GALCIT series which was a mixture of 75% potassium perchlorate and 25% asphalt oil. Another variety was the NDRC mixtures. A typical example of these was about 46% each ammonium picrate and sodium nitrate mixed with *8%* plastic resin binder. Other composite mixtures used ammonium nitrate as oxidizer and still others utilized synthetic rubber as fuel. An important advantage of composite propellants was their ability to be cast directly in the case.

Generally speaking, a solid rocket propellant may be formulated and designed to wide performance specifications with individual motors operating from a fraction of a second to *30* sec. or more burning time; from a fraction of *1* lb. to 500,000 or more pounds thrust. Rocket motors containing more than 25.000 lb. of propellant have been made and fired. Total impulse, *i.e.*, thrust (lb.) × time (sec.), of many million pound-seconds have been achieved in the U.S. Solid-propellant rocket systems are generally lower in performance than liquid systems but offer advantages in readiness of operation and ruggedness desired for field operations.

Classic problems in solid-propellant production include variation in performance with temperature, development of cracks or shrinkage in storage or transit and sensitivity to moisture. Most propellants tend to have higher burning rates in warm climates. Rocket stores may vary in military field operations from −70° F. to 150° F. Cracks, fissures or shrinkage increase the burning surface area so that pressure build-up on firing may reach disastrous proportions. X-ray inspections are a common specification of rocket grain manufacture. Some formulations are hygroscopic and must be stored in dry atmosphere or moisture will be absorbed and performance reduced. A new technology of rocket propellant surveillance has developed which treats the practice and procedures of storage and periodic inspection of rocket materiel. Procedures are evolved during development of rockets so that safe and adequate provisions may be put into effect when production programs are under way. Rocket propellants are inherently high-energy, unstable substances, intimately mixed. Physical-chemical processes such as deterioration, degradation and autoignition are important as well as variations in shape, size and density resulting from temperature and humidity effects as well as stress relief processes resulting from aging.

With better understanding of rocket propellants and improved design and production techniques, operational reliability is improving while performance and size of motors increase.

2. Liquid Propellants. — Generally speaking, liquid propellants have higher specific impulse than solid propellants and are more flexible in use, since throttling is possible. But liquid rocket systems are more complex and tend to be less rugged and reliable.

Rocket systems using liquid propellants fall into two general classes: monopropellant and the more common bipropellant. Monopropellants may be substances which decompose when heated or upon contact with a catalyst and give off large quantities of heat. An example is 90% hydrogen peroxide which decomposes into water (steam) and oxygen. By mixing hydrogen peroxide with a fuel such as an alcohol. a combustion reaction also takes place yielding more beat. Other monopropellants are nitromethane, ethylene oxide, hydrazine and propyl nitrate. Monopropellant systems are simpler but are lower in performance than bipropellant systems. Specific impulses of the above monopropellants range from 160–220 sec.

Tsiolkovski, Oberth and Goddard all independently recognized and wrote of the advantages of liquid bipropellants. In these systems one propellant is the oxidizer and the other the fuel. Common oxidizers are liquid oxygen, hydrogen peroxide and fuming nitric acid. The fuels used most have been ethyl alcohol (75% + 25% water), kerosene or gasoline, hydrazine derivatives, aniline and furfuryl alcohol.

Although experiments have been performed on literally thousands of fuels and a lesser number of oxidizers, no completely ideal propellants have emerged. Each propellant has some minor or major disadvantages that must be weighed against the particular design application and mission. For example, the problems of corrosivity and toxicity of fluorine or the low density of hydrogen may be accepted to obtain the high performance of these propellants in space applications. Or. the lower specific impulse of solid propellants may be accepted to obtain the advantages of readiness in antimissile defense systems.

In evaluation of liquid propellants the following properties are of engineering importance to the rocket designer: heat of reaction, average molecular weight of combustion products, stability (*e.g.*, to heat, shock), speed of reaction, ignition characteristics, density, viscosity, vapour pressure, specific heat and corrosivity. For re² generative cooling — and all large, long-burning engines are so cooled — at least one of the propellants must have sufficient stability, specific heat capacity, thermal conductivity and high saturation temperature to serve as a coolant. Despite its low temperature (−183° C.), for example, liquid oxygen is unsatisfactory as a regenerative coolant. In the case of the V-2, the ethyl alcohol fuel was diluted to *75%* with water to improve its cooling ability.

Quite apart from properties affecting rocket power plant design, are logistic and handling qualities of liquid propellants. For bulk storage and transfer of propellants, corrosivity, stability and vapour pressure are important as well as freezing point and inflammability. Toxicity is important to personnel. Cost and bulk availability are further important considerations to program planners.

By 1959 achievable specific impulses of rocket motors in operational missiles had climbed to about 270 sec. In the U.S., development programs for storable oxidizers such as nitrogen tetroxide, chlorine trifluoride and perchloryl fluoride were under way as well as major programs for liquid hydrogen and liquid fluorine. Fruition of these propellant programs and development of rocket motors with higher operating pressures may result in specific impulses of 370 sec. or better — near the maximum for chemical-combustion rockets.

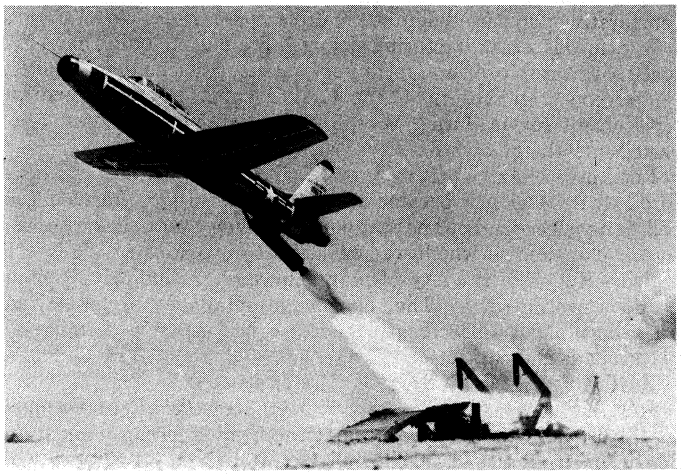
In the realm of exotic propellants, considerable research effort has been applied to the study of free radicals in the hope of stabilizing these energetic metastable substances. Also, studies of liquid ozone, boron hydrides and metal additives have been conducted. See also PROPELLANTS.

VIII. CONTROL OF ROCKET FLIGHT

Most rockets require stabilization of some sort to minimize flight path deflection caused by wind, nonuniformity of rocket structure, rocket jet misalignment and/or other factors Also. in the case of long-range ballistic missiles or satellite launchers. it is necessary for the rockets to take off vertically, programing a pitch deflection (tilt) at some high altitude and velocity. The techniques used for flight control vary according to type of mission and accuracy requirements. Radio control and/or inertial guidance (stabilized platform) systems initiate the correction and deflection signals to the vehicle.

In the case of some barrage-type rockets, launched by the thousands, dispersion errors may be accepted because of overlapping explosive effect in the target area. Aircraft rockets are often stabilized by fixed fins located at the rear of the rocket. Folding fins which open, by inertia, after firing are also used. Short-range bazooka rockets and ballistic rockets of j-to-10-mi. range are usually fin stabilized. Spin stabilization is used on some rockets. In these designs, the rocket nozzle is replaced by a series of smaller nozzles, canted at an angle to impart torque as well as thrust. A unique method of wire control, based upon the Ger-

man air-to-air X-4 rocket has been used. This technique is utilized by some antitank rockets of about one mile range. Fine wire is trailed from a pair of bobbins on the fins of the rocket and command signals given by the operator watching through a telescope.



BY COURTESY OF U.S. DEPARTMENT OF DEFENSE

FIG. 5.—A SOLID-PROPELLANT ROCKET, ATTACHED BENEATH THE TAIL OF A U.S. AIR FORCE F-84 FIGHTER PLANE. BOOSTS THE AIRCRAFT INTO THE AIR FROM A ZERO-LENGTH LAUNCHER. ELIMINATING THE NEED OF A GROUND TAKE-OFF RUN

Moveable control surfaces, or spoilers, alter the initial flight trajectory toward the target.

If the rocket is designed to operate at high altitudes, as in the case of sounding rockets, satellite launchers and ballistic missiles of ranges greater than 100 mi., aerodynamic forces are no longer available because of the low density of the air. One technique, employed first by Goddard, is to place carbon and molybdenum deflection vanes within the rocket exhaust. Usually two pairs are employed for corrections about all three axes; one pair for pitch, the other for yaw, and in opposition, for roll. In flight, deviations from flight path are sensed by gyros within an automatic control (autopilot) system and corrective signals are sent to servomotors which operate the vanes. This deflection system may be used also to program the tilt from vertical launch to ballistic flight path. Radio command may also be used to initiate the tilt program. A modification of the jet vane method is the jetevator, a ring-shaped deflector mounted at the nozzle periphery which rotates slightly into the edge of the rocket jet as required. Gimbal mounting of the engine. permitting the motor to swivel a few degrees in any direction, is another method of flight path control. This system was developed for the U.S. Viking and has been used successfully on IRBM's and ICBM's. Another technique suggested is the use of plug valves in the divergent portion of the nozzle which would release pressure when opened, thus causing change in thrust alignment. Magnetohydrodynamic (MHD) deflection of a rocket jet is another possible flight control concept. Since a rocket jet may be highly ionized it is conceivable that a magnetic field may induce deflection of the exhaust gases without physical contact.

Roll control (*i.e.*, rotation about the long axis) is sometimes required, particularly on larger ballistic missiles. Small jets mounted transversely on the side of the missile are commonly used for this purpose.

IX. MISCELLANEOUS APPLICATIONS OF ROCKET POWER

In addition to the primary uses of rocket power—for missile propulsion, fireworks, aircraft and for upper-atmosphere research and space exploration—rocket systems have been used for a great variety of other purposes.

Rockets are used in the U.S. to propel supersonic sleds along a twin-rail track. These sleds serve as test beds for acceleration tests of various components such as parachutes, aircraft ejection seats and nose cones. Important aeromedical tests on men have also been performed with rocket sleds. Accelerations as high as 100 gravity (g), decelerations of 150 g and velocities up to 4,600 ft. per second are possible. Both liquid- and solid-propellant rockets are used. Braking is accomplished by a parachute or, more often, by extending a scoop beneath the sled into a trough of water between the track rails.

During World War II one of the problems of hunting submarines from aircraft was that the submarine was not visible until it was directly beneath the airplane. Dropping a bomb from this point was not feasible because the forward velocity of the airplane would cause the bomb to follow a ballistic arc, landing far away. A novel solution to this problem was the retro bomb which, when released from the wing of an airplane, fired a rocket canceling the forward momentum. The bomb then dropped vertically on the target. Various sized rocket charges accommodated the different cruise air speeds of several types of aircraft.

Buried land mines were attacked in World War II by rocket-propelled devices. One of these devices, known as the Snake, pulled a 100-ft. train of skis, linked together and carrying TNT. Another version was a U-shaped motor which dragged primacord explosive to detonate the mine field.

A unique device based upon a German development was the Wedge. This item used a powerful rocket to drive a 1-in. rod, 6 ft. long into the ground. By pulling out the rod, inserting a length of primacord and detonating, a hole of 10–12 in. in diameter was created. Various other wartime rocket-propelled material included smoke bombs which in barrage-firing could swiftly erect a smoke screen. Antiradar rockets, used in the Allied invasion of Normandy, released metal foil strips, known as window. at peak of trajectory. These foil strips caused spurious radar reflections and appeared as swarms of aircraft on radar screens. Grapnels, even rope ladders, have been boosted over heights by rocket in commando-type operations. Recoilless rifles and mortar-fired rockets have been developed.

Solid rocket propellants have been used for turbojet engine starters, to furnish gas pressure to power small gyroscopes or electric turbogenerators for guided missiles, and to pressurize flame throwers. Firing solid-propellant charges in specially designed tools in oil wells creates high pressures which fracture the earth and increase oil production. Rocket jets have been used to drill holes through earth and rock. Rocket motors provide a high-temperature jet which is useful for materials tests as in the case of ballistic missile nose-cone development.

In the U.S. X-I j research airplane, the rocket motor is designed to accelerate the vehicle to 100 mi. altitude. In the outer reaches of the atmosphere the craft's wings and tail surfaces would be useless to orient the airplane correctly for re-entry flight on the downward side of the ballistic trajectory. Accordingly, rocket jet nozzles on the wings and fuselage are designed to rotate and correctly orient the X-15 under these conditions.

Rockets have been used to propel target aircraft and missiles, parachute-test vehicles, helicopter rotor blades; to spread fire extinguishing fluid over brush and forest fires, to spread a fine spray of oil over rough seas to calm the surface, to string telephone wires and to accurately deliver emergency supplies, food, ammunition and communications equipment.

The possibility of delivering a number of men and equipment accurately and at long ranges with IRBM and ICBM vehicles has been proposed. Even rocket boost of individual soldiers for short distances over ditches and streams has been achieved.

Rockets have been attached to automobiles, boats, gliders, iceboats, motorcycles. rail cars and even a man on skates. Needless to say, these experiments, which occurred mostly in the 1920s and 1930s, were more ingenious than efficient, more publicity-seeking than sound.

X. ROCKET'S AND SPACE FLIGHT

Man's dream of traveling through space to the moon and the planets is an old one—as old as astronomy itself. Centuries before the Christian era the courses of planets and stars were plotted but there was no appreciation then of the distance to these "abodes of the gods"; no understanding of the lack of atmosphere a short distance from the earth's surface; nor even that the world

was round. However, once man had learned that the moon and planets were actual bodies, a long way off, he had an urge to visit them. Willy Ley (see Bibliography) traces the story of man's interest in space flight from its earliest beginnings; 17th-century authors related fantasies in which man was drawn by "wild swans" or carried aloft "on the dew" to visit the moon. As the telescope developed and Newton's laws became applied, the physical problems of space journeys became more apparent. Jules Verne's famous De la terre *à* la *lune* ("From the Earth to the Moon") was published in 1865. Verne shot a space ship with passengers on a flight around the moon appreciating correctly many aspects of the voyage such as weightlessness in free fall.

By 1900 the recognition of rocket propulsion as the key to space flight began to spread. Individual scientists such as Tsiolkovski, Goddard and Oberth wrote serious technical treatises on the potentialities of rocket-powered flight. Rocket and space flight societies focused public attention on their experimental efforts. Their dreams were great but financial support was limited and successes were few. And each society had its share of crackpots. The aim of these societies was interplanetary flight rather than improved war rockets, but the latter were to appear first, in World War II.

The German heritage of the V-2 to the postwar world made it abundantly clear that with only a small extrapolation, payloads could be accelerated to satellite velocity. The development of the ICBM by the U.S. and C.S.S.R. furnished the additional power necessary for escape velocity. During the International Geophysical year (July 1, 1957–Dec. 31, 1958) the U.S. placed five satellites in orbit and the U.S.S.R. three. But the largest U.S. satellite payload was only 150 lb. whereas the Russian sputnik 3 carried 2,925 Ib. of instruments. This greater rocket capability of the U.S.S.R. enabled that nation in 1959 to launch a i94.9-lh. payload as a planetoid into solar orbit to impact 858.4 lb. on the moon and to photograph, albeit crudely, 70% of the unseen side of the moon irom a satellite and to transmit the picture (11 days later) to the earth.

It was clear by 1960 that the space age had arrived. Projects were under way for reconnaissance, meteorological and communications satellites. In May 1960 the U.S.S.R. put into orbit around the earth a 9,983-lb. spaceship that included a pressurized cabin containing a dummy figure of a man. On April 12 the following year Russian Maj. Yuri Gagarin orbited the earth in Vostok 1 and landed safely 108 min. later. In Xug. 1961 Gherman Titov (U.S.S.R.) orbited ior 24 hr. By mid-1962 the U.S. had made two manned suborbital (ballistic) flights (Alan B. Shepard, Jr., and Virgil I. Grissom) and orbited John H. Glenn. Jr., and M. Scott Carpenter.

Whenever a new scientific frontier has been penetrated the eventual results have been of economic benefit to mankind. It could only be hoped that in moving into this new dimension man would also learn better thr art of living with his neighbours, and that the rocket. developed as a machine of war, would become a tool for peaceful research and understanding.

(F. C. D. III)

ROCKFORD, a city of Illinois. U.S.. the seat of Winnebago county, is located on the Rock river in the midst of an important industrial, agricultural and commercial area in the north-central part of the state. 17 mi. S. of the Wisconsin line and 90 mi. N.W. of Chicago, Founded by New Englanders in 1834, it was named for the rock bottomed ford, the site of a stagecoach stop on the trip between Chicago and Galena. It mas incorporated as a village in 1839 and as a city in 1852. Supplied with water power by a dam constructed in 1844, the town grew rapidly; in 1960 the population of the city was 126,706 and that of the standard metropolitan statistical area (Winnebago county) was 209,765. (For comparative population figures see table in ILLINOIS: *Population.*)

Rockford is a'manufacturing city, its products including machine tools, hardware, furniture, farm implements, household appliances, leather goods and paint. Camp Grant, a reception and medical replacement centre during World Wars I and II, has been converted into the greater Rockford airport.

Rockford college, a private institution founded in 1847 as Rockford Female seminary, became coeducational in 1959. In 1958 the college acquired land on the east edge of the city for a new campus, the development of which was expected to extend over a 15-year period. Rockford is a city of many churches, including a Roman Catholic procathedral. The town has a symphony orch'estra, an art gallery and a little theatre and also has many well-equipped playgrounds and parks. (H. E. B.)

ROCK GARDENING: see HORTICULTURE.

ROCKHAMPTON, a seaport on the east coast of Queensland, Austr., on the Fitzroy river at the head of ocean navigation 35–40 mi. from the sea. Pop. (1961) 44,102. The Fitzroy and its tributaries (Dawson, Mackenzie, etc.) drain a basin of 54,522 sq.mi. of great diversity and econoinic value. The hinterland of Rockhampton includes rich agricultural and dairying lands and large mineral resources including coal fields. Around Rockhampton itself a fertile agricultural area produces tropical fruits, maize and dairy products. The harbour is kept open by dredging. Difficulties are the shifting sand and mud banks caused by severe floods which usually occur during summer. Railway repairing and other industries are carried on and nearby are large meat-preserving and freezing works. Mt. Morgan, 24 mi. S.S.W., became one of the richest gold mines in Australia after 1885. The Dawson river valley is the centre of the cotton region in Australia and also has wheat.

ROCK HILL, a city of York county, S.C., U.S.. 27 mi. S. of Charlotte, N.C. Having become the site of a U.S. post office in 1852, it was incorporated as a village in 1870 and as a city in 1892. Major industries include textiles and paper manufacturing. Located in Rock Hill are Winthrop college (the South Carolina state college for women), the Glencairn (azalea) garden, a children's nature museum and the York County hospital. The city has a council-manager form of government, in effect since 1915. For comparative population figures see table in SOUTH CAROLINA: Population. (J. H. Wo.)

ROCKINGHAM, CHARLES WATSON WENTWORTH, 2ND MARQUESS OF (1730–1782), twice prime minister of England, received his education at Westminster school and St. John's college, Cambridge. In 1751 he became lord-lieutenant of the north and east ridings of Yorkshire and a lord of the bedchamber, and in 1760 was made a knight of the Garter. In May 1i62 the earl of Bute became first lord of the treasury, and the marquess of Rockingham was among those who in the following year were dismissed from their lord-lieutenancies. In July 1765 Lord Rockingham formed his first administration with Gen. Henry Seymour Conway and Augustus Henry Fitzroy, duke of Grafton, as secretaries of state. In May 1766 the duke of Grafton, a far abler man than Rockingham, seceded from the government; in Aug. 1766 he succeeded his former chief as first lord of the treasury and prime minister. Lord Rockingham again became prime minister in 1782, with Charles Fox and Lord Shelburne (afterward marquess of Lansdomne) as secretaries of state. He died on July 1. 1782.

ROCK ISLAND, a city and the seat of Rock Island county, western Illinois, U.S., lies along the Mississippi river near the mouth of the Rock river and opposite the large federal island which gave the settlement its name. With Moline, East Moline and Davenport, Iowa, it forms a complex known as the "Quad Cities." Settlers were attracted by the presence of Ft. Armstrong on the island and by the cornfields of the Fox Indians. Ft. Armstrong (now a federal arsenal) was headquarters of operations in

the Black Hawk war. As settlers moved in. Rock Island (originally called Stephenson) became a transportation hub and was first incorporated in 1841. In 1854 the town was reached by the Rock Island railroad. whose promotors built the first bridge across the hlississippi. Industry is diversified, including railroad shops and the manufacturing of foot ear and farm equipment. Swedish immigrants established Augustana college and theological seminary in 1860. The college library contains material rich in Swedish Americana. Pop. (1960) 51,863. For comparative population figures *see* table in ILLINOIS: *Population;* for the metropolitan area *see* DAVENPORT. (D. L. A)

ROCKNE, KNUTE KENNETH (1888–1931), was head football coach at Notre Dame university. Notre Dame, Ind., 1918–1931. He was born in Voss, Nor., on March 4, 1888, and went to the United States in 1893. A star in football and track at Notre Dame in 1911, 1912 and 1913, when he was captain of the football team, he was assistant coach from 1914 until he became head coach in 1918. His won-lost record at Notre Dame was 105 victories, 12 defeats and 5 ties. He had five undefeated seasons. His "four horsemen" backfield, Harry Stuhldreher, Don Miller, Jim Crowley and Elmer Layden, was football's most famous.

Rockne, recognized as one of the greatest coaches the game has known, was the first to use shock troops in football, substituting virtually complete teams as players tired, and he perfected the famous Notre Dame shift. He was only 43 when he was killed in a plane crash in Kansas on March 31. 1931. (J. D. McC.)

ROCK RIVER, a nonnavigable river in the north central U.S., rises in Washington county in eastern Wisconsin and flows in a generally southwesterly direction to join the Mississippi river at Rock Island, Ill. Its 300-mi. length is shared about equally by the two states and from source to mouth it drops about 500 ft. Ten small dams on the river have a total power generating capacity of 12,545 kw. The river drains an area of 10.879 sq.mi., most of which is good agricultural land. The bottom lands along the lower course are frequently subjected to extensive flooding in the spring and require levee protection. Major cities along the river include Watertown, Janesville and Beloit, Wis., and Rockford, Dixon, Sterling and Rock Island. Ill. Its principal tributaries are the Pecatonica, Kishwaukee and Green rivers. Sear Oregon, Ill., in Lowden Memorial state park. Lorado Taft's heroic 48-it. statue of "Black Hawk" rises majestically above the wooded slopes of the valley. (E. HG.)

ROCKVILLE CENTRE, a village of Nassau county on Long Island in the southeastern part of New York state. U.S., about 20 mi. E. of New York city. The area was first skttled in the 17th century when a few families built several log huts. In 1853 the settlement, which was mainly a farming community, was named Rockville Centre after the Rev. Mordecai ("Rock") Smith.

The village. which was incorporated in 1893, became one of the residential suburbs on Long Island with a large portion of its population commuting to New York city for employment. For comparative population figures *see* table in NEW YORK: *Population.* (D. L. *D.)*

ROCKY MOUNT, a city of North Carolina. U.S., in Nash and Edgecombe counties, 54 mi. E. of Raleigh on the Tar river. Incorporated in 1867, it grew up around the state's second cotton mill. built in 1818 on the river. Its name derives from unusual outcroppings of rock at this coastal plains site. There in 1836 P. T. Barnum made the first recorded stop with his own circus troupe. It was chartered as a city in 1907 and in 1927 the city manager-council form of government was adopted.

Rocky Mount is one of the largest bright-leaf tobacco markets in the world. Its varied industry includes cotton mills, railroad shops, and plants producing fertilizer, lumber, bricks, steel tanks and cottonseed oil. For comparative population figures *see* table in NORTH CAROLINA: *Population.* (W. S. P.)

ROCKY MOUNTAIN NATIONAL PARK, in north central Colorado, U.S., 406 sq.mi. in area, was established in 1915 to preserve an outstanding section of the front range of the Rocky mountains. Located about 64 mi. N.W. of Denver, the region is famous for its high mountain peaks, broad valleys, rugged gorges, flowered meadows, alpine lakes and plunging streams, and also for its abundant wildlife, with such animals as the Rocky mountain bighorn sheep, mule deer, American wapiti, mountain lion, beaver and many species of birds inhabiting the area. A remarkable variety of plant life can be seen within the park, with more than 700 species of plants known to be present. The tundra of the high country in the park is a unique island of arctic vegetation, surrounded on all sides by plant communities of lower latitudes. Within the park are 65 named peaks which are more than 10,000 ft. in elevation. Long's peak (14,255 ft.) is the highest summit in northern Colorado, and one of the world's most popular climbs. The pastoral landscapes of the meadows and the rolling moraines are the result of glacial deposition. About 300 mi. of trails permit hiking, and the national park service provides guided field trips and informal nature walks. Trail Ridge road traverses the park, with about 11 mi. of the highway being above the 11,000-ft. timber line. Except for 12 mi. between Estes park and Hidden valley kept open for winter sports enthusiasts. this road is closed by snow to transmountain travel from about Oct. 15 to May 30. Slopes and ski runs are available for skiing during the winter months.

ROCKY MOUNTAINS, the principal division of that vast system of highlands occupying part of the western United States, northern Mexico, western Canada and extending into northern Alaska. Standing between the great continental plains on the east and the region of elevated basins, ranges and plateaus extending from central Mexico through Nevada to northern British Columbia on the west, they constitute the backbone of the continent. as well as a major topographical feature of the entire globe. The Rocky mountain system does not include any of the Pacific border mountain system of North America (the Alaska range, Coast range, Cascade range, Sierra Nevada, Sierra Madre Occidental), from which it is separated by the basin, range and plateau province of Mexico. Nevada and British Columbia.

At the south the Rockies begin in the Sierra Madre Oriental, north of Oaxaca, Mex. North of Monterrey, Mex., the Sierra Madre Oriental is submerged in a rugged plateau region through which the Rio Grande has cut a narrow gorge at the Big Bend. North of the Mexican border, in west Texas and southern New Mexico, the mountain zone consists of a series of separate ranges and mountain basins between the Rio Grande on the west and the Pecos river on the east. In northern New Mexico the mountains become prominent again, reaching elevations above 13,000 ft. Thence they sweep northward and northwestward through the United States. Canada and across northern Alaska to the Arctic ocean near Point Hope. As a whole the mountain system is about 4,700 mi. long. The section designated as the Rocky mountains extends only 2,200 mi., 1,290 mi. of which are in the United States. Its greatest width is attained in Utah and Colorado, where the system of ranges is 350 mi. across. In Colorado there are 55 summits surpassing 14,000 ft., Mt. Elbert (14.431 ft.) being the highest of the system outside of Mexico. Colorado contains more than 250 mountains between 13,000 and 14,000 ft. Northwest of Colorado breadth and elevation diminish until at the Canadian boundary the ranges are less than 100 mi. wide, with few elevations exceeding 9,500 ft. In Canada, for 450 mi.. the system forms the boundary between British Columbia and Alberta. From Colorado almost to the Peace river in British Columbia, the Rockies carry the watershed of the continent (the continental divide). But this does not mean that they present a continuous chain of great peaks. On the contrary, the zone of uplift is rather a vast complex of separate ranges, interrupted at places by wide gaps of lofty rolling plateaus and intermontane basins or parks. In the Yukon territory of Canada, the system is a broken highland zone between the upper Yukon river on the southwest and the Mackenzie river on the east and northeast. At about 67° N. latitude the system swings westward across the border into Alaska and continues in

a southwesterly arc to the Arctic ocean south of Point Hope. In Alaska the system is designated the Brooks range and contains the highest, most rugged mountain zone north of the Arctic circle, reaching heights a little over 9.000 ft.

Geology.— The Rocky mountain system is one of the younger systems of the world, although very old rocks are found at the core of many of the ranges. The major uplift of the system occurred in Late Cretaceous and Early Tertiary time, in what is called the Laramide revolution, about 70,000,000 years ago. However, the portion of the continent now occupied by the Rocky mountains had undergone a number of vicissitudes prior to its final uplift. Though individual ranges vary somewhat in their story. a generalized geologic history of the system includes the following events: the oldest rocks in the system were-laid down as sediments in a shallow sea in Pre-Cambrian time—1,000,000,000 to 2,000,000,000 years ago. About 1,000.000.000 years ago this thick accumulation of shales, sandstones and limestones was compressed, folded and contorted by mighty forces within the earth's crust and uparched into an ancestral mountain system. The sedimentary rocks were altered by the heat and pressure into metamorphic rocks such as schist, slate, gneiss and marble. During the upheaval great masses of molten material were injected or melted their way upward into the core of the uplift. When it cooled, this material became granite. The processes of erosion now began to wear down this ancient mountain system. Rain fell; streams ate valleys into the surface; mud, silt and sand were carried out of the highlands into the adjacent water bodies. Gradually the uplift was carved into a rugged mountain system and then slowly reduced to a vast low-level plain, called a peneplain. Eventually the region again sank below the level of an encroaching shallow sea.

Throughout most of the two succeeding geologic eras, the Paleozoic and Mesozoic, the site fluctuated between low-lying swamp ground and shallow seas. In these seas were deposited a great depth of sedimentary material. Silt, mud and pebbles were carried down from highlands on the west. This material eventually consolidated into shales and conglomerates. Limey material was precipitated from sea water to form limestone. Sand accumulated along the shore and in river estuaries to form sandstones The skeletons and shells of a complex assemblage of life forms were left in the sediments as fossils. These run a wide range from simple shells to dinosaurs. The depth of the sediments laid down during these times is very great. In some localities the total thickness from top to bottom is more than 10 mi. The greatest extent of sea occurred near the end of this episode. when a Cretaceous water body extended from the Gulf of Mexico to the Arctic ocean, and from the Mississippi to the Nevada plateaus. This vast continental trough with its great accumulation of sedimentary rocks is called the Rocky Mountain geosyncline.

Then at the end of the Cretaceous period, the bottom of the geosyncline began to arch upward. Great compressive forces from the west thrust folds and blocks of the thick sedimentary rocks upward and eastward along a zone from southern Mexico to western Alaska. Accompanying the uplift and folding was the breaking of great sheets and plates of rock, which were pushed eastward along nearly horizontal or gently dipping fractures (thrust faults) like cards in a deck pushed one over another. Displacement along some of these thrust planes is measured in tens of miles. Weakening of the earth's crust permitted molten material from below to break through in volcanic upheavals at numerous points. pouring forth lava and ash. Other steep angled faults were formed along the eastern margins of the emerging ranges. This vast upheaval is called the Laramide revolution, taking its name from the Laramie range of Wyoming and lasted through several million years.

During the upheaval and after its close, the processes of wind and water erosion ate away at the uplift, carving it first into a magnificent group of mountain ranges and eventually wearing it down again to a low peneplain. Then only several million years ago the peneplain was again uplifted as a broad highland plateau. The process of dissection was begun anew. By now many of the canyons and valleys were cutting down through the great masses of sedimentary beds to expose the old metamorphic and granite rocks which had comprised the ancestral Rockies over a billion pears earlier. About 1,000.000 years ago the Pleistocene ice age capped all of the higher ranges with glaciers. These crept outward through the valleys, scouring them into their typical U-shaped profile and fretting the highlands with cirques and serrated ridges. The present-day configuration of most of the higher ranges can be traced to glacial scouring. Greatly diminished glaciers still are found in the high mountains from the Wind River range of central Wyoming northward.

Divisions.— The Rocky mountain system can be divided conveniently into six divisions. From south to north these are: (1) the Sierra Madre Oriental of eastern Mexico; (2) the southern Rocky mountains of New Mexico. Colorado and Utah; (3) the middle Rocky mountains of Wyoming; (4) the northern Rocky mountains of Montana and Idaho; (5) The Canadian Rockies of British Columbia, Alberta and Yukon territory; (6) The Brooks range of Alaska. There are natural gaps or low passes in the crest of the system between all of these divisions except one. The Rio Grande and Pecos uplands divide the Sierra Madre Oriental from the southern Rockies. The Wyoming basin (Great Divide basin) lies between the southern and middle Rockies. The Yellowstone plateau separates the middle Rockies from the northern Rockies. There is no natural break between the northern Rockies and the Canadian Rockies. The Yukon-Porcupine-Mackenzie lowland separates the Canadian Rockies from the Brooks range.

Szerra *Madre Oriental*.—The Sierra Madre Oriental serves as the eastern rim of the central plateau of Mexico from a point just north of Oaxaca to north of Monterrey, a distance of about 700 mi. (See MEXICO.) On the east it falls away abruptly to the gulf coastal lowland. Westward it descends gently onto the dissected central plateau. At the north the range is relatively low—5,000 to 7,000 ft. At the south, however, the range is met from the west by the primary east-west volcanic axis of the central plateau, At this junction stands Mexico's highest peak, the magnificent volcanic cone of Orizaba or Citlaltépetl (18,701 ft.). Nearby is Cofre de Perote or Nauhcampatépetl (14,045 ft.).

Southern Rockies —In the Rockies of Colorado, the most magnificent groups are probably the Sawatch range (96 mi. by 32 mi.) and the Sangre de Cristo range (220 mi. long) in the central part of the state. In the southwestern corner the Elk, San Miguel (with the spectacular Lizard Head, 13,113 ft.), Needle and San Juan groups, form a wild and rugged mass of peaks.

The Wasatch mountains of central Utah. overlooking the great basin for 100 mi. present abrupt ranges. Associated with the Wasatch mountains is the Uinta group (96 mi. by 40 mi.), of which Kings peak (13.498 ft.) is loftiest.

Central Rockies.—The ranges just mentioned connect with the main axis of elevation of the Rockies in the region of Yellowstone park through a belt of rather indefinite uplands running north and south along the western boundary of Wyoming. There are the Crawford mountains. the Wyoming range, the Gros Ventre mountains, the Snake River range and the Teton range. The Teton range presents perhaps the most splendid spectacle of all the Rocky mountain ranges. It is 40 mi. long and 10 mi. wide, rugged and precipitous. Granite spires rise abruptly 6,000 to 7.000 ft. above the flats of Jackson's Hole. The principal peaks are the Three Tetons (Grand Teton, 13,766 ft.) and Mt. Moran (12,800 ft.) at the northerly extremity. Reverting to the continental divide of the western part of Wyoming, the important uplift of the Wind River range is next in order, northwest of Great Divide basin. It is about 100 mi. long; the core is more than 13.000 ft. in elevation and sends out long lateral ridges between which remarkable canyons occur Its most prominent summits are Fremont peak (13,730 ft.) ascended in 1842 by John C Fremont; Gannett peak (13.785 ft.), the highest in Wyoming, and Chimney Rock (13,340 ft). Numerous small glaciers are on the northeast slopes. The largest, Dinwoody, covers several square miles.

Northeast of the Wind River range, across the Big Horn basin, lie the Big Horn mountains, a prodigious offshoot of the main range toward the great plains, 146 mi long and 40 to 50 mi. wide. The axis averages 12.000 ft in elevation, rising about 9,000 ft. above the neighbouring prairies. A few of the peaks surpass 13,000 ft and bear small glaciers in their rugged amphitheatres.

The highest is Cloud peak (13,165 ft.).

Northern Rockies.—Between the northern boundary of Yellowstone park and the Yellowstone river. the Beartooth and neighbouring ranges display what are probably the principal mountain masses of this division. In the vicinity of Mt. Cowen (11,206 ft) and Emigrant peak (10,921 ft.) the relief becomes as great as 6,400 ft., and Granite peak (12,799 ft.), the highest mountain in Montana, is situated there, as are Grasshopper glacier and other small ice bodies. The Beartooth range has a score of summits of 12,000 ft. or more.

The continental divide, however, leaves Yellowstone park in a northwesterly direction. At the 114th meridian it swings off abruptly to the northeast through the Butte and Helena districts. Beyond this swing, the western axis of elevation continues northwestward as the Bitterroot mountains to within 125 mi. of the Canadian border along the boundary between Idaho and Montana. The average elevation is between 7,000 and 8,000 ft. The highest peaks occur on projecting lateral spurs—Scott peak (11,393 ft), El Capitan (9,936 ft.) and St. Mary (9,335 ft.). This 125-mi. interval is filled by the Coeur d'Alene (6,000 ft) and Cabinet ranges. the latter culminating in Snowshoe peak (8,712 ft.). West of the Bitterroots in central Idaho lies a labyrinth of peaks and ridges (11.000 to 12,000 ft.); Mt. Borah (12,662 ft.) is the highest point in that state.

In the region of Butte and Helena, Mont., the continental divide is generally featureless, the passes around Butte averaging 6,000 ft. or less. The Anaconda range contains Mt. Haggin (10,598 ft.) and Mt. Evans (10,635 ft.). Beyond Helena, the divide veers to the north-northwest and follows the Lewis range, which is so wild and rugged that no roads for vehicles cross it for 200 mi. Opposite the Lewis range, the westerly margin of the Rockies is defined by the White Fish range (west of the north fork of Flathead river) and the Mission range (60 mi long, southeast of Flathead lake). The latter culminates in the glacier-bearing Mt MacDonald (10,-300 ft). Between the Mission and Lewis ranges is the Swan range (Mt Holland. 9.272 ft.). The principal continental pass there is Marias pass (5.215 ft). crossed by the Great Sorthern railroad. The finest scenery in this quarter is within Glacier Sational park (*q.v.*), nith 20 peaks between 9,000 and 10.000 ft and six between 10,000 and 10.438 ft. Mt. Cleveland is the loftiest summit. The park contains about 40 small glaciers and several large ones (from 2 to 5 sq mi apiece), besides a myriad of attractive lakes.

Canadian Rockies.—In Canada the axis of the Rockies is continuous for 1.000 mi. It is simpler, straighter and more sharply defined Prominent passes of the divide are: Crows Nest pass (Canadian Pacific railnay). 4.453 ft.; Vermillion pass (motor road). 5.376 ft ; Kicking Horse pass (Canadian Pacific railway). 5,320 ft , and Yellowhead pass (Canadian Sational railway), 3.717 ft. Proceeding northwesterly from the U.S. boundary. there are no glaciers for 100 mi . the peaks being mostly below 9,000 ft. A little farther on is Mt. Joffre (11.316 ft.), the first real glacier-hung peak. From there to beyond Mt. Robson (12,972 ft., the highest of all) the system is continuously alpine for about 285 mi. The Canadian Pacific railway crosses the chain 200 mi from the boundary near the famous Lake Louise. Halfway between this and Mt. Joffre stands the handsome Mt. Assiniboine (11,870 ft.). In the 150-mi. gap between the Canadian Pacific and the Canadian National railways at Jasper, are situated Mt Forbes (11,902 ft.) and Mt. Columbia (12.294 ft.), the fifth and second in rank in the Canadian Rockies respectively. In these mountains about 50 peaks surpass 11,000 ft. Glaciers and snon fields abound. and with the neighbouring groups just mentioned there is presented the best sweep of truly alpine territory to be found in Xorth America outside of Alaska. The northwesterly 500 mi. of the range are imperfectly known, although the mountains are lower.

The *Brooks* Range.—Across northern Alaska, the Brooks range serves as a watershed betneen the Yukon river drainage and that of the Arctic ocean. It includes. from east to west, such separate mountain groups as the Davidson, Romanzof, Franklin, Philip Smith. Endicott. Schwatka, Baird and De Long mountains. The highest peak is Mt Michelson (9.239 ft.) in the Romanzof mountains near the east end of the range. To the west the range crest lowers to 3,000–4,000 ft. Anaktuvuk pass (2,200 ft.) lies near the centre of the range. Almost the entire range is devoid of trees, being north of timberline. See also the articles on the states and provinces in which the Rocky mountains lie and on the national parks found in the Rocky mountains.

See W. W Atwood, The Rocky Mountains (1945) ; N. M. Fenneman, Physiography of Western Untted States (1931). (T. M. G.)

ROCKY MOUNTAIN SPOTTED FEVER AND OTHER SPOTTED FEVERS. Rocky mountain spotted fever is a typhuslike disease (see TYPHUS FEVER), first described in the Rocky mountain section of the U.S., caused by a specific microorganism (Rickettsia rickettsii) and transmitted to man by ticks. It is identical with a disease known as São Paulo fever in Brazil and with the spotted fever of Colombia. A closely related disease, but distinct etiologically, is *fièvre* boutonneuse caused by R. conorii, transmitted by ticks and occurring in the countries bordering on the Mediterranean sea and scattered localities of eastern and southern Africa.

History and **Distribution.**—Rocky mountain spotted fever was known along the Snake river in Idaho as early as 1873, but its first clinical description in a medical journal was given by E. E. Maxey in 1899. It was characteristically a disease of the open range and was noted to occur most frequently among hunters, trappers, fishermen, cattlemen and sheepherders. Up to 1930, it was thought to be confined to 11 states of the northwest, although one case was reported in Indiana. In connection with field investigations of endemic typhus in the southeastern U.S., it was noted that some cases in rural districts in the more northern states and among urban dwellers vacationing in the country were severe and did not exactly correspond to the clinical picture of endemic typhus. A high proportion of these patients had histories of tick bites within a short time preceding their illness. In 1931 L. F. Badger, R. E. Dyer and A. S. Rumreich recovered the causative agent from three patients who were residents of northern Virginia, and proved that it was identical with that of Rocky mountain spotted fever. After that time, the disease was shown to be widely distributed in the U.S., present in two provinces of western Canada, in two states of Brazil and in Colombia.

Epidemiology.—The predominance of the disease in the western U.S. among persons exposed to the open range. and the seasonal limitations to late spring and early summer months, were explained when the vector (carrier) species was identified as a wood tick, Dermacentor andersoni. It is widely distributed in the adult form upon large mammals, particularly cattle and sheep, in the western range country of the Pacific coast states, Nebraska. North and South Dakota and Nevada, and from New Mexico and Arizona on the south to Alberta, Saskatchewan and British Columbia on the north. Adult ticks live two to four years or more. Engorged females deposit their eggs in the soil. The winter is passed in the adult, nymphal or egg stage. Larvae, or seed ticks, emerge in the late spring and seek a blood meal on small animals. If successful, they molt to the nymphal stage, which may not become active until the follo ing spring.

Many small animals. especially rodents, are susceptible to infection with the rickettsiae of Rocky mountain spotted fever and after having been bitten by an infected tick develop an inapparent form of the disease. While the microorganisms are in the peripheral circulation, these animals serve as a source of infection for uninfected larval, nymphal or adult ticks which chance to feed upon them. The rickettsiae pass through the stage-to-stage development in the tick and are carried to successive generations in decreasing numbers by transovarial passage. The infection is thus maintained in nature by the alternation of the small animal and tick hosts. Among the rodent hosts should be mentioned particularly the jack and the cottontail rabbits. The rabbit tick *Haemaphysalis leporis-palustris*, although it does not attack man, is one of the vectors in maintaining continuous passage in small animals.

The occurrence of the human disease in the eastern and southern U.S. was explained when it was discovered that the common dog tick, Dermacentor variabilis, which attacks man also acts as a vector. Dogs and field mice are involved in maintaining the reser-

voir of infection. In the southwestern U.S. human cases were also traced to the lone star tick *Amblyomma americanum*. In Brazil the common vector is *Amblyomma cajennense*. Many other tick species were found to be experimentally infectable but were epidemiologically unimportant.

Clinical and Pathological Features. — The clinical course of the disease is essentially similar to that described for typhus fever (*q.v.*). In severe cases of spotted fever the rash tends to be more hemorrhagic and to be accentuated on the extremities, particularly about the wrists and ankles. Occasionally, a lesion may be detected at the site of the tick bite, but a typical primary eschar is lacking. Nervous and mental symptoms are common; restlessness. insomnia, disorientation and delirium are frequent manifestations of involvement of the central nervous system. Prostration may be marked from the beginning, merging into coma with death possible as early as the sixth or seventh day. Convalescence is apt to be slow and may be complicated by visual disturbances, deafness and mental confusion. Although recovery may be delayed it is usually complete. The case-fatality rates, as in typhus, vary directly with age. The crude rate for reported cases in the U.S. is about 18%.

The underlying pathology is essentially the same as that of typhus fever. The microorganism (R. *rickettsii*) proliferates in the endothelial cells lining the smaller blood vessels. causing damage to the vessel walls with hemorrhage. infiltration with round cells and thrombosis. Lesions are widely distributed in the tissues of the body but are characteristically common in the central nervous system and skin. Occasionally, there may be large areas of subcutaneous hemorrhage, particularly in the scrotum. Diagnosis is confirmed by blood tests. The Weil-Felix reaction becomes positive with *Bacillus proteus* X 19 and usually with X 2 and negative with *B. proteus* X K during the second week of the illness. The complement-fixation test becomes positive about the same time. The microorganisms may be recovered and identified following inoculation of guinea pigs with blood obtained from a patient early in the course of the illness. Reports in the 1950s indicated that early institution of treatment with antibiotics — chloramphenicol (chloromycetin) and aureomycin — greatly shortens the disease and decreases the risk of death.

Prevention. — Prevention depends primarily upon exercise of personal care in protection against tick bites. Persons exposed to known infected areas should frequently examine the clothing and body for ticks. Usually the tick does not become attached to its host immediately but crawls about for several hours. The chance of receiving infection from the bite of a tick is directly proportional to the length of time that the tick has fed. Ticks should be removed from the person or from a pet with a small forceps or with a piece of paper. The skin area involved should be swabbed with an antiseptic and the forceps disinfected with heat or chemicals. Hands should be washed with soap and water after such an operation.

There is a satisfactory vaccination procedure against Rocky mountain spotted fever; it should be administered in the spring or early summer before the beginning of the tick season, and should be repeated annually as the maximum degree of protection conferred is for less than a year. The degree of immunity afforded is relative. but the chance for subsequent infection is lessened and the risk of death is greatly reduced.

Fievre Boutonneuse (**Fièvre** Exanthematique).—A. Connor and **A.** Bruch in 1910 described a mild typhuslike fever which they believed to be an endemic disease of Tunisia, north Africa, and proposed the name boutonneuse fever. It was subsequently observed to occur in Marseilles, France, and still later was discovered to have a wide geographic distribution. It was reported from most of the Mediterranean countries and the Crimea. Available evidence suggests that the diseases described as Kenya typhus and South African tick-bite fever are probably identical with boutonneuse fever, although conveyed by a different species of tick. One review indicated the widespread distribution of this human tick-borne rickettsiosis in Africa.

Primarily, the vector was found to be a brown dog tick, *Rhipicephalus sanguneus;* subsequently. other ticks were incriminated. The microorganism is *Rzckettsia conorii.* The reservoir probably exists in nature in the lower animals, but the dog is apparently an important source of infection. The course of the disease is somewhat similar to Rocky mountain spotted fever, but it is milder. The case fatality rate is less than 3%. A primary lesion, called a *tache noire* ("black spot") is frequently found. It is somewhat similar in appearance to the primary eschar characteristically seen in tsutsugamushi disease. It is, of course, located at the site of the infecting tick bite and, therefore, may be found on any part of the body, but usually on a part covered by clothing. The Weil-Felix reaction with X 19 strain of *B. proteus* becomes positive late in the disease. Experimental evidence suggested that both chloramphenicol (chloromycetin) and aureomycin would be highly effective in the treatment of boutonneuse fever. Prevention depends upon protection from tick bites as outlined above. *See* also RICKETTSIAE.

See M. C. Pincoffs, E. J. Guy, L. M. Lister, T. E. Woodward and J. E. Smadel, "The Treatment of Rocky Mountain Spotted Fever with Chloromycetin," *Ann. Int. Med.*, 29 656 (1948); W. H. Price, "The Epidemiology of Rocky Mountain Spotted Fever," *Am. J.* Hyg., 60:292 (1954) (K. F. M.)

ROCOCO, a term used to describe a phase of European art originating in France and commencing in the first quarter of the 18th century. Its name is derived from the French word *Rocailles* which was used to designate the artificial grottoes and fantastic arrangements of rocks in the gardens of Versailles; and it indicates one of the features of the rococo style in its typical form — its absolute freedom and irregularity of rhythm. the twisted curves of a shell being as it were the standard of the whole system of design. Historically, it was an extreme development of the ideas of individual imagination and love of broken curves which characterized baroque (*q.v.*).

For the grave and pompous dignity of the style of Louis XIV, the rococo substitutes playfulness and exquisite gracefulness and charm. Up to about the middle of the 18th century, rococo art remained gay and freakish and showed much exotic influence as, for instance, the influence of Chinese art. Then a renewal of interest in classical art and archaeology which had meanwhile taken place in Italy began to make itself felt in French art. During the later phase of the rococo, much of the playfulness disappeared, and a greater calm and balance were introduced into the style; but it retained gracefulness and charm, till eventually, between 1780 and 1790, the severe neoclassical movement superseded it. This later phase of the rococo must be regarded as a stage of transition from the rococo proper to the neoclassical art of Louis XVI.

See LOUIS STYLES.

ROCROI, a town of northern France. in the *département* of Ardennes, 22 mi. N.N.W. of Charleville by rail, and within 2 mi. of the Belgian frontier. Pop. (1954) 863. Originally called Croix-de-Rau or Rau Croix, it was fortified in the 16th century and besieged by imperialists in 1555. Invested by the Spaniards in 1643, it was relieved by Louis II, the duc d'Enghien (afterward the great Condé). Captured in 1658 by the same duke for Spain, it was not restored to France till the treaty of the Pyrénées in 1659. In 1815 Rocroi was besieged by the Allies. The fortifications constructed by Vauban close in the town.

Battle of **Rocroi.**—In 1643 (*see* THIRTY YEARS' WAR) the Spaniards, under Francisco de Mello, invading France through the Ardennes, laid siege to Rocroi. The town lay in a small plain surrounded by woods and marshes, and could only be approached through a narrow defile. Contrary to the advice of Marshal de l'Hôpital, the young duc d'Enghien (*see* CONDÉ, LOUIS II DE BOURBON), decided to attack the Spaniards before the town. Mello omitted to block the defile and Enghien led his army through it in safety and formed up on a low ridge facing the Spanish lines. His infantry, commanded by Espenan, was in the centre, cavalry under Gassion on the right, cavalry under La Ferté on the left, a small reserve under Sirot in rear — altogether 16,000 infantry and 7,000 cavalry. with 12 guns.

The Spanish army, now concentrated on a parallel ridge facing the French. was similarly organized, 18,000 infantry in the centre under Fontaine, cavalry on the right under Isembourg, on the

left under Albuquerque—27,000 men and 18 guns. Mello also expected a reinforcement of 6,000 men under Beck. Evening was approaching when La Ferté suddenly led his wing forward without orders. Enghien instantly ordered him back, and Mello surprisingly allowed him to return untouched.

On May 19 the French army stood to arms at 3 A.M., Enghien, like Henry of Navarre, donning a hat adorned with white plumes instead of an armoured helmet. A deserter had reported that a battalion of musketeers was in ambush in a wood on the French right. Enghien sent a regiment of infantry to dislodge them, while cavalry caught them as they retired and cut them to pieces. Relieved of this danger, Enghien led eight squadrons against Albuquerque's front, while Gassion with a similar force attacked his left flank. Albuquerque's force gave way, and Enghien, ordering Gassion to pursue, swung against the left of the Spanish infantry.

Meanwhile La Ferté led an unauthorized attack against Isembourg and was completely defeated, himself and his guns captured, while his men fled, hotly pursued by the Spaniards. Fortunately Sirot's reserve stood firm and threw off Isembourg's attack. Espenan also had advanced against the Spanish infantry, but seeing La Ferté's disaster, drew off. At this critical moment Enghien with his cavalry struck the second line of Spanish infantry in the rear and, dispersing them, swept on to attack Isembourg's victorious cavalry who fled, leaving their own and La Ferté's captured guns in Enghien's hands. There now remained only the front line of the Spanish infantry, standing in square upon the ridge. The Spaniards stood motionless till the French were within 50 paces; then the front face of the square opened and 18 guns belched death at the oncoming French; crashing musketry joined their roar and the attackers fell back with terrible loss. Twice Enghien renewed the attack, only to be beaten off, but the Spanish ammunition was running low, their losses were heavy, the recaptured French guns were brought into action, Sirot came up with his reserve and Gassion from his pursuit.

Realizing that further resistance was hopeless, the Spanish officers signaled their desire for quarter; Enghien stepped forward to receive their surrender, but the Spanish infantry, misunderstanding his intention, opened fire upon him. Infuriated, the French massacred the Spaniards almost to a man. Beck, warned of his danger, retreated and the victory was complete.

ROD, EDOUARD (1857–1910), French-Swiss novelist, was born at Nyon on March 31, 1857. He studied at Lausanne and Berlin, and in 1878 found his way to Paris. In 1881 he dedicated his novel *Palmyre Veulard* to Zola, of whom he was at this period a disciple.

A series of novels of similar tendency followed. In *La Course à la mort* (1885) he turned to the analysis of moral motives. He is at his best in presenting cases of conscience, the struggle between passion and duty, and the virtues of renunciation. *Le Sens de la vie* (1889), one of his most famous books, is in the nature of a complement to *La Course à la mort*. Of his many later works, *La* Vie *privée de Mzchel Teissier* (1893), translated as *The Private Life of an Emznent Politician* (1893), is justly famous. He was an ardent student of Rousseau, and his play *Le Réformateur* (1906) is based on an episode in Rousseau's life. He died in Jan. 1910.

RODBERTUS, JOHANN KARL (1805–1875), German economist, author of a conservative interpretation of social reform and a strong supporter of monarchy and economic nationalism, was born at Greifswald on Aug. 12. 1805, the son of a university professor. Educated in law at Prussian universities, Rodbertus acquired in 1836 the landed estate of Jagetzow in Pomerania. Until his death, on Dec. 6, 1875, he carried on economic studies as well as historical studies and participated in Prussian politics.

The substance of his social-economic reasoning is a principle of government regulation of wages so that they might rise in proportion to increases in national productivity. Unlike Malthus and Ricardo—who believed that wages rise naturally in conformance with rising conceptions of a conventional standard of living—Rodbertus maintained that wage earners, when left to their own devices, cannot earn more than a bare minimum of physical existence. All increases of national productivity therefore accrue to the owners of property. Since property owners constitute a minority of the population, crises of underconsumption and retarded production occur while yet a majority of the population is not prosperous: "thus society pays dearly because labour is hired too cheaply."

Rodbertus, unlike Marx, did not call into question the entire complex of the political and economic institutions of capitalism, but in entrusting the government with legislating the conditions of wage payments, he furnished a conservative basis of state intervention; thus in his time he won support for social legislation in circles inaccessible to socialist agitation or fearful of it.

See H. Dietzel, *Karl Rodbertus: Darstellung seines Lebens und seiner Lehre* (1886); *E.* C. K. Gonner, *Social Philosophy of Rodbertus* (1899). (G. W. Z.)

RODENT, a member of the Rodentia (*q.v.*), order of gnawing mammals, more numerous than any other order and containing about 2,000 species. More widely distributed than any other group, they are found on all but the most desert oceanic islands. Most are small to medium-sized, but the pygmy mice are among the smallest of mammals, while the capybara may attain a length of 4 ft. and a weight of 100 lb. Rodents are largely terrestrial, many burrowing, many tree-living, a few gliding by skin-folds and some partly aquatic.

Rodents are noted for destroying or injuring crops and food stores. Many small species eat quantities of insects and their eggs. Most rodents are eaten in primitive societies, while rabbits, hares, and squirrels (*qq.v.*) are eaten by civilized people. Beavers, chinchillas, muskrats and squirrels (*qq.v.*) produce valuable furs. Plague (*q.v.*) is transmitted by rats and ground squirrels, tularemia (*q.v.*) by rabbits. (J. E. Hl.)

RODENTLA, an order of placental mammals characterized by their front or incisor teeth, which are reduced to a single functional pair in each jaw, chisellike and growing throughout life. Rodents are small or medium in size, plantigrade or partly so and generally five-toed. Canine teeth are absent; the cheek teeth, $\frac{3}{3}$ to $\frac{6}{6}$ in number, may be rooted or ever-growing and are arranged in an unbroken series. (*See* TEETH.) The orbits are not surrounded by bone except in the aberrant maned rat, *Lophiomys*. The skull is characterized by large premaxillae, completely separating the nasals from the maxillae; by the wide space between incisors and cheek teeth and (except in the Duplicidentata) by the anteroposteriorly elongated groove for the articulation of the lower jaw.

Rodents feed chiefly on vegetable matter, but most species eat also insects and other animal matter, while a few are fishers or predators.

A wide difference of opinion exists as to the classification of this order; the scheme here followed being that of T. Tullberg (1899), with modifications.

SUBORDER SIMPLICIDENTATA

The Simplicidentata have only one pair of incisors, above and below; these have enamel only on the front surface, and in chewing the movement is obliquely backward and forward. True rodents may be divided into two sections or infraorders: the angle of the lower jaw arises from the underside of the incisor socket in the Sciurognathi; in the Hystricognathi the angle arises from the outer side. Rodents are an ancient group; and the earliest members are quite as distinct from other mammals as are the recent types, and almost as different from each other. Adaptations to similar habits occur in unrelated groups, leading to superficial similarities of structure and appearance that are frequently very detailed.

SCIUROGNATHI

This section contains nine superfamilies, some of which may be more closely related than this classification indicates.

Aplodontioidea.—The skull is characterized by a small or moderate infraorbital foramen; the masseter muscle does not pass through this, nor does it extend in front of the zygomatic

arch on the rostrum. Postorbital processes are absent or poorly marked. The tibia and fibula are free.

Family Ischyromyidae is known from the Lower Eocene to the Upper Oligocene. These rodents had marmotlike skulls and primitively cusped, rooted molars, which in later forms became crested. The dentition included $\frac{2}{1}$ premolars.

Family Aplodontiidae has as its sole existing representative the sewellel or mountain beaver of the Pacific United States. It is about the size of a marmot, with short tail, small rounded ears and small eyes. Aplodontia is burrowing in habit, living in damp woods. The cheek teeth are rootless and early lose the pattern; the premolars are $\frac{2}{1}$.

Family Mylagaulidae includes the strange horned rodents of the Miocene and Pliocene. In habits these animals were much like pocket gophers of the present, living in burrows on the plains. The male had a pair of horns on the nose, while the female was hornless.

Family Protoptychidae contains a few forms from the Eocene, characterized by an inflated mastoid bulla. Eomys of the European Upper Eocene is type of another primitive family, often referred to the Muroidea or Dipodoidea, from its generalized structure.

Sciuroidea.—Only the family Sciuridae can be placed here. The infraorbital foramen is small, while the masseter muscle arises in front of the zygomatic arch from the rostrum. Postorbital processes are present. The premolars are $\frac{2-1}{1}$. This group is a successful one, represented all over the world, except the Australian region and the oceanic islands.

Subfamily Sciurinae includes the tree and ground squirrels; it may be divided into six tribes.

Sciurini, the typical squirrels (see SQUIRREL) of Eurasia and America, includes numerous species. A number of genera have been allowed by authors; most of these are better considered subgenera. *Sciurus,* the typical genus, is complex and is most widespread. The European red squirrel (S. vulgaris) is found from Great Britain to Japan and eastern Siberia; it varies from reddish to dark gray and black in different parts of that range. The gray squirrel of the eastern United States, the Pacific gray squirrel and numerous other American species are closely related. Seven or eight subgeneric groups occur in the Neotropical region, exhibiting a great variety of colour and size.

The pygmy squirrels of Central and South America, *Microsciurus,* are the smallest of the American species, hardly larger than mice. with delicate skull and narrow rostrum. Rheithrosciurus, the tufted-eared ground squirrel of Borneo, has many grooves on the front of the upper incisors. It is doubtfully referred to the typical tribe.

Tamiasciurini, the common North American red squirrels, *Tamiasciurus,* differ from all other squirrels in the reproductive system of the male; the baculum (*os* penis) is absent and the accessory glands are unique.

Funambulini includes the tree squirrels of Africa and several oriental genera. The Indian palm squirrels, *Funambulus,* are striped blackish, white and olive. Ratufa, the largest of the tree squirrels, includes black, red or yellowish forms, with white or yellowish undersides; they are found in India and the Malay region as far as Bali and Borneo. The African giant squirrels, Protoxerus, are characteristic of the tropical forest area. These squirrels are about 11 in. long, with scantily haired underparts. The red-faced giant squirrels, *Epixerus,* resemble the preceding genus but have an elongated skull. The African side-striped squirrels, *Funisciurus,* have cheek teeth $\frac{5}{4}$, the lower molars basined. The brush squirrels, *Paraxerus,* are found in the scrub of the hill country of central Africa; most are olive-gray but several striped species are known and several mountain species are handsomely coloured. Heliosciurus is a common squirrel from Rhodesia to Gambia; the forms vary from gray and olive to rich reddish brown. Myosciurus, the African pygmy squirrel, with head and body about two and one-half inches, is restricted to the Cameroons and Gabun.

Callosciurini contains mostly oriental species. *Callosciurus,* the common oriental squirrel, is represented by several species in Burma, China, the Malay region, the Philippines and Celebes. A great variety of coloration is exhibited in this genus; white, gray, buff, olive and reddish species or races are known, while one group, often separated as *Tamiops,* is striped. Menetes, a long-nosed ground squirrel from Burma, Siam and the Malay peninsula, is distinguished by well-marked flank stripes. Red-cheeked ground squirrels, Drenzomys. characterized by long-nosed skulls, are found from S. China and Burma to the Malay peninsula and Borneo. The oriental pygmy squirrels, *Nanosciurus,* occur from Malaya to the Philippines and Celebes. Striped ground squirrels, Lariscus, of Borneo, Java, Sumatra and the Malay peninsula, are distinguished by short tails and three dark dorsal stripes. Rhinosciurus, the long-nosed ground squirrel of the Malay region, including Sumatra and Borneo, is largely insectivorous. It has weak, tweezerlike incisors and extensile tongue. The Celebes long-nosed ground squirrel, *Hyosciurus,* has long front claws and normal incisors. The pygmy ground squirrel of North Borneo has broad incisors and black and white flank stripes.

Xerini, the spiny squirrels (*q.v.*) of Africa, are represented in North Africa by Atlantoxerus, and throughout the plains country and grasslands south of the Sahara by Xerus. X. rutilus, the typical form, occurs in Ethiopia, Somaliland and Kenya; it is yellowish-brown without stripes, the skull with convex profile. X. (Euxerus) erythropus of Equatorial Africa has a long narrow skull and white flank mark; its colour is reddish. X. (Geosciurus) *inauris* of South Africa is pale yellowish-brown, with a well-marked white lateral stripe.

Marmotini, containing the marmots and typical ground squirrels, is best represented in Asia and North America. The chipmunks (*q.v.*), Tamias and Eutamias, have cheek pouches, are light in build and climb well. Eutamias is found in eastern Asia and in western North America, while Tamias is restricted to eastern North America. The spermophiles (*q.v.*), sousliks (see SUSLIK) or ground squirrels (*q.v.*), Citellus, are found from Hungary through Asia and North America south to Mexico. The tail is usually short and flattened and the claws enlarged; the size varies from about five inches to more than one foot, excluding the tail. Cynomys, the prairie dog (*q.v.*) is confined to western North America. Marmots (*q.v.*), *Marmota,* are found in the Alps and eastward from Poland through Asia and in North America as far south as Alabama and New Mexico. Cheek pouches are absent. *Spermophilopsis,* the sand marmot of southern Siberia. may belong here. It is golden in colour, the pelage silky. The single species is a little smaller than the marmots. Cheek pouches are present and the cheek teeth are simplified in pattern.

Subfamily Petauristinae. The flying squirrels (*q.v.*) of the northern hemisphere are found from Scandinavia and northern Asia to the Malay region and throughout the forested parts of North America. The fore- and hindlimbs are connected by a broad skin fold, supported by a cartilaginous spur arising from the wrist, by means of which they glide from tree to tree. About 11 genera are recognized. Petaurista, the giant flying squirrel of southern Asia, occurs from India and Japan to Java and Palawan; the various forms are red or black, sometimes spotted with white. The woolly flying squirrel, *Eupetaurus* of the Himalayan region, is about the same size (head and body about 24 in.; tail 18 in.); its cheek teeth are high-crowned, unlike those of other Sciuridae. Sciuropterus, a smaller type, is found in northern Europe and Asia, east to Japan. Closely related species, usually recognized as generically distinct (*Glaucomys*), are found in North America as far south as Honduras. In the Malay region a number of other genera occur, varying in size from that of a mouse to that of a rat; they are distinguished by dental and cranial characters.

Castoroidea.—Two families are included here, one of which is extinct. The masseter muscle is similar in its attachment to that in the Sciuridae, but postorbital processes are absent; the cheek teeth are complicated in pattern and rootless in Recent forms, although originally four-cusped and rooted.

Family Castoridae is represented by two living species of beaver (*q.v.*), although formerly it was a large and varied group. Fossil forms carry the beavers back to the Middle Oligocene but, except for differences in tooth pattern, the earlier forms are much like the later ones. Subfamily Castoroidinae includes giant forms

almost as large as a bear, with cheek teeth of a different pattern. These were characteristic of the Pleistocene of North America and Europe. Older types were smaller, the earliest appearing in the Lower Miocene.

Family Eutypomyidae includes a few Middle Oligocene castoroids, with two upper premolars. The cheek teeth have numerous small enamel islands.

Geomyoidea.—Two families of American rodents are referred to this superfamily. They combine characters of the squirrel, beaver and mouse groups; the masseter muscle and structure of the infraorbital canal agree with that of the squirrels. Postorbital processes are absent and all have external fur-lined cheek pouches.

Family Geomyidae. The pocket gophers (*q.v.*) are stout-bodied, burrowing rodents with small eyes and ears and large front claws. The skull is massive and flat. The fossil subfamily, Entoptychinae of the Oligocene and Miocene, had rooted teeth but otherwise resembled Recent gophers. The Geomyinae contains forms with simple, ever-growing cheek teeth.

Family Heteromyidae includes three subfamilies. The pocket mice (*q.v.*), Perognathinae, are known from Oligocene times on. The cheek teeth are rooted, the cusps of the lower premolars form a quatrefoil pattern, those of the other teeth form cross-crests. The kangaroo rats (*q.v.*), Dipodomyinae, have rootless teeth without pattern when worn; the enamel is restricted to bands. The spiny pocket rats, Hetcromyinae, have rootless teeth, which when worn form a C-pattern, narrow anteroposteriorly. *Heteromys*, the typical genus, occurs in Central America and northern South America, also in Trinidad.

Anomaluroidea.—Part of the masseter muscle passes through the infraorbital canal, while the lateral masseter is restricted to the zygomatic arch, differing in these respects from other rodents except the Dipodoidea and Hystricoidea.

Family Anomaluridae includes arboreal rodents without postorbital processes, cheek teeth $, and large auditory bullae. On the underside of the tail is a series of imbricated scales. A skin membrane extends between fore- and hindlimbs, supported by a cartilaginous spur from the elbow, except in *Zenkerella*. *Anomalurus* includes various species which are confined to Equatorial Africa as far south as Northern Rhodesia. The subfamily Idiurinae contains two genera: *Idiurus*, with a flying membrane, and *Zenkerella*, which is without this membrane. These are found in the West African forest area.

Family Pseudosciuridae may belong here; it agrees in the attachment of the masseter. The cheek teeth are cusped or crested, with low crowns, while the skull is long and flattened. The several genera are found in the Eocene and Oligocene of Europe.

Family Theridomyidae is also extinct, known only from the Middle Eocene to the Oligocene of Europe. The earliest forms had teeth somewhat squirrellike in pattern, while in later types the pattern was reduced to enamel islands.

Family Pedetidae. *Pedetes*, the jumping-hare (*q.v.*) of eastern and southern Africa, is a kangaroolike rodent about the size of a fox, buffy brown in colour with white hip stripe. *Parapedetes*, a similar form, occurs in the Miocene of Africa.

Ctenodactyloidea.—The African family Ctenodactylidae includes three genera. Part of the masseter muscle passes through the infraorbital foramen, which is large. The mandible lacks a coronoid process, the teeth are prismatic and the auditory and mastoid bullae are inflated. *Ctenodactylus*, the gundi of North Africa (Morocco to Tripoli) is about the size of a squirrel, with short tail and pale buffy coloration. *Massoutiera* is the long-tailed gundi of the Sahara desert and Senegal. *Pectinator* of Somaliland and Eritrea has a long bushy tail and $\frac{5}{5}$ cheek teeth, more than in any rodent except certain Bathyergidae. *Pectinator* is known from the Miocene of India, while other representatives of the family are reported from the Pliocene of the Mediterranean region.

Gliroidea.—This subfamily includes the dormice and their relatives. They resemble squirrels in habit and general appearance. The tail is bipennate or bushy. The cheek teeth are usually $\frac{4}{4}$ but may be $\frac{3}{3}$, with transverse crests. The lower leg bones are fused. The caecum is absent in most species.

Family Gliridae, the true dormice. The typical genus, *Glis*, includes the large edible dormouse (*q.v.*) found from France and Spain to Asia Minor. *Muscardinus*, the common dormouse, ranges from England to the Mediterranean and near east; it is much smaller than *Glis*, about as long as a house mouse but with heavier body. Several other types occur in Europe and Asia. The African dormice are often given subfamily rank (Graphiurinae), differing from the typical group in having a more primitive attachment of the lateral masseter muscle, and the teeth have only poorly marked cross-crests. *Graphiurus*, a large gray dormouse, is restricted to South Africa. *Claviglis* is smaller, with more rounded skull; it contains a number of species in various parts of Africa south of the Sahara. Subfamily Platycanthomyinae is characterized by cheek teeth $\frac{3}{3}$ in number; the crowns wear flat. The pelage is mixed with flat spines, while the tail is tufted. *Platycanthomys* is found in India and is arboreal. *Typhlomys* of China is apparently fossorial, with reduced eyes; it has a small caecum. Subfamily Seleviniinae contains only the Recent *Selevinia*, described in *1938* from central Asia. It differs from typical dormice in its mouselike tail, vestigial basin-crowned molar teeth and large incisive foramina.

Dipodoidea.—The jerboas and jumping mice (*qq.v.*) are included here. Cranially, they have a large infraorbital canal through which the medial masseter muscle passes, as in the Anomaluridae and Ctenodactylidae. The cheek teeth are typically $\frac{4}{3}$, the first upper one small.

Family Zapodidae. These mouselike rodents differ from the true mice chiefly in the characters of the superfamily. Subfamily Sicistinae, found in Europe and Asia, includes only *Sicista*, the birch mouse. This yellowish-brown rodent is marked by a single black dorsal stripe; it climbs readily, living in birch forest and feeds on seeds. The North American jumping mice (*q.v.*), subfamily Zapodinae, are long-tailed, long-legged rodents, found also in China.

Family Dipodidae includes jumping rodents resembling kangaroo rats but with even longer feet. The three middle metatarsal bones are usually fused into a cannon bone. Cheek teeth are $\frac{4-3}{3}$. The lateral toes are reduced or lost. The bullae are large and the mastoid inflated. *Euchoreutes* of central Asia is type of a sub. family; it is characterized by ungrooved incisor teeth, cheek teeth $\frac{4}{3}$, the zygomatic arch slanting gradually upward to the lachrymal, and enormous ears. *Cardiocranius* and *Salpingotus* of Mongolia and central Asia form a third subfamily characterized by unfused metatarsal bones and less angular zygomatic arch than in the Dipodinae.

Muroidea.—The mice and their allies are characterized by the slitlike infraorbital foramen, through which the medial masseter muscle passes and which is compressed by the development of the zygomatic plate, the flattened area from which part of the lateral masseter arises. The cheek teeth are $\frac{3}{3}$. The cardiac part of the stomach is lined by a cornified layer; the colon forms a spiral loop.

Family Cricetidae is characterized by the upper molars, the cusps of which are arranged in two rows. This pattern is frequently obscured, the cusps wearing down to form zigzag crests. Cricetids, only slightly different from modern types, are known from the Oligocene of America and Asia. Subfamily Cricetinae includes the native American muroids with the exception of the Holarctic voles and their allies. *Cricetus* and several related hamsters (*q.v.*) are found in Europe and Asia; they are heavy-bodied, short-tailed burrowing rodents. *Oryzomys*, found from Patagonia to New Jersey, is represented by numerous species, one group of which extends to the Galapagos Islands. The American harvest mice, *Reithrodontomys*, vary from small to large mice characterized by grooved incisors, while the white-footed or deer mice, *Peromyscus*, with internal cheek pouches, are the dominant North American forms from Alaska to Panamá. *Onychomys*, the grasshopper mouse, resembles the old world hamsters in appearance but lives chiefly on insects and other mice. ***Neotoma***, the pack rat, is quite ratlike in appearance but its teeth are more like the Microtinae in their zigzag pattern. A great variety of tropical American genera are known.

Subfamily Myospalacinae includes a gopherlike genus from Siberia and northern China. The cheek teeth are ever-growing and prismatic,

resembling the Microtinae. Subfamily Nesomyinae includes a few genera from Madagascar. *Nesomys* has teeth much like *Oryzomys. Hypogeomys,* a burrowing form, has prismatic teeth suggestive of those of *Neotoma,* as has also *Macrotarsomys. Eliurus* differs from these in having cross-crested teeth.

Lophiomys, the maned rat of eastern Africa, is given subfamily or even family rank because of its odd skull; the temporal fossa is completely roofed over by bone, the surface of which is granulated; the teeth, however, are cricetid. The tail is bushy. The feet are specialized for an arboreal life, with a partly opposable hallux.

Subfamily Microtinae includes the voles and lemmings (*qq.v.*) found in the northern hemisphere south to Guatemala and Burma. The cheek teeth are high-crowned and prismatic, forming a complex zigzag pattern. The skull is angular, marked with muscle ridges. As a rule, voles are heavy-bodied, short-tailed rodents, more or less modified for burrowing. *Ondatra,* the muskrat (*q.v.*), is the largest of the group, with a long dorso-ventrally flattened tail and partly webbed hind feet. This is connected with the following forms by intermediates like *Arvicola,* the Eurasian water vole, and *Neofiber,* the round-tailed muskrat of Florida. *Microtus,* the voles or meadow mice, are usually small. The lemmings, *Lemnus* and allies, have ever-growing cheek teeth with short lower incisor (the root ending in the lower jaw opposite the molars): they are chiefly arctic and northern forms. A few genera have rooted cheek teeth: *Ellobius* and *Prometheomys,* the subterranean voles of southern and central Asia; *Clethrionomys,* the red-backed bank vole of northern Europe, Asia and America; *Phenacomys,* including the red tree mouse and other North American voles. *Brachytarsomys* of Madagascar shows many similarities to the voles but it has probably developed independently from the primitive Cricetidae, probably the Nesomyinae.

Subfamily Gerbillinae contains a number of jumping rodents, with broad brain case, inflated mastoid and auditory bullae and prismatic cheek teeth, the transverse crests developed from paired cusps both above and below. The upper incisors are grooved in all but a few species. Gerbils (*q.v.*) are widespread in Africa and southern Asia. The typical genus *Gerbillus* occurs in both regions. The mastoids are not highly inflated, nor prominently bulging when the skull is viewed from above. *Tatera* is found throughout the range of the subfamily; it is more ratlike. *Ammodillus,* a dwarf form from Somaliland, lacks a coronoid on the mandible. *Pachyuromys* of North Africa, has extremely inflated bullae and mastoids and a short clublike tail in which fat is stored, while *Desmodzllus* is a fat-tailed gerbil from the deserts of South Africa. *Meriones,* found in Africa and Asia, has molars which are laminated throughout life and rootless. *Psammomys* has high-crowned but rooted molars; it is found in North Africa and Palestine.

Family Spalacidae contains several burrowing rodents of the old world, resembling the American pocket gophers in general appearance but with cheek teeth of a different pattern, and the zygomasseteric structures are derived from a primitive muroid type. *Spalax,* the blind mole rat of southern Europe, Egypt and western Asia, forms a subfamily by itself. Rhizomyinae contains the bamboo rats, *Rhizomys,* of India, China and the Malay region, large rodents with soft, silky gray fur and short tail. The east African mole rats, *Tachyoryctes,* are smaller, about eight inches head and body length, with soft reddish-brown fur.

Family Muridae is an old world group, although some species have accompanied man to almost all parts of the globe. The upper molars have three rows of cusps, which often unite to iorm cross-crests. Subfamily Murinae contain the typical rats and mice, with a few aberrant forms. About 400 species are recognized. *Mus,* the house mouse and closely allied species, is almost world-wide. *Rattus,* containing the well-known black and brown rats and many other species native to Asia and Africa, is especially varied in the Austro-Malayan region; several species have been carried all over the world on ships and even on primitive native boats. The bandicoot rats (*q.v.*), *Nesokia* and *Bandicota,* are burrowers, found from Egypt to China and the Malay region. African giant rats, *Cricetonzys,* measure 30 in. in total length, the tail long with a white tip. The spiny mice, *Acomys,* are widely distributed in east Africa, southwestern Asia, Cyprus and Crete; these are almost as spiny as hedgehogs. The field rats of hirica, *Arvicanthis* and its relatives, are volelike but coarse-haired, some with stripes. Genera oi various relationships have become arboreal, oiten becoming quite similar in appearance. Several shrew rats (*Mycteromys, Echiothrix* and *Melasmothrix),* with long wedge-shaped head and shrewlike appearance, are found in Java, Sumatra and Celebes. The Philippine shrew rat *(Rhynchomys)* has minute cheek teeth and short white incisors; it may feed on insects and worms. Two bushy-tailed rats *(Phlaeonzys* and *Crateromys)* occur in the northern Philippines. The Australian native mice and rats form a varied group, some rabbitiike, others with saltatorial or leaping adaptations. Several giant rats occur in Celebes, New Guinea and the Solomons. heavy-bodied and as large as the African species.

Subfamily Hydromyinae contains the water rats of Australia and New Guinea and several genera in the Philippines. Most species have only two molars, characterized by basined crowns, and the infraorbital foramen is wide. Large feet and the otterlike pelage fit them for a life in the water. Subiamily Dendromurinae contains the African tree mice, characterized by reduced number of cusps on the molars. The tree mice *(Dendromus)* have opposable first toes, often with nails; the yellowish brown upper parts often have a single black stripe. The West African bush mouse *(Prionomys)* is pale chocolate in colour. Spiny tree rats *(Deomys)* from West Africa and the Congo, are remarkable for their long tails. The fat mice (*Steatomys*), widely distributed in Africa, are hamsterlike, short-tailed members, while *Saccostomys* of the savannas is coloured a handsome pale gray and possesses internal cheek pouches. The mouse gerbils of South-West Africa *(Malacotlzrix)* also belong here. Subiamily Otomyinae contains several African swamp rats, resembling large voles but with laminated teeth and long soft fur.

HYSTRICOGNATEII

These rodents are characterized by the angle of the lower jaw, arising from the side of the root of the incisor. Except in the Bathyergidae, the medial masseter muscle passes through the infraorbital foramen, which is large.

Bathyergoidea.—This superfamily includes only the burrowing molerats of south and tropical Africa. The tibia and fibula are fused. *Heliophobius* is remarkable in having $\frac{6}{6}$ cheek teeth, some of which may be deciduous. *Bathyergus* has normal incisors and large claws; the other genera have long-rooted incisors, the upper incisor roots extending to the back of the palate or into the pterygoids. *Georychus* has cheek teeth $\frac{4}{4}$; it is widespread in tropical and southern Africa. *Heterocephalus,* the naked mole-rat of Kenya, Ethiopia and Somaliland, has only $ cheek teeth. The Bathyergidae is represented by two genera in the Oligocene of Mongolia, one of these a large form. The cranial characters of the family were even then well established.

Hystricoidea.—The porcupines (*q.v.*) of both the old and new worlds are included here, although some doubt exists as to their relationships. Quite possibly most of their similarities may be convergence. Both families have a covering of quills and the teeth are complex, wearing flat at an early age.

Family Hystricidae includes the old world porcupines. They are ground-living rodents and their long quills are firmly attached to the skin. *Hystrix* contains the larger forms, two ieet oi more in length, with short tails and inflated skulls, and is found in southern Europe, Africa and southern Asia. *Thecurus* is smaller, with a flattened skull profile and nasals ending opposite the infraorbital canal; it is restricted to Borneo, Sumatra and Palawan, in the Philippines. *Atherurus* is widespread in Africa and Asia, extending south to Sumatra. It is smaller, like a large rat, with a tail about half the length of the body, ending in a brush of hollow quills, each of which resembles a string of flat beads. The long-tailed porcupine (*Trichys*) has short spines and the skull has postorbital processes.

Family Erethizontidae contains the American tree porcupines, characterized by less complex patterns on the cheek teeth, short paroccipital processes on the skull. The hind feet are modified for an arboreal life, the first toe being replaced in function by a movable pad. *Erethizon,* the North American porcupine, is a large, heavy-bodied rodent, the quills of the body nearly hidden by long hairs. *Coeadou,* from South and Central America, is smaller and has a long prehensile tail. *Echinoprocta,* found in Colombia, has a short tail, only a little longer than the foot and not prehensile, but it resembles *Coendou* cranially. *Chaetomys* deserves subfamily rank; its teeth are more simple, the skull has well-developed postorbital processes and the spiny covering is restricted to the head and forelimbs. The tail is long and scaly.

Cavioidea.—The mandible differs from that in the Hystricoidea in that the angle is not distorted laterally. The coronoid is small and a deep groove indicates the insertion of the deep masseter.

Family Caviidae includes the guinea pigs, cavies and capybara (*qq.v.*). The cheek teeth are ever-growing and prismatic. The clavicles are absent, the lateral toes of the hind foot are lost and the tail is much reduced. Subfamily Caviinae is characterized by two- or three-lobed teeth. *Cavia* is represented by a number of South American species related to the well-known guinea pig and rather similar to it. *Kerodon rupestris* of Brazil is characterized by blunt nails on the toes. *Dolichotis,* containing two distinct species, is restricted to Argentina; it is rabbitlike in appearance and habits, especially D. *patagonzca,* the mara.

Several rodent families described from the Santa Cruz Miocene of South America are related to the Caviidae and others are referable to this family.

Subfamily Hydrochoerinae, *Hydrochoerus,* the aquatic capybara, with complicated posterior molars, is found irom Panamá to Paraguay. It is the largest existing rodent, uith a body length of four feet and heavy build Fossil rodents closely allied to the capybara are known irom the Pleistocene of both South and North America.

Family Dinomvidae includes only one living species, with mandible more like that of the Hystricoidea The tail is longer than the broad feet. The skull is broad and porcupinelike; the molars consist of iour transverse alates. The family is known from the Miocene of South America and the West Indies.

Family Heptaxodontidae contains a number of extinct forms of the Pliocene, among them rodents even larger than the capybara.

Family Dasyproctidae includes the pacas and agoutis (*qq.v.*) of tropical America. The agoutis, subfamily Dasyproctinae, are the size of rabbits, with short tail and three toes on the hind foot. The

pacas, subfamily Cuniculinae, have an enormous cheek plate developed from the zygomatic arch. The teeth are lobate, the crowns wearing flat and the lobes becoming enamel lakes. The hind foot has five toes.

Chinchilloidea.—The cheek teeth are ever-growing, consisting of two or three transverse plates. The skull has large bullae and inflated mastoid. The angle of the mandible is narrow and produced posteriorly, while the coronoid is minute. The fibula is small. The lateral toes of the hind foot are vestigial or lost. Only the family Chinchillidae is included here; it has been distinct since the Oligocene and is unknown outside of South America, the plains of Argentina and the Andes from Ecuador south. *Chinchilla lavigera* and *C. brevicauda* are soft-furred rodents, about the size of a large squirrel (*see* CHINCHILLA). Almost equally soft-furred are the rabbit-eared species of *Lagidium*, found from Peru and Chile to southern Argentina.

The larger viscachas *(Lagostomus)* of the Argentine pampas are the size of a hare (head and body 20 in., tail 8 in.), with large head and robust body. They live in colonies like prairie dogs but are nocturnal. The viscacha (*q.v.*) is gray, with blackish and white facial markings and a white stripe on the hind leg.

Octodontoidea.—The zygomasseteric structure resembles that in the Hystricoidea. The cheek teeth usually have an E-pattern, the branches of which may become islands on wear; in some forms there are four branches instead of three.

Family Capromyidae includes two groups. The hutias (*Capromys*) of the Greater Antilles and Venezuela are harsh-haired, robust rodents, with ever-growing cheek teeth of the E-pattern. The coypu or nutria rat (*Myocastor*) is a large beaverlike rodent found from Brazil and Argentina to Chile. *(See* NUTRIA.*)*

Family Octodontidae contains a number of rodents, chiefly Chilean or Argentine in distribution, with simplified kidney-shaped or bilobed cheek teeth. Subfamily Ctenomyinae includes the fossorial tuco tucos *(Ctenomys)*, which resemble burrowing rodents of other groups. The cheek teeth are kidney-shaped. Subfamily Octodontinae contains ratlike or mouselike forms with tufted tails, chiefly found in the southern Andes. *Spalacopus* and *Aconaemys* of this group are fossorial types, resembling *Ctenomys* but with cheek teeth of the figure-eight pattern.

Family Abrocomidae includes only a single Recent genus *Abrocoma*, characterized by ratlike appearance, short hairy tail and inflated bullae. The cheek teeth are ever-growing, prismatic, the upper ones like a distorted figure eight, the lower ones somewhat E-shaped, with a single re-entrant angle on the cheek side. The incisive foramina are large.

Family Echimyidae contains many rodents of ratlike appearance, with pelage coarse or spiny and rooted cheek teeth. These have a distorted E-pattern, both above and below, wearing down to produce transverse enamel islands. Subfamily Echimyinae includes genera with narrow cheek teeth. Subfamily Dactylomyinae is characterized by broad upper cheek teeth with four lateral lobes and by soft fur. The third and fourth digits of the feet are usually elongated.

Family Thryonomyidae is represented by the cane rats of Africa, *Thryonomys*. The incisors are broad and powerful, the upper ones three-grooved. The cheek teeth show a modified E-pattern.

Family Petromyidae. The rock rat of South-West Africa *(Petromys)* resembles a large, bushy-tailed rat. The cheek teeth have a distorted eight-pattern.

SUBORDER DUPLICIDENTATA

Two pairs of upper incisors are present, the second pair small and situated behind the first; the enamel extends completely around the Incisors. This group is often considered a distinct order, the Lagomorpha.

Family Ochotonidae includes the pikas or mouse hares; these have no external tail, the ears are short and the hind legs not modified for leaping. Pikas (*q.v.*) are widely distributed from southeastern Europe through Asia to western North America.

Family Leporidae contains the hares and rabbits (*qq.v.*); the hind limbs are elongated, the tail short and recurved and the ears are long. The cheek teeth number $\frac{6}{5}$. *Lepus*, the hare genus, occurs throughout the northern hemisphere and in Africa, represented by numerous species. *Caprolagus* of Assam and adjacent areas has harsh pelage, a brown tail and ears shorter than the head. *Nesolagus* of Sumatra is striped with black, while the rump is mahogany brown. *Pentalagus*, found in the Liu Kiu Islands, has only five upper cheek teeth; it has a black dorsal stripe. *Romerolagus*, which occurs in high mountains of southern Mexico, is tailless and is otherwise primitive. The cottontails (*q.v.*) of North and South America, *Sylvilagus*, have short ears but dig little. The red hares of South Africa (*Pronolagus*) are heavily built types with brown or red tails. The true rabbit, *Oryctolagus*, originally distributed over North Africa and southern Europe, is distinguished from *Lepus* by its short ears and limbs, its digging habits and the young, which are born blind and helpless.

(J. E. HL.)

RODEO, a series of cowboy contests deriving from the days of the early cattle industry of the southwestern plains of the United States nhen men, forced to spend months and even years on the range, would gather together in the "cowtowns" at the end of the trails and vie for the unofficial title of best bucking horse rider, roper, etc., the contests being accompanied by heavy betting. As the cowboy was curtailed in scope by the railroads and fencing, the contests became regular, formal programs of entertainment.

Many western towns and areas claim the distinction of being the first place to hold a rodeo in the United States, among them Cheyenne, Wyo., in 1872 and Winfield, Kan., in 1882, but at best such early contests were merely exhibitions of riding and roping skill and not the highly organized shows that modern rodeo became. Denver, Colo., is traditionally accepted as the birthplace of paid spectator rodeo, Oct. 1887.

Formerly, as now, various titles were given to these shows, such as stampede, frontier day, roundup or fiesta. The word rodeo, which is of Spanish origin, did not come into general use until the 1920s. Originally an outdoor sport, rodeo moved indoors in 1917 at the Stockyards coliseum in Fort Worth, Tex., thus becoming a year-round sport with a season extending from the second week in January until the end of December.

Both professional and amateur rodeo programs are built around the five standard events: saddle bronc riding, bareback riding, calf roping, bull riding and steer wrestling. Other events such as team roping, steer roping, steer decorating, wild cow milking, barrel bending and a variety of races are added as facilities and funds permit. The specialty numbers. such as trick riding, fancy roping and the dog. horse and steer acts (known as contract acts) are held simultaneously or spaced in the program to permit officials to prepare'chutes. equipment, etc., for following contests. Integral parts of every rodeo are the queen and clown, the latter serving a useful purpose in distracting the attention of the contest animals while the dismounted or thrown rider has a chance to leave the arena. Other features such as mounted quadrilles and allied western classes may be presented, and often a popular motion-picture or television star entertains.

Organized on Nov. 1, 1936, and originally called the Cowboy's Turtle association, the Rodeo Cowboy's association (R.C.A.) raised the standards of rodeo. The R.C.A. represents the contestants' interests and regulates their personal behaviour and the types of shows to be entered, provides insurance for contestants and establishes a system of fines and black lists to regulate managers' and contestants' activities. In 1929 the Rodeo Association of America, an organization of rodeo managers and producers, was founded to standardize events, rules, judging and arena conditions and to nork out common problems pertaining to the production of professional rodeos. In 1946 the group was renamed the International Rodeo association (I.R.A.). In 1959 the I.R.A. was renamed International Rodeo Management, Inc. (I.R.M.I.). The R.C A. established its own point award system, naming an all-around champion and champions in the five standard events, team roping and steer roping each year.

Rodeo contestants originally were the working cowhands of the west; today they come from all parts of the country. This highly specialized field demands a great degree of skill and stamina of the professional contestants, who may compete in as many as 80 rodeos during the year; participation does not guarantee a living. since events to be remunerative must be won, and the contestant is continually faced with the hazards of accidents and injury.

Rodeo stock is valuable, and the horses and bulls are well cared for to the point of being pampered. Good bucking horses are not from wild herds or killers but are usually halterbroken and gentle until mounted. They are encouraged in their dislike of being mounted and further annoyed by the flank strap, which is placed around the hind quarters; any foreign object on the rear of a horse has a tendency to make him buck.

After the end of World War II, rodeo became an important amateur sport among small saddle clubs, high schools, colleges and even prisons in the United States. This resulted in formation of the National High School and National Intercollegiate Rodeo association and the American Junior Rodeo association. Rodeo

spread to other parts of the world, becoming especially popular in Canada and Australia. (L. SR.; E. W. Co.)

RODERICK or RUADRI (d. 1198), king of Connaught and high king of Ireland, was the son of Turlough (Tordelbach) O'Connor, king of Connaught, who had obtained the overkingship in 1151, but had lost it again in 1154 through the rise of Muirchertach O'Lochlainn in Ulster. Roderick succeeded to Connaught in 1156, and after ten years' fighting won back the title of high king. His ill-advised persecution of Dermot (Diarmait MacMurchada), king of Leinster, furnished the pretext for the Anglo-Norman invasion of Ireland. Roderick endeavoured to expel the invaders, but was driven behind the Shannon. He delayed his submission to Henry II until 1175, when a treaty was concluded at Windsor. Roderick, under this agreement, held Connaught as the vassal of England, and exercised lordship over all the native kings and chiefs of Ireland; in return he undertook to pay an annual tribute. The treaty did not put an end to the wars of the Norman adventurers against Connaught and Roderick's dependents.

He held out till 1191, but then, weary of strife, retired to the cloister. He died in 1198, the last of the high kings of Ireland.

RODEZ, a town of southern France, capital of the *département* of Aveyron, 51 mi. N.N.E. of Albi by rail. Pop. (1954) 17.136. Rodez, *Segodunum* under the Gauls. *Ruthena* under the Romans, was the capital of the *Rutheni,* a tribe allied to the Arverni, and was afterward the chief town in the district of Rouergue. In the 4th century it became Christian, and St. Amans, its first bishop, was elected in 401. In the middle ages the bishops held temporal power in the "cite," and the counts in the "bourg." The Albigenses were defeated near Rodez in 1210. The countship of Rodez, detached from that of Rouergue at the end of the 11th century, belonged first to the viscounts of Carlat, and from the early 14th century to the counts of Armagnac. From 1360 to 1368 the English held the town. After the confiscation of the estates of the Armagnacs in 1475 the countship passed to the dukes of Alençon and then to the D'Albrets. Henry IV finally annexed it to the crown of France. Rodez is situated on the southern border of the Causse of Rodez, on an isolated plateau bordered on the east and south by the Aveyron river. The cathedral (1277–1535) has a great Flamboyant rose window in the principal facade, which is flanked by two square towers and has no portal. Each transept has a fine Gothic doorway. On the north side of the building rises a 16th century tower. The episcopal palace (17th and 19th centuries) is flanked by a massive tower, relic of an older palace.

The industries include wool spinning, and the weaving of woolen goods.

RODGERS, JOHN (1773–1838), U.S. naval officer, one of a family noted for its naval officers, was born in 1773 on a farm in Harford county, Md., the son of a Scottish immigrant, Col. John Rodgers. After service from an early age on merchant ships, John Rodgers entered the U.S. navy when it was organized in 1798. He was second in command to Commodore Samuel Barron (1763–1810) in the expedition against the Barbary pirates and succeeded him in the command in 1805, in the same year bringing both Tunis and Tripoli to terms.

In 1811 Rodgers was in command as commodore of the U.S. frigate "President" off Annapolis when he heard that a U.S. seaman had been '(pressed" by a British frigate off Sandy Hook. Commodore Rodgers was ordered to sea "to protect American commerce." On May 16, 1811, he sighted and followed the British sloop "Little Belt." and after some hailing and counter-hailing. of which very different versions were given by both sides, a gun was fired. Each side accused the other of aggression, and an action ensued in which the "Little Belt" was cut to pieces.

The action was one of the incidents leading up to the War of 1812. A U.S. court of inquiry later confirmed Rodgers' version of the encounter, and he was acclaimed by the United States government for his conduct. When hostilities broke out, Rodgers commanded a squadron and was wounded by the bursting of one of his guns while pursuing the British frigate "Belvidera." He was subsequently president of the board of navy commissioners, 1815–24 and 1827–37. He died in Philadelphia, Pa., on Aug. 1, 1838.

His brother GEORGE WASHINGTON RODGERS (1787–1832) served in the War of 1812 and in the war with Algiers (1815). He was commander of the "Peacock" in the Mediterranean squadron from 1816 until 1819.

Rear Admiral JOHN RODGERS (1812–1882), a son of Commodore John Rodgers. served in the Union navy during the Civil War and from 1877 to 1882 was superintendent of the Naval observatory at Washington, D.C.

G. W. Rodgers had two sons who were naval officers, CHRISTOPHER RAYMOND PERRY RODGERS (1819–1892) and GEORGE WASHINGTON RODGERS (1822–1863). The former served as commandant of midshipmen at the U.S. naval academy, 1860–61, and as superintendent. 1874–78. The latter succeeded his brother as commandant of midshipmen in Sept. 1861, but the following year he went on active duty with the West India squadron. He was killed on Aug. 17, 1863, while attacking Charleston. S.C., as commander of the "Catskill."

RODGERS, RICHARD (1902–), U.S. composer who, with Lorenz Hart (1895–1943) and Oscar Hammerstein II (1895–1960), was responsible for some of the most popular U S. musical comedies from the mid-1920s. Born in New York city on June 28, 1902. Rodgers began writing show tunes about 1925. Among his more successful scores were those for *Connecticut Yankee* (1927); *Present Arms* (1928); *Jumbo* (1935); *On Your Toes* (1936); *Babes in Arms* (1937); *The Boys From Syracuse* (1938); *Pal Joey* (1940); *Carousel* (1945); *The King and I* (1951); *Flower Drum Song* (1958); and *Sound of Music* (1959). *Oklahoma* (1943) and *South Pacific* (1949) were awarded Pulitzer prizes.

RODIN, (FRANÇOIS) AUGUSTE (RENÉ) (1840–1917), French sculptor, was born in Paris on Nov. 12, 1840. From 1854 to 1857 he was a pupil at the Petite École de dessin (later renamed École des Arts Decoratifsj; then, having been refused admission to the École des Beaux-Arts, he began to earn his living as an ornament maker and became an assistant to the sculptor A. E. Carrier-Belleuse. His "Man With a Broken Nose" (1864), which was rejected by the Salon, early revealed his ability. In 1871 he was in Brussels, working for Carrier-Belleuse on the "Caryatides" of the new Bourse and also undertaking a certain amount of work on his own account. In 1875 he visited Florence and Rome, where he was much impressed by the works of Donatello and Michelangelo.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART GIFT OF THOMAS F RYAN 1910

"THE THINKER" BY AUGUSTE RODIN. IN THE METROPOLITAN MUSEUM OF ART NEW YORK

Rodin's plaster maquette of "The Bronze Age," exhibited in the Salon of 1877, attracted considerable attention; the modeling, indeed, was so fine as to give rise to the accusation of its having been cast from a living man. In 1880. however, when he exhibited his "John the Baptist Preaching" and the final bronze of "The Bronze Age," Rodin silenced his critics and established his position in the world of sculpture. Thenceforward. he was to receive commission after commission; and the first of them was from the French government, which ordered a door for the Musée des Arts Decoratifs, with a series of bas-reliefs representing scenes from Dante's *Divine Comedy.*

Rodin worked on this commission for the rest of his life. His original idea was to divide the door into panels, as Ghiberti had divided his "Gate of Paradise" for the baptistery in Florence. One panel was to represent Paolo and Francesca; another was to show Ugolino devouring his children; and the upper part of the door was to contain a seated figure of Dante himself (eventually entitled "The Thinker"). However, his old friend Alphonse Legros

then invited Rodin to London (1881–82), and there Rodin made a close study of the illustrations of Dante by John Flaxman and William Blake; thereafter, he abandoned architectural considerations entirely and no longer followed Dante's text. The project underwent many changes, and Rodin's studio was filled with works begun as components of the door and then set aside. The plaster maquette of "The Gate of Hell" (1917), which was finally cast in bronze in **1938,** constitutes the last version of the project that Rodin left, but there is no doubt that he would have worked still longer on it had he lived. He died at Meudon on Nov. **17,** 1917.

"The Gate of Hell" does, in fact, show Ugolino, Paolo and Francesca among swirling processions of damned souls; and "The Thinker" occupies the lintel. However, a number of other works which are now quite separate from "The Gate" were originally conceived also as subsidiary themes for it. These include "Adam" (1880), "Eve" **(1881),** "The Fair Armouress" (François Villon's Belle Heaulmière, **1885)** and "The Prodigal Son" **(1889).** Even "The Kiss" (1886), often regarded as Rodin's masterpiece, was originally conceived to form part of "The Gate" as a figure of Faith.

Other sculptures commissioned from Rodin were "The Burghers of Calais," "Victor Hugo" and "Balzac." The first of these, uhich was not set up in Calais until **1896,** is based on Jean Froissart's account of the famous incident and shows the burghers going barefoot, with nooses round their necks, to deliver the keys of Calais to the king of England. (There is a replica of this on the embankment at Westminster.)

The "Victor Hugo" was commissioned by the state for the Panthéon in **1889,** but the first maquette (1890), which showed the poet seated with the upper part of his body naked, proved to be unacceptable. Rodin eventually produced a standing version, which mas set up in the garden of the Palais Royal in 1909 but withdrawn afterward. The "Balzac" was commissioned by the Société des Gens de Lettres in **1891.** The maquette, sent to the Salon in **1898,** consisted of a block nearly ten feet high, with the subject's head emerging from the folds of a voluminous dressing gown. This provoked an indignant outcry, but the bronze cast of it was eventually set up on the Boulevard Raspail in 1939. Meanwhile, Rodin was producing other sculptures, including "Thought" **(1886)** and a series of portrait busts. The latter may be counted among his finest achievements; they comprise "Dalou" (1883), "Victor Hugo" (1883), "Rochefort" **(1884);** "W. E. Henley" (1884), "Octave Mirbeau" (1889), "Puvis de Chavannes" (1891), "Gustave Geffroy" (1905), "Clemenceau" **(1911)** and "Pope Benedict XV" (1915).

In 1900, Rodin's reputation stood so high that he could envisage a special exhibition of his work as a feature of the Paris universal exhibition. Altogether **168** examples were assembled, and an unprecedented success was achieved. The sculptor received the homage of Europe. Among Rodin's later works. mention must be made of the series of "Hands." in which hands are made to exemplify some literary or moral idea. This theme may perhaps be traced back to **1898,** when he produced "The Hand of God" as an image of creativity. "The Hand of the Devil," holding a woman, appeared in 1903, "The Secret," or "Prayer," in 1910 and "The Hand Coming Out of the Tomb" in 1910 also. At the same time, Rodin turned toward literature; his conversations on art were collected by Paul Gsell and published as *L'Art* in 1910 (Eng. trans., Art, **1912);** and his book, *Les Cathédrales de France,* appeared in 1914.

From 1908, Rodin was living in the former Hôtel Biron, where the state had provided accommodation for a number of artists and writers. There, Rainer Maria Rilke, a close friend of Rodin's, suggested that they should establish themselves together, and Rodin thereupon offered to bequeathe all the works of his own that remained in his possession, all his collections and his villa at Meudon to the French state, on condition that he be allowed to spend the rest of his life in the Hôtel Biron and that on his death the building be converted into a Rodin museum. The hotel and the villa now constitute the two sections of the Musée Rodin, which contains most of Rodin's sculpture, his drawings, some paintings, his library and his art collections.

Numerous replicas of Rodin's sculptures can be seen in museums outside France. The Rodin museum in Philadelphia, inaugurated in 1929, is an architectural copy of the villa at Meudon.

RODNEY, GEORGE BRYDGES RODNEY, BARON (1718–1792), English admiral. who won the important battle against French forces off Dominica in 1782, was born in Feb. 1718. George was sent to Harrow, being appointed, on leaving, by warrant dated June **21,** 1732, a volunteer on board the "Sunderland." While serving on the Mediterranean station he was made lieutenant (1739) on the "Dolphin." In 1742 he attained the rank of post captain, having been appointed to the "Plymouth." After serving in home waters, he obtained command of the "Eagle" (60 guns), and in this ship took part in Hawke's victory off Ushant (Oct. **14, 1747)** over the French fleet. On that day Rodney gained his first laurels for gallantry, under a chief to whom he was in a measure indebted for subsequent success. In 1749 he was appointed governor and commander in chief of Newfoundland, with the rank of commodore, it being usual at that time to appoint a naval officer, chiefly on account of the fishery interests. He was elected M.P. for Saltash in 1751.

During the Seven Years' War Rodney rendered important services. In 1757 he had a share in the expedition against Rochefort, commanding the "Dublin" **(74).** Next year, in the same ship. he served under Boscawen at the taking of Louisburg (Cape Breton). In 1759 and again in **1760** he inflicted great loss on the French transports collected on the Normandy coast for an attack on Great Britain. Elected M.P. for Penryn in **1761,** he was in October of that year appointed commander in chief of the Leeward Islands station, and within the first three months of 1762 had reduced the important island of Martinique, while both St. Lucia and Grenada had surrendered to his squadron. At the peace of **1763** Admiral Rodney returned home, having been during his absence made vice-admiral of the blue and having received the thanks of both houses of parliament. In **1764** Rodney was created a baronet. From 1765 to 1770 he was governor of Greenwich hospital. In 1771 he was appointed rear admiral of Great Britain, and in **1778** admiral of the white. From 1771 to 1774 he held the Jamaica command, and during a period of quiet was active in improving the naval yards on his station. Election expenses and losses at play in fashionable circles had shattered his fortune; he could not secure payment of the salary as rear admiral of Great Britain; and he lived for some time in Paris until the generosity of a friend enabled him to meet his debts.

Sir George was appointed once more commander in chief of the Leeward Islands late in 1779. His orders were to relieve Gibraltar on his way to the West Indies. He captured a Spanish convoy off Cape Finisterre on Jan. **8,** 1780, and eight days later defeated the Spanish admiral Don Juan de Langara off Cape St. Vincent, taking or destroying seven ships. On April **17** an action, which, as a result of the carelessness of some of Rodney's captains, was indecisive. was fought off Martinique with the French admiral Guichen. Rodney, acting under orders, captured the valuable Dutch island of St. Eustatius on Feb. **3, 1781.** It had been a great entrepôt of neutral trade, and was full of booty. which Rodney confiscated. As large quantities belonged to English merchants, he was entangled in a series of costly lawsuits.

After a few months in England, recruiting his health and defending himself in parliament, Rodney returned to his command in Feb. **1782,** and a running engagement with the French fleet on April **9** led up to his crowning victory off Dominica, when with **35** sail of the line he defeated the comte de Grasse, who had 33 sail (April **12).** The French inferiority in numbers was counter-

balanced by the greater size and superior sailing qualities of their ships, yet five were taken and one sunk after 11 hours' fighting. This important battle for Jamaica was a blow to French naval prestige, and it enabled Rodney to write: "Within two little years I have taken two Spanish, one French and one Dutch admiral."

On his return to England Rodney received a barony and a pension of £2,000 a year. From this time he led a quiet country life till his death (May 24. 1792), in London.

Rodney was unquestionably an able officer, but he was also vain, selfish and unscrupulous, both in seeking prize money and in using his position to push the fortunes of his family. He made his son a post captain at 15. for example. He was accused by his second-in-command. Samuel Hood. of sacrificing the interest of the service to his own profit, and of showing want of energy in pursuit of the French on April 12, 1782. It must be remembered that he was then prematurely old and racked by disease.

See Sir George Mundy, *Life and Correspondence of Admiral Lord Rodney* (2 vol., 1830); Rodney letters in 9th *Report* of Hist. manuscripts Corn., pt. iii; "Memoirs," in *Naval Chronicle,* i, 353–393 (1799); and J. Charnock, *Biographia Navalis,* v. 204–228 (1794–98).

RODÓ, JOSÉ ENRIQUE (1872–1917), Uruguayan philosopher, author and politician, was born in Montevideo on July 15, 1872. He was educated in a free lay school and at the University of Montevideo, where he showed extraordinary aptitude ior history, literature and philosophy. In 1895 he was one of the founders of the *National Review of Literature and Social Sciences,* in which, in the following year, he published an essay on literary criticism, "El que vendrá." which brought him immediate recognition as a writer and critic. In 1898 he was made professor of literature in the university and two years later was appointed director of the National library, but in 1901 he gave up both positions to enter congress, to which he was elected in 1902 and 1908 and where he took an earnest part in initiating social legislation; he was not, however, a radical, and in a pamphlet. *Liberalismo y jacobismo* (1907), he strenuously opposed government antichurch legislation. In 1910 he represented Uruguay at the centenary of Chilean independence. Rodó's influence. however, as a rallying point of Latin-American youth was due to his authority as exponent of optimism. as stylist and as advocate of unity in Spanish-American literature and culture. His first important philosophical work. *Ariel,* based on Renan's eclecticism, appeared in 1900 in defense of Latin-American culture against the utilitarianism of the United States. In 1909 he published *Motivos de Proteo,* an assertion of the inevitability of change and the possibility of self-improvement, which represents Rodó's highest attainment as thinker and master of the Spanish language, and caused him to be hailed by Spanish-Americans as their philosopher par *excellence.* His essays on Rubén Dario (1899), Bolivar and Montalvo won him a similarly unique place in Spanish-American letters. to which, in those on. Bolivar and Montalvo, included in El *Mirador de Próspero* (1913), he gave models of historical and critical essays. He died at Palermo in May 1917.

RODOSTO: *see* TEKIRDAG.

RODRIGUEZ (officially RODRIGUES), an island in the Indian ocean in 19° 41′ S., 63° 23′ E.; a dependency of the British colony of Mauritius, from which it is 350 mi. distant. It has a length from east to west of 9½ mi., a width of 4½ mi. and an area of 40 sq.mi. It is surrounded by a fringing reef of coral, studded with islets. This reef. only 100 yd. wide on the east. extends 3 mi. west, and both north and south forms a flat area partly dry at low water. Two passages through the reef are available for large vessels—these passages leading respectively to Port Mathurin on the north coast and to Port South East. The island is a mass of volcanic rock. rnainly a doleritic lava, rich in olivine. The land is hilly and the main ridge rises abruptly on the east, but more gradually on the west, where there is a wide plain of coral limestone, studded with caves. Of several peaks on the main ricige the highest is Mt. Limon (1,300 ft.). The ridge is deeply cut by ravines, the upper parts of which show successive belts of lava separated by thin beds of ashes, agglomerate and ochre-coloured clays. In places the cliffs rise 300 ft. and exhibit 12 distinct lava flows. The climate is like that of Mauritius, but Rodriguez is more subject than Mauritius to cyclones during the northwest monsoon (November to April).

Flora and Fauna.—When discovered, Rodriguez was clothed with fine timber trees; but goats, cattle and bush fires combined to destroy the greater bulk, and indigenous plants in many cases were ousted by intrusive foreigners. Parts are still well wooded, and elsewhere there is excellent pasturage. The sweet potato, manioc, maize, millet, sugar cane, cotton, coffee, rice and tobacco are cultivated. Wheat is seldom seen, but Sieva beans (*Phaseolus lunatus*), lentils, gram (*Cicer arietinum*), dhal (*Cajanus indicus*) and peanuts are all grown. Mangoes, bananas, guavas, pineapples, custard apples, and especially oranges, citrons and limes flourish.

At present the only indigenous mammal is a species of fruit-eating bat (*Pteropus rodericensis*), and the introduced species are familiar creatures such as deer, pig, rabbit, rat, mouse, etc. Until recently there occurred a large land tortoise (*Testudo vosmaeri*). The island's limestone caves have yielded a large number of skeletons of the now extinct bird, the solitaire (*Pezophaps solitarius*). Of indigenous birds 13 species have been registered. The guinea fowl (introduced) has become exceedingly abundant, partly owing to a protective game law; and a francolin (*Francolinus ponticerianus*) is also common. The marine fish-fauna does not differ from that of Mauritius, and the fresh-water species, with the exception of *Mugil rodericensis* and *Myxus caecuticus,* are common to all the Mascarenes. The insects comprise at least 60 species of Coleoptera, 1j Hymenoptera. 21 Lepidoptera, 1j Orthoptera, and 20 Hemiptera. Forty-nine species of coral have been collected, showing a close affinity to those of Mauritius, Madagascar and the Seychelles.

History.—Rodriguez or Diego Ruy's island was discovered by the Portuguese in 1645. In 1690 the Dutch government sent a body of French Huguenots under François Leguat to the Island of Bourbon. but they, finding the French authorities in possession, proceeded to Rodriguez where eight of their number were landed on April 30, 1691, with a promise that they should be visited within two years. Though the two years passed without misadventure, the colonists, instead of awaiting the arrival of their friends, left the island on May 8. 1693, and made their way to Mauritius, where they were treated with great cruelty by the governor. From the Dutch the island passed to the French, who colonized it from Mauritius. Large estates were cultivated and the islanders enjoyed considerable prosperity. In 1809–10 Rodriguez was seized by the British, in whose possession it has since remained. The abolition of slavery proved disastrous to the prosperity of the island and in 1843 the population had declined to about 250. Thereafter there mas a gradual recovery in the economic condition and a steady increase in population.

Population.—By 1956 there were 16,535 inhabitants, most of them fishermen and small cultivators, and mainly of African origin, being descendants of slaves introduced by the French, and Negro immigrants direct from Africa. There are a few families of European descent and a small colony of Indians and Chinese. The bulk of the people are French-speaking and Roman Catholic. There are two small settlements. Port Mathurin, the capital, and Gabriel, in the centre of the island.

Administration.—The island is under the charge of a civil commissioner aided by officers of the police, health and agricultural departments of Mauritius. The civil commissioner, a magistrate, administers justice. (W. H. Is.)

RODZIANKO, MIKHAIE VLADIMIROVITCH (1859–1923), Russian politician. was born in 1859, of a family of great landowners. In 1906 and 1907 he was a member of the council of the empire for the zemstvo of the province of Ekaterinoslav He was a member of the third and fourth dumas. He joined the right wing of the Octobrist (moderate Liberal party) and with the support of the conservatives was elected president of the third duma. As president of the fourth duma he took part in the struggle for constitutional changes in the government opposing the re-

actionary policy of the government and defending the rights of the duma. At the revolution, he sent a telegram to the tsar, urging his abdication. After the revolution he emigrated to Yugoslavia, where he died on Jan. 24, 1923.

RODZINSKI, ARTUR (1894–1958), U.S. conductor, was born at Split (Spalato), in the former kingdom of Dalmatia (Yugoslavia), on Jan. 2, 1894. After World War I he became a choral director and opera conductor in Lwów (Lvov), Pol., and later conducted opera and the Philharmonic orchestra in Warsaw. He became a U.S. citizen in 1933, served as assistant to Leopold Stokowski, conductor of the Philadelphia orchestra, from 1926 to 1929, and later conducted the orchestras of Los Angeles, Cleveland, New York and Chicago: He died on Nov. 27, 1958, in Boston, Mass.

ROE, later changed by deed poll to VERDON-ROE the name of two English brothers who were aviation pioneers.

SIR (EDWIN) ALLIOTT VERDON-ROE (1877–1958), British aircraft designer, the first Englishman to construct and fly his own airpiane. He was born at Patricroft, near Manchester, Eng., on April 26, 1877, and educated at St. Paul's school, London. He went to British Columbia at the age of 14, but returned a year later and served a five-year apprenticeship at the Lancashire and Yorkshire Railway's locomotive shops. He then spent two years at sea, after which he entered the motor industry. On June 8, 1908, he flew a distance of 75 ft in a biplane of his own design with a 24 h.p. Antoinette engine, nearly a year before the first officially recognized flight in England (by J. T. C. Moore-Brabazon, later Lord Brabazon of Tara, in 1909). He founded the aviation firm of A. V. Roe and Co., Ltd.. with his brother, Humphrey, in 1910. Avro aircraft were used with great success in World War I and Avro 504N airplanes were the standard training aircraft for the Royal Air Force for a long period between World Wars I and II Verdon-Roe later turned his attention to the design of flying boats, founding Saunders-Roe, Ltd.. of Cowes, Isle of Wight. Knighted in 1929, he died on Jan. 4, 1958.

HUMPHREY VERDON-ROE (1878–1949) was born at Patricroft, near Manchester, Eng., on April 18, 1878. Commissioned in the Manchester regiment, he served in the South African War, retiring from the army soon afterward. He joined the firm of Everard and Co., webbing manufacturers in Manchester, and when his elder brother, Alliott, founded the firm of A, V. Roe and Co., he cooperated with him. He was not a pilot, but flew much as a passenger and in 1917 joined the royal flying corps as an observer. In 1918, he married Marie Carmichael Stopes and with her founded the first birth control clinic, at Holloway, London, in 1921. He died in London on July 25, 1949. (D. CR.)

ROE, SIR THOMAS (*c.* 1581–1644), English diplomatist, was born at Low Leyton, Essex, and was educated at Magdalen college, Oxford. He was appointed esquire of the body to Queen Elizabeth I, was knighted in 1605 and in 1610 was sent by Henry, prince of Wales, to the West Indies and South America to discover gold. Elected M.P. for Tamworth (1614) and Cirencester (1621), his reputation was secured by his successful mission (1615–19) to the court of the great mogul, Jahangir, at Agra, where he obtained protection for an English factory at Surat. Appointed ambassador to the Ottoman Porte in 1621, Roe secured further privileges for English merchants, concluded a treaty with Algiers in 1624 and gained support from Transylvanian prince Gabriel Bethlen for the European Protestant alliance and the Palatinate cause.

Through his friendship with the patriarch of the Greek church the *Codex Alexandrinus* was presented to James I, and Roe himself collected several valuable manuscripts, which he gave to the Bodleian library. In 1629 he mediated successfully between the kings of Sweden and Poland and in 1630 negotiated treaties with Danzig and Denmark. In 1637 he was appointed chancellor of the order of the Garter. Subsequently he took part in the peace conferences at Hamburg, Kegensburg and Vienna. In June 1640 he aas made a privy councillor and in October he became member of parliament for the University of Oxford. He died on Nov. 6, 1644.

His *Journal* of the mission to the Mogul was re-edited for the Hakluyt society, 2 vol (1899). Of his correspondence, *Negotiations in His Embassy to the Ottoman Porte (1621–28)*, vol. i, was published in 1740, but the work was not continued. Letters relating to his mission to Gustavus Adolphus (1629–30) were edited by S. R. Gardiner for the Camden Society Miscellany, vol. vii (1875), and his correspondence with Lord Carew in 1615 and 1617 by Sir John Maclean for the same society in 1860. Roe published a *True and Faithful Relation . . . Concerning the Death of Sultan Osman . . . 1622;* a translation from the anonymous work once attributed to Paolo Sarpi, A *Discourse Upon the Reasons of the Resolution Taken in the Valteline . . .* (1628); and in 1614 T, Wright published *Quatuor Colloquia,* consisting of theological disputations between himself and Roe. Several of his speeches, chiefly on currency and financial questions, were also published.

Two other works are mentioned by Anthony a Wood: *Compendious Relation of the Proceedings . . . of the Imperial Dyet Held at Ratisbon in 1640 and 1641* and *Journal of Several Proceedings of the Knights of the Order of the Garter.*

ROEBLING, JOHN AUGUSTUS (1806–1869), U.S. civil engineer, designer of many great suspension bridges, among which the Brooklyn bridge is the most famous, mas born at Mühlhausen, Prussia, on June 12, 1806. Soon after his graduation from the polytechnic school at Berlin he moved to the United States, and in 1831 began to practise his profession in western Pennsylvania. He established near Pittsburgh, Pa., a wire rope factory, and in May 1845 completed his first important structure, a suspended aqueduct across the Allegheny river. This was followed by the Monongahela suspension bridge at Pittsburgh and several suspended aqueducts on the Delaware and Hudson canal. Moving his wire factory to Trenton, N.J., he began in 1851 the erection at Niagara falls of a long-span wire suspension bridge with double roadway. for railway and vehicular use *(see* BRIDGES), which was completed in 1855. Because of the novelty of its design, the most eminent engineers regarded this bridge as foredoomed to failure; but, with its complete success, demonstrated by long use. the number of suspension bridges rapidly multiplied, the use of nire ropes instead of chain cables becoming virtually universal.

The completion, in 1867, of the still more remarkable suspension bridge over the Ohio river at Cincinneti, O., with a clear span of 1,057 ft., added to Roebling's reputation, and his design for the great bridge spanning the East river between Manhattan and Brooklyn, New York city, was accepted, While personally engaged in laying out the towers for the bridge, Roebling received an accidental injury, which resulted in his death, at Brooklyn, from tetanus, on July 22, 1869. The bridge was completed under the direction of his son, Washington Augustus Roebling (1837–1926).

See H. Schuyler, *The Roeblings; A Century of Engineers, Bridgebuilders and Industrialists (1931)*; D. B. Steinman, *The Builders of the Bridge* (1945).

ROEBOURNE, a settlement of the northwest division of Western Australia, 8 mi. from the northwest coast, 920 mi. N. of Perth. It is a centre for the West Pilbara Goldfield district. There were extensive pearl fisheries off its port at Cossack bay. Pop. (1954) 463.

ROEBUCK, JOHN ARTHUR (1801–1879), English politician, was born at Madras, India, on Dec. 28, 1801, and was brought up in Canada. He returned to England in 1824 and was called to the English bar in 1831. He became M.P. for Bath in 1832. In his youth he was strongly influenced by Benthamite ideas and was a close personal friend of John Stuart Mill. He was an original member of the Reform club in 1836, and in 1838 appeared at the bar of the house of commons to protest, in the name of the Canadian assembly, against the suspension of the Canadian constitution. Roebuck was out of parliament from 1837 to 1841, but on his return he spoke eloquently in favour of many of the Chartist claims. He opposed Sir Robert Peel's income tax of 1842 and frequently scted as a radical spokesman. At the general eiection of 1847 Roebuck lost his seat, but two years later he was returned for Sheffield. He became a vigorous advocate of a firm and active foreign policy. In 1850 he strongly supported Lord Palmerston, and in 1855, dissatisfied with Lord Aberdeen's conduct of the Crimean War, he moved for a committee of inquiry. When Aberdeen's government tried to resist Roebuck's motion, the government was defeated and Aberdeen resigned. In later life,

his radicalism faded and he became a bitter critic of trade unions and Gladstonian liberalism, although he continued to support administrative reform. In 1877 he was a supporter of Lord Beaconsfield's policy. and in 1878 he nas made a privy councilor. He died in London on Nov. 30, 1879.

Sre R E Leader, *Life* (London, 1897). (*A.* BRL.)

ROEBUCK, the smallest European deer (a full-grown buck standing 27 in. at the shoulder), the typical representative of a genus *(Capreolus)* in which the antlers lack a brow tine and belong to the forked type, while the tail is rudimentary *(see* DEER). The antlers are short, upright, and deeply furrowed, the beam forking at about t o-thirds of its length and the upper prong again dividing, thus making three points. The coat in summer is foxy red above and white below; in winter this changes to a grayish fawn, with a white rump patch. The roebuck or roedeer (C. *capreolus*) inhabits southern and temperate Europe and Asia, represented by various races in Sweden. Scotland, Armenia. Spain and parts of Asia. They frequent woods, preferring those that have underwood and are in the neighbourhood of cultivated ground where they visit in the evening in search of food. Before pairing, the bucks pursue the does round specially trodden circular or octagonal runs. Pairing takes place in August, but the fawns are not born till the following May. Roe were formerly abundant in all the wooded parts of Great Britain, but are now restricted to the Highlands of Scotland and a few localities farther south. They take readily to water. The Siberian roe (C. *c. pygargus),* common in the Altai, is larger and paler. with shorter and more hairy ears and small irregular snags on the inner border of the antlers. The Manchurian roe (C. *c. bedfordz)* is about the size of the European species, with antlers of the type of those of the Siberian roe, but more slender.

ROEMER, OLE (Latinized OLAUS) (1644–1710), Danish astronomer. was born at Aarhuus, Jutland, on Sept. 25, 1644. He became in 1662 the pupil and amanuensis of Erasmus Bartholinus at Copenhagen. In 1671 he assisted J. Picard to determine the position of Tycho Brahe's observatory (Uraniborg, on the island of Hveen). In 1672 he went to Paris with Picard, and spent nine years on observations at the new royal observatory and hydraulic works at Versailles and Marly. After a scientific mission to England (1679), on which he met Newton, Halley and Flamsteed, he returned to Copenhagen in 1681 as royal mathematician and professor of astronomy in the university. He also held several public offices, including that of mayor (1705). He died at Copenhagen on Sept. 23, 1710.

Roemer is remembered as the discoverer of the finite velocity of light. which was suggested to him by his observations on the eclipses of Jupiter's moons. The first noteworthy transit instrument was in 1690 erected at his house. He also set up at the university observatory an instrument with altitude and azimuth circles. and an equatorial telescope. He also built and equipped the "Tusculan" observatory at Vridlosemagle, near Copenhagen. His observations perished in the great fire of Oct. 21, 1728, except those discussed by J. G. Galle in *O. Roemeri triduum' observationum astronomicarum a. 1706 institutarum* (Berlin, 1845).

ROENTGEN, DAVID (1743–1807), German cabinetmaker to Queen Marie Antoinette, was born at Herenhag on Aug. 11, 1743, and died at Wiesbaden on Feb. 12, 1807. He was the eldest son of Abraham Roentgen, who in 1750 moved to Neuwied, on the Rhine near Coblenz, where he produced furniture of outstanding quality, often decorated with inlay work of ivory and other material, much of it for the courts of German princes. David Roentgen learned his trade in his father's workshop and succeeded to the business in 1772, his father continuing as a partner until 1784. His father's firm having already achieved renown in Germany, the son won European reputation after he had displayed his furniture in Paris in 1779 and secured King Louis XVI, Queen Marie Antoinette and other members of the French court as customers. Roentgen was appointed cabinetmaker to the queen and in 1780 was granted admission as master (*maître ébéniste*) to the trade corporation of Paris cabinetmakers, a fact which made it possible for him to keep in Paris a stock of the furniture manufactured at Neuwied. In this fashion he was able to compete with such great French cabinetmakers of the period as Jean Henri Riesener and others. King Frederick the Great of Prussia and Empress Catherine II of Russia were also customers of Roentgen. The latter, after Roentgen's first visit to St. Petersburg in 1783, bought great quantities of his furniture. When in 1795 the French Revolutionary armies threatened to cross the Rhine, Roentgen evacuated his establishment and moved his stock of furniture farther inland. While he never succeeded in starting production again, former apprentices of his whom he had helped to establish in Berlin (David Hacker) and in Brunswick (Christian Harder) were successful in their enterprises.

Roentgen had begun his career by continuing and developing the style of furniture his father had introduced. His so-called French style is characterized by furniture of curved outline sometimes decorated with rich carvings. His "English" cabinetwork is based on elements dating from the early years of George III and occasionally influenced by Thomas Chippendale. Both types of furniture are frequently decorated with rich inlay work of outstanding charm and elegance made up of a variety of woods, some tinted and composed to form figural and floral compositions. often in the *chinoiserie* manner. Between 1775 and 1780 Roentgen's previous style is altogether abandoned and rigid. classical forms are introduced, the effect of which is often based on the contrast of mahogany with rich bronze appliqués. The Roentgen workshop indulged in mechanical devices which made appear or disappear drawers and mirrors by pressing on hidden releases. Peter Kinzing was the mechanical genius who invented many of these tricks and provided clockworks. Furniture by Roentgen is in most large museums in Europe, at the Metropolitan Museum of Art in New York and at the Art Institute of Chicago.

See Hans Huth, *Abraham und David Rontgen und ihre Neuwieder Werkstatt* (1938). (Hs. H.)

ROERICH, NICHOLAS KONSTANTIN (1874–1947), Russian painter of Scandinavian origin, established his reputation with pictures of Russian prehistoric life and the wanderings of Vikings. He was born in St. Petersburg on Sept. 27, 1874. After beginning with realistic pictures. his manner evolved under the influence of the Byzantine icon and of oriental art toward a purely decorative and monumental style. He studied the technique of ancient Russian frescoes and his wall paintings for the Kazan railway station at Moscow, representing combats between Russian? and Tatars, are his most important work. He executed a number of works for the theatre: for the Russian ballet he painted the scenery in *Prince Igor;* for Stanislavsky the setting of *Peer* Gynt. He wrote the libretto and designed the scenery and costumes for *The Rite of Spring,* for which Igor Stravinsky composed the music. After the Russian Revolution of 1917 he settled successively in the United States and in India. More than 1,000 of his works are in the Roerich museum, New York, and in other famous galleries. He died Dec. 13, 1947, in Kulu, East Punjab.

ROERMOND, a town in the province of Limburg, the Netherlands, on the right bank of the Maas at the confluence of the Roer. and a junction station 28 mi. by rail N.S.E. of Maastricht. Pop. (1957 est.) mun. 25.840. The old fortifications were dismantled and partly converted into promenades. A bridge across the Roer, dating from 1771, connected Roermond with the suburb of St. Jacob. Roermond was the seat of a Roman Catholic episcopal see. The Romanesque minster church dates from the first quarter of the 13th century. In the middle of the nave is the tomb of Gerhard III, count of Gelderland, and his wife Margaret of Brabant. It was formerly the church of a Cistercian nunnery, and in modern times was elaborately restored. The cathedral of St. Christopher is also of note; on top of the tower (246 ft.) a copper statue of the saint was erected. The interior was adorned with paint-

ings by Rubens, Jacob de Wit (1695–1754) and others. The old bishop's palace became the courthouse, and the old Jesuits' monastery a higher-burgher school. Woollen, cotton, silk and mixed stuffs, paper, flour and beer are manufactured there. Roermond suffered damage during World War II.

ROGATION DAYS, in the Calendar of the Christian Church, the three days before Ascension Day. Their observance, by fasting and chanting litanies in procession, was introduced by St. Mamertus, bishop of Vienne (d. *c.* 475), and was ordered throughout France by the first Council of Orleans in 511. Leo III. (pope 795–816) introduced rogation days, but without fasting, at Rome. The custom had spread earlier into the English Church, where it was confirmed in 747 by the Council of Clovesho. After the Reformation the processions gradually ceased to be ecclesiastical in England, and now survive only in the perambulation of the parish boundaries on or about Ascension Day.

See also PROCESSION and LITANY.

ROGER (d. 1181), archbishop of York, known as Roger of Pont l'Evêque, was a member of the household of Theobald. archbishop of Canterbury, where he quarrelled violently with another future archbishop, Thomas Becket. In 1148 he was appointed archdeacon of Canterbury, and soon afterwards chaplain to King Stephen, who sent him on an errand to Rome in 1152; then in Oct. 1154 he was consecrated archbishop of York in Westminster abbey. When Henry II. entered upon his struggle with Becket he secured the support of Roger, and having been appointed papal legate in England, the archbishop visited Pope Alexander III. and the French king, Louis VII., in his master's interests. In June 1170 he crowned the king's son Henry, in spite of prohibitions from the pope and from Becket, and for this act he was suspended. He quarrelled with Richard, the new archbishop of Canterbury, about the respective rights of the two archiepiscopal sees, until 1176, when the king arranged a truce; and he was constantly endeavouring to assert his supremacy over the Scottish church. He died at York on Nov. 21, 1181.

ROGER (d. 1139), bishop of Salisbury, was originally priest of a small chapel near Caen. The future King Henry I., who happened to hear mass there one day, was impressed by the speed with which Roger read the service, and enrolled him in his own service. Roger, though uneducated, showed great talent for business, and Henry, on coming to the throne, almost immediately made him chancellor (1101). Soon after Roger received the bishopric of Salisbury. In the Investitures controversy he skilfully managed to keep the favour of both the king and Anselm. Roger devoted himself to administrative business, and remodelled it completely. He created the exchequer system, which was managed by him and his family for more than a century, and he used his position to heap up power and riches. He became the first man in England after the king, and was in office, if not in title, justiciar. He ruled England, while Henry was in Normandy, and succeeded in obtaining the see of Canterbury for his nominee, William of Corbeil. Duke Robert seems to have been put into his custody after Tinchebrai. Though Roger had sworn allegiance to Matilda, he disliked the Angevin connection, and went over to Stephen, carrying with him the royal treasure and administrative system (1135). Stephen placed great reliance on him, on his nephews, both bishops and on his son Roger, who was treasurer.

Roger himself had built at Devizes a splendid castle. He and his nephews seem to have secured a number of castles outside their own dioceses, and the old bishop behaved as if he were an equal of the king. At a council held in June 1139, Stephen found a pretext for demanding a surrender of their castles, and on their refusal they were arrested. After a short struggle all Roger's great castles were sequestrated. This quarrel with the church, which immediately preceded the landing of the empress, had a serious effect on Stephen's fortunes. Roger died at Salisbury in December 1139. He was a great bureaucrat, and a builder whose taste was in advance of his age. But his contemporaries were probably justified in regarding him as worldly, ambitious, avaricious, unfettered by any high standard of personal morality.

See Sir J. Ramsay's *Foundations* of *England,* vol. **ii., and** J. H. Round's **Geoffrey *de Mandeville.***

ROGER I. (1031–1101), ruler of Sicily, was the youngest son of Tancred of Hauteville. Arriving in Southern Italy soon after 1057, he shared with Robert Guiscard the conquest of Calabria, and in a treaty of 1062 the brothers apparently made a kind of "condominium" by which each was to have half of every castle and town in Calabria. Robert now commissioned Roger to reduce Sicily, which contained, besides the Muslims, numerous Greek Christians subject to Arab princes who had become all but independent of the sultan of Tunis. In May 1061 the brothers crossed from Reggio and captured Messinz. After Palermo had been taken in January 1072 Robert Guiscard, as suzerain, invested Roger as count of Sicily, but retained Palermo, half of Messina and the north-east portion of the island. Not till 1085, however, was Roger able to undertake a systematic crusade. In March 1086 Syracuse surrendered, and when in February 1091 Noto yielded the conquest was complete. Much of Robert's success had been due to Roger's support. Similarly the latter supported Duke Roger, his nephew, against Bohemund and other rebels, in return for which the duke surrendered to his uncle in 1085 his share in the castles of Calabria, and in 1091 the half of Palermo.

At the enfeoffments of 1072 and 1092 no great undivided fiefs were created, and the mixed Norman, French and Italian vassals owed their benefices to the count. No feudal revolt of importance therefore troubled Roger. Politically supreme, the count became master of the insular Church. While he gave full toleration to the Greek Churches, he created new Latin bishoprics at Syracuse and Girgenti and elsewhere, nominating the bishops personally, while he turned the archbishopric of Palermo into a Catholic see. The Papacy granted to him and his heirs in 1098 the Apostolic Legateship in the island. Roger was tolerant towards Arabs and Greeks, allowing to each race the expansion of its own civilization. In the cities the Muslims, who had generally secured such terms of surrender, retained their mosques, their kadis, and freedom of trade; in the country, however, they became serfs. He drew from the Muslims the mass of his infantry, but the Latin element began to prevail with the Lombards and other Italians who flocked into the island in the wake of the conquest, and the conquest of Sicily was decisive in the steady decline of Mohammedan power in the western Mediterranean. Roger, the "Great Count of Sicily," died on June 22, 1101, and was buried in S. Trinità of Mileto. His third wife, Adelaide, niece of Boniface, lord of Savona, gave him two sons, Simon and Roger, of whom the latter succeeded him.

See E. Caspar, *Roger II. und die Gründung der normannisch-sicilischen Monarchie* **(Innsbruck,** 1904). (E. Cu.)

ROGER II. (1093–1154), king of Sicily, son of the preceding, began to rule as count in 1112, and from the first aimed at uniting the whole of the Norman conquests in Italy. In 1127, Roger claimed the Hauteville possessions, and the overlordship of Capua, for which Richard II. in 1098 had sworn homage to Duke Roger, in virtue of a promise made by William, the late duke of Apulia. The union of Sicily and Apulia, however, was resisted by the subjects of the duchy itself, and by the pope at Capua (Dec. 1127) who preached a crusade against the claimant, setting against him Robert II. of Capua and Ranulf of Alife, or Avellino, brother-in-law of Roger. The coalition, however, failed, and in August 1128 Honorius invested Roger at Benevento as duke of Apulia. The baronial resistance, backed by Naples, Bari, Salerno and other cities, whose aim was civic freedom, also gave way, and at Melfi (Sept. 1129) Roger was recognized as duke by Naples, Capua and the rest. He at once began to enforce order in the Hauteville possessions, where the ducal power had long been falling to pieces. For the binding together of his states the royal name seemed essential, and the death of Honorius in February 1130, followed by a double election, seemed the decisive moment, While Innocent II. fled to France, Roger supported Anacletus II. The price was a crown, and on Sept. 27, 1130, a bull of Anacletus made Roger king of Sicily. He was crowned in Palermo on Dec. 25, 1130.

This plunged Roger into a ten years' war. Bernard of Clairvaux, Innocent's champion, built up against Anacletus and his

"half heathen king," a coalition joined by Louis VI. of France, Henry I. of England and the emperor Lothar. Meanwhile the forces of revolt in South Italy drew to a head again, and on June 24, 1132, the king was defeated at Nocera by Ranulf. Nevertheless, by July 1134, he forced Ranulf, Sergius, duke of Naples, and the rebels to submit, while Robert was expelled from Capua. Meanwhile Lothar's contemplated attack upon Roger had gained the backing of Pisa, Genoa and the Greek emperor, all of whom feared the growth of a powerful Norman kingdom. In February 1137 Lothar moved south and was joined by Ranulf and the rebels; in June he besieged and took Bari. At San Severino, after a victorious campaign, he and the pope jointly invested Ranulf as duke of Apulia (Aug. 1137), and the emperor then retired to Germany. Roger, freed from the utmost danger, recovered ground, sacked Capua and forced Sergius to acknowledge him as overlord of Naples. At Rignano the indomitable Ranulf again utterly defeated the king, but died in April 1139, leaving none to oppose Roger, who subdued the rebels pitilessly.

The death of Anacletus (Jan. 25, 1138) determined Roger to seek the confirmation of his title from Innocent. The latter, invading the kingdom with a large army, was skilfully ambushed at Galuccio on the Garigliano (July 22, 1139), and on July 25 the pope invested him as "Rex Siciliae ducatus Apuliae et principatus Capuae."

Roger, now become one of the greatest kings in Europe, made Sicily the leading maritime power in the Mediterranean. A powerful fleet was built up under several "admirals," or "emirs," of whom the greatest was George of Antioch, formerly in the service of the Muslim prince of El Mehdia. Mainly by him a series of conquests were made on the African coast (1135–53) which reached from Tripoli to Cape Bona. The second crusade (1147–48) gave Roger an opportunity to revive Robert Guiscard's designs on the Greek Empire. George was sent to Corinth at the end of 1147 and despatched an army inland which plundered Thebes. In June 1149 the admiral appeared before Constantinople and defied the Basileus by firing arrows against the palace windows. The attack on the empire had, however, no abiding results. The king died at Palermo on Feb. 26, 1154, and was succeeded by his fourth son William.

Personally Roger was of tall and powerful body, with long fair hair and full beard. With little of Robert Guiscard's personal valour, he yet showed to the full his uncle's audacity, diplomatic skill and determination. It is Roger II.'s distinction to have united all the Norman conquests into one kingdom and to have subjected them to a government scientific, personal and centralized. The principles of this are found in the Assizes of the kingdom of Sicily, promulgated at Ariano in 1140, which enforced an almost absolute royal power. At Palermo Roger drew round him distinguished men of various races, such as the famous Arab geographer Idrisi and the historian Nilus Doxopatrius. He maintained a complete toleration for the several creeds, races and languages of his realm; he was served by men of the most diverse nationalities.

Contemporary authors are: Falco of Benevento, Alexander of Telese, Romuald of Salerno and Hugo Falcandus, all in the *Scrittori e cronisti napoletani*, ed. Del Re, vol. i. *See* also E. Caspar, *Roger II. und die Grundung der normannisch-sicilischen Monarchie* (Innsbruck, 1904). (E. Cu.; X.)

ROGER OF HOVEDEN or HOWDEN (*fl.* 1174–1201), English chronicler, was, to judge from his name and the internal evidence of his work, a native of Howden in the East Riding of Yorkshire. But nothing is known of him before the year 1174. He was then in attendance upon Henry II., by whom he was sent from France on a secret misson to the lords of Galloway. In 1175 he again appears as a negotiator between the king and a number of English religious houses. In 1189, he was a justice of the forests in the shires of Yorkshire, Cumberland and Northumberland. About the year 1192 he began to compile his *Chronica*, a general history of England from 732 to his own time. Up to the year 1192 his narrative adds little to our knowledge. From that time, however, Hoveden is an independent and copious authority. Both on foreign affairs and on questions of domestic policy he is unusually well informed. He is particularly useful on points of constitutional history. His work breaks off abruptly in 1201. Probably his death should be placed in that year.

See W. Stubbs's edition of the *Chrdnica* (Rolls Series) and the introductions to vols. i. and iv. This edition supersedes that of Sir H. Savile in his *Scriptores post Bedam* (1596).

ROGER OF WENDOVER (d. 1236), English chronicler, whose *Flores Historiarum* is the fullest narrative source for the reign of Henry III, was probably a native of Wendover, Buckinghamshire. He became a monk of St. Albans, Hertfordshire, and later prior of the cell at Belvoir, Leicestershire, but was found guilty of wasting the endowments and deposed. His latter years were passed at St. Albans where he died on May 6, 1236. He was the first of the important chroniclers who worked in the scriptorium there. The *Flores Historiarum*, which begins at the Creation and extends to 1235, becomes of fully original value from the beginning of Henry III's reign and contains the sinister, savage, portrait of King John, which Matthew Paris later exaggerated in his *Chronica Majora*, which incorporated and continued the *Flores Historiarum*.

The *Flores Historiarum* survives in Douce Manuscript 207 (*c.* 1300; Bodleian library, Oxford) and Cotton Manuscript Otho B v (*c.* 1350; British museum, London). Matthew Paris' *Chronica Majora* was edited by H. R. Luard, 7 vol., Rolls series (1872–80). H. O. Coxe edited the *Flores*, 447 and after, 5 vol., English Historical society (1841–44), and H. G. Hewlett, 1154 and after, 3 vol., Rolls series (1886–89).

(R. V.)

ROGERS, HENRY DARWIN (1808–1866), U.S. geologist. was born at Philadelphia, Pa., on Aug. 1, 1808. At the age of 21 he was chosen professor of chemistry and natural philosophy at Dickinson college. Pennsylvania. After holding this post for three years, he went to Europe and took up the study of geology. Subsequently he was engaged for 22 years in the state surveys of Pennsylvania and New Jersey, his reports on which were published during the years 1836–41. In 1842 he and his brother WILLIAM BARTON ROGERS (1805–82), who had been similarly occupied in Virginia, brought before the Association of American Geologists and Naturalists their conclusions on the physical structure of the Appalachian chains and on the elevation of great mountain chains. The researches of H. D. Rogers were elaborated in his final *Report on Pennsylvania* (1858), in which he included a general account of the geology of the Cnited States and of the coal fields of North America and Great Britain. In 1857 he was appointed professor of natural history and geology at Glasgow. One of his later essays (1861) was on the parallel roads of Lochaber (Glen Roy), the origin of which he attributed to a vast inundation. He died at Glasgow, May 29, 1866.

ROGERS, JAMES EDWIN THOROLD (1823–1890), English economist whose fame rests on his study of agriculture and prices, was born at West Meon, Hampshire, in 1823, and educated at King's college. London, and Magdalen hall, Oxford. In 1846 he was ordained and became a curate in Oxford. Subsequently he resigned his orders. Although he was a classical scholar, his friendship with Richard Cobden (*q.v.*) led him to study economics. In 1859 he became professor of statistics and economic science at King's college, London, a post he filled till his death. From 1862 he was also Drummond professor of political economy at Oxford. In 1866 he published the first two (of eight) volumes of his *History of Agriculture and Prices in England*, a masterly record upon which his reputation mainly depends. An acquaintance with Cobden and John Bright (*q.v.*) led Rogers to take an active part in politics: he represented Southwark in parliament 1880–1885, and Bermondsey 1885–86, as an advanced Liberal. His latter years were mainly spent as professor of political economy at Oxford, where he died on Oct. 12, 1890. Rogers did much to promote the historical study of economics. His most important publications are: *Manual of Political Economy* (1868); an edition of Adam Smith's *Wealth of Nations* (1869); *Cobden and Modern Political Opinion* (1873); edited *The Speeches of J. Bright* (1868);

Six Centuries of Work and Wages (1884); and *The First Nine Years of the Bank of England* (1887). (D. F. Dd.)

ROGERS, JOHN (c. 1500–1555), English Protestant martyr, born at Aston, near Birmingham, was educated at Pembroke Hall, Cambridge, where he graduated B.A. in 1526. Six years later he was rector of Holy Trinity, Queenhithe, London, and in 1534 went to Antwerp as chaplain to the English merchants. Here he met William Tyndale, under whose influence he abandoned the Roman Catholic faith, and married an Antwerp lady. After Tyndale's death Rogers pushed on with his predecessor's English version of the Old Testament, which he used as far as 2 Chronicles, employing Coverdale's translation (153j) for the remainder and for the Apocrypha. Tyndale's New Testament had been published in 1526. The complete Bible was put out under the pseudonym of Thomas Matthew in 1537; it was printed in Xntwerp, and Richard Grafton published the sheets and got leave to sell the edition (1,500 copies) in England. Rogers had little to do with the translation, but he contributed some valuable prefaces and marginal notes. His work was largely used by those who prepared the Great Bible (1539–40), out of which in turn came the Bishop's Bible (1j68) and the Authorized Version of 1611. After taking charge of a Protestant congregation in Wittenberg for some years, Rogers returned to England in 1548, where he published a translation of Melanchthon's *Considerations of the Augsburg Interim.* In 1550 he was presented to the crown livings of St. Margaret Moyses and St. Sepulchre in London, and in 1551 was made a prebendary of St. Paul's, where the dean and chapter soon appointed him divinity lecturer.

On the accession of Mary, Rogers preached at Paul's Cross commending the "true doctrine taught in King Edward's days," and warning his hearers against "pestilent Popery, idolatry and superstition." Ten days after (16th August 1553), he was summoned before the council and bidden to keep within his own house. In January 1554 Bonner, the new bishop of London, sent him to Newgate, where he lay with John Hooper, Laurence Saunders, John Bradford and others for a year. On January 22, 1555, Rogers with ten others came before the council at Gardiner's house in Southwark, and held his own in the examination that took place. On the 28th and 29th he came before the commission appointed by Cardinal Pole, and was sentenced to death by Gardiner for heretically denying the Christian character of the Church of Rome and the real presence in the sacrament. He met his death on the 4th of February 1jjj at Smithfield. He was the first Protestant martyr of Mary's reign, and his friend Bradford wrote that "he broke the ice valiantly."

ROGERS, JOHN (1627–1665?), English preacher, a Fifth Monarchy man, second son of Nehemiah Rogers, a royalist and Anglican clergyman, was born at Messing, Essex; he studied medicine at King's college, Cambridge. In the quarrel between the army and the parliament Rogers sided with the army, and he was one of the first to join the Fifth Monarchy movement. He approved of the expulsion of the Long Parliament, but the establishment of the Protectorate at once threw the Fifth Monarchy men into antagonism. Rogers addressed a warning letter to Cromwell, and attacked him from the pulpit on Jan 9. 1654 His house was searched and his papers seized. and Rogers then issued another denunciation against Cromwell, *Mene, Tekel, Perez: a Letter lamenting over Oliver Lord Cromwell.* On March 28, on which day he had proclaimed a fast for the sins of the rulers, he preached a violent sermon against the protector. He was arrested in July. He confronted Cromwell with great courage when brought before him on Feb. 5, 1655, and was imprisoned successively at Windsor and in the Isle of Wight, being released in Jan. 1657. He returned to London, and. being suspected of conspiracy, was again imprisoned by Cromwell in the Tower (Feb. 3–April 16. 1658). On the protector's death and the downfall of Richard Cromnell, the ideals of the Fifth Monarchy men seemed nearer realization, but Rogers was engaged in political controversy with Prynne and became a source of embarrassment to his own faction, which endeavoured to get rid of him by appointing him "to preach the gospel" in Ireland. On the outbreak of Sir George Booth's royalist insurrection. however, he became chaplain in Charles Fairfax's regiment, and served throughout the campaign. He was imprisoned in Dublin in Jan. 1660 by order of the army faction and released subsequently by the parliament. At the Restoration he withdrew to Holland, studied medicine at Leyden and Utrecht, where he obtained his M.D. in 1662. He was admitted to the degree of M.D. at Oxford in 1664, and is supposed to have died soon afterwards.

Besides the above pamphlet, Rogers wrote in 1653 *Ohel or Beth-shemesh, a Tabernacle for the Sun,* in which he attacked the Presbyterians; *Sagrir, or Doomesday drawzng nzgh,* from his new standpoint as a Fifth Monarchy man, *Challah, the Heavenly Nymph* (1653); *Dod, or Chathan; the Beloved or the Brzdegroom going forth for his Bride* . . . (1653); *Prison-born Morning Beams* (1654); *Jegar Sahadutha* . . . (1657); *Mr. Prynne's Good Old Cause stated and stunted 10 Year ago* . . . (1609); Διαπολιτεία a *Christtan Concertatzon* (1659); *Mr. Harrington's Parallel Unparalleled* (1659); *A Vindication of Sir H. Vane* (1659); *Dtsputatio Medica Inauguralis* (1662).

Authorities.—Ed. Rogers, *Life and Opinions of a Fifth Monarchy Man* (1867), compiled from Rogers's own works; Wood, *Athenae Oxonienses and Fasti; Calendars of State Papers (Domestic).* See also "English Ancestry of Washington," *Harper's Magazine,* xxi. (1891); "John Rogers of Purleigh," *The Nation,* vol. 53 (1891).

ROGERS, JOHN (1829–1904), U.S. sculptor, creator of a popular series of small groups illustrating literary, historical and humorous subjects, the so-called "Rogers groups." was born in Salem. Mass.. Oct. 30, 1829. He was largely self-taught although he did work for a brief time in the studio of the English sculptor Benjamin Spence in Rome. In 1859 he settled in New York: Eight thousand copies of his most popular group, "Coming to the Parson," were sold, and it is estimated that the total number of groups sold came to about 80,000. Rogers also made portrait busts; the equestrian statue of Gen. John F. Reynolds in Philadelphia. Pa., and the statue of Pres. Abraham Lincoln in Manchester. N.H. The small plaster "Rogers groups" were reproduced from bronze master models. A large collection of these bronzes was acquired by the New York Historical society. New York city, which also has the Rogers family portraits and papers. He died in New Canaan. Conn , July 26. 1904. (A. T. G.)

ROGERS, ROBERT (1731–1795), American frontier soldier, was born at Methuen, Mass., and in 1739 removed to Starktown (now Dunbarton), N.H. During the Seven Years' War he raised and commanded a force of militia, known as Rogers's Rangers, which won wide reputation for its courage and endurance in the campaigns about Lake George. He took part in Wolfe's expedition against Quebec and in the Montreal campaign of 1760. Afterwards he was sent by Gen. Amherst to take possession of the north-western posts, including Detroit. He was again in the West in 1763 during the Pontiac uprising, accompanying Dalyell's expedition and participating in the battle of Bloody Bridge. Soon after he went to England and in 1765 published in London a *Concise Account of North America* and his *Journals* of service in the Seven Years' War. In 1766 was published *Ponteach: A Tragedy,* one of the first American dramas, supposedly also written by Rogers. He further laid before the king a memorial proposing to lead an overland expedition from the Mississippi river to the Pacific ocean. This was refused him but instead he was given command of the north-west post of Llichilimackinac. From here in 1766 he sent out on his own initiative, under Captains Tute and Carver, the first English expedition to explore the upper Mississippi and Great Lakes region, but it failed to penetrate to the Pacific as intended. Rogers's ambitions caused him to be tried for treason but he was acquitted. He again went to England to retrieve his fortune but was unsuccessful. During the Revolutionary War he came to America but was regarded as a loyalist spy. He then openly joined the British and organized and commanded the Queen's Rangers which saw service in operations around New York city. Later he organized the King's Rangers, but the command was taken by his brother, James Rogers, and Robert Rogers returned to England, where he lived in obscurity until his death in 1795.

There is a scholarly biography by Allan Nevins of 172 pages in the Caxton Club edition of *Ponteach* (Chicago, 1914). *See* also F. Parkman, *Montcalm and Wolfe* (Boston, 1884).

ROGERS, SAMUEL (1763–1855), English poet, was born at Newington Green, London, on July 30, 1763. His father,

Thomas Rogers, was the son of a Stourbridge glass manufacturer, who was also a merchant in Cheapside. Thomas Rogers had a place in the London business, and married Mary Radford, daughter of his father's partner, becoming himself a partner shortly afterwards. On his mother's side Samuel Rogers was connected with the Noncomformist divines Philip and Matthew Henry, and it was in Nonconformist circles at Stoke Newington that he was brought up. He was educated at private schools at Hackney and Stoke Newington. Samuel Rogers entered the banking business in Cornhill, but his delicate health necessitated long holidays, during which he met the literary society of the day in Edinburgh as well as in London. He had already published a volume of verse when his *Pleasures of Memory* was printed in 1792. This poem may be regarded as the last embodiment of the poetic diction of the 18th century. Here is carried to the extremest pitch the theory of elevating and refining familiar themes by abstract treatment and lofty imagery.

In 1793 his father's death gave Rogers the principal share in the banking house in Cornhill, and a considerable income. He left Newington Green in the same year and established himself in chambers in the Temple. In his circle of friends at this time were "Conversation" Sharp and the artists Flaxman, Opie, Martin Shee and Fuseli. He also made the acquaintance of Charles James Fox, with whom he visited the galleries in Paris in 1803, and whose friendship introduced him to Holland House. In 1803 he moved to 22 St. James's Place, where for 50 years he entertained all the celebrities of London. Flaxman and Stothard had a share in the decorations of the house, which Rogers had almost rebuilt, and now proceeded to fill with pictures and other works of art. His collections at his death realized £50,000. An invitation to one of Rogers's breakfasts was a formal entry into literary society, and his dinners were even more select. His social success was due less to his literary position than to his powers as a conversationalist, his educated taste in all matters of art, and no doubt to his sarcastic and bitter wit, for which he excused himself by saying that he had such a small voice that no one listened if he said pleasant things. Above all, he seems to have had a genius for benevolence. "He certainly had the kindest heart and unkindest tongue of any one I ever knew," said Fanny Kemble. He helped the poet Robert Bloomfield, he reconciled Moore with Jeffrey and with Byron, and he relieved Sheridan's difficulties in the last days of his life. Moore, who refused help from all his friends, and would only be under obligations to his publishers, found it possible to accept assistance from Rogers. He procured a pension for H. F. Cary, the translator of Dante, and obtained for Wordsworth his sinecure as distributor of stamps.

Rogers played the part of literary dictator in England over a long period. He made his reputation by *The Pleasures of Memory* when Cowper's fame was still in the making. He became the friend of Wordsworth, Scott and Byron, and lived long enough to give an opinion as to the fitness of Alfred Tennyson for the post of poet laureate. Alexander Dyce, from the time of his first introduction to Rogers, was in the habit of writing down the anecdotes with which his conversation abounded. From the mass of material thus accumulated he made a selection which he arranged under various headings and published in 1856 as *Recollections of the Table-Talk of Samuel Rogers, to which is added Porsoniana.* Rogers himself kept a notebook, in which he entered impressions of the conversation of many of his friends—Charles James Fox, Edmund Burke, Henry Grattan, Richard Porson, John Horne Tooke, Talleyrand, Lord Erskine, Sir Walter Scott, Lord Grenville and the duke of Wellington. They were published by his nephew William Sharpe in 1859 as *Recollections by Samuel Rogers;* and *Reminiscences and Table-Talk of Samuel Rogers, Bunker, Poet, and Patron of the Arts, 1763–1855* (1903), by G. H. Powell, is an amalgamation of these two authorities. Rogers held various honorary positions: he was one of the trustees of the National Gallery; and he served on a commission to inquire into the management of the British Museum, and on another for the rebuilding of the houses of parliament.

Rogers's later works are *An Epistle to a Friend* (Richard Sharp) (1798); *The Voyage of Columbus* (1810); *Jacqueline* (1814), a narrative poem; *Human Life* (1819) and *Italy* (1822–28). Rogers was in Italy in 1814 and again in 1820, when he visited Byron and Shelley at Pisa. The 1828 edition of *Italy* was not a success. But in an enlarged form the poem was republished in 1830, and in 1838 a sumptuous edition of *Poems* was brought out. Rogers declined the laureateship in 18jo when upon the death of Wordsworth it was offered him. He died in London on Dec. 18, 1855.

See P. W. Clayden, *The Early Life of Samuel Rogers* (1887) and *Rogers and his Contemporaries* (2 vols., 1889).

ROGERS, WILL (WILLIAM PENN ADAIR ROGERS) (1879–1935), U.S. humorist and motion-picture actor, writer of a newspaper column famous for its homespun humour and for its good-natured but extremely sharp criticism of contemporary men and affairs, was born Nov. 4, 1879, at Oologah, Indian Territory (now Oklahoma). Utilizing the rope twirling and lassoing he learned on his father's ranch, he began a career as a rope-throwing cowboy in steer-roping contests, Wild West shows and vaudeville. In 191j, appearing in Ziegfeld's *Midnight Frolic* in New York, he introduced a humorous political commentary into his act. This developed into a newspaper column, syndicated weekly in 1922 and daily in 1926. Rogers also wrote a series of books in a similar vein, including *The Cowboy Philosopher on Prohibition* (1919), *Illiterate Digest* (1924) and *There's Not a Bathing Suit in Russia* (1927). Rogers was equally successful as a motion-picture actor. His films included *A Connecticut Yankee* (1931), *State Fair* (1933) and *David Harum* (1934). With Wiley Post he was killed in a plane crash in Alaska on Aug. 15, 193j. (M. S. BY.)

ROGERS, WILLIAM (1819–1896), English clergyman and educational reformer, was born in London on Nov. 24. 1819, and died there on Jan. 19, 1896. He was ordained in 1843, and in 1845 was appointed to St. Thomas' Charterhouse, where he remained for 18 years, throwing himself passionately into the work of education of his poor and often criminal parishioners. He began by establishing a school for ragamuffins in a blacksmith's abandoned shed, and he gradually extended its scope until schools were provided throughout the parish. In 1863 he became rector of St. Botolph's, Bishopsgate, and at Bishopsgate Rogers tackled the middle-class schools. He believed in secular education. To the cry against "godless education," Rogers replied. "Hang theology; let us begin," earning the nickname of "Hang-theology Rogers." Rogers reconstructed Edward Alleyn's charity at Dulwich and founded the Bishopsgate institute.

ROGIER, CHARLES LATOUR (1800–1885), Belgian statesman, descended from a Belgian family settled in the department of the Nord in France, was born at St. Quentin on Aug. 17, 1800. His father, an officer in the French army, perished in the Russian campaign of 1812; and the family moved to Liége, where the eldest son, Firmin, held a professorship. Charles, after being called to the bar, founded, in collaboration with his lifelong friends, Paul Devaux and Joseph Lebeau, the journal *Matkieu Laensberg* (afterwards *Le Politique),* which by its ardent patriotism and its attacks on the Dutch administration soon acquired a widespread influence. When the insurrection of 1830 broke out at Brussels, Rogier put himself at the head of 150 Liégeois, and inscribing on his banner the motto, "Vaincre ou mourir pour Bruxelles," he obtained arms from a local factory, and marched upon the capital. Here he took his place at once among the leaders of the revolutionary party. His influence saved the town hall from pillage on Sept. 19.

On the 25th a *commission administrative* was formed, of which Rogier became president. The energetic measures of this body and of its successor, the *gouvernement provisoire,* soon freed the greater part of the country from the Dutch troops. Rogier was sent in October to suppress an outbreak among the colliers of Hainaut, and then as delegate of the provisional government to Antwerp, where the citadel still held out for Holland. He arranged an armistice, and reorganized the entire administration of the city. He sat for Liége in the National Congress, voted for the establishment of an hereditary monarchy, and induced the congress to adopt the principle of an elective second chamber. In the long-drawn debates on the bestowal of the crown he ranged himself on the side of Louis Philippe: but when Louis Philippe de-

clined the crown on behalf of his son, Rogier voted with the majority for Leopold of Saxe-Coburg.

In June 1831 he was appointed governor of the province of Antwerp, a post rendered exceptionally difficult by the continued presence of Dutch troops in the citadel. In October 1832 he was made minister of the interior in the Goblet-Devaux cabinet. During his office he carried, in the teeth of opposition, a law that established in Belgium the first railways on the continent of Europe, and thus laid the foundation of her industrial development. Owing to dissensions in the cabinet, he retired in 1834, together with Lebeau, and resumed the governorship of Antwerp. On Lebeau's return to power in 1840, Rogier became minister of public works and education. His education proposals were defeated by the Clerical party, and on the resignation of the ministry in 1841, Rogier gave his support to a compromise measure, which passed into law in 1842. He led the Liberal party in Opposition till 1847, when he formed a cabinet in which he held the ministry of the interior. He carried out a liberal policy which enabled Belgium to escape the general revolutionary movement of 1848.

Rogier retired in Oct. 1852, but was brought back into office by the liberal reaction of 1857. He again became president of the council and minister of the interior in a cabinet of which Frère-Orban was the most conspicuous member. The first important measure passed by the ministry was one for the fortification of Antwerp. In 1860 the fear of French designs on the independence of Belgium led to a movement of reconciliation with Holland, and inspired Rogier to write his poem "La Nouvelle Brabançonne." In 1861 Rogier exchanged the ministry of the interior for that of foreign affairs. He achieved a diplomatic triumph in freeing the navigation of the Scheldt, and thus enabling Antwerp to become the second port on the mainland of Europe. Defeated at Dinant, he sat for Tournai from 1863 till his death. In 1868 Rogier finally retired from power. He continued, however, to take part in public life, and was elected president of the extraordinary session of the chamber of representatives in 1878. From this time his age, his devoted patriotism and the unassuming simplicity of his life made him the idol of all classes. He died at Brussels on May 27, 1885, and was accorded a public funeral.

See T. Juste, *Charles Rogier, 1800–1885, d'après des documents inédits* (Verviers, 1885).

ROHAN, the name of one of the most illustrious of the feudal families of France, derived from that of a small town in Morbihan, Brittany, and claimed connection with the ancient sovereigns of Brittany. Hercule de Rohan, duc de Montbazon (1568–1654) served Henry III. and Henry IV. against the League, and was made by Henry IV. governor of Paris and the Isle of France, and master of the hounds. His grandson, Louis de Rohan-Guéménée, the chevalier de Rohan, conspired with the Dutch against Louis XIV. and was beheaded in Paris in 1674. In the 18th century the Soubise branch of the family furnished several prelates, cardinals and bishops of Strasbourg, among others the famous cardinal de Rohan, the hero of the affair of the diamond necklace. René de Rohan, seigneur of Pontivy and Frontenay, of the Gié branch, commanded the Calvinist army in 1570, and defended Lusignan with great valour when it was besieged by the Catholics (1574–75). His son Henry, the first duke of Rohan (*q.v.*), had an only child, Marguerite de Rohan, married in 1645 to Henri Chabot. The property and titles of Henry de Rohan thus passed to the Chabot family, which under the name of Rohan-Chabot produced some distinguished soldiers and a cardinal archbishop of Besançon.

ROHAN, HENRI, Duc de (1579–1638), French soldier, writer and leader of the Huguenots, was born at the château of Blain, in Brittany, in 1579. His father was René II., count of Rohan (1550–86). Henri appeared at court and in the army at the age of sixteen, and was a special favourite with Henry IV., after whom, failing the house of Condé, he might be said to be the natural chief of the French Protestants. Having served till the peace of Vervins, he travelled for some time. On his return to France he was made duke and peer at the age of twenty-four, and two years later (1603) married Marguerite de Béthune, the duc de Sully's daughter. He fought from time to time in the royal army, and it was not till the decree for the restitution of church property in the south threw the Bearnese and Gascons into open revolt that Rohan appeared as a rebel. His ability and constancy contributed to the happy issue of the war for the Huguenots, and brought about the treaty of Montpellier (1623). Rohan renewed the war when the compact of Montpellier was broken. Again a hollow peace was patched up, but it lasted but a short time, and Rohan undertook a third war (1627–29), the first events of which are recounted in his celebrated *Memoirs*. After the peace he made his way to Venice, where his hosts wished to make him their general-in-chief, a design not executed owing to the peace of Cherasco (1631). At Venice he wrote his *Memoirs;* at Padua, *Le Parfait Capitaine*. Rohan returned to the French service, and was entrusted with the war in the Valtelline (1633). But Rohan was still considered dangerous to France, and was soon again in retirement. At this time he wrote his *Traité du gouvernement des treize cantons*. Rohan fought another Valtelline campaign, but without the success of the first, for the motives of France were now held in suspicion. The unfortunate commander retired to Geneva and thence went to the army of Bernhard of Saxe-Weimar. He received a mortal wound at the battle of Rheinfelden on Feb. 28, 1638, and died at the abbey of Konigsfeld, canton Berne, on April 13.

Rohan's *Mémoires sur les choses qui se sont passées en France*, etc., rank amongst the best memoirs of the 16th and 17th centuries. The first three books which deal with the civil wars appeared in 1644; the fourth, containing the narrative of the Valtelline campaigns, not till 1758. His famous book on the history and art of war, *Le Parfait Capitaine*, appeared in 1631 and subsequently in 1637 and 1693 (*see* also Quincy, *Art de la guerre*, Paris, 1741). The *Memoirs* may be conveniently found in the collection of Michaud and Poujoulat, vol. 19.

See Fauvelet de Foix, *Histoire du Duc Henri de Rohan* (1667); Schybergson, *Le Duc de Rohan et la charte du parti protestant en France* (1880); Biihring, *Venedig, Gustaf Adolf, und Rohan* (Halle, 1885); Laugel, *Henri de Rohan, son rôle politique et militaire* (1889); Veraguth, *Herzog Rohan und seine Mission in Graubünden* (Berne, 1894); and Shadwell, *Mountain Warfare*.

ROHAN, LOUIS RENÉ EDOUARD, Cardinal de (1734–1803), prince de Rohan-Guéménée, archbishop of Strasbourg, a cadet of the great family of Rohan, was born at Paris on Sept. 25, 1734. After taking orders, in 1760, he was nominated coadjutor to his uncle, Constantine de Rohan-Rochefort, archbishop of Strasbourg, and he was also consecrated bishop of Canopus. But he preferred the gaiety of Paris to his clerical duties, and had political ambitions. He joined the party opposed to the Austrian alliance, which had been cemented by the marriage of the archduchess Marie Antoinette to the dauphin. This party was headed by the duc d'Aiguillon, who in 1771 sent Prince Louis on a special embassy to Vienna to find out what was being done there with regard to the partition of Poland. Rohan arrived at Vienna in Jan. 1772, and made a great noise with his lavish fêtes. But the empress Maria Theresa was implacably hostile to him; not only did he attempt to thwart her policy, but he spread scandals about her daughter Marie Antoinette, laughed at Theresa, and shocked her ideas of propriety. On the death of Louis XV. in 1774, Rohan was recalled from Vienna, and coldly received at Pads; but in 1777 he was made grand almoner, and in 1778 abbot of St. Vaast. In 1778 he was made a cardinal on the nomination of Stanislaus Poniatowski, king of Poland, and in the following year succeeded his uncle as archbishop of Strasbourg and became abbot of Noirmoutiers and Chaise-Dieu.

In an attempt to procure reinstatement at court he fell into the hands of the comtesse de Lamotte, the notorious Cagliostro and others, whose actions form part of the "affair of the diamond necklace" (*see* Diamond Necklace, Affair of the). Rohan certainly was led to believe that his attentions to the queen were welcomed, and that his arrangement by which she received the famous necklace was approved. He was the dupe of others, and at the trial in 1786 his acquittal was received with enthusiasm, and regarded as a victory over the court and the queen. He was deprived, however, of his office as grand almoner and exiled to his abbey of Chaise-Dieu. He was soon allowed to

return to Strasbourg, and was elected to the states-general. As a prince of the church in Jan. 1791 he refused to take the oath to the constitution, and went to Ettenheim, in the German part of his diocese. He spent what wealth remained to him in providing for the poor clergy of his diocese who had been obliged to leave France; and in 1801 he resigned his nominal rank as archbishop of Strasbourg. On Feb. 17, 1803, he died at Ettenheim.

ROHILKHAND, a tract in Uttar Pradesh, republic of India. The name is associated with the Rohilla tribe, but historically refers to an area almost coincident with the modern division of Bareilly (*q.v.*), for which it is now the official title. This division has an area of 11.705 sq.mi. and a population (1961) of 8,505,041. It comprises the districts of Bareilly, Bijnor, Budaun, Moradabad, Shahjahanpur and Pilibhit, and the district of Rampur (*q.v.*), formerly a princely state, but fully absorbed into Uttar Pradesh in 1950. The Rohillas trace their ancestry to Sardar Daud Khan, an Afghan adventurer, whose adopted son annexed a large area north of the Ganges and was created a nawab by the Delhi emperor. He died in 1749, and the family split up into a number of petty chiefs. In 1774 (see BIJNOR) the Rohilla power was broken by a confederacy of the British and the nawab of Oudh. The state of Rampur was left under the sovereignty of Nawab Faizullah Khan and the rest of Rohilkhand was annexed to Oudh. The division was ceded to the East India company in 1801.

ROHLFS, CHRISTIAN (1849–1938), German Expressionist painter and graphic artist, was born at Niendorf, Dec. 22, 1849, the son of a north German peasant. He studied at the Weimar academy where he stayed on as teacher. There. his landscape painting first developed toward a very personal Impressionism. In 1901 Rohlfs became a teacher in the drawing school of the Folkwang museum in Hagen, a centre of European art. After 1927 he divided his time between Hagen and Ascona, Switz. In his Expressionist views of Soest cathedral and in the flower pieces he painted when he was an old man, he dissolves form into transparencies of colour and light, transmuting substance into the energy of emotion. He died in Hagen, Jan. 8, 1938.

See Peter Selz, German Expressionist Painting (1957); Paul Vogt, *Christian* Rohlfs (1958). (P. H. S.)

ROHTAK, a town and district of Punjab state, India. The town. which is of great antiquity. became the headquarters of a British district in 1824. It is 44 mi. N.W. of Delhi. Pop. (1951) 71,902. It is an important trade centre, with factories for ginning and pressing cotton.

The DISTRICT OF ROHTAK has an area of 2,329 sq.mi. It is situated on the level tableland between the Jumna and Sutlej rivers, and the northern areas are watered by the Rohtak and Butana branches of the Western Jumna canal; but the greater part of the central plain is entirely dependent upon the uncertain rainfall. The population in 1961 was 1,416,915.

ROKITANSKY, KARL, FREIHERR VON (1804–1878), Austrian pathologist and pioneer in the science of pathological anatomy, was born at Koniggratz, Bohemia. on Feb. 19, 1804. He studied medicine at Prague and Vienna, where he was appointed professor extraordinary of pathological anatomy in 1834. He became president of the Vienna Academy of Sciences in 1869 and was named Freiherr in 1874.

Rokitansky was the first to detect bacteria in the lesions of malignant endocarditis and to differentiate between lobar and lobular pneumonia. He first described acute dilatation of the stomach (1842) and left a classic account of the pathologic appearance in acute yellow atrophy of the liver (1843), which became known as Rokitansky's disease. He described and defined the bronchial and pulmonary complications of typhoid as bronchotyphus and pneumotyphus and completed René Laennec's picture of emphysema of the lungs by describing the microscopic appearances. In obstetrics and orthopedics he is credited as the first to describe spondylolisthetic deformities (1839). His Handbuch der *pathologischen* Anatomie (1842–46, Eng. trans: 1849–52) was an important work.

Rokitansky, who made more than 30,000 post-mortems during his life, was one of the chief founders of the Vienna school of pathological anatomy. He was also active in the legislature, where he favoured the Liberal party and became speaker of the house. He died in Vienna, July 23, 1878.

ROLAND [ROLAND DE LA PLATIÈRE], **JEAN MARIE** (1734–1793), French statesman, was born at Thizy on Feb. 18, 1734. After working as a clerk, he joined a relative who was inspector of manufactures at Amiens, and himself rose to inspector. In 1780 he married Jeanne Manon Phlipon (1754–93), famous as Madame Roland. About 1785 the Rolands moved to Lyons. A correspondence sprang up with J. P. Brissot and other friends of the revolution in Paris, and in 1791 the Rolands settled there. Jean Roland became a member of the Jacobin club. Madame Roland's salon soon became the rendezvous of many leaders of the popular movement, above all of F. N. L. Buzot. In person Madame Roland was attractive though not beautiful; her ideas were clear and far-reaching, her manner calm and her power of observation extremely acute.

On March 23, 1792, Roland was appointed minister of the interior. As a minister of the crown Roland exhibited a bourgeois brusqueness of manner and a remarkable combination of political prejudice with administrative ability. The decrees against the emigrants and the nonjuring clergy still remained under the veto of the king. A letter was penned by Madame Roland and addressed by her husband to Louis. It remained unanswered. Thereupon, in full council and in the king's presence, Roland read his letter aloud. It contained many and terrible truths as to the royal refusal to sanction the decrees and as to the king's position in the state; but it was inconsistent with a minister's position, disrespectful if not insolent in tone. Roland's dismissal followed. He then read the letter to the assembly; it was ordered to be printed, became the manifesto of disaffection and was circulated everywhere.

After the insurrection of Aug. 10, Roland was recalled to power, one of his colleagues being G. J. Danton, but he was dismayed by the progress of the revolution. He was above all a provincial, and was soon in opposition to the party of the Mountain. He was hostile to the insurrectional commune of Paris, and proposed transferring the government to Blois; he attacked Robespierre and his friends. His neglect to seal the iron chest discovered in the Tuileries, which contained the proofs of Louis XVI's relations with the enemies of France, led to the accusation that he had destroyed a part of these documents. Finally, in the trial of the king he demanded, with the Girondists, that the sentence should be pronounced by a vote of the whole people, and not simply by the convention. He resigned office on Jan. 23, 1793, two days after the king's execution.

The Rolands remained in Paris. Once Madame Roland appeared personally in the assembly to repel the falsehoods of an accuser, and secured acquittal. But violence succeeded violence, and early on the morning of June 1, she was arrested and imprisoned in the Abbaye. Roland himself escaped secretly to Rouen. Released for an hour from the Abbaye, Madame Roland was again arrested and thrown among the horrors of Sainte-Pélagie. Finally, she was transferred to the Conciergerie. In prison she won the affections of the guards, and was allowed the privilege of writing materials and the occasional visits of devoted friends. She there wrote her *Appel à l'impartiale postérité,* those memoirs which display a strange alternation between self-laudation and patriotism, between the trivial and the sublime. On Nov. 8, 1793, she was guillotined. Before her execution, she bowed before the clay statue of Liberty erected in the Place de la Révolution, uttering her famous apostrophe—"0 Liberty! what crimes are committed in thy name!" When Roland heard of his wife's condemnation, he wandered several miles from his refuge in Rouen; maddened by despair and grief, he wrote a few words .expressive of his horror at those massacres which could be inspired only by the enemies of France, protesting that "from the moment when I learned that they had murdered my wife I would no longer remain in a world stained with enemies." He affixed the paper to his breast, and unsheathing a sword-stick fell upon the weapon, which pierced his heart, on Nov. 10, 1793.

Madame Roland's *Mémoires,* first printed in 1820, have been edited

among others by P. Faugère (1864), by C. A. Dauban (1864), by J. Claretie (1884), and by C. Perroud (1905). Some of her *Lettres inédites* have been published by C. A. Dauban (1867); C. Perroud published a critical edition of her *Lettres* (1900–02), and a new series (1767–80) in 1913–15. *See* also C. A. Dauban, *Étude sur Madame Roland et son temps* (1864); *V.* Lamy, *Deux femmes célèbres, Madame Roland et Charlotte Corday* (1884); *C.* Bader, *Madame Roland, d'après des lettres et des manuscrits inédits* (1892); A. J. Lambert, *Le mariage de Madame Roland, trois années de correspondance amoureuse* (1896); Austin Dobson, *Four Frenchwomen* (1890); articles by C. Perroud in the review *La Rdvolution française* (1896–99); *U.* Birch, *Madame Roland, a Study in Revolutzon* (1917).

ROLAND, LEGEND OF. The legend of the French epic hero Roland (transferred to Italian romance as Orlando) is based on authentic history. Charlemagne invaded Spain in 778, and had captured Pamplona, but failed before Saragossa, when the news of a Saxon revolt recalled him to the banks of the Rhine. On his retreat to France through the defiles of the Pyrenees, part of his army was cut off from the main body by the Basques and entirely destroyed. The incident is related in Einhard's *Vita Karoli* (cap. ix.; Pertz. ii. 448), where the names of the leaders are given. "In this battle were slain Eggihard *praepositus* of the royal table; Anselm, count of the palace; and Hruodland, praefect of the Breton march. . . ." The scene of the disaster is fixed by tradition at Roncevaux, on the road from Pamplona to St. Jean Pied de Port. The fiction of the 12 peers may possibly arise from a still earlier tradition. In 636–637, according to the *Chronicles* of Fredegarius (ed. Krusch, p. 159), 12 chiefs, whose names are given, were sent by Dagobert against the Basques. The expedition was successful, but in the valley of Subola, identified with Mauléon, near Roncevaux, the Duke Harembert, with other Frankish chiefs, was slain. Later fights in the same neighbourhood and under similar circumstances are related in 813 *(Vita Hludowici;* Pertz ii. 616), and especially in 824 (Einhard's *Annales;* Pertz. i. 213). These incidents no doubt served to strengthen the tradition of the disaster to Charlemagne's rearguard in 778, the importance of which was certainly magnified in popular story.

The choice of Roland or Hruodland as the hero probably points to the borders of French Brittany as the home of the legend. The exaggeration of a rear-guard action into a national defeat; the substitution of a vast army of Saracens for the border tribe mentioned by Einhard; and the vengeance inflicted by Charlemagne, where in fact the enemy escaped with complete impunity—all are in keeping with the general laws of romance. Charlemagne himself appears as the ancient epic monarch, not as the young man he really was in 778. There is evidence of a continuous tradition dating from the original event and, as Roncevaux lay on the route to Compostella, the many pilgrims who must have passed the site, from the middle of the 9th century onwards, may have helped to spread the story. Whether the actual *cantilena Rollandi* chanted by Taillefer at the battle of Hastings (William of Malmesbury, *De gestis regum angl.* iii. 242, and Wace, *Brut.* ii. 11, 8035 *seq.)* was any part of the existing *Chanson de Roland* cannot be stated, but the choice of the legend on this occasion by the trouvkre is proof of its popularity.

The oldest extant forms of the legend are: *(a)* chapters xix.–xxx. of the Latin chronicle, known as the *Pseudo-Turpin,* which purports to be the work of Turpin, archbishop of Reims, who died about 800, but probably dates from the 12th century; (b) *Carmen de proditione Guenonis,* a poem in Latin distichs; and *(c)* the *Chanson de Roland,* a French *chanson de geste* of about 4.000 lines, the oldest recension of which is in the Bodleian library, Oxford (ms. Digby, 23). It is in assonanced *tirades,* of unequal length, many of them terminated with the refrain *Aoi.* This ms. was written by an Anglo-Norman scribe about the end of the 12th century, and is a corrupt copy of a text by a French trouvkre of the middle of the 11th century. The poem, which was first printed by Francisque Michel (Oxford, 1837) is the finest monument of the heroic age of French epic.

The *Pseudo-Turpin* represents a different recension of the story and is throughout clerical in tone. It was the trouvkre of the *Chanson de Roland* who developed the characters into epic types; he invented the heroic friendship of Roland and Oliver, the motives of Ganelon's treachery, and many other details. The famous fight between Roland and the giant Ferragus appears in the *Pseudo-Turpin* (ch. xviii.), but not in the poem. The *Chanson de Roland* contains allusions to many events outside the narrative, some of which refer to *chansons* which are lost. Roland was variously represented by the romancers as the son of Charlemagne's sister Gilles or Berte and the knight Milon d'Anglers. The romantic episode of the reconciliation of the pair with Charlemagne through Roland's childish prattle *(Berte et Milon)* is probably foreign to the original legend. His *enfances,* or youthful exploits, were, according to *Aspremont,* performed in Italy against the giant Eaumont, but in *Girais de Viane* his first taste of battle is under the walls of Vienne, where Oliver, at first his adversary, becomes his brother-in-arms.

In the 12th century the *Chanson de Roland* was modernized by replacing the assonance by rhyme. Several mss. of this rhymed recension, sometimes known as *Roncevaux,* are preserved. The English romances of Charlemagne (*q.v.*) are mostly derived from late and inferior sources. It was in Italy that the Roland legend had its greatest fortune; Charlemagne and Roland appear in the *Paradiso* (canto xviii.) of Dante; the statues of Roland and Oliver appear on the doorway of the cathedral of Verona; and the French *chansons de geste* regularly appeared in a corrupt Italianized French.

BIBLIOGRAPHY.—For a complete bibliography of the editions of the various mss. of the *Chanson de Roland,* of the foreign versions, and of the enormous literature of the subject, *see* Léon Gautier, *Les Epopdes françaises* (2nd vol. iii. 1880) and the same author's *Bibliographie des chansons de geste* (1897). *See* also P. Boissonade, *Du Nouveau sur le Chanson de Roland* (1923). Among critical editions of the *Chanson* are those by Wendelin Foerster in the *Altfranz. Bibliotek,* vols. vi. and vii. (Heilbronn, 1883–86), and by E. Stengel *Das altfranzosische Rolandslied* (Leipzig, 1900, etc.). The most popular edition is *La Chanson de Roland* (Tours, 1872, and numerous subsequent editions), by Léon Gautier. L. Petit de Julleville published in 1878 an edition with the old French text, and a modern French translation in assonanced verse. There are English translations in prose by I. Butler (Boston, Mass., 1904); in verse by A. Way and F. Spencer (1895); and "in the original measure" by C. S. Moncrieff (1919). Consult further *G.* Paris, *Hist. poét. de Charlemagne* (reprint, 1905), and *De Pseudo Turpino* (Paris, 1865); P. Rajna, *Le Origini dell 'epopea francese* (Florence, 1884) and *Le Fonti dell' Orlando Furioso* (2nd ed. Florence, 1900); F. Picco, *Rolando nella storia e nella poesia* (Turin, 1901); G. Paris, "Roncevaux," in *Légendes du moyen âge* (1903), on the topography of the battlefield.

ROLANDSECK, (Ober-winter) a village in the Rhineland-Palatinate, Ger.. situated on the left bank of the Rhine, 8 mi. above Bonn. with a station on the railway Cologne-Coblenz. The place consists almost entirely of villas and is a favourite summer resort. Behind it lie the ruins of the castle.

ROLL. Primarily the word "roll" is used of a piece of writing material, such as parchment or paper, which is rolled up for the purpose of convenient storage or handling, in which form it represents an early stage in the evolution of the book, an example being the Rotulus or Rodl of Joshua of *c.* 700 in the Vatican library. By extension it became the name for any document kept in this form as an official record, and hence for any register, record, catalogue or official list. "The Rolls" was the name of the building where the records of the chancery court, a division of the English high court of justice, were kept, the keeper of which was the master of the rolls (*q.v.*), now the title of the third member of the English supreme court of judicature.

The word is used in this sense for the list of those admitted as qualified solicitors, whence the phrase "to strike off the rolls" of removal by the court of a solicitor for offenses or for delinquencies.

In architecture, a "roll" or "scroll" molding is one resembling a section of a roll or scroll of parchment with the end overlapping; a "roll and fillet" molding is a section of a cylindrical molding with a square fillet running along the centre of the face.

ROLLAND, JOHN (*fl.* 1560), Scottish poet, appears to have been a priest of the diocese of Glasgow, and to have been known in Dalkeith in 1555. He is the author of two poems, the *Court of Venus* and a translation of the *Seven Sages.* The former, which was printed by John Ros in 1575, may have been written before 1560. The latter was translated from a Scots prose version.

The *Court of Venus* was edited *by* Walter Gregor (1884). The *Seven*

Sages was printed in 1578, and reprinted by David Laing (1837).

ROLLAND, ROMAIN (1866–1944), French man of letters, was born at Clamecy. Nièvre, on Jan. *29, 1866.* From *1889–91* he was a member of the French school in Rome, and in *1895* became professor of art history at the Ecole Normale Supérieure. Later he was appointed professor at the Sorbonne, where he introduced the study of the history of music. He produced many critical and historical works, among them *Les origines du théâtre lyrique moderne, Histoire de l'opéra en Europe avant Lulli et Scarlatti* (1895), *Des causes de la décadence de la peinture italienne* (1895), *Le théâtre du peuple* (1901), besides studies on *Millet* (1902), *Beethoven (1903)* and *Michel-Ange* (1906), *Les Tragédies de la foi, Saint Louis, Aert, Le Triomphe de la raison (1913).* His most famous work. however, is the romance of *Jean-Christophe* (1904–12), the biography of a German musician. It is in three series, *Jean-Christophe, Jean-Christophe à Paris* and *La Fin du Voyage,* and appeared in 10 volumes *(1904–1912).*

When World War I broke out Rolland became unpopular in France because of a series of articles published in the *Journal de Genève* during Sept. and Oct. *1914.* These were subsequently published in book form under the title *Au-dessus de la mêlée.* Although his reputation in France suffered from his political views, it increased abroad, and the performances of *Danton* and *Le 14 juillet,* which with *Les Loups* and *Le Jeu de l'amour et de la mort* belong to his *Théâtre de la Revolution* (1909), caused a furore in Berlin. His aork *Mahatma Gandlzi (1924)* is an impassioned defense of the Indian leader. His later works include. *Colas Breugnon (1918); Les précurseurs (1919); Clerambault, Pierre et Luce (1919); Voyage musical aux pays du passé (1919); Liluli (1919).* In *1922* appeared the first volume of a series entitled *L'Ame Enchantée.* To this series belong *Annette et Sylvie* (1922), *L'Été* (1924), *Mère et Fils* (1927), *Beethoven the Creator (1929).* Rolland received the Nobel prize for literature in *1915.* He died in Vezelay, France, Dec. *30, 1944.*

ROLLE OF HAMPOLE, RICHARD (*c.* 1300–1349), early English mystic and author of mystical and ascetic tracts. The *Officium et Miracula,* prepared after his death by Cistercians of Yorkshire in anticipation of his canonization (which was never effected), provides the most certain information about his life: many apparently autobiographical passages in his own writings are cloudily expressed. Rolle nas born *c. 1300* at Thornton, Yorkshire. and was sent to the University of Oxford by Thomas Neville. archdeacon of Durham, but, dissatisfied with the subjects of study and the disputatiousness, left without a degree. There is no evidence that he ever went to the Sorbonne, or took priest's orders. Against the wishes of his family, Rolle established himself as a hermit on the estate of John Dalton of Pickering, but later moved to other hermitages, and probably always led a wandering life, rousing some opposition but winning much admiration. He kept in touch with a number of religious communities in the north and seems to have become spiritual adviser to the nuns at Hampole, in south Yorkshire, before his death there on Sept. *29, 1349.* His influence and reputation lived to the Reformation.

It is often difficult to distinguish his writings from those of his many followers. *The Pricke of Conscience,* formerly ascribed to him, has been denied him by 20th-century scholars. Among the genuine works is a number of scriptural commentaries of which that on the Psalms is the most important. Two distinct versions exist: one in Latin, the other written in English at the request of Margaret Kirkby, a recluse at Anderby, Yorkshire. His range of reading is wide: he draws on Gregory, Anselm, Bernard, Peter Lombard, the Victorines. Bonaventura; his knowledge of the Bible is profound. Among his Latin treatises, *Melos Amoris* is something of an *apologia* offered to his detractors. *Incendium Amoris* most comprehensively presents his doctrine which, though in the main conforming with the usual mystical theology of the late middle ages, has some emphases and terms of its own. Throughout his diffuse and repetitious writings the life of contemplation and solitude is exalted. Strict physical self-control is urged, but spiritual progress consists in the development of love of God. This life of love is consummated in mystical union, which is considered to be self-authenticating. Rolle's method is essentially a concentration and directing of the affections toward the person of Christ, nith a resulting experience of intense joy. In *Melos,* ch. ix, and *Incendium,* ch. xv, he provides notable accounts of rapture, which he invariably refers to in terms of *calor, dulcor, canor* ("fire, sweetness and song"). The terms suggest the quasi-physical accompaniment of his own mystical experiences.

His English writings on similar themes, handled more simply, include *Ego dormio* for a nun at Yedingham, Yorkshire, the *Commandment of Love to God* for a Hampole nun and the *Form of Perfect Licing,* for Margaret Kirkby again. Rolle's literary importance lies in these contributions to the vernacular stream of devotional prose for women readers. His English prose style is much commended: it is lively, persuasive, highly figured. The verse ascribed to him has more fervour than grace. Although he had mastered scholastic style. his Latin prose is usually fantastically rhetorical, exhibiting a curious syntax, a rich, obscure vocabulary and heavy alliteration and assonance.

BIBLIOGRAPHY.—C. Horstmann's edition of his works. in *Yorkshire Writers,* 2 vol. (1895–96), provided the basis of later study. H. E. Allen, "R'ritings Ascribed to Richard Rolle, Hermit of Hampole, and Materials for his Biography," *Publications of the Modern Language Association of America* (1927), established the canon. ROLLER, one of several old world birds, especially the common roller *(Coracias garrulus),* so called from its way of occasionally rolling in its flight, after the fashion of a tumbler pigeon. It is widely though not numerously spread over Europe and western Asia in summer. breeding as far north as the middle of Sweden, but retiring to winter in Africa. It is seen almost every year as a straggler in the British Isles. Except the back, scapulars and tertials, which are bright reddish-brown. the plumage of both sexes is blue (of various shades, from pale turquoise to dark ultramarine) tinted in parts with green. The bird is purely insectivorous.

Coracias forms the type of the family Coraciidae, allied to the bee eaters (Meropidae) and kingfishers (*q.v.*) (Xlcedinidae). in the order Coraciiformes. There are *16* species, found throughout Europe. Asia and Africa. The oriental roller or dollarbird *(Eurystomzrs orientalis)* ranges from southern Siberia to Australia.

ROLLER SKATING. The roller skate and the sport of roller skating having been traditionally accredited to an unknown Hollander who during the early 18th century created crude devices that could be attached to his shoes in the manner of ice skates. The first record of roller-skate manufacture is by Joseph Merlin of Huys. Belg. A contemporary described "a pair of skaites" as being among Merlin's many inventions while he was living in London shortly after 1760. Other early roller skates include the French *patin-à-terre* and the German *Erdschlittschuh* (both terms meaning literally "ground skate"). each about *1790.* Several attempts were made to improve upon the traditional four-wheeled roller skate by aligning the wheels after the fashion of the ice skate blade and in numerous other ways. None proved satisfactory, and further manufacture of the product adopted the earliest idea, still the design of modern roller-skate equipment.

During the 19th century considerable trial and error went into the search for an action device that would allow its user to perform upon curved strokes (again similar to the action of the "rocker style" ice skate) and thus take better advantage of the force of gravity in keeping a firm and upright balance. Until the invention of the now common cushioned truck for roller skates by James L, Plimpton of Medfield. Mass., in *1863,* roller skating was not widely popular; the sport was simply too difficult to master. Plimpton patented his rocking skate that year, and the first great roller skating craze swept the United States and western Europe. The first of the large roller-skating rinks was opened in New York that year, and the first organized roller skating was developed.

Shortly before Plimpton's rocking skates appeared, the composer Giacomo Meyerbeer had written into his opera *Le Prophkte* an ice-skating scene, which was performed on the stage on roller skates. The opera was a great success and the skating scene became famous. In 1849 the choreographer and composer, Paul Taglioni wrote a ballet, "The Skaters," again depicting an ice-skating scene, again performed on roller skates. In spite of the difficulties in performing upon the earlier roller skates. a U.S. ballet master, Jackson Haines, who had mastered ice-skating techniques with the application of ballet technique, turned his attention to roller skating; beginning in 1864 he captivated all who saw him perform. His interpretations became the foundation for what is known as the "international style" of skating on both ice and rollers, and his influence is still felt. One of the unusual positions in spinning is officially named after Haines.

Roller-skate wheels (or rollers) became the next subject of research. In the early skates Turkish boxwood had been widely used. The ball-bearing wheel, patented by Levant M. Richardson in 1884, required a better substance, and during succeeding years maple and then a fibre were introduced.

Throughout the years a variety of surfaces have been used for roller skating. However, nothing has provided a better floor than the fine, close-grained wood of the American sugar maple, preferably from trees grown in the northlands of Maine, Michigan, Wisconsin and Minnesota.

A variety of sports are available to the roller-skating enthusiast. Roller speed skating was a highly skilled and well-attended event during the first quarter of the 20th century. Gradual growth of roller skating as a participant sport during the early 1930s brought about in the U.S. the organization of a large and permanent association, the United States Federation of Amateur Roller Skaters. This was one of the first to be completely separated from the control of and linkage with the ice-skating sport. In England the two sports have been tied together for nearly 100 years. There has been gradual organization throughout the world, but however extensive the organizing efforts, only a very small fraction of all roller skaters belong to the associations. *See* also ICE SKATING.

(R. D. MA.)

ROLLI, PAOLO ANTONIO (1687–1765), Italian poet and librettist who played a leading part in the italianization of taste in 18th-century London, was born in Rome on June 13, 1687, the son of an architect. As a young man he studied with Gian Vincenao Gravina; and in 1715 he went to England as the protégé of Lord Thomas Pembroke. Soon after his arrival Rolli was appointed Italian master to the royal household; and during a sojourn lasting for some 30 years (1715–44) he wrote many cantatas and operatic libretti which were set to music by Bononcini *(Astarto),* Handel (*Il Floridante*) and Porpora *(Arianna in Nasso).* Rolli is best remembered however as the author of innumerable *endecasillabi,* odes and *canzonette* in which he aspired to recapture the rhythms of Catullus and the light-hearted charm of Anacreon. His other works include a translation of *Paradise Lost* (1735), *Marziale in Albion* (published posthumously 1776) and editions of the Italian classics.

Rolli died at Todi on March 20, 1765.

ROLLING MILL, an establishment where metal, especially iron and steel, is rolled into plates and bars of various sections. *See* IRON AND STEEL: *Rolling Mills;* SHEETS, IRON *AND* STEEL; TIN PLATE AND TERNEPLATE.

ROLLS, CHARLES STEWART (1877–1910), English pioneer motorist, aviator and motorcar manufacturer, technical managing director of Rolls-Royce, Ltd., was born in London on Aug. 27, 1877, the third son of Lord Llangattock. He was educated at Eton and at Trinity college, Cambridge, graduating in mechanical and applied sciences. Rolls owned and drove a car prior to the Locomotives on Highways act of 1896, commonly called the "Emancipation" act, and in the early days he drove George V and Queen Mary when they were prince and princess of Wales. He drove his own 12 h.p. Panhard car in the Thousand Miles trial of 1900 and took part in many of the early long-distance European classic races. In 1902 he started in business as a motor dealer, and in 1906 his firm merged with the company of Sir Frederick Henry Royce to form Rolls-Royce Ltd. Rolls was the first man to fly across the English channel and back nonstop, in 1910, but on July 12 of that year he was killed in a flying accident at Bournemouth, Hampshire.

ROMA, in ancient Roman religion, the city of Rome personified and later worshiped as Dea Roma. She was first revered simply as the genius or guiding spirit of the city and from this came to be worshiped as a goddess. Like emperor worship, the worship of Roma flowered first in the provinces. She had temples in Asia Minor as early as the 2nd century B.C. (Tacitus, Annals, iv, 56), often in association with other deities (*e.g.,* Tyche, Greek goddess of fortune; *cf.* Fortuna). From the time of Augustus the worship of Roma and the emperor in association became widespread outside Rome, but it was not until the time of Hadrian that Roma was recognized officially with the construction of a temple of Venus and Roma on the Velia. Her representations are numerous. Her head, symbolic of the Roman state, appears continuously on republican coins. In the empire she is a goddess with the symbols of war, victory and plenty.

ROMAINS, JULES (1885–). French poet and novelist, was born on Aug. 26, 1885, at St.-Julien-Chapteuil in the Ardèche. He entered the Ecole Normale Supérieure in 1906, and graduated in philosophy in 1909. His claim to fame is principally based on his position as one of the heads of the unanimist school of writers (Arcos, Vildrac, Duhamel, Chennevière and others). Romains' work falls into three categories: poems, novels and plays. The most important of his books of verse, *La Vie unanime* (1908), deals with what may be called the spiritual life inherent in the various groups of humanity. The *Odes et Prières* (1913) and *L'Ode gênoise* (1925) should also be mentioned. Some of his novels, such as *Les Copains* (1913), owe their merit to a sort of Rabelaisian verve and truculent jollity. Others are in a loftier style. *Mort de* quelqu'un (1910) traces the brief survival of a dead man in the society in which he had lived, and how he gradually fades out of memory. The dramatic works of Jules Romains include farces, the best of which is probably *Knock* (1925), dramatic prose poems, such as *L'Armée dans la ville* (1911) and *Cromedeyre-Ee-Vieil* (1920), and the tragedies *Le Dictateur* (1926) and *Jean le Maufranc* (1927). He went to the U.S. in 1940 and returned to France in 1945. He wrote an epic work in 27 volumes, *Les Hommes de bonne volontk* (Eng. trans. in 14 vol., 1932–46). (G. ML.; X.)

ROMAN, a city of Rumania, in the region of Bacău, on the main line from Czernowitz to Galatz, and on the left bank of the river Moldava, 2¼ mi. W. of its junction with the Sereth. Pop. (1960 est.) 31,882. Roman has been the seat of a bishop since 1401. Its seminary dates from 1402. There are old churches, including a cathedral, built in 1541.

ROMAN ARCHITECTURE refers to the architecture of the community of ancient Rome on the Tiber, as well as to that of the empire that spread from Britain to Mesopotamia, from the 5th century before Christ to the 4th century after Christ. Roman architecture was almost as complex as the Roman empire itself; it was influenced by a multitude of geographic, climatic, political, economic, social and cultural factors. The cohesive factor through all the differences was the Roman character, which possessed the talent and felt the necessity to organize in large and complex terms, politically or architecturally or otherwise.

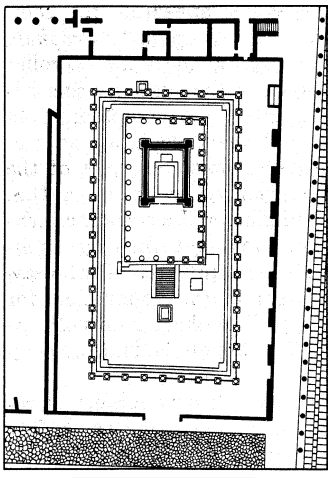
(For a discussion of the architecture of classical Greece, from which many of the elements of Roman architecture were derived, *see* GREEK ARCHITECTCRE. The impact of Roman architecture on succeeding cultures is discussed in BYZANTINE ARCHITECTURE and ROMANESQUE ARCHITECTURE. *See* also ARCHITECTURE and ROME: *The Ancient City.)*

Our knowledge of Roman architecture derives primarily from extant remains scattered throughout the area of the empire. Some are well preserved, others are known only in fragments and by theoretical restoration. Another source of information is the vast store of records, including dedicatory and other inscriptions on public works. Especially important is the book on architecture by Vitruvius who lived about the time of Christ. His book *De Architectura* is a handbook for Roman architects and covers almost every aspect of architecture, but it is limited, since it was based on Greek models and was written at the beginning of the more creative phase of Roman architecture, in the period of the empire.

HISTORY

Roman monumental architecture emerged around the 6th century B.C. as an Italic style, closely related to that of the Etruscans (*q.v.*). The Capitoline temple in Rome, built about this time, resembled Etruscan buildings at Signia, Orvieto, Veii and elsewhere, in resting on a podium with a triple cella, the broad low Etruscan porch and characteristic terra-cotta adornment. The Capitolium at the Roman foundation of Cosa, in the 3rd century, was similarly conceived. The forms, plastic and spatial, had evolved locally in a tradition of wood and terra cotta, though even at this time there was a slight Greek influence.

From about 200 B.C. to about A.D. 50, the rise of republican Rome and the increasing contacts with Greece resulted in a Greek influence strong enough to control the plastic forms and even to modify the spatial effects. A temple at Gabii, perhaps of the 3rd century, and the temple of Apollo at Pompeii of around 120 B.C., had approximately the Greek single-cella peripteral plan; the latter retained the Italic podium and open porch, and had pronounced modifications of the Greek Ionic order. Buildings like the temple under S. Nicola in Carcere (*c.* 31 B.C.), the round building by the Tiber (*c.* 31 B.C.), the Temple of Fortuna Virilis (*c.* 40 *B.C.*), all in Rome, show the height of the hellenizing movement. But the slightly later Augustan temples of Concord, Castor and Pollux in the Roman forum, and Mars Ultor in the Forum of Augustus had a native freedom of arrangement of the limited spaces. and highly elaborated moldings, particularly in the entablature, where new forms, mostly floral, were lavishly displayed in finely worked, full masses, and consoles became increasingly important.



FROM J. OVERBECK, "POMPEII," 4TH ED., LEIPZIG (1884)

FIG. 1.—PLAN OF THE TEMPLE OF APOLLO, POMPEII

During this period the more peculiarly Roman concepts developed chiefly in secular architecture. The Stabian baths at Pompeii, perhaps as early as 120 B.C., were already composed in vaulted spaces, though quite compactly and with little of the later freedom and spaciousness. In some buildings, like the Carcer and Tullianum of about 100 *B.C.* and the Tabularium, about 78 B.C., arches and concrete were basic, though hellenizing orders were used for ornament. The small theatre at Pompeii was built about 75 B.C. with the Roman interior forms already established but with no monumental exterior. The Theatre of Marcellus (*c.* 11–10 *B.C.*). however, had the high external façade with orders and arches blended, which became standard. The basilica, even of the 1st century, was experimental.

The beginning of Roman influence outside Italy is evidenced by theatres and amphitheatres at Arles and Nîmes. perhaps as early as 30 B.C.; by the Maison Carrée at Nîmes about 16 B.C.; and by small buildings in Greece and Syria, about the turn of the century.

Around the middle of the 1st century A.D. there was a surge of development of spatial composition. The orders and other ornament inherited from Greece were increasingly modified and elaborated in nonfunctional perspective effects, and other kinds of

ornament and spatial configurations gained importance. Of course many buildings like the Colosseum (A.D. 75–82) preserved a more conservative character, but with the baths and palaces of Nero began the series of imperial compositions of grand, elaborate spaces. The movement came to a climax under Trajan and Hadrian (c. 98–138): in the Forum of Trajan and the great complex at Baalbek; the Pantheon; the villa of Hadrian at Tivoli, with its intricate composition of enclosed spaces and interrelated buildings and of interior and exterior vistas.

Through the 2nd and 3rd centuries countless buildings were erected in cities and towns all over the empire, in part under imperial patronage, in part by local enterprise. The provincial huildings had great individuality, but the more ambitious usually followed the influence of the capital. The forms evolved by about A.D. 140 were followed conventionally for the next 50 years—and longer—but from about A.D. 200 to the age of Constantine, there was a growing trend toward increased majesty and less emphasis on material substance. Even before the end of the 2nd century deep cutting with sharply contrasting light and shadow had begun to detract from the impression of the solid forms in carved ornament; in the arches of Septimius Severus (c. A.D. 200) light and shadow alone formed the design, not the masses of the forms of the motifs. Especially in Africa illogical composition of the elements of entablatures robbed them of structural significance. In the palace of Diocletian (c. A.D. 300) extensive use of arched colonnades, free and blind—even, as at the main gate, on consoles—emphasized the movement rather than the mass. The sheer faces of some wall surfaces, like those of the towers flanking the gates, became, with a minimum of structural articulation, austere geometric forms. Experimentation and elaboration in vaulting, as in the Temple of Minerva Medica (c. A.D. 260), was toward making the supports lighter structurally and aesthetically. Compared to the Baths of Caracalla (c. A.D. 215), the Basilica of Maxentius (c. A.D. 310–320) was more simple and concentrated, increasing its sense of elemental vastness and permanence, whereas in contrast to the Pantheon its shape and ornament is less tangible.

Finally, evolving into the early Christian art to come, the Constantinian mausoleum of Sta. Costanza. with its dome resting on a drum supported on arches on a circle of pairs of slender columns, and its ambulatory vaults smooth and sheathed with mosaic, already was striving to suggest the independence of roof and space from material support.

BUILDING TECHNIQUES

Building Materials.—The material employed around Rome in the earliest buildings was tufa, a volcanic rock of varying hardnesses, some soft enough to be worked with bronze tools. Later other harder volcanic stones were used such as peperino and the stone from the Alban hills. Under the later republic and the empire the most important stone for building was travertine, a limestone quarried mainly at Tibur (Tivoli). An example of the use of travertine is the exterior of the Colosseum.

The use made by the Romans of marble was mainly decorative. It was applied in slabs to brick and concrete walls, and set in cement. It was used for pavements either in slabs cut and arranged in patterns, or as mosaic. Under the empire a great demand arose for coloured marbles and such stones as porphyry, granite and alabaster, which were imported from various parts of the empire. The abundant use of these marbles is well illustrated by the remains of the Flavian palace on the Palatine and of Hadrian's villa at Tivoli.

Unburned bricks faced with stucco were used especially for private houses under the republic. Of these, naturally, very few remain. Under the empire kiln-baked bricks and tiles were the most common facing for concrete. They were never used to build a whole wall in the modern manner but merely as a protective skin. These bricks or tiles were almost always used in triangular shapes. Large tiles about two feet square called bipedales were employed as bonding courses. (See also BRICKWORK.)

The use of stucco over unbaked brick and over coarse stone was prevalent from the earliest times in Greece, Sicily and Italy. It served as a protection against the weather and also as a finish. Later it was used over brick and concrete. It was often made of lime, sand and fine marble dust and some would take a high polish or fine molding. Thus it became the usual ground for decoration especially in the interiors of houses. Examples of its use abound at Pompeii, and at Rome in the House of Livia, in Nero's Golden house and others. Another material the use of which was mainly decorative is bronze. Doors, grilles, panels of ceilings, etc., were made of it.

For their concrete the Romans used pozzuolana, of which there are extensive beds at Pozzuoli, near Naples, and also around Rome. It is a fine chocolate-red volcanic earth, which when mixed with lime forms an excellent natural hydraulic cement that will set well even under water. With this cement was mixed an aggregate of broken tufa, travertine, brick or even marble, pumice stone being used in vaults after the 1st century A.D. to lighten the weight. It was used in all the great imperial buildings (*e.g.*, Pantheon, Baths of Caracalla and Basilica of Maxentius). The new forms of architecture that were developed by the use of this material spread all over the Roman empire, although in the provinces other, often weaker, kinds of concrete were used.

Construction.—Walls were built of ordinary masonry or of concrete (faced or unfaced). While there are several examples of early stone walling without courses (cyclopean and polygonal) especially in some towns (*e.g.*, Norba, Praeneste, near Rome), most of the stone walls existing were built of squared blocks laid in regular courses as headers and stretchers (opus quadraturn). The blocks of stone in these walls are fairly large, 2 ft. by 4 ft. or more, and were often held together by iron cramps fixed in lead.

Concrete walls, except below ground, were always faced. They are divided into types according to the kind of facing used. (1) Opus quadraturn, *i.e.*, ordinary stone walling, was used as a facing for concrete, especially for important public buildings under the earlier empire (*e.g.*, exterior of the Colosseum). (2) Opus *incertum* was the most common facing for ordinary concrete walls of the 2nd and 1st centuries B.C. The face of the concrete was studded with three-inch to four-inch irregularly shaped pieces of stone, usually tufa. (3) Opus *reticulatum* came into vogue in the 1st century B.C. and remained until the time of Hadrian. The construction was like that of opus *incertum* but the pieces of stone were pyramid shaped with square bases set diagonally and wedged into the concrete walls. (4) Brick- and tile-faced concrete (so called opus *testaceum*) was by far the most common material for walling under the empire. Triangular tiles were used with their points turned into the concrete and their long sides showing, thus giving the appearance of a wall built of thin bricks. Bonding courses of bipedales were employed at intervals of two or three feet. (5) Mixed brick and stone facing (called opus *mixtum*) was popular under the later empire and especially under Diocletian.

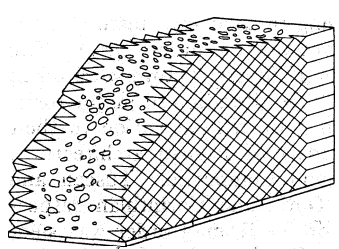

FIG. 3.—DRAWING SHOWING OPUS RETICULATUM TYPE OF WALL CONSTRUCTION

Other kinds of supports included columns and piers. Columns were usually of stone and often monolithic; occasionally small columns were of brick covered with stucco. Piers, too, were often of stone, but those serving as primary support for large vaults were usually of concrete.

Columns and piers both bore horizontal architraves or, from the 2nd centur, B.C. (later for columns), arches. These occurred in gates, bridges and aqueducts as well as colonnades and doors and other openings. Not only round but segmental and flat arches were used freely. The discovery of concrete enormously facilitated the spread of arch construction. Concrete arches were faced with stone or tile voussoirs.

The vaults used by the Romans were simple geometrical forms: the barrel vault, the intersecting (groined) barrel vault and the segmental vault. By the 1st century B.C. extensive systems of barrel vaulting were employed (*e.g.*, in the substructions of the

Tabularium in Rome, the Temple of Hercules at Tivoli and others. When set the concrete vault exerted no thrust. The surfaces of the vaults were tile faced or covered with stucco. A fine example of Roman vaulting is the Basilica of Maxentius.

The construction of the dome (*q.v.*) naturally follows that of the vault. Here again the fact that the concrete dome was a dead weight without thrust simplified the problem. Tie ribs of brick were used and sometimes relieving arches, as in the case of the Pantheon where the facing bricks were laid horizontally. At the crown of the dome was a brick ring. Characteristic of imperial Roman design was the elaboration of complex forms of domes to fit multilobed ground plans.

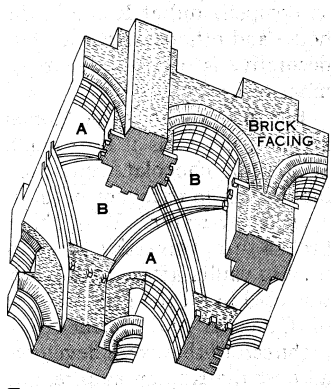

FIG. 4.—ROMAN CROSS VAULT FROM THE PALACE OF SEPTIMIUS SEVERUS, THE PALATINE. ROME (3RD CENTURY)
(A) Brick groin ribs; (B) concrete filling

Most monumental buildings were erected for public use and the income, if any, from rents or fees went to the public treasury. Many of these, however, were built by wealthy individuals and given to the community in a form of voluntary but well-recognized income tax. Construction was done by state agencies or private contractors, employing slave or free labour. Techniques and crafts were highly developed, though machines were simple and powered by men or animals.

Design.—The pervasive Roman predilection was for spatial composition, for organization of lines and surfaces and masses and volumes in space. In this the Romans differed from their predecessors in the ancient Mediterranean world, and however freely they used the elements of earlier styles, in Rome or in the provinces, they recast them according to their own taste.

Their most conspicuous inheritance was the order (*q.v.*). The columns and their associated motifs of superstructure were taken directly from Greek tradition, with little alteration of major form, although the Romans did use them with little attention to their internal logic. There were five orders of Roman architecture: Tuscan, Doric, Ionic, Corinthian and Composite. Tuscan and Composite were modifications of Doric and Corinthian respectively. In general the proportion of the Roman order was slenderer than that of the corresponding Greek order and there was a tendency toward greater elaboration. Columns were often unfluted, but the faces of the entablature, left plain in Greek work, were covered with decoration.

The Doric order almost invariably had a base molding that was probably taken from the Etruscan Doric or Tuscan column. Examples of Roman Doric are to be found in the Tabularium (78 B.C.) and in the lowest order of the Colosseum (A.D. 79) where it was used in conjunction with the arch. The Temple of Hercules at Cori (c. 80 B.C.) is one of the few known Roman Doric temples.

The Ionic order was used in some temples and public buildings and the number of isolated capitals found suggests that it had a certain vogue in private homes. Notable examples of this order are the Temple of Fortuna Virilis, the second orders of the Theatre of Marcellus and the Colosseum, Trajan's forum at Rome and various buildings at Pompeii.

The Corinthian order was by far the most popular with the Roman builder. It was popular for its richness and for the ease with which it could be used in any position resulting from the identity of the four faces of the capital. The columns removed (by Sulla) from the temple of Zeus Olympios at Athens were the model, but the whole order became progressively elaborated in detail and showed a tendency toward sharp contrasts of light and shadow. Examples of this order are seen at the temples of Mars Ultor and of Castor and Pollux (the latter is one of the most beautiful examples in Roman architecture) in Rome, the Temple of Vesta at Tivoli, Agrippa's portico to the Pantheon and the third order of the Colosseum.

The Composite capital is really a Corinthian capital with the tendril at the corner replaced by an Ionic volute. Examples of this capital are to be found on the triumphal arches of Titus and Septimius Severus and the Baths of Diocletian. (See also CAPITAL.)

Although these forms were taken bodily from Greek architecture their real use in Roman design was wholly different. In Roman work columns came to carry arches as well as architraves, permitting more varied linear patterns, wider intercolumniations and greater freedom in articulating spatial forms. Moreover, columns were used not only as primary supports but also as detached columns and pilasters, together with other projecting elements and recessed niches of all kinds, so as to modulate the sheer face of wall or pier into a composition of mass and volume in depth, supplementing the larger forms of the main volumes. Realistic or fanciful architectural compositions were even painted on some walls to give an illusion of the same effecr. So, too, carved moldings, cornices, etc., were designed with deep interplay of mass and volume.

In terms of primary architectural forms, Roman design from its first emergence from the Italic and Etruscan traditions favoured temples with spacious porches, like the Temple of Apollo at Pompeii. The very elevation of the podium poses the temple in the surrounding volume. with external spatial relationships established by the special approach and enclosing colonnades. In imperial architecture the design of the temple precinct, forum, thermae, etc., was normally conceived as a complex of variously formed spaces related to variously formed masses; even landscaping was incorporated, as, conspicuously. at Tivoli and Praeneste. Interiors of smaller houses as well as of grand structures were designed in terms of vistas through variously shaped rooms of varying qualities of illumination. There was a powerful. even rigid final dominant of axial symmetry, but against this was exploited richly every kind of spatial form in some highly developed system of organization.

TYPES OF BUILDING

Temples.—The Roman temples differed in many important respects from those of the Greeks. For the comparatively low stylobate with its three steps all round, the Romans substituted a high platform or podium with a flight of steps on the entrance faqade. Greek temples were isolated from other buildings and almost always faced east and west; those of the Romans were turned to all points of the compass, their orientation being governed by their relation to other buildings. This resulted in an increased emphasis on the entrance faqade, with an increased depth to the portico. The cella was wider and the colonnade that surrounded the Greek temple was often reduced to a row of engaged columns or pilasters along the cella walls, except on the entrance front. In some cases the cella was vaulted in concrete and might have an apsidal end (*e.g.*, the so-called Baths of Diana at Nîmes and especially the double Temple of Venus in Rome). The best preserved example of a Roman temple now existing is that known as the Maison Carrée at Nimes. Among the most important temples of which remains exist are those of Fortuna Virilis, Mars Ultor, Castor and Pollux, Concord and Antoninus and Faustina in Rome; in Italy, the Temple of Minerva at Assisi and the temples at Pompeii; and in Syria, the temples of Bacchus at Baalbek and of the Sun at Palmyra.

Among the most important circular temples are those of Vesta and Mater Matuta in Rome, Vesta at Tivoli, Rome and Augustus on the Acropolis at Athens, and Venus at Baalbek, which has detached Corinthian columns joined to the cella walls by a segmental architrave. The greatest circular temple and in many respects the most important Roman building is the Pantheon (*q.v.*). It consists of a rotunda 142 ft. 6 in. in diameter surrounded by concrete walls 20 ft. thick, in which are alternate circular and rectangular niches. Light is admitted through a central opening about 28 ft. across, at the crown of the dome. In front is a portico which originally belonged to a temple built by Agrippa, re-erected when the rotunda was built under Hadrian, A.D. 120–124. The

rotunda and the dome are among the finest examples of Roman concrete work. The construction is strengthened by immense relieving arches and piers of brick set above one another in the thickness of the walls. The interior was lined with precious marbles, the coffers of the dome were decorated with bronze rosettes and the dome itself was covered externally with bronze plates. (See also TEMPLE ARCHITECTURE.)

Tombs.—The large Roman tomb consisted of an earth mound or tumulus surrounded by a ring of masonry rising usually to a considerable height. Few of the type now exist, the most notable being the tomb of Cecilia Metella on the Via Appia and the mausoleum of Hadrian, now the castle of St. Angelo. The smaller tombs, in particular those of the columbarium (*q.v.*) type are usually underground, though there is sometimes an upper story (often in the shape of a small temple in antis) built of brick, from which steps lead down to the tomb proper. There is a line of such tombs just outside Rome along the Via Appia and also along the Via Latina and such a cemetery has been found under the church of St. Peter in Rome. Examples of Roman funeral monuments of various kinds exist along the Street of Tombs at Pompeii and in the provinces (*e.g.*, at Palmyra, Jerusalem and Petra).

Forums and Markets.—A principal focus of Roman life anywhere was the forum. This was a place or space in which important business might be conducted. In a small community most business would be conducted in a forum, though gradually special buildings were built on the periphery for particular activities, civic, commercial, religious. Characteristically such a forum was lined in part with small one-room shops built in long, low buildings, sometimes with colonnades.

A city might have more than one forum, for special reasons. Conspicuous examples are the imperial forums in Rome itself, of which the Forum of Trajan is the most developed example. It consisted of a colonnaded square with great hemicycles on the

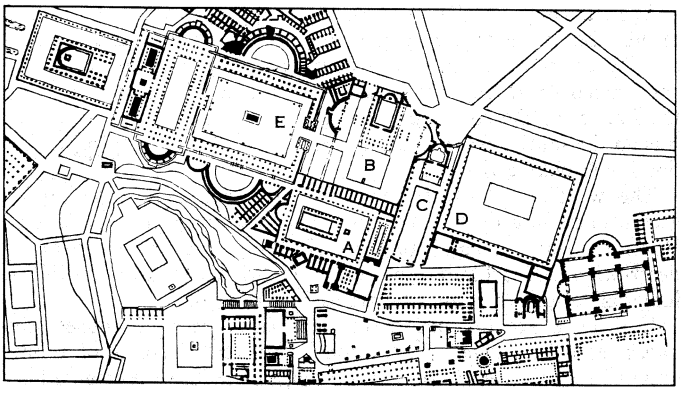

FIG. 5.—PLAN SHOWING IMPERIAL FORUMS AT ROME
(A) Julius Caesar, (B) Augustus, (C) Nerva, (D) Vespasian, (E) Trajan

sides and the tremendous Ulpian basilica lying across one end; beyond the basilica was a library with the commemorative Column of Trajan in the central court, and beyond this a (slightly later) temple in another colonnaded square. (See also GOVERNMENTAL ARCHITECTURE.)

Architecturally and functionally distinct from the forum, though superficially similar, is the *macellum*. This was not a square, but a market building consisting of shops around a colonnaded court. Great warehouses, called horrea, were another kind of market building.

Basilicas.—The basilica (*q.v.*) was a large covered hall for the holding of courts of justice and for banking and other commercial transactions. On the forum at Rome are the Basilica Julia on the south side and the Basilica Aemilia on the north side. both of which had a central hall and side aisles. The Basilica Ulpia in Trajan's forum was similar in plan but had at either end semicircular halls which served as law courts. The fourth and greatest of the basilicas was that begun by Maxentius and finished by Constantine, *c.* A.D. 313. This huge building covered 7,000 sq.yd. and followed in construction and plan the great hall of the Roman baths. The vaults over the bays on the north side are still to be seen overhanging without support, a striking testimony to the marvelous cohesion and enduring strength of Roman concrete. The basilica at Pompeii is an example of the simpler type general in the provinces.

Baths.—By the end of the republic, baths (balneae) had become a recognized feature of Roman life. Under the empire their numbers increased until at the beginning of the 4th century A.D. they numbered 1,000 in Rome alone. They were of the type of the Turkish bath with rooms at different temperatures. Remains of these ordinary establishments are common throughout the empire. The Stabian baths at Pompeii are the best preserved.

The imperial thermae were more than baths. They were immense establishments of great magnificence with facilities for every gymnastic exercise, with halls to which resorted philosophers, poets and rhetoricians and those who wished to hear them. The earliest of these thermae were those built by Agrippa c. 21 B.C. Others were built by Nero, Titus, Trajan, Caracalla, Diocletian and Constantine. The best preserved are the Baths of Caracalla, which covered an area about 1,000 ft. square, and those of Diocletian with accommodation for 3,200 bathers. Parts of the latter are now occupied by the church of Sta. Maria degli Angeli and by the Museo delle Terme. The remains of these two great establishments are among the most impressive examples of Roman concrete construction. (See also BATH.)

Theatres, Amphitheatres, Circuses.—The Roman theatres differed in several respects from the Greek. The auditorium was not excavated and the walls surrounding stage and seating were continuous, the entrance to the orchestra being by vaulted passages. As the chorus played no part in the Roman theatre the orchestra or dancing space became part of the auditorium. The facade behind the stage was elaborately adorned with architectural fantasies.

The only theatre in Rome of which any remains exist is that of Marcellus built by Augustus (c. 11–10 B.C.) but there are numerous examples throughout the Roman empire especially in Asia Minor. The theatre at Orange, France, is the best preserved example. Others of importance are those at Taormina in Sicily; Pompeii and Ostia in Italy; at Termessus, Alinda, Aizani, Aspendus in Asia Minor; the Odeon of Herodes Atticus at Athens. The Odeon of Agrippa in Athens was a good example of a completely enclosed music hall.

The largest and most important amphitheatre (*q.v.*) of Rome was the Colosseum (*q.v.*) built by the emperors Vespasian, Titus and Domitian in A.D. 72–80 on the site of Nero's lake. It is a huge ellipse about 620 ft. by 513 ft. covering six acres and shows remarkable skill in planning. It had seating accommodation for about 45,000 spectators, and its 80 entrances were so arranged that the whole building could be cleared in an incredibly short time. The whole is built of concrete, the exterior being faced with travertine and the interior with precious marbles that have long since disappeared. Other important amphitheatres are those at Capua, Pompeii, Pozzuoli, Verona, Pola, Arles, Nimes, etc.

The circus (*q.v.*) was essentially a racecourse, lined, ideally, with tiers of seats along each side and curving around one end, with the opposite end squared off and provided with arrangements for chariots to enter and draw up for the start. Down the middle ran a barrier, on which judges and referees might perform their functions. Since it was the largest facility for watching some function the circus was used for other spectacles than racing, such as, traditionally, for the burning of the Christians by Nero.

Streets, Arches, Gateways.—Characteristic of Roman towns were colonnaded avenues for main lines of traffic; even secondary streets were sometimes lined with colonnades for protection from weather. Such avenues were sometimes adorned with ornamental arches. Often these served simply to dramatize or punctuate the implied movement of the avenue. A triumphal arch (*q.v.*) was sometimes erected to commemorate an important event or campaign, often isolated rather than spanning a roadway. The triumphal arches of Septimius Severus at Rome and of Trajan at Ancona are accessible only by flights of steps and the archways themselves are too narrow for ordinary use. The triumphal arch

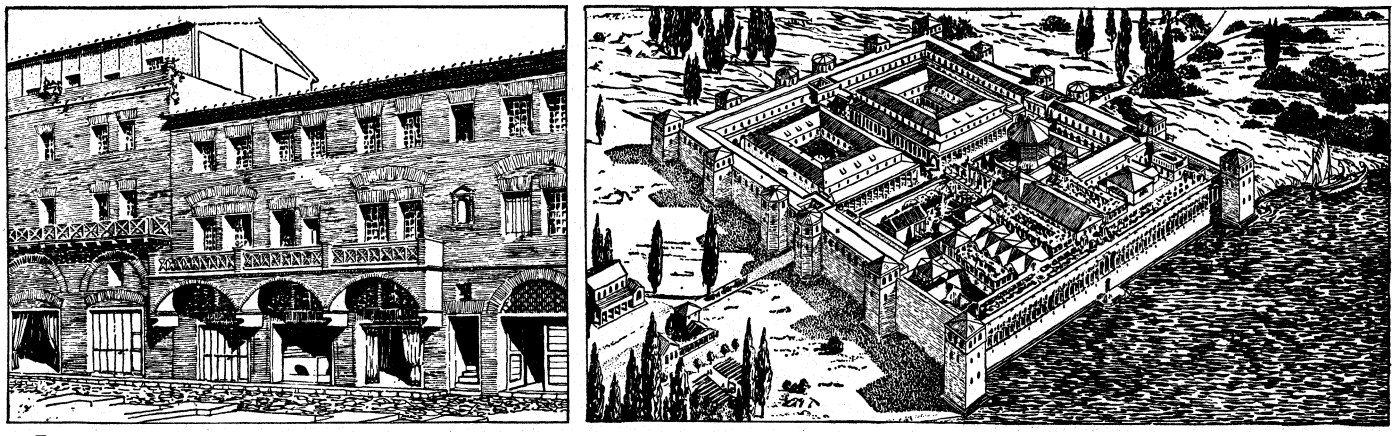

FIG. 6.— (LEFT) RESTORED VIEW OF A STREET OF SHOPS AND TENEMENTS IN OSTIA AND (RIGHT) OF THE PALACE OF DIOCLETIAN AT SPALATRO
(Service portions of the palace are at left and top, the palace proper below and to the right facing the Adriatic)

was usually decorated with columns and bas-reliefs of the chief events it commemorated and was frequently surmounted by a group of sculpture. The most important of these arches are the Arch of Titus (*c.* A.D. 81) commemorating the capture of Jerusalem, the arches of Septimius Severus and Constantine in Rome and Trajan's arches at Benevento and Ancona. There are several other triumphal arches in the provinces, notably those of Tiberius at Orange, of Augustus at Susa and Caracalla at Tebessa. Others exist at Rheims, Pola, Timgad and Maktar.

The monumental city gate while sometimes serving a commemorative purpose differs from the arch in being part of the defenses of the city. Of these gates one of the most famous and best preserved is the Porta Nigra at Trier. (See also *MONUMENTS AND MEMORIALS.*)

Bridges and Aqueducts.— The bridges (*q.v.*) and aqueducts (*q.v.*) of the Romans rank among their greatest monuments. They knew the principle of siphon conduits, but the conduit elevated to grade on arches or even tiers of arches was often cheaper for them and always more spectacular. The most famous examples of Roman aqueducts are the Pont du Gard at Nîmes, the aqueducts at Tarragona and Segovia in Spain, and those which crossed the Campagna bringing water to Rome.

There are not many of the larger Roman bridges now remaining. The best preserved is that built by Augustus and Tiberius at Rimini. The finest is that across the Tagus at Alcantara in Spain.

Domestic Architecture.— Private houses, even palaces, were usually of the style that emphasized interior courts and gardens rather than external façade; this tradition was even maintained so far as possible in northern Europe and Britain, where elaborate arrangements for heating had to be added. In the native Mediterranean climate, however, construction tended to be light and open rather than compact and imposing.

Even the palaces of the Caesars in Rome consisted essentially of series of gardens and, considering their purpose, relatively unmonumental buildings, spread somewhat casually over the Palatine hill. Augustus himself bought and enlarged the house known as the House of Livia which still exists. Tiberius built a palace on the northwest side of the hill. Another palace was built on the southeast corner of the hill by Claudius or Nero. The central space was covered by the palace of the Flavians, Domitian with his architect Rabirius being responsible for a magnificent suite of state apartments and for the sunken garden called the *hippodromus*. Hadrian extended the palace toward the forum. Septimius Severus raised a huge structure overlooking the Circus Maximus, partly on top of Hadrian's work and partly on an artificial platform supported on arches, finishing it with his Septizonium. Of the famous Golden House of Nero on the site now covered by the Baths of Titus, the Colosseum and the Basilica of Maxentius. very little remains.

The villa of Hadrian at Tivoli, begun about A.D. 123, was another sumptuous imperial residence with parks and gardens on a large scale. There are remains of great brick and concrete structures and the unevenness of the site necessitated large terraces and flights of steps. All the buildings are Roman in style and method of construction, though with Greek names.

The palace of Diocletian at Spalato (Split), to which he retired on his abdication in A.D. 305, combined a palace with a fortress and was truly monumental. It consisted of an immense rectangle surrounded on three sides with walls guarded by towers and on the fourth, to the south, protected by the sea. The palace itself was on the south side with a great gallery 520 ft. long with 51 windows overlooking the sea.

The word villa pertains to an estate, complete with house, grounds and subsidiary buildings. There are very few remains of Roman villas; our chief authority is Pliny, who gave a detailed description of his Laurentine villa. Hadrian's villa at Tivoli, an imperial residence, cannot be treated as typical.

In Roman architecture there were two types of houses, the *domus* and the *insula*. The *domus* consisted of suites of rooms grouped round a central hall or atrium, to which were often added further suites at the rear grouped round a colonnaded court or peristyle. The atrium, a rectangular room with an opening in the

FIG. 8.— PLAN OF THE TOWN OF TIMGAD IN NORTH AFRICA

roof to the sky, and its adjoining rooms, was the peculiarly Roman element; the peristyle, or patio garden, was Greek or oriental. There were few windows on the street, light being obtained from the atrium or peristyle. The *domus,* as exemplified at Pompeii and Herculaneum (*qq.v.*) has long been regarded as the typical Roman house.

In Rome itself, however, very few remains of the *domus* have come to light, the chief examples being the House of the Vestal Virgins on the forum and that of Livia on the Palatine.

From Latin writers it has long been known that there were in Rome great blocks of flats or tenements to which the term *insulae* was applied. Excavations at Ostia (*q.v.*) have revealed the design of these blocks. Planned on three or four floors with strict regard to economy of space they depended on light from the exterior, as well as from a central court. Independent apartments had separate entrances with direct access to the street. Since Ostia was a typical town of the 1st and 2nd centuries A.D. and was almost a suburb of Rome itself, it is supposed that *insulae* at Rome would present similar features.

The street front of either *domus* or *insula* might be lined with shops.

(See also HOUSE.*)*

Town **Planning.**—Vitruvius clearly indicated that the Romans were keenly aware of the fundamentals of town planning, *i.e.,* the location of the city and its parts in terms of necessities, climate, functions and the like. When a new town was established such considerations were energetically examined.

A characteristic Roman plan, either inherited from early Italic towns or developed in the discipline of army camp engineering, was used. The over-all plan was square, with main avenues bisecting the sides and intersecting at the centre. The rest of the streets were in checkerboard grid.

At or near the centre was the forum; theatres, baths and other structures were located according to the site.

Long-established communities, which had developed by accretion rather than by plan, were often gradually brought, under Roman influence, within some approximation of this scheme, sometimes with considerable subtlety. Often, however, as in Rome itself, the scale and topography prevented the achievement of any fully logical order. In general, colonnades lined the important streets; water was conveyed to spectacular ornamental fountains or to practical neighbourhood basins from reservoirs fed by aqueducts (in some climates cisterns were necessary); many large sewers collected waste water from the street if not from private homes; also building codes were devised and enforced.

The layout of a whole town can be most easily seen in some of the towns in north Africa (*e.g.,* Timgad, Tebessa, Thuburbo Maius), where there has been little or no subsequent building to modify the original lines of the plan. See also *CITY* PLANNING.

(H. C. BR.; M. BRA.; R. L. SN.)

ROMAN ARMY. In the long life of the ancient Roman army, the most effective and long-lived military institution known to history. we may distinguish four principal stages. (1) In the earliest age of Rome the army was a national or citizen levy such as we find in the beginnings of all states. (2) This grew into the Republican army of conquest, which gradually subdued Italy and the Mediterranean world. A citizen army of infantry, varying in size with the needs of each year, it eventually developed into a mercenary force with long service and professional organization. This became (3) the Imperial army of defence, which developed from a strictly citizen army into one which represented the provinces as well as Italy. and was a garrison rather than a field army. Lastly, (4) the assaults of the Barbarian horsemen compelled both the creation of a field force distinct from the frontier garrisons and

the inclusion of a large mounted element, which soon counted for much more than the infantry. The Roman army had been one of foot soldiers; in its latest phase it was marked by that predominance of the horseman which characterized the earlier centuries of the middle ages.

So far as we can follow this long development in its details, it was continuous. So unbroken, indeed, is the growth that many of the military technical terms survived in use from epoch to epoch, unchanged in form though deeply modified in meaning, and ordinary readers often miss the diversity which underlies this seemingly unchanged system. The term *legio*, for example, occurs in all the four stages above outlined. But in each its significance varies. Throughout, it denoted citizen-soldiers; throughout, it denoted also a force which was chiefly, if not wholly, heavy infantry. But the setting of these two constant features varies from age to age. In the first period legio was the "levy," the whole host summoned to take the field. In the second period it was not the whole levy, but one of the principal units into which developing organization had divided that levy; the "legion" was now a body of some 5,000 men—the number of "legions" varied with the circumstances, and the army included other troops besides citizens, though they were for the most part unimportant. In the third or Imperial age there were many legions (indeed, a fixed number) quartered in fixed fortresses; there were also other troops, numerous and important, if not yet so formidable as the legionaries. Finally, the legions became smaller units, and the other troops of the army, notably the cavalry, became the real fighting-line of Rome. (See LEGION.)

First Stage.—The history of the earliest Roman army is, as one might expect, both ill-recorded and contaminated with much legend and legal fiction. We read of a primitive force of 300 riders and 3,000 foot soldiers, in which the horseman counted for almost everything. But the numbers are clearly artificial and invented, while the pre-eminence accorded to the cavalry has no sequel in later Roman history. We reach firmer ground with the organization ascribed to Servius Tullius. In this system the army included all citizens from 17 to 60 years of age, those under 47 for service in the field, the older men for garrison duty in Rome. The soldiers were grbuped at first by their wealth—that is, their ability to provide their own horses, armour, etc.—into cavalry, heavy infantry, a remainder which it would be polite to call light infantry, and some artificers. The heavy infantry counted for most. Armed with long spears and divided into the three orders of hastati, principes and *triarii* (the origins and real senses of these names are lost), they formed a phalanx, and charged in a mass, while the cavalry protected the wings. The men were enrolled for a year—that is, for the summer campaign; in the autumn, like all primitive armies, they went home.

Second Stage.—From this Servian army a series of changes which we cannot trace in detail produced the Republican army of conquest. Our ancient authorities ascribe the chief reforms to the half-legendary Camillus (*q.v.*), who introduced the beginnings of pay and long service, improved the armour and weapons, abolished the phalanx and substituted for it an open order based on small subdivisions (maniples), each containing two centuries.

Whatever the truth about Camillus, some such reforms must at some time have been carried through, to convert the Servian system into the army which was engaged for nearly three centuries (from 350 B.C.) in conquering Italy and the world. This army broke in succession the stout native soldiers of Italy and the mountaineers of Spain and overthrew the trained Macedonian phalanx. Once only did it fail—against Hannibal. (See PUNIC WARS.) But not even Hannibal could oust it from entrenchments, and not even his victories could permanently break its moral. Much of its strength lay in the same qualities which made the Puritan soldiers of Cromwell terrible—the excellent character of the common soldiers, the rigid discipline, the high training. Credit, too, must be given to the genius of Scipio Africanus and to the more commonplace capacities of many fairly able generals. But the organism itself deserves attention, and, as it chances, we know much about it, mainly from Polybius. Its elements were three:—

(A) The principal unit was the legion, generally a division of 4,500 men—3,000 heavy infantry, 1,200 lighter-armed (velites), 300 horse—though sometimes including as many as 6,000 men. The heavy infantry were the backbone of the legion. They were levied from the whole body of Roman citizens who had some private means and who had not already served 16 campaigns, and in effect formed a yeoman force. For battle they were divided into 1,200 hastati, 1,200 principes and 600 triarii: all had a large shield, metal helmet, leather cuirass, short Spanish thrusting and cutting sword, and in addition the hastati and principes each carried two short heavy throwing spears (*pila*), while the triarii had ordinary long spears. They were drawn up in three lines: (1) hastati, (2) principes, (3) triarii; the first two were divided into ten maniples each (of 120 men, when the legion only counted 4,500), the third into ten maniples of half the strength. According to the ordinary interpretation of our ancient authorities, the maniples were arranged in a chess-board fashion (quincunx), the idea being that the front row of maniples could retire through the intervals in the second row without disordering it, and the second row could similarly advance. The procedure in fighting seems to have been simple: the front line discharged a volley of *pila* and rushed in with the short sword—a sequence much like the volley and bayonet charge of the 18th century—and if this failed, the second line went in turn through the same process; the third line of triarii, armed with spear instead of *pilum*, formed a reserve. The velites, armed with javelins, came to be used as skirmishers. The cavalry seem to have been of little account—a natural result if, as we have reason to think, the horses were small and stirrups were not used. Scipio Africanus alone developed his cavalry into a decisive instrument.

The officers of the legion consisted of: (a) Six tribunes, in part elected by the comitia, in part appointed by the consuls, and holding command in rotation. They were either veteran officers, sometimes even ex-magistrates, or young noblemen beginning their career. (b) Sixty centurions, each commanding one century, or, rather, a pair commanding each maniple. They were chosen by the tribunes from among the veteran soldiers serving at the time and were arranged in a complicated hierarchy, by means of which a centurion might move upwards till he became *primus pilus*, senior centurion of the first maniple of triarii, the chief officer of that rank in the legion. (c) There were also standard-bearers and other under-officers, for whom reference must be made to specialist publications.

(B) Besides the legions, composed of citizens, the Roman army included contingents from the Italian "allies" (socii), subjects of Rome. These contingents appear to have been large; in many armies we find as many socii as legionaries, but we are ignorant of details. The men were armed and drilled like the legionaries, but they served not in legions but in cohorts, smaller units of 400–500 men, and their conventional positions seem to have been on the wings of the legions. They were principally infantry, but included also a fairly large proportion of cavalry.

(C) Besides legionaries and socii, the Roman army included non-Italian troops of special kinds, Balearic slingers, Numidian horsemen, Rhodians, Celtiberians and others: at Trasimene, for example (217 B.C.), the Roman army included 600 Cretan archers. The numbers of these auxilia varied; probably they were not numerous till the later days of the Republic.

Composition and Size *of* Armies in the Second Stage.—According to the general practice, each of the two consuls, if he took the field alone, commanded an army of two legions with appropriate socii. If the two consuls combined their forces, commanding the joint force in rotation (as often occurred), the total would be—according to our authorities—four legions, each of 4,200 infantry, the same number of "allied" infantry (in all 33,600 infantry), 1,200 legionary cavalry and about 3,600 "allied" cavalry = 38,400 men. Such, for example, was the Roman army at Trebia (218 B.C.), where (says Polybius) there fought 16,000 legionaries and 20,000 allied infantry. The total number of men in the field could be increased; we even hear of 23 legions serving at one time in the Second Punic War. Just before this war, in 225 B.C., the total man-power of Rome was reckoned at three-quarters of a million, of which about 65,000 were in the field and 55,000 were in a re-

serve at Rome; of the total, 325,000 were Roman citizens and 443,000 (apparently a rough estimate) were allies. The battle order in normal circumstances was simple. In the centre stood the legionary infantry: on each side of that was the allied infantry: on the wings the cavalry. But sometimes the legions were held in reserve and the brunt (and honour) of the fight was left to the allies. Frequently the attack was begun by one wing, as by Caesar at Pharsalus. At Ilipa in Spain Scipio surprised his enemy by a last hour variation of the accustomed order. Putting his Spanish auxiliaries in the centre, his Roman troops on the wings, he "re-fused" his centre and attacked with both wings.

Development from the Second Stage to the Third.—Towards the end of the Republic many changes began to work themselves out in the Roman army. If Camillus began the system of pay and long service, it was effectually developed by long foreign wars in Spain and in the East. Moreover, the growth of Rome as a wealthy state tended to wreck the old theory that every citizen was a soldier, and favoured a division of labour between, *e.g.*, the merchant and the military, while the increasing complexity of war required a longer training and a more professional soldier. In consequence, the old restriction of legionary service to men with some sort of private property was abolished by Marius about 104 B.C. and the legionaries now became wholly proletariate and professionals. By a second change, also connected with the name of Marius, the legion was reorganized as a body of 6,000 men in 60 centuries, divided into ten cohorts instead of (as hitherto) into 30 maniples; the unit of tactical action thus became a body of 600 instead of 120. This was probably an adaptation within the legion of the system of cohorts already in use for the contingents of the *socii*. Soon after, the extension of the Roman franchise to all Italians converted allies and subjects into citizens, and the socii into legionaries. A fourth change abolished the legionary cavalry and greatly increased the auxilia (C., p. 396).

Third Stage.—The Imperial Army of Defence.—The evils of the Civil Wars (49–31 B.C.) furnished the first emperor, Augustus with both the opportunity and the necessity for reforming the army. Disorganization had reigned for 20 years. It was needful to restore loyalty and system alike. Augustus did this, as he did all his work, by adapting the past: yet there is some truth in the view that his army reforms were his greatest and most original work. The main lines of his work are simple. The Imperial army consisted henceforward of two classes or grades of troops, about equal in numbers if unequal in importance. The first grade was the legions, recruited from Roman citizens, whether resident in Italy or in the provinces. The second grade was formed by the auxilia, recruited from the subjects (not the citizens) of the Empire in the provinces, organized in cohorts and alae and corresponding somewhat to both the socii and the auxiliaries (B, C, above) of the Republican army. There were also in Rome special "household" troops (see PRAETORIANS), and a large body of vigiles who were both fire brigade and police.

Details of Troops.—(A) The legion of the Empire was what Marius had left it—6,000 heavy infantry divided into ten cohorts: Augustus added only 120 horsemen to serve as despatch-riders and the like. The supreme command was no longer in the hands of the six tribunes. According to a practice which had sprung up in the latest Republic it was in the hands of a *legatus* legionis, deputy of the general (now of the emperor, commander-in-chief of the whole army) and a man usually of senatorial rank and position. The six tribunes assisted him in theory; in practice they were now little more than young men of good birth learning their business or wasting their time. The real officers of the legion were the 60 centurions, men who (at least in the early Empire) generally rose from the ranks, and who knew their work. The senior centurion, *primus pilus*, was an especially important officer, and on retirement frequently became praefectus castrorum, "camp adjutant," or obtained other promotion. Below the centurions were under-officers, standard-bearers, *optiones*, clerks and the like. The men themselves were recruited from the body of Roman citizens (though we may believe that birth-certificates were not always demanded). During the 1st century Italy, and particularly north Italy, provided the bulk of the recruits. After A.D. 70, recruiting in Italy for the legions practically ceased and men were drawn from the Romanized towns of the provinces. After Hadrian, each province seems to have supplied most of the men for the legion (if any) stationed in it, and so many sons of soldiers born during service (castrenses) flocked to the army that a military caste almost grew up. The term of service was, in full, 20 years, at least in theory, but recruiting was voluntary and when men were short discharges were often withheld. On discharge the ex-legionary received a bounty or land: many coloniae (municipalities) were established in the provinces by certain emperors for the special purpose of taking discharged veterans—according to a custom of which the first instances occur in the late Republican age. On the whole, the legionary was still the typical "Roman" soldier. If he was no longer Italian, he was generally of citizen birth, and always of citizen rank, and his connection with the Empire and the Government was real. Each legion bore a number and a title (*e.g.*, II. Augusta, III. Gallica). The custom of using such titles and numbers can be detected sporadically in the late Republic, and many titles and numbers then borne by legions passed on into the Empire with the legions themselves. As Augustus gradually became master of the world, he found himself with three armies, his own and those of Lepidus and Antony; from the three he chose certain legions to form his new standing army, and he left these with the titles and numbers which they had previously borne, although that concession resulted in three legions numbered III. and two numbered IV., V., VI. and X. respectively. Similar titles and numbers were given to legions raised afterwards either to fill up gaps caused by disaster or to increase the army.

(B) Besides the legions Augustus developed a new order of auxilia. Auxiliaries (as is said above) had served occasionally in the Republican armies since about 250 B.C., and in the later Republic large bodies of them had been enlisted in the armies of contending generals. Thus Caesar in Gaul enrolled a division of native Gauls, free men but not citizens of Rome, which ranked from the first in all but legal status as a legion, the "Alaudae," and in due course was formally admitted to the legionary list (legio V.). But this use of non-citizens had been limited in extent and confined in normal circumstances to special troops such as slingers or bowmen. This casual practice Augustus reduced, or rather extended, to system, following in many details the scheme of the Republican socii and veiling the novelty under old titles. Henceforward, regiments of infantry (cohortes) or cavalry (alae), 500 or 1,000 strong, were regularly raised (apparently, by voluntary recruiting) from the non-citizen populations of the provinces and formed a force almost equal in numbers (and ultimately much more than equal) to the legions. The men who served in these units were less well paid and served longer than the legionaries; on their discharge they received a bounty and the Roman franchise for themselves, their wives and children. They were commanded by Roman *praefecti* or tribuni, and were no doubt required to understand Roman orders; they must have generally become Romanized and fit for the citizenship, but they were occasionally (at least in the 1st century A.D.) permitted to retain tribal weapons and methods of fighting and to serve under the command of tribal leaders, who were at once their chiefs and Roman officers. These auxiliaries provided both the whole of the archers, etc., and nearly the whole of the cavalry of the army; they also included many foot regiments. A peculiar arrangement (to which no exact parallel seems to occur in any other army) was that a cohort of 500 men might include 380 foot and 120 horse and a cohort of 1,000 men or 760 foot and 240 horse (cohors equitata), and an *ala* might similarly include a proportion of foot (ala peditata). Each regiment bore a number and a title, the latter often derived from the officer who had raised the corps (ala Indium, raised by one Julius Indus), or, still more often, from the tribe which supplied the first recruits (cohors VII. Gallorum, cohors *II. Hispanorum* and the like). To what extent recruiting remained territorial is uncertain: after the 1st century, probably, the territorial names meant in most cases very little.

Composition of Armies and Distribution of Troops in the Third Stage.—If the system of legions and auxilia in the early Empire was novel, the use made of them was no less so. The later Repub-

lic offers to the student the spectacle of large field armies, and though it also reveals a counter tendency to assign special legions to special provinces, that tendency is very feeble. Augustus ended the era of large field armies: he could not afford to leave such weapons for future pretenders to the throne. By keeping the Empire within set frontiers, he developed the counter tendency. That policy exactly suited the military position in his time. The early Roman empire had not to face — like modern empires — the danger of a war with an equal enemy, needing the mobilization of all its national forces. From Augustus till A.D. 250 Rome had no conterminous foe from whom to fear invasion. Parthia, her one and dangerous equal, was far away in the East and little able to strike home. Elsewhere, her frontiers bordered more or less wild barbarians, who might often harass, but could not do serious harm. To meet this there was need, not of a strong army concentrated in one or two cantonments, but of many small garrisons scattered along each frontier, with a few stronger fortresses to act as military centres adjacent to these garrisons.

Accordingly, a system grew up under Augustus'and his immediate' successors whereby the whole army was distributed along the frontiers or in specially disorderly districts (such as northwest Spain) in permanent garrisons. On the actual frontiers and on the chief roads leading to them were numerous cohorts and *alae* of auxiliaries, garrisoning each its own *castellum* of 3–7 acres in extent. Close behind the frontiers, or even on them, were the 25 legions, each (with a few exceptions of early date) holding its own fortress (castra stativa or hiberna) of 50–60 acres. Details varied at different times. Sometimes, where no Rhine or Danube helped, and outside enemies were many, the frontier was fortified by a wall of wooden palisades (as in part of Germany; see LIMES GERMANICUS) or of earth or stone (as in Britain, see **BRITAIN**: *Roman* Britain), or the boundary might be guarded by a road patrolled from forts planted along it (as in part of Roman Africa). The result was a frontier guard covering Britain and Europe from the German ocean to the Black sea, and the upper Euphrates valley, and the edge of the Sahara south of Tunis and Algeria and Morocco, while the wide Empire within saw little of its soldiers.

Change from the Third Period to the Fourth. — Two principal causes brought gradual change to the Augustan army. (1) The pax Ronzana brought such prosperity to many districts that they ceased to provide sufficient recruits. The Romans, like the British in India. had more and more to look to uncivilized regions and even beyond their borders. Hence comes, in the 2nd century and after, a new class of numeri or cunei or vexillationes who used (like the earlier auxiliaries) their national arms and tactics and imported into the army a more and more non-Roman element. This tendency became marked in the 3rd century and bore serious fruit at its close. (2) The old days of mere frontier defence were over. The barbarians began to beat on the walls of the Empire as early as A.D. 160: about A.D. 250 they here and there got through. and they came henceforward in ever-growing numbers. Moreover, they came on horseback, bringing new tactics for the Roman infantry to face, and they came in masses. We may doubt if any military system could have permanently stayed this series of human tides. But the Empire did what it could. It enlisted barbarians to fight barbarians, and added freely to the non-Roman elements of the army. It increased the relative strength of its cavalry and began to organize a distinct field force.

Fourth Period. — The results are seen in the reforms of Diocletian and Constantine the Great (A.D. 284–circa 320). New frontier guards, styled limitanei or *riparienses*, were established, and the old army was reorganized in field forces which accompanied or might accompany the emperors in war (comitatenses, palatini). The importance of the legions dwindled; the chief soldiers were the mercenaries, mostly Germans, enlisted from among the barbarians. New titles now appear, and it becomes plain that in many points the new order is not the old. The details of the system are as complicated as all the administrative machinery of that age. Here it is enough to point out that the significance of such officers and titles as the dux and the comes (duke, count) lies ahead in the history of the middle ages, and not in the past, the history of the Roman army itself.

War Office, General Staff. — Under the Republic we do not find, and indeed should not expect to find, any central body which was especially entrusted with the development of the army system or military finance or military policy in wars. Even under the Empire, however, there was no such organization. The emperor, as commander-in-chief, and his more or less unofficial advisers doubtless decided questions of policy. But the army was so much a group of provincial armies that much was left to the chief officers in each province. Here, as elsewhere in the Empire, we trace a love if not for Home Rule, as least for Devolution. There was, however, a central finance office in Rome for the special purpose of meeting the bounties (or equivalent) due to discharged soldiers. This was established by Augustus in A.D. 6. (F. J. H.; X.)

ROMAN ART. There are at least five different ways in which Roman art can be defined: (1).The term might be restricted to works produced in or near Rome itself, which reflect specifically the national life and traditions of the city or the exploits of its citizens and rulers. (2) "Roman art" and "art in Rome" might be treated as convertible terms, including all imported works which mirror the effect of foreign contacts and ever-widening horizons on thought and taste in the metropolis. (3) The phrase might be extended to cover works of art that were made in, or imported into, Italy as united under Roman hegemony. (4) The phrase might be stretched to denote all works of art produced in. or brought into, the predominantly Latin-speaking countries of the western Roman empire. (5) "Roman art" may mean nothing less than the artistic output of the entire world dominated by ancient Rome. The art of the Greek-speaking provinces may justly be described as "east Roman." where existing Hellenistic traditions not merely survived conquest by Rome but gained fresh vigour and scope through incorporation into its system. It is in this fifth and widest sense that the term "Roman art" will be used in this article. As regards chronology, "Roman" is taken as covering a period extending to c. A.D. 500; in respect of content. the word includes works of Jewish and Christian subject matter, indistinguishable in style from their pagan contemporaries and often borrowing some of their motives.

The Romans themselves did not, it seems, have an innate and spontaneous capacity for art. Such works of art as were made in. or imported into, Rome during the periods of the monarchy and the early republic were produced almost certainly by Greek and Hellenized Etruscan artists, or by their imitators from the cities of central Latium; while throughout the later republican and the imperial epochs all the leading masters at least and many of the lesser craftsmen had Greek names and were Greek, or at any rate Greek-speaking, by extraction. References in ancient literature and the signatures of artists preserved in inscriptions leave no doubt on this point. According to tradition, the earliest image of a god made in Rome dated from the 6th century B.C. period of Etruscan domination and was the work of Vulca of Veii. The magnificent terra-cotta statue of Apollo found at Veii may give some notion of its character, while the celebrated bronze figure of the wolf in the Conservatori museum, Rome, is generally assigned to the same Veientine school. In the 5th, 4th and 3rd centuries, when Etruscan influence on Rome was declining and Rome's dominion was spreading through the Italian peninsula, contacts with Greek art were no longer chiefly mediated via Etruria, but were made directly through Campania and Magna Graecia; the paintings and the "idealizing" statues of gods and worthies that are mentioned in literature as executed in the capital during this period were clearly the works of visiting or immigrant Greek artists. The plundering of Syracuse and Tarentum at the end of the 3rd century marked the beginning of that flow of Greek art treasures into Rome which continued for several centuries and played a leading role in the aesthetic education of the citizens.

It was therefore to Greek artists that the Romans turned when, in the course of the 3rd century, they first apparently became aware of the potentialities of works of art for the visual expression of their own political, social and religious life and history. Greeks designed the dies for the silver coinage that Rome inaugurated in 269 to circulate through Italy, with types that displayed an ever-increasing richness and variety of style and content, par-

ticularly during the later 2nd and 1st centuries B.C., until the close of the republican epoch. Six documentary paintings depicting events from Roman history between 264 and 168 are known from literary sources. These events were, for the most part, military victories; the pictures themselves were ephemeral affairs shown at triumphs and on other public occasions to the Roman populace; and the artists who produced them were very probably Greeks, since in 158 L. Aemilius Paulus, the victor at Pydna, employed Metrodorus, a painter from Athens, to execute the topical pictures exhibited in Rome for his Macedonian triumph, and Demetrius, an Alexandrian "place painter," was in Rome in 164. The fragment of a historical wall painting with scenes from the Samnite wars, found in a family tomb on the Esquiline, probably dating from the 3rd century B.C. (in the Conservatori museum). may give some idea of the nature of these early triumphal pictures. Literature shows that by the middle of the 2nd century B.C. the Roman forum was thronged with honorific statues of Roman magistrates which, although none of them has survived. may be assumed to have been carved or cast by Greeks, since no native Roman school of sculptors of that time is known. And it is significant that the earliest account of Roman realistic portraits of private individuals is that contained in Polybius' description of the ancestral *imagines* ("masks") displayed and worn at patrician funerals — a description written about the middle of the 2nd century B.C., when the tide of Greek artistic influences was sweeping into Rome and Italy from countries east of the Adriatic, where a highly realistic late-Hellenistic portrait art, that sometimes depicted Roman or Italian subjects, had already blossomed.

The first appearance of the three art forms that expressed the Roman spirit most eloquently can be traced back to the Hellenistic age. These forms are realistic or veristic portraiture, in which every line, crease and wrinkle. and even blemishes were ruthlessly chronicled; the continuous. or "film," style in narrative art of all types; and the three-dimensional rendering of atmosphere, depth and perspective in relief work and painting. Of these three art forms there is no evidence in the early art of pre-Hellenistic central Italy, and it would be safe to guess that if Rome had not met them in the homelands of Greek art it would never have evolved them in its great art of imperial times. But Rome's own contributions to art, if of a different order, were vitally important. Its historical aims and achievements furnished late-Hellenistic artists with a new setting and centre, new subjects, new stimuli, a new purpose and a new dignity. Rome provided the external circumstances that enabled the sculptors, painters and other craftsmen to exploit on a much more extensive scale than before artistic movements initiated in the Hellenistic world, and Rome became a great new patron of art and a great new wellspring of inspiration and ideas. Thus Roman art is the child of the marriage of two traditions — one. the Hellenistic art tradition and the sculptural branch of that tradition in particular, the other. the political, social, religious and psychological tradition of Rome.

SCULPTURE

The Last Century of the Republic. — The ancestral *imagines*, or funerary masks, made of wax or terra cotta. had become extremely individualized and realistic by the middle of the 2nd century B.C. The source of this realism is in the impact on Rome of late-Hellenistic veristic iconography; although this use of masks was rooted in ancient Roman social and religious practice, there is no basis for the statement that the Romans and Etruscans had. from early times, been in the habit of producing death masks proper. cast directly from the features of the dead. It was undoubtedly their funerary customs that predisposed the Romans to a taste for portraits. But it was not until *c.* 100 B.C. that realistic portraiture, as an art in its onn right, appeared in Rome as a sudden flowering. and to that time belong the first beginnings of the highly realistic and veristic heads, busts and statues of contemporary Romans, in marble, stone or bronze. that have actually survived. The coin portraits of public men, whose names and dates are recorded, greatly assist in determining the chronological sequence of the large-scale likenesses, the earliest of which can be attributed to the period of Sulla. The veristic style reached its climax in the stark, dry, linear iconographic manner of c. 75–65 B.C., which expressed to perfection current notions of the traditional Roman virtues; of this manner the marble head of an elderly veiled man in the Vatican is an outstanding illustration. After that, an admiration for the earlier phases of Greek art came into fashion in the west, and verism, was toned down at the higher social levels by a revival of mid-Hellenistic pathos and even by a classicizing trend that was to stamp itself upon Augustan portraits. Meantime, in sepulchral custom, the ancestral bust had become an alternative to the ancestral mask, a development exemplified in a togate marble statue of a man carrying two such busts in the Museo Capitolino Nuovo; while the portrait busts and figures on the numerous stone and marble grave *stelai,* characteristic of the late-republican epoch, proclaim the persistence of veristic tastes in middle-class and humbler circles. Furthermore, there are some 1st-century B.C. portraits which suggest that the making of death masks proper (a sophisticated and essentially nonprimitive idea) was occasionally practised at this time. None of the vividly veristic Etruscan portraits, such as the bronze orator *(Arrzngatore)* at Florence and the terra-cotta married pair on the lid of a well-known ash chest at Volterra, is earlier than c. 100 B.C.; works of that type must be reckoned as provincial imitations of the new metropolitan, 1st-century B.C. portrait style.

There are no narrative reliefs from Rome that can confidently be assigned to a pre-1st-century B.C. period. The only definitely dated 2nd-century B.C. relief depicting an episode from contemporary Roman history, the frieze with the battle of Pydna on L. Aemilius Paulus' victory monument at Delphi, was worked in 168 in Greece. The most familiar republican example of this form of art as practised in the west is the frieze decoration, partly in the Louvre, Paris, and partly at Munich. from the so-called "Altar of Ahenobarbus," which has been shown to have no sure connection either with an altar or with any of the Ahenobarbi. The Louvre section gives a matter-of-fact and accurate representation of the Roman census ceremonies, while the Munich section depicts a marine procession of Neptune and Amphitrite with their train. Assuming that the two scenes belonged to the same monument. as the identity of their dimensions and material suggests, the most attractive theory of them is that they adorned the temple of the nymphs in the Campus Martius, when it was restored after its burning by Clodius in 57 B.C. That temple was the *archivium* of the census. while the nymphs were equated with the nereids and associated with Neptune; this would be an early and striking instance of that juxtaposition of Hellenistic and Roman motives, of human and divine persons and of mythology and history which was to characterize imperial state reliefs throughout their development. Fragments of a marble frieze, presenting successive scenes from Roman legendary history. were recovered from the Basilica Aemilia in the Roman forum and reconstructed before World War II. The subjects include the building of a city, probably of Rome itself. the rape of the Sabine women and the punishment of Tarpeia, and although there is no evidence for determining its date with certainty, the frieze could have been carved for the basilica's rebuilding between 54 and 34 B.C. Funerary narrative sculpture of the late republic is exemplified in the monument of the Julii at St. Rémy (Glanum), France. The base of this structure carries four great reliefs with battle and hunt scenes that allude. not only to the mundane prowess of the family, but also to the "other-worldly" victory of the souls of the departed over death and evil. since figures of the deceased. accompanied by personifications of death and victory, merge into one of the battle scenes. It is possible that these highly pictorial reliefs were partly based on lost Hellenistic monumental paintings. Southern Gaul had direct connections with Greek lands east of the Adriatic.

The Augustan Age. — The hallmark of the portraits of Augustus is a naturalistic classicism. The rendering of his features and of the forking of his hair above the brow is individual. But the emperor is consistently idealized and never shown as elderly or aging The marble statue from Livia's villa at Prima Porta (in the Vatican). which presents him as addressing. as it were. the whole empire, is the work of a fine Greek artist who, while adopt-

ing the pose and proportions of a classical Hellenic statue, understood completely what Augustus meant to Rome. On the ornate cuirass the princeps' aims and achievements are recorded symbolically in a series of figure groups, among which that of the restoration of the Roman standards by a Parthian to Mars occupies the central place. A marble portrait statue found on the Via Labicana represents the emperor as heavily draped, veiled and in the act of sacrificing as Pontifex Maximus; while a bronze head from Meröe in the Sudan (in the British museum, London), the work of a Greco-Egyptian portraitist, depicts him as a Hellenistic king. Of the female portraits of the period, one of the most charming is the green basalt head (in the Louvre) of the emperor's sister, Octavia, with the hair dressed in a puff above the brow and gathered into a bun behind—a popular coiffure in early Augustan times. The noblest, in many respects, of all the Roman public monuments that were adorned with sculpture is the Ara Pacis Augustae, founded in 13 B.C. and dedicated four years later. It stood in the Campus Martius and has been restored, with different orientation, not far from its original site; and in the harmonious blending, on its reliefs of Luna marble, of contemporary history, legend and personification, of figure scenes and decorative floral motives, it set a standard of distinction which no later work outrivalled. The altar proper was contained within a walled enclosure, measuring about 11½ by 10½ m., with entrances on east and west. On the upper part of the external faces of the south and north precinct walls ran a frieze representing the actual procession of Augustus and members of his family, of lictors, priests, magistrates and of the Roman people on the altar's foundation day (July 4, 13 B.C.) to its chosen site, where sacrifice was offered in thanksgiving for the emperor's recent return to Rome from the provinces. On either side of the western entrance were Augustus' prototype Aeneas sacrificing on his "home-coming" to the promised land of Italy and, since Augustus was also hailed as Rome's second founder, the suckling of the twins, Romulus and Remus, by the she-wolf. The eastern entrance was flanked by the personification of Italia with children on her knees, and by that of Roma. On the exterior of the walls, beneath all these figure scenes, was a magnificent dado filled with a naturalistic pattern of acanthus, vine and ivy, perhaps the translation into marble of a gorgeous carpet or tapestry used in the ceremony; while the swags of fruit and flowers that decked the interior faces of the precinct walls may represent real swags that were hung on the temporary wooden altar erected for the foundation sacrifice. The procession was continued in a much smaller frieze on the inner altar, from which figures of the vestal virgins and of the sacrificial victims and their attendants have been preserved. Delightful studies of imperial and other children and such homely incidents as conversations between persons taking part in the procession introduce an element of intimacy, ihformality and even humour into this solemn act of public worship. The Ara Pacis in fact sums up all that was best in the new Augustan order—peace, serenity, dignity without pompousness, moderation and absence of ostentation, love of children and delight in nature. The style of the altar's floral decoration strongly suggests that the sculptors who carved it were Greeks from Pergamum.

The **Julio-Claudian** Period.—The somewhat cold, precise and academic portraits of Tiberius and Gaius show little further development, but it was probably from her son's principate that the finest of Livia's monumental portraits date. A seated statue of the empress, found at Paestum with a seated figure of Tiberius (in Madrid), shows her with hair simply waved from a central parting, an aquiline nose and the smooth brow and rounded cheeks of quite a young woman, although she was 72 when her son succeeded. The likeness of Antonia, Augustus' niece, is known from posthumous portraits dating from the reign of Claudius. These show her with a coiffure even simpler than Livia's and sometimes wearing the *tutulus* ("woolen fillet") appropriate to her office of priestess of Divus Augustus, as in the case of her colossal portrait head, the so-called "Juno Ludovisi," in the Roman National museum. Portraits of Agrippina I, of Agrippina II, who again occasionally wears the *tutulus* as priestess of Divus Claudius, and of the latter's rival Messalina display more elaborate hair-styles. In Claudius' portraits fine, plastic modeling is combined with a realistic rendering of the subject's angular nose, sagging cheeks, clumsy neck and double chin; while those of Nero reveal an exuberant, idealizing treatment that matches his philhellenic interests. Of historical sculpture of this period relatively little has survived. Fragments of processional and sacrificial scenes, somewhat reminiscent of the Ara Pacis carvings (walled up in the Villa Medici on the Pincio) may have come from the Ara Pietatis Augustae which Claudius dedicated in A.D. 43. The "Jupiter-Column" set up in Nero's honour at Mainz (Mogontiacum) in Roman Germany, with figures of gods and personifications carved in relief on its base and shaft, is the only existing public monument which can be connected with that bizarre ruler.

The **Flavian** Period.—In Vespasian's portraits something of the old, dry, relentless verism returned. This can be observed in his striking likeness on one of the two historical reliefs that were unearthed in Rome near the Palazzo della Cancelleria just before World War II. A similarly sketchy and impressionistic handling of the hair is found on Titus' portraits, whereas Domitian affected a more pictorial hairdo in imitation of the coiffure introduced by Nero. Still more picturesque are the female hair styles of the time, which display piles of corkscrew ringlets or of tight, round curls. The Cancelleria reliefs date from the close of Domitian's reign and depict respectively Vespasian's *adventus* and reception in Rome in A.D. 70 and Domitian's *profectio*, under the aegis of Mars, Minerva and Virtus, for one of his northern wars. They are worked in a two-dimensional, academic, classicizing style that is in marked contrast with the vivid, three-dimensional rendering of space and depth with brilliant interplay of light and shade on the panels of the arch of Titus in the Roman forum. Those familiar reliefs, which present two excerpts from Titus' Jewish triumph, were carved in the early 80s. The late-Domitianic classicizing manner appears again in the frieze of the Forum Transitorium, which Nerva completed. This conflict of relief styles within the Flavian period is but one illustration of the ceaseless, unpredictable ebb and flow of different aesthetic principles throughout the history of imperial art.

The Age of **Trajan.**—In portraits of Trajan the deepening of the bust, already seen in the later Flavian period, was carried a stage further; there is a new fluidity in the molding of the face; in the hair, which is plastered down across the brow, there is a partial revival of the late republican linear style. Aesthetically, one of the finest known likenesses of the emperor is a marble head in the Ostia museum; while on his monumental column there is a series of less idealized and probably more faithful renderings of his features. The coiffures of Trajanic ladies are, if anything, even more elaborate and extravagant than those of their Flavian predecessors.

The reliefs of Trajan's column, illustrating the two Dacian wars of 101–102 and 105–106 and winding up the shaft in a spiral band of Parian marble, one metre wide, is generally recognized to be the classic example of the continuous method of narration in Roman art. The scenes develop like a film, merging into one another and interlocking without any lines of demarcation between them, apart from an occasional tree that serves to punctuate the flowing text; while Trajan appears again and again in different situations, activities and costumes. A statuesque figure of Victory separates the histories of the two wars. There are 23 spirals and about 2,500 figures. But a high level of technical accomplishment is maintained throughout, and the interest and excitement of the theme never flag. Since the figures of men and animals had to be distinguished from a distance, they are inevitably overlarge in proportion to their landscape and architectural settings; and in order to avoid awkward empty spaces along the upper edges of the band and to preserve an allover, even, tapestrylike effect. the background figures in the scenes are reared in bird's-eye-view perspective above the heads of those in the foreground. These carvings must be visualized as once brightly painted, with weapons and horse trappings added in metal. The sources of the scenes were probably wartime sketches made by army draftsmen at the front, but the fusing together of those isolated pictures into a single scroll was the work of a single master artist, perhaps Apol-

METALWORK AND MINOR ARTS

lodorus of Damascus, who designed the whole complex of Trajan's forum. basilica and column. The interior of the shaft contains a spiral staircase and the column, dedicated in 113. was intended primarily as a lookout post for vieuing Trajan's architectural achievements—his forum and its adjacent markets. to accommodate which he sliced away the slope of the Quirinal hill; secondly, as a war memorial. when the relief bands were added and an eagle was to top the capital; and thirdly, as Trajan's future tomb. crowned by his statue (which was replaced by that of St. Peter) and containing the funerary chamber for his and his consort's ash urns.

To the last years of Trajan's reign or to the early years of that of his successor should be attributed the four horizontal panels that adorn the main passageway and the attic ends of the arch of Constantine. If fitted together they would form a continuous frieze of three main scenes which are, from left to right. an imperial *adventus*, a battle and the presentation to the emperor of prisoners and the severed heads of captives by Roman soldiers. The fact that the enemy is clearly Dacian, that the Roman soldiers are all clean-shaven and that the lictors on the left wear the Trajanic hair style, combined with the close resemblances betneen this frieze and that of the column. leaves no room for doubt that these sculptures were made between *c*. 115 and 120. perhaps for the temple of Divus Trajanus and Diva Plotina which was erected by Hadrian just to the north of the column. The presence on this frieze of chain-mail corselets, never seen on Trajan's column, seems to indicate that that type of armour. so common under the Antonines. first came into use in late-Trajanic or early-Hadrianic times. These reliefs depict, not realistic fighting. as do those of the column, but a kind of ideal or dramatized warfare, with the emperor himself participating in the mêlée and the soldiers wearing plumed and richly embossed parade helmets; the scenes melt into one another with total disregard of spatial and temporal logic. A third example of Trajanic monumental sculpture is the relief decoration of the arch at Beneventum, spanning the new Via Trajana and completely covered on passageway, pylons and attics with pictorial slabs, the subjects of which are arranged to carry out a carefully balanced and nicely calculated order of ideas. Those on the side facing the city and on one wall of the passageway present themes from Trajan's policy and work for Rome and Italy; those on the side toward the country and on the other wall of the passagenay allude to his achievements abroad. With two exceptions. where a pair of scenes forms a single picture, each panel is a self-contained unit, and these reliefs already show something of the classicizing, two-dimensional character of Hadrianic nork. Indeed. it seems likely that, although the arch itself was either decreed or dedicated in 114–115. some of the panels in which Hadrian is given a peculiar prominence were not carved until the early years of the latter's principate. The frieze of the great, circular Tropaeum Trajani, set up in the Dobruja (Rumania) to commemorate the Dacian victories, contains a series of metopes carved with figure scenes in an unbelievably naive, flat and linear style that betrays the hands of army artists of provincial origin.

The Age of **Hadrian.**—In the iconography of the age of Hadrian, certain Hellenizing features. the wearing of a short Greek beard by the males and the adoption by the females of a simple, classicizing coiffure,are harmonized nith new experiments. The depth of the bust increases, there is greater plasticity in the modeling of the face, the men's curly hair and beards are pictorially treated and the irises and pupils of the eyes are marked in. Many marble portraits of the emperor survive from all over the empire, but of his likenesses in bronze only one is extant—the colossal head recovered from the river Thames in London, torn from a statue erected in the Roman city and probably the work of a good Gaulish sculptor. The portrait statues of Hadrian's Bithynian favourite. Antinous, reveal a conscious return in the pose and proportions of the body to classical Greek standards, combined with a new emotionalism and sensuousness in the rendering of the head. The exquisite relief in Rome of Antinous-Silvanus is signed in Greek by Antonianus of Aphrodisias in Asia Minor.

The monumental reliefs of Hadrian's day cannot vie with those of his predecessor's. The most interesting and perhaps the earliest of them are the two familiar horizontal slabs once exposed in the Roman forum but later transported to the shelter of the curia. Both carry on one side similar figures of the victims for the Suovetaurilia sacrifice and different historical scenes on the other side, in the one case. Hadrian doling out the *alimenta* ("poor relief") to Roman citizens in the presence of a statuary group of Trajan and Italia with children, in the other case, the burning of debt registers. At one end of each of these scenes is carved a figure on a base of Marsyas, whose statue in the forum may once have been in part enclosed by the panels. In the background of both historical pictures are carved in low relief various buildings in the Roman forum that can be identified. The two scenes display the characteristically Hadrianic two-dimensional style, as do also three large panels in the Conservatori museum, with the emperor's head restored and depicting an imperial *adventus*, an *adlocutio* and an apotheosis respectively—somewhat rigid. academic works. The eight medallions gracing the arch of Constantine give pleasantly composed and lively, if Hellenizing, pictures of sacrifice and hunting, in some of which can be recognized Antinous accompanying the emperor, whose portraits have been recut as likenesses of Constantine the Great and of his colleague Licinius. Finally, the historical reliefs found at Ephesus (now in Vienna)—one of the very few examples of provincial state reliefs that have survived—may be claimed as late-Hadrianic (not as of the period of Marcus Aurelius, to which many critics have assigned them). The most important of these Ephesian carvings shows a group of four imperial personages. who can be identified as Hadrian, his heir Antoninus Pius and the latter's adopted sons, Marcus Aurelius and Lucius Verus. The panels would, then. date from between Pius' adoption by Hadrian in Feb. 138 and the latter's death in the July of that year. Pius had been a popular proconsul of Asia, and the unorthodox representation of him in this relief as Hadrian's equal and colleague. unthinkable in Rome, could have passed muster on a provincial monument. The most imposing of the other panels of the series carries an imperial apotheosis—Divus Trajanus in full military costume mounting the chariot of the sun-god for his journey heavenward. Some fragmentary battle scenes may be excerpts from Trajan's Dacian or eastern wars. reflecting glory on his adopted son, Hadrian, and succeeding generations. In Rome and Italy during the second quarter of the 2nd century inhumation began to supersede cremation as a method of disposing of the dead, and Hadrian's reign saw the beginnings of the long line of carved sarcophagi that constituted the most significant class of minor sculptures down to the close of the ancient Greco-Roman world.

The **Antonine** and **Severan** Periods.—Portraits of Antonine imperial persons, of which the bronze equestrian figure of Marcus Aurelius on the Capitol and the great marble bust of Commodus-Hercules in the Conservatori museum are perhaps the most arresting examples, display a treatment of hair and beard, deeply undercut and drilled. that grew ever more pictorial and baroque as the 2nd century advanced. This produced an impression of nervous restlessness that contrasts with the still. satin smoothness of the facial surfaces, particularly in the iconography of Commodus. To all this picturesqueness Septimius Severus added yet another ornamental touch—the dangling, corkscrew forelocks of his patron deity, Serapis. The female hair styles of the time are characterized, first by a coronal of plaits on top (Faustina I), next by rippling side waves and a small, neat bun at the nape of the neck (Faustina II, Lucilla) and then by stiff, artificial. "permanent" waving at the sides and a flat, spreading "pad" of hair behind (Crispina, Julia Domna).

Of the state reliefs of this epoch the earliest are on the base (in the Vatican) of the lost column set up in honour of Antoninus Pius and Faustina I. The front bears a dignified, classicizing scene of apotheosis: a powerfully built winged figure lifts the emperor and empress aloft. uhile two personifications, Roma and Campus Martius, witness their departure. On each side is a *decursio*, or military parade, in which the riders farthest from the spectator appear, not behind the foot soldiers, but high above their heads —a remarkable instance of the bird's-eye-view perspective carried

to its logical conclusions. All the figures in these side scenes are disposed on projecting ledges, a device employed again about 20 years later on Marcus Aurelius' column Eleven rectangular sculptured panels, similar to those on Trajan's arch at Beneventum but displaying greater crowding of figures, livelier movement and a pronounced effect of atmosphere and depth, depict official occasions and ceremonies in the career of Marcus. Three are in the Conservatori museum, the other eight are on the attics of the arch of Constantine. They may have been carved for two triumphal arches (a 12th panel being lost) or for some single monument. The contrast between the reliefs of Marcus' column, put up under Commodus, and those of its Trajanic predecessor measures the change of mood that the Roman world experienced during the course of the 2nd century. The diminished proportions of the squat. doll-like figures, their herding together in closely packed, undifferentiated masses, their angular, agitated gestures and the stress laid throughout on the horror and tragedy of war, suggest that the empire is facing an unknown future with diminished security and that man is at the mercy of some unaccountable power, of which the awe-inspiring winged, dripping figure, brooding above the famous rainstorm episode, represents the supreme embodiment. Again, in the imperial *adlocutiones* that punctuate this frieze, where the emperor stands in a strictly frontal pose high above the heads of his audiences, can be seen the first attempts at externalizing in art the concept of the ruler as a transcendental being. The content of these spiral bands is Marcus' German wars of 173–175 and 177–180.

The spirit of the times is reflected no less vividly in the carved sarcophagi. with their crowded compositions, seething movement, brilliant highlights and deep wells of shadow. Their themes—familiar myths, battles, hunts. marriages, etc—allude allegorically to death and the destiny of the soul hereafter. Meanwhile, the classicizing, statuesque tradition is maintained in the late 2nd- and early 3rd-century columned sarcophagi, originating in the workshops of Asia Minor but freely imported into, and sometimes imitated in, Rome and Italy. On such pieces single figures, or small groups of figures, occupy the niches between the colonnettes. Among the most impressive examples is the great sarcophagus at Melfi, in Apulia, Italy, with a couch-shaped lid. on which the figure of a girl lies prostrate in the sleep of death.

The novel features that have been noted in the reliefs of the Marcus column were worked out more completely in those of the official monuments set up in Septimius Severus' honour, both in Rome and abroad. The three-way arch that stands at the northern end of the Roman forum was erected in 203 to commemorate both the emperor's Parthian victories and his *decennalia* (the conclusion of his first ten years of rule). Large-scale flying Victories and groups of Roman soldiers and Parthian captives occupy respectively the spandrels above the central passage and the column bases on both faces of the arch; while above both the side passages on either face are scenes from the campaigns. There are masses of small, crowded figures, arranged in superimposed registers in laterally spreading pictures. which in the extensive use of bird's-eye-view perspective recall the spiral bands of the Trajan and Marcus columns. They, too, were doubtless based on military artists' sketches and may represent permanent versions of the public paintings of the eastern wars which, so Herodian says, Septimius exhibited in Rome. The small but richly ornamented Ports Argentariorum, dedicated in the Velabrum in 204 to Septimius and his family by the bankers and wholesale cattle dealers of the capital, carries two major sculptured panels. one of which shows Septimius and his Syrian wife. Julia Domna, sacrificing at a tripod. This composition is strictly tno-dimensional and the figures are arranged in stiff, hieratic, frontal poses. They express no interest in the rite which they profess to be performing, but gaze out into the distance as though in search of the spectators' homage The figure of Septimius' younger son Geta which nas once in the group, was removed after his murder by his elder brother Caracalla who now appears alone in the second major panel, from which the figures of his wife Plautilla and of her father Plautianus were likewise obliterated at the time of their disgrace and deaths. But of all Septimius' state reliefs the most interesting are those found fallen from the four-way arch that was set up in his birthplace, Leptis Magna in Tripolitania, to commemorate his visit to that city c. 203. On the attics were four long, friezelike scenes. of which the most impressive depicts the triumphal entry into the town of the frontally-posed emperor and his sons. The other attic panels, one of which portrays the proclamation of Caracalla as his father's colleague (*dextrarum innctio*) in the presence of Julia Domna and representatives of Leptis, and most of the minor panels from the inner faces of the piers, refer to ceremonies held at Leptis on the same occasion. But one pier carried a great vertical picture of the siege of an oriental city, with the defenders at the top and the attackers climbing up. as it were. from below in mounting series—a magnificent example of the bird's-eye viewpoint. Flying Victories filled the spandrels and on the outer faces of the piers were groups of strangely elongated captives and flat pilasters carved from head to foot with peopled vines scrolls, deeply undercut and drilled—a very distinctive type of design. which recurs on the pilasters that are grouped on either side of the apses of the Severan basilica at Leptis. The handsome inhabited floral scrolls. on pilasters, and the heads carved on brackets, that adorned the Hadrianic baths at Aphrodisias in Caria, are so remarkahly similar to the scrolls from the arch and basilica and to the heads from the Severan forum at Leptis, that there can be little doubt that sculptors from Asia Minor nere imported to carve these great Severan buildings in the African emperor's native city.

The Third and Fourth Centuries.—A new tension between naturalism and schematization marks the history of late-antique portraiture. In likenesses of Alexander Severus (222–235) the facial planes are simpiified, while all the tumbling curls of the 2nd-century baroque have been banished in favour of a skullcap treatment of the hair and sheathlike rendering of the beard. Toward the middle of the 3rd century. under Philip the Arabian (244–249) and Decius (249–251), this clipped technique in hair and beard is combined with a return to something of the old, ruthless realism in the depicting of facial furrows. creases and wrinkles. For a time Gallienus (253–268) reinstated the baroque curls and emotional expression, but in the later decades of the century the schematic handling of hair, beards and features reappears. Finally. in the clean-shaven heads of Constantine the Great and his successors of the 4th and early 5th centuries the conception of a portrait as an architectonic structure comes to stay and the naturalistic, representational art of the Greco-Roman world is exchanged for the hieratic, transcendental style that was the hallmark of Byzantine and medieval iconography. The hair is combed forward on the brow in rigid, striated locks, and the eyes are unnaturally enlarged and isolated from the other features as the channels through which the soul communicates with a higher power. The face is now so formalized that the identification of any given portrait becomes a problem. The colossal bronze emperor at Barletta, for example, has been given the names of several different rulers of the late 4th and early 5th centuries. Throughout these centuries the favourite female coiffure shows a plait or twisted coil of hair carried across the back and top of the head from neck to crown, while under Constantine there was a brief revival of the two Faustinas' styles.

Throughout the 3rd and 4th centuries carved sarcophagi carry on the story of relief work. Aesthetically, the most notable 3rd-century example is the allover tapestrylike battle piece (in the Ludovisi collection in the Roman National museum) probably made for Decius' son Hostilianus. One of the main interests of this field of art, as regards content, lies in the Christian sarcophagi, which are in style and in technique indistinguishable from their pagan counterparts. During the 3rd century their themes are still allusive and symbolic. but with the peace of the church under Constantine Biblical subjects of a very varied range are openly depicted. Of 3rd-century state reliefs in Rome virtually nothing has survived. The narrow historical friezes that were carved de *novo* for the arch of Constantine, completed for his *decennalia* celebrations in 315, show dwarfish. dumpy, niggling figures. Both these reliefs and those of the slightly earlier arch of Galerius at Salonika look as though they had been worked by artists whose

experience had been confined to the production of small-scale sculptures. The last examples of Roman carving are the reliefs on the base of the obelisk of Theodosius in the Hippodrome at Constantinople, where the emperor and members of his court, ranged in rigid, hieratic poses. watch the shows. S o original portions are extant of the spiral relief bands that entwined the columns of Theodosius and Arcadius in Constantinople, in imitation of the Roman prototypes.

PAINTING AND MOSASCS

Wall Painting. — Evidence for painting in Rome and Latium before the 1st century B.C. is virtually confined to the fragment. described above. of a historical tomb painting from the Esquiline, to the literary accounts of triumphal pictures, already mentioned and to the record by ancient writers of the names of three painters each of whom worked in a temple — Fabius Pictor in the temple of Salus in Rome at the end of the 4th century; Pacuvius, the dramatist and a native of Brundisium, in the temple of Hercules in the Forum Boarium in Rome during the first half of the 2nd century; and Lycon, an Asiatic Greek, in the temple of Juno at Ardea in the late 3rd or early 2nd century. Of the nature of the work of these three artists no idea can be formed.

At Pompeii during the 2nd century B.C. the interior walls of private houses were decorated in the so-called "masonry" or "incrustation" style; *i.e.*, by the imitation in painted stucco of veneers of *crustae* ("slabs") of coloured marbles. But in the second half of the 1st century B.C. there suddenly appeared in Rome and in the Campanian cities a brilliant series of domestic mural paintings of the so-called "second style," the aim of which was to deny the walls as solid surfaces confining the room space. This was sometimes done by covering the whole area of the walls with elaborate landscapes, in which depth. atmosphere and light are rendered in a highly pictorial, illusionistic manner. Such are the famous Odyssey paintings, found in a Roman house on the Esquiline (now in the Vatican), consisting of a continuous flow of episodes that unfold, filmlike, beyond a colonnade of pilasters with vertical. bird's-eye-view, perspective and the human figures strictly subordinated to their settings. At other times there appears the representation of a great park or garden. filled with trees, shrubs. flowers and birds. with no pilasters in the foreground to interrupt the prospect and with no human figures to distract attention. as in the case of the room from Livia's villa at Prima Porta (transferred to the Roman National museum). The paintings in this style are so highly developed that it seems unlikely that they suddenly sprang into being at this time in Rome and Italy without any Hellenistic precursors. Nevertheless. no late-Hellenistic paintings at all like them have come to light in Greek lands, and they constitute what is perhaps the most original and interesting western Roman-age contribution to ancient art. Possibly Hellenistic painted stage sets were, in part at least. their models; Vitruvius mentions three types of back scenes, tragic, comic and satyric, which seem to be reflected in the paintings from a room in the Villa of Fannius Synistor (or of L. Herennius Florus) at Boscoreale near Pompeii. Again. the triumphal "place paintings" may have played a certain role in this development.

The celebrated frieze of life-size figures. depicting the Dionysiac initiation rites and prenuptial ordeals of a bride, in the so-called *triclinium* of the Villa of the Mysteries (or Villa Item) outside the Herculaneum gate of Pompeii, also belongs to the "second style." There the walls are denied by the device of substituting for them a narrow stage on which the ritual is carried out before a drop scene of continuous painted panels. But the commonest "second-style" paintings are known as architectural and show a threefold horizontal division of the wall into dado, central area and cornice, combined nith a triple vertical scheme of design which consists of a large central panel (in the main, intermediate horizontal area). framed by flanking columns and a pediment, and of two smaller panels on either side. The central panel, and often the lateral panels as well. are views seen through nindows that break through the walls and link the spectator nith the world outside. as in the house of Augustus on the Palatine. In the "third style." which covers most of the Xugustan period, the central panel picture on a wall is no longer thought of as a scene through a window, but as a real picture hung on or inserted into a screen, or woven into a tapestry. which partially conceals an architectural vista behind it The columns, entablatures, etc . are completely unreal and so complicated that this form of the "second style" is sometimes dubbed ornate The "fourth style" nhich runs from the close of the Augustan age to the destruction of the Campanian cities in A.D. 79, is less homogeneous than its predecessors and exhibits three main variants — first. a soberer more realistic architectural design, but still with a central screen or tapestry partly covering a retreating vista; second. an architectural setout that imitates a *scaena* ("stage background"): and third, a method (sometimes known as "intricate") by which the whole surface of the wall is covered with a flat, white, neutral ground that is painted with an all-over, latticelike pattern of fantastic architectural elements, arabesques, grotesques small figure motifs or small panels containing pictures. This third type of "fourth-style" painting came into vogue at Pompeii between the earthquake of A.D. 63 and the catastrophe of 79, and one of its most impressive exponents is the Golden House of Nero in Rome.

The subjects of the panel pictures of the "second," "third" and "fourth" styles are for the most part drawn from Greek mythology. Some of them recall the literary descriptions of famous classical Greek and Hellenistic paintings or shon motifs which suggest that their originals were painted on the Greek mainland or in Asia Minor. It is certain that many masterpieces of Greek painting did make their way to Rome as the booty of Roman generals of republican days, and wall painters could have studied them at first hand. But often those artists must have had to rely only on sketches of the celebrated pictures, and it is not known how faithfully the Roman and Campanian murals reproduce the prototypes. Other panel pictures present scenes from contemporary religious ritual, while a few show themes from Roman legend. Frequently, in the case of the Greek mythological subjects and of those taken from rustic religious cult the artist had produced landscape with figures, as in the Odyssey frescoes. not figures with landscape. as on Trajan's column. These late-republican and early-imperial set pieces are competently executed, remarkably vivid and extremely naturalistic. But, with a few exceptions. they reveal that the principles of a single vanishing point, on which all receding lines converge. and of unified lighting from a single source of illumination. either were not understood by the Roman-age painters, or did not interest them.

The flat. uniform background of the last phase of the "fourth style" remained a constant feature of mural painting in houses, tombs, temples and other religious shrines throughout the 2nd, 3rd and 4th centuries. The decoration which stands out against that ground takes the form of latticelike, allover floral, etc., patterns. as in many pagan tombs; of small groups of figures, or of figure panels, spread out at intervals across the field, as in the Christian catacombs of Roine: of a mixture of large human figures and extensive scenes nith small-scale figures, as in the early 3rd-century Hypogeum of the Aurelii on the Viale Manzoni in Rome, the interesting painted content of nhich is Gnostic or crypto-Christian; of large scenes with relatively big figures, such as the group of marine deities in the 2nd-century Rcman house under the church of SS. John and Paul on the Caelian, the late 2nd- or the early 3rd-century leopard hunt on the south wall of the *frigidarium* of the hunting baths at Leptis Magna, or the early 3rd-century Biblical scenes from the Christian baptistery at Dura Europos on the river Euphrates The walls of the main assembly room of the early 3rd-century synagogue in the last-mentioned city are covered nith an exceptional series of great self-contained figure panels, arranged side by side in superimposed registers with no intervening tracts of empty background between them.

In the case of Roman tombs the cross- or barrel-vaulted ceilings. where preserved. carry out normally the painted decoration of the walls, shoaing either a latticelike scheme of small ornamental motives or a series of small, spaced-out, figured panel pictures. At Trier in 1945–46 were found the remains of a flat, coffered ceiling with panels of painted plaster from an early 4th-century imperial hall that was destroyed to make room for the

first Christian basilica built on the site of the present cathedral. Large portions of eight painted panels are preserved. Four depict female busts, three of them nimbed, which may be either personifications or portraits of members of the royal family; while the other four show pairs of dancing or sporting cupids. As the skillful modeiing and lively naturalism of these figures shorn. Roman painting could maintain a high level of achievement in late-antique times.

Floor Mosaics.—Few categories of works of Roman art can show more surviving examples than can that of mosaic pavements. *Opus tessellatum*, made of *tesserae* ("cubes") regularly disposed in geometric designs, and *opus sectile*, in which the floor consists of a polychrome intarsia of marble fragments, larger than *tesserae* and generally forming abstract or stylized floral patterns, cannot be discussed in detail here. But *opus vermiculatum*, where figure pictures and naturalistic floral compositions are produced by small and subtly shaped *tesserae*, is almost a branch of painting, in which stone or marble or, in later times, glass paste replace the liquid medium. This type of work appeared in Italy during the 2nd century B.C. and was directly inspired by such late-Hellenistic mosaics as those unearthed in the royal palace of the Attalids at Pergamum and in private houses on the island of Delos, and from Italy it spread rapidly through the empire. Sometimes these floor mosaics are large, self-contained, panel pictures. of which an early example, of the late 2nd, or early lst, century B.C., is the well-known Alexander mosaic (in Naples) from the House of the Faun at Pompeii. It depicts the battle of Issus and probably represents fairly faithfully a late 4th-century monumental painting. This was the work of a master mosaicist, as were also many of the small mosaic pictures or *emblemata*, which were often mounted on marble or terra-cotta trays and transported, at first from east Mediterranean workshops to Italy, and later from Greek and Italian centres of production to the provinces, where they were inserted into surrounds of geometric patterns laid by inferior local craftsmen. The master mosaicists themselves often traveled far afield to execute *emblemata* or large designs on the spot, as their signatures testify. The subjects of mosaic pictures cover an extensive range—Greek myths (the most popular). Roman legends, Nilotic and other landscapes, scenes from natural history, portraits of famous characters, personifications, topics inspired by the games and shows, by the hunting field, by rural life and by religious ritual, and naturalistic running scrolls of acanthus, vine and ivy. A most remarkable discovery is that of the pavements in the 4th-century country villa near Piazza Armerina, Sicily. These form the largest continuous area of Roman mosaic floors known and include a vast scene, in a corridor 70 yd long, of the hunting, capturing and transport of wild birds and beasts for display in the arena. The most important and the richest dated series of floor mosaics, running from the early 2nd to the 6th century, is that unearthed, mainly in private houses, at Antioch-on-the-Orontes in Syria. The floor mosaics of the 4th-century Christian basilica at Aquileia display an interesting mixture of Christian, pagan and neutral themes.

Wall and Vault Mosaics.—Wall and vault mosaics that have survived are relatively rare. The earliest and best-preserved examples are those adorning fountains in the courtyards of houses at Pompeii and Herculaneum. These show brilliant polychrome designs, with a lavish use of glass-paste *tesserae* and borders of natural shells. But in the House of Neptune and Amphitrite at Herculaneum most of one wall of the internal courtyard has been turned into a species of *nymphaeum*, with a central rounded niche flanked by two rectangular niches and the whole facade overlaid by an exquisite glass-paste mosaic depicting naturalistic vine sprays, hunting scenes and festoons of fruit and foliage. A curved fountain niche of late 2nd- or early 3rd-century date, found in a Mithraeum at Ostia (in the Lateran museum), bears a glass-paste mosaic figure of Silvanus, nimbed and equipped with pruning knife and dog, seen against a blue background. From Pompeii and Herculaneum there are a few mosaic panel pictures, mythological in content, that were set on malls; while part of a wall panel representing a harbour, found on the Quirinal, is in the Conservatori museum.

The number of pre-5th-century vault mosaics known to have survived has considerably increased. At Ostia the semidome and arch soffit of a large niche in the House of the Seven Sages are faced with polychrome mosaic worked in delicate and naturalistic plant designs. Somewhat fragmentary, but still impressive, mosaic figures—a nymph suckling a kid. a triton and a crocodile in a Nilotic landscape—appear in the semidome of the east plunge in the *frigidarium* of the hunting baths at Leptis Magna. In the mausoleum of the Julii in the necropolis beneath St. Peter's. Rome, are the earliest Christian vault and wall mosaics known, dating from about the middle of the 3rd century and worked in glass-paste *tesserae*. Their subjects are the divine angler, Jonah and the whale, the good shepherd and Christus-Helios in his chariot, with a great, spreading vine linking together the four pictures. All these are comparatively new finds, and there is quite a number of lesser fragments of vault mosaics that cannot be described here. The familiar mosaic decoration on the vault of the circular ambulatory in the church of Sta. Costanza in Rome contains a curious mixture of subjects disposed in large, rectangular panels; these mosaics, once held to be an instance of the early Christian use of pagan or neutral art motifs, have been shown to belong to the late 3rd- or early 4th-century pagan shrine or mausoleum that the building originally was, before it was converted to Christian purposes. The 4th-century Christian mosaic from the apse of old St. Peter's in Rome, and the 5th-century Christian wall and vault mosaics at Ravenna and in the church of Sta. Maria Maggiore in Rome, while ranking as Roman, cannot be described here.

Finally, mention must be made of figured wall panels of brightly coloured *opus sectile*, such as that with a beast fight in the Ostia museum and those showing beast fights, Hylas and the nymphs and the decorative group of horsemen and a frontal chariot, which came from the 4th-century basilica of Junius Bassus on the Esquiline (in the Palazzo del Drago at the Quattro Fontane).

Painted Portraits.—Roman portrait painting comes but a short way behind portrait sculpture in excellence of execution and in its superbly realistic style. One of the earliest extant examples of this art is the group of Terentius Neo and his wife, from Pompeii (in the Naples museum). Both figures recall the celebrated mummy portraits from the Fayum in Egypt, painted in encaustic, the technique by which the colours were mixed with liquid wax and fixed by heat, and ranging in date from the Flavian period to the 3rd century. A circular portrait group of frontal figures painted on wood, probably in Egypt (now in Berlin), shons Septimius Severus, Julia Domna. Caracalla and Geta, the elder (so it seems) of the two boys having been subsequently washed out. Particularly attractive are the portraits of the gold-glass medallions ahich, in the exquisite refinement of their treatment. may be compared to modern miniatures. The medallion at Brescia, dating from the 4th century and carrying the portrait group of a mother with her boy and girl, is a veritable masterpiece; while some of the portraits of Christians in the same medium and found, for the most part, in the catacombs, continue the best traditions of Roman veristic iconography.

Book Illustration.—That book illustration existed in the late-Hellenistic world can be inferred from some of the so-called "Megarian" bowls, imitations in clay of gold or silver vessels and ranging from the 3rd century B.C. to the 1st century A.D. These often bear on their exteriors scenes in relief from literary texts which are sometimes accompanied by Greek quotations. They must, in part at least, have served as models for the Roman age artists. and this art is heard of in Rome comparatively early—the 700 pictures, for example, illustrating Varro's 15 books of *Imagines* and a portrait of Virgil prefixed to an edition of his poems. The miniatures in the famous codex of the *Iliad* in the Ambrosiana library, Milan, were probably painted at the end of the 5th or beginning of the 6th century, but reflect pictures of the 3rd. 2nd and even 1st century; as do also those of the codex of Virgil in the Vatican (No. 3225), written *c.* 400. The miniatures in the second great Virgilian illustrated codex in the Vatican (No. 3867 "Romanus"). written *c.* 500, are still Roman in spirit, if less classical in style; the tenacious influence of Graeco-Roman painting can be clearly traced in the illustrations to such early Byzantine books as the Vienna Dioscurides (written in 512), the Vienna Genesis

(6th-century) and the Vatican Joshua *rotulus* (10th-century). A most remarkable, if aesthetically crude, mid-4th-century mosaic pavement, found in a Romano-British villa at Low Ham, Somerset, and showing scenes from the first and fourth books of the Aeneid, undoubtedly reflects the illustrations in some Virgilian codex.

STUCCO WORK

Of the minor forms of sculpture none is more attractive than the art of modeling, in relief or in the round, in fine, white stucco. Decorative stucco work was cheaper and easier to produce than carving in stone or marble, soft and delicate in texture and equally elegant whether left white or gaily painted. It mas used at all levels of society. in public as well as in private buildings. In domestic architecture it was a useful alternative or accessory to painting; here it is sufficient to recall such examples as the pure white and exquisite vault decoration, showing ritual scenes with small-scale figures, of the late-republican or early-imperial house near the Villa Farnesina in Trastevere (in the Roman National museum); the handsome pairs of large white griffins, framed in acanthus scrolls against a vivid red ground, in the late republican House of the Griffins on the Palatine; and the frieze depicting the story of the Iliad, in white figures on a bright blue background, in the House of the Cryptoporticus or Homeric house at Pompeii. For the use of this technique in palaces the figure work in Domitian's villa at Castel Gandolfo in the Alban hills can be cited; it can be found on public buildings, in the Stabian and forum baths and in the temple of Isis at Pompeii; while the most lovely and extensive stucco relief work in a semiprivate shrine is that in the underground basilica near the Porta Maggiore, Rome, where the scenes all allude to the world beyond the grave, to the soul's journey to it and to its preparation for it in this life. Some of the best surviving stuccoes are in tombs—in the tomb of the Innocentii and the tomb of the Axe under the church of S. Sebastiano on the Via Appia; in the tomb of the Valerii and the tomb of the Pancratii on the Via Latina. in the latter of which stucco work is most attractively combined with painting in the flat; and in the tomb of the Valerii under St. Peter's, Rome, where the interior walls of both the main and subsidiary chambers are almost completely covered with recesses, niches and lunettes containing stucco figures. The whole effect is most impressive, and the Vatican tomb of the Valerii must be reckoned as a locus *classicus* for the study of this delightful and all too scantily represented branch of Roman art.

MINOR ARTS

Decorated Metalwork.— The Roman taste for costly silverware. with figured or floral relief decoration, is attested by the elder Pliny and by the numerous surviving pieces. Among the earliest-known examples in a Roman context is the cantharus ("goblet") with myrtle sprays, discovered at Alesia in one of Julius Caesar's siege trenches of 52 B.C. The treasure from Boscoreale containing 108 pieces (of which 102 are in the Louvre) and that of 118 pieces. which had been packed away in a strongroom in the House of Menander at Pompeii (now in the Naples museum), obviously antedate the disaster of A.D. 79. The former treasure contains two scyphi ("cups," in the Rothschild collection in Paris) with scenes from contemporary Augustan history. The latter comprises not only cylindrical cups and canthari of the early-imperial period, but also late-Hellenistic scyphi, perhaps dating from as early as the late 2nd century B.C., one pair being signed by Apelles. Probably belonging to the Augustan period are a number of the pieces in the two treasures found respectively at Berthouville, Normandy (in the Bibliothèque Nationale. Paris), and at Hildesheim, Germany (in Berlin), although the former hoard includes some objects that may well be later, while the latter also contains some earlier Hellenistic works; to the Augustan epoch should again probably be attributed the two scyphi that came to light at Hoby, near Copenhagen, signed by Cheirosophos and depicting the ransoming of Hector and the story of Philoctetes. A round *patera* ("dish") from Aquileia (in Vienna), portrays a Julio-Claudian emperor as the "new Triptolemus." Of the British museum silver pieces found in France, the Chatuzanges and Chaource treasures probably date from the 2nd century A.D.; whereas the Seasons bucket (situla) from Tourdan, near Vienne, often described as Augustan, and the treasure from Caubiac, near Toulouse, display the superficially naturalistic classicism combined with a certain clumsiness and faultiness in drawing that is the hallmark of 4th- and 5th-century Roman decorated metalwork. It is. indeed, to this late-antique period that some of the most spectacular and interesting extant silver pieces and hoards belong. As regards the single pieces, special mention should be made of the silver-gilt *patera* found at Parabiago, Italy (in the Antiquities department, Milan), with scenes relating to the cult of Cybele and Atys; of the rectangular lanx ("dish") recovered from the river Tyne and in the duke of Northumberland's collection, which depicts Apollo, Artemis, Leto, Athena, etc., on the island of Delos, where Julian the Apostate sacrificed in 363; of the *missorium* ("circular dish") at Madrid, portraying Theodosius enthroned in the midst of his court; and of the silver-gilt *missorium* discovered at Cesena, Italy, the central medallion of which shows a group of persons picnicking *al* fresco, above, and a groom leading out a horse from its stable, below. Of the late hoards, four are in the British museum. These are the Esquiline treasure, which includes the bridal casket presented to a Christian lady, Proiecta, on the occasion of her marriage to Secundinus, and four statuettes of city-personifications; the Carthage treasure. partly Christian; the cache of pieces from Coleraine, Ireland; and the Mildenhall treasure from Suffolk, also containing some Christian objects. but of which the most outstanding items are pagan—the great Oceanus dish, nearly two feet in diameter, and the two smaller dishes with Bacchic figures, completely classical in style and virtually free from the late-antique designer's usual defects of draftsmanship. The hoard from Traprain Law, Scotland, comprising both pagan and Christian pieces, is in the National Museum of Antiquities, Edinburgh. Where precisely the Roman silversmiths' workshops were located is not known, but the great Mediterranean cities—Rome, Alexandria, Antioch and Ephesus—and also some of the leading Gaulish cities were certainly centres of this art and the master craftsmen often traveled in the service of their patrons.

Of the goldsmith's art one example only can be cited—the *patera* from Rennes (in the Cabinet des Médailles, Paris). The central scene is the drinking contest between Hercules and Bacchus, encircled by a frieze containing a Bacchic procession; the outer zone of decoration consists of 16 inset *aurei,* of which the obverse portraits of emperors and empresses from Hadrian to Caracalla are exposed to view and date it in the early 3rd century.

Decorated bronze objects of the Roman age include vessels of various types, mounts for chariots, horse harness and domestic furniture and also brooches, which in the northwestern areas of the empire were often inlaid with polychrome enamel. Of particular interest are the pieces of decorated bronze armour used by gladiators, legionaries on parade and, above all, the auxiliary horsemen of the Roman army when taking part in the sports or tournaments described by the Hadrianic writer Arrian. Examples of the face-mask-visor helmets worn by horsemen on those occasions are especially impressive and have come to light in many regions of the empire, notably in Britain, Germany, the Danubian countries and northern Syria. Remarkable finds were made at Straubing, Bavaria, in 1950.

Ivories and Wood Carving.— Ivory was a popular material for minor sculpture. It was worked both in the round and in relief and in such forms as small portraits, figurines, caskets, such as that at Brescia (5th-century) and furniture ornaments, of which the carved plaques composing the "Cathedra of Maximianus" at Ravenna (probably 5th-century) provide a notable instance. The consular and other diptychs (see DIPTYCH) are one of the most distinctive types of ivory relief work in the 4th and 5th centuries. Among them are such masterpieces that kept alive the traditions of Hellenistic carving as the diptych of the Symmachi and Nicomachi (of which one leaf is in the Victoria and Albert museum, London, the other in the Cluny museum, Paris) and some outstandingly fine examples of late antique portraiture, for instance, the Probus diptych at Aosta with the double portrait of Honorius, the Felix diptych in Paris (dated 428) and that of Boethius, consul in 487, at Brescia. Of wood carving one example must suffice—

the panels with Biblical scenes on the 5th-century door of the church of Sta. Sabina on the Aventine.

Gems, Cameos, **etc.**—Many types of carving in precious stones were practised by Roman-age craftsmen, and it is to them that the credit goes for the great majority of the *intaglios* which have survived from ancient times. The widespread taste for *intaglios* is witnessed to by the large numbers of existing glass-paste imitations reproducing their subjects, which include portraits of both imperial and private persons, and a large variety of divine and mythological groups and figures, personifications. animals, etc. Many bear the signatures of Greek artists. But the most impressive series of Roman gems consists of the great cameos, cut in different stones and representing imperial persons. Among the earliest of these pieces are the Blacas cameo of onyx in the British museum. portraying Augustus in the guise of Jupiter with aegis; the Gemma Augustea, a sardonyx in Vienna and the Grand Camée de France, a sardonyx in the Bibliothèque Nationale. which were probably carved under Gaius and respectively present the apotheosis of Augustus and of Tiberius. the latter nith Divus Augustus also; and the sardonyx cameo of Claudius with Jupiter's aegis in the royal collection at Windsor castle. Late antique examples of the craft are the rectangular sardonyx in the city library at Trier, portraying Constantine I and members of his house, and the onyx in the Rothschild collection in Paris with busts of Honorius and Maria.

Other varieties of carving in precious stones are represented by the miniature head of a girl in the British museum, wearing the hair style of Messalina and Agrippina II, which is cut in *plasma* (root-of-emerald); the onyx vase at Brunswick, possibly of the 1st century, depicting an emperor and empress, as Triptolemus and Demeter; and the late antique Rubens vase in the Walters Art gallery, Baltimore, carved in honey-coloured agate and decorated on the front and back with a naturalistic vine and nith the head of a Pan, cupped in acanthus, on either shoulder.

Figured Glass.—Closely akin to cameos and vessels cut in precious stones are their substitutes in opaque "cameo glass," worked in two layers, with the designs standing out in white against a dark-blue or bright-blue background. To this class belong the Blue vase from Pompeii (in the Naples museum), aith vintaging Cupids; the Auldjo vase (in the British museum) with an exquisitely naturalistic vine; and the celebrated Portland vase, also in the British museum. the scenes on which, recently interpreted as the dream of Atia, mother of Augustus, more probably depict myths relating to the afterlife. Similar imitations of carving in precious stones are the late antique *diatreta* ("cage cups"), the decoration of nhich is cut back from the outer surface of the mold-cast blank. This "openwork" ornamentation sometimes represents the crisscross meshes of a net, while on other vessels it consists of an elaborate figure scene, the design in either case being very deeply undercut and. for the most part, only connected with the background by short shanks of glass. Of the figured examples the most spectacular surviving specimens are the dark-blue *situla* with a hunting scene in the treasury of St. Mark's. Venice, and the dull-green cup presenting the story of Lycurgus (the Rothschild vase in the British museum). Of the other types of glass with figured decoration, the molded cups with gladiatorial and circus scenes are characteristic of the early imperial period, while the 4th-century glass-worker's craft is represented by vessels with cut or incised designs, the subjects of which are chariot races, hunting and Bacchic scenes and. in the case of the Christian pieces, episodes from the Old and New Testaments. Among the most important centres of glass production under the empire were Syria, Alexandria and the Cologne region.

Figured Pottery.— The figured terra-cotta tablewares *(terra sigillata— a* term often incorrectly stretched to cover plain wares) were cheaper versions of the costly decorated silveraares. During the last century of the republic and in the early decades of the 1st century of the empire, Arretium (Arezzo) was the most flourishing centre of the manufacture of a fine type of red-gloss pottery. As the signatures on the pots reveal, the Italian firms often employed Greek and oriental craftsmen, and the mythological and floral themes of the vessels' molded ornamentation owe much to the inspiration of Hellenistic art. From shortly before the middle of the 1st century A.D. onward, the markets enjoyed by the Italian fabrics were captured by the products of potteries now established in southern, central and eastern Gaul. These manufactured cheaper, more mass-produced and aesthetically inferior red-gloss and black-gloss wares, popularly known as "Samian." some varieties of which continued into the 4th century. The decoration of the Gaulish pots was, for the most part, molded; but some vessels carry applied motifs made in individual molds; while others show designs incised to counterfeit cut glass. Yet another type of ornament was carried out in the *en bavbotine* technique, by which relief work was produced by trailing liquid clay across the surface of the pot. As regards the content of the decoration, themes from daily life were added to the traditional subjects based on Greco-Roman mythology and on natural history; and it is the *en barbotine* hunt cups, of which the leading centre of production was at Castor. Northamptonshire, that are the highlight of the native Romano-British potter's craft. A late-antique class of red-gloss pottery, knonn as late A ware, with scenes in relief from Greek mythology and from the Roman spectacles and shows, was manufactured in some southern Mediterranean area. probably in Egypt.

Coins and Medallions.— Lastly, a brief allusion must be made to the die-sinker's art, closely linked aith that of the gem engraver. The imperial portraits displayed on coins throughout the period of the empire, and on medallions from the early 2nd century onward. provide a continuous iconographic series that can rank nith the best works of the portrait sculptors. Many of the reverse designs, beginning nith those of the late republic, show figure scenes and single figures treated with the utmost delicacy and finish. Especially noteworthy for their pictorial character are the reverse types of the large 2nd-century bronze medallions, with themes from Greek mythology, Roman legend and contemporary Roman history. The reverse designs of some of the late 3rd- and 4th-century gold and silver presentation pieces illustrate most conspicuously the high standards of craftsmanship to which the late antique could still attain. For interest of content few medallions can rival the large gold multiple, found at Arras, which Constantius Chlorus struck in 296 to commemorate his entry into London after defeating the usurping "British emperor" Carausius. *See* also Index references under "Roman Art" in the Index volume.

ROMAN CATHOLIC CHURCH. The word "ecclesia" appears in the New Testament 106 times: twice in its ordinary Greek sense of the assembly of the city-state of Ephesus, once of the community of the Israelites at Sinai and on all other occasions of the society or Church of Christ. whose members were called Christians first at Antioch. St. Paul uses the word both of local societies. "churches" of Judaea, Asia, Galatia, Macedonia, the Thessalonians or in Philemon's house (as he speaks of "them of Laodicea"), and also of the "whole Church of God." In Matt. xvi, 18. Christ answers St. Peter's confession, "Thou art Christ, the Son of the living God." by saying. "Thou art Peter: and upon this rock I will build my church." In Matt. xviii. 15–20, He defines what may be called ecclesiastical jurisdiction: "If thy brother shall offend against thee . . . tell the church. And if he will not hear the church, let him be to thee as the heathen and publican; . . . whatsoever you shall bind upon earth, shall be bound also in heaven: and whatsoever you shall loose upon earth. shall be loosed also in heaven. Again I say to you, that if two of you shall consent upon earth, concerning anything whatsoever they shall ask, it shall be done to them by my Father who is in Heaven. For where there are two or three gathered together in my name, there am I in the midst of them." In tracing the origin of the church back to the apostles, Catholic theologians also cite as the most mature and conscious definition of the Apostolic Church the following passage in the Epistles to the Ephesians and Colossians: ". . . the Kingdom of the Son of His love: in whom we have our redemption, the forgiveness of our sins; who is the image of the invisible God, the firstborn of all creation; for in Him were all things created in the heavens and upon the earth . . . all things have been created through Him and unto Him; and He is before all things and in Him all things consist. And He is the head of the Body, the Church." (Col. i, 13–18). "To sum up all things in Christ . . . and He put all things in subjection under His feet and gave Him to be head over all things to the Church which is His Body, the fullness of Him that filleth all in all" (Eph. i, 10, 22–23).

This organic unity of Christ, "the fullness of the godhead bodily," with the church "which is his body" is the essence of Catholic ecclesiology. In Christ, according to Roman Catholic doctrine, the godhead assumed human nature: the nature of man is united in Christ with the nature of God. and the church is therefore the divine organism. But the nature of man implies a historical and instituted existence on earth. "By the very fact of being a body," said Leo XIII, "the church is visible." Its existence, institution and operation are therefore sacramental. It is the mystery of the incarnate godhead perpetually realized and available in all time and for all the purpose of the divine incarnation. There can be but one such church and, as it is historical and instituted on earth, there can be but one church visible on earth. As it is divine as well as human, it contains and consummates the whole divine creation, "the Church triumphant, the Church suffering and the Church militant: and is the fullness [*pleroma*] of Him that filleth all in all." Hence it is holy and catholic. Its institution is simultaneously divine and human. Historically and therefore upon the authority of its divine Founder, this church is the church of His apostles. It is apostolic and its apostolicity is its perpetual attribute. Within the compass of its sacramental purpose it is infallible. in the sphere of faith (*i.e.*, man's apprehension of God) and in the sphere of morals (*i.e.*, man's essential relation with God and man). This infallible authority. Catholic theologians point out, is not to be confounded in any sense with "power": it is the infallible authority of knowledge which is of the essence of the union of man with God—knowledge not achieved as in the natural sciences externally by observation, hypothesis and experiment, but inherent and essential as God knows Himself and His creature and the nature of the unity which He wills and accomplishes. The effectual operation of this entire sacrament, the vital activity of the divine organism, is known as grace.

Grace is the universal operation of the church. It is the initiation, process and fulfilment of the divine activity of redemption by which God unites His creatures organically with Himself and endows them thus with His own vitality. This universal grace or sacrament is effectually realized and defined in seven sacraments, acts of God in and through the divine organism by which the divine life is bestowed and the organic union is accomplished and sustained. In the Eucharist "under the appearances of bread and wine, Jesus Christ Himself is contained, offered and received." It is the whole act of redemption, the sacrifice—that is, the making holy—of the whole universe in the person of Christ, "the most divine gift emanating from the depth of the heart of the Redeemer 'with desire desiring' this wonderful union with men which was especially designed to spread everywhere the life-giving fruit of His redemptive work" (Leo XIII, encyclical Mirae caritatis, 1902). Baptism is the initial reception of the human being into the body of Christ. Confirmation given to members of an age to recognize and will their membership is the sacrament of moral maturity. Marriage is the sacrament which sustains in Christ human generation and family life. Penance restores the union with God when it has been injured or broken by sin. Holy Order creates and sustains the whole institution of priesthood and episcopacy by which the divine organism lives and functions on earth. Thus the penitent confesses his sin to Christ, who hears, judges and absolves him by means of the human priest, and the sacrifice of Calvary is contemporary with all times as the same sacrifice is offered by the same High Priest employing successive generations of men ordained by Him for that purpose. The passage or expectation of death is sanctified by the sacrament of extreme unction. Thus the whole earthly life of every human being is organized in the body of Christ, and the whole organization of the church exists to realize that divine-human community. The history of the church cannot be understood unless its nature and function as the

divine-human organism, wholly divine and wholly human and indissolubly one, is first recognized.

St. Luke ends his account of St. Paul's apostolate at Rome with the words "This salvation of God is sent unto the Gentiles." St. Paul himself explains the significance of that climax in the Epistle to the Galatians. As a Jew turning to the Gentiles he must claim that the old dispensation has been superseded and that to be "in Christ" (a phrase repeated six times in this Epistle and constantly used thereafter by St. Paul) is to belong to "the Jerusalem that is above" in which "there can be neither Jew nor Greek." It was only by the act of God that the sanctities and exclusions of the old law could be at once fulfilled and superseded, and hence the same authority which united Jew and Gentile realized the purpose of history. "If ye are Christ's then are ye Abraham's seed, heirs according to promise." In the Epistle to the Ephesians written probably from Rome this doctrine of divine consummation becomes explicit, "a dispensation of the fullness [*pleroma*] of the times, to sum up all things in Christ. . . . for he is our peace who made both one and brake down the middle wall of partition . . . that he might create in himself of the twain one new man, so making peace, and might reconcile them both in one body unto God through the Cross." "So then ye are no more strangers and sojourners but ye are fellow citizens with the saints and of the household of God, being built upon the foundation of the apostles and prophets, Christ Jesus himself being the chief comer stone: in whom every building fitly framed together groweth into a holy temple in the Lord." (T. S. GY.)

This article is divided into the following sections and divisions:

I. ORGANIZATION

The Catholic Church is governed by a hierarchy of bishops with the pope as bishop of Rome at the head (see PAPACY). Under him patriarchs, archbishops and other greater prelates are possessed of various local jurisdictions over the bishops of their respective provinces. The church teaches that the origin of all this varied jurisdiction must be sought in the authority given by our Lord Himself, and recorded for us in the Gospels. Just as no man, not even an apostle or the chief of the apostles, could institute a sacrament, so it was not in the power of man alone to originate the fundamental organization of the church. Christ Himself before He ascended into heaven left the church an organized body, with a system of rule that could indeed be developed indefinitely to meet the constant changes which must inevitably occur as the centuries passed. but which in its fundamental principles must remain unchanged to the end of the world.

The bishop of Rome, who as head of the whole church acquired later on the exclusive title of "pope," was also the sole patriarch of the west, while Alexandria and Antioch governed most of the east. In the 5th century two other bishops attained to the patriarchal rank. Constantinople as being the seat of the empire and civil capital of the world, and Jerusalem as the cradle of the church. Under these was a complicated and ever-varying system of jurisdictions of exarchs, metropolitans and archbishops, but the principle by which alone the whole system of subordination of one bishop to another can be justified, in view of the essential equality of all, can be found only in the special grant by our Lord of the primacy to St. Peter and the delegation of some share in that primacy to the rest of the hierarchy.

This principle, which was recognized even at Nicaea, is symbolized and expressed by the practice of sending the pallium by the pope to every archbishop in possession of jurisdiction. The pallium comes from the tomb of St. Peter, where a supply is kept in readiness, and symbolizes and conveys such share in the Petrine primacy as belongs to the particular office. Until an archbishop has received his pallium from the pope, he cannot exercise any archiepiscopal jurisdiction, though he is possessed as soon as he is fully appointed of all the jurisdiction which belongs to him as bishop of his own diocese.

In 1960 the number of Catholics in the world was estimated at about 538,000,000, governed by about 1.500 archbishops and bishops, each in his own diocese.

A. THE CURIA

As the pope has the care of the whole church (that is, of many millions of Catholics spread throughout the world), there is need for an extensive and detailed organization at Rome adequate to cope with the varied questions that arise. This organization is called the Curia. (See CURIA ROMANA for details.)

Cardinals. — At the head of the Curia is the College of Cardinals whose members form the supreme senate of the church and are the pope's direct advisers. Historically the cardinals are the occupants of the "suburban" sees, known as cardinal bishops; the incumbents of the principal parishes of Rome, known as cardinal priests; and a number of cardinals who are the successors of the seven deacons responsible in early times for the more secular details of administration and who are known as cardinal deacons. But these ranks are distinct from the orders of the church and the cardinal priests are always bishops, half their number being the occupants of various important sees and nonresident in Rome, while the cardinal deacons in the 20th century are always priests.

The cardinal secretary is, so to speak, the prime minister of the pope. It is his office to deal with all political affairs, and especially all diplomatic relations with the separate countries and governments. From his department depend the nunciatures and delegations which represent the Holy See abroad, and it is with him that the ambassadors from foreign countries to the Holy See do their business.

Congregations. — The work of the Curia is done by 11 permanent departments, called congregations, each with a cardinal at its head. These comprise: (1) the Holy Office; (2) the Congregation of Ceremonies; (3) the Consistorial Congregation, dealing with the appointment of bishops and other dignitaries, with the erection and division of dioceses and with episcopal administration; (4) the Congregation of the Eastern Church, dealing with the Uniates (see below); (5) the Congregation of Rites; (6) the Congregation of Seminaries and Universities; (7) the Congregation of Sacramental Discipline; (8) the Congregation for Religious, dealing with the affairs of regular orders; (9) the Congregation of the Council, dealing with the summoning and management of councils and also regulating parish priests. benefices and property; (10) the Congregation for the Propagation of the Faith, for missionary organization; and (11) the Congregation for Extraordinary

Affairs. The Congregation for the Fabric of St. Peter's is supernumerary.

Offices.—Some of the ordinary routine business of the church is carried on by the offices; these, however, had declined in importance by the 20th century. They are: (1) the Chancery. which has little to do apart from the sending out of papal bulls; (2) the Dataria. dealing with those benefices the appointment to which is reserved to the Holy See; (3) the Apostolic Camera, which once controlled the affairs of the papal states and now has the care of the property of the Holy See; and (4) the Office of Briefs (sent to princes) and of Latin Letters.

Tribunals.— The tribunals, which control the judicial functions of the Curia, are. (1) the Sacred Penitentiary, handling matters of conscience; (2) the Sacred Rota, formerly the chief court of the papal states, now the court of appeals from bishops' courts to the Holy See, consisting of ten judges who sit generally in threes but for important cases in greater numbers; (3) the Apostolic Signatura. the supreme court of appeal, consisting of six cardinals and their assistants, to which an appeal lies from the Sacred Rota.

B. THE LATIN RITE

The great majority of Catholics are those of the Latin rite; *i.e.*, those who use the Roman liturgy and generally have used it without interruption since the establishment of a Christian church in their country; there are local variations of little significance. The following paragraphs describe the hierarchical system of the Latin rite.

1. Archbishops.— Besides their own episcopal jurisdiction over their own dioceses. these greater prelates, whatever their title. have a provincial jurisdiction over their "suffragan" bishops. This jurisdiction is one strictly limited by law, the presumption being always in favour of the bishop and against the archbishop. It is attached to the office and therefore is "ordinary" jurisdiction and affects the suffragan' bishops immediately and the faithful of their dioceses through them. The extent of this jurisdiction varies considerably in different localities and is everywhere less extensive than in former years. It is the archbishop's duty to summon his comprovincials to the provincial synod, which need be done only once every 20 years, and in that synod he presides of right, though his vote counts for no more than that of any other bishop. If the suffragan bishop has neglected to carry out the canonical visitation of his diocese, the archbishop may visit, after obtaining permission from Rome, and has full power of redressing abuses. When any one of the suffragan sees becomes vacant it is generally the duty of the archbishop to see that the cathedral chapter elects a vicar capitular to carry on the administration of the diocese during the vacancy. An appeal lies from the court of any one of the suffragan bishops to that of the archbishop, and where the rights of the bishop are involved he may hear cases from that bishop's diocese as a court of first instance. Appeals from his own diocesan court, which formerly had to be taken to the Holy See, are heard by some one bishop selected by the archbishop for that purpose once for all and approved by the Holy See. The archbishop has always the right of pontificating in any church in his province and may bless the people, grant 100 days' indulgence and have the cross carried before him in the church. He may not, however, except when he holds a visitation. perform any other acts which imply jurisdiction.

2. Bishops and Dioceses.—The bishop and the diocese form the most essential part of the church's organization, being of divine institution under the primacy of the pope.

Bishops.—A bishop is nominated under different conditions in different parts of the world, but even after he has been thus canonically nominated he has no power until that nomination has been confirmed by the Holy See. Once this confirmation has been given and has been communicated to his cathedra1 chapter he has full possession of all episcopal jurisdiction, though he can do no acts involving the power of order, such as ordaining clergy or confirming children, until he has been consecrated. His jurisdiction is ordinary, limited by restrictions imposed by the Holy See, but independent of his people and even of his clergy. In certain important matters he is bound to seek the advice of his cathedral chapter, though he is not usually bound to follow it. He is bound to make a visit ad *limina* ("to the thresholds"; *i.e.*, to the graves of St. Peter and St. Paul at Rome) to the Holy See at stated intervals to report on the state of his diocese. His authority over his diocese is fourfold: (1) teaching, with authority over all schools, and the right of superintending all the publications of the faithful and especially of the clergy within his diocese; (2) *legislative,* in which his power is strictly limited by the common law and by all existing laws which have wider scope than the bounds of his own diocese. though he can dispense from all diocesan laws; (3) *judicial,* whereby he is judge of first instance in all cases that belong to the ecclesiastical tribunal. can in the internal forum reserve to himself the absolution from certain sins and can enforce his sentences of ecclesiastics by suspending them from their functions; (4) administrative, whereby he can nominate, subject to any local rights of patronage, to all benefices in his diocese, can oblige ecclesiastics to undertake special work (though he can not force the care of souls upon them if they are unwilling) and has authority over all ecclesiastical property, so that none can be alienated or sold without his consent. But in nothing is his power unlimited: he is always subject to the precepts of canon law.

The Cathedral Chapter.—In the general regulations of his diocese the bishop must conform to the general laws of the church and must not do anything which would impair the general unity of church government. He has as his constitutional council, to assist him in the work of government, the canons of his cathedral chapter. The cathedral itself is the church in which he has his seat (cathedra), and this he cannot choose at will, the pope reserving to himself the right of erecting a church to be a cathedral, as well as that of instituting a chapter. Generally, of course, the bishop finds both already established and in existence. The appointment of individual canons is generally in the hands of the bishop, though the appointment of dignitaries in the chapter is often reserved to the Holy See. As the chapter constitutes the diocesan senate, the bishop is bound to convene it and to ask its consent or advice in important matters. In some matters which touch diocesan rights or affect diocesan property. its consent is necessary and the bishop cannot validly act without it. In other matters, though the advice of the chapter must be asked. the bishop is not bound to act upon the counsel tendered. When the see is vacant by the death or resignation of the bishop, the chapter succeeds to his ordinary jurisdiction. but not to any jurisdiction that was personal to himself. Within eight days after the vacancy the chapter must elect a vicar capitular. to whom the whole administration of the diocese immediately passes. In the Cnited States and elsewhere: where cathedral chapters are not yet constituted, a body of diocesan consultors has generally to be appointed by the bishop, and he is bound to ask the advice of these consultors on important matters, though they have not the power of vetoing his action.

The Vicar-General.—The bishop generally appoints one or more priests to assist him. deputing to them with a certain universality of power all his own jurisdiction within the diocese, so that the vicar-general is his alter ego, and no appeal lies from the one to the other. By virtue of this general mandate the vicar-general exercises ordinary jurisdiction throughout the diocese in the bishop's name. This jurisdiction however, being dependent on that of the bishop, ceases at the bishop's death, or with the cessation of the bishop's own jurisdiction. The office of a vicar-general ceases also with his own death or resignation, or with the withdrawal of his vicarial mandate, which last, horvever, can be taken from him only for a grave cause, allowing of an appeal to the Holy See.

The Diocesan *Chancery.*—This is the office through which the ordinary and routine work of the diocese is carried on. At its head is the chancellor. His duties are to carry on the official correspondence of the diocese and to see that records are duly kept. He can be removed by the bishop, but by the vicar capitular during a vacancy only with the consent of the whole chapter.

The Parish.—Where the full organization of the church is in force. the diocese is subdivided into parishes covering the whole ground. Each parish should have its own church and be under its own pastor, having care of souls and irremovable except

for grave cause. But where the full organization is not in force, there are quasi parishes, with pastors who do not possess the full rights of parish priests. The bishop can alter the boundaries of parishes, erect new ones or join two together where there is just cause for so doing. He is bound, however, first to ask the counsel of the chapter, though he is not bound to follow it.

The pastor of a properly constituted parish has ordinary jurisdiction. His rights within the parish are regulated by canon law and include the faculties of preaching, celebrating Mass, hearing confessions and administering the sacraments, though he can delegate this authority. Where the parish is too large to be administered by one priest, assistant priests are sent by the bishop to help him. These assistants are appointed by the bishop (though in some places the parish priest has the right of nomination) and are removable by him, but only for just cause. Their jurisdiction is delegated and they receive their faculties from the bishop.

If the parish priest is ill or incapacitated for any reason, the bishop must send a coadjutor to fill his place and in like manner will appoint an administrator of the parish during a vacancy.

3. Vicars Apostolic.—In districts where the ordinary hierarchy of the church has not yet been established and there are no proper dioceses erected, the Holy See governs directly by means of a delegate who has received episcopal consecration to a titular see and who has the title of vicar apostolic or prefect apostolic. The main difference between the two is that the vicar apostolic is bound to make the visit *ad limina* at certain intervals, while the prefect apostolic is not. They are not diocesan bishops and therefore have no cathedral and no chapter, and all their powers are delegated and not ordinary. Otherwise they enjoy as a rule all the powers that bishops have by canon law in their own dioceses. They have no vicar-general, though they can give special faculties to individual priests to enable them to assist in the rule of the district, and as they have no chapters they are bound to nominate three or more of their leading priests to act as counsellors. There are vicariates apostolic, prefectures apostolic and "missions."

C. THE UNIATE RITES

All that has been written so far about the local organization of the Catholic Church applies only to the western church and the Latin rite, which include the vast majority of Catholics But there are also a number of so-called Gniate churches in full communion with the Holy See but organized separately. These do not represent, as is often thought, any sort of compromise or intermediate position between western Catholicism and the various schismatic or heretical churches of the east. All the Cniate churches accept the full Catholic faith and are in matters of doctrine absolutely at one with Rome. They all accept the full primacy of the Holy See and are subject to its supreme jurisdiction. Each Uniate church retains its old privileges and represents the church of its district or country as that church would have been had the schism never occurred. In no case, however, has the succession from the ancient hierarchy been preserved, but a new hierarchy has been instituted from Rome, with the old titles and privileges and with the preservation of the ancient rite. The object aimed at by Rome in instituting a Uniate church is not the latinizing of the ancient rites but the union of hearts in the one faith and under the one primacy of the Holy See.

Religion in the east has always been far more a matter of nationality than it has in the west. It has been found impossible, therefore, to carry out the strict system of territorial jurisdiction which obtains everywhere in the west. In the east the churches are distinguished rather by nationality, by languages and by rite than by locality, and in consequence there is a system of interpenetrating jurisdictions. There are, for instance, seven patriarchs of Antioch. Of these, three are schismatic, but four are in communion with the Holy See: the Latin patriarch, whose position is merely titular (originating during the crusades) and who resides in Rome; the Melchite patriarch, the Maronite patriarch and the Syrian patriarch. These last three have jurisdiction over the Catholics of their own rite only.

The Uniates in Europe are more or less directly subject to the general system of the Catholic Church. Those in Asia and Africa, however, since the rights of the patriarchates have been preserved, enjoy greater autonomy, being ruled by the Holy See mainly through their respective patriarchs. (A. S. BA ; X.)

1. The Byzantine (Greek Catholic or Graeco-Slavonic **Rite).**—Uniates of this rite represent churches that maintain, in their various languages, the liturgy of Constantinople a-hile acknowledging the doctrinal and hierarchical supremacy of the Holy See. The most important of these churches is the Ruthenian: this includes an archbishopric of Lwow (with suffragan bishoprics at Przemysl and Stanislawow) and bishoprics of Uzhorod, of Presov (under the Holy See), of Hajdudorog (under the Latin archbishop of Esztergom) and of Krizevci (under the Latin archbishop of Zagreb). The important dates for its union with Rome are those of the synod of Brest-Litovsk (Brzesc; 1596) and of the submission of Lwow (1700). New persecution came to the Greek Catholics after World War II when the Soviet authorities ruthlessly followed policies designed to tear them from union with the See of Rome.

The Rumanian Uniates have an archbishopric (Alba Iulia and Fagaras, established in 1701) with four suffragan bishoprics. The Russian Uniate archbishopric (Mogilev, with four suffragans) was subjected to a compulsory latinization under the tsar Alexander II. There are Catholics of Byzantine rite, however, in Greece, Bulgaria and Turkey. The Italo-Greek (Albanian) Church in Calabria and Sicily has the bishoprics of Lungro (founded in 1919) and Piana, both under Latin archbishoprics.

Of the Byzantine rite also are the Melchites (or, more properly, Melkites) of Syria, Lebanon, Jordan and Egypt, whose liturgy is in Arabic. They are so much to be distinguished from the Europeans of the Byzantine rite, however, that the term "of the Melchite rite" is now used of them. Their name, meaning "king's men," was originally a term of disparagement bestowed by their Monophysite fellow countrymen on those oriental Christians who remained loyal to Constantinople and therefore to the eastern Roman emperor's ("king's") religion after the council of Chalcedon (451). Their change from the Byzantine allegiance to the Roman is generally dated at 1724, when the patriarch Athanasius Dabbas acknowledged the Holy See on his deathbed; but his Catholic successor, Cyril VI Tanas, was deposed, and it was not until 1834, after the Egyptian invasion of Syria, that a Catholic patriarch was returned in the person of Maximus III Mazlum (confirmed by Rome in 1836). The Melchite patriarch of Antioch resides at Ain Traz in Lebanon. There are archbishops of Aleppo, of Beirut and Jebeil, of Bostra and Hauran, of Damascus (two suffragans), of Emesa, of Tyre (four suffragans) and of Jordan.

2. The Armenian Rite.—Uniates of this rite use a liturgy adapted from that of the Gregorian (Monophysite) Armenian Church. Their connection with Rome is sometimes dated from 1198; but a stronger movement of union began with the Dominican missions in the 14th century, although the specifically Armenian hierarchy was not established until the middle of the 18th. The patriarch of Cilicia resides at Bzommar near Beirut. There are archbishoprics of Mardin, of Sebaste (Sivas) and Tokat, of Aleppo, of Constantinople and of Lwow; bishoprics of Isfahan, of Beirut and of Alexandria, as well as 12 bishoprics in Turkey; and also churches in Greece and in Rumania. The Mechitarists (*q.v.*) of Venice are Armenian Uniates.

3. The Coptic Rite.—The Uniate church of this rite, in Egypt, in Ethiopia and in Eritrea, is drawn from the Coptic Church of the Egyptian Monophysites and has a liturgy in the Coptic language. The Catholic Coptic patriarchate of Alexandria was founded in 1895. There are suffragan bishoprics of Hermopolis Magna and of Thebes.

4. Syriac Liturgies.—Whereas the provenance of the Byzantine, the Armenian and the Coptic rites of Uniates is easily understood, that of the various Syriac rites may require some preliminary explanation. Historically, there are two sources: the East Syrian, Assyrian or Nestorian *Liturgy of the Apostles Addai and Mari;* and the West Syrian, Jacobite or Monophysite *Liturgy of St. James.* The former gave rise to two Uniate rites, the Chaldaean and the Syro-Malabarese; the latter to three, the Syrian, the

Maronite and the Syro-Malankarese. However, a classification here by East Syrian and West Syrian groups would involve difficulties of nomenclature and a misleading fusion of distinct bodies. The rites will therefore be introduced separately.

The Chaldaean Rite.—The Uniates of this rite, mainly in Mesopotamia and Kurdistan, use the Liturgy of Addai and Mari and have also a Syriac vernacular. Union with Rome is dated at 1551, when John Sulaka led the first group of converts from Nestorianism, and at 1680, when Joseph of Amida (Diarbekr) led the second. The patriarch of Babylon resides at Mosul, and there are archbishoprics of Keruk and of Urmia and eight suffragan bishoprics.

The *Syro-Malabarese* Rite.—Catholics of this rite represent those Christians of St. Thomas (see THOMAS, SAINT) who nere converted to the Roman allegiance by the Portuguese at the synod of Diamper (Udayamperur, in Cochin) in 1599. They use a form of the Liturgy *of* Addai and Mari, as their antecedents were Nestorian. The archbishopric of Ernakulam has suffragan bishoprics of Changanacheri, of Kottayam and of Trichur.

The Syrian Rite.—The term "of the Syrian rite," though in a general sense applicable to several churches, is used specifically to designate Uniates using the Syriac Liturgy of St. James, with certain formulas in Carshuni (Arabic written in Syriac), and representing Christians formerly of the Jacobite persuasion who were united with Rome in 1646. Their patriarch of Antioch resides at Mardin in Turkey, and there are archbishops of Damascus, of Emesa, of Baghdad and of Mosul, as well as four diocesan bishoprics.

The Maronite Rite.—The Maronites (*q.v.*) of Lebanon represent a community which was probably at first Monothelite, originating after the council of Constantinople in 680–681. Though they renounced Monothelitism in 1182 and were united with Rome until the end of the Latin kingdom of Jerusalem (1187). the connection was subsequently broken and not permanently resumed until 1736. As the Syrian Uniates, they use principally the Liturgy of St. James and formulas in Carshuni. Their patriarch of Antioch has authority over bishops of Aleppo, of Beirut, of Cyprus, of Damascus. of Heliopolis, of Jebeil and Batrun (Botrys). of Sidon, of Tripoli and of Tyre.

The *Syro-Malankarese* Rite.—When the Dutch in 1663 put an end to the Portuguese domination of Malabar, numbers of the Malabarese abandoned the Roman connection (see above, The Syro-Malabarese Rite) but, instead of reverting to Nestorianism, accepted in 1665 a Monophysite bishop from' the Jacobite patriarch at Mardin. In 1930, therefore, when some of these Jacobites were united with Rome again. the Liturgy of St. James was retained. The archbishopric of Trivandrum (established in 1932) has a suffragan bishopric at Tiruvalla. (X.)

II. HISTORY

The human institution that is the fullness of the godhead bodily was to be governed on earth by a sacramental sovereign as agent or representative, the apostle or "vicar" of Christ. That this "vicar of Christ" should be the bishop of Rome belongs to the "logic of history"; and, in the faith that "the Word which is God. became flesh and dwelt among us," history assumed a validity not realized before or elsewhere. If, in "the fullness of time. God sent forth His Son born of a woman," He selected the Roman imperium as the historical circumstance of that incarnation. Rome was not merely the metropolis of that humanity but the seat of an actual and formative sovereignty beyond comparison more effective and significant than that of any other imperial city. Here if anywhere the City of God must encounter the "fullness of manhood bodily." Within a generation of the death of the apostles, Roman legions had destroyed the temple at Jerusalem. Less than a century later the tradition of St. Peter's presence in Rome was. as Louis Duchesne (*q.v.*) stated. "precise and universal." Duchesne further declared that Dionysius of Corinth in Greece, Irenaeus in Gaul, Clement and Origen in Alexandria and Tertullian in Africa all referred to it, that in Rome itself Caius. about 200, pointed out the tomb of the apostles. that by the 3rd century popes built on their title of successors of St. Peter and that their right to this title is nowhere denied. Clement (c. 97) thinks it natural for the church in Rome to address a letter of advice to the church in Corinth upon the outbreak of an "execrable and godless schism." Ignatius of Antioch apostrophizes the Roman Church with a series of titles such as he addresses to no other. It is above all "a church presiding in charity, maintaining the law of Christ, and bearer of the Father's name." At his martyrdom he asks for the prayers of the Roman Church for the church in Syria since "Jesus Christ alone will be their bishop, together with your charity." (Ancient Christian *Writers,* vol. i, tr. J. A. Kleist, Newman Press, Westminster. Md., 1946.) Irenaeus, who came from Asia Minor and wrote Greek in southern Gaul, and whose work found an immediate public in Egypt, was world-conscious and belonged to a world community not only as a theologian but as a subject of the Roman empire.

The city of the Caesars and of the senate and people of Rome was the seat of the apostles; it was also the city of martyrs and heretics. Persecution and heresy contributed to the mature self-consciousness of the church. The offense of Christianity as defined by Trajan (c. 112) was of the nature of treason—otherwise harmless. The greatest persecutions, those under Decius (250–253), Valerian (257–260) and Diocletian (303–311), were virtual acts of war against "a sovereignty within a sovereignty" which seemed to threaten the empire. The danger would have been as real as it seemed but for the peculiar combination of faith and morals which enabled Christians to "dwell on earth as citizens of heaven" (Epistle to Diognetus). They could thus pray for the emperor's welfare while they denied his divine title (Cyprian). "They obey the established laws, yet their conduct goes beyond those laws"; and "Exposed to the wild beasts to make them renounce the Lord, are they not seen to remain invincible?" (Epistle to Diognetus). Origen's confidence that Christ is stronger than the emperor, the army and the senate and people of Rome was inevitably and essentially Christian. The organic unity of the church was vigorous and visible in ceaseless missionary activity at every level of society and in every province. Christians nursed the sick, visited the prisoners, found employment for the idle and cared for the poor, orphans, widows and slaves. All this, inspired and confirmed by a naïve sense of divine presence, omnipotence and justice. gave the church not only authority over the whole life of its rapidly multiplying membership but an independence of imperial sanctions. Half the interval between Nero and Constantine was persecution, and Diocletian had reason to complain that Christians did not fear death. The martyrs were not only the army of the church: they made explicit what the Christian faith had always implied, a totally new conception of the majesty of the human being as such and of human institutions. Constantine may have been a mystic, but he was certainly a political realist. Paganism died of its unreality. Julian's attempt to revive it in revolt against a corrupt and heretical Christianity (361–362) was no more than an adventure of sentiment and ideology.

Meanwhile the church defined its faith and established an orthodoxy. Definition is not, in the Catholic view, identical with the faith, but it is the means by which the faith becomes incarnate and available in the world and, as such, is implied in and authorized by the incarnation of God. It is thus conditioned by the "fullness of time" and is given to the church by the same authority that created the church, when and as the purpose of redemption and the existence of the church require it. So given it is infallible and final; but it is also the conclusion of a stage in the history of the church on earth, and its enunciation is prepared by a period of questions and uncertain or inadequate or controversial answers. The New Testament, whose canon was fixed c. 120, and the formulary known as the Apostles' Creed, used for the instruction of catechumens at the beginning of the 3rd century, both reveal the doubts and questions which assailed the primitive Christian. The Gospels and the Acts were historical documents; the creed is a catalogue of facts. As against the Jews, the apostolic church proclaimed an eschatology which was no longer a promise but a present reality. As against the docetism and gnosticism which represent the perennial reluctance to accept the faith as a fact, the New Testament and the creeds emphasized the event

and the institution. Gnostic theories—those of Cerinthus. Valentinus, Basilides. Carpocrates and others—were not and did not claim to be histories. They were cosmological myths and speculations, ingenious and sometimes profound metaphysical guesses, against which the primitive church affirmed the supernatural history and, in doing so. realized its own divinely appointed form and existence Fact implied revelation; revelation implied authority and tradition; and all implied the presence on earth of God in the person of Christ and in the Holy Spirit who informed the Holy Catholic Church. Irenaeus (c. 186) finds the authority in "the tradition of the great and ancient church known to all men which was founded and constituted by the most glorious apostles Peter and Paul. by its traditions and its faith announced to all men and descended through the succession of its bishops to us, we confound all those who gather where they ought not" (*Adversus haereses,* iii, 381). Irenaeus. who wrote against the Valentinians, gave also an account of all the principal heresies down to his time. Justin wrote, besides his *Apology,* a *Syntagma* against all heresies, which is lost. Hippolytus in his *Syntagma* attacked 32 heresies. Epiphanius in the 4th century catalogued 80 heresies in the *Panarion.* "The Jewish strain in Christianity with its abomination of the Gentile worships and its assumption that they connoted immorality; the links of community to community which prevented unfettered development; the hierarchic system; the principle of apostolic authority and apostolic tradition; the numerical preponderance of folk with the *foi du charbonnier* [*i.e.,* "implicit faith"] prevented what would in effect have been the absorption of Christianity in Graeco-Roman culture." (A. D. Nock, *Cambridge Ancient History,* vol. xii, p. 446.)

A. FROM CONSTANTINE TO CHARLEMAGNE

Imperial conversion brought into the church all the problems of the empire. Of these the most urgent was the pagan habit of toleration expressed in the Edict of Milan (313), issued in the name of Licinius and Constantine, that "everyone may have licence to worship whatever he pleases." Such toleration came to the Christians as relief. but imperial protection raised the old question of Christ and Caesar in a new, subtle and dangerous form. It not only threatened to confound the church with imperial administration but exposed the faith to the speculative ingenuity and dispute endemic in paganism. These two secular problems coalesced to make theology the subject of party strife. The teaching of Arius, according to whom the Logos was a creature not divine but free, mutable and adopted as Son of God in prevision of his merits, revived the ancient reluctance of the philosophical pagan to accept the incarnation as a fact and relieved the Arian of the revelation and authority which faith in the supreme mystery demanded and presupposed. It was a rationalization not apostolic or holy or catholic, and the Christians who adopted it ceased to be Christian. At the council of Nicaea (325) the word *homoousios* ("consubstantial"), accepted to affirm the deity of Christ against the Arians, was probably suggested by Roman legates. Eusebius, bishop of Nicomedia, who had learned his theology from Lucian of Antioch, used the heresy of his fellow-student Arius as an occasion of intrigue. Without disputing the decrees of the council of Nicaea he devised an imperial formula to comprehend Arians and Catholics and gained the support of Constantine and Flavius Julius Constantius (337–361) for a policy which seemed to promise imperial peace and actually promoted ecclesiastical dissension. This policy not only raised Arian bishops to most of the eastern sees but meant also constant secret interference *a latere* by bishops in the jurisdiction of their brother bishops, the employment of imperial prefects and police in the enforcement of partisan decrees and the habit of using theological formulas not to define the faith but as instruments of ecclesiastical diplomacy. Thus by the carefully packed council of Tyre (335) Athanasius mas deposed on frivolous charges and an Arian, George of Cappadocia, raised with the aid of imperial police to the see of Alexandria. At Antioch in 341 an assembly of roo bishops issued an ambiguous formulary denying that they were followers of Arius but evading the Nicene Creed. Finally, in 359, imperial pressure enforced a similar evasion on the whole episcopate, both western and eastern, at the councils of Ariminum and Selencia. In 360 the formula was accepted which "with a little complaisance Athanasius and Aetius might have repeated together"; and in 361 Constantius was succeeded by Julian, and Arian victory by pagan reaction.

Rome and the west remained comparatively free from the heresy and policy of the east. No longer head of the empire, Rome was still head of the church; the decline from its imperial status emphasized its ecclesiastical independence. The bishop's residence was established on the Caelian hill in the ancient house of the Laterani. owned by Fausta, the emperor's wife; and there Pope Miltiades held a council in 313. A basilica was raised, the existing church of the Lateran. Athanasius, exiled from Alexandria, visited Rome in 339. His news of Antony, Pachomius and the desert fathers kindled among wealthy Romans an interest in ascetic and monastic life which bore fruit in the next generation; and before Pope Julius and a council of 50 western bishops he was acquitted of the charges which had led to his deposition at the council of Tyre. The eastern bishops, who had asked to be invited to this council in Rome, nevertheless declined the invitation when it came. To their ultimatum requiring him to choose betueen Athanasius and themselves, Pope Julius replied that it was natural to hear complaints of bishops who said that they had been unjustly deposed; that in the absence of accusers he had examined the only available evidence, which they had themselves supplied at the council of Tyre; and that he was concerned not with trifling stories but with the unity of the church (340).

1. Eastern Schisms.——Roman theology had not generated the controversial and speculative subtleties which divided the east. A schism left by persecution, between those who had endured and those who compromised with the pagans, had occasioned some disorder which was soon overcome. A greater schism, that of the Donatists, rent the diocese of Carthage. To the historian its main interest lies in its effect upon Augustine, who during 16 years of controversy matured his conception of the Catholic Church. From 413 to 426 he was writing *The City of God.* He was baptized by Ambrose in 387. Two years earlier Jerome (c. 340–420) had retired to Bethlehem to complete his translation of the Bible (Vulgate). Ambrose, born at Trier about 340, son of the prefect of Gaul, became prefect of Upper Italy in 369 and, on the death of Auxentius (nho had accepted the confession of Ariminum), was appointed bishop of Milan. So complete was the popular acclaim that the bishops accepted it as a sign of divine will, as it was certainly human prudence. One of the best of Roman governors thus became one oi the greatest of Christian bishops. His most significant task was to resist the inclination of the empire to control the church. A little younger than Ambrose, his friend Theodosius was made Augustus in 379 and in 380 was baptized a Catholic. In 381 he summoned a council to Constantinople (the second general council). Ambrose at the same time presided over a council at Aquileia. Both condemned Arianism; Theodosius decreed that "all beliefs contrary to the faith clearly taught by the pontiff Damasus and by Peter, bishop of Alexandria, were heresy." He ordered all church property to be restored to the orthodox and named the bishops who were to be so accounted. The council also declared that "the bishop of Constantinople shall have the pre-eminence of honour after the bishop of Rome, for this city is the new Rome," thus founding ecclesiastical dignity on imperial status. Rome rejected this principle. In 383 Theodosius convoked a meeting of Catholic and Arian leaders, and upon its failure issued another edict, never strictly enforced, forbidding heretical worship public and private. So in Milan, Ambrose refused to allow a single Arian church even for Justina. The murder of Gratian and the advance of Maximus through Gaul and Italy called Theodosius to the west, where, after the defeat and death of Maximus, he resided for nearly three years at Milan. Valentinian II also lived there, likewise under the personal influence of Ambrose. The bishop proclaimed and maintained the principle that "the emperor is within the church, not over the church," a principle repeated by Pope Leo I (the Great) after the council of Chalcedon (451): *"Alia tamen ratio est rerum secularium, alia divinarum; nam praeter illam petram quam Dominus*

in *fundamento posuit, stabilis* erit *nulla constructio.*" (As to the distinction between divine and secular authority, it was thus stated, that God's authority is the firm, rocklike foundation, complete and perfect, without need of further strengthening to maintain it.)

Pope Leo was called upon to state once more and in uncompromising terms the fact in which and by which the Catholic Church exists. The heresy at Chalcedon was that of the Monophysites. who declared that there was but one nature in Christ, the divine — another form of the perennial desire to evade the central Christian dogma. The pope's definition, acclaimed by the council as "the voice of Peter," was an uncompromising statement of the fact:

Following, then, in the footsteps of the holy fathers, we all teach in harmony that the Son and our Lord Jesus Christ are one and the same, one and the same perfect in godhead, the same perfect in human nature, true God and true man, the same made of a rational soul and body, consubstantial with the Father according to His godhead, consubstantial nith us according to His human nature. made in all things like us without sin according to His godhead begotten of His Father before all ages; the same in these last days for us and for our salvation born according to human nature of the Virgin Mary, the Mother of God; one and the same to be acknowledged as Christ the Son, the Lord, the only begotten, in two natures not removed by reason of their union, but rather the characteristics of each preserved united together in one person and subsistence, not divided nor shared among tno persons but one and the same: Son, Only-begotten, God, Word, Lord, Jesus, Christ, as the prophets before had said of Him, as He Himself taught us and as the creed of the fathers has handed down to us.

In that statement, there is obviously no attempt to placate human reason and no appeal to human experience. Words are used to command a rational submission of faith to a fact which transcends reason. It is the voice of original authority, not a resultant explanation; foundation. not superstructure — "the stone which the Lord laid as a foundation." Man is whole, is perfectly and eternally human in Christ who is Very God. Nothing can violate the distinction between God and man. The incarnation does not violate but transcends it. and it is thus not an evolution but the consummate act of transcendent godhead which the church announces and embodies. It purports to be a statement of the atonement and sacrifice in which human nature is restored to perfect unity with divine or absolute being. It is announced and accepted as fact by the Roman bishop, "the voice of Peter," at the council of Chalcedon. Thus by the 5th century the church is fully conscious of itself as the issue of that supernatural union, wholly human, wholly divine. From that position there could be no retreat.

2. Fall of the Roman Empire. — The fall of the western empire (476) completed the isolation of the Roman see. Arianism, expelled from the empire, had been established meanwhile among the Goths of the Danube by Ulphilas (Wulfila; d. 383), appointed their bishop by Eusebius of Nicomedia. He taught a Gothic Christianity in the Gothic language, inventing an alphabet and translating the Scriptures. Untrammelled by orthodoxy, this faith needed no apostolic see and was adopted by Goths, Suebi, Burgundians, Vandals and Lombards as a kind of national religion. Gradually the west had been subdued by conquest and infiltration to these races: Africa to the Vandals. Spain to the Suebi and Visigoths. Gaul to the Visigoths and Burgundians. The Avars wasted Pannonia, the Slovenes Styria, Carinthia and Carniola. The Croats and Serbs established themselves south of the Save. Italy was defended by a barbarian army under the Herulian Odoacer, a Catholic, until his defeat and death in 493 at the hands of Theodoric the Ostrogoth, an Arian. who ruled Italy from Ravenna with conspicuous ability and tolerance with the advice of the Catholics Boethius (480–524) and Cassiodorus (*c.* 490–*c.* 585). After Theodoric's death (526) Italy mas conquered by the Catholic emperor Justinian's armies (535–554) under Belisarius and was until the 8th century officially a province of the Byzantine empire under the exarch of Ravenna. The Lombards conquered northern Italy and established themselves at Pavia. At once subject to repeated attacks from the Franks and extending their own conquests in Italy. the Lombards, unlike the Goths. had neither genius nor opportunity for peace. Thus when Gregory I the Great became pope he succeeded to what might be described as "the grave of the deceased Roman empire." He had been praetor and then monk and had lived three years in Constantinople as the nuncio of Pelagius II seeking imperial aid against the Lombards. As Roman and as pope, he saw the world as a whole. Lawyer and judge by training, monk, bishop and apostle by vocation, he realized the creative and redemptive possibilities of the papacy and of the Catholic Church at the moment when outside it and apart from its supernatural certainty all civilization in the west was dead beyond hope of resurrection.

3. Episcopacy and Monasticism. — During the next six centuries the function of the church was to create Christendom, and its chief instruments in this work were episcopacy and monasticism. During Gregory's pontificate the Arian rulers of the Lombards in Italy and of the Visigoths in Spain were baptized Catholics. In j97 his mission of 40 monks landed in Kent under Augustine, "their abbot made bishop, with my permission, by the bishops of Germany and aith their assistance conducted to that nation at the limit of the world." A century earlier (496) Clovis with 3,000 Franks had been baptized by Remigius, bishop of Reims, and was exhorted by Avitus, bishop of Vienne, to spread the faith among the barbarians "corrupted by heretical doctrines." Clovis had respected the property, person and advice of bishops even as a pagan, and he owed his conversion partly to the prudence which recognized in them the virtual rulers of Gaul. He broke the power of the Visigoths at Vouillé near Poitiers and extended his dominion to the Pyrenees, everyahere requiring Arians to become orthodox and restoring their churches after their reconsecration. In Paris, the seat of his government, he built and dedicated a basilica to the Holy Apostles. In the 5th century the monk St. Severinus, a friend of Odoacer, established the authority of personal sanctity over the peoples of the upper Danube. During the 7th. 8th and 9th centuries the Croats were Christianized by Roman missionaries; the Bavarians of Upper Austria by St. Rupert of Worms, who founded a see and a monastery at Salzburg (c. 700) that Charlemagne made an archbishopric (798); Moravia by the Greek monks Methodius and Cyril (Constantine); and Bohemia by its prince, whom St. Methodius baptized (871). Prague became a see in 973. The Magyars, who had withstood a succession of missions from east and west, were at length converted under Stephen I. who established the metropolitan see of Esztergom (Gran) and founded the monastery of Pannonhalma near Gyor Szent Marton (Martinsberg) with five other houses and was crowned with the golden crown sent by Pope Silvester II on the Feast of the Assumption, 1001.

Monasticism was the Christian equivalent of the imperial army, the means by which the church subdued and enlisted, colonized and administered the new peoples and revived or defended the old. The first western monk, St. Martin of Tours (c. 316–c. 400). was a Pannonian, born of pagan parents and bred a soldier; he secured his discharge in order to renounce the world. Under St. Hilary of Poitiers (c. 300–*c.* 368). himself a convert. Martin established a monastery at Ligugé and another at Marmoutier on the banks of the Loire. As monk and bishop of Tours he devoted himself to an ascetic discipline and to the conversion of pagans. Other monastic communities gathered at Marseilles (St. Victor) and at Lérins (St. Honoratus or Honoré) whence another St. Hilary was appointed bishop of Arles (426). St. Patrick visited Lérins and Marmoutier before setting out on his mission to Ireland, for which he was consecrated by Germanus. bishop of Auxerre. About 480 was born St. Benedict of Nursia (*q.v.*), whose *Regula monachorum* or "Rule for monks" (c. 515) became the pattern of all western monasticism. "For thee. therefore, whosoever thou be, my words are intended who, giving up thy own will, dost take the all-powerful and excellent arms of obedience to fight under the Lord Christ, the true King." In that conception of service and society lay the seeds of the rivalry between natural and supernatural sovereignty which appeared full-grown in the 11th and 12th centuries. (See also BENEDICTINES.)

A few years older than the Digest of Justinian (who was certainly acquainted with it), the Rule established a discipline and constitution and regulated a liturgical society with impersonal precision. It represented the religious as the Institutes repre-

sented the civil society. The Rule required self-surrender rather than self-abnegation. Rased on long monastic experience and devotion to the person of Christ (who is to be seen and served in the abbot and in all the brethren, in strangers who visit the monastery and in all its life and work), it was the perfect instrument for creating centres of Christian society above all in rural and pagan territory and for reforming the religious communities of the west. Thus a rational economy, moral training and education in the arts of peace developed about the altars of the church and were available to transform the secular barbarity of war and heroic solitude into Christian civilization. The Irish monk St. Columban, whose rule followed the older pattern of extreme austerity, established four houses for men and two for women in Gaul. His disciple Gallus founded St. Gall on the shores of Lake Constance. Columban died at Bobbio, which he founded as a mission to the Arian Lombards and equipped with books, the nucleus of the most famous of mediaeval libraries. Cassiodorus. Theodoric's minister. attempted in 53j to found a Christian academy in Rome and, failing this, established a house at Squillace in Calabria (Vivarium) with a library for which he composed his two handbooks on divine and liberal learning. "But for the existence of such a sanction for literary culture, it is quite possible that, with the exception of Virgil. no Latin classic would have reached us in a complete form" (Montague James, *Cambridge Medieval History*, vol. iii, p. 486).

The greatest single achievement of monastic missions was the conversion of Britain. Thanks to Gregory I and Augustine. English monasticism mas Benedictine. The Benedictine abbey at Canterbury was the metropolitan church. The influence of this type of mission was apparent at once. It created a culture. introduced the Roman alphabet and inspired a literature first in Latin and then in the vernacular. It acquired lands and rights which were recorded in documents and, as its teaching influenced custom, it codified the laws, as Bede says, *"justa exempla Romanorum,"* after the model of Roman justice. The fact that England unlike Gaul, Italy and the lands of the continental barbarians, had nothing but pagan custom and a rudimentary civilization gave the monks a more complete victory.

The attachment of English Christianity to the Roman see was the stronger as Gregory I was the apostle of the English; and Christianity without imperial tradition and Roman law was free to develop with and through indigenous custom. Benedict Biscop (q *v*) is said to have made seven pilgrimages to the tomb of the apostles. He visited Lérins. On the third journey he brought with him Theodore of Tarsus and Abbot Adrian of Naples, both monks who brought a knowledge of Greek and an infectious love of learning (668). Aldhelm (*c.* 640–709), trained at Malmesbury and Canterbury, abbot of Malmesbury and bishop of Sherborne, architect, Latin scholar and English poet, represents the first fruits of this English culture, whose greatest figure is Bede (*c.* 673–735). His contemporary St. Boniface or Wynfrith (d. 754), a monk of Exeter, carried the mission with the sanction of Pope Gregory II and the help of Charles Martel into Bavaria, Thuringia. Friesland. Hesse and Saxony. He established eight bishoprics and founded many monasteries, above all Fulda, where he hoped to die. He reformed the work of Irish monks with Roman and Benedictine discipline. In 747 he was appointed primate of his great province of Mainz. In 751 he consecrated Pippin, who with the authority of Pope Zacharias had been elected king of the Franks and in imitation of the English kings wished to be anointed. St. Boniface finally resigned his see and went to preach the faith to the Frisians. by whom he was martyred (754).

4. The Rise of Temporal **Power.**—Meanwhile, in the civilized east the Christological discussion continued. The pope, though a subject of the (Byzantine) emperor, was head of the church, and the east, always divided in faith, had always been uncertain in ecclesiastical submission. The churches of Egypt and Syria, strongholds of Monophysite theology and jealous for the dignity of Alexandria, had refused the decision of the council of Chalcedon. The emperor Zeno tried an accommodation, the *Henoticon* (481). Justinian, a Macedonian Catholic, in the controversy of the "Three Chapters" (553), forced the aged Pope Vigilius to attend the fifth general council at Constantinople and to assent to the condemnation of Theodore of Mopsuestia. Theodoret and Ibas, three writers who had been accused and acquitted of Nestorian heresy at Chalcedon. The emperor Heraclius tried the formula known as Monothelitism, which ascribed one "active energy" to the Saviour, translated by the Latin bishop as "one will"; and Pope Honorius, mistaking the question, professed himself willing to assent. Pope Martin I (649–653) refused this concession and was exiled by the emperor Constans II (641–668) to the Crimea. The sixth general council (680) vindicated Martin I, condemned Monothelitism and criticized Honorius. Nevertheless, in 692 the council *in Trullo* (Quinisext) was deliberately anti-Roman, and Pope Sergius, arrested at the orders of Justinian II, was saved only by force from the imperial officer. Finally the emperor Leo III the Isaurian (717–740) had initiated his campaign of iconoclasm in 725, the most unpopular and unnecessary of reforms, enforced by persecution and confirmed by the council of Hieria in 753. The schism endured until 843.

But the emperor, if he was willing to force the Roman bishop to submit in matters of doctrine. was quite unable to defend his Roman subjects from their enemies in the flesh. It mas out of long Roman experience that Pope Zacharias (741–752) answered Pippin's question concerning kingship that the king should be he who really has power to rule. Neither Roman nor Byzantine sovereignty had been bound by a doctrine of legitimacy: the prince was the guardian of law and peace. In Rome the bishop and the people were bound together by ties of faith, history and administration. The walls, defenses, aqueducts, food, hospitals, finance, justice and religion were in the bishop's charge. Not only the city but the west as a whole was in need of defense. In 711 Spain and Sardinia had fallen to the Arabs. Sicily was frequently raided by Saracens, who exacted tribute from Syracuse. In 732, at Poitiers, Charles Martel broke the Moslem invasion! saved Aquitaine and established his title as defender of Christendom. Thus. when, in 751, the Lombard Aistulf seized Ravenna, threatened Rome and meditated the conquest of Italy, Pope Stephen II (752–757), having appealed in vain for help to the emperor, turned to Pippin. He journeyed into Francia, crowned Pippin at St. Denis and, returning to Italy with the army of the Franks, received Ravenna from Pippin, who destroyed the Lombard forces (756). Charles the Great completed the conquest by capturing Pavia (772–774).

Thus the pope became a sovereign prince. His "temporal power" was the consequence of an inevitable severance of west from east, of the barbarian and Moslem invasion and of his apostolic function to maintain the faith as against the heresies and schisms which were endemic in the eastern imperial system and to evangelize the pagans of the west. Gregory I, reminding bishops that they were the salt of the earth and that, above all else. men expected of them the salvation of souls, said that "nevertheless even now there are no worldly affairs which priests do not administer" *(Liber regulae pastoralis,* 59j). Pippin, son of Charles Martel, brought up by the monks of St. Denis and consecrated by St. Boniface, held much the same conception of episcopacy.

Charles the Great. after 800, was not only Augustus but "crowned of God, great and peace-bringing emperor who rules the Roman empire and who by the grace of God is king of the Franks and Lombards." He read St. Augustine's *De civitate Dei* and, admitting that the old Roman empire was the *civitas terrena* ("the earthly city"), regarded himself as governor under the Emperor of Heaven of the City of God. For 30 years (772–804) he made holy war on the pagan Saxons, and when he died in 814 his empire, extending from the Elbe to the Pyrenees, from the English sea to the Tiber. was united in so far as it was Christian. His school under Alcuin of York (735–804) was the cultural centre of this empire. Louis I the Pious, crowned at Reims by Stephen IV (816), co-operated with Pope Paschal I in his desire to convert the Danes. The archbishop of Reims. the bishop of Cambrai and a mission of monks under Anskar spread the faith about the mouth of the Elbe. A monastery was founded at Korvey (822) and a bishopric at Hamburg (831). In 826 the Danish prince Harold

with many hundred followers was baptized at Mainz. Meanwhile, St. Benedict of Aniane, having reformed the monasteries of Aquitaine. was brought to advise Louis on the moral reform of the kingdom and was established in a monastery at Xachen. Under his influence the rule of St. Benedict was imposed on all monastic houses in the Frankish kingdom.

B. THE FORMATION OF CHRISTENDOM

At the death of Louis the Pious (840) the natural divisions of the empire and local needs, attachments and traditions were reasserted. The idea of empire derived from Rome, taught by Alcuin of York and realized by the genius of Charlemagne, receded. The invasion of the Normans or Northmen intensified the confusion of dynastic war. Based in Flanders, they ravaged Saxony, the Rhineland and France, burned Cologne, Rouen, Paris and Aachen, captured Trier, besieged Orléans, seized Bordeaux and advanced to Toulouse. They sacked the monasteries and completed the destruction of towns and communes surviving from Roman times. The Edict of Mersen (847) commanding every man to serve a lord only defined the actual situation; feudal organization was partly. if not mostly, a defense against the anarchy the Normans left behind. In 876 they settled in Normandy. Two centuries of war thus isolated and established the church in the west as the one continuous, unifying and civilizing institution and (as it were) defined its double function of evangelizing and civilizing mankind.

This isolation of the west was emphasized by the schism of Photius in Constantinople during the pontificate of Nicholas I (858–867). The elevation of Photius, a layman, to the patriarchate and the deposition of Ignatius, his predecessor. were uncanonical. On the other hand. the interference of the Roman legates in the newly founded Bulgarian church was perhaps unlawful. The *Filioque* question (the double procession of the Holy Ghost) was used mainly as an occasion. though the theological difference between east and west is implied in the dispute. As always, the west was more simply and uncompromisingly Trinitarian and laid greater emphasis on the incarnation with its consequent exaltation of the church. Nicholas I, a canonist and political realist, advanced from the traditional Gelasian doctrine of "two swords" to that which foreshadowed the papal doctrine of Hildebrand. To the emperor Michael III he wrote that, whereas the emperor needed the pope in religion. the pope had no need of the emperor in temporal matters. At the same time (86 j) he demanded obedience from Charles the Bald and even quashed a judgment of the great archbishop Hincmar of Reims and declared that what the pope decides all must observe. For a century, however, the Roman see, lacking temporal protection, suffered from its temporal status. The Roman nobles, the house of Spoleto, the counts of Tusculum and the kings of Germany made and unmade popes in a succession down to John XII, deposed by Otto the Great in 963.

Weakness at the centre encouraged and exaggerated the centrifugal tendencies revealed in the wide, half-civilized rural areas that were exposed to waves of pagan and barbarian invasion. The urban organization of the church in the Roman empire was not suited to this scattered and insecure continent. The church needed an imperial idea and the co-operation of temporal powers. During the 10th century the house of Saxony laid the foundations of the mediaeval empire, Cluny revived monasticism and the canon law was gradually developed; and these three factors, together with intensified theological controversy, prepared the great reform of the 11th century, which was initiated by a reformed papacy.

1. Foundation of the Mediaeval Empire.—Otto the Great (912–973), occupied during the first 25 years of his reign in uniting the German peoples and defending them against Hungarians, Slavs and h'ormans, was crowned emperor in 962 by Pope John XII in Rome and thereafter was employed in restoring order in Italy. He founded a metropolitan see at Magdeburg, whose first archbishop, Adalbert. monk of Trier and abbot of Weissenburg, had been missionary to the Russians. Bishoprics were founded also at Oldenburg and Havelberg (946), at Prague (976), at Olomouc (Olmutz; for Moravia) and at Odense (for Denmark; 980). In 936 St. Unni of Bremen undertook a mission to Scandinavia, where he died. The second bishop of Prague, St. Adalbert, who baptized St. Stephen of Hungary. left his see in defiance of papal and imperial injunction to preach the Gospel to the Poles and Russians, by whom he was martyred in 997. The frontier churches of Bohemia, Hungary and Poland looked to Rome rather than to Germany; and Pope Gregory V (996–999), cousin and chaplain of Otto III, revived the missionary tradition of the Holy See but fell a victim of city faction prompted by local nobles. At his death, Otto III appointed the Frenchman Gerbert of Aurillac (Silvester II, 999–1003). Silvester dreamed of an empire independent of the German kings which should embody a world faith and a world culture. Like other learned men he underestimated local ties and traditions, and like other Frenchmen he failed to realize the needs of German administration. Simony he counted the greatest evil in the church. But it was much more than the "sin of Simon Magus": in France it mas, indeed, a corruption which was the result of generations of insecurity strengthening the hands of unscrupulous lords; in Germany it was rooted in Teutonic and feudal custom and continued by social and economic necessity.

The spread of Christianity among remote and barbarous peoples implied local autonomy and the adaptation of ancient pagan administrative custom. Churches were built. maintained and possessed by their chiefs. The mission church was virtually autonomous; its priest was the vassal and servant, often the kinsman, of the local landowner and protected by the local saint. Clovis, the champion of orthodoxy, accepted this arrangement. In 794 the council of Frankfurt allowed churches to be given or sold so long as they were maintained. Hincmar of Reims (c. 805–882), monk, canonist and archbishop, approved the principle and wished only to reform the abuses. Bishops were imperial and royal ministers. often viceroys. The most pious of emperors, St. Henry II, employed them in every function of government and insisted on his right to appoint bishops and to control or approve episcopal elections. Bishops trained in the imperial chancery were indispensable in the administration of the empire. Pope Leo IX (1048–54) was related to Henry III and had been employed as soldier and diplomat in the imperial service. The Holy See was constantly subject to imperial interference and protection, and the great reformer, though elected at Rome, was Henry III's nominee. Thus at every level—parochial, episcopal, papal—the question awaited decision whether the church was in effect a holy, catholic and supernatural institution appointing its own bishops and priests upon its own authority or (in the language of a later age) part of the body politic.

The system evolved by nature was subject to natural corruption. The emperor Conrad II and King Philip I of France made a traffic of bishoprics. But deeper than these abuses mas the question presupposed in all movements of reform of the true function of Christian priest and bishop. Councils repeatedly forbade lay interference in parochial benefices (Ingelheim, 948; Augsburg, 952; Seligenstadt. 1023; Bourges, 1031). Linked with this question was that of clerical celibacy, since a married clergy was tied by natural duties and interests to worldly affairs. Marriage implied inheritance and tended to absorb the clergy in local and feudal tenancies and obligations. At the council of Pavia (1018) Benedict VIII (1012–24) denounced clerical marriage mainly on the ground that church property should not be exploited for priests' families. But there was also the question of sexual morality and the traditional attitude of the church to virginity. Celibacy was admired by Tertullian, recommended by Eusebius, required by Cyril of Jerusalem and said to be the general practice by Jerome. Epiphanius said that the church "does not admit even sub-deacons to live in marriage and beget children." Two popes, Siricius (384–399) and Innocent I (402–417), had condemned clerical marriage. Six councils in Carthage, Spain and Gaul required continence of married clergy. The Theodosian code pronounced the children of priests illegitimate. Celibacy was a tribute to the supernatural and sacramental vocation and as such was bound up with the supernatural and sacramental body which

the confusion and expansion of the 9th and 10th centuries tended to obscure.

2. Revival of Monasticism. — Monks were the exemplars and instruments of the supernatural society. It was their business to live in "the course of these declining times" as in and for the "solid estate of eternity." Monasticism (*q.v.*) was in essence a lay movement, and the multiplication of monasteries and the constant succession of monastic reforms was evidence of the hold of the Catholic faith on the lay population. In 910 William I the Pious, count of Auvergne and duke of Aquitaine, founded Cluny. Odo of Cluny reformed Fleury and then. invited to Rome by Alberic, reformed the monasteries in and about the city and Monte Cassino. The reform spread through northern Italy and France. Cluny became the head of an order whose 300 houses, subject to the abbot of Cluny and exempt from all other authority but that of the pope, were organized in ten provinces extending from Spain to Poland. Cluny, "a spiritual field where earth and heaven meet" (Pietro Damiani), trained Urban II and Paschal II. It not only revived liturgical discipline and the Benedictine rule but realized on a world scale the practical order and common prudence of Benedictine monasticism. At the same time, Gerard of Brogne in Flanders and Dunstan of Glastonbury (d. 988) in England initiated monastic reform. In Italy St. Romuald founded the order of Camaldoli (*c.* 1012). In Normandy Herluin founded Bec (c. 1040), which under Lanfranc and St. Anselm became one of the great schools of Europe. There Pope Alexander II, Ivo of Chartres and Theobald of Canterbury received their training. The last wave of monastic reformation produced the Carthusian order founded by St. Bruno (1084) and the Cistercian founded by Robert of Molesme (1098). St Bernard with the 30 companions entered Citeaux in 1112 and with 12 monks founded Clairvaux in 1115. He was the "greatest of the monks" and one of the greatest preachers of the middle ages.
