RAYNAL TO SARRAUT

RAYNAL, GUILLAUME THOMAS (1713–1796), French writer and propagandist, widely read and very influential in his day, was an important precursor of the French Revolution. Born at Saint-Geniès in the Aveyron, April 12, 1713, he was educated at the Jesuit college at Rodez, and himself became a Jesuit. He taught at Pézenas, Clermont and Toulouse, left the Society of Jesus at about the age of 34 and went to Paris; he exercised minor ecclesiastical functions at Saint-Sulpice. Meanwhile he entered the world of letters and from 1747 to about 1752 was literary correspondent to the duchess Dorotea of Saxe-Gotha to whom he addressed his *Nouvelles litte'raires.* His first major publications were *Histoire du stadhoudkrat* (1747) and *Histoire du Parlement d'Angleterre* (1748), both hack work. In the first he appeared as an opponent of despotism; in the second, as an advocate of absolute monarchy, a discrepancy to be explained by the different orientation of French foreign policy in relation to Holland and to Great Britain. From 1750 to 1754 he edited the *Mercure de France.* This literary activity won for him a place in French society and he became a guest at the tables of Helvétius and D'Holbach and a friend of Montesquieu.

His most celebrated work was *Histoire philosophique* et *politique des e'tablissements et du commerce des Européens dans les deux Indes,* first published in 1770 in six volumes, revised in 1774 and again, with changes of an outspoken and audacious character, in 1780. This was not his unaided work. Diderot, in particular, contributed extensively to it and Alexandre Deleyre, a disciple of Montesquieu, is reputedly responsible for the 19th book, which contains a general statement of political philosophy and is of more lasting interest than the rest. The whole work is a compendium of information and ideas on history, economics and politics, with an advanced anticlerical bias. Reprints were extremely numerous. The book fell foul of the Holy See in 1774, when it was placed on the Index, and of the *parlement* of Paris in 1781, when it was sentenced to be burned and the author was sent into exile. Raynal thereupon went first into Belgium, where he was the subject of many hostile lampoons, then into Prussia, where his reception at the hands of Frederick II was less cordial than he expected, and finally into Switzerland. In 1784 he was permitted to return to France, though not to Paris. He settled first at Toulon, then at Marseilles, where he entertained the youthful Napoleon, who read *Histoire philosophique.* His banishment from Paris was rescinded in 1790; he returned to the metropolis and engaged cautiously in political activity. He died at Chaillot on March 6, 1796.

See A Feugère, *Un précurseur de la Revolution: l'abbé Raynal (1922)* and *Bibliographie critique de l'Abbé Raynal* (1922) ; *H.* Wolpe, *Raynal et sa machine de guerre* (1957). (*R*T. S.)

RAYNALD OF CHÂTILLON (d. 1187), a knight in the service of Constance, princess of Antioch, whom she chose for her husband in 1153, four years after the death of her first husband, Raymund (*q.v.*). One of Raynald's first acts was a brutal assault on the patriarch of Antioch; while two years later he made an unjustifiable attack on Cyprus, in the course of which the island was ravaged. The act brought its punishment in 1159, when he had to humiliate himself before the emperor Manuel, doing homage and promising to accept a Greek patriarch; and when Manuel came to Antioch in the same year, and was visited there by Baldwin III, Raynald led his horse into the city. Later in the year he was captured by the Mohammedans and held for 17 years. Released in 1176, he married Stephanie, the widow of Humphrey of Toron, and heiress of Krak and Mont Royal, to the southeast of the Dead Sea—fortresses which controlled the trade routes between Egypt and Damascus. and gave him access to the Red sea. In Nov. 1177, at the head of the army of the kingdom, he won a victory over Saladin, who only escaped with difficulty from the pursuit. But in 1181 the temptation of the caravans which passed by his fortress proved too strong, and in spite of a truce between Saladin and Baldwin IV, he began to plunder. Saladin demanded reparations from Baldwin IV. Baldwin could only reply that he was unable to coerce his unruly vassal. The result was a new outbreak of war between Saladin and the Latin kingdom (1182). In the course of the hostilities Raynald launched ships on the Red sea, partly for buccaneering, partly, it seems, with the design of attacking Mecca, and of chaiienging Mohammedanism in its own hoiy place. His ships were captured by one of Saladin's officers; and at the end of the year Saladin himself attacked Raynald in his fortress of Krak, at a time when a number of guests were assembled to celebrate the marriage of his stepson, Humphrey of Toron. The siege was raised, however, by Count Raymund of Tripoli; and until 1186 Raynald was quiet. In that year he espoused the cause of Sibylla and Guy de Lusignan against Count Raymund, and his influence contributed to the recognition of Guy as king of Jeru-

salem. His policy at this crisis was not conceived in the best interests of the kingdom; and a step which he took at the end of the year was positively fatal. Hearing of a rich caravan. in which the sister of Saladin was traveling. he swooped down from his fortress upon it. Thus, for the second time, he broke a truce between the kingdom and Saladin. Guy could not extort from him the satisfaction which Saladin demanded: Raynald replied that he was lord in his lands, and that he had no peace with Saladin to respect. Saladin swore that Raynald should perish if ever he took him prisoner; and next year he was able to fulfill his oath. He invaded the kingdom, and, at the battle of Hittin, Raynald along with King Guy and many others fell into his hands. Saladin, after rebuking Raynald strongly for his treachery, offered him his life if he would become a Mohammedan. He refused, and Saladin slew him with his own hands or caused him to be slain.

RAYNAUD'S DISEASE, first described by P. Edouard Raynaud in 1862, is characterized by a reaction in a susceptible person following exposure to cold or emotional disturbance such as anger or fear. Typically there are three stages. During the first, the affected parts, most commonly the fingers or toes, less commonly the nose, cheeks or ears, become blanched or waxen and cold. They are relatively bloodless and if cut bleed little. This is caused by a spasm in the arterioles, the smallest arteries through which blood normally flows to the capillaries. In some patients the local colour changes to slate gray (the second stage). This persists while the stimulating factor continues and is associated with numbness, tingling and sometimes pain. Return to a warm environment or release from tension results in the relaxation of the arterioles and a flush of blood into the area together with a throbbing sensation, increased local warmth and intense redness. after which the part returns gradually to normal. The symptoms of this disease may occur frequently for years, with no evidence of serious damage; gangrene is extremely rare. The underlying cause is unknown. The onset usually occurs between the ages of 15 and 35 years; 90% of the cases are in females.

A similar phenomenon, Raynaud's syndrome, is known to be present in some patients in the early stages of arteriosclerosis and thromboangiitis obliterans, two diseases affecting the arteries of the extremities (see ARTERIES, DISEASES OF). The syndrome may also develop following repeated blows to a hand. as in the use of a pneumatic hammer or in the playing of handball, and has occurred in concert pianists and typists. Since it does not occur in all who are exposed, individual susceptibility must be assumed. Raynaud's syndrome is also associated with other diseases, such as scleroderma, a condition producing a hardening of the skin and sometimes the deeper tissues, and with some blood diseases such as cryoglobulinemia, in which the blood solidifies if reduced much below the usual body temperature.

Treatment for the classical Raynaud's disease is not specific. The patient should try to avoid exposure to stimulating factors. A warm climate is beneficial and it is advisable for the patient to wear warm gloves and socks and to avoid winter sports. Neurologic surgery has been widely used; it is more successful for Raynaud's disease of the feet than of the hands. Many drugs have been tried without much effect.

Treatment of Raynaud's syndrome secondary to some other condition must depend on the primary condition. If repetitive injury is responsible, the only recourse is to discontinue the activity causing it. The primary diseases mentioned above must be treated. In addition cold, being an aggravating factor, must be avoided.

See I. S. Wright, Vascular Disease in Clinical Practice, 2nd ed. (1954).
(I. S. W.)

RAYNOUARD, FRANÇOIS JUSTE MARIE (1761–1836), French dramatist and Romance philologist who also played some part in the politics of the Revolutionary and Napoleonic period, was born at Brignoles in Provence, Sept. 18, 1761, and educated for a legal career. Sent as deputy to the legislative assembly in Paris (1791), he was imprisoned on the fall of the Girondins (1793) but released in the Thermidorian reaction (1794). His first play *Caton d'Utique* was then published. After practising as a lawyer at Draguignan, he returned to Paris in 1803. His second play, Les *Templiers* (1805), was a great success in the theatre. He was made a member of the Corps Législatif (1806) and of the Académie Française (1807). His next play, Les *États* de Blois, ou la *mort* du *duc* de Guise (1810), offended Napoleon and was banned; his later tragedies attracted little notice. After Waterloo, Raynouard abandoned politics. despite the protests of constituents in the Var *département,* and devoted himself to the study of the language and literature of the troubadours. His major works were *Choix* des poe'sies originales des troubadours, 6 vol. (1816–21; vol. 6 was also published separately as *Grammaire comparée* des langues de *l'Europe latine dans leurs* rapports avec la langue des *troubadours,* 1822) and the posthumous Lexique roman, 6 vol. (1838–44). He was a member of the Académie des Inscriptions from 1816.

Raynouard died at Passy on Oct. 27, 1836.

RAYON: see SYNTHETIC FIBRES.

RAYONNANT STYLE, in architecture, the fully developed French Gothic style (see GOTHIC ARCHITECTURE) of the latter half of the 13th and the first three-quarters of the 14th centuries. It is characterized by a complete mastery of the structural ideas of the Gothic vaulted church; great skill in stone-cutting; the elimination of wall surface; the reduction in area of all supports to the minimum; thorough development and lavish use of bar tracery (*q.v.*) based on geometric forms; reduction in size and importance of the triforium gallery; and a general attempt to accent all vertical lines. In carved ornament the spherical crocket of the earlier Gothic was replaced by a fully opened, upturned leaf and naturalistic foliage-decorated capitals, string courses and the like.

"Rayonnant" pertains to the radiating tracery of the rose windows, a single, although characteristic, detail; the term has been nearly abandoned, even in France. Marcel Aubert in Robert de Lasteyrie's posthumous work, *L'Architecture* Religieuse en *France* a *l'Epoque* Gothique, vol. ii. p. 5, calls the style from 1140 to 1200 *le gothique primitif* and that of the years 1200 to 1400 simply *gothique.*

Characteristic examples are: Sainte Chapelle, Paris (1243–48); the choir of Amiens cathedral (1258–69); additions to the transepts of Notre Dame in Paris (1258–1315); St. Urbain in Troyes (1262–76); Portail des Libraires at Rouen cathedral (1280); and the choir of the abbey church of St. Ouen at Rouen (1318). Chronologically, this phase of French Gothic corresponds to the Decorated period (*q.v.*) in England and the High Gothic style in Germany. In France it was followed by the Flamboyant style (*q.v.*).
(P. F.)

RAYY, one of the great cities of Iran, the ancient Ragha, Latin Rhages. The expedition of the Boston and Pennsylvania museums disclosed a prehistoric settlement on the site dating from the third millennium B.C. Rayy is mentioned in the Avesta as a sacred place and is also mentioned in the Apocrypha. In the 9th century, the Caliph Al-Mahdi became governor and there his son, Haroun-al-Rashid, was born. Under Al-Mahdi's rule the city rapidly became a magnificent metropolis, rivaled in western Asia only by Damascus and Baghdad. It covered at least 25 sq.mi., and according to Mustawfi it contained 20,000 mosques, 2,750 minarets, innumerable baths and colleges. It continued to be a city of political, commercial and artistic importance through Seljuk times. In the 12th century it was tormented and greatly weakened by the fury of rival religious sects, was overcome by the Mongols in 1220 and, according to some probably much exaggerated reports, completely destroyed and the inhabitants massacred. Mongol occupation, however, terminated the dominance of Rayy. It was famous for its decorated silks of an unsurpassed finesse and artistic perfection. Rayy has been wrongly credited with the bulk of the luxurious type of Persian pottery of the 12th and 13th centuries. (See POTTERY AND PORCELAIN: Persia and tlze Near East.) Only one architectural monument, the tower of Toghrul (1137) survives. The centre of Rayy was situated about 6 mi. S. of modern Tehran.

RAZI, AL- (FAKHR AL-DIN ABU ABDALLAH MOHAMMED IBN UMAR IBN AL-HUSAIN AL-RAZI) (1149–1209), Moslem theologian and scholar, was born the son of a preacher at Rayy (Rhagae),

near the modern Tehran. After devoting himself to alchemy in his youth, he studied theology and philosophy at Rayy and Maragha. In law he followed the school of Shafi'i (*q.v.*), on whose merits he composed a celebrated book; in theology that of Ash'ari (*q.v.*). Although he could not come to terms with the anti-intellectualism of the mystics. he was recognized as an authority on the mystic life as well as on scholastic theology and the law. As a student of tradition, however, he was considered weak. His contemporaries saw in him above all the defender of orthodoxy against dissenters and heretics. During an extensive journey to Khwiirizm and Transoxiana he preached (in Arabic and Persian) against the local sectarians and more particularly against the philosophical school of the Mu'tazilites, who, in the end, compelled him to withdraw to his birthplace. Subsequently, he found honour at the court of Shihāb ad-Din Ghūrī (d. 1205) and especially in the entourage of the Khwārizmshāh 'Alā' ad-Din Mohammed (1199–1220), whom he followed to Khurasan. Later he settled in Herāt, where he died, as some would have it, poisoned by one of the sects which he had combated.

His greatest work, *Mafātīḥ al-Ghaib* ("Keys of the Hidden"), an extensive commentary on the Koran, has been printed at various times in Cairo and Istanbul. Razi studied the Koran also from the point of view of its style and examined the rare expressions in the holy book. Some of his dogmatic and legal writings continue to enjoy a high reputation, as do his contributions to philosophy. His dogmatic position was analyzed by Schmolders in his *Essai sur les écoles philosophiques chez les Arabes* (1842). His disputations with the Mu'tazilites were studied by P. Kraus in *Islamic Culture* (1938) and the *Bulletin de l'Institut Egyptien* (1939).

For a list of Razi's works see C. Brockelmann, Geschichte der *arabi*schen Litteratur, 2nd ed., vol. i, pp. 666–669 (194349); and M. Schreiner, Zeitschrift d. deutschen morgenlaend. *Gesellschaft*, vol. lii. The most extensive source for his biography is Tāj ad-Din Subki (d. 1370), *Ṭabaqāt ash-Shāfi'iyya al-kubrā* (1323–24 and 1905–06).

(G. E. V. G.)

RAZIN, STENKA (STEPHEN TIMOFEEVICH) (d. 1671), Cossack hetman and rebel, whose parentage and date and place of birth are unknown. We first hear of him in 1661 in a diplomatic mission from the Don Cossacks to the Kalmuck Tatars, and in the same year we meet him on a pilgrimage of 1,000 miles to the great Solovetsky monastery on the White Sea "for the benefit of his soul." After that all trace of him is lost for six years, when he reappears as the leader of a robber community established at Panshinskoe, among the marshes between the rivers Tishina and Ilovlya, from whence he levied blackmail on all vessels passing up and down the Volga. His first considerable exploit was to destroy the "great water caravan" consisting of the treasury barges and the barges of the patriarch and the wealthy merchants of Moscow. He then sailed down the Volga with a fleet of 35 galleys, capturing the more important forts on his way and devastating the country. At the beginning of 1668 he defeated the voivode Jakov Bezobrazov, sent against him from Astrakhan, and in the spring embarked on a predatory expedition into Persia which lasted for 18 months. Sailing into the Caspian, he ravaged the Persian coasts from Derbend to Baku, massacred the inhabitants of Resht, and in the spring of 1669 established himself on the isle of Suina, off which, in July, he annihilated a Persian fleet sent against him. Stenka, as he was generally called, had now become a potentate with whom princes did not disdain to treat. In Aug. 1669 he reappeared at Astrakhan, and accepted a fresh offer of pardon from the tsar there. In 1670 Razin rebelled against the government, captured Cherkask, Tsaritsyn and other places, and on June 24 burst into Astrakhan. After massacring all who opposed him, and giving the rich bazaars of the city over to pillage, he converted Astrakhan into a Cossack republic. After a three weeks' carnival of blood and debauchery Razin quitted Astrakhan with 200 barges full of troops to establish the Cossack republic along the whole length of the Volga, as a preliminary step toward advancing against Moscow. But his forces were stayed by the resistance of Simbirsk, and after two bloody encounters close at hand on the banks of the Sviyaga (Oct. 1st and 4th), Razin was ultimately routed and fled down the Volga.

But the rebellion was by no means over. The emissaries of Razin, armed with inflammatory proclamations, had stirred up the inhabitants of the modern governments of Nizhniy-Novgorod, Tambov and Penza, and penetrated even so far as Moscow and Great Novgorod. It was difficult to rouse the oppressed population by the promise of deliverance from their oppressors. Razin proclaimed that his object was to root out the boyars and all officials, to level all ranks and dignities, and establish cossackdom, with its corollary of absolute equality, throughout Muscovy. Even at the beginning of 1671 the issue of the struggle was doubtful. Eight battles had been fought before the insurrection showed signs of weakening, and it continued for six months after Razin had received his quietus. At Simbirsk his prestige had been shattered. Even his own settlements at Saratov and Samara refused to open their gates to him, and the Don Cossacks, hearing that the patriarch of Moscow had anathematized Stenka, also declared against him. In 1671 he was captured at Kagalnik, his last fortress, and carried to Moscow, where, on June 6, after bravely enduring unspeakable torments, he was quartered alive.

See N. I. Kostomarov, The Rebellion of Stenka Razin, 2nd ed. (1859); S. M. Solovev, History of Russia, vol. ii (1895); R. N. Bain, *The* First Romanovs (1905). (R. N. B.)

RAZOR. The razor is an instrument used for shaving. The early razor of modern times was made of steel which had a wedge-shaped section, with straight sides tapering to a sharp edge, and although simple in form it was a good and durable instrument for its purpose. Early in the 19th century, the practice was introduced of hollowing out the sides of the blade by grinding, to facilitate sharpening the blade, and improve fineness of the cutting edge. At first the degree of hollowness, or concavity of the sides of the blade was small, but with great skill, hollow-grinding has been carried considerably further, increasing the lightness and flexibility of the blade. The full hollow blade is thinner in the centre than nearer the cutting edge.

Safety Razor.—The razor is naturally considered a dangerous instrument, and many attempts have been made to make it safe. Not until the introduction of the "Gillette" type of razor, at the beginning of the 20th century, was a satisfactory solution found. The principle of the "safety" razor is to place a guard between skin and cutting edge of the razor blade, so that the guard permits the edge to pass over the uneven surface of the part to be shaved, removing the hair without cutting the skin. In some cases devices are provided to enable the user to strop or resharpen the blades. Other safety devices are based on the desire to retain the general form of the ordinary razor, while rendering it safe in use. These take the form of fitting a suitable guard to the blade of the ordinary razor, or the substitution of a holder, carrying an adjustable blade of the strip-steel type.

Electric Razor.—With the invention of the Schick Dry Shaver by Jacob Schick, an entirely new technique was introduced to the art of shaving. This dry shaver consists of a shearing head mounted on a powerful little motor encased in an insulated handle. The shearing head includes an outer and an inner member—the outer member having a very thin shear plate with openings or slots in it to rest against the skin, while the inner member has teeth which co-operate with the nether edges of the walls of the shear plate slots or openings in a shearing action. The toothed inner member is held up tightly against the inside surface of the shear plate by means of springs or other appropriate means and is made to reciprocate very rapidly underneath the shear plate by the motor. The hairs of the face which penetrate the openings or slots in the shear plate are thus sheared off by the reciprocating motion of the inner member in co-operation with the nether edges of the slot walls of the stationary shear plate.

The electric dry shaver operates without the use of sharp blades, soaps, brushes, creams and lotions.

RAZOR-BILLED AUK (RAZORBILL), ***Alca torda***, a member of the auk family (Alcidae), known also as marrot, murre, scout, tinker or willock; some of these names it shares with guillemot (*q.v.*) and puffin (*q.v.*). It is a common sea bird of the North Atlantic, resorting in vast numbers to rocky cliffs for

breeding, and returning to the open sea for the rest of the year. It is in many respects intermediate between the guillemot and the garefowl (*q.v.*). In habits the razorbill agrees with the guillemots, laying its single egg on ledges of cliffs. It breeds on both sides of the north Atlantic, wandering as far south as the Mediterranean on the east and Long Island on the west in winter. It feeds on fish.

RAZZIA (an adaptation of the Algerian Arabic *ghāzīah*, from ghasw, to make war), a foray or raid made by African Moslems. As used by the Arabs, the word denotes a military expedition against rebels or infidels, and razzias were made largely for punishment of hostile tribes or for the capture of slaves. English writers in the early years of the 19th century used the form ghrazzie, and Dixon Denham in his Travels (1826) styles the raiding force itself the ghrazzie. The modern English form is copied from the French, while the Portuguese variant is *gazia, gaziva.*

RE, ÎLE DE, an island 1½ mi. off the port of La Pallice in the southwestern part of France. The island, with a northwest-southeast length of 15 mi. and an average width of 2¼ mi., is separated from the coast of Vendée to the north by a shallow bay, the Pertuis Breton, 6 mi. broad, and from the island of Oléron to the south by another, the Pertuis d'Antioche, 7½ mi. broad. The Atlantic coast is reef-fringed, but there are small-craft harbours on the landward side. The most important of these is La Flotte. The largest shore indentation on the east coast, the Fier d'Ars, nearly divides the island, leaving an isthmus only 230 ft. wide to maintain the island's continuity. Dunes and salt marshes cover a large part of the northern end of the island. Many salt pans for the collection of salt by evaporation have been built along the landward shore. Industries are fishing, oyster cultivation, and the collection of seaweed for fertilizer. The island has some cropland which is in vineyards or in early spring vegetables. Île de Ré is included in the department of Charente-Maritime. Population of the island (1946), 7,908.

REA, SAMUEL (1855–1929), **U.S.** railroad official, was born at Hollidaysburg, Pa., on Sept. 21, 1855. In 1871 he entered the service of the Pennsylvania railroad as chainman and rodman. From 1875 to 1877 he was assistant engineer on construction of the Monongahela river bridge at Pittsburgh. He was next appointed assistant engineer for the Pittsburgh and Lake Erie railroad and returned to the Pennsylvania lines in 1879 in a similar capacity. In 1888 he was appointed assistant to the second vice-president of the Pennsylvania railroad, which position he retained until 1889 when he was made chief engineer on construction of the belt line tunnel under Baltimore for the Baltimore and Ohio railroad.

In 1892 he again returned to the Pennsylvania railroad as assistant to the president, and became first vice-president in 1911. In 1913 he was elected president. He was in charge of the construction of the Pennsylvania station in New York city (completed in 1910), the connecting tunnels under the Hudson and East rivers, the New York Connecting railroad and Hell Gate bridge over the East river (opened in 1917). In 1917 he became a member of the executive committee on national defense of the American Railway association, known as the Railroads War Board. He retired from the presidency of the Pennsylvania railroad on Sept. 30, 1925. He died at Gladwyne, Pa., on March 24, 1929. He wrote *The* Railways Terminating in London (1888).

REACTION KINETICS is that branch of physical science which deals with the determination and interpretation of the rates of chemical change. The subject includes the consideration of the rates both of everyday but complicated reactions such as hard-boiling an egg (an example of protein coagulation) and of simpler but less commonplace reactions such as the one between hydrogen and chlorine. Rates have been measured for slow reactions (*e.g.*, the disintegration of ordinary uranium, only half of which will decompose in 5,000,000,000 years) and for fast reactions (*e.g.*, the dissociation of oxygen from haemoglobin, which is almost complete in a tenth of a second). An attempt is made in each case to show quantitatively the effect of changes in the experimental conditions upon the reaction velocity, and to describe in as much detail as possible the behaviour of the molecules at the moment of their reaction.

Many familiar processes involve chemical reactions which proceed at measurable rates. For example, the rusting of iron, the fermentation of sugar, the "drying" of paint, the hardening of plaster of Paris, the baking of bread and the growth of plants, all involve chemical reactions of greater or lesser complexity, and for each example there is considerable interest in the rate of reaction. In general, these familiar processes are very complex, partly because many of the materials are not single pure compounds, but mixtures. It is well known, however, that the rusting (oxidation) of iron requires both air and water, and that the reaction proceeds much more rapidly near the ocean (where salt is deposited on the iron) than it does elsewhere. The rate of rusting also depends upon the composition of the metal (pure iron and stainless steel corrode less rapidly than do cast iron and mild steel) and on temperature (corrosion is rapid in a stream of steam and air). (See CORROSION AND OXIDATION OF METALS.)

Scientists have been largely concerned with measuring the rates of reactions such as the decomposition of ozone, the oxidation of sulphur dioxide and the nitration of hydrocarbons; they assume that an understanding of these and similar reactions of pure chemicals will eventually lead to an understanding of more complex (if more familiar) reactions.

Studies of reaction velocity have not only played a fundamental role in the growth of theoretical chemistry; the concepts developed in these studies have also been highly fruitful in industry, especially in the field of catalysis (*q.v.*). A case in point is the Haber process for the manufacture of ammonia (*q.v.*), which is based in part on studies of reaction kinetics. Both theoretical and practical research in the field of reaction kinetics was by mid-century under way in hundreds of laboratories.

A specific example of a rate study is the work on the decomposition of hydrogen iodide to form hydrogen and iodine.

$$2HI \longrightarrow H_2 + I_2 \qquad (1)$$

This reaction proceeds at a rate convenient for measurement in the neighbourhood of 320° C., at which temperature not only the hydrogen and hydrogen iodide but even the iodine is gaseous. (This reaction is a reversible one; however, for the moment, it is better to postpone discussion of this complication and to consider only the reaction as written.) The rate of decomposition of hydrogen iodide increases as the quantity of hydrogen iodide per unit volume is increased; quantitatively, the rate is proportional to the square of the concentration of hydrogen iodide. The rate increases by a factor of 1.9 when the temperature is increased from 320° C. to 330° C. The reaction occurs within the body of the gas, and not on the glass walls of the vessel in which the experiment is performed.

The facts just cited have been interpreted to indicate that when two molecules of hydrogen iodide collide, a chemical change occurs only if the velocity of one of them with respect to the other exceeds 2.4 km./sec. (about 5,000 m.p.h.). The average diameter (so far as collision is concerned) of these hydrogen iodide molecules can also be calculated from the kinetic data; it is of an order of magnitude (0.8×10^{-8} cm.), roughly consistent with the results of other measurements of the sizes of molecules. The effective collisions (*i.e.*, those which lead to reaction) result in a simple interchange of atoms; here the hydrogen and iodine atoms in each of the two colliding molecules of hydrogen iodide separate; simultaneously, the two hydrogen atoms combine to form a hydrogen molecule, and the two iodine atoms combine to form an iodine molecule.

For the discussion of even the simple example of the decomposition of hydrogen iodide, it has been necessary to employ the elementary concepts of chemistry (*q.v.*) and of the kinetic theory (*q.v.*) of matter. For the more detailed treatment of reaction kinetics which follows, a somewhat more extensive knowledge of these subjects is assumed. In the last sections of this article, a precise presentation is attempted.

History.—Gross differences in the rates of chemical reactions have long been recognized. By the beginning of the 19th century, several instances were known where the rate of a chemical change could be greatly increased by adding to the reacting system a small quantity of some apparently inert material. For example, it was discovered in 1796 that the dehydrogenation of alcohols pro-

ceeds much more rapidly in the presence of metals than it does in their absence. In 1836, Jons Jakob Berzelius grouped together many reactions of this type and gave the name "catalysts" to the materials which accelerate chemical change. (The modern definition of catalysts is given below.) Although the qualitative concept of reaction rate was by that time well established, the first quantitative measurement and mathematical formulation of reaction velocity is generally credited to L. F. Wilhelmy, who, in 1850, measured the rate of "inversion" (hydrolysis) of cane sugar.

Definitions. — Chemical reactions can be classified as homogeneous or heterogeneous. Homogeneous reactions are those (like the decomposition of hydrogen iodide) which occur completely within one phase (gaseous, liquid or solid). Heterogeneous reactions are those (like the reaction between a metal and an acid) where the reactants are components of two or more phases (solid and gas, solid and liquid, two mutually immiscible liquids, etc.) or where one or more reactants undergo chemical change at an interface; *i e*, on the surface of a solid catalyst.

Reactions may also be classified as "reversible" or "irreversible." An irreversible reaction is one in which the reactants, if mixed in the proper proportions, are almost completely converted to the reaction products; a reversible reaction is one in which appreciable quantities of all the reactants and of all the reaction products are present in the system no matter how long the reaction is allowed to proceed. The mixture eventually formed in such a reversible reaction is called the equilibrium mixture; the same equilibrium mixture may be prepared from suitable amounts of either the reactants or the reaction products. For example, the same equilibrium mixture of hydrogen, iodine and hydrogen iodide (at definite temperature and pressure) can be prepared by starting either with equivalent quantities of hydrogen and iodine or with pure hydrogen iodide. If the definition of equilibrium is that adopted in thermodynamics (*q.v.*), then every reaction is, in principle, reversible. There are reactions, however, where the extent of the reverse reaction is too small to be detected by any experimental means at present known; such reactions are usually regarded, for the purposes of kinetics, as irreversible.

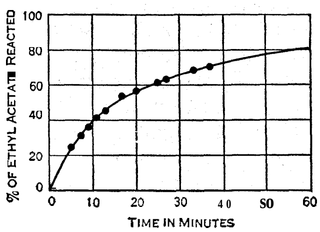

FIG. 1.—SAPONIFICATION OF 0.01M ETHYL ACETATE WITH 0.01M NaOH AT 25° C. CIRCLES, EXPERIMENTAL POINTS, LINE. THEORETICAL FOR $k = 6.5\ \text{MIN}^{-1}\ (\text{M/l})^{-1}$

"Order" of Reaction. — The fundamental law of reaction kinetics was developed by C. M. Guldberg and P. Waage around 1867 (an independent and similar formulation was made by Jacobus Henricus van't Hoff). These authors assumed that, at constant temperature, the rate of any simple chemical reaction is proportional to the product of the concentrations of the various reacting substances. They showed in a general way that their law of chemical change is consistent with the kinetic molecular theory of matter, and that the data for many chemical reactions could be formulated quantitatively in terms of their theory. Since 1870, the concepts of Guldberg and Waage have been extended and modified, but most of reaction kinetics is still based upon their work.

Consider the simple homogeneous, irreversible reaction between two compounds, A and B (the reactants), to form C and D (the reaction products).

$$A + B \longrightarrow C + D \qquad (2)$$

An example of this sort of reaction is the saponification of ethyl acetate by alkali:

$$\underset{A}{CH_3CO_2C_2H_5} + \underset{B}{OH^-} \longrightarrow \underset{C}{CH_3CO_2^-} + \underset{D}{C_2H_5OH} \qquad (2')$$

Equations (2) and (2') as written represent the stoichiometry of the chemical change; *i.e.*, the equations show the relationship between the weights of the initial reactants and those of the final products. The reaction rate may be proportional to the concentrations of the reactants which appear in the stoichiometric equation; if, however, the reaction occurs in several consecutive chemical steps, or requires a catalyst, the kinetics may be more complicated (see below) than those which could he impiied from the stoichiometry. The treatment for a simple case follows.

At the beginning of the reaction, the compounds A and B are present in definite concentrations, say a_0 and b_0 moles per litre respectively[1]; the concentrations of C and D are zero. As the reaction proceeds, the concentrations of A and B decrease, whereas the concentrations of C and D increase. If the concentrations of A and B at any instant are represented by the symbols (A) and (B), then the law of Guldberg and Waage states that wherever equation (2) represents the true kinetic course of the reaction, the reaction velocity, v, is proportional to (A) and to (B). This statement in mathematical form is

$$v = k(A)(B) \qquad (3)$$

where k, the proportionality factor, is called the rate constant. Note that the rate of reaction, v, and the rate constant, k, are not the same, but are connected by an equation of the form of (3).

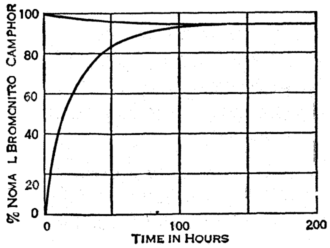

FIG. 2.—RATES AT WHICH EQUILIBRIUM IS ESTABLISHED BETWEEN THE TWO FORMS OF BROMONITROCAMPHOR

An equation such as (3) may accurately describe the rate of a chemical reaction. Unfortunately, however, a good experimental method for directly measuring the rate, *v*, of a reaction is usually not to be found. The quantities which can usually be determined experimentally are the time and the concentrations of the reactants or reaction products. An equation such as (3) can be transformed by the methods of calculus (*q.v.*) into an equation expressing a relationship between these concentrations and time. Although the details of this transformation are in no way necessary for the succeeding argument, they are nevertheless presented here for the sake of continuity.

If the concentration of C at any instant is represented by x, then the rate, *v*, of formation of C is dx/dt, the derivative of x with respect to time; and equation (3) can be replaced by (3').

$$v = \frac{dx}{dt} = k(A)(B) = k(a_0 - x)(b_0 - x) \qquad (3')$$

The integrated form of equation (3) is

$$\log_e \frac{b_0(a_0 - x)}{a_0(b_0 - x)} = kt(a_0 - b_0) \qquad (4)^2$$

where *t* is the time measured from the beginning of the reaction; the other symbols have been previously defined. In principle, it should be possible to obtain for every reaction an equation, analogous to (4), from which the concentrations of the various reactants and products at any moment may be calculated.

One method of testing experimentally whether equations (3) and (4) adequately describe the rate of any particular reaction is to measure x (the concentration of C) at several different times, *t*. An attempt is then made to choose a single value for the rate constant k such that all the sets of corresponding values of x and t satisfy equation (4). If this attempt is successful, the experiment is then repeated at the same temperature but with different initial concentrations (a_0 and b_0). If these new data also satisfy equation (4) with the rate constant k unchanged, the demonstration that the reaction obeys the rate equations (3) and (4) is complete. The constant, k, is thus independent of the initial concentrations of A and B; it is, however, a function of the temperature and it depends of course

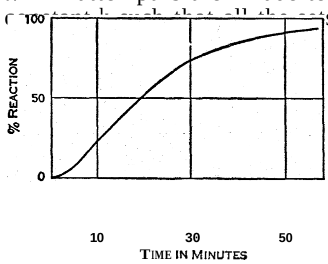

FIG. 3.—SUCCESSIVE FIRST ORDER REACTIONS, WHERE THE RATE CONSTANT OF THE SECOND IS FOUR TIMES AS GREAT AS THAT OF THE FIRST (DIAZOTIZATION OF PHENYL MERCURIC NITRATE IN 20% HNO_3 WITH 0.16 M/l HNO_2)

[1] For reactions in the gas phase, the partial pressure of each gas is used as a measure of its concentration.

[2] Where $a_0 = b_0$, the corresponding equation is $\frac{x}{a_0(a_0 - x)} = kt \qquad (4')$

upon the chemical nature of the reactants A and B. Fig. 1 is a graphical representation of equation **(4)** for the saponification of ethyl acetate.

If the equations for various chemical reactions are treated as was equation (3) for reaction (2′), then these reactions fall into a number of different classes. A reaction, the rate of which may be described by an equation of the form

$$v = k(\mathrm{A}) \qquad (5)$$

is called a first order reaction; one described by an equation of the form

$$v = k(\mathrm{A})^2 \quad \text{or} \quad v = k(\mathrm{A})(\mathrm{B}) \qquad (6) \text{ or } (6')$$

is called a second order reaction, etc. In general, a reaction the rate of which may be described by the equation

$$\mathrm{v} = k(\mathrm{A})^m(\mathrm{B})^n(\mathrm{C})^p(\mathrm{D})^q \ldots\ldots \qquad (7)$$

is called a reaction of order r, where $r = \mathrm{m} + n + p + q +$. Such a reaction is said to be of order m with respect to A, of order n with respect to B, etc. (Some reactions may be of nonintegral order; *e.g.*, half-order. The majority of known reactions are of first or second order.)

In certain reactions, such as the inversion of cane sugar,

$$\mathrm{C_{12}H_{22}O_{11}} + \mathrm{H_2O} \longrightarrow 2\mathrm{C_6H_{12}O_6} \qquad (8)$$

the rate is proportional to the concentration of some substance (in this instance, the hydronium ion of the acid) (see ACIDS AND BASES), which does not appear among either the reactants or the reaction products in the chemical equation; the reaction cited (equation [8]) is said to be catalyzed by hydronium ion $\mathrm{H_3O^+}$, or hydrated hydrogen ion.

$$v = k(\mathrm{C_{12}H_{22}O_{11}})(\mathrm{H_3O^+}) \qquad (9)$$

If the catalyst is one of the reaction products, the reaction is said to be autocatalyzed.

Reversible Reactions. — The reactions hitherto described have been assumed to be irreversible, in the sense defined above. If the reaction between the compounds A and B, on the one hand, and C and D, on the other, is reversible, then equation **(2)** must be rewritten.

$$\mathrm{A} + \mathrm{B} \rightleftharpoons \mathrm{C} + \mathrm{D} \qquad (2'')$$

Wherever equation **(2″)** represents the true kinetic course of the reactions, the rates v_f of the "forward" and v_r of the "reverse" reactions are given by equations (10) and (10′).

$$v_f = k_f(\mathrm{A})(\mathrm{B}) \qquad (10)$$

$$v_r = k_r(\mathrm{C})(\mathrm{D}) \qquad (10')$$

If the reaction is begun by mixing A and B (either pure or in solution), the initial concentrations of C and D are each zero; hence the rate, v„ of the reverse reaction is also zero. However, as A and B react to form C and D, these products in turn react to regenerate A and B. The net rate at which C and D are formed is therefore the difference between v_f and a,.

$$v = v_f - v_r = k_f(\mathrm{A})(\mathrm{B}) - k_r(\mathrm{C})(\mathrm{D}) \qquad (11)$$

The net rates of the forward and reverse reactions for a particular case are shown graphically in fig. 2. In the reaction in question, a mixture of the two tautomers (see TAUTOMERISM) of bromonitrocamphor is formed both from the normal (N) and from the pseudo (P) isomer.

The rate at which the equilibrium mixture is formed from pure N is shown in the upper curve; the rate at which the equilibrium mixture is formed from pure P is shown in the lower curve.

As the latter reaction proceeds, P is converted into N; hence. the forward rate decreases and the reverse rate increases. Eventually, the two rates become equal, and the net rate, v, is zero; thus, a dynamic equilibrium is achieved. This state of dynamic equilibrium is not a condition in which no reaction occurs, but is one in which the rates of the forward and reverse reactions are equal. This kinetic concept of dynamic equilibrium has been experimentally verified by the use of radioactive tracers (see ISOTOPE).

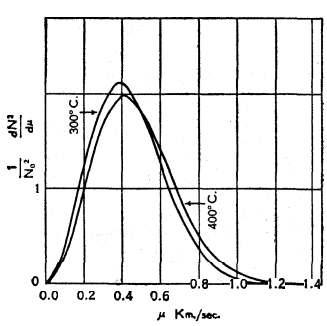

FIG. 4A.—MAXWELL-BOLTZMANN DISTRIBUTION OF PAIRS OF MOLECULES OF HYDROGEN IODIDE (AT 300° C. AND AT 400° C.). THE VELOCITY OF ONE MEMBER OF ANY PAIR RELATIVE TO THE OTHER MEMBER OF THE PAIR IS μ

When, for a reaction which follows equation (2″), the forward and reverse reactions proceed at equal rates, it is seen that

$$v_f = v_r = k_f(\mathrm{A})(\boldsymbol{B}) = k_r(\mathrm{C})(\boldsymbol{D}) \qquad (12)$$

From equation **(12)** it follows that

$$\frac{(\mathrm{C})(\mathrm{D})}{(\mathrm{A})(\mathrm{B})} = \frac{k_f}{k_r} = \mathrm{K_e} \qquad (13)$$

where $\mathrm{K_e}$, the ratio of the rate constants for the forward and reverse reactions, is called the equilibrium constant. Equation (13) gives the relative concentrations of the compounds A. B, C, and D at equilibrium; these concentrations need not be even approximately equal, for in general the rate constants of the forward and reverse reactions differ considerably from one another.

An equation analogous to (13) but more general is obtained by a parallel treatment of a reaction (7). Although this more general expression is correct as a first approximation, it nevertheless disagrees with the precise thermodynamic definition of equilibrium. Consideration of this and similar difficulties is postponed to the sections on collision theory and on activated-complex theory.

Complex Reactions. — The reactions so far considered are of simple types; all sorts of combinations of these types are possible. For example, reactions sometimes occur in several steps.

$$\mathrm{A} \longrightarrow \mathrm{B} \longrightarrow \mathrm{C} \qquad (14)$$

Here the rate of formation of B is proportional to the concentration of A, and the rate of formation of C is proportional to the concentration of B. Since, initially, the concentration of B is zero, the initial rate of formation of C is zero. Fig. 3 shows graphically the concentration of C at any time, t, in a system where the rate constants for the two consecutive reaction steps are of comparable magnitude. Other cases of interest are those in which one of the successive reactions is reversible, or of second order, etc. Considerable complexity is not only possible but common.

What has already been said makes it evident that the kinetic equation for a reaction cannot be inferred from the chemical equation, which gives only the relationship between the weights of reactants which will combine with one another and the weights of the final products (*i.e.*, the stoichiometric relations). The kinetic expression, it is true, must account for the stoichiometric findings, but it should do more than that. Usually more than one reaction path between the initial reactants and the final products is conceivable. Under favourable conditions kinetic considerations permit the selection of just one of these reaction paths, and kinetic measurements demonstrate that the path selected, and no other, is the one which the reaction takes. Under less favourable conditions, kinetic considerations are insufficient to eliminate all reaction paths but one. Even here, however, they serve to rule out many of those paths which from mere stoichiometric considerations might be considered possible.

A simple example will illustrate the ideas just expressed. A chemist might investigate an irreversible reaction, the stoichiometric expression for which is A⟶ C. This expression means that each molecule of the reactant A is converted (eventually) into one molecule of the product, C. It does not tell whether each molecule of A is converted directly into a molecule of C or whether each molecule of A is converted first into a molecule of an intermediate, B, which is in turn converted into a molecule of C. In the former instance, the proper kinetic expression for the reaction A ⟶ C may coincide with the stoichiometric expression. In the latter instance, the proper kinetic expression is A ⟶ B ⟶ C. Measurements of the extent of the reaction at various stages in its course are often sufficient to decide questions of the kind here raised. In the particular instance cited, if the reaction followed a curve of the sort shown in fig. 3, that fact would show that the kinetic expression for the reaction was A ⟶ B ⟶ C. If, on the other hand, the reaction followed a curve predicted from equation (j), and somewhat resembling the one shown in fig. 1, that fact would show that the kinetic expression for the reaction was **A ⟶** C, coinciding with the stoichiometric expression.

This fact alone would not rule out compound B as an intermediate, but it could be an intermediate in the reaction only under certain special circumstances (*i.e.*, the reaction B → C would have to be very fast as compared with the reaction A → B).

If any individual reaction is to be thoroughly understood, its reaction kinetics must be investigated. The object in view is to determine by inference from the kinetic measurements whether the reaction proceeds in one or more stages, to determine the order of each reaction stage with respect to each one of the reactants, and to determine for each particular stage whether or not it is catalyzed by some substance (possibly an ion) which does not appear in the stoichiometric expression for the over-all reaction. It should, however, be stated that kinetic considerations by themselves, although they greatly aid in the treatment of the problem stated, are often insufficient for its solution in all details.

If a kinetic study shows that two molecules (of the same or of different compounds) react with one another directly, then the reaction is said to be bimolecular. In a many-stage reaction, some individual step may be bimolecular, although the over-all reaction is not of second order and may indeed (like [14]) be of no definite order. It is likewise possible for a reaction to be of the second order, but to contain no single step which is truly bimolecular. The interpretation of the reaction kinetics for any individual reaction is thus a difficult matter, and for many important reactions the conclusions are still tentative.

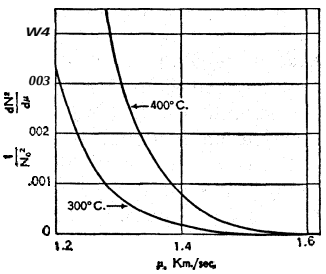

FIG. 4B.—EXPANDED SCALE DRAWING OF HIGH-VELOCITY END OF FIG. 4A

Application of the Kinetic Molecular Theory.—Guldberg and Waage assumed that the rate of any reaction is proportional to the product of the concentrations of the reactants (equation [7]); they interpreted this hypothesis in terms of the kinetic molecular theory. The number of collisions between the molecules of compound A and the molecules of compound B is proportional to the product (A)(B) of their concentrations; Guldberg and Waage's law amounts then to a statement that molecules react only if they collide, and that the rate at which they react is proportional to the number of collisions per second.

But although reaction between two molecules cannot occur unless these molecules collide, it does not follow that reaction must occur every time two molecules collide, even though these are molecules of substances which can react chemically one with another. For most reactions, it has been fully determined that the vast majority of collisions are "elastic"; *i e*, that the molecules rebound from one another without chemical reaction. It is possible by means of the kinetic molecular theory to compute the number of collisions per second between the molecules of two compounds which are present in a solution or a gas in known concentrations. For example, the number of collisions between pairs of molecules of hydrogen iodide at a temperature of 320° C. and a total Pressure of one atmosphere is approximately 10^{28} per cubic centimetre per second. Under the conditions stated, there are only about 10^{19} molecules of hydrogen iodide in a cubic centimetre of gas. Hence, if every collision between two molecules of hydrogen iodide led to chemical change, the reaction would be over in a small fraction of a second, too short a time indeed to measure. It has been computed that in the system described, only one collision in about 10^{15} leads to chemical change.

Temperature Coefficients of Reaction Rates.—Another (and historically older) consideration leading to the conclusion that not all collisions cause reaction is based on the increase of reaction rates with increase in temperature. According to kinetic-molecular theory, the number of collisions between molecules of two compounds present at definite concentrations increases as the square root of the absolute temperature. For example, the number of collisions at 25° C. (298° absolute) is only about 1.5% greater than the number at 15° C. (288° absolute). But the rates of most reactions increase by a factor of two or more when the temperature is raised by 10° C.; as much material may react in an hour at 100° C. as in a year at 0° C. In some instances, such as the denaturation of egg albumin, the reaction rate increases one hundredfold when the temperature is raised 10° C.

However, the assumption that only those molecules which collide with high energy of impact react with one another not only furnishes an explanation for the high temperature coefficients of reaction rates, but also accounts for the fact that collisions effective in bringing about chemical change are usually rare. To bring out the connection between the assumption and the conclusions, it is necessary to consider the velocity of one molecule relative to another. This relative velocity is not the same for all colliding pairs, but there is a determinable probability that for any one particular pair the relative velocity will lie close to any chosen value, u, of the relative velocity. This probability is calculated from the Maxwell-Boltzmann distribution curve (see KINETIC THEORY OF MATTER) shown in figs. 4a and 4b for hydrogen iodide at 300° C. and 400° C. The horizontal co-ordinate represents the velocity, μ, in km./sec., of one molecule of hydrogen iodide relative to the one with which it collides; the vertical co-ordinate represents the probability that the relative velocity is μ. (More precisely, the ordinate is equal to $1/N_0^2 d(N^2)/d\mu$, where N_0 is the total number of molecules under consideration, and $d(N^2)$ is the number of pairs of molecules with velocity lying between μ and $\mu+d\mu$.) Fig. 4b is an enlargement in vertical scale of part of fig. 4a. Figs. 4a and 4b indicate (1) that only a minute number of molecular pairs have relative velocities in excess of the 2.4 km./sec. required for reaction (see above), and (2) that, although the average value of the relative velocity is not greatly increased by raising the temperature from 300° C. (573° absolute) to 400° C. (673" absolute), the number of molecular pairs with high relative velocities is increased by a large factor. Thus the assumption that reaction is limited to molecular pairs with high relative velocities at the moment of collision qualitatively explains both the fact that few collisions are "effective" in producing reaction and the fact that the rates of most chemical reactions increase sharply with increase in

The complete equation (24) for the reaction rate derived from the kinetic collision theory is given in the next to last section of this article. Here it is sufficient to say that this complete equation is consistent (within experimental error) with an empirical equation (15) advanced by Svante August Arrhenius in 1889 which has proved

$$\log_e \frac{k_2}{k_1} = \frac{Q}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right) \qquad (15)$$

In equation (15) k_1 and k_2 are the rate constants at the absolute temperatures T_1 and T_2 respectively, Q is a constant called the activation energy, and R is the gas constant (1.98 cal./mole degree) (log, refers to natural logarithms). The larger the value of Q, the more sensitive is the reaction rate to changes in temperature. Reactions with values of Q varying from less than 500 up to about 100,000 cal./mole have been discovered. Q divided by the number of molecules in a mole (Avagadro's number) is (roughly) equal to the relative kinetic energy of a molecular pair which is just sufficient to make the members of the pair react upon collision.

Reaction Mechanism.—In this section, it will be shown how reaction kinetics may be used to determine the path or mechanism of a somewhat puzzling reaction. The example chosen is the reaction in aqueous solution between acetone and bromine. Here the stoichiometric

$$CH_3COCH_3 + Br_2 \longrightarrow CH_3COCH_2Br + HBr \qquad (16)$$

expression (16) is of the same form as equation (2). In 1904, however, A. Lapworth discovered that the rate of this reaction is proportional to the concentration of the acetone and of the hydrogen bromide (one of the reaction products) but independent of the concentration of the bromine and of all other substances known to be present in the system. The kinetic equation, therefore, is

$$v = k(CH_3COCH_3)(HBr) \qquad (17)$$

These facts suggest the hypothesis that the acetone is slowly converted into some reactive intermediate by the action of the acid;

this reactive intermediate then combines rapidly with bromine. The hypothesis has more recently been elaborated as follows:

$$(CH_3)_2CO + H_3O^+ \rightleftharpoons (CH_3)_2COH^+ + H_2O \text{ ("steady state" rapidly reached)} \quad (18)$$

$$(CH_3)_2COH^+ + H_2O \longrightarrow CH_3C(OH)=CH_2 + H_3O^+ \text{ (slow reaction)} \quad (18')$$

$$CH_3C(OH)=CH_2 + Br_2 \longrightarrow CH_3COCH_2Br + HBr \text{ (rapid reaction)} \quad (18'')$$

The proposed reaction between the catalyst and the acetone results in the transformation of the acetone into a reactive intermediate (the "enolic" modification of acetone; see TAUTOMERISM), which subsequently reacts rapidly with bromine. The rate, v, of the entire reaction is equal to that for the slowest step in the process. namely reaction (18'). The kinetic equation for this step is

$$v = k'((CH_3)_2COH^+) \quad (19)$$

The concentration of water is essentially constant and does not enter into equation (19); its concentration can be included in the rate constant, k'. The ion $(CH_3)_2COH^+$ would be in equilibrium with the acetone and acid present in the solution if it were not for the reactions (18') and (18'') which slowly but essentially irreversibly remove some of this ion.

The ion $(CH_3)_2COH^+$ is described as in pseudoequilibrium with acetone and acid, or as in a "steady state." The "steady state" concentration of the ion is given to a good approximation by the equilibrium expression

$$\frac{[(CH_3)_2COH^+]}{[(CH_3)_2CO][H_3O^+]} = K \quad (19')$$

When the theoretical equations (19) and (19') are combined, the experimentally verified kinetic equation (17) for the bromination of acetone is obtained; the rate constant k is the product of k' and K.

Not only does the mechanism presented in equations (18), (18') and (18'') agree with equation (17), but it will further explain many other facts. It is consistent, for example, with the observation that acetone reacts with chlorine, or with iodine at the same rate as it does with bromine. This is in accord with the proposed mechanism, since equation (18'), which does not involve the halogen at all, is postulated as the rate-determining step in the halogenation.

A more detailed investigation of the reaction has revealed that it is catalyzed not only by hydronium ion but also by molecules of un-ionized acids; it is also catalyzed by bases. The catalysis by un-ionized acid molecules can be accounted for by substituting equation (18'') for equation (18')

$$(CH_3)_2COH^+ + B \longrightarrow CH_3C(OH)=CH_2 + BH^+ \quad (18'')$$

where B represents a molecule of any base. (The detailed mathematical analysis needed to prove the above statement, although beyond the scope of this article, is treated by L. P. Hammett in *Physical Organic* Chemistry.)

The proposed mechanism is thus consistent with a large and varied selection of auantitative kinetic evidence. This is a necessary. condition, but not a sufficient one to establish the mechanism; it does, however, make the proposed mechanism quite probable.

Catalysis. — A catalyst is defined as a substance which increases the rate of a chemical reaction, but which can be recovered quantitatively and unchanged at the end of the reaction. There are many substances which (for specified reactions) approach this definition closely. Typical examples of homogeneous catalysis are the action of acids to increase the rate of hydrolysis ("inversion") of cane sugar, the action of bases to increase the rate of polymerization in the preparation of bakelite, the action of oxides of nitrogen in the chamber process for manufacturing sulphuric acid. Typical examples of heterogeneous catalysis are the action of finely divided iron to increase the rate at which nitrogen and hydrogen combine to form ammonia, the action of vanadium pentoxide to increase the rate at which sulphur dioxide and oxygen combine to form sulphur trioxide in the contact process for manufacturing sulphuric acid, and the action of finely divided nickel to increase the rate at which hydrogen combines with vegetable oils to form solid fats (*e.g.*, "Crisco"). (For a discussion of theory, manufacture and use of catalysts see CATALYSIS.)

Catalysts accelerate chemical reactions in various different ways. The bromination of acetone (cited above) illustrates one of the most common modes of action. Here the acid which in this case is the catalyst combines with one of the reactants (acetone) to form an intermediate chemical compound. Then, in a later step of the complex reaction, the catalyst is regenerated and so becomes available for further reaction. In this way the catalyst goes through a complete cycle, and a trace of catalyst increases the rate at which a large amount of material reacts.

It is interesting to note that a catalyst can increase the rate of a chemical reaction but cannot change its point of equilibrium. If this statement were not correct, it would be possible to construct a perpetual motion machine. Since perpetual motion is an impossibility (see THERMODYNAMICS), it follows that in a reversible reaction the catalyst must accelerate both the forward and the reverse rate and in the same proportion.

Photochemical Reactions. — Reactions which take place in the presence of light but not in the dark are called photochemical reactions; their rate depends upon the amount of light absorbed. This subject is treated fully in the article on PHOTOCHEMISTRY. The principles here needed are the following: (1) Only the light which is absorbed by the system is effective in promoting chemical change; (2) radiant energy (light) is available only in units called quanta (see LIGHT); (3) a molecule which absorbs light and is thereby activated (*i.e.*, enters into a reaction with light) absorbs one and only one light quantum (A. Einstein). Subsequently, the activated molecule may enter into other, more complicated chemical reactions.

Chain Reactions. — Hydrogen gas reacts with chlorine at room temperature provided that the mixture is illuminated; the reaction (except under special circumstances, see below) does not occur in the dark. The form of the equation for the chemical reaction

$$H_2 + Cl_2 \longrightarrow 2HCl \quad (20)$$

resembles that of the reaction for the formation of hydrogen iodide (reverse of equation 1); the kinetics of the two reactions are, however, quite different. The reaction between hydrogen and chlorine proceeds when visible light is used. Since light of this wave length is absorbed by chlorine, but not by hydrogen, it follows that chlorine is the reactant affected by the light. Measurements have shown that as many as 1,000,000 molecules of hydrogen chloride are produced for every light quantum absorbed. Evidently a very special mechanism must be postulated to account for this fact. It has been assumed (W. Nernst, M. Bodenstein) that, as an indirect or direct result of the illumination. the molecules of Cl_2 which absorb light quanta are dissociated into chlorine atoms (21). These atoms then react as shown in equations (21') and (21'').

$$Cl_2 \longrightarrow 2Cl \quad (21)$$

$$Cl + H_2 \longrightarrow HCl + H \quad (21')$$

$$H + Cl_2 \longrightarrow HCl + Cl \quad (21'')$$

Each chlorine atom obtained by the illumination reacts with a molecule of hydrogen to produce a molecule of hydrogen chloride and an atom of hydrogen (21'); the latter in turn reacts with a molecule of chlorine to produce another molecule of hydrogen chloride and to regenerate an atom of chlorine (21''). The cycle is then repeated. Reactions characterized by such cycles are called chain reactions. If there were no side reactions to destroy the intermediate hydrogen and chlorine atoms, then, in principle, one chlorine atom could convert all the hydrogen and chlorine in the system to hydrogen chloride. In fact, the chain length varies from a few units to a million, depending upon the experimental conditions. The chains are broken (or terminated) when the chlorine or hydrogen atoms are removed. There are several means of removing these reactive atoms. For example, oxygen combines with either chlorine or hydrogen atoms, and traces of oxygen are effective in decreasing the rate of the reaction in question. In this reaction then, oxygen acts as a negative catalyst, or an inhibitor, or a chain breaker. (These terms are not, however, exactly synonymous.) Another means of breaking the chain is

the combination of hydrogen atoms and chlorine atoms present in the gas mixture to form hydrogen chloride. Such combination occurs on the walls of the vessel, or when a hydrogen atom and a chlorine atom, in what is called a three-body collision, collide simultaneously with some third particle (such as a chlorine molecule); interestingly, the combination does not occur when only a hydrogen and a chlorine atom collide. Such a combination independent of the wall or of any third particle would violate either the law of the conservation of momentum or the law of the conservation of energy, or both. (*See* MECHANICS.) The fact that no such combination is observed simply means that the molecular system in question obeys the laws of mechanics, as do the molecular systems in all similar reactions which have been carefully studied.

The validity of the proposed chain mechanism for the reaction between hydrogen and chlorine is supported (1) by the high photochemical yield of the reaction (*i.e.*, the large amount of hydrogen chloride produced per quantum of light absorbed), (2) by the fact that kinetic equations based upon the chain mechanism adequately describe the reaction velocity and (3) by experiments showing that the reaction can be initiated in the dark by the introduction into the reaction mixture of hydrogen or chlorine atoms from some outside source. There is good reason to believe that hydrogen atoms are produced by an electric arc discharge in hydrogen gas, and that chlorine atoms are produced in the reaction between sodium vapour and chlorine. If the products from either of these reactions are rapidly introduced into a mixture of hydrogen and chlorine, the formation of hydrogen chloride is initiated.

Reaction kinetics has provided much evidence to show that many reactions either in the gas phase or in solution proceed by chain mechanisms.

Heterogeneous Reactions.—Heterogeneous reactions include the solution of solids in solvents, and the reverse process, the crystallization of solids from solution. The reaction of metals with acids and problems of corrosion are part of the subject of heterogeneous reactions. However, by far the majority of the research on heterogeneous reactions is devoted to heterogeneous catalysis (*e.g.*, reactions between gases or liquids catalyzed by solids, etc.). For example, finely divided iron greatly accelerates the rate at which nitrogen and hydrogen unite to form ammonia. Recent studies have shown that iron adsorbs nitrogen in such a fashion as to activate it (by a reaction analogous to the formation of iron nitride); the hydrogen subsequently reacts with the adsorbed nitrogen. Although heterogeneous reactions of this sort are of considerable theoretical and practical interest (*see* ADSORPTION; CATALYSIS) the present article is devoted largely to a consideration of homogeneous reactions.

Enzymes.—Almost the earliest chemical reactions known are the fermentations by which sugar is converted to alcohol or vinegar (fermentation) or lactic acid (souring of milk). These and similar reactions occur in the presence of living organisms, such as yeasts, fungi, etc. In 1897 E. Buchner discovered that, in the fermentation of sugar, the function of the living yeast is to produce a catalyst for the reaction. He destroyed the yeast cells by grinding them with sand. The filtered juice, although it contained no living organisms, nevertheless rapidly converted sugar to alcohol. The complex organic catalysts produced by living cells are called enzymes; those so far investigated in detail have proved to be protein complexes.

The extensive investigation, largely by methods of reaction kinetics, of the fermentation of sugar has revealed the fact that the reaction is a complex one in which many enzymes take part. Active research is at present under way to elucidate the path of many enzymatic processes, and to determine if possible the detailed mechanisms by which enzymes function as catalysts.

There are enzymatic systems which convert starch into sugar and sugar into alcohol; others hydrolyze proteins into a mixture of amino acids; still others synthesize proteins in the body; such systems are responsible for the conversion (by a form of combustion) of sugar to carbon dioxide and water, with the liberation of energy. The accelerating effect of some of these enzyme systems is enormous. For example, one part of beef catalase can be detected in 25,000,000 parts of water by the acceleration it produces in the decomposition of hydrogen peroxide. Since the mechanism of enzyme action is unknown, and since the kinetics of enzyme action differs considerably from the kinetics of reactions accelerated by ordinary catalysts, direct comparisons are difficult and likely to be inaccurate. As a rough first approximation, however, catalase is about 10,000 times as active a catalyst as is an equal weight of ferrous ion in catalyzing the decomposition of hydrogen peroxide, and urease is about 10,000 times as active (at 20° C. and in neutral solution) as is an equal weight of sodium hydroxide in accelerating the hydrolysis of urea.

Explosions.—Chemical explosions are rapid reactions which are strongly exothermic; that is to say, these reactions are very rapid ones which evolve large quantities of heat. The hot gases formed in the chemical reaction, or the air heated by the energy released, produce a region of high pressure near the site of the explosion. This region of high pressure travels outward through the air in the form of an explosion wave which usually causes much of the destruction resulting from the explosion (*see* COMBUSTION; EXPLOSIVES). It is of interest to inquire what are the necessary conditions, and what are the possible mechanisms for a reaction which consumes many pounds of material in (say) 10^{-5} seconds. There are two well-known types of mechanism for explosions: the chain branching mechanism and the thermal mechanism. The latter type was suggested by Van't Hoff, the former by N. N. Semenoff; examples of both types have been discovered.

The theory of the chain-branching mechanism is that, during the early stages of a chain reaction, more chains are initiated per unit time than are terminated. The most spectacular example of an explosion caused by chain branching is the fission of atomic nuclei, such as occurs in atomic bombs. Here the disintegration of a particular sort of uranium, U^{235} (or of plutonium) is initiated by neutrons, but, in the disintegration, neutrons are also produced. (*See* ATOMIC ENERGY; ISOTOPE; NUCLEUS.) If exactly one neutron were produced from each disintegrating nucleus of U^{235}, a chain reaction analogous to the reaction between hydrogen and chlorine would result. In fact, however, more than one neutron is produced by each nuclear disintegration; the average number is probably about two. An equation for the atomic disintegration is

$$U + n \longrightarrow I + Y + 2n \qquad (22)$$

where U, n, I and Y are the symbols for uranium, the neutron, iodine, and yttrium, respectively. (Other elements besides iodine and yttrium are also produced in the disintegration; the principles involved are, however, the same.) The faster the reaction proceeds, the more rapidly are neutrons produced and the more rapidly does the reaction rate increase. Since the disintegration of the uranium is accompanied by a large evolution of energy, the reaction is an explosion.

The second type of explosion mechanism is the thermal one. Most chemical reactions are carried out under conditions such that the heat evolved (or absorbed) by the reaction is taken away (or supplied) by the surrounding medium. If, however, a highly exothermic reaction is carried out under conditions such that the heat is not carried away by the surroundings, the reaction mixture must become hotter. At the more elevated temperature, the rate of the reaction is much greater; the rate of heat evolution, therefore, becomes much greater also, and the reaction mixture rapidly becomes still hotter. Such a reaction must necessarily lead to an explosion. The question whether a particular exothermic reaction will lead to an explosion is thus largely a question of the conditions under which the reaction is carried out. If the reaction can be made to proceed at such a rate that the heat lost to the surroundings per unit time is small compared with the heat input caused by the chemical reaction during the same interval, a thermal explosion ensues.

Reactions of Isotopes.—In general, the reaction rates of compounds which differ only in that they contain different isotopes of the same element are identical within experimental error. When, however, one of the lighter elements is involved, this need not be the fact. A compound which contains atoms of C^{14} (radioactive carbon) may react at a rate which differs appreciably (*e.g.*,

by 10%) from that of a compound identical except that it contains only normal carbon atoms. The rate of the reactions of compounds containing deuterium (heavy hydrogen) may, in certain cases, differ from those of the corresponding compounds of light hydrogen by a factor as large as eight. These large differences in rate, which may occur when a bond to a hydrogen atom is formed or broken, arise from an effect (zero-point vibrational energy) predicted by quantum mechanics (*q.v.*). Although a discussion of the theory of this effect is out of place here, the phenomenon is proving a most useful tool in investigations of reaction mechanisms.

The Collision Theory.—In the theory of reaction kinetics as so far presented, several difficulties have been noted. The present section is devoted to a discussion of these difficulties and the methods of avoiding them; a knowledge of physical chemistry on the part of the reader is assumed.

The ratio of the rates of a forward and of the corresponding reverse reactions gives an approximate expression for the equilibrium constant of the reaction in question, as shown for a special case by equation **(13).** In the more general case, an analogous treatment of the reaction

$$mA + nB + pC + \ldots \rightleftharpoons gR + hS + iT + \ldots \qquad (23)$$

leads to equation (24).

$$\frac{(R)^g(S)^h(T)^i\ldots}{(A)^m(B)^n(C)^p\ldots} = K_c \qquad (24)$$

The ratio of concentrations on the left side of equation (24) is obtained even if the kinetic equation for the reaction is a complex one. For example, if the reaction is catalyzed, the catalyst concentration appears in the expression for the rate of both the forward and the reverse reaction; it thus cancels out in equation (24). Careful inspection shows that other possible complexities are likewise of no effect on K,. But equation (24) is nevertheless not precisely correct. The true equilibrium expression (see THERMODYNAMICS) is defined in terms of the "activities," not the concentrations, of the reactants and reaction products. Although in dilute solutions the concentration of any substance closely approaches its activity, the two functions are by no means identical. (An analogous statement applies to gases at low pressure.) It is therefore clear that the law of Guldberg and Waage, although approximately correct, is not and cannot be uniformly valid.

The difficulty noted cannot be avoided by the assumption that reaction rates are proportional to activities rather than to concentrations; this assumption has been proved false by investigations of the rates of ionic reactions. The ratio of the activity of any substance to its concentration defines its activity coefficient. The activity coefficients of ions depend upon the ionic strength of the solution in which they occur (see SOLUTIONS, Solutions of Electrolytes). This ionic strength is a function of the concentrations and of the charges on all the ions present; in dilute solutions the activity coefficients of all ions decrease with increasing ionic strength, But the rates of reactions between two ions of like charge increase with increase of ionic strength; only for reactions between ions of opposite charge do the rates (like the activity coefficients) decrease with increasing ionic strength. Thus the rate of a reaction is not proportional to the "activities" of the reactants; it has already been shown that only as a first approximation is this rate proportional to the ionic concentrations.

The difficulty, at least insofar as ionic reactions are concerned, has been resolved by the assumption that reaction rates are proportional not to concentrations or activities, but to the number of collisions per second between the reacting ions. The number of collisions between charged particles should not be strictly proportional to the product of their concentrations. Let W be the ratio between the number of collisions among the reacting ions and the product of the ionic concentrations. Then, because of interionic effects, W should increase with increasing ionic strength for reactions between ions of like charge, and decrease with increasing ionic strength for reactions between ions of unlike charge. This predicted behaviour is in qualitative agreement with the anomaly in ionic reaction rates already cited.

J. A. Christiansen's calculation (1924) based on the theory of P. Debye and E. Hiickel, accounts quantitatively for the observed rates of ionic reactions in dilute solution. Further, although the forward and reverse rates, taken separately, are not proportional to the activities of the reactants and reaction products, the expression obtained by setting equal the rates of the forward and reverse reactions (corrected to account for interionic effects) yields the thermodynamic equilibrium expression in terms of activities, not concentrations. How this happens is made clearer in the consideration (see below) of the activated-complex theory of reaction velocity. In general, it has been assumed that consideration of the actual number of collisions always leads to corrections for the law of Guldberg and Waage, such that the dynamic and thermodynamic equilibrium constants become equal.

It should be pointed out that interionic and other forces not only affect the change in the number of collisions with change in concentration; they also affect the actual number of collisions per unit time. Thus, in a reaction between two positively charged ions, forces of electrostatic repulsion lower the number of collisions far below that computed from the kinetic molecular theory. Furthermore, it is not true that every collision between reactant particles moving, relative to one another, with a velocity greater than the critical one, u_0, leads to chemical change. There must also be a definite orientation of the molecules with respect to one another at the moment of collision. This consideration holds especially for complex molecules, which may be capable of reacting only at one end. The collision theory is thus considerably less precise than may at first have appeared.

Application of kinetic molecular theory to a simple bimolecular reaction (*e.g.,* the decomposition of hydrogen iodide) leads to equation (25), which relates the rate constant, k, with u_0 the minimal velocity at collision, necessary for reaction.

$$k = \frac{4N^2d^2}{c^2}\sqrt{\frac{\pi kT}{m}}\left(1+\frac{mu_0^2}{2kT}\right)e^{-mu_0^2/2kT} \qquad (25)[8]$$

$$\frac{1}{\mu} = \frac{1}{m_1} + \frac{1}{m_2} \qquad (26)$$

Here N molecules of effective diameter d and weight m are present at a concentration of c moles per litre and at an absolute temperature T. The symbol e is the base of the system of natural logarithms, and k is Boltzmann's constant, 1.38 X 10^{-16} ergs/degree. If the values of k are experimentally determined for a series of temperatures, the values of both u_0 (the minimal velocity of one molecule relative to another required for effective collisions) and of d (the effective diameter of the particles) can be determined. The difficulties previously discussed then appear as anomalously large or small values of d^2. That is to say, when the reacting particles attract each other, the cross sections of the molecules (proportional to d^2) which are "effective" for collisions, will be large compared to these cross sections as determined by other methods; conversely, when the particles repel one another, or when a preferred orientation is necessary for reaction, the "effective" cross section will be small. The latter condition holds (although not to a marked degree) for the hydrogen iodide reaction.

An alternative description of the reaction process may be obtained by computing a collision number on the basis of the best available estimates for molecular cross sections and by replacing equation (25) by (27), to which it is approximately equivalent.

$$k = PZe^{-Q/RT} \qquad (27)$$

Here Z is the "normal" collision factor, P is the "probability" factor defined by equation (27), and Q is the activation energy which does not differ greatly from $\frac{1}{2}Mu_0^2$, where M is the molecular weight of the substance in question. The difficulties of the collision theory are then contained in the factor P, and the problem of obtaining precise agreement between theory and experiment is reduced to that of computing P correctly.

One additional aspect of collision theory deserves attention. Some reactions (as previously stated) are of the first order. Such reactions would seem to be independent of collisions. In what way can these reactions be correlated with collision theory? Some first-order reactions probably cannot be so correlated. The disintegration of radium is strictly of the first order; the rate of the

[8] If the two molecules which react are not identical, this expression must he somewhat modified. Among other modifications, the reduced mass μ replaces m. If the masses of the two molecules in question are m_1 and m_2, then the reduced mass μ is defined by equation (&).

reaction depends upon changes in the radium nucleus, which are unaffected by collisions of the molecule as a whole. But in ordinary chemical, as opposed to nuclear, reactions, the energy necessary for reaction is probably acquired by the decomposing molecule through previous collisions.

The Activated-Complex Theory.—An alternative general theory of reaction kinetics is formulated in terms of the so-called "activated complex." (S. A. Arrhenius, J, N. Brönsted, N. Bjerrum, H. Eyring). In this theory, it is assumed that all the reactants are in pseudoequilibrium with an activated complex, X,

$$mA + nB + pC + \ldots\ldots \rightleftharpoons X \longrightarrow \text{products} \qquad (28)$$

which in turn decomposes to give the reaction products. The activated complex X is not a true molecule; it is merely a stage in the process by which the reactants become the reaction products. Hence, the activated complex is not in true equilibrium with the reactants. The activated-complex theory, however, is founded on the assumption that the concentration of the activated complex may be computed just as if it were a real, stable chemical compound. The rate of reaction is then the product of the concentration of X multiplied by the rate at which it decomposes. This rate can be computed by the general methods of quantum mechanics (*q.v.*); it is the same for all activated complexes, regardless of the materials out of which they have been formed. For a reaction such as (23), the activated-complex theory leads to equation (29)

$$v = \kappa \frac{kT}{h} K^*(A)^m(B)^n(C)^p \ldots\ldots \frac{\gamma_A{}^m \gamma_B{}^n \gamma_C{}^p}{\gamma_X} \qquad (29)$$

where k is the Boltzmann constant, h is Planck's constant, K* is the equilibrium constant for the formation of the activated complex (its decomposition into the reaction products being disregarded), and $\gamma_A, \gamma_B, \gamma_C, \ldots\ldots \gamma_X$ are respectively the activity coefficients of the reactants and of the activated complex. The constant κ is called the transmission coefficient; it is usually nearly unity. When the activated-complex theory is used to describe a reversible reaction, a distinction must be drawn between the activated complex formed from the reactants and that formed from the reaction products. The two complexes, although structurally the same, differ with respect to the materials from which they have been formed and into which they are decomposing. Unless the distinction in question is made, the theory is self-contradictory.

Equation (29) contains γ_X, the activity coefficient for the activated complex. Although this coefficient cannot be measured (since the activated complex is not a stable entity) it can be estimated for the complexes which occur in ionic reactions. The charge on the activated complex must be the sum of the charges on the reactants; furthermore, the charge on an ion, as a first approximation, determines its activity coefficient. Equation (29) correctly predicts the rates of ionic reactions; it leads to results identical with those obtained by Christiansen. Although in particular instances the collision theory may be more convenient to apply than is the activated complex theory, or vice versa, the two always lead to the same results; they are, in essence, two different languages in which the same phenomena may be described.

At equilibrium, the rates of the forward and reverse reactions are equal. When two rate expressions analogous to (29) are used, an equation (30) is obtained from which the activity coefficient of the activated complex and the transmission coefficients have been eliminated.

$$\frac{(R)^q(S)^h(T)^i \ldots\ldots (\gamma_R)^q(\gamma_S)^h(\gamma_T)^i \ldots\ldots\ldots\ldots}{(A)^m(B)^n(C)^p \ldots\ldots (\gamma_A)^m(\gamma_B)^n(\gamma_C)^p \ldots\ldots\ldots\ldots} = K \qquad (30)$$

Here K is the true thermodynamic equilibrium constant, expressed in terms of activities (concentrations multiplied by activity coefficients).

The pseudoequilibrium constant, K*, of equation (29) is related to the free energy of activation, AF*, the heat of activation AH*, and the entropy of activation ΔS^*, by equation (31).

$$-RT \log_e K^* = \Delta F^* = \Delta H^* - T\Delta S^* \qquad (31)$$

The heat of activation, ΔH^*, corresponds roughly with the energy of activation, Q, of the collision theory; the entropy of activation, ΔS^*, may be roughly related to the logarithm of the "probability" factor, P, of equation (27).

The thermodynamic concept of entropy has been interpreted, through statistical mechanics, in terms of molecular vibrations. Likewise, entropy of activation can often be interpreted in terms of the geometry and of the estimated vibrational frequencies of the activated complex.

The application of the activated-complex theory depends upon the computation of the pseudoequilibrium constant, K*. Thus, the kinetic problem is replaced by a thermodynamic one, and all the powerful tools of thermodynamics and of statistical mechanics become immediately available for its solution. It is possible in principle (always) and in practice (occasionally) to calculate the rate of a chemical reaction without the use of any experimentally determined kinetic data. The difficulties reside principally in the selection of appropriate constants for the activated complex. For the reaction between a hydrogen atom and a hydrogen molecule (which has been investigated by the use of ortho- and parahydrogen and of deuterium), the absolute reaction rate has been computed by methods related to the activated-complex theory (E. Wigner). Most reactions are, however, too complex for complete mathematical solution by methods now known.

READE, CHARLES (1814–1884), English novelist and dramatist, the son of an Oxfordshire squire, was born at Ipsden, Oxfordshire, on June 8, 1814. He entered Magdalen college, Oxford, proceeded B.A. in 1835, and became a fellow of his college. He was subsequently dean of arts, and vice-president of Magdalen college, taking his degree of D.C.L. in 1847. His name was entered at Lincoln's Inn in 1836; he was elected Vinerian fellow in 1842, and was called to the bar in 1843. He kept his fellowship at Magdalen all his life, but after taking his degree he spent the greater part of his time in London. He began as a dramatist, and it was his own wish that "dramatist" should stand first in the description on his tombstone.

His first comedy, *The Ladies' Battle,* appeared at the Olympic theatre in May 1851. It was followed by *Angelo* (1851), *A Village Tale* (1852), *The Lost Husband* (1832) and *Gold* (1853). But Reade's reputation was made by the two-act comedy, *Masks and Faces,* in which he collaborated with Tom Taylor. It was produced in Nov. 1852, and later was expanded into three acts. By the advice of the actress, Laura Seymour, he turned the play into a prose story which appeared in 1853 as *Peg Woffington* as did also *Christie Johnstone,* a study of Scottish fisher folk. In 1854 he produced, with Tom Taylor, *Two Loves and a Life* and *The King's Rival;* and, unaided, *The Courier of Lyons*—well known under its later title, *The Lyons Mail*—and *Peregrine Pickle.* In 1855 appeared *Art,* afterward known as *Nance Oldfield.*

He made his name as a novelist in 1856, when he published *It's Never Too Late to Mend,* a novel written with the purpose of reforming abuses in prison discipline and the treatment of criminals. Five minor novels followed in quick succession—*The Course of True Love Never Did Run Smooth* (1857), *Jack of All Trades* (1858), *The Autobiography of a Thief* (1858), *Love Me Little, Love Me Long* (1859), and *White Lies* (1860), dramatized as *The Double Marriagz.* In 1861 his masterpiece, *The Cloister and the Hearth,* appeared, relating the adventures of the father of Erasmus. It is one of the finest historical novels in existence. Returning from the 15th century to modern English life, he produced another novel with a purpose, *Hard Cash* (1863), in which he directed attention to the abuses of private lunatic asylums. Three other novels "with a purpose" were *Foul Play* (1869), in which he exposed the iniquities of ship-knackers, and paved the way for the labours of Samuel Plimsoll; *Put Yourself in His Place* (1870), in which he grappled with the trade unions; and *A Woman-Hater* (1877), on the degrading conditions of village life. *The Wandering Heir* (1875), of which he also wrote a version for the stage, was suggested by the Tichborne trial.

Outside the line of these moral and occasional works Reade produced three elaborate studies of character—*Griffith Gaunt* (1866), *A* Terrible Temptation (1871). *A* Simpleton (1873). The first of these was in his own opinion the best of his novels. His greatest success as a dramatist attended his last attempt—Drink—an adaptation of Zola's *L'Assommoir,* produced in 1879. In that year his friend Laura Seymour, who had kept house for him since 1854, died. Reade's health failed from that time, and he died on April 11. 1884, leaving behind him a completed novel. *A* Perilous *Secret,* which showed no falling off in the arts of weaving a complicated plot and devising thrilling situations. Reade was an amateur of the violin, and among his works is an essay on Cremona violins with the title, *A* Lost Art Revived.

READING, RUFUS DANIEL ISAACS, 1ST MARQUESS OF (1860–1935), British statesman. was born on Oct. 10, 1860, in London, the second son of Joseph Isaacs, merchant. He was educated at Cniversity College school, London, and abroad. At the age of 16 he went to sea, his parents believing that the discipline would be good for him. A subsequent venture on the stock exchange was a failure. He then read for the bar and was called in 1887; his legal career was unbroken and successful. He entered parliament as a Liberal Imperialist, winning a seat for his party at Reading in 1904, which he retained until he went to the house of lords. He became attorney general in 1910, and in 1912 was given a seat in the cabinet, which no attorney general had held before. On Oct. 22, 1913, he was made lord chief justice, and in Jan. 1914 was created Baron Reading of Erleigh. In this office he distinguished himself by humanity in the conduct of criminal cases and by the establishment of the principle that the court of criminal appeal should act as a real court of revision, upsetting verdicts or reducing sentences even of the individual high court judges.

After the outbreak of the war in Aug. 1914, he assisted in the drafting and the administration of those measures which saved England from financial ruin. In 1915 he was president of the Anglo-French Loan commission to the United States, where he succeeded in floating a great war loan. In 1917 he was appointed high commissioner and special envoy to the United States, and in November of that year was created an earl. In 1918 he was appointed high commissioner and special ambassador at Washington.

Lord Reading's term as viceroy of India began in 1921. At that time he was faced immediately by four acute problems. First, the dyarchy system of the Montagu-Chelmsford Government of India act, devised as a step in advance toward complete self-government, was definitely rejected by the leaders of the united Hindu and Mohammedan educated population, who in the movement known as *Swaraj* had resolved to make it unworkable. The second was the influence of Mahatma Gandhi, one of the most remarkable men of all time, who had inflamed millions of Indians to a boycott of the west by the east and a kind of gigantic movement of passive resistance, in which both British products and British government were to be alike rejected. The third was that the national temper of India had been aroused by prohibitions and indignities put upon Indians in other parts of the empire. The fourth, the story of the Punjab rebellion and the slaughter at Amritsar in 1919, with the support of Gen. Reginald Dyer's action there by the governing classes in England, had excited a feeling of such fierce resentment through the length and breadth of the peninsula as might have caused a general uprising. In dealing with the revolt against the dyarchy, he was compelled to imprison the two Mohammedan leaders, the brothers Ali. And although he was able to establish some kind of self-government in most of the local provinces and even something like friendly co-operation in the central legislative council, the constitution broke down in the Central Provinces and had to be suspended in Bengal, with a return to complete autocratic government. In the case of the boycott of the west the viceroy, after attempts at reconciliation with Gandhi, authorized his prosecution for inciting to mass civil disobedience.

Cpon Lord Reading's return to England in April 1926 he was created a marquess. the first commoner to be so created since the duke of Wellington. He was secretary of state for foreign affairs, Aug.–Nov. 1931, in Ramsay MacDonald's national government. He died Dec. 30, 1935. (See INDIA: History.)

READING, a county and parliamentary borough and the county town of Berkshire, Eng., 38 mi. W. of London by road. Pop (1961) 119,870. Area 14.2 sq.mi. Reading is an important junction of railways running west from London and south from the midlands, and the Kennet and Avon canal, to Bath and Bristol, and the Thames afford it connections by water. It lies on the Kennet river near where it joins the Thames. All the ancient churches are restored: Greyfriars church, formerly monastic, was completed early in the 14th century and after the dissolution of the monasteries served successively as a town hall, a workhouse and a jail, being restored to its proper use in 1864; St. Mary's was rebuilt in 1551 from the remains of a nunnery founded by Aelfthryth in expiation of the murder of her stepson Edward the Martyr; St. Laurence's is a Perpendicular building with Norman and Early English features; St. Giles's was much damaged during the siege of 1643 by the parliamentary forces and is almost wholly rebuilt. Public gardens occupy most of the site of the Benedictine abbey.

A University college was opened in 1892 and affiliated to Oxford; its success led to the gathering of an endo ment fund and it became an independent university with a charter in 1926. Its researches into agriculture, horticulture and dairying are of special importance. The National Institute of Research in Dairying, established in 1912, is part of the university. At the grammar school, founded in 1485 and now occupying modern buildings. Archbishop Laud (a native of Reading) was educated. There is also a bluecoat school (1656) now just outside the borough at Sonning. The municipal museum, besides an art gallery and other exhibits, includes Roman relics from Silchester (*q.v.*) and finds from the Thames.

Reading early became a place of importance. In 871 the Danes encamped there, and in 1006 it was burned by Sweyn. It consisted of only 30 houses at the time of the Domesday survey. It is thought that a fortification existed there before the Conquest, and Stephen built a masonry castle which Henry II destroyed. On the foundation of a Benedictine abbey in 1121, the town, hitherto demesne of the crown, was granted to the abbey by Henry I. Henry VIII converted the abbey, whose church was among the largest in the country, into a palace and it was destroyed during the Civil War. From the 12th until the 16th century, Reading's history was that of the struggle as to rights and privileges between the abbey and the merchants' guild. A 16th-century account of the merchants' guild shows that many trades were then carried on, but John Leland says the town "chiefly stondith by clothing." By the 17th century the trade had begun to decline; the bequest of the clothier John Kendrick (d. 1624) did little to revive it. and it was greatly injured by the Civil War. In the 18th century the chief trade was in malt.

The first town charter is that of Henry III (1253), confirmed and amplified by succeeding sovereigns. The governing charter until 1835 was that of Charles I (1639), incorporating the town under the title of the mayor, aldermen and burgesses. The market, chiefly held on Saturday, can be traced to the reign of Henry III; four fairs granted by the charter of 1562 are still held.

Reading is an agricultural centre with famous nursery gardens. Its biggest and best-known industry is biscuit manufacture, but there is much business in printing, iron foundries, engineering works, malting and brewing. The sale of corn, cattle and flour is carried on extensively, and there are pottery and brick works, together with riverside boatbuilding yards. The parliamentary borough. which used to return two members before the Reform act of 1885, regained that privilege in 1948.

READING, a city of southeastern Pennsylvania, U.S., the seat of Berks county, is located on the Schuylkill river, 58 mi. N.W. of Philadelphia.

The population in 1950 was 109,320 and decreased by 10.2% in 1960 to 98.177. However the population of the Reading standard metropolitan statistical area comprising Berks county increased from 255.740 in 1950 to 275,414 in 1960.

History.— In 1748 Reading was laid out and surveyed at the great ford on the Schuylkill. The plans were supervised by Thomas Penn, who insisted on the large open square, Penn common, for market purposes, as was common in England. He named the town for the seat of Berkshire. Eng., the ancestral home of the Penns. Four years later, when Berks county was created. Reading became the county seat. It was incorporated as a borough in 1783 with a population of 2,100 and was chartered as a city in 1847.

Though there were many Germans among the first settlers they were not politically minded and control of local affairs remained in the hands of the English. As a result of the Revolutionary War. the German element in Reading and elsewhere in Pennsylvania began to assert itself and eventually elected three governors from Reading and Berks county. As early as the spring of 17'75 two companies of infantry (mostly Germans) left the district for service under Gen. George Washington near Boston. Reading served as a depot for supplies, as a manufacturer of cannon and it maintained a prison camp for the Hessians captured at the battle of Trenton. The thrifty Pennsylvania Germans hired out some of the Hessian prisoners in their charge. During the American Civil War, Reading was the first to send a military unit to defend the national capital when Abraham Lincoln called for troops. The Ringgold light artillery, largely locally recruited, was later named the first defenders.

The local citizens are still proud of their predominantly Pennsylvania-German heritage, which they seek to keep alive at the widely attended annual Pennsylvania Dutch folk festival at nearby Kutztown.

Industrial Growth.--From the earliest days the making of iron and steel was important. In this area the first cold-blast furnace in America was set up and the first steel was commercially produced in Pennsylvania. At the middle of the 19th century Berks county had more iron and steel producing plants than any county in the U.S. The prosperity of Reading's primary iron and steel production continued until the upper Great Lakes ore replaced the use of Pennsylvania ore. Reading made the adjustment by shifting to the fabrication of iron and steel. The opening of the Schuylkill canal to Philadelphia in 1824 (abandoned in 1922), the Union canal to Lebanon and Middletown on the Susquehanna in 1828 (abandoned in 1880) and the building of the Philadelphia and Reading railroad in 1838 (extended to Pottsville in 1842) greatly stimulated industrial growth, as did the building of the Pennsylvania railroad to Reading in 1884.

An interesting feature of Reading's industrial history was the sudden mushrooming of safety-bicycle manufacturing to satisfy the fad of the 1890s. When the bicycle boom passed much hope was held out for automobile manufacturing. From 1900 to 1912 Charles E. Duryea manufactured a durable car that won a number of speed and endurance tests but did not sell well. The Reading Steamer produced from 1900 to 1903 was a novel machine that did not catch the fancy of the buying public.

The decline of primary iron and steel manufacturing and the blasted hopes of the bicycle and the automobile business were offset by the development of the textile and hosiery industry by two German technicians, Ferdinand Thun and Henry Janssen, around 1900. Other Germans built textile and hosiery factories and gave the city a national reputation.

Reading became an important retail and wholesale tradingcentre. It is located in the midst of a rich agricultural, dairy and industrial county and ranks third industrially in the state, with about 700 industrial establishments in the city and its suburbs. These include railway shops and plants producing builders hardware, foundry products, hosiery machinery, clothing, optical goods, chemicals, dairy products and pretzels. One of the largest full-fashioned hosiery mills in the world is located there, as are also an extensive single-unit foundry and a huge brick-burning kiln.

Skilled craftsmen form a large proportion of the population and union organizations are strong in the community, which has a tradition of unionism and socialism.

Reading was the second city in the U.S. to elect a socialist government. "Jim" Maurer was for many years nationally known as the leader of a moderate brand of socialism. (In contrast to the usual moderation, during the railroad strikes in 1877 ten men were killed and scores seriously wounded.)

The hosiery business, which once employed more than half the wage earners of Reading, has declined, but the city anticipated the slump and in the 1950s and 1960s stimulated new industries and the growth of old industries to take up the slack.

Education and Cultural Activities.— The public-school system comprises evening and summer schools in addition to the usual kindergarten through senior high school. A unique feature is the ownership by the school district of an extensive museum and art gallery, both of which are thoroughly integrated into the public school work at all levels. The butterfly collection and the collection of Carboniferous Age insects are nationally recognized. Pennsylvania State university, the University of Pennsylvania and Temple university maintain extension centres and institutes at Reading. Albright college (Evangelical United Brethren; founded in 1856), a four-year liberal arts college, is also located there. The county historical society has a valuable collection of ancient fire-fighting equipment. Both the symphony orchestra and the Ringgold band are among the oldest in America.

Parks and Historic Sites.—Mt. Penn, to the east of the city, rises to an elevation of 1,100 ft. and is the centre of a park system of more than 2.000 ac. The Duryea drive winds to the immense Chinese pagoda on the top. Penn common (50 ac.) is still a popular recreational area in the heart of the city. The anchor of the battleship "Maine" rests there.

Among the many historical landmarks in Reading and its environs are the Conrad Weiser farm, Hopewell Village National Historic site, Daniel Boone homestead and the sites of early forts and furnaces. (L. A. GR.)

READING is the mental process of securing and reacting to an author's message represented by written or printed symbols. To read, one must recognize words, know the meaning of the words, understand the ideas expressed by the author, sense the mood and tone of the selection, evaluate the accuracy of the ideas and use or apply them.

Children in the primary grades usually learn to read simple materials. These abilities are expanded and refined in the middle and upper grades. Many high schools in the United States began to teach reading between 1930 and 1950 and a number of colleges initiated courses to improve reading. By the 1950s many adult education courses included reading improvement classes, and some industrial concerns were offering reading courses to their employees. It is recognized that one learns to read, then reads to learn, and that the growth of these two abilities continues from childhood into adulthood.

Stages in Learning to Read.—Studies show that pupils' attainments in reading at various grade levels differ widely. Some at the end of first grade may be reading as well as the average of those in third grade. By the fourth grade a few pupils are reading at first-grade level, others at second, several at third and many at fourth. In addition, a number will attain scores at fifth, several at sixth and a few at seventh and eighth grades. Arthur I. Gates pointed out that all pupils go through the same stages in learning to read, but that individuals vary in the rate at which they master successive stages. Usually the stages are not clear-cut. but each merges gradually into the next.

The first stage is called reading readiness, or preparation for learning to read. Much of this preparation takes place in the home, but kindergarten is also an effective aid. Pupils who are not judged ready to read usually have additional preparation in first grade. Mental, social, emotional and language maturity appropriate to the average pupil of six years is considered optimal. An interest in books and in printed words is usually exhibited at this time.

The second stage is that of learning to read. During this period, children learn to recognize about 300 words by sight. In addition, their interest in reading increases, and they become thoughtful about what is read. Gradually, as this stage progresses. children learn to read simple books independently.

During the third stage there is considerable progress in learning to do good oral reading and rapid silent reading which is fully

understood. Sight vocabulary increases to 1.500–2,000 words. Concurrently, pupils learn the skills necessary to figure out independently the words in their speaking vocabulary. At this stage pupils begin to use reading as a tool in other school subjects, to satisfy their curiosity and for pleasure.

The fourth stage is characterized by the acquisition of more mature reading interests and tastes. During this period all of the previously learned abilities are refined and enhanced. Word recognition is gradually increased; knowledge of meanings is extended and precision of meaning is acquired. Understanding or ability to interpret grows as the reader secures a better background against which to evaluate what he reads. He is able to apply new knowledge acquired from his reading to assist him in adjusting his attitudes and behaviour. His reading interests become broader and. in worthwhile areas, more intensified. He begins to become what William S. Gray described as the mature reader.

Methods of Instruction. — One of the earlier methods of teaching reading in most parts of the western world was the so-called ABC method. Children first memorized the names of the letters. Then the letters were combined to form syllables and words. Words were combined to form sentences, and sentences to form paragraphs. Since saying the names of the letters in a word often bears little resemblance to the sound of the word when it is pronounced, learning was largely by memory and without much meaning. According to Nila B. Smith there was a vigorous protest against the ABC method between 1840 and 1850, although this method continued to be used long afterward.

However, experimentation turned in two directions. One involved learning words as units, since they have more meaning for young children than do letters. There were a staggering number of words for pupils to learn by sight without methods for attacking unfamiliar words. A second method developed in just the opposite direction. Instead of learning the names of letters, the sounds of the letters were taught. This was known as the phonetic method. Because some English letters have two or more sounds, a great deal more drill was required to learn all the combinations than was necessary in learning the names of the letters. However, the advantage of the phonetic method was that words could be built or dissected if the proper sounds were known. Several highly formalized phonetic systems were devised and used extensively.

Oral reading predominated during the early periods. Books were scarce and expensive, so reading was shared by many through listening. Early in the 20th century, scientific studies revealed that the processes of oral and silent reading were different. In the meantime, many educators criticized mord calling which was done without a knowledge of the meanings expressed. Beginning about 1920, emphasis was placed on silent reading and oral reading was not considered important. Standardized tests of reading had been devised and were used to appraise growth in reading by different methods. Furthermore, studies of learning revealed that young children tend to grasp ideas or units as a whole and later to identify the elements composing the unit. Based on this concept, a different method became prevalent.

The experience method begins when all of the pupils have an experience which is interesting and exciting to them. For example, they may visit a farm or a park or a zoo. Then, as the children talk about this experience, the teacher prints their story on the blackboard. Pupils take turns in reading back to the class the story they have composed. Thus. meaning is emphasized to a greater extent, and the words are viewed as carriers of meaning. Additional experiences use many of the same words and some new ones. Gradually, the sentences are divided into phrases, and finally nords per se are identified. After a sufficient number of words are learned in this fashion, children begin to read simple books called preprimers. New words are learned and pupils read their primers, first readers, etc. Subsequently, pupils are introduced to the most common sounds of the letters by being shown the similarity of familiar words which begin and end alike. In later stages, emphasis is placed on the phonetic elements and their application. The pupil is taught to guess what a new word might be to make sense in the story and then to check the sounds to be sure that he has identified the correct word. The names of the letters are learned in connection with spelling, and the order of the alphabet is learned when pupils must use the dictionary.

The experience method seems to appeal to children and most of them learn rapidly as soon as they are ready for this stage. If progress is not satisfactory, teachers may place greater emphasis on visual, auditory or kinesthetic clues to words. The first reading experiences are oral but silent reading is taught as soon as possible.

Recognition of words is basic to the other skills in reading, but it is useless unless the meanings of words are known. Thus in effective teaching word meanings, often called vocabulary, are taught throughout school. Not only in the reading period is this true. but teachers of all subjects in which reading is used teach the meanings of unfamiliar words. Best results are achieved when children and young people have direct rather than incidental instruction in word meanings. However, independence must be developed as pupils progress in school so that they may continue to expand their reading vocabularies throughout life.

Comprehension and interpretation of printed and written materials are taught from the early school levels on through high school, and sometimes in college. At first the materials used are simple and within the realm of experience of the pupils. Gradually, the materials become more difficult, less familiar and even abstract. A variety of adaptations must be made. For example, in literature a student may read one selection to get the general idea; another to sense the mood and tone of the author; another to study the characters and plot; and poetry may be read orally for the beauty of the language. Thus, comprehension and interpretation may include reading to get the main idea, details, to follow directions, to arrive at conclusions, to interpret the author's ideas and feelings, to evaluate for accuracy or bias or for the appreciation of the literary expression and content.

As word recognition, word meanings and comprehension improve, rate of reading usually increases accordingly. The first-grade pupil reads silently and orally at about the same rate. By third grade the average pupil begins to read silently at a rate more rapid than when he reads orally. Rate of reading for the mature adult should vary with the difficulty of the material and the purpose for reading it. For example, a person might read a novel for sheer pleasure at 300 words per minute. The same person might read an article dealing with politics at 200 words per minute. A technical article on the atom bomb might be read at 100 words per minute. Thus, the mature reader has many reading rates.

Teachers encourage pupils to read large amounts of materials of interest to them and at an appropriate level of difficulty. Thus, children learn to read widely for information, to solve problems and for pleasure. At the upper school levels, young people are guided by teachers and librarians to better literature and to sources designed to help them solve their personal and social problems'. It is the aim of schools and colleges to develop refined reading tastes and permanent reading interests.

Reading Interests. — Many studies of reading interests have been made of school children, young people and adults. The results show certain trends. In the primary grades, children are usually interested in familiar experiences and enjoy stories about other children of their ages and about animals. They prefer narrative to other types of materials.

In the preadolescent period, the majority of boys exhibit an interest in adventure, descriptions of "how-to-do-it," hero worship, hobbies and science. At the same period. girls' interests turn toward home and family life and fantasy and some interest is shown in adventure. It is significant that girls will often choose boys' books while boys do not like girls' books. Near the end of this period most pupils do more free reading than at any time in their school careers.

Adolescent boys are interested in reading about mysteries, sports and recreational activities. On the other hand, girls frequently turn to romance and stories of teen-age problems. The reading interests of adults are varied and complex. Douglas Waples and Ralph W. Tyler concluded that "international attitudes and problems" and "personal hygiene" were the only two

topics of interest to all the groups they studied. Otherwise, the reading interests of adults vary with sex, years of schooling, occupation, age and environment. Ease of securing reading materials is also related to interests. Newspapers and magazines are read more frequently than books.

Effects **of** Reading. — The emphasis on teaching and use of reading reflects the confidence that reading contributes to personal and social development, either positively or negatively. The widespread concern about reading crime and thrill comic books about the middle of the 20th century bears witness to the negative effects assigned to reading. On the positive side, studies summarized by William S. Gray revealed that reading influences the extent and accuracy of information, the attitudes, morale, beliefs, judgments and actions of readers.

Bibliotherapy, which is the personal interaction between the reader and literature, has been shown to be one method of therapy for some maladjusted persons. Librarians report progress in the adjustment of young people when books dealing with adolescent tasks are read and discussed.

Propaganda in reading materials has been shown to be an effective tool unless people learn to think critically about what they read and to evaluate sources carefully.

Reading Retardation. — Some pupils who grow physically and mentally at the same rate as their age mates make little or no progress in learning to read. Others move through one or more stages of growth and do not progress to the next stage. Such persons are known as retarded readers. Causes for reading retardation include visual difficulties, emotional disturbances, home and family problems, school methods improperly adapted to individuals and, in a few instances, other factors, according to Helen M. Robinson. In most cases, an examination of the retarded reader by a reading specialist results in charting a course for correcting the difficulty. Reading clinics or centres are staffed by persons especially qualified to prescribe and carry out the kind of instruction which results in adequate reading progress. In general, the methods are similar to those used to teach all children, but special adaptations are made for each learner.

Retarded readers are found in elementary schools, high schools, colleges and in adult life. While most of them are retarded in all aspects of reading, some have deficiencies in specific areas such as comprehension or rate of reading.

About the middle 1930s Guy T. Buswell and others demonstrated that many adults could increase their rates of reading without loss of comprehension. A widespread interest in rate improvement followed. Several manufacturers made instruments designed to increase reading rate. Practice has shown the value of the instruments when used wisely with the proper persons.

It seems quite likely that most adults can learn to read better and more rapidly if they want to do so. Reading is best improved by motivated practice with a purpose in mind and a strong desire to secure the information available on the printed page. There is no substitute for a teacher and for books.

REAGAN, JOHN HENNINGER (1818–1905), U.S. politician, a member of the cabinet of the Confederate States of America and an advocate of conciliation in the post-Civil War period, was born in Sevier county, Tenn., on Oct. 8, 1818. He moved to Texas in 1839, was admitted to the bar in 1846, and in 1857–61 was a representative in congress. In 1861 he was appointed postmaster general in Pres. Jefferson Davis' cabinet and served in this capacity throughout the Civil War. Captured with the Davis party on May 10, 1865, he was imprisoned in Ft. Warren, Boston harbour, until the following October.

While in prison he wrote the "Fort Warren letter" (Aug. 11), in which he urged the people of Texas to recognize their defeat, grant civil rights to the freedmen and try to conciliate the North. From 1875 to 1887, when he entered the U.S. senate, he was again a representative in congress. In 1891, believing that his first duty was to his state, he resigned from the senate to accept the chairmanship of the newly established state railway commission. He retired from public service in 1901 and died at Palestine, Tex., on March 6, 1905.

REALGAR, a mineral species consisting of arsenic monosulfide and occurring as crystals of a bright red colour. usually occurs with ores of silver and lead in mineral veins. Realgar has been produced commercially in Europe and Asia and has been mined in small quantities in the United States. It has been used as a paint pigment and as a depilatory in tanning and for producing a brilliant white fire in pyrotechnics, but has largely been replaced by artificially prepared arsenic sulfide. The composition is AsS. It crystallizes in the monoclinic system and there is a perfect cleavage parallel to the plane of symmetry; hardness is 1.5–2, specific gravity 3.55. On exposure to light the crystals crumble to a yellow powder. The other native arsenic sulfide, As_2S_3, is known as orpiment (*q.v.*). (L. J. s.; X.)

REALISM (Latin res, "a thing"), a term used in several senses in various disciplines.

In metaphysics realism has two quite distinct meanings. First, in the history of scholasticism, it is used to designate the doctrine that universals (see UNIVERSAL) have real existence: extreme realism in this sense maintained that universals, such as goodness, justice, roundness, redness, humanity and so on, exist independently of the particular objects in which they are perceived, and that these objects are real only in so far as they participate in the universal; moderate or mitigated realism maintained that the universals really exist *in* the particular things in which they are perceived by the mind as forming their common nature. Conceptualism (*q.v.*), on the other hand, maintained that universals exist only in the mind, whereas nominalism (*q.v.*), in its extreme form, would deny universals altogether. The second metaphysical use of the term realism is to designate the contention that the objects of sense perception have real existence outside the perceiving mind, as opposed to idealism (*q.v.*). (See further KNOWLEDGE, THEORY OF.)

In ethics, realism is occasionally used to mean conduct based on considerations of practical advantage, without regard for ideal goodness or equity.

In literature, the term realism may be loosely applied to any writing that seeks to portray life exactly as it is (or, in histories and historical novels, is believed to have been), without embellishment or idealization. In a more restricted sense, it is applied to the style of such novelists as Gustave Flaubert (*q.v.;* and see NOVEL), in opposition both to romanticism and to naturalism; the latter tended eventually to emphasize the more sordid aspects of life that the realists had not gone out of their way to stress. See also Index references under "Realism" in vol. 24.

RÉAUMUR, RENÉ ANTOINE FERCHAULT DE (1683–1757), French scientist who devised the Réaumur thermometric scale, was born on Feb. 28, 1683, at La Rochelle. In 1710 he was charged with the official description of the useful arts and manufactures of France, which led him to many practical researches. He examined and reported on the auriferous rivers, the turquoise mines, the forests and the fossil beds of France; devised a method of tinning iron and investigated the chemical composition of Chinese porcelain and the chemical differences between iron and steel.

Réaumur's thermometric scale (1730) was constructed on the principle of taking the freezing point of water as 0°, and graduating the tube of the thermometer into degrees each of which was one-thousandth of the volume contained by the bulb and tube up to the zero mark. It was an accident dependent on the coefficient

of expansion of the particular quality of alcohol employed which made the boiling point of water 80° R.; and mercurial thermometers the stems of ahich are graduated into 80 equal parts between the freezing and boiling points of water are Réaumur thermometers in name only. Réaumur wrote widely on natural history (see ENTOMOLOGY: *History* of *Entomology*), his best-known work on this subject being the *Mémoires pour* servir *à l'histoire* des insectes (6 vol., 1734–42). He died at La Bermondière, Maine, on Oct. 18, 1757.

REBATES, DEFERRED. A deferred rebate is a discount on the invoice price returned after a lapse of time to a trader, on certain conditions, as a means of maintaining monopoly and keeping out would-be competitors from the trade. In Great Britain the system consists in returning to the trader (merchant or retailer) at the end of every 6 or 12 months a rebate equal to perhaps 10% or 15% on his purchases, on condition that he shall not, during the period. have sold, displayed (or, it may be, offered) any of the kind of goods produced by the combination except those made by the combination. (J. H.; X.)

REBEC (REBECK), a medieval stringed instrument played with a bow, derived from the Oriental rebab, and sometimes regarded as the ancestor of the viol and violin. Like the rebab, the rebec assumed at first one of two forms—the pear-shaped body with a wide base, strung with three strings, or the long, narrow pear- or boat-shaped body with two strings and, in addition, the other oriental characteristics of the rebab, *i.e.,* the vaulted back, the absence of ribs, and pegs set in the back of the head. Except for the addition of a finger board. what is now recognized as the rebec underwent no structural development and never entered the domain of art, despite the wide favour which it enjoyed throughout the middle ages.

REBECCA RIOTS, the name given to some disturbances which occurred in 1843 in south Wales. The rioting was directed against the charges at the tollgates on the public roads, and the rioters took as their motto the words in Gen. xxiv, 60, "And they blessed Rebekah, and said to her, 'Our sister, be the mother of thousands of ten thousands; and may your descendants possess the gate of those who hate them!' " Many of the rioters were disguised as women and were on horseback; each band was led by a captain called "Rebecca," his followers being known as "her daughters." They destroyed not only the gates but also the tollhouses, the work being carried out suddenly and at night, but usually without violence to the tollkeepers, who were allowed to depart with their belongings. Emboldened by success, the Rebeccaites turned their attention to other grievances. The government dispatched soldiers and police to south Wales, and the disorder was auelled. South Wales was relieved from the burden of tollgates, while the few rioters who were captured were only lightly punished. The movement was separate from Chartism (*q.v.*), but was supported by the same class and arose from the same economic causes.

REBELLION, armed resistance for political purposes by nationals of a state against the government, usually resulting in insurrection, civil war or revolution. In lam, rebellion is the act of one who engages in such resistance and is therefore subject to prosecution for treason, sedition or rebellion. In British history, for example, supporters of the Old Pretender in 1715 and of the Young Pretender in 1745 were punished as rebels. In the U.S. Civil War the federal government regarded the Confederates as rebels although they had been recognized as belligerents by neutral states. A general amnesty after the war terminated prosecution against the leaders. In the South African war of 1899–1902 the supreme court of the Cape of Good Hope held that those who joined the burgher forces were liable for treason, although the burghers had been recognized as belligerents (Rex *v.* Louw, 21 C.G.H. Supreme Court Rep. 36, 1905). See TREASON; SEDITION.

For historic rebellions see titles of specific rebellions. For the status of rebellion in international law see BELLIGERENCY and INSURGENCY. For the usual justifications for rebellion, see DEMOCRACY; HUMAN RIGHTS; IMPERIALISM; NATIONALISM; SELF-DETERMINATION. (Q. W.)

REBIKOV, VLADIMIR (1866–1920), Russian composer, was born at Krasnoyarsk in 1866, and studied in Moscow. Berlin and Vienna. He then went to live at Odessa, where, in 1894, his first opera. The Thunderstorm, was produced. Other dramatic works are Tlze Christmas Tree (1903); Narcissus, Tlze Fables of *Krylov* (his best-known work); Przнce *Charming,* a fairy opera; and the pantomime *Snow-White* (1909). He also wrote suites for pianoforte, including the *Mélomimiques,* and mimetic vocal pieces. His music makes no appeal to the popular mind, and is difficult to grasp because of its harshness and lack of form. Rebikov's literary work includes a translation of Gevaert's *Traité d'Instrumentation* (1899) and La *musique* de 1960.

REBUS. A simple rebus is the representation of a word or part of a nord by a picture of a thing with a similar name. Several may be combined—in a single device. or successively—to make a phrase or sentence. Literary rebuses use letters, numbers, musical notes or specially placed uords to make sentences. Complex rebuses combine pictures and letters. As a means of communication, rebuses may convey direct meanings, especially to inform or instruct illiterate people; or they may deliberately conceal meanings to inform only the initiated or to puzzle and amuse.

An early form of rebus occurs in semiprimitive picture writings, where abstract words, difficult to portray. were represented by borrowing pictures of objects pronounced the same way. These are common in Egyptian hieroglyphs and early Chinese pictographs. Rebus pictures were used to convey names of to ns on Greek and Roman coins, or names of families in medieval heraldry (in the so-called canting arms). and they have often been used for instructional symbols in religious art and architecture. In the far east, especially in China and Korea, rebus symbols were commonly employed to carry auspicious wishes. Rebusmaking was long considered a specialty of Picardy, in France.

Elsewhere in Europe literary rebuses often appeared on family mottoes, personal seals, ciphers and bookplates and ultimately in games or riddles. A familiar English rebus is the debtor's I O U, for "I owe you."

Popular in the United States since the mid-19th century were rebus picture puzzles in which the indicated addition or subtraction of letters in illustrated words produced another word or a name. Hundreds of these were devised by the puzzlemaking genius Sam Loyd. Such picture riddles have been widely used in U.S. advertising, and, beginning in the 1930s, sequences of them were presented in newspaper contests designed to attract readers. Huge prizes were offered but the final problems were so difficult that only groups of experts could solve them. Attempts at solution became a nation-wide hobby in which hopes for material gain were usually disappointed, but many persons were led to further interest in self-education and research.

(S. V. R. C.)

RECALL, a device, principally used in the United States, by which voters may remove a public official from office before the expiration of his regular term. Recall is based upon the principle that officials are mere agents of the popular will, and as such should be constantly subject to its control (see REPRESENTATION). Under the plan, if a specified percentage of the electorate are dissatisfied uith an official's conduct and sign a petition for his removal, the officer must face a general election to determine the majority opinion.

Though the general principle of the recall is simple, there are many variations in its practical application. Under some plans the question of removal may be decided in one election, and the question of a successor in a subsequent election, but for economy's sake the two are often combined in one election. The vote required to remove an official is usually a simple majority of those voting. The percentage of signatures required to force an election ranges widely, the average being about 25% of those who participated in the last general election in that electoral district. An officer elected at a recall election serves out the unexpired portion of the term of the office.

The recall is, in fact, infrequently resorted to and then almost

entirely for local officers. The recall found state-wide application in North Dakota in 1921 when the governor, attorney general and commissioner of agriculture were removed. At mid-20th century only a few instances of its being applied to judges were on record, all of them in minor courts. In its state-wide application it becomes too cumbersome to be resorted to frequently.

Recall originated in Switzerland where it was made applicable not only to individuals but to the entire legislature. It was suggested in the American Articles of Confederation and discussed in the Constitutional Convention of 1787, but its first practical application in the U.S. was in 1903 in the Los Angeles, Calif., city charter. It was soon adopted by many cities with the commission form of government as the most effective way to control the commissioners in whose hands large powers were placed. It was subsequently adopted in the following states: Oregon (1908), California (1911), Arizona, Idaho, Washington, Colorado and Nevada (1912), Michigan (1913) and Louisiana, North Dakota and Kansas (1914). Most of these states had many elective officers not subject to removal by the governor who were, in effect, beyond administrative control during their terms of office.

The term was also applied in the early 20th century to various proposed restraints on the judiciary. Under the slogan "recall of judicial decisions," the Progressive party under the leadership of former Pres. Theodore Roosevelt in 1912 advocated that "when an act, passed under the police power of the State, is held unconstitutional under the State Constitution, by the courts, the people . . . shall have an opportunity to vote on the question whether they desire the Act to become law, notwithstanding such decision." The 1912 proposal was not adopted, and in some states (Idaho, Louisiana, Michigan and Washington) the recall was not made applicable to judges on the ground that the judiciary should be independent of popular passions and political pressures.

A general increase in the size of electorates, plus a greater demonstration of responsibility on the part of executives and legislative bodies alike in the second half of the 20th century, tended to diminish use of the recall. Its effectiveness is perhaps not to be measured by its use, but by the restraining influence it may exercise. See also REFERENDUM AND INITIATIVE.

RÉCAMIER, JEANNE FRANÇOISE JULIE ADÉLAÏDE (1777–1849), a famous Frenchwoman in the literary and political circles of the early 19th century, was born on Dec 4, 1777, at Lyons. Her maiden name was Bernard. She was married at 15 to the banker Jacques Récamier (d. 1830), who was more than old enough to be her father. From the early days of the consulate to almost the end of the July monarchy her salon in Paris was one of the chief resorts of literary and political society that pretended to fashion. The habitués of her house included many former royalists, with others, such as Bemadotte and General Moreau, more or less disaffected to the government. Through her friend Madame de Stael, Madame Récamier became acquainted with Benjamin Constant (*q.v.*). She was eventually exiled from Paris by Napoleon's orders. After a short stay at Lyons she proceeded to Rome, and finally to Naples, where she was on good terms with Murat and his wife, who were then intriguing with the Bourbons. She persuaded Constant to plead the claims of Murat in a memorandum addressed to the congress of Vienna, and also induced him definitely to oppose Napoleon during the Hundred Days. Her husband had sustained heavy losses in 1805, and she visited Madame de Stael at Coppet in Switzerland. In her later days she lost most of the rest of her fortune; but she continued to receive visitors at the Abbaye-aux-Bois, the old Paris convent to which she retired in 1814. There Chateaubriand was a constant visitor, and in a manner master of the house; but even in old age, ill-health and reduced circumstances Madame Récamier never lost her attraction. She numbered among her admirers Mathieu de Montmorency, Lucien Bonaparte, Prince Augustus of Prussia, Ballanche, J. J. Ampère and Constant, but none of them obtained over her so great an influence as did Chateaubriand, though she suffered much from his imperious temper. Her sincerest affection seems to have been for Prosper de Barante, whom she met at Coppet. She died in Paris on May 11, 1849.

RECEIVER, in English and U.S. law, a person appointed by a court to collect and conserve assets and income, making disbursements only as authorized by the court. He may or may not be entrusted with the active carrying on of a business. Receivers were traditionally appointed by courts of chancery in Great Britain. The Judicature act of 1873, however, conferred power to appoint receivers upon all divisions of the high court. In the United States receivers may be appointed by any court of general equity jurisdiction. State statutes have contributed to the development of the law of receiverships in various types of cases.

In theory a receivership is properly only incidental to the realization of another primary objective and is not recognized as an independent object of litigation. A receiver may be appropriate whenever the court finds a need to conserve property or to distribute funds in litigation. The receiver is deemed an "arm of the court," and the property which he takes into possession is said to come into the custody of the court. Unlike a trustee in bankruptcy in the U.S., he is not deemed to take "legal title."

Typically receivers are appointed on special or general creditors' bills. A court of equity, discharging a long recognized duty to furnish an effective remedy when the remedy at law is inadequate, will entertain a special creditor's bill to reach intangible or concealed property beyond the reach of execution or other legal process and to apply the proceeds to the complainant's claim. A general creditors' bill is particularly appropriate when a creditor can show the need for appointing a receiver to avert the liquidation of a going business enterprise with threatened loss to all concerned. An ensuing general equity receivership may lead to the reorganization of a business association. The receiver may be authorized to conduct the business during the litigation in hopes of effectuating a sale of the business as a going concern. The purchaser may be a business association, frequently a new corporation in which creditors and sometimes former proprietors have interests represented by new securities distributed under a plan of reorganization which has been negotiated by the parties and approved by the court. In the last third of the 19th century, a procedure for reorganizing insolvent railroad corporations was developed in the United States, substantially without statutory authorization, under the description of the "federal equity consent receivership." Certain United States district judges became expert in resuscitating insolvent railroad corporations. A few unsecured creditors of a failing railroad, citizens of some state or states other than that in which the railroad was incorporated, would file a general creditors' bill, showing the need of conserving the liquid assets of the road. A federal court would then have jurisdiction of the proceeding by reason of diversity of citizenship of the parties. Collusive proceedings were entertained in order to keep the railroad running under the protection of a federal court. A plan of reorganization could be negotiated, approved by the court and consummated through judicial sale, typically by the issuance of securities of a new corporation with a revised capital structure.

The equity receivership practice was elaborated and partly codified and reformed by sec. 77, added in 1933 to the U.S. Bankruptcy act of 1898. Initial experience with this statute led to substantial amendments in 1935. The court administers the property through an official called a trustee, but he has the powers of an equity receiver, as well as "legal title" as a statutory successor to the debtor, a concept developed with reference to trustees in strict bankruptcy.

Industrial and mercantile corporations may be reorganized under Chapter X of the Bankruptcy act. Statutory provisions for the intervention of the plans of reorganization make Chapter X proceedings elaborate and expensive affairs, transcending but still largely founded upon equity receivership practice.

In strict bankruptcy in the U.S., the receiver is merely a temporary conservator appointed when needed to serve until the trustee to liquidate the property can be elected by creditors. In Eng-

land, however, permanent officials designated receivers administer bankrupt estates, but they proceed more in the tradition of bankruptcy liquidation than that of receivers in chancery. The official receiver may take charge of the affairs of a company in compulsory winding up proceedings. Creditors or stockholders may. however, nominate liquidators other than the official receiver.

See also BANKRUPTCY. (J. A. MACL.)

English Practice.— In English law there is a clear distinction between a receiver appointed under an instrument (such as a debenture) and a receiver appointed by order of a court. The powers of a receiver appointed under an instrument depend upon the terms of that instrument and upon the general law of agency. Receivers appointed by a court are generally appointed under section 45 of the Judicature act, 1925. A court has power to appoint a receiver whenever this appears just and convenient, and the typical reason for such appointment is the protection of property for the benefit of interested persons as, for example, pending the trial of an action. Although all divisions of the high court, besides the court of appeal, have power to appoint a receiver, the chancery division most frequently does so. An appointment is as a rule only made in the queen's bench division by way of equitable execution. .Applications should be made in the probate, divorce and admiralty division when, for example, proceedings are pending to determine who shall administer a deceased person's estate, or when a wife entitled to alimony needs a receiver of her husband's interest under a settlement. Normally the court can only appoint a receiver when litigation is in process.

In English practice a named person is often made receiver .on the motion for an appointment, but if there is any difficulty or dispute the matter is referred to chambers. The court or the court of appeal will not interfere with the master's discretion in appointing unless he makes a mistake in principle. (W. T. Ws.)

RECHABITES (SONS OF RECHAB), a sort of religious order among the Israelites, analogous to the Nazirites (*q.v.*), with whom they shared the rule of abstinence from wine. They eschewed settled life and lived in tents, refusing to sow grain or to plant vineyards.

The Rechabites represented a protest against the contemporary civilization and a reaction toward simplicity of life. Their "father." or founder. was that Jehonadab (or Jonadab), son of Rechab. who encouraged Jehu to abolish the Tyrian Baal worship.

The "house of Rechab" fled for protection into Jerusalem at the approach of Nebuchadrezzar (Jer. xxxv), and Jeremiah promised them, as a reward of their adherence to the ordinance of Jehonadab. that they should never lack a man to represent them (as a priest) before Yahweh. Later Jewish tradition states that the Rechabites intermarried with the Levites.

RECHBERG-ROTHENLÖWEN, JOHANN BERNHARD, COUNT (1806–1899), Austrian statesman, was the second son of the Bavarian statesman Count Aloys von Rechberg-Rothenlöwen (1766–1839). Johann Bernhard was destined for the Bavarian public service, and he was educated at the universities of Strasbourg and Munich, but incurred the displeasure of King Louis I by the part he played as second in a duel, and in 1828 transferred to the Austrian diplomatic service. After being attached to embassies in Berlin, London and Brussels, he became envoy at Stockholm (1841) and at Rio de Janeiro (1843).

Returning to Europe in 1847, on the outbreak of the revolution of 1848 in Vienna he accompanied and assisted Prince Metternich in his flight to England. In July 1848 he was appointed Austrian plenipotentiary in the German federal diet at Frankfurt; in 1851 he became Austrian *internuncius* at Constantinople, and in 1853 Radetzky's civilian colleague in the government of Lombardo-Venetia.

In 1855 he returned to Frankfurt as Austrian representative and president of the federal diet. There his constant disputes with Bismarck, at that time Prussian envoy at the diet, were much sharpened by Rechberg's choleric temper, and on one occasion nearly led to a duel. Bismarck, however, always expressed a high appreciation of his character and abilities. In May 1859, on the eve of the war with Italy, he was appointed Austrian minister of foreign affairs and minister president, surrendering the latter post to the archduke Rainer the next year.

The five years during which Rechberg held the portfolio of foreign affairs covered the war with Italy and France, the insurrection in Poland, the attempted reform of the German confederation through the Frankfurt *fürstentag* and the Austro-Prussian war with Denmark. (See AUSTRIA, EMPIRE OF; EUROPE.)

Concerning the German question Rechberg's policy was one of compromise, and he generally advocated peaceful arrangement between Prussia and Austria as the indispensable preliminary to a reform of the confederation. In the Schleswig-Holstein question he was, however, consistently outwitted by Bismarck, and on Oct 27, 1864. Rechberg resigned He received the Golden Fleece from the emperor as a sign of special favour. He had been made a hereditary member of the upper house of the reichsrat in 1861, and as late as 1879 continued occasionally to take part in debates. Rechberg died near Vienna on Feb. 26, 1899.

RECIDIVISM. The term recidivism refers to chronic criminal behaviour which results in numerous arrests and incarcerations. Studies of the yearly intake of prisons, reformatories and jails in the United States show that from one-half to two-thirds of those imprisoned have served previous sentences in the same or other institutions. Statistics from European penal institutions come to a similar conclusion. This fact reveals two important facets of the crime problem: one is that the criminal population is made up largely of those for whom criminal behaviour has become habitual, or a way of life; the other indication is that penal institutions do little to change the basic behaviour patterns of their inmates.

Though the percentage of recidivists runs high for both felons and misdemeanants, for the latter group it is far greater. A veritable army of petty offenders appear as repeaters in courts of minor jurisdiction on charges of vagrancy, drunkenness, prostitution. disturbing the peace and other minor offenses. The short jail sentences they receive do nothing toward rehabilitation.

The most extensive and reliable studies of persistent criminal behaviour have been made by Sheldon and Eleanor T. Glueck in a series of research monographs of which the first was Five Hundred Criminal Careers (1930). These studies revealed the factors in the life situation of recidivists which differentiate them from other prisoners who make a good adjustment after their release from custody

Among the factors that are more prevalent with the recidivists are poor family situations, broken homes, mothers working outside the home, early onset of delinquency, truancy, poor economic status and adjustment, improper use of leisure and mental deficiency or other personality disorders. Similar factors abound among those offenders aho fail to succeed on probation or parole.

It is certain that longer sentences and existing penal methods are no solution to the problem of the chronic offender. Two improvements on current practice would seem to be necessary: one, the adoption of really indeterminate sentences that would enable authorities to keep recidivists in custody until their attitudes change for the better; another essential would be the equipment of penal institutions with personnel and facilities for more thoroughgoing work of rehabilitation. See also HABITUAL OFFENDERS; PRISON; PROBATION.

RECIFE or PERNAMBUCO, a city and seaport of Brazil, capital of the state of Pernambuco. Pop. (1956 est.) 673,821, largely Negro and mulatto.

Located at the mouth of the Capiberibe river near the easternmost point of South America, the city is comprised of four separate parts (Recife, Santo Antonio, São José and Boa Vista) uhich are integrated by many bridges. Because of its numerous waterways the city is often referred to as the "Venice of America."

The district of Recife occupies the southern end of the Olinda peninsula and is the principal commercial centre of the city. In addition to warehouses and terminal facilities, there are the cus-

tomhouse, observatory, naval arsenal, government offices, several of the consulates and many of the more important banks, business houses and retail stores.

Santo Antonio is located on an island of the same name. Among the important institutions and public buildings in this part of the city are the government palace, the state treasury, the courthouse, the state museum, public library, several fine churches, including the city's famous church of São Francisco de Assís, the Santa Isabel theatre and many historic landmarks, including the Dutch fort of Cinco Pontas.

São José embraces a large district on the mainland and is chiefly residential. In this section of the city is Restoration square, which commemorates the end of Dutch domination.

Boa Vista, also on the mainland, is both a commercial and residential district and contains many of the educational institutions of Recife, including a normal school and schools of law, medicine, engineering, commerce and fine arts.

The hot, humid climate is mitigated somewhat by the southeast trade winds. July, the coolest month, has a mean temperature of 77°, whereas from December through March it is 82°. The total annual rainfall is 65 in., more than 80% of which falls from March through August.

The port of Recife is one of the most important of Brazil because of its proximity to Europe and its convenience for vessels passing around the east shoulder of the continent. Its harbour consists of a narrow body of water, about 2 mi. in length, which is sheltered on the east by a reef and breakwater. The latter extends about 3,600 ft. in a north and northeasterly direction from the reef—an ancient beach of firmly consolidated materials. A second breakwater (Olinda Mole), about 2,500 ft. in length, runs in a southeasterly direction from the mainland and forms the other wing of the entrance channel. The distance between the heads of these two breakwaters is about 900 ft. The northern part of the harbour is approximately 1,600 ft. in width and has been dredged to a low water depth of 32 ft. The southern part is considerably smaller and has been dredged to a depth of 25 ft. The quay is along the eastern margin of the peninsular district of Recife. The port is equipped with a modern coaling plant and grain conveyor, a sugar conveyor and more than 50 electric and steam cranes. Three sets of tracks, which connect with the Great Western of Brazil railway, serve the wharf and warehouses. There are several concrete warehouses, a cold storage warehouse, a warehouse for commodities which create a public hazard and tanks for petroleum products and alcohol. The terminal facilities are operated by a state *directoria* under the authority of the federal government. The principal imports of Recife are coal, petroleum and wheat. Exports consist largely of sugar, cotton and other agricultural products.

More than 1,600 mi. of railways serve the states of Pernambuco, Alagoas, Paraiba and Rio Grande do Norte, having outlet through Recife, and a well-developed system of surfaced roads provides additional transportation facilities. The city is served by several national and European air lines, has national and international cable connections and radio, telegraph and telephone communications.

Recife was settled about 1535, when Duarte Coelho Pereira landed there to take possession of the captaincy granted him by the Portuguese crown. The site of Coelho's capital was Olinda, but Recife remained its port and did not become an independent *villa* (town) until 1709.

Down to the close of the 18th century, when Rio de Janeiro became important, Recife was the second city of Brazil and for a time its most important port. It mas captured and plundered in 1595 by the English privateer James Lancaster. It was also captured by the Dutch in 1630 and remained in their possession till 1654, during which time the island of Santo Antonio was occupied and the town greatly improved. At the end of the Dutch war the capital was removed from Olinda to Recife, where it has since remained. (R. E. P.)

RECIPROCATING ENGINE: *see* STEAM; INTERNAL-COMBUSTION ENGINES.

RECIPROCITY, the condition or state of being reciprocal, *i.e.*, where there is give and take, mutual influence, or correspondence between two parties, persons or things (Lat. *reciprocus,* "returning back the same way," "alternating," probably from re "back" and *pro* "forward"). In a more particular sense, reciprocity refers to the commercial policy under which a country grants special tariff advantages to imports of another country in return for special tariff advantages granted to it by the other country. In American usage the terms "reciprocity" and "reciprocity agreements" have acquired a highly specialized meaning as a result of the tariff policy formerly pursued by the United States, particularly under the tariff acts of 1890 and 1897, in the negotiation of tariff agreements with other countries. In this specialized sense, a reciprocity agreement is one in which the contracting states grant to each other particular tariff concessions, in return for particular tariff concessions, without the intention or expectation that these concessions will be generalized, *i.e.*, extended to third countries. Reciprocity agreements are to be distinguished from reciprocal trade agreements concluded by the United States since 1934, in which the tariff reductions made by the United States (except in the Cuban agreement) have been generalized to all countries except those found to be discriminating against American trade. (H. F. G.)

RECKLINGHAUSEN, FRIEDRICH DANIEL VON (1833–1910), German pathologist, one of the numerous students of Rudolf Virchow, who contributed significantly in expanding the science of pathology carrying his researches into many fields. was born in Gütersloh, Westphalia, on Dec. 2, 1833. He received his degree in medicine at Berlin (1855) and spent the next six years as assistant to Virchow. This was the period of Germany's emergence as the centre of medical progress, marked by Virchow's *Cellular Pathology* (1858), which put forward the doctrine that formed the basis for modern knowledge of the nature of disease. Recklinghausen became professor of pathology at the University of Konigsberg in 1865, accepted the chair at Wiirzburg the following year and in 1872 became the first professor in that department at the University of Strasbourg.

Recklinghausen's name is familiar in medicine from the eponym associated with two diseases he described. Multiple neurofibromatosis, a condition in which there are numerous fibrous tumours of the skin distributed along the course of the cutaneous nerves, is called Recklinghausen's disease since his description of it in 1882. Similarly, Recklinghausen's disease of bone, a generalized fibrosis and cystic degeneration of the bony skeleton, now known to be caused by a hyperfunctioning tumour of the parathyroid gland, still bears his name. These are but a few of the many significant observations and discoveries made during his long career. He resigned his professorship at Strasbourg in 1906 and died on Aug. 26, 1910.

See H. Bailey and W. J. Bishop, *Notable Names in Medicine and Surgery (1959).* (L. M. Z.)

RECKLINGHAUSEN, a town in the province of North Rhine-Westphalia, Germany, 22 mi. N.W. of Dortmund. Pop. (1950) 104,791. The county of Recklinghausen belonged to the archbishopric of Cologne until 1803, when it passed to the duke of Arenberg. It was known as the West Recklinghausen. After 1815 the duke of Arenberg held it as a fief under Prussian sovereignty. In the neighbourhood of Recklinghausen are extensive coal-mines, iron and tin foundries and brick works, and the industries embrace the manufacture of linen, beer, spirits, cement, soap and ammonia.

RECLAMATION OF LAND: *see* LAND RECLAMATION.

RECLUS, ÉLISÉE (1830–1905), French geographer and anarchist who was awarded the gold medal of the Paris Geographical society in 1892 for *La Nouvelle Géographie universelle,* was born the second son of a Protestant pastor on March 15, 1830, at Sainte-Foy-la-Grande (Gironde). He was educated at the Protestant college of Montauban and studied geography under Karl Ritter in Berlin. Having identified himself with the republicans of 1848, he was obliged to leave France after the *coup d'état* of Dec. 1851. He spent the years 1852–57 visiting the British Isles, the United States, Central America and Colombia. Returning to France, he applied himself to geography, publishing La *Terre,*

description des phénomènes de la vie du globe, 2 vol. (1867–68; Eng trans . 4 vol., 1871–73) and *Histoire d'un ruisseau* (1869). During the siege of Paris (1870–71) he participated in A. Nadar's balloon ascents. Serving in the national guard in defense of the commune, he was taken prisoner in April 1871; but his sentence of transportation for life was commuted in Jan. 1872 to one of perpetual banishment after European scientists had appealed to the government on his behalf. After a visit to Italy, he settled at Clarens, Switz.

His great work, *La Nouvelle Géographie universelle, la terre et les hommes,* 19 vol (1875–94; Eng. trans.. *The Earth and Its Inhabitants,* 1878–94), is a stupendous compilation, profusely illustrated with maps, plans and engravings and characterized by the accuracy and brilliance of exposition that give his work permanent scientific value. His *Histoire d'une montagne* was published in 1880. Though benefiting under the amnesty of 1879, Reclus had meanwhile lost none of his revolutionary enthusiasm; and in 1882 he initiated the Anti-Marriage movement, in accordance with which he allowed his two daughters to marry without civil or religious sanction. When proceedings were instituted at Lyons against the International Workingmen's association, P. A. Kropotkin (*q.v.*) and Reclus were designated as leading promoters of anarchism; but Reclus. as domiciled in Switzerland, escaped imprisonment. In 1892 he was appointed professor of comparative geography in Brussels. He died at Thourout, near Bruges, on July 4, 1905. His other works include *L'Homme et la terre,* 6 vol. (1905–08) and several anarchist pamphlets.

RECOGNITION, DIPLOMATIC. This term may refer either to the procedure by uhich a new state is formally accepted by other states as a member of the international community, or to the procedure by which a new government of an existing state is accepted as the legal representative of that state. The two procedures, although frequently confused. raise distinct legal questions. The recognition of a new state involves the sovereignty of the state and its independent position in relation to other states; the recognition of a new government merely involves the determination of the particular organized group that is to be accepted as having the right to speak in the name of the state, without raising any issue of the legal personality of the state.

While the term "recognition" has been applied to states already enjoying independent existence but not maintaining diplomatic relations with the western powers, as in the case of Ethiopia until its admission into the League of Nations in 1923, its more normal application is to colonies or dependencies that have declared their independence of the mother country and have proved their ability to maintain their separate existence, as in the case of the recognition by the United States of the Latin American states beginning in 1822. The provisions of the United Nations Charter concerning "the self determination of peoples" and the administration of "nonself-governing territories" support such recognitions.

On occasion, political motives have led to the recognition of a new state before it actually proved its ability to maintain its independence, as in the case of the recognition of the United States by France in 1778. Recognition by the Netherlands came in 1782 on the eve of the treaty of peace. After that treaty, the United States was in due time recognized by other states, as by Sweden, Spain and Prussia in 1783, by Portugal in 1794 and by Russia as late as 1809. Premature recognition has regularly been regarded as an offense that the mother country might resent, as Mexico resented the recognition of Texas by the United States in 1837 and Colombia, that of Panamá in 1903.

During the 19th century the great powers gave collective recognition to certain new states before they had as yet won their independence by arms, as when Greece was recognized in 1827, Belgium in 1831, and Rumania, Serbia and Montenegro in 1878. Since the close of World War I recognition has frequently been given by voluntary act of the mother country or more recently by collective act of the members of the United Nations. Great Britain, for example, recognized the independence of Ireland in 1920, of Egypt in 1922, and of India and Pakistan in 1947. Recognition by other states followed promptly. Indonesia was recognized by the Netherlands as independent in 1949, and Ghana and Malaya by Great Britain in 1957, followed by their admission to the UN. New African nations (the republics of Cameroun, Congo and Togo, Federation of Mali, Malagasy Republic, Somalia and Nigeria) received or awaited recognition in the early 1960s.

The "Stimson doctrine" declared by the United States secretary of state in 1932, and subsequently supported by the League of Nations. asserted that recognition should not be extended to new states or to territorial changes effected by illegal use of armed force. In accordance with this doctrine the United States and the members of the League of Nations refused to recognize the Japanese-supported state of "Manchoukuo" and the United States refused to recognize the Italian conquest of Ethiopia (1936) and the German conquest of Austria (1938).

In the case of new governments the procedure of recognition is applied only when an existing *de jure* government is overthrown by revolution and it becomes necessary for the governments of other states to decide whether the new government has the stability required to justify holding it responsible for the obligations of the state and is entitled in turn to claim the rights of the state. Recognition in such cases raises no question of the legal personality of the state or of its place in the community of nations. but merely the question whether a particular group can properly speak in the name of the state. Governments actually in power are described as *de facto* until such time as recognition by other states makes them *de jure.*

In addition to stability. the condition has frequently been put that the new government must not have been established by immoral behaviour, such as assassination, and must manifest an intention to observe the rules of international law. Such political or subjective conditions of recognition have given rise to numerous controversies and conflicting practices, the new government being recognized by some states and not by others. The United States, for example, refused to recognize the government of Gen. Victoriano Huerta established in Mexico by assassination of President Madero in 1913, and, until 1933, the Soviet government of Russia established by revolution in 1917. The U.S. also refused to recognize the Communist government of China established in 1949 and recognized by many states but continued to recognize the Nationalist government of China on the Island of Formosa. The U.S., however, promptly recognized the government of Iraq established by assassination of King Faisal II in 1958. During World War II the United States and Great Britain refused to recognize the governments of the countries occupied by the German armies and continued to recognize the refugee governments.

Efforts have been made to establish rules of international law on the subject of recognition in addition to the prohibitions of "premature recognition" and "non-recognition of the forces of aggression," but the political element of recognition has dominated and states have been unwilling to accept a collective decision applying law on a matter on mhich diametrically opposite points of view may be taken with respect to the conduct that may be expected of the new government.

(C. G. FE.)

RECOGNIZANCE, a term of common law usually employed to describe an obligation of record, entered into before some court or magistrate duly authorized, whereby the party bound acknowledges that he owes a personal debt to the Crown, with a defeasance, *i.e.,* subject to a condition that the obligation to pay shall be avoided if he shall do some particular act—as if he shall appear at the assizes, keep the peace, or the like. Recognizances are now used almost solely with reference to criminal proceedings. The security given by a receiver appointed by the High Court is still in the form of a recognizance acknowledging a debt to named officers of the court, and securing it on the real and personal estate of the receiver.

There is a general jurisdiction on conviction of misdemeanour both at common law and by statute to put the offender under recognizances to keep the peace and (or) be of good behaviour in addition to or in substitution for other punishment. On refusal

to enter into recognizances as above, the court may order imprisonment for the refusal, limited in cases within the Acts to 12 months, and in cases within the Act of 1879 to six months.

The recognizances above described may be described as a form of punishment or a judicial security for good conduct. Recognizances are, however, most used with reference to proceedings before conviction and judgment. In preliminary enquiries into indictable offences the enquiring justices take recognizances to ensure the attendance of the accused if liberated during any adjournment, and on committal for trial take the recognizances of the accused (if allowed bail) to attend the court of trial and take his trial, and of the prosecutor and the witnesses for the prosecution or defense to attend and prosecute or give evidence. Recognizances taken are returnable under penalty to the court of trial, which orders their estreat if the conditions are breached. Similar powers as to the recognizances of persons prosecuted summarily mere given by the Summary Jurisdiction acts, 1848 and 1879, amended by the Criminal Justice act, 1925.

By the Land Charges act, 1925, a recognizance, whether obtained or entered into on behalf of the crown or otherwise, did not operate as a charge on land or on any interest on land or on the unpaid purchase money for any land, unless a writ or order for the purpose of enforcing it was registered in the office of the land registry. This enactment was clearly applicable to receivers' recognizances; and on purchases of land search was made for registered recognizances and an official certificate could be obtained affirming or negativing the existence of a registered entry.

In the U.S.A., the states allow by either common law or statutes recognizances in much the same way as in England.

RECONNAISSANCE, a military term for reconnoitring or examination of an enemy's position or movements. A topographical reconnaissance is a survey of a tract of country or route by officers with small patrols, escorts or assistants. Strategical reconnaissance was formerly carried out by cavalry formations or squadrons. but it has now been taken over almost entirely by aircraft. Tactical reconnaissance falls to the lot of troops of all arms, whether in contact with the enemy or for self-protection. A reconnaissance by a large force of all arms with the idea of provoking an enemy into showing his hand, if necessary by fighting, is called a reconnaissance in force.

RECONSTRUCTION FINANCE CORPORATION. The Reconstruction Finance corporation in the United States was established by congress on Jan. 22. 1932, "to provide emergency financing facilities for financial institutions, to aid in financing agriculture, commerce and industry." After a few years of unprecedented depression and steady price declines, an institution was required which could pump dollars into financial institutions, railroads. etc., to enable them to meet their commitments. The RFC in turn was to obtain dollars from the federal government. In moderating the epidemic of bankruptcies in the 1930s, the RFC helped lay the groundwork of recovery.

The RFC was to operate as an independent agency, not subject to political influences. Every application would be considered on its merits, not on political considerations. It was also generally assumed that loans would be made on the condition that private financing was not available and that an important public interest would be served.

In the early years Jesse Jones, chairman of the board of directors, managed the institution without much interference. But as the functions of the RFC grew, and particularly as the RFC, even in the 1930s, began to assume responsibility for disbursing huge sums of money for other government agencies, without the delays incident to the voting of funds through the appropriation committees of the congress, the agency tended to become involved in politics.

By the 1940s the situation had become precarious. The Hoover commission in 1949 noted that "direct lending by the government to persons or enterprises opens up dangerous possibilities of waste and favoritism. . . . It invites political and private pressures, or even corruption" *(Report on Federal Business Enterprises,* March 31, 1949). As early as 1948 a congressional committee (Senate Committee Report no. 974 on the RFC act) had noted that attempts to influence the business judgments of RFC by the use of political influence. even though well intended, were a constant menace to sound administration. In a report in 1951, the senate banking and currency committee (Report no. 649) complained of the increasing practice of applicants seeking direct access to the directors of the RFC through members of the Democratic national committee; and many cases of corruption were aired.

Despite this, the Democratic majority of the banking and currency committee in 1951 proposed only to correct abuses, not to destroy the RFC, for the majority emphasized the important financing contributions of the RFC in a financial market that was imperfect at best. Once the Republicans came into power in 1953, however, they provided for a quick liquidation of the RFC (RFC Liquidation act, July 30, 1953). Effective June 30, 1957, the RFC was abolished and its remaining functions transferred to the Housing and Home Finance agency, the General Services administration, the Small Business administration and the treasury department.

During 21 years and 8 months of RFC lending, more than $12,000,000,000 was disbursed. When, in Sept, 1953, its lending authority was terminated, it had $800,000,000 outstanding in loans, securities and commitments. Aside from its peacetime activities, the RFC under legislation in 1940 and 1950 had assumed large military responsibilities; *e.g.,* purchases of strategic items, building of plant facilities. (S. E. H.)

RECORDER. The principal legal officer of an English city or borough having a court of quarter sessions. He must be a barrister of five years' standing, appointed by the crown. The recorder holds once in every quarter of a year, or oftener if he thinks fit. a court of quarter sessions in and for the borough He is sole judge of the court, "having cognizance of all crimes. offences, and matters cognizable by courts of quarter sessions for counties in England," except that he may not allow or levy any borough rate or grant licences (s. 165). He is not eligible to serve in parliament for the borough or to be an alderman or councillor, or stipendiary magistrate for the borough, though he is eligible to serve in parliament except for the borough. He may be appointed recorder for two or more boroughs conjointly. Appeals from the city and borough justices and under the Rating and Valuation act. 1925, are to the recorder as sole judge.

The recorder of London is judge of the lord mayor's court and one of the commissioners of the central criminal court. (See QUARTER SESSIONS, COURT OF.)

In the United States most of the states have county recorders elected by the voters of the county. In some of the states the duties of the recorder fall upon the clerk of one of the courts. In all of the states provision is made by constitution or statutes for some official to record deeds and other legal instruments. In New York the recorder is one of the criminal court judges.

RECORDER, FIPPLE FLUTE or ENGLISH FLUTE, a mediaeval flute, blown by means of a whistle mouthpiece and held vertically in front of the performer like a clarinet. It consisted of a wooden tube which was at first cylindrical or nearly so but became, as the instrument was developed and improved, an inverted cone.

Being very easy to play. the recorder enjoyed great popularity in all countries after the middle of the 18th century until the greater possibilities of the transverse flute turned the tide against it.

After 1800 a smaller variety, called the flageolet, played a certain role as an amateur instrument in England (where even double and triple flageolets were built). In the 20th century an increased interest in ancient music brought forth a renaissance of the recorder, produced in various sizes.

RECORDING, PHONOGRAPH: *see* PHONOGRAPH.

RECREATION. Recreation is easier to describe than to define. It has been variously characterized by different writers as any activity engaged in voluntarily just for the pleasure and satisfaction that it brings to the participant, whether through relaxation, refreshment of strength after toil, reneaal of spirit, the opportunity for self-expression, relief from boredom. release of emotional tension. the provision of an outlet for repressed impulses, the testing of one's powers, the attainment of a sense of achievement, the for-

getting of one's worries, sheer fun or the mere strengthening of the ego that comes from feelings of adequacy and self-esteem. Recreation is more than activity as such, however. It is activity plus an attitude on the part of the reacting individual and, of these two ingredients, the attitude of the individual is the more important.

Properly defined. the term recreation has an even broader meaning than implied thus far, for it can occur in the absence of any discernible activity. To virtually exhausted players, for example, the quiescent break that occurs between the periods of an athletic contest is likely to be recreative. Similarly, to one who bas long toiled without respite, a vacation with pay spent mainly at just resting could be highly recreative.

But inactivity is not always recreative. It is the total situation and how the individual feels with reference thereto that determines what is and what is not recreation. For example. a patient sitting in a dentist's waiting room who is scheduled to have a tooth extracted is not likely to find the period of waiting recreative. Similarly, during an economic depression, an individual long unemployed and eager to find profitable employment is likely to find his involuntary leisure not recreative but crushing. Thus. because the attitude of the individual concerned is so important, the same objective situation can be either recreative or quite the opposite.

Although recreation is sometimes defined as consisting of activities in which the individual engages just because he wants to, this statement has limitations. At certain times an individual may eat, sleep, etc., just because he wants to. Most people, however, would not regard such activities as recreation per se. But most of the remaining activities in the behaviour stream (when such reactions as eating, sleeping, etc.. are eliminated) in which the individual takes part of his own volition are considered his recreation.

Though not usually regarded as recreation, even eating and sleeping can provide a convivial background and even be essential parts of a gala occasion. This holds true, for example, for birthday parties, banquets, Christmas dinners and informal treats enjoyed with friends. At so-called "slumber parties," a popular pastime among teen-age girls in the United States, it is not the forty winks of sleep but the entire occasion that is recreative. Although we may identify one element as more prominent than another, it would be futile to try to analyze and isolate the specific elements that are recreative and those that are not. In such matters it is the total event that is recreative.

Although activities which are enjoyed by large numbers of people are usually labelled recreations, these activities are recreative only to individuals who find them so. Recreation, therefore, is more than a mere list of activities and festive occasions. Because of individual differences in tastes and preferences, no specific activity is recreative to everyone. On the other hand, under suitable circumstances such as might be found in dramatic play, for example, almost every conceivable human activity can be recreative to someone.

Recreation is sometimes defined as the physical recuperation of adults, and play as characteristic childish activity. These interpretations make a distinction between recreation and play largely because of the fact that small children often start to play immediately upon waking in the morning when they are not in need of physical recuperation. Despite the possible validity of this distinction, in order to avoid the monotonous repetition of any one word, the terms recreation, play, diversion and pastime will be employed interchangeably.

Because thousands play at what is work for professionals, it is impossible to make a sharp distinction between work and play. This fact is well illustrated by the endless amateur-professional controversy. Who is an amateur and who is not depends largely upon what game one plays, the country in which one plays it, and the decade during which it is played. Although various committees have attempted to specify who is and who is not an amateur, the definitions of all such committees have been arbitrary and unsatisfactory, and so have failed to gain general world-wide acceptance.

This discussion implies that, desirable though it might be from the view-point of the ardent behaviourist, recreation cannot be defined objectively in a way that gains general acceptance. It indicates also that it is impossible to make any accurate computation of the total time devoted to recreation or its total monetary cost. This is revealed by the great disparity in the estimates made. For example, one writer held that 5% of the money annually spent by U.S. consumers went for recreation, while another estimated that, broadly interpreted, not far from 25% of the entire U.S. national income was expended for play and recreation.

Obviously, such estimates are based on different definitions of the term recreation. The specific recreational activities engaged in by different individuals are determined by such factors as chronological age, sex, the social and geographic environment, the season of the year, economic status, the available facilities and equipment, fads and fashions and the skills and abilities of the participants.

Spectator Versus Active Participant **Activities.**—Recreations are sometimes divided into two general types: those which imply direct participation and those which involve looking on or listening to. The claim is sometimes made that witnessing games, viewing them on television or listening to radio accounts, is less beneficial than direct participation. Others challenge this allegation arguing that we misunderstand the nature of recreation when we try to impose our recreation values upon others. No one but the individual concerned is able to decide whether the role of spectator or that of active participant is more satisfying to him and hence more recreative. Relaxation, it has been argued, is one of the benefits to be obtained from recreation and it would be difficult to prove that, for those engaged in physical occupations, direct participation always provides more real relaxation from the strain of modern productive effort than does appreciative observation. Active participation is often not so much a form of recreation as an ordeal. Either because they are unqualified to perform skilfully or because they feel inadequate to play in a manner that enhances their opinions of themselves, millions are unable to enjoy direct participation, but this need not and should not preclude them from enjoying, as witnesses, the expert performances of others. Moreover, since no crustworthy method for measuring recreative values is available, the relative worth of active participation and of observation are matters of conjecture.

With reference to this entire subject, the Educational Policies commission of the National Education association maintained that it is idle to quarrel over the relative values of participation and observation. Both are important and both should be encouraged, for in the modern urban environment it is difficult to provide the space and the equipment for all who might wish to participate actively in certain kinds of activities. Therefore, many persons must engage in certain forms of recreation vicariously or not at all.

The Change in Attitude and Practice.— In earlier times the attitude of many persons was that play was wasteful and to some it was even wrong. This attitude was, in part, the product of religious convictions and was modified only gradually. The influences of Jean Jacques Rousseau, Friedrich Wilhelm Froehel, John Dewey and others were potent forces in effecting this change. By the beginning of the 20th century, the belief had gained wide acceptance that it is both undesirable and impossible to suppress either the need or the perfectly normal tendency to play; carefully planned leisure-time investment can be a direct and potent educational agent; and, if society does not provide opportunity for wholesome recreation and train the individual's capacity for seeking and finding it, the suppressed drives will frequently find various socially objectionable outlets.

It seems important, therefore, that efforts be made to enable both children and others to engage in those recreational activities which they will pursue whether they are instructed or uninstructed in them. In 1918 the National Education association adopted "worthy use of leisure" as one of seven cardinal principles of education, and in 1946, the Educational Policies commission of the National Education association stated that education for recreational pursuits is imperative. Modern schools, provide after-school and recess recreational opportunities for those of school age and by means of an expanding extracurricular program teach skills and interests that can be used by the pupils as recreation after gradua-

tion.

The legal function of the schools has been extended to include the right to provide facilities, purchase supplies and equipment and employ leaders for many kinds of community recreation. School auditoriums are supplied with stages for dramatics and portable school furniture is installed so that classrooms can readily be cleared for social occasions. In some communities classes in arts and crafts are provided for adults as well as for children, and neighbourhood clubs are permitted to use the school facilities for their recreational activities.

Churches came to assume favourable attitudes toward recreation, and some sponsor their own youth groups in which a social and recreational program receives major emphasis. Although its main purpose is religious, it is not uncommon for a church to own separate quarters that can be used for basketball, parties, dramatics, social dancing, etc. For many persons church work is a major social and recreational activity, and in some small communities and rural districts the church is the centre of the community's recreational life.

Recreation has assumed an increasingly vital role in the program of various churches, partly because it can be a powerful tool in developing church loyalty, partly because by promoting wholesome forms of recreation, the church can more effectively combat and lessen some of the depravities of civilization, and partly because of the general change in public opinion regarding man's basic need for recreation, including that of ecclesiastic authorities themselves.

Interrelations With Other Aspects of Living.—Recreation is so closely associated with other kinds of human endeavour that it is almost impossible to tell where it begins or ends. For example, most voluntary youth-serving organizations such as the Boy Scouts, the 4-H clubs and a host of others do not regard recreation as their main function. Nevertheless. it is an important feature in the program of all such groups, and it undoubtedly has much to do with their success in attracting and retaining members. This is true also for many adult organizations, such as women's clubs, fraternal orders, veterans' organizations and service clubs. The existence of numerous noonday luncheon clubs in the U.S. is probably due largely to a desire on the part of the members not merely to eat at regularly specified times but also to talk to congenial companions.

Wholesome recreation is a correlate of mental and physical health. For example, well-adjusted persons have more hobbies and they pursue them with more zest than do psychiatric patients. Although this correlation does not prove that good mental health is caused by recreational interests, many mental hygienists believe that such interests can help to direct troublesome feelings into socially approved channels and that they thus can be a valuable morale builder and a preventative of mental ill-health.

During World War II. both as a morale builder and for reasons of social hygiene, the special services division of the U.S. army, for example, provided recreation for 8,000,000 men scattered all over the world by means of movies, athletics, soldier shows, handicrafts, library service, post exchange services, games, clubs and rest camps.

Juvenile Delinquency and Recreation.—Research has shown that legally recognized delinquents differ from nondelinquents in their play behaviour, the delinquents participating more often in desultory, unguided and socially undesirable leisure-time pursuits. Although recreation is often heralded as a sovereign remedy for juvenile delinquency, it is a product of so many unfavourable causative factors that it probably cannot be eliminated by any one preventative measure. The case for recreation is sometimes hurt by overstatement of what it can do. Planned recreation can provide the opportunity for character development, but it cannot work miracles. Indeed, when the conditions are unfavourable, the participant in sports and games may learn not honesty but dishonesty.

Commercial Recreation.—Commercial recreations are those operated for monetary profit. Examples are the theatre, amusement parks, motion-picture theatres, radio and television, horse and dog races, prize fights, wrestling matches and professional sports. Although some fine programs are operated by commercial interests. the tawdry and even vicious nature of certain others resulted in nidespread criticism and popular demand for their more rigorous control. Activities and devices most often criticized are unregulated burlesque shows, pulp magazines. bingo games, fraudulent pinball machines which exploit the gullible, slot machines, sadistic comic books, roadhouses, taxi-dance halls and similar questionable resorts. Pool and billiards are sometimes condemned but chiefly because of the unsavory setting in which it is alleged they are played. When played under properly supervised conditions. such games of skill are unlikely to elicit objections.

The chief value of commercial recreation is that its promoters can provide equipment and facilities for specific types of recreation at a time when the call for them is still too slight to justify public expenditure. When public demand has increased and the need justifies the cost, public facilities can be provided. This has happened in the case of golf, tennis and several other recreations nhich are now offered in many communities by both commercial and public agencies.

Public Recreation.—Playgrounds were first established in the U.S. by philanthropic agencies to help keep underprivileged children off the streets. The Playground Association of America was organized in 1906 and renamed the National Recreation association in 1930. By means of its publications, field studies, consulting and advisory service and annual meetings, this organization led in the drive for a better understanding of community recreation systems, and also served as a public forum for the exchange of ideas and information regarding recreation in general. Any list of outstanding individual promoters of the U.S. play movement would have to include among others Henry S. Curtis, Luther Halsey Gulick, George E. Johnson and Joseph E. Lee.

Governmental responsibility for recreation was accepted in the United States on the national, state and local levels. Because leisure-time interests are far too numerous for any one agency to handle, about 35 different federal agencies rendered one or more types of recreational service in the 1950s, such as the preservation of areas of natural scenic beauty, the conservation, development and extension of fish and wildlife resources, the maintenance of national parks and forests and a host of others.

North Carolina, Vermont, Washington and California were the first states to accept recreation as a separate service of state government. Each of them created a state recreation commission empowered by law to aid local communities in developing their recreational resources. Practically every state passed enabling legislation permitting local communities to conduct recreational programs with public funds, and some states established game refuges and bird sanctuaries, as well as state parks and forests. Many also operate roadside parks and picnic areas, provide camping sites for tourists and furnish swimming, boating and other facilities.

Provisions for recreation in local communities throughout the U.S., many of which have continuous year-round, tax-supported programs, are implemented by means of municipal and school playgrounds, athletic fields, golf links, school gardens, field houses, community centres and, most important, the employment of trained leaders.

Outlook For the Future.—Modern industrial efficiency has provided man with a bewildering array of possibilities for entertaining himself, more income per family with which to pay the cost, more leisure time in which to play and more congested urban areas where children do not perform the daily chores that occupied their grandparents and where their opportunities for wholesome recreation are much curtailed. Although the machine has greatly increased man's free time, it cannot solve his problem of what to do with it. Therefore, leisure is not only an opportunity, but a social problem.

Recreation has become far more than mere diversion. It is an important social force. Its pattern is incredibly complex. It is, among other things, a big business. In many countries of Europe and in certain states of the United States the tourist or recreation business is among the most important economic assets. Recreation pulls in many directions. It merges with other things so gradually

that its boundaries are hard to locate. Perfectly respectable places of entertainment shade off imperceptibly into notorious subterfuges. This poses a problem in policing but government faces serious difficulties when it attempts to operate in the field of morals or of good taste.

Sports have long been considered useful in promoting social cohesion and as agencies for social direction. Since there probably will be even more leisure in the future, the modern community faces no more serious responsibility than that of making adequate provision for ways in which both children and adults can fill their free time with constructive and healthful recreational activities.

PLAY THERAPY

Since play is the child's easiest and most natural medium of self-expression and an outlet for feelings which he cannot otherwise express, clinical psychologists have experimented extensively with play therapy as a method useful for diagnosing and treating children who have grave emotional problems and personality disturbances. In play therapy the ability of the preschool child to employ toys and dramatic play as a medium for expressing his fantasy life is utilized. For example, a play situation is arranged in which dolls represent the several members of the child's family. The child is asked to tell something about the dolls or to do something with them. Or he may be requested to complete a partly finished story pertaining to the dolls, or to interpret a picture.

The purpose here is to provide a means whereby the young child may indirectly and perhaps unwittingly reveal his real attitudes toward the members of his own family or toward others. In employing this technique, the therapist tries to create a permissive atmosphere which will encourage the child to express his deepest feelings, either by means of words or gestures, movements, clay modelling, finger painting, etc. The proponents of such therapy maintain that the child's play often gives insights into family situations which can be obtained by no other means. They report also that this psychotherapy often dissipates the child's unconscious conflicts and improves his self-expression, thus leading to better personal adjustment.

Play therapy has also been employed for understanding and helping children who have reading problems. Investigators even reported that, for children suffering from severe emotional conflicts, significant increases in intelligence test scores were obtained. The explanation offered for this increase was that the play therapy frees children from paralyzing inhibitions resulting from their emotional problems and that, as one result of this, the children are enabled to employ their capacities more freely and adequately. More research and analysis along these lines was needed in order that these claims might be further tested and verified.

RECTIFIER, a device which converts one or more alternating-current waves into a unidirectional wave. It may be an electron tube (of either vacuum or gaseous type), vibrator, barrier-layer cell or mechanical device. Although they often serve the same purposes, rotary converters and motor-generator sets are not usually classified as rectifiers.

If an alternating-current wave is applied to the diode vacuum tube, the resulting output is a succession of pulses similar in shape to the positive portions of the input wave but separated from each other by an amount of time corresponding to the negative portions of the input wave. This is termed half-wave rectification.

Two diodes may be connected in such a manner that one will conduct when the other does not. This type of operation, called full-wave rectification, results in a continuous train of pulses.

Both the half-wave and full-wave rectifier outputs may be smoothed by inserting a capacitor across the output.

Gaseous tube operation in rectifier applications is quite similar to that of the vacuum tube but the power capabilities are much greater.

Copper-oxide rectifiers, consisting of a layer of cuprous oxide on a copper disk, and selenium rectifiers, consisting of a layer of selenium on iron, are examples of the barrier-layer types. In both cases, the boundary (barrier-layer) offers relatively low resistance to the passage of current in one direction but very high resistance to current in the other direction.

Regardless of the form it may take, the rectifier's fundamental property is one of unidirectional conductivity.

See also AMPLIFIER, ELECTRONIC. (A. L. SY.)

RECTOR, a title given to the bearers of certain ecclesiastical and academical offices. In the Roman empire, after Constantine, the title rector was borne by governors of provinces subordinate to the prefects or exarchs. In the middle ages it was given to certain secular officials (*e.g.*, the podestas of some Italian towns), but more especially to the heads of the universities, the representatives and rulers of the *universitas magistrorum et scholarium,* elected usually for a very short time. After the humanistic movement of the Renaissance the style rector was also given to the chief masters of schools containing several classes, and in some parts of modern Germany (*e.g.*, Saxony, Wiirttemberg) it continued to be used instead of the more modern title of director. Rector is also still the title of the heads of German universities, of Exeter and Lincoln colleges, Oxford, and of other institutions of higher education. As an ecclesiastical title, rector was once loosely used for rulers of the church generally, whether bishops, abbots or parish priests, but it was later confined, as in Poland and Spain, to a priest with a cure of souls, in England to the incumbent of a parish where the tithes are not impropriate and in the U.S. to the Protestant Episcopal clergyman in charge of a parish.

RECUSANT, the name given in the 16th and 17th centuries to persons, particularly to adherents of the Roman Catholic faith, who persisted in refusing to attend the services of the English Church and became thereby liable to prosecution and penalties.

REDBREAST or EUROPEAN ROBIN, *Erithacus rubecula* (Linnaeus), is the sole member of its genus, which is included in the thrush family of birds (Turdidae). The species is divided into a number of races in the Palaearctic region. The British race, *melophilus* Hartert, is famous for its close association with man and enjoys a unique place in affection and folklore. Hence British colonists overseas bestowed its name on various small redbreasted birds (*e.g.*, the American robin). Actually the breast is orange, which colour extends over the face, being divided from the olive-brown upper parts by a narrow blue-gray border. The underparts are white; the legs, bill and iris brown. The sexes are alike, and there is little difference in summer and winter. The juvenile plumage is speckled. The robin is originally a woodland bird and remains so on the European continent. Many British robins breed in woodland or its edge and winter near houses. Continental robins are migratory in the north of their range, partly so in the middle and resident in the south; in Great Britain many females, but few males, appear to migrate.

Both the biology and the folklore of the robin were intensively studied by David Lack in the period 1935–50 and his books, *The Life of the Robin* (rev. ed., London, 1947) and *Robin Redbreast* (Oxford, 1950) are standard works. Lack's technique of marking individual birds with coloured rings followed pioneer work by J. P. Burkitt in Northern Ireland. The robin shows highly developed territorial behaviour. In the breeding season each pair defends an area containing the nest against others of their own species; in winter each bird maintains a territory with equal rigidity, except in very severe weather. Robins are therefore extremely aggressive, and Lack, using stuffed dummies, was able to separate and analyze the complicated threat and courtship displays.

Robins usually nest from March to June. rearing two broods from clutches typically of five or six white, pink-spotted eggs. Nests in natural woodland sites are hard to find. but many are built in holes of walls, creepers, tins, nestboxes and various bizarre situations. Robins feed on invertebrate animals. especially worms, and on berries and food scraps.

The song is simple but melodious and can be heard almost throughout the year; after a break at midsummer it is resumed with a slightly changed quality. (B. C.)

REDBUD: *see* JUDAS TREE.

REDCAR, a municipal borough in the Cleveland parliamentary division of the North Riding of Yorkshire, Eng., on the northeast coast 8 mi. E.N.E. of Middlesbrough. Pop. (1951) 27,516. Area is 8.1 sq.mi. Lying midway along the continuous stretch of sand between the Tees estuary and Saltburn, it serves as residential town and holiday resort for the industrial population of south Tees-side. Incorporated in 1922, Redcar was growing rapidly in the 1950s. Huge industrial developments on its western boundaries include chemical works, a steel rolling mill and docks on the borough's frontage to the Tees river.

Kirkleatham hall, in the lovely village of Kirkleatham, was the home of the Turner family from the 17th century until 1948 after which it was demolished.

RED CEDAR: *see* JUNIPER.

RED CROSS, a national and international agency, was founded with the original purpose of protecting and caring for the sick and wounded of war. Later, the Red Cross extended its activities to include the prevention and alleviation of human suffering in peacetime as well as in war.

Origin of the Movement.— The Red Cross idea was born in 1859 on a battlefield in northern Italy. Henri Dunant, a young Swiss, came upon the scene of the bloody battle of Solferino. fought betneen the armies of France and Italy on one side and the Austrians on the other. About 40.000 men lay dead or dying on the battlefield. without adequate medical care. In the town of Castiglione nearby, thousands of wounded filled every available building—churches, schools and private homes—until the whole town became a temporary hosgital.

Dunant organized a corps of attendants from the people of the town, travelers, priests, housewives, anyone he could press into service, to bind wounds and to feed and comfort the injured. In 1862 Dunant published *L'n Souvenir de Solférino,* in Geneva, Switz., in which he described the horror of the plight of the thousands of wounded he had seen left without proper care.

For four years, Dunant carried on a persistent campaign throughout Europe to ensure better care for victims of war. "It should be possible," he said, "to form a society in every country when nations are at peace, in which men and women could be organized and trained so that they could give aid to the wounded in time of war." In 1863 a committee was formed, which later became the International Committee of the Red Cross, and this committee issued a call for a meeting later that year "to turn Dunant's inspiration into fact." Thirty-six delegates from 16 countries met at Geneva on Oct. 26 to 29 and there set forth the fundamental principles of the Red Cross.

A diplomatic conference was set for Aug. 8, 1864, in Geneva, at which representatives of 12 governments drew up the first international treaty whereby governments agreed to care for the wounded of war, whether friend or enemy. The outcome of this conference was the first Geneva convention (*q.v.*) to protect the wounded, the personnel caring for them and medical supplies for their use. A red cross on a uhite field was adopted as an emblem to be used so that hospitals, ambulances, doctors and nurses could be recognized on the battlefield. The International committee was urged to continue its work as guardian of the principles laid down in the convention and to promote the formation of national societies in all countries to develop the Red Cross movement and to organize aid for wounded soldiers.

As a result of experience in war. the original convention was later revised and new conventions adopted to extend protection to victims of warfare at sea (1907), to prisoners of war (1929) and to civilians in time of war (1949).

INTERNATIONAL COMMITTEE OF THE RED CROSS

The International Committee of the Red Cross (Comité International de la Croix-Rouge) is guardian of the principles of the Red Cross. Its purposes are to recognize new national Red Cross societies after verification of the basis upon which they are founded; to work for the observance and development of international humanitarian conventions (especially the Geneva conventions), to act as benevolent intermediary between governments and national Red Cross societies in time of international or civil war. In wartime it establishes information agencies concerning prisoners of war, visits the prisoners in their camps and uses all available influence to improve their material and moral conditions. Finally, in both war and peace, it acts as benevolent intermediary among governments, Red Cross societies and other relief organizations for the purpose of relieving or enabling others to relieve the suffering caused by war.

The International committee, with headquarters at Geneva, is comprised of 2j Swiss nationals, elected by the members themselves. Its activities are governed by the principles upon which the Red Cross was founded: absolute impartiality and independence, especially in political and religious matters, and equality of all the Red Cross national societies. A link between the committee and the national societies is provided by the *Bulletin international de la Croix-Rouge* (1864–) and the *Revue internationale de la Croix-Rouge* (1919–).

In 1928 the 13th International Red Cross conference, at The Hague, established the statutes of the International Red Cross, which includes the national societies. the International committee and the League of Red Cross societies. These three elements are the basis of the universal Red Cross movement, the assembly of which, the International conference, normally meets every four years.

The committee is entrusted by the International Red Cross conference with the distribution of Florence Nightingale medals, awarded periodically to the most deserving nurses of all countries. In 1917 and again in 1944 the committee was awarded the Nobel peace prize.

World War I.—At the outbreak of World War I, the committee opened the International Prisoners of War agency in Geneva with a staff of about 1.200 persons, mostly volunteers. Committee delegations visited internment camps, and facilities were obtained for the evacuation of civilians from the occupied regions of northern France, and the repatriation or accommodation in neutral countries of sick and wounded combatants and medical personnel. Committee work on the eastern front was delegated to the Danish Red Cross, which set up an extensive information bureau for this purpose in Copenhagen.

Between World Wars I and 11.—After World War I, the International committee organized the repatriation from Russia and central Europe of 450,000 prisoners of war of all nationalities. It also effected the exchange of hostages in Upper Silesia, the return of Bulgarians interned in Greece and the exchange of prisoners between Greece and Turkey. In medical relief and reconstruction work in war-stricken countries, the committee co-operated with a number of Red Cross societies and other organizations. World War I had revealed grave deficiencies in international law. notably with regard to the treatment of prisoners of war and civilian internees, and had shown the urgent need of protecting civilians. Ten years' intensive preparation led, in 1929, to the revised convention for the relief of sick and wounded combatants and the adoption of a new convention relative to the treatment of prisoners of war. Both the Gran Chaco War in the early 1930s and the Spanish civil mar (1936–39) called into action one of the International committee's most important humanitarian functions—to persuade belligerents not legally bound by conventions to accept their terms. Combatants and civilians were spared much suffering in these conflicts through the intervention of the committee's delegates. The committee also served during the wars in Ethiopia and China.

World War 11.—Under article 79 of the Prisoner of War convention, the committee opened the Central Prisoner of War agency in Geneva in Sept. 1939. The committee staff, almost half serving

without pay, maintained a card index on the location of millions of prisoners of war and internees, forwarded relief supplies, letters and telegrams to prisoners and aided in prisoner exchange. The committee's delegations made more than 11,000 visits to prisoner-of-war camps.

Relief for civilian war victims was the purpose of the Joint Relief commission of the International Red Cross, created in July 1941 by the International committee and the League of Red Cross societies. Foodstuffs, clothing and pharmaceutical supplies bought and dispatched by the commission were distributed in the war-stricken countries by national Red Cross societies and other welfare organizations in the presence, whenever possible, of a delegate of the committee. The chief countries helped were Belgium, France, Greece, Yugoslavia, the Netherlands, Norway and Poland. Relief for the famine-stricken Greek people during the winter of 1941–42 was carried out jointly by the Swedish government and the Swiss Red Cross society, with the assistance of the Turkish Red Crescent.

The strictness of the blockade and counterblockade during World War II, the scarcity of neutral shipping available and the vast extent of the relief scheme led to the creation of a Red Cross maritime transport system. The Foundation of the Organization of Red Cross Transports, set up by the committee in April 1942, had a fleet of 12 ships operating in the Atlantic, the Mediterranean and, later, in the North sea. These ships, sailing under neutral colours, were always accompanied by the committee's agents.

Special Problems.—Total warfare called into question the fundamental principles embodied in the Red Cross conventions and the international humanitarian agreements. Unforeseen problems and complex situations on a vast scale and of extreme urgency arose which had to be dealt with as they presented themselves. The committee made spontaneous appeals to belligerent governments in behalf of war victims. During World War II the committee's main task was to secure progressive improvement in implementing the conventions, especially regarding the treatment of prisoners of war. To this end, the committee made almost daily application to the detaining powers.

A convention, which had been drawn up at the 15th International Red Cross conference in Tokyo in 1934, paved the way for the protection of interned enemy aliens. However, the civilian populations subjected to evacuation, deportation and the rigours attending military occupation remained outside the scope of existing conventions. The committee had no legal basis whatever in international law for intervening in behalf of prisoners in concentration camps, which were regarded by the detaining authorities as a purely internal affair and were closed to the committee's delegates. In the autumn of 1943 the committee was able to send food parcels to civilian detainees whose exact addresses were known. But it was only during the last days of the war that several of the committee's delegates succeeded in entering certain concentration camps and saving the lives of many persons.

Two chief belligerents, the U.S.S.R. and Japan, had not ratified the Geneva Prisoner of War convention of 1929. Despite constant efforts before World War II, the committee was unable to secure agreements between Russia and Germany which would have allowed it to forward relief supplies to prisoners of war of either country. In the far east the greatest obstacles were raised to any systematic relief work by the committee, and its delegates had access only to a limited number of camps in Japan proper, Shanghai and Hong Kong.

After World War 11.—At mid-century the committee engaged in the following tasks: (1) aid and protection for many prisoners of war and civilian internees who were detained, despite the close of hostilities and steps taken for their repatriation; (2) aid to civilian populations suffering from the consequences of war; (3) preparatory work for the revision of the Geneva conventions and the establishment of a new convention for the protection of civilians in time of war. The Geneva conventions of Aug. 12, 1949, for the relief of sick and wounded members of the armed forces in the field and at sea, prisoners of war and civilians had been ratified in the mid-1950s by 52 states; (4) interventions in conflicts in Indochina, Indonesia, Kashmir, Greece, Palestine, Bengal and Korea.

LEAGUE OF RED CROSS SOCIETIES

The League of Red Cross Societies was formed in 1919, on the proposal of H. P. Davison, president of the War council of the American Red Cross, to organize an informal association of Red Cress societies to develop peacetime activities. The initial members were France, Great Britain, Italy, Japan and the United States. The foundation of the league preceded by a few weeks the signing of the covenant of the League of Nations, of which article 25 read as follows:

The Members of the League agree to encourage and promote the establishment and co-operation of duly authorized voluntary national Red Cross organizations having as purposes the improvement of health, the prevention of disease, and the mitigation of suffering throughout the world.

This was indicative of the widespread sentiment that caused the national Red Cross societies after World War I to extend their activities to relieving suffering wherever it was found.

The idea of an international movement that sought to protect mankind against its natural enemies in time of peace made an immediate appeal, and the most immediate result of the decision of the national societies and of the consequent activities of the League of Red Cross Societies was the extension of the Red Cross movement to many other countries. By the mid 1950s, the league included 74 national Red Cross societies with a total adult and junior membership of more than 105,000,000 persons. Its statutes defined among its duties the following:

To act as a permanent liaison agent between national Red Cross societies; to co-operate in all spheres of their work, especially for the improvement of health, the prevention of disease and the mitigation of suffering; to represent and to speak for the national societies on the international level in accord with resolutions adopted by the board of governors; to encourage and facilitate the establishment and the development of the activities of national societies; to be the guardian of the integrity and interests of the member societies.

The league has a board of governors comprising one representative from each member Red Cross society; and the board, when not in session, delegates its authority to an executive committee consisting of the chairman and vice-chairman of the board and representatives of 12 other societies designated by the board. The board meets biennially and the executive committee at least twice a year. The expenses of the league are met by the voluntary contributions of member societies.

The international activities of the league are supervised by the chairman of the board of governors and carried out by an international secretariat with headquarters at Geneva. In addition to the various branches of the secretary-general's office, there are technical divisions on disaster relief, health, nursing, social service and Junior Red Cross activities corresponding to the principal activities of member societies.

Among the most important functions of the league are the coordination of international relief in great natural disasters and the encouragement of interchange of technical material, experience and information on health and welfare programs by the various societies. Since the league secretariat is kept informed of all society programs, it can offer guidance to societies in developing and extending these programs. The secretariat also gives special attention to creating opportunities for frequent and regular contact between Red Cross representatives from different countries. In 1922 a program of study visits was begun under which delegates visit the headquarters of the league and of national societies to study Red Cross activities. This program is supplemented by regular visits by officers of the secretariat to the headquarters of the national societies.

The establishment of regional conferences, another important function of the league, began when the Red Cross societies of the far east were first brought together in conference in Bangkok, Thai., in 1922, and again at Tokyo in 1926. The first regional conference for central and eastern European societies was held in Warsaw, Pol., in 1923, the second in Vienna, Aus., two years later, and, after World War II, in Belgrade, Yugos., in 1947. Inter-American conferences started in Buenos Aires, Arg., in 1923, and one was held in Mexico City in 1951. These meetings facilitate

exchange of views and techniques concerned with problems common to the geographic, economic and social conditions of the respective countries and make possible collective action toward the solution of problems that transcend political boundaries.

The activities of the league in the technical fields of disaster relief, health, nursing, social service and Junior Red Cross have led to steady developments and to improved standards.

The Relief Bureau.—In 1924 the league established a relief organization to promote participation of national societies in international relief, especially in disaster. When recovery from a major disaster is beyond the resources of a government and its relief organizations, an international appeal is made and relief activities stemming from this appeal are co-ordinated by the league. After World War II the League of Red Cross Societies co-ordinated international relief in dozens of major catastrophes, through which a number of national societies provided food, clothing, medical supplies and shelter to victims of disasters in India, Pakistan, Greece, Italy, the Netherlands and other countries. For example, in 1953 the league appeal for victims of western European floods yielded relief consisting of commodities and money, contributed by 34 national societies.

The Health Bureau.—The health bureau of the league secretariat after World War II acted primarily in the promotion, extension and co-ordination of the medical and public health activities of the national societies and in providing materials for health education. In 1951 priority was given to first aid, accident prevention, blood banks, standardization of blood transfusion equipment, tuberculosis control, maternal and child health, mental health and the training of health teachers. Co-operative relations exist with the World Health organization of the United Nations, the United Nations Children's fund, the International Cnion Against Venereal Diseases, the International Blood Transfusion society. the International Union for Child Welfare and other governmental and intergovernmental agencies.

Nursing and Social Service Bureau.—The bureau, whose nursing activities are guided by an advisory committee composed of world leaders in the field, was set up originally in 1919 as a nursing bureau. In 1951 steps were taken to include a social service section. From its beginning, the bureau assisted national societies to develop public health and visiting nurse programs. Higher standards for the training of nurses were developed, and programs were extended to include instruction in home care of the sick. A significant contribution was the establishment by the league of an international nursing centre in London in 1920.

Under the auspices of the Florence Nightingale foundation, sponsored in part by the league and with the collaboration of the British Red Cross society, graduate nurses from all over the world were given supplementary training. In 1944 responsibility for the centre was transferred to the International Council of Nurses but with the league represented on the governing body.

The nursing and social service bureau set up an extensive information service, including documents collected or compiled for the use of national societies, and introduced a quarterly in English, French, German and Spanish. It also helps select candidates for Red Cross scholarships and study visit grants and helps arrange suitable training for accepted candidates. In 1951 priority was given to guidance in the organization of Red Cross nursing schools, in training nurses' aides, teaching home nursing and enrollment of qualified nursing personnel.

Junior Red Cross Bureau.—The bureau co-ordinates and promotes the work of Junior Red Cross sections in national societies throughout the world. By the early 1950s there were sections in 60 countries with more than 40,000,000 members. Many sections were in the elementary and secondary schools. In others, membership was maintained outside the schools. A newsletter published in four languages gives assistance in organizing Red Cross activities appropriate for the several age groups and suitable to the needs, resources and cultures of different countries, such as correspondence between school children, the making of albums, art exchanges and international training centres.

Co-operative Relationships.—The league maintains co-operative relationships with international governmental organizations with objectives related to Red Cross activities, such as the World Health organization, United Nations Educational. Scientific and Cultural organization, Food and Agriculture organization, International Refugee organization, Children's Fund, etc.

NATIONAL RED CROSS SOCIETIES

The national Red Cross societies were begun in most countries to support and assist the army and navy medical services in time of war. Charters granted them by governments, public demand and the absence of other resources to meet urgent social needs caused them to broaden their activities. To obtain international recognition, a national Red Cross society was required to fulfill the following conditions:

The government of its country must have adhered to the Geneva conventions; the society must have been recognized by its legal government as an auxiliary of the public authorities in the sense of the Geneva conventions; it must adopt the name and emblem of the Red Cross (except in Mohammedan countries the Red Crescent and in Iran the symbol of the Red Lion and Sun are used); its activity must extend throughout the country and its dependencies; its membership must be open to all citizens irrespective of sex, politics or religion; and, finally, it must undertake to maintain regular contact with the other national societies and with the International Committee of the Red Cross at Geneva. Only one national Red Cross society may be recognized in each country. Each national society is directed by a central committee and includes a suitable number of regional and local committees which assist the central committee and ensure co-operation from all sections of the country. In most cases there are general meetings once a year of delegates from each local branch.

National Red Cross societies are autonomous and independent within their own territory. The first national Red Cross societies came into existence in Europe immediately following the Geneva conference of 1863. There were in the mid-1950s 74 national societies in existence with headquarters in the capitals of their countries, except in Canada, the German Democratic Republic and Australia, where the headquarters are in Toronto, Dresden and Melbourne respectively. The first national societies were the French and the Italian, founded in 1864. Altogether 27 national Red Cross societies were founded before 1900 and an additional nine by the outbreak of World War I. Between that time and the beginning of World War II, another 24 national societies were founded. The remaining 14 were founded after World War II.

War Work.—National societies began early to discharge their primary duty as auxiliaries to the medical services of the armed forces. The first opportunity for the relief of the wounded by Red Cross societies occurred in the Dano-Prussian War of 1864. In the Seven Weeks' War of 1866, the Franco-German War of 1870–71, the Russo-Japanese War of 1904–05 and the Balkan Wars of 1912–13 the Red Cross societies of the belligerent countries provided ambulances, hospitals and medical and nursing personnel to the combatant forces.

World War I led to a vast expansion of Red Cross activity. The American Red Cross supplied ambulance service for the wounded, staffed and equipped base hospitals, maintained rest homes for convalescent soldiers and set up canteens for troops in transit. The British Red Cross, in collaboration with the Order of St. John of Jerusalem (*q.v.*) and the dominion societies, provided trained nurses, voluntary aid detachments, ambulances and hospitals wherever British forces were engaged. Motor ambulance convoys were organized by the British Red Cross for the evacuation of wounded, in addition to ambulance trains and (in Mesopotamia) motor ambulance launches.

Similar energy mas shown by the Red Cross societies of other belligerents, notably the French, German, Belgian, Italian, Austro-Hungarian, Russian, Serbian and Turkish societies. The Red Cross societies of such neutral countries as Switzerland: the Netherlands, Sweden, Denmark, Norway and Spain also provided assistance to prisoners of war, hospital facilities for the seriously sick and wounded and food for the occupied territories.

In World War II the work of the Red Cross societies again increased enormously. The United States armed forces, not the

American Red Cross as in World War I, operated their own hospitals and maintained their own nursing services. The American Red Cross, however, recruited and assigned 70,500 nurses to the military and established about 1,500 overseas clubs, many of which, in addition to recreation facilities, provided meals and billets. To meet military needs, the American people gave 13,000,000 pints of blood through the Red Cross blood bank program.

In World War II the British Red Cross and the Order of St. John of Jerusalem operated as a joint war organization, and their welfare workers served with British forces in all theatres of operation. Home services were adapted and increased. County committees met requests for comfort items for hospitalized sailors, soldiers and airmen. Hundreds of thousands of people were trained in first aid, many of whom joined the Air Raid Precaution organization. Although originally formed to relieve suffering among the sick and wounded of the fighting forces, the British Red Cross in 1940 extended many of its activities to civilian victims of the war. Outstanding among its many activities was packing parcels for prisoners of war who received them regularly. In all their services for prisoners of war the British Red Cross and the dominion societies worked through the International Committee of the Red Cross, in close co-operation with the American Red Cross and the societies of the Allied nations.

After World War 11.—Following World War II intergovernmental agencies financed by governments, such as the United Nations Relief and Rehabilitation administration, were formed to ease the suffering of millions of victims of war throughout the world. The Red Cross was, however, of assistance in locating families and friends separated through war and upheaval. Red Cross societies in all parts of the world co-operated in this humanitarian work. Red Cross societies, which had conducted vast civilian relief programs during and immediately following World War II, gradually limited their civilian relief work to victims of natural disasters. However, where conflicts created human needs that were not being met by intergovernmental action, Red Cross societies worked together with other agencies to extend relief. For example, in 1948 the United Nations asked the league, the International Committee of the Red Cross and the American Friends Service committee to organize a relief program to help thousands of refugees in Palestine, and in 1949 the league, working closely with the Red Cross and Red Crescent societies of Lebanon, Syria and Jordan, provided health and welfare services to more than 300,000 persons. The International committee took care of approximately the same number of refugees inside Palestine and the American Friends Service committee assumed responsibility for 212,000 in southern Palestine. The American Red Cross sent a four-man team to help conduct the relief program and furnished a large part of Red Cross supplies distributed.

In the 1950s in war-devastated Korea, about 30 national Red Cross societies provided welfare teams and supplies to help alleviate disease and poverty; in Vietnam, other Red Cross societies answered the appeal of the Vietnamese Red Cross for relief for the hundreds of thousands of refugees from the north.

Prisoner-of-War Relief.—In earlier conflicts the International Committee of the Red Cross arranged for the exchange of the sick and wounded and for the delivery of mail and food packages to prisoners of war, but during the Korean conflict, Communist authorities of China and North Korea refused to allow the committee to function in the area under Communist control. Various national Red Cross societies therefore took the initiative to provide relief to the prisoners. League activities were partly responsible for ending the stalemate over compulsory repatriation of war prisoners and for speeding exchange of sick and wounded prisoners after the Korean armistice. Red Cross societies of belligerents also provided personnel for joint teams that offered welfare services for prisoners as they were exchanged. Other prisoner exchanges effected through international Red Cross co-operation included return of Japanese prisoners of war and civil internees from China and the U.S.S.R., Greeks from Rumania, Hungary, Bulgaria and Czechoslovakia and Spaniards from Russia following World War II. Negotiations continue for return of war prisoners and civilians as long as they are detained.

Other Services.—In many national societies emphasis has been placed on the training of nurses' aides, visiting housekeepers and mothers' assistants. Red Cross programs often include public education in accident prevention, swimming and water safety and first aid, as well as beach and highway aid stations and ambulance service for emergencies. Maternal and child welfare centres and clinics, such as those of the Iranian Red Lion and Sun and the infants' clinics of the Guatemalan Red Cross, are maintained by many societies. The Indian Red Cross trains midwives. Some societies specialize in service for handicapped children; *e.g.,* the service of the Australian Red Cross to spastic children. School hygiene is emphasized by many. Summer colonies and preventoria are operated, and some societies also have homes for orphans and deserted children.

Members of the armed forces and their families are given financial aid, counseling services, referral, reporting and communications and other welfare services. Particularly in the American, Australian and Philippine societies, help for former servicemen and their dependents includes assistance in establishing veterans' claims for governmental benefits, retraining the disabled, financial assistance, supplying orthopedic appliances, etc.

Maintaining hospitals, clinics and dispensaries are the major programs of many societies, particularly in the Latin-American countries, where mobile clinics are often used for rural work. Nurses' training schools vary from the postgraduate training provided by the French Red Cross to those conducted by the British Red Cross for the training of voluntary auxiliary aides for civil defense. The training and enrollment of nurses and of personnel for ambulance, pharmaceutical, radiological, poliomyelitic and tuberculosis work are activities of many societies. Public health nursing is also a growing activity in many societies. Health education is likewise a part of Red Cross activities, including lectures and distribution of pamphlets, campaigns against tuberculosis, poliomyelitis, cancer and venereal diseases, and courses in the care of the sick and in household hygiene.

Procurement of blood for the treatment of the sick and wounded is yet another activity in many Red Cross societies. Some societies maintain blood banks; others limit their blood program to recruiting donors. Some furnish blood and blood derivatives to the armed forces as well as to civilians. Outstanding examples of comprehensive blood programs are those of the American and Canadian Red Cross societies.

Many societies, such as the Canadian Red Cross, have active international programs, including disaster relief, Junior Red Cross and co-operation with other societies.

Outpost work is featured by many societies in a variety of ways, such as the visiting housekeepers for isolated areas furnished by the Australian Red Cross, the first-aid posts and clinics of the South African society; the air ambulances of the Swedish Red Cross and those of the British Red Cross for service to the mines of Tanganyika, the east coast of Africa, Kenya and Uganda.

THE AMERICAN RED CROSS

The American Red Cross was organized in 1881 in Washington, D.C., largely through the efforts of Clara Barton, who had served as a volunteer welfare worker on the battlefields of the Civil War and had distributed relief supplies contributed by the people. While she was in Europe, regaining her health after the war, Miss Barton became familiar with the work of the Red Cross in Europe and did relief work during the Franco-German War. Returning to America, she placed all the force of her dynamic personality behind obtaining government adherence to the Geneva convention and gaining support for the Red Cross movement.

In 1881, anticipating government approval of the convention, the American Association of the Red Cross was organized with Clara Barton as its first president. That the Geneva convention was finally ratified in 1882 by the senate was largely the result of Miss Barton's writings, influence and persistent effort to have the United States join with other nations to see that proper care was given the wounded of war.

In 1900 the American Red Cross was reincorporated by congress and in 1905 was given a revised charter. The president of the

United States was to be its president and the war department, its auditor. The revised charter, largely the work of Mabel T. Boardman, in addition to recognizing the organization as the agency through which relief is extended to the armed forces in wartime, also called upon Red Cross to establish a system of national and international disaster relief.

During its first few years, Red Cross was primarily involved in helping in disaster. Time and again Red Cross was called upon to speed aid to disaster victims—to feed, clothe and shelter them and to care for the sick and injured. Besides this emergency aid, in order to help restore victims to normal living after a disaster, the organization developed a program which included repair, rebuilding and refurnishing of homes and re-establishment of small businesses on which the family depended. All help given by Red Cross is without cost to the victims, without any obligation to repay and is designed to meet family needs.

By the mid-1950s Red Cross engaged in an average of 300 disaster relief operations a year. The year 1955 was a record disaster year in Red Cross history; the organization spent $30,000,000 helping victims of 270 disasters. Emergency relief was given to 336,000 persons, and more than 36,000 families were aided through assistance in rebuilding, repairing and refurnishing homes; providing equipment and maintenance; meeting medical and hospital bills; and helping small businesses to recover. In addition to giving assistance to members of the armed services and ex-servicemen and their families, Red Cross operates a medically approved program of recreation and welfare services in military hospitals. In the mid-1950s the Red Cross spent approximately 40% of its annual budget to provide services for the armed forces, veterans and their families.

In addition to the Red Cross blood program under which, in the mid-1950s, about 165,000 volunteer donors each month gave blood to meet civilian and defense needs, the Red Cross conducts many other activities that contribute to the health, safety and well-being of the American people, including courses in home nursing, first aid and water safety, taught mostly by volunteer instructors. One of every 15 registered nurses in the country is enrolled in Red Cross for service—in disaster, epidemics and other emergencies, as well as in teaching home nursing, helping in mass X-ray programs, etc.

Each year an average of 1,500,000 volunteers serve their communities through more than 3,700 local Red Cross chapters. Red Cross volunteers work as Gray Ladies in hospitals and as nurses' aides in hospitals and clinics, drive patients to and from hospitals and clinics and provide recreation and entertainment for hospital patients and shut-ins. Other volunteers make bandages and compresses needed in hospitals; still others provide canteen service at embarkation points for servicemen, set up feeding operations in disaster areas and provide refreshments at blood centres. Nutritionists volunteer their services in activities related to food planning and budgets and nutrition education.

The American Junior Red Cross, the largest young people's organization operating in the schools, participates in a number of community and international services. Established during World War I, the organization had a membership by the mid-1950s of more than 21,000,000 enrolled through approximately 75,000 public, private and parochial schools. Among the programs promoting international understanding is the gift box program, through which each year about 200,000 gift boxes are packed by American school children and sent overseas to children in areas crippled by war or other disaster. In their communities junior members produce articles for persons in hospitals and homes for the aged, for orphans and for servicemen; serve as messengers in disaster; and take part in other service activities.

The American Red Cross has been active from the beginning in international relief work. Through the League of Red Cross Societies, the American Red Cross joins with other national societies to send supplies and other assistance to countries stricken by disaster. The American Red Cross also gives technical and advisory assistance to other societies, and has aided substantially in helping societies in war-crippled countries to re-establish and strengthen Red Cross services. It also works closely with other national societies in developing joint programs of assistance to prisoners of war.

Pioneer Work.—The American Red Cross has pioneered in a number of fields, in some of which the organization discontinued its work when tax-supported or other private agencies were created or expanded to take over meeting such needs. For example, Red Cross first launched the sale of Christmas seals to attack tuberculosis in the U.S. Later, in co-operation with the National Tuberculosis association, annual drives were carried on jointly until 1919, when Red Cross withdrew, turning the program over in its entirety to the National Tuberculosis association, together with a grant to help carry on the work. Similarly, Red Cross was the first organization to set up a national nutrition education program to teach better food habits through instruction in dietetics and household economics in 1908. Later, Red Cross joined with the U.S. department of agriculture to pioneer the school lunch program. In 1912 Red Cross began a public health nursing program, directed particularly toward providing nursing care in rural areas. Nurses, given special training through grants and loans by Red Cross, went out to rural and isolated communities as "town and country" nurses, teaching sanitation and hygiene, helping fight epidemics, counseling in proper diet, instructing in first aid, often providing the only available nursing care. As other agencies took over, Red Cross gradually withdrew from this field. By the time the program terminated in 1950, Red Cross had been responsible for establishing about 3,000 services in 3,700 chapters throughout the country. At their peak, these public health programs employed more than 2,000 nurses. In 1919 Red Cross began a national program to supply Braille books for blind servicemen. Thousands of volunteers in local chapters helped prepare the raised-image books. During the 1940s this program was taken over by the Library of Congress. Following World War I Red Cross pioneered in hospital recreation work and in medical and psychiatric social work in military and later in veterans' hospitals. Other fields in which Red Cross pioneered and in which the organization still participates are: disaster work; welfare services for the armed forces, veterans and their dependents; a nation-wide program of instruction in home nursing, first aid and water safety; a nation-wide blood program; and many others.

Red Cross is supported by voluntary contributions from the American public. Through its annual membership and fund campaign it seeks to enroll all citizens as members. In the mid-1950s, membership was about 44,000,000 including 21,000,000 junior members enrolled through the schools. The American Red Cross operates under a charter last amended by the U.S. congress in 1947. The governing body of the organization is a 50-member board of governors, 8 of whom are appointed by the president of the U.S.; 30 are elected by chapters and the remaining 12 by their fellow board members. The president of the U.S. is honorary chairman.

National headquarters are in Washington, D.C. There are four area offices—at Alexandria, Va., Atlanta, Ga., St. Louis, Mo., and San Francisco, Calif.; each has administrative responsibility for all Red Cross activities in the states under its jurisdiction.

Local chapters have a wide discretion in deciding on the Red Cross services they believe are needed in their communities. Each chapter, however, is required by charter to conduct a program of assistance to the armed forces and veterans and to engage in disaster activities. The work of each chapter is determined by a volunteer board of directors drawn from the community.

BIBLIOGRAPHY.—Of the reports and publications of the International Committee of the Red Cross and the League of Red Cross Societies, the following are important: *Handbook of the International Red Cross* (Geneva, 1953); *The Geneva Conventions of August 12, 1949,* 2nd rev. ed., vol. I, II (Geneva, 1950); *The International Red Cross Committee in Geneva 1863–1943* (Geneva, 1943); *The League of Red Cross Societies, Its Foundation, Organization, Programme* (Geneva, 1956); *Do You Know the Red Cross?* (Geneva, 1953). *See* annual reports of the American National Red Cross and the British Red Cross. *See* also Marcel Junod, *Warrior Without Weapons* (New York, London, 1951); Foster Rhea Dulles, *The American Red Cross: a History* (New York, 1950); *For the Common Weal* (Washington, D.C., 1956); Sir James Magill, *The Red Cross, the Idea and Its Development* (London, 1926); Jean S. Pictet, *The Sign of the Red Cross* (Geneva, 1952).

(C. L. BT.)

RED DEER (Cervus elaphus), the male of which, the stag, par excellence, reaches a height of 4 ft. 6 in. at the shoulder. The antlers are rounded, possessing bez tines and in well-developed animals at least 12 points, the record number for a British wild specimen being 20, though an ancient Irish skull was found bearing 34 and a park specimen had 39. The tail is rather long and the coat is spotted in the young and occasionally even in the adult. The males. which alone bear antlers, often have a "mane" on the throat. and in the breeding season utter a roaring cry. There are numerous local races of the red deer, which inhabit Europe, northern Africa, Asia Minor and north Iran; the species has been successfully introduced into New Zealand. Typically a woodland animal, the red deer in Britain is now confined to open mountainsides in the highlands of Scotland, Exmoor and a few other localities, and to parks; as a result, there has been a decided decline in the size and condition of the Scottish animals, which cannot compare with those from the continent. (See DEER.)

REDDITCH, an urban district in the Bromsgrove parliamentary division of Worcestershire, Eng., 14 mi. S. of Birmingham by road. Pop. (1951) 29,183. Area 18.8 sq.mi. It is a centre for the manufacture of needles, fishhooks and fishing tackle and there is a large motorcycle and cycle works.

REDEMPTION, in religion, has both a larger association and a more limited biblical context. In the first sense it is broadly identified with salvation, atonement (*q.v.*), reconciliation and forgiveness. It refers to the action of God within history whereby mankind has been delivered from sin and death through the life, death and resurrection of Jesus Christ (see JESUS CHRIST). "In him we have redemption through his blood, the forgiveness of our trespasses according to the riches of his grace" (Eph. i, 7). The biblical metaphor is that of buying back a parcel of land or of purchasing someone from slavery. In the Old Testament redemption is usually described as deliverance from material disasters, but in Ps. cxxx it is promised that God "will redeem Israel from all his iniquities." Jesus' saying that "the Son of man also came not to be served but to serve, and to give his life as a ransom for many" (Mark x, 45) found its deepest expression in his crucifixion.

Emphasis has been placed on the voluntary and loving character of Christ's sacrificial act, on the costliness of this deliverance, on the representative and substitutionary activity of Christ in doing for men what they could not do for themselves, and on the needed response of men in faith, worship and newness of life to this initiative of God in Christ.

REDEMPTORISTS (CONGREGATION OF THE MOST HOLY REDEEMER; CONGREGATIO SANCTISSIMI REDEMPTORIS; C.SS.R.), a religious congregation founded by St. Alfonso Maria de' Liguori (*q.v.*) at Scala, Italy, Nov. 9, 1732. Benedict XIV granted papal approbation Feb. 25. 1749. Neapolitan regalism was an obstacle to the congregation, and steps were taken to settle also in the papal states. In 1785 through St. Clement Hofbauer (*q.v.*) the congregation entered the transalpine world, and eventually secured foundations throughout Europe and, during the centenary year, 1832, the United States. The congregation now is established on the five continents. The purpose of the congregation is the sanctification of the members through the imitation of Jesus Christ and the preaching of the word of God, especially to the poor, through various means, particularly parish missions. The Redemptorists also conduct parishes and foreign missions.

The congregation, composed of priests, clerical students and lay brothers, is ruled by a superior-general, who is elected for life and resides in Rome at the general mother house. He is aided by general consultors who represent geographical areas. Provincials, vice-provincials and rectors are appointed by him. The Redemptorists number more than 8.000. There is also an order of Redemptorist nuns, founded by St. Alfonso Liguori in 1731 and approved in 1750.

See M. de Meulenieester, *Outline History of the Redemptorists* **(1956)**; G. Stebbing, *The Redemptorists* **(1924)**. (A. C. RU.)

REDFIELD, ROBERT (1897–1958). U.S. anthropologist, developed concepts that brought into a single purview preliterate tribes, folk peasantries and complex civilizations. Born Dec. 4, 1897, in Chicago, he was associated all of his life with The University of Chicago, as student, professor and dean. The son of a lanyer, Redfield married Margaret Park (daughter of the sociologist Robert E. Park) before graduating in law. A summer visit to Mexico turned him to anthropology. His Ph.D. dissertation (1928) reported field work in a community in Mexico; Tepoztlan received immediate attention as a pioneer study of the "folk" community as a way of life. After extended field work with his family in Yucatan, he showed through comparison of tribe, village, town and city how the growth of a small isolated community into a large heterogeneous society involves social disorganization and the substitution of formal institutions for a "moral order." Later, study of the civilizations of China and India, which he visited, suggested how the intellectual-aesthetic "great tradition" alters the character of small communities and their continuing "little traditions." Peasants are seen as living in small part-societies, somewhat tribal-like but affected by cities and the great tradition. Concerned with the good life as conceived by different groups, Redfield then traced continuities and changes in thought and values in the history of all mankind. In so doing he developed a new humanism in which careful and comparative methods are brought to problems that cannot escape questions of better-and-worse. The clarity of his thought and expression and the breadth of his conception greatly influenced men of affairs as he spoke for the free mind, the just society and the world united for peace. He died on Oct. 16, 1958, in Chicago.

Among his writings are Tepoztlan (1930); Chan Kom (1934); The Folk *Culture* of Yucatan (1941); *A* Village *That* Chose Progress (1950); *The* Primitive World and Its Transformations (1953); The Little Community (1955); Peasant Society and Culture (1956).

See Fay-Cooper Cole and Fred Eggan, "Robert Redfield," in *American Anthropologist,* vol. lxi, no. 4 (Aug. 1959), with full bibliography. (S. Tx.)

RED JACKET (Sagoyewatha—"he who keeps them awake") (c. 1751–1830) was a Seneca Indian chief born near Geneva, N.Y., about 1751. He was an eloquent orator—whence his Indian name—and possessed considerable influence over his people. He fought for the British during the Revolution and because of his ability as a runner was a favourite among the officers, one of whom presented him with a heavily embroidered red coat. This made him conspicuous among his people and he was henceforth known as Red Jacket. He first appeared as a conspicuous figure when he made a notable speech in opposition to the treaty which was signed at Ft. Stanwix in 1784 by the United States and the Six Nations. In 1792 he went to Philadelphia, then the capital, to conclude a treaty of friendship with the United States. Under his leadership the Senecas allied themselves with the Americans against the British in the War of 1812. Red Jacket understood the whites well and became more and more hostile to them as he realized their overwhelming power. "You are a kindhearted people, seeking your own advantages," he said in one of his speeches. He tried to consolidate his people and preserve their ancient ways and rites, but by his stand only lost his leadership. He died in Seneca village, N.Y., on Jan. 20, 1830.

REDLANDS, a city of San Bernardino county, Calif.. U.S., is situated at the foot of the San Bernardino mountains, 65 mi. E. of Los Angeles. (For comparative population figures see table in CALIFORNIA: Population.)

The city lies at the upper end of San Bernardino valley at an elevation of 1,200 to 2,100 ft , surrounded by peaks more than 10.000 ft. high. While the navel orange-growing area has been its basic economy, Redlands also provides homes for military and civilian personnel who work at nearby Norton and March air force bases and the local rocket company. Within easy commuting distance of Los Angeles, the nearby beaches, mountain resorts and desert playgrounds, with a mild sunny climate, Redlands is an ideal residential town.

The University of Redlands, affiliated with the American Baptist convention, was established in 1907. The Watchorn Lincoln memorial, the only one of its kind in the west, stands on the grounds of the public library. The San Bernardino *asistencia* is a link with the city's Spanish heritage, and the Redlands Music association provides weekly summer concerts in the Prosellis bowl.

The present city was founded in 1887 by New Englanders and incorporated in 1888. While retaining "Yankee" characteristics, it is representative of all areas of the country. A council-manager system of government was adopted in 1949.

(G. B. BE.)

REDLICH, JOSEPH (1869–1936), Austrian historian and politician, was born in Göding, Moravia, on June 18, 1869. He studied jurisprudence and history in Vienna, traveled extensively, especially in England, and in 1901 published his first work, *Die englische Lokalverwaltung (Local Government in England,* 1904). He afterward became professor at Vienna university, and sat in the Austrian parliament till 1911 as deputy for his birthplace. Both in the Austrian parliament in Vienna and the Moravian diet he did much to further the idea of an understanding between the German and Czech peoples. In 1905 he published another study of English political life: *Recht und Technik des englischen Parlamentarismus* (1905; Eng. trans., *The Procedure of the House* of *Commons,* 3 vol., 1907), a standard work on the subject and indispensable to the student. During World War I he was politically active, and in 1918 was appointed minister of finance in the Lammasch cabinet. He then retired from active politics, to produce *Das oesterreichische Staats- und Rechtsproblem* (vol. 1, 1920; vol. 2, 1926), a history of Austrian domestic policy from 1848 onward. His other works include *Das Wesen der oesterreichischen Kommunalverfassung* (1910); *The Common Law and the Case Method in American University Law Schools* (1914); *Oesterreichische Regierung und Verwaltung im Weltkriege* (English and German, 1925) and a biography, *Franz Joseph von Oesterreich* (1928). Redlich's attitude was usually rather that of a student of political theory and practice than of a pure historian, and his works were apt to be too voluminous to be easily read; but they were founded on encyclopaedic knowledge, carefully presented, and were exhaustive.

REDMAYNE, SIR RICHARD AUGUSTINE STUDDERT (1865–), K.C.B. (1914), was born at Gateshead-upon-Tyne, on July 22, 1865, and educated privately and at the Durham College of Science, Newcastle. In 1883 he became under-manager at a colliery firm in Durham, and eight years later went to South Africa. On his return in 1893 he was appointed manager of the Seaton Delaval collieries, Northumberland (1893–1902). He then obtained an appointment at Birmingham university as professor of mining. He acted as chairman on numerous government committees on questions affecting the mines, and in 1908 was appointed chief inspector of mines, a post which he held until 1920. He was chairman and governor of the Imperial Mineral Resources bureau (1918–25), and chairman of the advisory council on minerals to the Imperial institute (1925–35). His writings include *Men, Mines and Memories* (1942), *The Problem of the Coal Mines* (1945) and many official reports on mining.

REDMOND, JOHN EDWARD (1856–1918), Irish politician, son of W. A. Redmond, M.P., was born at Ballytrent. He was educated at Trinity college, Dublin, and was called to the bar at Gray's Inn in 1886, and subsequently to the Irish bar, though he never practised. He was a clerk in the vote office of the house of commons before he entered parliament in 1881 as member for New Ross. From 1883 to 1891 he represented North Wexford. As party whip he rendered great service to the Irish members by his thorough grasp of the procedure of the house. At the time of the rupture of the Irish party consequent on the Parnell scandals, Redmond was the most eloquent member of the minority who continued to recognize his leadership, and in 1891 he became the accredited leader of the Parnellites. In 1900 the two nationalist parties were amalgamated under his leadership. He contested Cork unsuccessfully in 1891, but was elected for Waterford. where he was re-elected in 1906. (For the political events under his leadership of the Irish parliamentary party up to 1910, *see* IRELAND: *History;* ENGLISH HISTORY, etc.)

Redmond obtained for the first time a position of real power in parliament after the general election in Jan. 1910. Though he had amalgamated the two Irish Nationalist parties under his own lead in 1900, he had never hitherto been able, because of the large Unionist majority of 1900 and the Liberal majority of 1906, to hold that balance of power in the house of commons which had proved such a formidable weapon in the hands first of O'Connell and then of Parnell. But the reduction of the Liberal forces in Jan. 1910 made if impossible that Asquith's government should long continue unless it found favour with Redmond.

The first use which he made of this new authority was to insist that Lloyd George's famous budget of 1909, on which the dissolution had turned, should be postponed till after the constitutional resolutions directed against the house of lords—his one object being to remove the veto of the upper house, which was the main barrier against home rule. This order of procedure was also demanded by the Labour party and by the Radicals; and the government complied. But Redmond pressed further for an assurance that the royal prerogative would be at the prime minister's disposal to overbear any rejection by the lords of the veto resolutions. He was impatient at the constitutional conference called in the summer at the beginning of King George's reign to endeavour to discover a solution by consent, and went to America to secure sympathy and funds. The conference having broken down, he conducted a strenuous campaign on behalf of the ministerial program for the second general election of the year, in spite of a harassing movement on his flank by a small party of independent Nationalists under O'Brien and Healy, who accused him of having sold the Irish vote to the government.

When the result of the polling had confirmed Redmond in his tenure of the balance of parliamentary power, he forwarded the progress of the Parliament bill in 1911 by the steady vote of his party. In the autumn he was regularly consulted on the details of the forthcoming Home Rule bill, and when the bill was introduced, in April 1912, he procured its enthusiastic acceptance from a nationalist convention in Ireland. His speeches during its passage through parliament were, on the whole, moderate; he disclaimed separation but denounced any attempt to take Ulster out of the bill as a mutilation of Ireland. In token of the union of feeling between Nationalists and Liberals, he attended the meeting of the National Liberal federation at Nottingham in Nov. 1912, and spoke for the first time on the same platform as Asquith. When the determined attitude of Ulster began to suggest to the Liberals the advisability of compromise. Redmond was very loth to agree, denouncing the Unionists and Ulster as engaged in "a gigantic game of bluff and blackmail." He insisted that Asquith's county option scheme was the extreme limit of concession. He was being pressed in Ireland by the rising power of Sinn Feiners and other extremists who had raised, in reply to Ulster, a great body of 100.000 nationalist volunteers, over whom Redmond only obtained control in June 1914 after a sharp struggle. Nevertheless he took part, at the end of July, in the abortive Buckingham Palace conference.

Then came World War I, and in the debate succeeding Sir E. Grey's famous declaration on bank holiday, Aug. 3, Redmond created a profound sensation by a speech in which he declared that the events of recent years had completely altered the nationalist feeling toward Great Britain. The government, he said, might withdraw its troops from Ireland, whose coasts would be defended by its own sons, nationalist volunteers joining with Ulster volunteers in the task. This attitude was met by the decision of the government to pass the Home Rule bill into law. suspending its operation till after the war. Redmond took an active part in promoting recruiting in Ireland, and stood on the platform in Dublin mansion house on Sept. 25 by the side of the prime minister and the lord lieutenant. Unfortunately, his efforts were only moderately successful, but he refused Asquith's offer to join the first coalition government. and he successfully opposed all attempts to apply conscription to Ireland. It was a stunning blow to him when the smouldering dissatisfaction of southern Ireland broke

out into a blaze in the Dublin rebellion of Easter 1916. He expressed his opposition in the house of commons, and lent his assistance to the attempt which was made by the government in the summer through Lloyd George to arrange an agreed settlement of the Irish question.

But the effort failed; Duke, a Unionist, was appointed chief secretary; and Redmond treated the whole transaction as a fresh outrage on Ireland, moving on Oct. 18 a resolution (which was rejected) charging ministers with maintaining a system of government in that country inconsistent with the principles for which the Allies were fighting in Europe. Next year he threatened a return of his party to the old obstructionist opposition; but when in May 1917 Lloyd George, as prime minister, suggested an Irish convention to produce a scheme of self-government, Redmond agreed; and in the convention he played a conciliatory part. During its sittings, however, his health failed, and he died in London on March 6, 1918.

See I. G. Redmond Howard, *John Redmond* (1910) ; *Home Rule: Speeches of John Redmond, M.P.,* ed. by R. Barry O'Brien (1919) ; S. Gwyn, *John Redmond's Last Years* (1919).

REDON, ODILON (1840–1916), French Symbolist painter, lithographer and etcher, was born in Bordeaux on April 20, 1840. An early friendship with the botanist Armand Clavaud stimulated his tastes in literature and philosophy and encouraged his love of drawing. He studied for a short time with Jean Léon Gérôme in Paris, but it was a meeting with the vagabond artist Rodolphe Bresdin in Bordeaux which had the greatest influence on him. During a life which was passed almost in retirement he produced 172 lithographs, 26 etchings and many paintings and drawings which are the testimonials of his sincerity, unalterable integrity and unselfish dedication to his art. The largest collection of his prints is in the Art Institute of Chicago. Due to his friendship with the poet Stéphane Mallarmé and the character of his work he is associated with the Symbolists. He died in Paris on July 6, 1916.

See André Mellério, *Odilon Redon* (1923). (H. Es.)

REDONDA: see ANTIGUA.

REDONDO BEACH, a resort city in Los Angeles county, Calif., U.S., is situated 19 mi. S.W. of Los Angeles on the Pacific ocean. Once seriously considered for the port of Los Angeles, Redondo Beach was developed in the 1880s with an iron pier and a narrow-gauge railroad. Though it mas a commercial port for some years while San Pedro was being developed, its wide beaches and sharp palisades were tourist attractions, and proinoters took advantage of its natural beauty by building fine hotels, a salt-water plunge, amusement facilities and an interurban rail line with Los Angeles. The city was incorporated in 1892 and adopted the city-manager form of municipal government in 1949. After 1945, the beach city also became a residential community for many people working in the oil refineries of Torrance, Wilmington and El Segundo. It has a public library, a symphony orchestra and a light-opera association. El Camino college (1948) and Loyola university (1911) are nearby. King harbour provides excellent boating facilities. For comparative population figures see table in CALIFORNIA : Population. (J. A. Sz.)

RED PEPPER: see CAPSICUM.

REDPOLL, the name given to several birds of the finch family (Fringillidae), allied to the linnet (*q.v.*), and possessing a reddish head. The best known is the lesser redpoll (Carduelis *linaria*). The mealy redpoll is a subspecies with a more northern range, visiting England in the winter. The type ranges over the north temperate zone. There are three additional subspecies in northern North America, but these rarely reach the U.S.

RED RIVER, sometimes called Red River of the South to distinguish it from the Red River of the North (*q.v.*), is formed in the high plains of the Texas panhandle. It flows generally eastward into Arkansas, where it turns southeast through Louisiana to its junction with the Old river, which connects the Mississippi with the Atchafalaya river. Though the Red is considered a tributary of the Mississippi, much of its normal discharge goes directly to the gulf by way of the Atchafalaya.

The Red is 1,018 mi. long; for about half this distance it serves as the Texas–Oklahoma boundary. Its drainage basin is approximately 81,300 sq.mi. Discharge at Shreveport, La., has varied from 1,500 to 260,000 cu.ft. per second. Among the many tributaries are the North Fork of the Red, Kiamichi, Little and Black (Ouachita) rivers.

Early navigation of the Red above Natchitoches, La., prior to 1832 was impeded by a jam of driftwood almost 160 mi. long. Capt. Henry M. Shreve cleared this "great raft" to Oklahoma by 1837. A later raft which formed above Shreveport was cleared in 1873. After removal of these rafts navigation prospered for a time, with Alexandria and Shreveport, La., being the chief beneficiaries. Though Fulton, Ark., 455 mi. upstream, is now considered the head of navigation, vessels drawing over four feet can reach it only a few months of the year. Most of the 1,000,000-ton annual traffic is in the lower 35 mi. portion.

In the early 1930s Denison dam was completed on the Red 726 mi. above the mouth. This multipurpose dam forms Lake Texoma, a 223-sq mi. lake with a storage capacity of over 5,500,000 ac.ft. (M. W. M.)

RED RIVER OF THE NORTH, formed by the juncture of the Bois de Sioux river from the south and the Otter Tail river from the east at the twin cities of Wahpeton, N.D., and Breckenridge, Minn. It flows north, forming the North Dakota–Minnesota boundary, then crosses the U.S.–Canadian border and enters Lake Winnipeg 40 mi. N. of Winnipeg, Man. The distance from its source to its mouth is 320 mi. but the river winds in such intricate curves over the flat plain of former glacial Lake Agassiz that the actual river mileage is 545 mi. It has cut a gorge 20 to 50 ft. deep through clay deposits throughout the greater part of its course. The principal tributaries from the west are the Assiniboine, Sheyenne, Wild Rice (of North Dakota) and Pembina rivers; from the east are the Otter Tail, Red Lake, Wild Rice (of Minnesota) and the Roseau rivers.

The river drains an agricultural region that is famous for the production of cereal grains, potatoes, sugar beets and livestock. Important recreation areas are found on the margins of the basin. The leading cities on the river are Winnipeg, and Fargo and Grand Forks, N.D. (B. L. W.)

RED RIVER SETTLEMENT, a Scottish colony founded in 1811 near the present city of Winnipeg by a philanthropic Scottish nobleman, Lord Selkirk, who at that time controlled the Hudson's Bay company and received from it a grant of 113,000 sq.mi. in the basin of the Assiniboine and Red rivers. Quarrels soon arose with the French and half-breed employees of the North-West Fur company, and were fostered by its officials. On June 19, 1816, in a fight between the rivals, Governor Semple of the Hudson's Bay company and 20 of his 27 attendants were killed, an affair known as the Battle of Seven Oaks. New settlers were sent by Selkirk and founded the village of Kildonan, now part of Winnipeg. In 1821 the rival companies united, and in 1836 repurchased from Selkirk's heirs all rights to the territory. In 1821 and in 1835 two forts, known as Lower and Upper Ft. Garry, were built to command the junction of the Red and Assiniboine rivers.

The purchase in 1869 of the territorial rights of the company by the dominion of Canada led to a rebellion and the setting up of a provisional government under Louis Riel, which was dispersed.

BIBLIOGRAPHY.—J. J. Hargrave, *Red River* (1869); George *F.* G. Stanley, *Birth of Western Canada* (1936) ; Vera Kelsey, *Red River Runs North* (1951).

RED SEA, a narrow strip of water extending south-southeast from Suez to the Strait of Bab el Mandeb in a nearly straight line, and separating the coasts of Saudi Arabia and Yemen from those of Egypt, Sudan and Eritrea. The Red sea was so named because of a free floating form of blue-green algae (*Trichodesmium* erythraeum) which has a red accessory pigment and occasionally gives a red colour to the surface waters. Its total length is about 1,200 mi., and its breadth varies from about 250 mi. in the southern half to 130 mi. in 27° 45' N., where it divides into two parts, the Gulf of Suez and the Gulf of Aqaba, separated from each other by the peninsula of Sinai. Structurally, the Red sea is part of a great rift-valley system forming one of the most

marked features of the earth's crust. The rift valley of the Jordan and the Dead sea is continued southward by the Wadi el Araba, and its submerged southern section gives the Gulf of Aqaba. This well-marked north-northeast to south-southwest line meets the north-northwest to south-southeast line, already marked in the Gulf of Suez, and together they form, to the south, the main basin of the Red sea. The rift may be traced still farther southward among the great African lakes.

This great structural depression is probably of Tertiary age, being let down between two ancient Archean blocks—Arabia and north Africa. Secondary and Tertiary deposits appear on both flanks in Egypt and Arabia, while Archean material appears at the surface in many places on the Red sea coast. These extensive earth movements were accompanied by much volcanic activity, traces of which are still evident. A group of volcanic islands occurs in 14° N., and on Jebel Teir, near 15° 30' N., jets of steam still appeared in the second half of the 20th century. The margin of the Red sea itself consists, on the Arabian side, of a strip of low plain backed by ranges of barren hills of coral and sand formation, and here and there by mountains up to 6,000 ft. and more in height. The greater elevations are for the most part formed of limestones, except in the south, where they are largely volcanic. The coasts of the Gulf of Aqaba are steep, with numerous coral reefs on both sides. On the African side there are, in the north, wide stretches of desert plain, which toward the south rise to elevated tablelands, and ultimately to the mountains of Abyssinia. The shores of the Red sea are little indented; good harbours are almost wanting in the desert regions of the north, while in the south the chief inlets are near 15° N. at Massaua, and at Kamaran, almost directly opposite. Coral formations are abundant; immense reefs, both barrier and fringing, skirt both coasts, often enclosing wide channels between the reef and the land.

Depths.—The mean depth of the Red sea is approximately 1.611 ft. and its area and volume are approximately 169,100 square miles, and 52,000 cubic miles respectively. The Gulf of Suez is shallow, with a maximum depth of about 210 ft., and outside its mouth the bottom in the Red sea slopes rather steeply to a depth of about 4,140 ft. at 27° 30′ N. The Gulf of Aqaba attains a depth of 4,200 ft. in 28° 39' N. and 34" 43' E. Its deeper waters are separated from the deep water of the Red sea by an entrance sill much of which is considerably less than 600 ft. below the surface. Along the mid-line of the Red sea an irregular trough about 30 mi. broad between the 3,000 ft. depth contours extends from 27° 30' N. to 17° N. where it is interrupted by a transverse submarine ridge rising to within 1,200 ft. of the surface. Between 25" N. and 17° N. mid-channel depths occasionally exceed 7,200 ft., with a maximum of over 9,000 ft. reported near 20° N., whereas to the south the maximum depth is about 4,020 ft. and the channel shoals to about 300 ft. off Hanish Island in crossing the entrance sill which separates the deeper basin of the Red sea from that of the Gulf of Aden. From the north end of the Red sea to the banks of Suakin and Farasan in 20° N. the 600-ft. line keeps to a belt of coral reef close inshore, but in lower latitudes the shallow coral region, 300 mi, long and 70 to 80 mi. across, extends farther and farther seaward until at 15° N., off Hodeida, the part of the channel that is deeper than 600 ft. is only 20 mi. broad, all the rest of the area being dangerous to navigation even for small vessels. The Strait of Bab el Mandeb, the southern entrance to the Red sea, is divided by Perim Island into two channels. The eastern channel is 1.7 mi. broad between the 30 ft. curves and has a maximum depth of 96 ft. The western channel preferred for navigation, is 1,020 ft. in mid-channel and is 10.4 mi. wide between Perim Island and the islands near the African coast.

Meteorology.—In the northern part, down to almost 19° N., the prevailing winds are north and northwest. The middle region, to 14°–16° N., has variable winds in an area of low barometric pressure, while in the southern Red sea southeast and east winds prevail. From June to August the northwest wind blows over the entire area; in September it retreats again as far as 16° N., south of which the winds are for a time variable. In the Gulf of Suez the prevailing wind is northerly or northwesterly, but the westerly or "Egyptian" wind occurs occasionally during winter, sometimes blowing with violence, and generally accompanied by fog and clouds of dust. Strong north-northeast winds prevail in the Gulf of Aqaba during the greater part of the year; they are weakest in April and May, sometimes giving place at that season to southerly breezes. The mean monthly air temperature ranges from 71° F. at Suez to 86° at Massaua. Rainfall is light, generally less than an inch a year along the northern shores, and nowhere exceeding about ten inches. At some points a year may pass without a trace of rain. The high temperature and great relative humidity in summer make it a difficult region for active life.

Water Temperature.—The mean annual surface temperature of the waters varies from about 75° F. near the head to 80° F. in about 22" N., to 84° in 16° N., and drops again to 82° at the Strait of Bab el Mandeb. Temperatures in February are about 5° below and in August 5° above the annual mean. Temperature is, on the whole, higher near the Arabian than the Egyptian side. During summer the temperature decreases rapidly, dropping as much as 10° in the upper 150 ft. and then decreasing more slo ly to about 70.7°, in water at depths of 600 to 1,200 ft.; this latter temperature is constant throughout the sea and the year. In winter as a consequence of increased density caused by rapid evaporation and cooling, sinking of surface water apparently occurs north of about 22° N., and the temperature changes but slightly with depth. In the southern part of the area, however, the temperature still decreases with increasing depth, but because of surface cooling the drop is less pronounced than in summer. In the Gulf of Suez temperatures are relatively low, ranging from about 64° in February to 79° in August, and decreasing quite rapidly from south to north. The waters in the Gulf of Aqaba are reportedly warmer toward the Arabian than the Sinai coast, but here as well as in the Red sea proper temperatures will vary locally in response to wind and circulation patterns; a uniform temperature of 70.2° is observed in the deeper water.

Salinity.—The salinity of the waters is very high compared to that found in the open ocean, the surface values being highest, $41^0/_{00}$ (per mille), in the Gulf of Suez, and decreasing to about $36.5^0/_{00}$ near Perim Island at the southern entrance. Below a depth of 600 ft. the salinity ranges between $41^0/_{00}$ in the north and $40.5^0/_{00}$ in the south. South of about 20° N. the salinity increases with depth, the increase being particularly rapid between 300 and 600 ft., whereas in the north, there is little change from top to bottom. In general the surface salinity is somewhat greater on the western than the eastern side. In the Gulf of Aqaba the salinity is quite uniform averaging about $40^0/_{00}$. Salinities of $50^0/_{00}$ to $55^0/_{00}$ are encountered in the Bitter lakes section of the Suez canal, but the prevailing current carries most of this water toward the Mediterranean.

Circulation.—The movements of the waters are of great irregularity and complexity, rendering navigation difficult and dangerous. Two features stand out with special distinctness; the exchange of water between the Red sea and the Indian ocean, and the tidal streams of the Gulf of Suez. During the north-northwest winds of summer surface water and a layer of highly saline bottom water flows from the Red sea to the Gulf of Aden, and between these layers a contrary current of Indian ocean water sets into the Red sea. In winter surface waters enter the Red sea from the Gulf of Aden but Red sea water continues to discharge at depth. The water carried by the bottom current was formed and sank in the northern part of the Red sea in winter and has a high salinity and temperature and a low concentration of dissolved oxygen. Through these characteristics it has been traced at intermediate depths in the Indian ocean south past the equator. In the Gulfs of Suez and Aqaba, almost the only part of the Red sea in which tidal phenomena are well developed, a sharply defined tidal circulation is found. Elsewhere, the surface movements at least are controlled by the prevailing winds, which give rise in places to complex transverse currents, and near the coast are modified by the channels enclosed by the coral reefs. During the prevalence of the north and northwest winds the surface level of the northern part is depressed by as much as two feet.

The Red sea was important in Egyptian maritime commerce at least as early as the 2nd millennium B.C. and it had associations

with India early in the 1st millennium B.C. Under the Arabs the Red sea was an important highway of trade with connections to India, Persia and east Africa. This sea helped to keep Islam in touch with the thinkers of the east and with the glories of the ancient world during the dark ages in the west; with the revolutions in shipping and movement by sea that followed the age of discovery the Red sea seemed to retreat into the background; but with the cutting of the Suez canal (1869) and the shortening of the route to India, Australia and the east, the Red sea not only recovered its former importance but became one of the greatest commercial highways in the world.

Bs.)

REDSHANK, the name of a bird, Tringa *totanus*, so called from the colour of its long legs. In suitable localities it is abundant throughout the greater part of Europe and Asia, retiring southward for the winter, though a considerable number remain along the coasts of some of the more northern countries. The body of the redshank is as big as a snipe's, but its longer neck, wings and legs make it appear larger. Above. the general colour is grayish drab, freckled with black, except the lower part of the back and a conspicuous band on each wing. which are white, while the flight quills are black. The bird nests in inland localities as well as by the sea. The males in spring have a beautiful song-flight, rising and falling with quivering wings, and a striking courtship on the ground. They are very pugnacious, fights often continuing for over an hour. The redshank is very wary, and is disliked by shore gunners for giving the alarm to other species. The nest is generally concealed in a tuft of rushes or grass in the swamp whence the bird gets its sustenance, and contains four eggs of a warmly tinted brown with blackish spots or blotches.

The black, dusky or spotted redshank (T. erythropus) is a larger and less common bird, and in the greater part of Europe it only occurs on its passage to or from its breeding grounds, which are south of the Arctic circle. The spot chosen for the nest is nearly always in forests and at some distance from water. In breeding dress the head. neck. shoulders and lower parts are black, the back and rump white, while the legs become crimson. At other times of the year the plumage is similar to that of the common redshank and the legs are of the same light orange-red.

REDSTART (FIRETAIL), *Phoenicurus phoenicurus*, a small bird which is a summer visitor to Europe, where it haunts gardens, orchards and old buildings. Its habit of flirting its red tail, and the white forehead, black throat, and bay breast of the cock are distinguishing features; the hen is more plainly coloured, but the characteristic colouring and action of the tail pertain to her equally as to her mate. The nest is almost always placed in a hole of a tree or building, and contains from five to seven eggs of a delicate greenish blue, occasionally sprinkled with faint red spots. The young on assuming their feathers present a great resemblance to those of the redbreast (*q.v.*) at the same age; but the red tail, though of a duller hue than in the adult. forms even at this early age an easy means of distinguishing them. The redstart breeds regularly in all the counties of England and Wales. It also reaches the extreme north of Scotland; but in Ireland it is very rare. It appears throughout the whole of Europe in summer, and is known to winter in the interior of Africa. Several very nearly allied forms occur in Asia; one, P. aurorea, is found in Japan. The black redstart (P. ochrurus) is darker than the preceding, with a more southerly range. Like the last. however, it winters in Africa. It often haunts the vicinity of houses. The males of the black redstart seem to be more than one year in acquiring their full plumage. Allied to the redstarts are the bluethroats (*q.v.*). These groups belong to the subfamily Turdinae of the thrushes. The American redstart (Setophaga *ruticilla*) belongs to the purely new world family Mniotiltidae, and ranges from Canada (in summer) to Bolivia, but is rare on the Pacific coast. The salmon of the breast, wings, and tail of the male are replaced by yellow in the female. The painted redstart (*S.* picta) has a deep-red breast and belly. It inhabits the Mexican plateau, extending north to Arizona and New Mexico.

REDUCTION: see OXIDATION AND REDUCTION.

REDWING, a species of thrush (*q.v.*), *Turdus musicus*, a winter visitor to the British Isles, arriving in autumn about the same time as the fieldfare (*q.v.*). It is very similar to the song thrush, but it has a white streak over the eye, and the sides of its body, inner wing coverts and axillaries are reddish orange. The redwing breeds in colonies in woods in subarctic Europe and Asia to Lake Baikal. In winter it migrates as far south as north Africa and the Himalayas. Its song has often been praised, but is disappointing in comparison with that of the song thrush or blackbird. In its winter quarters it often gives a peculiar inward song in early spring, while still in flocks. Its nest and eggs resemble those of the blackbird.

REDWOOD (Sequoia sempervirens), a valuable, gigantic, coniferous tree extending along the Pacific coastal forests from southern Oregon to near Santa Barbara. Calif. The largest specimen upon which accurate measurements have been made is 364 ft. tall, 12 ft. 7 in. in diameter at breast height and about 18 ft. in maximum diameter. It is seldom found more than 3½ mi. inland or above 3,000 ft. in elevation. An unusual feature of this magnificent tree is its ability to develop thrifty, vigorous, stump sprouts which attain commercial proportions in a relatively short time. While coppice sprouts of this sort are a common feature of broad-leaved species, their occurrence among conifers is relatively rare. The allied big tree, Sequoia *gigantea* (syn. *Sequoia*dendron *giganteum*), also of California (discovered in 1850 in the Sierra Nevada), develops a much more massive bole but not quite the stature of coastal species (see SEQCOIA).

REDWOOD CITY, a city and the seat of San Mateo county, Calif., U.S., is located about 27 mi. S.E. of San Francisco on the San Francisco peninsula. Situated near the mouth of Redwood creek, it has the southernmost deep-water port on San Francisco bay. used since Spanish-Californian days when the town was on El Camino Real (historic mission trail, now a federal highway) and known as Embarcadero. Once the site of an early shipbuilding industry that served a flourishing lumber and shingle trade, the port is used mainly for the shipment of oil, cement and salt. It was first plotted in 1854 on sections of the old Rancho de las Pulgas, largest Spanish land grant in the area, dating back to 1795. Originally named Mezesville after S. M. Mezes. its Mexican founder, the town became known by its present name because of its redwood lumber business long before it was incorporated in 1867. It has been council-manager governed since 1929.

Redwood City is a residential and industrial community. The port has always attracted some industry and the number of industrial establishments grew steadily after World War II. Some of the largest electronics firms, which have made the San Francisco peninsula a centre of this industry, are located there. Redwood City's population increased by 81.1% from 1940 to 1960. For comparative population figures see table in CALIFORNIA: Population. (S. B. KN.)

REED, JOSEPH (1741–1785), U.S. politician, was born in Trenton. N.J., on Aug. 27, 1741. He graduated at Princeton in 1757, studied law in 1763–65 at the Middle Temple, London and then practised in Trenton until he moved to Philadelphia in 1770. He was aide-de-camp and military secretary to General Washington in 1775–76, and mas adjutant general in 1776–77. In 1777–78 he was a delegate to the Continental congress. From 1778 to 1781 he was president of the state executive council. During his administration the proprietary rights of the Penn family were abrogated (1779), and provision was made for the gradual abolition of slavery (1780). Reed was elected to congress in 1784, but died in Philadelphia on March 5, 1785.

The Life and Correspondence of Joseph Reed (1874), by his grandson William B. Reed is based upon the family papers.

His grandson WILLIAM BRADFORD REED (1806–76) graduated at the Pennsylvania university in 1822. He was professor of American history in the University of Pennsylvania in 1850–56, United

States minister to China in 1857–58, and in 1858 negotiated a treaty with China, proclaimed in 1860.

REED, THOMAS BRACKETT (1839–1902), U.S. statesman who as speaker of the house of representatives introduced a number of changes in the procedure of that body, was born in Portland. Me.. on Oct. 18, 1839, and graduated from Bowdoin college in 1860. Admitted to the bar in 1865, he began to practise law in Portland, and was elected to the state's house of representatives in 1868 and to the senate in 1870. From 1874 to 1877 he was city solicitor of Portland. In 1877 he was elected to the U.S. house of representatives on the Republican ticket and served continuously until 1899.

Reed's knowledge of parliamentary law and executive ability made him the leader of his party in the house, 1886–89 and speaker, 1889–91 and 1895–99. He mas a "strong" speaker in his control over proceedings; developing a committee system, he made the majority of the rules committee consist of the speaker and the chairmen of the ways and means and appropriations committees. The Reed rules, drawn by him, William McKinley and Joseph G. Cannon (*qq.v.*) were adopted Feb. 14, 1890; they provided that every member must vote unless financially interested in a measure, that members present and not voting be counted for a quorum and that no dilatory motions be entertained by the speaker. His dictatorial methods were bitterly attacked by the opposition; he was called "Czar" Reed. Nevertheless his rules and methods were adopted by the Democratic leadership in 1891–95 and the powers of the rules committee were increased. Reed's name is not associated with any particular legislation, but he exercised a powerful influence in guiding bills through congress. He vigorously opposed free silver and advocated protective tariffs. He opposed the McKinley administration on the outcome of the Spanish-American War and as a result resigned in 1899 and began the practice of law in New York city. Reed was a student, reading French literature for relaxation, and a powerful orator with a ready wit. His good humour led to many stories about him. While opinion varied as to his conduct as speaker, he was respected and admired by Republicans and Democrats as a man of rugged honesty and intense loyalty. He died in Washington, D.C., on Dec. 7, 1902. For subsequent developments in the office of speaker of the house *see* SPEAKER.

See William Robinson, *Thomas B. Reed, Parliamentarian (1930).*

(H. F. TT.)

REED, WALTER (1851–1902), U.S. bacteriologist, head of the U.S. army Yellow Fever commission, was born in Gloucester county, Va., on Sept. 13. 1851, and was educated at the University of Virginia and Bellevue Medical school (M.D., 1870). In 1875 he entered the medical corps of the U.S. army as assistant surgeon, with rank of lieutenant. In 1893 he was promoted to surgeon, with rank of major, and was made professor of bacteriology and clinical microscopy in the newly organized Army Medical school at Washington, D.C. When the Spanish-American War began, Reed was appointed chairman of a committee to investigate the causation and mode of propagation of typhoid fever, an epidemic of which had broken out among the soldiers. The committee's *Report on the Origin and Spread of Typhoid Fever in C.S. Military Camps* (published in 1904, after Reed's death) revealed a number of points concerning the disease not before known, and emphasized others that had been little appreciated.

In 1897 Reed and an associate proved erroneous the theory of Giuseppe Sanarelli that the *Bacillus icteroides* mas the specific cause of yellow fever. In 1900, when the disease broke out among U.S. troops in Cuba, Reed was made chairman of a commission to investigate its cause and method of transmission. The other members were James Carroll, Jesse W. Lazear (*q.v.*) and Aristides Agramonte. Reed's observation of many cases led him to discount the then prevalent idea that the disease was transmitted by fomites in bedding, clothing, etc., of patients suffering from yellow fever, and to revive the discarded notion of Carlos Juan Finlay that the yellow fever parasite was carried only by mosquitoes. Since the disease was not acquired by animals there was no method of proof except by experiment upon human beings. By a thorough set of experiments, in which some of his co-workers sacrificed their lives, Reed proved to a skeptical world that the yellow fever parasite was carried only by the mosquito then called *Stegomyia fasciata* (later classified as *Aedes aegypti)* and that the bite of this mosquito caused the disease only under certain conditions. Possessed of this knowledge, U.S. sanitary engineers eradicated yellow fever from Cuba (there was not one case in 1902), and it has since been largely eliminated from those parts of the world where scientific public health procedures are carried on. Reed returned in 1901 to Washington, where he died on Nov. 23, 1902. The army general hospital in Washington was named in his honour.

See H. A. Kelly, *Walter Reed and Yellow Fever* **(1923).**

REED, a term applied to several distinct species of large. water-loving grasses. The common or water reed, *Phragmites communis,* occurs along the margins of lakes, fens, marshes and placid streams, not only throughout Great Britain and the United States, but widely distributed in arctic and also in temperate regions extending into the tropics. Another very important species is *Ammophila arenaria* (also known as *Psamma arenaria),* the sea reed or marram grass, a native of the sandy shores of Europe and north Africa. Both species have been of notable geological importance, the former binding the soil and so impeding denudation, and actually converting swamp into dry land, largely by the aid of its tall (five to ten feet) close-set stems. The latter species, of which the branching rootstocks may be traced 30 or even 40 ft., is of still greater importance in holding sand dunes against the sea, and for this purpose has not only been long protected by law, but has been extensively planted on the coasts of Norfolk, Eng., the Netherlands, Gascony, etc. Other reeds are *Calamagrostis* (various species), *Gynerium argenteum* (pampas grass), etc., also *Arundo donax,* the largest European grass (6 to 12 ft. high), which is abundant in Europe. Reeds have been used from the earliest times in thatching and in other branches of construction, and also for arrows, the pipes of musical instruments, etc. Reed pens are still used in the east. Plants belonging to other orders occasionally share the name, especially the bur reed *(Sparganium)* and the reed mace *(Typha),* both belonging to the family Typhaceae. The bulrushes *(Scirpus),* belonging to the family Cyperaceae are also to be distinguished.

See also GRASSES.

REEDBUCK, a yellowish-red African antelope *(Redunca redunca),* about 30 in. high at the shoulder, with a bushy tail, a bare gland patch behind the ear, and in the male short, black, ridged horns which curve upward and outward and bend forward at the tip. There are several other African species of the genus *Redunca* to which the name of reedbuck is also applied. *See* also ANTELOPE.

REED INSTRUMENTS: *see* WIND INSTRUMENTS.

REESE, LIZETTE WOODWORTH (1856–1935), **U.S.** poet whose poetry is largely based on the rural simplicities of her childhood, was born in Baltimore county, Md., Jan. 9, 1856, and died in Baltimore, Dec. 17, 1935. She spent her childhood on the York road, near what became the village of Waverly, in what was then the outskirts of Baltimore. Educated privately, she began to teach in St. John's parish school in Waverly in 1873, and continued teaching in the public schools of Baltimore until her retirement in 1921.

Her lyric talent was strikingly evident even in her first book, *A Branch of May* (1887). and her reputation grew slowly. Her condensed form and sincerity of emotion broke with 19th-century conventional sentimentality and foreshadowed the tone and temper of 20th-century lyricism. The sonnet "Tears," published in 1891 in her fourth collection, A *Wayside Lute,* became deservedly well known. *Selected Poems* (1926) was followed by several other volumes of verse: *Little Henrietta* (1927), *White April* (1930) and *Pastures* (1933); and two books of reminiscences: A *Victorian Village* (1929) and *The York Road* (1931). (LE. BN.)

REEVE, CLARA (1729–1807), English novelist, was born at Ipswich, Suffolk. in 1729. She was an industrious writer and produced many works in prose and verse, including a history of fiction, the *Progress of Romance* (1785). Her only eminent success, however, was the novel *The Old English Baron* (1777), originally published under the title of *The Champion of Virtue.*

She died at Ipswich on Dec. 3, 1807.

REEVE, HENRY (1813–1895), English writer, an influential though inconspicuous figure in early Victorian politics, was born at Norwich, Eng., on Sept, 9, 1813, and educated at Geneva, Munich and Paris. In 1835 he translated Alexis de Tocqueville's *Démocratie en Amérique*.

In 1837 he was nominated head of the legal department of the privy council office, a post he held for 50 years. From 1840 to 1855 he wrote leading articles for the *Times*, and practically guided its foreign policy; friendships with Lords Clarendon and Granville, and with Guizot and Thiers (*qq.v.*), and his trenchant style gave his articles weight. From 1855 he edited the Edinburgh Review, contributing most of the articles on foreign affairs himself. His edition of the Memoirs of C. C. F. Greville (*q.v.*), in three series (1874, 1885 and 1887), though carefully expurgated, gave much offense. Reeve died near Bournemouth on Oct. 21, 1895.

See J. K. Laughton, **Memoirs** of . . . Henry ***Reeve***, 2 vol. (1898).

(M. R. D. F.)

REEVE, a bailiff, steward or business agent; in early English history, one entrusted with the administration of a division of a country; also the chief magistrate of a town or district. The name survives in Canada for the president of a village or town council and in the United States, in composition, as port-reeve, town-reeve, etc.

REFECTORY, the dining hall of a monastery, convent. etc. There frequently was a sort of ambo (*q.v.*), approached by steps, from which to read the lives of the saints, etc., during meals. The refectory was generally situated by the side of the south cloister (*q.v.*), so as to be removed from the church but contiguous to the kitchen.

The word is also sometimes applied to any large hall used for community meals. as in a college, school, etc.

REFEREE, a person to whom anything is referred; an arbitrator. The court of referees in England was a court to which the house of commons committed the decision of all questions as to the right of petitioners to be heard in opposition to private bills. The court was charged with the duty, as defined by a standing order, to decide upon all petitions against private bills, or against provisional orders or provisional certificates, as to the rights of the petitioners to be heard upon such petitions. In the high court of justice, under the Judicature act of 1873, cases might be submitted to three official referees, for trial, inquiry and report, or assessment of damages. Inquiry and report might be directed in any case. trial only by consent of the parties, or in any matter requiring any prolonged examination of documents or accounts, or any investigation which could not be tried in the ordinary way.

United States. — The term referee is commonly applied to persons to whom a court sends a cause or some question therein for determination or for the purpose of taking evidence and reporting upon the same. In this connection it is synonymous with such terms as auditor, commissioner, arbitrator, assessor, etc.

In some states the term is applied to a master, who is appointed in equity suits pursuant to statute as distinguished from masters appointed pursuant to the old equity practice. (See EQUITY.)

REFERENDUM AND INITIATIVE, two methods by which the wishes of the electorate may be expressed with regard to proposed legislation. They exist in a variety of forms. The referendum may be obligatory or optional. Under the former type certain classes of actions by a legislature are required, ordinarily by constitutional provision, to be referred to a popular vote for approval or rejection. Amendments to constitutions proposed by legislatures are subject in most states of the United States, for example, to an obligatory referendum. Under the optional (or facultative) referendum a specified number of voters by petition may demand a popular vote on a law passed by a legislative body. By this means the actions of a legislature may be overruled.

The referendum may also be constitutional or legislative depending on the nature of the matter referred. In the United States questions subject to the obligatory referendum are mostly constitutional while those subject to the optional referendum are invariably legislative. The obligatory and optional forms are to be distinguished from the submission by legislative bodies of particular questions to a referendum or plebiscite, the effect of which may be determinative of the issue or only advisory to the legislature.

By the initiative a specified number of voters may invoke a popular vote on a proposed state or local law or a proposal to amend the state constitution. In its direct form a proposal supported by the requisite number of voters is submitted directly to a popular vote for decision. Under the indirect form the legislature has an opportunity to enact such a proposal. If rejected, the proposition is submitted to a popular vote, in some instances with an alternative proposal by the legislature or with a statement of its reasons for rejection.

The initiative and referendum came into common use in Switzerland in the liberal reaction after the Paris revolution of 1830. In 1831 St. Gall first adopted the facultative referendum (then and for some time after called the veto), and its example was followed by several cantons before 1848. The obligatory referendum appears first in 1852 and 1854 respectively in the Valais and the Grisons, when the older system was reformed. but in its modern form it was first adopted in 1863 by the canton of rural Basel. The initiative was first adopted in 1845 by Vaud. In the cases both of the facultative referendum and of the initiative, each canton fixes the number of citizens who have a right to exercise this power. Both institutions have been used freely in federal and cantonal matters.

Suiss experience with the devices of direct legislation was influential in the'adoption of the initiative and the optional referendum in U.S. states and municipalities.

The United States. — The obligatory referendum on amendments to state constitutions proposed by state legislatures, first adopted by Connecticut in 1818, was in the second half of the 20th century the prevailing method for the amendment of state constitutions. In some states a referendum is obligatory on bond issues and a like rule is widespread in local government for bond issues, tax questions and related matters. Because of the detailed nature of state constitutions and the necessity for their frequent amendment many issues not of a nature to arouse great interest among the voters are referred to them for amendment.

In U.S. usage, the terms initiative and referendum or direct legislation refer not to the obligatory referendum but to the optional referendum on legislation and to the initiation of laws or constitutional amendments by the voters (with the assumption that a popular vote or referendum on the initiated measure will follow). These devices were adopted in the U.S. under the leadership of groups hostile to machine rule, distrustful of legislatures and with a deep faith in democracy. The belief was that by granting the people a means to overrule legislative action and to initiate popular votes on legislation, abuses at the time characteristic of state legislatures might be prevented. Conservative groups were hostile to the adoption of the institution of direct legislation. The chief resort to direct legislation was in the western states, principally in California and Oregon. It did not, however, fulfill the hopes of its advocates or the fears of its opponents. In practice the referendum is used by groups that consider themselves aggrieved by an action of the legislature and feel that they might persuade a majority of the electorate to support them in their demand that the law not go into effect. The initiative tends to be used by groups which have been unable to induce the legislature to enact a desired law. The initiative and referendum proved much less important than the obligatory referendum in bringing issues to the voters. In the legislative process as a whole the initiative and referendum are comparatively unimportant insofar as the volume of legislation directly affected is concerned. The devices may be regarded, in the words of Woodrow Wilson, as a "gun behind the door" to be used when abuses arise in the legislative body.

See also **RECALL.**

British Commonwealth. — Australia. — The Australian commonwealth constitution provides for neither the initiative nor the optional referendum, but the obligatory referendum exists with

respect to amendments to the constitution proposed by parliament. In fact the Australian electorate proved surprisingly hostile to constitutional innovation. In the first half-century of the commonwealth's life only 12 amendments were submitted to the people by referendum and of these only four were carried. The first in 1906 altered the date of senate elections, the second in 1910 enabled the commonwealth to take over state debts, the third in 1927 set up a Loan council and the fourth in 1946 confirmed the commonwealth's power to legislate upon certain social services. Proposals rejected included conscription for overseas service in 1916 and 1917, federal rent and price control in 1948, and anti-Communist legislation in 1951. The referendum was also used by the state governments.

New Zealand used the machinery of the referendum in repeated endeavours to secure the passage of prohibition — always without success. In 1949 proposals to amend the licensing laws were rejected, but off-the-course betting and the introduction of conscription were both carried by referendum.

Canada has no such obligatory referendum as Australia and in fact used the device on a national scale on only two occasions, in 1898 on the temperance issue and in 1942 when the government sought and obtained release from its pledge not to introduce conscription for service overseas. At the provincial and municipal level the referendum was much used for securing decisions on the control of liquor, resulting first in the imposition and later in the removal of prohibition in the western provinces; in local government for the submission of bylaws to the electorate. In Newfoundland in 1948 the voters were polled on the constitutional question of whether they wished to continue under commission government, or regain dominion status, or confederate with Canada. They chose the last-named course.

Ireland. — The Irish Free State constitution of 1922 made a referendum mandatory in cases of constitutional amendment and allowed for referendums on nonconstitutional issues in certain circumstances. There was also a provision for an optional initiative. In 1928 the constitutional referendum was suspended, and the optional referendum and initiative mere abolished. The 1937 constitution, however (itself ratified by plebiscite), restored the referendum (though not the initiative) in its 1922 form.

European Countries. — Formal adherence to democratic doctrines in drafting new constitutions in various European countries after World War I led to frequent provision for use of the initiative and referendum. Thus Germany's Weimar constitution of 1919 made generous provision for referenda in certain contingencies, although in fact they were little employed. The same was true of Austria. Less enthusiasm for direct democracy was felt by constitution makers after World War II, but some use of the referendum was provided for. In France the constitution originally proposed for the French republic was rejected by referendum in 1946 and its successor accepted five months later. The constitution later adopted required that any amendment must be submitted to the people unless it has obtained a two-thirds majority of the lower house of the French parliament or a three-fifths majority of both houses. In Italy the post-World War II constitution provided that 50,000 electors may present a proposal to the legislature, and, if 500,000 voters or five regional councils request it, a referendum must be held on the question of abrogating a law. Provision was also made for using the referendum as part of the amending process. Neither in France nor in Italy, however, had any of these provisions been put to the test of use by the latter 1950s.

REFLECTION. When waves of any kind traveling in one medium arrive at another in which their velocity is different, part of their energy is, in general, turned back into the first medium. This is termed reflection. If the surface of separation is smooth, *i.e.,* if the irregularities in it are small compared with the wave length of the incident disturbance, the reflection is regular; if the surface is rough each facet reflects the rays incident upon it in accordance with the laws of regular reflection *(see* OPTICS) and the reflection, as a whole, is irregular or diffuse. Consider, for example, the reflection of light at smooth and ruffled water surfaces. From the ruffled surface rays enter the eye after reflection from suitably inclined facets distributed over a wide area on the surface and a diffuse band of light is seen, while from the smooth surface only those rays reflected at the requisite angle from a small area on the surface can reach the eye. In the first case the optical system of the eye focuses the water surface on the retina just as it does all other rough surfaces. In the latter the rays appear to come from a laterally inverted replica of the luminous source situated as far below the surface as the source itself is above, and it is this image which is then focused on the retina. The diffusion of light by matt surfaces in general is an example of the same phenomenon differing only in the number and size of the facets which scatter the light. Echoes and reverberations are caused by the reflection of sound (see SOUND: *Reflection and Refraction of Sound)* and the "fading" of wireless signals (in part) by variations in the conditions under which the electromagnetic waves are reflected by the Heaviside layer in the upper atmosphere. *See* RADIO; see also references under "Reflection" in the Index volume.

REFLEX. Reflex actions consist of comparatively simple segments of behaviour in which the reactions usually occur as direct and immediate responses to particular stimuli uniquely correlated with them. Reflex actions may be regarded as universal forms of behaviour because of their widespread occurrence among all complex animals. For this reason, as well as for the fact that all psychological actions are at the same time biological events, it is essential to distinguish between psychological and purely biological reflexes.

Biological and Psychological Reflexes. — The basic criterion for distinguishing between these is that the former consist primarily of the functioning of organic structures, whereas psychological reflexes are definite interbehaviours with stimulus objects. A convincing illustration of this distinction is the contrast between unconditioned salivating reflexes and similar responses conditioned by being associated with stimulus objects other than those originally stimulating them.

Plainly, psychological reflexes are built-up adjustments to particular internal or external objects. Such conditioning processes were popularized by I. P. Pavlov (*q.v.*) and his co-workers. Pavlov. while investigating digestion, incidentally discovered that salivation occurred in dogs not only when food or acid was placed in the mouth, but also when a bell previously paired with food was sounded. What makes this a typical psychological interaction is the observable building up of co-ordinate stimulus and response functions in a unique system.

Biological reflexes and the biologist's approach to reflex actions are both exemplified by the reflex tests of the physician. When the neurologist elicits the knee jerk with his hammer stroke or the pupil-closing reflex by directing light to the eye, he is attempting to ascertain whether the organism's biological mechanisms are working properly. For this reason the stimuli may be regarded as simple energy releasers.

Development of Reflex Theory. — The notion of reflex action originally developed in a philosophical rather than scientific atmosphere. For example, René Descartes. who first elaborated the notion of reflex action, did so to distinguish between the automatic action of soulless animals and the voluntary and rational behaviour of human beings. When anatomy and physiology developed in the early 19th century. interest became centred on anatomical and physiological processes of behaviour mechanisms. Although notions of psychic or mental processes were not given up, both biologists and psychologists sought for precise biological locations of

"centres" for the production and control of actions. Actions involving mentality or consciousness were regarded as requiring brain centres, while reflex or mechanical actions were presumed to operate on the basis of isolated neural arcs located on various spinal cord levels.

Toward the end of the 19th century and the beginning of the 20th, however, the idea that animals act in parts gave way somewhat to the organismic notion that they act as units and that, therefore, the brain plays a significant part in all actions, including reflexes. In 1906 C. S. Sherrington published researches demonstrating that reflexes are very different from the traditional isolated arcs they were thought to be. Sherrington declared that the familiar diagrams of localized biological reflexes mere fictitious and insisted that they must be regarded as integrated actions of the total organism, even though they are simpler than actions classified as voluntary or rational. He also suggested that the stimuli for reflex actions were not simple energy releasers but definite environmental conditions to which the organism adjusted.

With the spread of evolutionary doctrine in the 20th century, reflex theory developed rapidly. The oversimplified notions of isolated neural mechanisms, and even the organismic concept, gave way in great part to the facts of embryological development and ecological adjustment. Important here was the work of C. J. Herrick, C. M. Child and G. E. Coghill, who showed that even simple reflexes are specialized environmental adaptations developed from original mass behaviours. The capstone of biological progress was the enlargement of the notion of reflexes to include ecologically based behaviour conditioned not only to one substitute object but to several.

Current reflex theory, then, envisages all animal behaviour, and not only reflexes, as continuous ecological evolutions. This does not in any way minimize the importance of the separate cells. tissues and organs with their normal or pathological participation in adjustments or maladjustments to environmental circumstances. The great importance of this achievement is that both biologists and psychologists are now able to describe all varieties of behaviour, from the simplest to the most complex, without invoking any vitalistic or psychic principles.

Reflexes **and** Psychological Theory. — Because of the close interrelationship of psychology and biology, the development of reflex theory exerted a great influence on psychological thinking. Especially those psychologists striving for a naturalistic evolution of their science followed the development of reflex notions and were so deeply impressed with the conditioned reflex as model that reflexology became assimilated to psychology. Early behaviourists, such as Pavlov, Karl Lashley and others, who wanted to construct laws of psychological action free from any psychic powers, overstressed the organism and hoped to trace conditioned reflex arcs through the cortex. J. B. Watson, however, advised against an invalid organism-centred viewpoint.

Later behaviourists (E. R. Guthrie, Clark Hull, E. C. Tolman, B. F. Skinner) reacted against a restricted reflexological viewpoint and stressed the conditioning process, which allowed stimulus objects and stimulating circumstances their place in the behaviour field along with the reacting organism. Conditioning became synonymous with learning. In various theories they proposed principles (contiguity of response and stimulus, the manner of stimulus reinforcement, and the effect of stimulation in reducing organic needs) to explain psychological actions. Despite the limitations of behaviouristic psychology, however, its attempt to dispense with psychic notions aided an objective psychology to emerge with broader interests than conditioned reflexes. See also CONDITIONING; ANIMAL BEHAVIOUR; BEHAVIOURISM.

REFORMATION. This word, like "Catholic," is in itself a question-begging term; but both are adopted. if only under protest, in modern speech. By "Reformation," then, is meant that religious revolution of the 16th century which divided western Christendom into two camps — Catholic and Protestant. This was in itself a complex movement for a multiplicity of causes.

Moral Causes. — These were the most important of all, for they lay at the very root. From St. Bernard at the beginning of the 12th century to Bishop Fox, nho founded Corpus Christi college at Oxford in 1516. there is no generation from which we cannot choose orthodox and distinguished churchmen who urged the crying need for Church reform in language which might seem harsh from the pen of a modern Protestant. From Innocent III. in 1215 to Leo X. in 1512, nine great world-councils were held, with Church reform in the forefront of their programme; yet each in turn confessed the failure of its predecessors, and the Council of Trent (1545) testified to the impotence of them all.

The attempt to saddle the Black Death (1348–50) with this state of things is grossly unhistorical. Two of the greatest cardinals of the 13th century, St. Bonaventura (d. 1274) and Hugues de St. Cher (d. 1260) were among the most outspoken of all our witnesses against the clerical morals of their day. Even plainer is the testimony of another very distinguished bishop, Guillaume Durand, who was consulted for the Council of Vienne (1311). In his long memorial, he drew a terrible picture of the reigning and growing abuses, and concluded that the thing most needful was "a reformation in head and in members," that is, from the pope and his court downwards; and this became a watchword not only at succeeding councils, not only among outside critics, but sometimes of popes. It is acknowledged on all hands that the abuses emphasized at the council of 1215 were in many respects even more rampant in 1512, and that the discipline so often demanded was never realized until after the Council of Trent had completed its long work (1564).

The celibacy of the clergy had presented great and continual difficulties. (See CELIBACY.) Even so energetic a reformer as St. Anselm was practically compelled to abandon his design of separating the English clergy from their partners.

It is rare to find any mediaeval author who, if he generalizes about monks, friars and nuns at all, fails to complain of the immoral example which they too frequently set.[1] St. Bernardino of Siena (d. 1444) tells us that "very many" men of his day had no belief in Heaven, and looked upon the Christian scriptures as merely interesting figments, because of the evil lives of cloisterers and other clergy. Pope Gregory X. had said the same at the Council of Lyons (1274), and by about 1500 it had become a commonplace that the lives of the clergy were mainly responsible for the increase of heresy. And some of the most distinguished mediaeval witnesses, such as Cardinal Hugues de St. Cher (d. 1260) and St Catharine of Siena (d. 1380) point out that clerical vices were naturally reflected and even exaggerated in the laity. Again, long before Luther's appearance, orthodox Catholics were emphasizing the abusive side of many Church ceremonies' and practices; the sale of indulgences (*q.v.*), the multiplication of holy-days and the vice and riot which often marked these festivals; the abuse of the mass and of the consecrated oils for witchcraft; and the extent to which clerical immunities encouraged crimes. The laity of the later middle ages, with all their faults, were improving far more rapidly than the clergy; and this gave a proportionately increasing impetus to criticism.

Doctrine. — Here the clergy had once been supreme, and would probably have had little difficulty in maintaining their authority if they had kept unquestionable moral superiority. Few people are really interested in pushing theological enquiries very far, and, as long as men's conduct corresponds to their doctrine, the vast majority of mankind are willing to accept this at least as a working theory. and are under no temptation to question the speculative basis of practices which they approve. So long as there was no deep gulf between what the clergy actually were and what the people had a right to expect of them, free-thought was mainly limited to a few philosophers here and there, to a few weavers at their loom or cobblers at their bench, and to that dead weight of indifference, of resistance against idealism of any kind, which

[1] More than 100 orthodox witnesses are cited on pp. 379–419 of G. G. Coulton's *Five Centuries of Religion,* vol. ii.

has prevailed in every generation among the masses who need to concentrate so much of their thoughts and their labour upon the elementary problems of daily bread. We have abundant proof that the majority of the mediaeval population were not actively religious; but for a long time the enthusiastic churchman had generally nothing worse to struggle with than inertia and complacent ignorance. About the year A.D. 1000, there came a revival comparable almost to that which we call the Renaissance. With this revival we also find signs of free-thought and religious friction; an ice-bound world was now thawing; therefore it moved less regularly and under less strict control than might have been desired. Many features of the then existing dogmatic scheme had been created less by profound philosophy than by popular feeling or by comparatively unreflecting impulses. All men, for instance, had gradually grown to assume that we must take that text "many are called, but few are chosen," in its most baldly literal sense. Even in the 13th century, and in a philosopher so remarkable for balance and moderation as St. Thomas Aquinas, we find that the "feu," who shall be saved are directly contrasted with the "very many" who shall go to hell. His contemporary, the Franciscan Berthold of Regensburg, whom Roger Bacon singles out as the greatest preacher of the day, actually commits himself in one passage to a rough numerical calculation; only about one in 100,000 shall be saved; and fe mediaeval theologians put it more favourably than one in 1,000.

Moreover, they exerted all their imagination and their rhetoric to impress upon their hearers the terrible significance of this separation between the sheep and the goats. All was to depend upon the last moment of life; and, even there, it must depend mainly upon the faith in which the sinner died. Berthold asks his hearers to imagine themselves writhing white-hot within a white-hot universe until the day of judgment, when the pains will be greatly increased. Let them imagine this continuing for as many years as all the hairs that have grown upon all the beasts in this world since the creation; and, even then, the sinner will be only at the beginning of his torments. Yet Berthold was one of the kindliest of men; if he defended the current dogma with this ferociously implacable logic, it was because he had inherited it as part of the deposit of faith, and because he now found himself faced by an opposition which no student of the Reformation can afford to ignore.

Heresy. — The first half of the 12th century had witnessed the rise of several powerful heretical sects, which even the eloquence and influence of men like St. Bernard could not extinguish, though the leaders could be taken and slain. All these sects were more or less antisacerdotal; and more than one held among its chief tenets that the personal unworthiness of the priest impairs or destroys the value of the sacrament which he administers, a doctrine to which some colour had been lent by the very methods taken to combat clerical concubinage by the great pope Gregory VII. (d. 1085).

Towards the end of the century, these popular and comparatively unlearned revolts were succeeded by others of very different intellectual weight. The Waldensians [1175] took their stand upon the Bible; this they read in the vernacular, and committed to memory with a diligence which, as even their persecutors complained, ought to have shamed the orthodox out of their ignorance.

About the same time, the complete works of Aristotle began to filter into the University of Paris through translations from the Arabic, and, a little later, through more accurate versions made by orthodox scholars. The Bible led the Waldensians to deny any essential distinction between clergy and laity; but they long persisted in regarding themselves as orthodox Catholics. The new Aristotle, and especially his Arabic translators and commentators, led a certain number of Paris teachers to adopt the teaching of Averroes (*q.v.*), and thus to deny such fundamental doctrines as the personality of God, the creation, and the immortality of the soul.

But stern measures of repression, first by bishops and clergy and then by the Inquisition (*q.v.*), prevented the general diffusion of these doctrines. In southern France, indeed, about 1200, it was complained that the heretics outnumbered the Catholics; but Innocent III. exterminated them in a merciless crusade; and the new orders of friars, instituted soon afterwards, did almost as much as the sword and the Inquisition to crush movements which were necessarily sporadic and disorganized, since there was no chance of bringing that side of university scholarship into quiet and steady co-operation with the less articulate impulses of the multitudes. Moreover, from the very first, there was naturally a good deal of base leaven in these revolts; and even the Waldensians, whose original tenets resembled modern Quakerism in a good many respects, were gradually compelled, under persecution, to make common cause with other rebels whom they had begun by opposing.

Orthodoxy. — Society as a mass was not ripe for revolution; the nonconformists had too little of a positive programme to substitute for that of the conformists. For the orthodox had gradually set themselves to systematize the theology which they had inherited. Peter Lombard, bishop of Paris (d. 1164) compiled his *Sentences, i.e.*, texts from the Bible and from the fathers, arranged with comments so as to present a fairly consistent foundation upon which most of later mediaeval theology was built. St. Thomas Aquinas (d. 1274) built up a powerful constructive plea for Christianity in his *Summa contra Gentiles* and a wonderfully complete synthesis of Christian tradition with Aristotelian philosophy in his *Summa totius Theologiae.*

From the mid 13th century onwards, there was a tendency in official circles to look upon the intellectual and social equilibrium as complete; philosophers were less concerned to advance than to hold the positions already gained and to strengthen the outworks from generation to generation. Roger Bacon, the slightly older contemporary of Aquinas, might indeed criticize this imposing philosophical structure in terms which almost anticipate Huxley; it rested (he said) upon a Bible misunderstood. and an Aristotle misunderstood, and upon an almost total neglect of the physical and mathematical sciences. But Bacon exaggerates so far as Aristotle is concerned; and he, like those few who thought with him, had no chance in face of the Inquisition; therefore, though a great deal of Averroism survived at the universities, and we have evidence throughout the later middle ages for groups of "intellectuals" who treated Christianity as an outworn superstition. it was improbable that these men would ever have led a revolt. The academic tendency was rather to evade serious issues under shelter of the theory of "double truth"; things (they said) might be theologically true even while they were philosophically false. Far more important was the gradual change of thought among the masses. These, as zealous teachers complained, had always looked too grossly for tangible and immediate results. Saints' images which refused to work expected miracles might be scorned or maltreated; the failure of St. Louis' crusade led common folk to say "nowadays, Mohammed is stronger than Christ." The Black Death inflicted a terrible shock, from which. all vital things recovered rapidly, but which shook all mere conventions to their base; to that extent, it must certainly be counted among the hastening factors of the Reformation.

The popes, by their voluntary desertion of Rome for Avignon, did much to impair their prestige, especially in England. where they seemed necessarily partisans of France in the Hundred Years' War. This was expressed in popular rhymes: "The pope is a Frenchman now, but Jesus is English; let us see who will do most, Jesus or the pope!" Then came the Great Schism, with 39 years of struggle between rival popes upon whose claims, though historians are mostly in agreement, the Roman church has never pronounced so clearly and unequivocally as to render it a question settled for all time. Among contemporaries, St. Catharine of Siena was certain that Urban was true pope, and Clement a pretender. But the Spaniard, St. Vincent Ferrer, proves with every reinforcement of scholastic logic, not only that Clement is true pope, but that no man who, having heard the pleas in his favour, decides for Urban, can hope for heaven. The effect of this upon the masses can scarcely be exaggerated; it mas the schism, perhaps, which lent its greatest force to the heresy of Wycliffe. For, at the same time, popular devotions and a popular theology were growing up under the wing of the Church,

yet in considerable independence of the priesthood.

Piers Plowman is only one of many books which show how pious and thoughtful folk, outside the hierarchy, were exercised by such problems as predestination, or the damnation of virtuous non-Christians, or the papal doctrine of indulgences (*q.v.*). The multiplication of books of popular piety in the last generations before the Reformation is enormous. For good or for evil, the people were beginning to outgrow clerical tutelage. Even in the foundation of schools and hospitals, the laity were beginning not only to pay their money, as they had done for long past, but to demand control of their own foundations. There was new life everywhere about 1500; but the gains were far more secular than sacerdotal.

Economic Causes.—During the later centuries of the middle ages, clerical possessions were enormous; churchmen owned a proportion which has been variously estimated at one-fifth or one-third of the whole landed property; yet they claimed to be free of taxation by the state. This naturally led to extreme friction; the preamble of Boniface VIII.'s celebrated bull *Clericis Laicos* (1296), in which he strongly asserted this claim for immunity, runs: "That the laity are bitterly hostile to the clergy is a matter of ancient tradition which is also plainly confirmed by the experience of modern times."

Equal friction arose from the farther claim, which had gradually grown up and was finally fixed by John XXII. (1316–34), that all Church benefices belong to the pope, who may appoint whom he will. This naturally led to a systematic trade in benefices at the Roman court: "Nothing is to be had at Rome without money," wrote Aeneas Silvius, the future pope Pius II. (1458–64). The popes took from each bishop half of his year's income (annates), and proportionately from abbots of great monasteries. Justice was sold in all the Church courts even more frequently than by secular judges; from at least the 12th century onwards, it was notorious that the archdeacons derived a large proportion of their income from bribes. These economic causes for reformation are most pithily summed up in the *Hundred Grievances* of *the German Nation,* laid before Adrian VI. (1522–23) by the German princes.

The Inquisition.—Moreover, the Inquisition itself, by its very constitution, had become a terrible economic burden. It had always paid its way by wholesale confiscations; even "reconciled" heretics must lose their goods. Therefore, when heresy had been nearly stamped out among rich and conspicuous folk, and the few that remained were such as had procured some sort of illegal protection, then (as we are frankly told by the Inquisitor Eymeric, writing about 1350) princes ceased to take an interest in the Inquisition, and it languished for want of funds.

In the later middle ages, the Inquisition directed much of its energies to the suppression of witchcraft; for an enormous number of heathen customs still survived, especially among the peasantry, who formed the overwhelming majority of the population. Many peasants, said Berthold of Regensburg (1250), and especially many peasant women, cannot take any step in life without having recourse to witchcraft. Therefore, easy though it was to raise an outcry against some unpopular individual, any general enforcement of severe measures against witchcraft must have been extremely unpopular. The enormous multiplication of witch-hunts during the 15th century—for on this side Joan of Arc's fate is quite typical—was both symptom and cause of a deep gulf between the ignorant multitude and the theology of leaders like Aquinas. "Every Inquisitor whom [the Church] commissioned to suppress witchcraft was an active missionary who scattered the seeds of the belief ever more widely" (Lea). A bull of Innocent VIII. in 1484 had the practical effect that thenceforward to question the reality of witchcraft was to question the utterance of the vicar of Christ, "Thus the Inquisition in its decrepitude had a temporary resumption of activity" (Lea). Here again, however, we are to some extent anticipating; for the Inquisition was not only an economic but also a political force.

But, before quitting the economic factors, we must remember that they brought as much weakness as strength into the Reformation movement. It is evident that an economically irreproachable Church would have been as impregnable as the earliest Christian society had been; but it is equally true that the purity of reform was very early tainted by greed; so that, when force was used on both sides, there was little or no moral difference between a defensive commercialized hierarchy and an aggressive squirearchy eager for plunder.

Political Causes.—The political factor, though by itself it might never have led to actual revolt, came in at the last stage with decisive effect. It was the struggle with Protestantism which evolved the half-way principle of *cuius regio, eius religio;* "the ruler's choice determines the established religion of his territory"; and this in turn has led to our modern toleration of all creeds. But the mediaeval ideal had been one empire with one religion; and the actual conditions cannot be better described than in the words of the jurist-historian F. W. Maitland *(Canon Law in the Ch. of England, p.* 100), "We could frame no acceptable definition of a State which would not comprehend the [mediaeval] Church. What has it not that a State should have? It has laws, law-givers, law-courts, lawyers. It uses physical force to compel men to obey the laws. It keeps prisons. In the 13th century, though with squeamish phrases, it pronounced sentence of death. It is no voluntary society; if people are not born into it they are baptized into it when they cannot help themselves. If they attempt to leave they are guilty of *crimen laesae maiestatis,* and are likely to be burned. It is supported by involuntary contributions, by tithe and by tax. And, it may be added, it claims to ovemde, all the world over, the power of the secular State."

Much of this power came to the Church by a process as legitimate as that which could be claimed by most of the civil Governments. The Church had consciously modelled her organization on that of the Roman empire; and she survived when the empire went to wreck. At first there was no question of serious rivalry with the earthly state. Gregory I., in face of an imperial edict or law which he might have been excused for interpreting as a trespass upon Church privileges, had no doubt about his duty of publishing the edict as he was commanded, even while he protested against it; "What am I," he wrote to the imperial council, "but dust and a worm? . . . a man set under authority."

It was only by degrees, and not without many reactions, even under Charles's weak successors, that the popes reached a position which rendered possible the claims of Gregory VII., a man of commanding genius and rare courage. Starting from Augustine's theory of the City of God, founded by Christ, in its contrast with the earthly city, founded by Cain, Gregory insists that the papal power of binding and loosing places him above all earthly sovereigns. It enables him to annul all oaths made contrary to God's will (of which the pope is interpreter) and to absolve all subjects from allegiance to an emperor whom the pope has deposed. Innocent III. (d. 1216) reasserted these claims both in theory and in practice; and at the death of the Emperor Frederick II. in 1250 the long struggle between papacy and empire was virtually decided in favour of the former.

National Spirit.—Yet the papacy now found a more formidable rival in the growing spirit of nationalism, which, no less than imperialism, must necessarily find itself in conflict with a non-national authority claiming moral dictatorship, and therefore political dominion, over the whole western world. It has sometimes been asserted that nationalism was unknown to the middle ages; that the one Church, with one Latin tongue for all educated Europe, effaced merely national divisions. This, however, is a very superficial view. In proportion as the heterogeneous mediaeval populations consolidated into nations, they developed also the consciousness of nationality; divisions became fewer than in the dark ages, but deeper; we may say that the papacy and the Latin tongue had scarcely more to do with the ending of the Hundred Years' War than with its outbreak; and Marsilius of Padua (1324) was on unassailable historical ground when he asserted that popes had very frequently been the authors of European wars.

France was the greatest nation in the 14th century; therefore she was nationally one of the most self-conscious; and it is she who came into directest conflict with the papacy. Boniface VIII.

(d. 1302) attempted to forbid taxation of the clergy by the State; again, he claimed that "all law is enclosed in the casket of the pope's breast." In his bull *Unam Sanctam*, he proclaimed to the world: "We declare that all human beings are subject to the pontiff of Rome; and we assert, define and pronounce this tenet to be essential and necessary to salvation." This attitude led to a conflict with Philippe-le-Bel of France, in which Boniface was humbled; this, again was a prelude to the transference from Rome to Avignon, where the popes in fact, though not in pretension, became virtually subjects of the French king. Even in England, where it might be argued that the clergy themselves were becoming more papalist than ever, and where Archbishop Arundel could proclaim that it was heresy to dispute any papal decretal (1408), yet king and parliament were putting very definite limits to papal control by their Statutes of Provisors and of Praemunire. Other sovereigns presently protected themselves by similar measures.

Publicists. — For, meanwhile, in the first half of the 14th century, publicists like Marsilius of Padua and William of Ockham (see OCCAM) enunciated theories which probably represented what a good many thinkers had long since been saying confidentially to each other in universities like Paris, and in great self-governing cities like Padua. For Marsilius and Ockham, the Bible is the great rule of life for Christendom; the supreme power resides in a council of the whole Church, to which Ockham, apparently, was ready to admit women, and which may judge the pope. Indeed, Ockham is ready to conceive a Christendom without the pope; true, there are certain functions which it would be difficult to arrange otherwise, but the papacy is not essential to the Church of Christ. These speculations formed a fitting prelude to the conciliar epoch (1414–57) during which, mainly at Constance (*q.v.*) and Basel, the Church attempted to put definite constitutional limits to papal autocracy. Both councils decreed, and compelled popes practically to admit, that a general council may judge and depose even a supreme pontiff, and that the pope cannot legislate without conciliar approval.

It is true that the constitutionalists here, as in the England of 1642, over-reached themselves, and the later mediaeval papacy profited by a reaction which rendered it despotic again within the Church. But the laity never forgot; and temporal princes grew more and more accustomed to maintain their own interests in open conflict with the pope.

Two factors contributed farther to this political independence. The monastic reforms decreed by the councils of Constance and Basel, in so far as they were carried out at all, owed much of their success to the secular authorities; in this field, at any rate, it became increasingly plain that the Church was not likely to reform herself merely from within. Again, the later mediaeval popes were predominantly politicians. The papacy had become an Italian principate; the pontiffs constantly involved themselves in those civil wars which made Italy a "hostelry of pain" (Dante); and they showed no less selfishness and duplicity than the princes with whom they were contending. They were ready to go any lengths to secure a little more authority or a few more square miles of territory; as when Clement V. (1309) decreed that the resisting Venetians should be sold into slavery, and Gregory XI. and Sixtus IV. decreed the same for the Florentines and Julius II. for both Florence and Bologna. The bull by which Nicholas V. (1442) encouraged Portugal to what became the organized trade in negro slaves did not immediately show these disastrous results; but when, in 1538, Paul III. decreed slavery against all Englishmen who should dare to support Henry VIII. against the pope, nobody was deceived as to the selfishness of this political move. (For evidence on these points see articles SLAVERY and INQUISITION; also T. Brecht, *Kirche* und *Sklaverei*, p. 156.) A quarrel with this spiritual autocrat, however moral or religious might be the original cause of difference, became *ipso* facto a political quarrel. Therefore, in 1500, any spark might have kindled a general conflagration.

Martin Luther. — This spark, when it came, was in fact moral and religious; but it at once kindled the mass of inflammable politico-economic material. The pope was working his indulgences to an excess which strained loyalty to the breaking-point. Berthold of Regensburg, long ago [1250], had complained that "many thousands" went to hell because they thought themselves to have bought absolution from these "penny-preachers." Gascoigne, the great Oxford chancellor [1450], wrote ever. more strongly, in proportion to the growing evil: "Sinners say nowadays 'I care not how many or what evils I do in God's sight; for I can easily and quickly get plenary remission of all guilt and penalty by an absolution and indulgence granted me by the pope, whose written grant I have bought for 4d or 6d, or have won as a stake for a game of tennis.' " (Lib. Veritatum, p. 86; full translation in G. G. Coulton, Social Life in Britain, p. 204.)

Then, in 1517, the rupture came. A scandalous archbishop of Mainz promised Leo X. 10,000 ducats as a bribe for permission to hold three archbishoprics at the same time. This money was to be paid in part from the sums which here, as everywhere else, were being raised by the sale of indulgences for the building of St. Peter's at Rome. An Augustinian friar and university professor of Wittenberg, Martin Luther, expressed the general indignation by drafting 95 theses on the indulgence system, on which he challenged dispute with all comers.

We may say "the general indignation," for Germany was thoroughly prepared for this revolt. She had many flourishing cities, and a high general level of education for that time; the printing press had long been active; several editions of the vernacular Bible had been published. and very many little books of popular piety. The Greek and Latin classics were being studied busily, and in a far less pagan spirit than in Italy. The Inquisition, again, was comparatively inoperative in Germany; there was little chance of its nipping any doctrine in the bud before it had time to gain popular support. And, lastly, the weakness of the central Government was favourable to Luther; it was the patronage of a few local princes that sheltered his movement in its first stages.

GERMANY

The political complications were here very great; the empire contained more than 300 separate states, small and great, which often rendered little more than nominal obedience to the emperor. Luther was first summoned to Rome and then commanded to present himself before the papal legate at Augsburg (Oct. 1518). Finding that the legate practically demanded submission without discussion, Luther published his account of the interview as an appeal to the German people (Actn *Augustana*). Leo X. then sent an envoy, Miltitz, who was so tactful that a reconciliation might conceivably have been effected but for the Leipzig disputation on the papal primacy and supremacy (June 1519), to which Luther was challenged by the Dominican friar Johann Eck. Luther, in his months of preparation for this debate, discovered how many forgeries there were among the documents which seemed to tell most against him; and Eck, by driving him to the admission that not all the tenets of the Hussite heretics were wrong, widened the breach still farther. The younger university teachers were now on Luther's side; and, encouraged by the growing approbation of all classes among the laity, he began to appeal unhesitatingly and unceasingly through the pulpit and the press.

In three great treatises (1520) he took up a position from which he never after retreated on any essential point. For he had a positive programme; a national Church, free from papal interference; inspection of monasteries; limitation of holy-days and pilgrimages, and marriage for the priesthood as the best remedy for the standing disgrace of concubinage.

Leo X. met this programme with a bull (*Exsurge Domine*, June 1520) in which he condemned 41 propositions attributed to Luther. One of these is all the more significant because the condemnation was repeated in other papa1 letters: Luther had said "It is against the will of the [Holy] Spirit that heretics should be burned." The pope condemns even the least harmful of these 41 propositions as "scandalous or offensive to pious ears or calculated to lead simple minds astray": those who hold or preach any of them are henceforward excommunicate and liable, unless they repent, to all the pains and penalties of heresy. This bull was entrusted to Luther's enemy Eck; but it overshot the mark Universities and bishops would not or dared not publish it, and

Luther received encouragement from many quarters.

He was now excommunicate, and his writings were solemnly burned; he retaliated by burning the papal decretals with equal publicity. Luther had great virtues and great faults; but at this crisis even his faults had a value for the world; for his courage and self-assertion precipitated the crystallization of a thousand thoughts and impulses with which society had gradually become saturated, but which had remained in solution until now.

This Church quarrel now became the most burning question in all German politics. The young Emperor Charles V. was crowned in Oct. 1520, and fixed January for his first Diet, at Worms. He had followed the fight, and was determined to uphold the traditions of his ancestors. The princes insisted that Luther should not be placed under the ban of the empire without being heard in his defence; he was therefore summoned under a safe conduct. He decided to go, "even though there were as many devils at Worms as tiles on the house-roofs." Nearly 2,000 people came out from the city to welcome him. He was brought before the Diet (April 17) and asked whether he would retract his books and their contents; he requested a day to consider his answer. His reply on the 18th was clear and decided: "The duty that I owe to my Germany will not allow me to recant." Pressed still farther: "It is impossible for me to recant unless I am proved to be in the wrong by the testimony of Scripture or by evident reasoning." Pressed farther again, while the torches began burning down to their sockets, as to the infallibility of general councils (the infallibility of the pope was not yet a necessary article of faith) he replied that these had sometimes erred by contradicting Holy Scripture, and he could prove it. At this, the emperor made a sign to break up the meeting.

The Credo of Charles. — Next day Charles read to the diet his own profession of faith; he stressed the authority not of popes but of councils; and upon that he was firm; here is a single friar now setting up his private judgment against 1,000 years of Catholicism, and "I have therefore resolved to stake upon this cause all my kingdoms and lordships, my friends, my body and my blood, my life and my soul." He called upon the diet to help him in this crusade; but "many turned paler than death." For the antagonism was here clearly stated; Luther was ready to stake all upon his own personal convictions, and the emperor upon his own loyalty to tradition. Here, then, was the clear parting of the ways. Both sides relied, fundamentally, upon the Bible. St. Thomas Aquinas had been as convinced as any later Protestant theologian that the Bible was inerrant not only in its spiritual teaching but even on matters of historical fact.

Authority and Judgment. — The real question which had gradually grown up during the Christian centuries, and which had now come to a point, was not as to the infallibility of the Bible but as to the methods of interpretation: was the book sufficient in itself, with no light beyond God's grace and the earnest searcher's conscience, or could it be rightly interpreted only in the light of ancient tradition, and by certain divinely-constituted teachers who, whenever they met in solemn conclave, were inerrant? Luther, in asserting that general councils had sometimes contradicted the Bible, had thrown down the gauntlet; at that point the emperor had naturally dissolved the assembly but only to take up the gauntlet solemnly next day; if the princes then turned pale, it was because they saw war imminent, and knew neither where it would end nor even (in most cases) on which side they must range themselves. To many, it seemed impossible to accept the existing constitution of Church and society as sacrosanct, to the extent of condemning all radical reform as sacrilegious, and all radical reformers as faggots for the stake.

Yet, on the other hand, they saw how intimately this treatment of nonconformity as heresy, this distrust of free discussion, and these methods of physical coercion, had grown into the whole social fabric, and therefore how great was the fear lest the edifice should collapse if once a friar were allowed to publish his own biblical interpretations against those of the councils, and to persuade the community that the burning of heretics is against the will of the Holy Spirit. Therefore, in the struggle that now follows, all other auestions, however important in themselves, are subordinate to this one fundamental antithesis between authority and private judgment. Did the princes desire a world in which the deposit of faith might safely be entrusted to the reason and religious feeling and good sense of the majority, or must physical force be held over men's heads everywhere and always as a menace, and be very frequently employed in fact? Were most men so firmly assured of the fundamentals that all contrary pleas of a small minority might be mainly left to work out their own confusion (as in More's *Utopia)* or was orthodox assurance so wavering that the centre of gravity might shift under the shock of a friar's contradictions, and the Church might turn upside down, and the State with it? The risk was plainly enormous; here was Luther, willing to take that risk for himself and for the world; but few of the politicians could have faced the crisis without serious misgivings.

The Wartburg. — No compromise between Luther and the emperor was now possible; on the 26th, it was announced that his safe-conduct would expire in 21 days. He left Worms; but he was seized by the advice and with the connivance of the elector of Saxony, and carried off to the elector's castle of the Wartburg near Eisenach. The emperor signed Luther's condemnation as a pestilent heretic (May 26); but his secretary wrote to a friend in Spain: "I am persuaded this is not the end, but the beginning. . . . Since [the Emperor's edict]. Luther's books are sold with impunity at every step and corner of the streets and market places."

Luther spent nearly ten months in hiding at the castle of the Wartburg, his "Patmos," as he afterwards called it. Here his pen was unceasingly busy with controversial pamphlets and his translation of the New Testament. But his body suffered from want of exercise, and his mind from natural doubts; could so many past generations and so many estimable contemporaries have been wrong, while he, the mere friar, was right as against them all? Might he not be dragging thousands down to hell with himself? Yet his convictions constantly returned more strongly than ever; and, by a natural reaction, he felt increasing confidence in his divine commission; to doubt of this, or to remain treacherously silent, would be to incur damnation. The gulf between authority and private judgment was thenceforward too wide to be bridged; and Luther emerged from the Wartburg as a determined revolutionary. Yet he was a conservative revolutionary; and this it was which brought him out of his retirement.

His doctrines had been spreading widely; the statistics of the German press are most eloquent here; in 1517 only 37 vernacular books were printed; in 1518 there were 71, and by 1523 the number had risen to 498, of which 180 were by Luther himself. For here was a population which, far beyond all others in Europe, had already been gaining a certain familiarity with the Bible in the vernacular. Fourteen editions in High German, and four in Low German, had appeared before 1518; and, though these editions were doubtless limited and therefore expensive, yet they must have done something to permeate popular thought. Most of the great cities were becoming Lutheran; the new doctrines spread, naturally enough, in Luther's own religious order (the Austin Friars) and in his University of Wittenberg.

Here, in fact, things went too fast. One of the Wittenberg professors, Andrew Bodenstein (Carlstadt), pushed matters to extremes; he lectured and preached and wrote against almost all the traditional ceremonies.

Momentum. — At the same time, and only 60 miles away, the populous weaving centre of Zwickau was in still greater religious commotion; three of the Zwickau enthusiasts came to Wittenberg, and Carlstadt persuaded the magistrates to publish an epoch-making ordinance, which practically transferred the whole direction of Church affairs to the laity, who at the same time undertook the poor relief and the moral discipline of the city. Carlstadt went even farther, and started an iconoclastic crusade. Luther's friend and colleague Melanchthon (*q.v.*) disapproved strongly, but could do nothing. The elector also was seriously troubled; other princes were taking the Wittenberg disturbances as a text for armed intervention; and Luther risked his own personal safety to return and restore order. He preached at Wittenberg on eight

successive days: "I will preach reform, I will talk about it, I will write about it, but I will not use force or compulsion with any one. . . . The word will drop into one heart to-day, and to-morrow into another, and so will work that each will forsake the mass."

A new pope came to the throne in 1522, Adrian VI., a pious man sincerely anxious for reform. At the diet of the empire held at Nuremberg (1522–3) his nuncio pressed that serious measures should be taken against Luther, since Charles V.'s decree, however decisively worded, was practically a dead letter. The members of the diet answered by presenting a list of 100 grievances against the Church; the nuncio reported to the pope that "among a thousand men scarcely one could be found untainted by Lutheran teaching." Then Adrian died suddenly, and was succeeded by Clement VII., a Medici by birth and by nature interested less in reform than in papal prestige. His legate, Campeggio, though a most dexterous diplomatist, could effect very little. The Diet of Speyer (1524) began to plan a Church council for Germany, which would have separated from Rome and anticipated England in the formation of a national Church.

The Peasants' War.—It is from this moment that we must date "the beginning of the separation of Germany into two opposite camps of Protestant and Roman Catholic, although the real parting of the ways actually occurred after the Peasants' War" (T. M. Lindsay). That war, though precipitated by the Lutheran revolt, was essentially a mere coctinuation of the struggles described above. Luther's message was democratic; his language displayed the defects of his qualities; its extraordinary force and directness constantly tempted him into exaggeration, and added fuel to the social discontent which had smouldered for generations side by side with anti-clericalism.

Seven years after Luther's attack on the indulgence system, the peasants' revolt broke suddenly out (June 1524). It began on the upper Rhine, encouraged doubtless by the successful assertion of freedom by the Swiss. In a few weeks the conflagration spread as far north as the Harz, and eastward to Tirol and Styria; cities, knights, and even princes made terms with the insurgents or joined their ranks. But the want of efficient leadership and discipline soon made itself felt; other princes and knights, with trained soldiers at their back, beat the insurgents in one battle after another, and the main revolt was subdued before the end of 1525, leaving the peasants in a worse plight than before, though the Tirolese held out longer and gained real concessions. Luther at first had sympathized with the insurgents and protested against harsh measures; he even risked his life by going among them and preaching peace and moderation.

But soon their excesses angered and dismayed him; his tract *Against the murdering, thieving hordes of peasants* breathed fire and slaughter. Its pitiless tone may be explained, though never excused, by the disastrous reaction of this social revolt upon Luther's own revolution; the more so, since the rebels had in nearly all cases claimed religious sanctions for the movement. It was thenceforth evident that the Reformation was bound to emphasize political and social differences. Hitherto it might have been called a national movement in Germany, but henceforward it was a party-question in every sense of the word.

A Religion of State.—The story is complicated by the multiplicity and kaleidoscopic changes of these 300 German States, and especially by the confusion between the two Saxonys. Catholicism and Protestantism were exposed to all the gusts of party politics. In Luther himself the prophet often gave way to the politician; and he, who in 1525 had at first insisted that the peasants must be met not with blows but with reasons, was soon ready to call upon secular princes to draw the sword against all enemies of the Reformation. He had begun by insisting on responsibility to God alone; but now with most of the Reformers, he ended by subordinating Church to State. In July 1525, a league of Catholic princes was being formed to quench the Reformation in blood; in October, the landgrave Philip of Hesse began to frame a defensive league of Protestant princes. This support could be bought only by abandoning absolute freedom of private judgment and by allowing many ecclesiastical endowments to be secularized. In order to avoid offending the landgrave, Luther, Melanchthon and Bucer agreed in allowing him to commit bigamy; a concession which may be paralleled by a few similar licences from popes, but which, coming from these Reformers, justly scandalized the public more than the papal actions. On both sides, Catholic and Protestant, self-interest now played a very great part.

The ups and downs may be very briefly summarized. The Diet of Augsburg (Dec. 1525) did little. That of Speyer (June 1526) refused to execute the edict of Worms, and procured the decision that each prince should so act in matters of faith as to be able to answer for his conduct to God and the emperor. This gave the Reformers a most valuable breathing space, but the Catholic States were presently provoked into organizing persecution against heretical subjects; the emperor, having now made up his private quarrel with the pope, was determined to fight the innovators, and a diet at Speyer (1529) altered the tolerant decree of 1526. Six princes and 14 cities read a solemn protest at the diet against this vote; and the action of this small minority gave to the party that name of Protestant by which it has ever since been known.

Schmalkalden.—For the Diet of Augsburg (June 1530) Melanchthon drew up a confession, which minimized the differences between Lutherans and Catholics, and exaggerated those which separated Luther from the more radical Swiss reformer Zwingli. The emperor granted a respite till April 15, 1531. By that date, eight princes and 11 cities had formed at Schmalkalden a defensive league for six years. The emperor, more and more hampered by the Turkish peril, finally granted the Peace of Nuremberg (July 1532) which guaranteed the Protestants from molestation until the next general council of the Church. But Clement VII. was in no haste to call such a council; he feared the emperor's encroachments scarcely less than Luther's heresy; and, meanwhile, Protestantism gained much ground, though in Switzerland it had received a check in the death of Zwingli. When at last the general council, in spite of dissensions among the orthodox, seemed imminent, the Protestant princes refused to attend it; they renewed the Schmalkaldic League (1537) and were joined by fresh allies. The emperor formed a counter-league (Nuremberg, 1538) and war seemed imminent, when a compromise was arranged at the Diet of Frankfort (1539).

A series of conferences, from 1540 onwards, produced no real agreement. In 1544 the Peace of Nuremberg was formally prolonged for another five years; but the continual spread of Protestantism, not always without a violence equal to that which their enemies were prepared to exercise, precipitated a struggle. The long-delayed council of the Church had at last met (Trent, 1542); but the Protestants refused to attend it. The emperor declared war; the Protestants were beaten at Miihlberg (1547), and promised to send representatives to Trent, but were freed from that undertaking by Catholic dissensions. At the Diet of Augsburg (1548), Charles drew up on his own responsibility a sort of compromise, the *Interim;* and in 1551 the Protestants sent representatives to Trent.

But the Interim was naturally unpopular on both sides; and, next year, Maurice of Saxony took advantage of the emperor's twofold embarrassments with France and Turkey to turn suddenly against him; he almost succeeded in taking him prisoner. Charles, foreseeing defeat and shrinking from the humiliation, soon transferred to his brother Ferdinand of Austria the direction of German affairs (1554). Maurice was killed in the moment of victory at Sievershausen; John Frederick of Saxony died soon afterwards; but Protestantism was too deeply rooted to be shaken.

"Cuius regio, eius religio."—While the Diet of Augsburg was hesitating to grant religious peace, a rival assembly at Naumburg was attended by more princes than the diet itself, and decided to abide by the confession of Augsburg (155j). *(See* AUGSBURG, CONFESSION OF.) The diet, after many struggles, agreed to one of those compromises which leave seeds for future war. It consecrated the principle *cuius regio, eius religio;* each prince might choose for himself between Catholicism and Protestantism; his subjects must submit to that choice unless they preferred to emigrate. We must here end the story of the Reformation in Germany. The mere fact that Catholicism had been compelled, over and over again, to negotiate with Protestantism on something

like equal terms, was a death-blow to the mediaeval conception of the Church. Now, by this Peace of Augsburg, Protestantism was actually legalized for about half the population of Germany; and this proportion has since maintained itself with little alteration.

SWITZERLAND

Switzerland had broken loose from the empire in 1499; and here was plenty of fuel for Luther's spark. Ulrich Zwingli (b. 1484) was ordained priest in 1506 and soon distinguished himself as an opponent of moral abuses both in the Church and among the laity. In 1518 he succeeded in expelling the indulgence-seller of St. Peter's from the canton of Schwyz; and was promoted to the great minster of Zurich. Here his learning and zeal, aided by the strongly democratic tendencies of this city of Ziirich, made him into a combination of prophet, priest and politician. The burghers of Zurich had long exercised a disciplinary control over their clergy which was far from usual; and here also was an important printing press. Zwingli, in his campaign against the wholesale enlistment of young Switzers as mercenaries for foreign countries, was bold enough to preach also "that it is no sin to eat flesh on a fast day, though it is a great sin to sell human flesh for slaughter." This brought him into conflict with the bishop of his diocese (Constance). In 1522, by a custom general among the Swiss clergy, he contracted a connection with the widow of a citizen, and joined with ten other priests in a petition to the bishop against the law of celibacy, on the ground that this was commonly broken in Switzerland. In April 1524 he married her publicly, in defiance of the Church.

Meanwhile the magistrates had arranged a public disputation between orthodox and innovators (Jan. 1523). More than 600 clergy and representative laity attended, and the magistrates decided in Zwingli's favour. In consequence of a second disputation in the autumn, all church pictures and images were abolished; presently the monasteries were disendowed, and their funds devoted to schools and the poor. The neighbouring canton of Lucerne sent to warn Zurich against its heresies; threats were added, and Ziirich began to prepare for war. In 1525 a new form of liturgy was prescribed, severely puritanical; and in 1529 the Catholic worship was forbidden.

Division. — Meanwhile the revolt spread to other cantons. At a disputation at Baden (May 1526), which Zwingli refused to attend, 82 clerical representatives voted for the conservative side, as against 20 reformers. Yet the movement went rapidly forward, in spite of Zwingli's quarrel with the more conservative Luther, and of the set-back which followed here, as in Germany, upon the Peasants' Revolt. The forest cantons, with their comparatively primitive and scattered peasantry, were naturally on the conservative side; they had formed an anti-heretical league (April 1524); and in Zwingli the prophet became more and more overshadowed by the politician. Between 1527 and 1530 Zürich succeeded in creating a league of the greater Protestant towns, to which the five forest cantons replied by a "Christian Union" (April 1529). Each party was ready to ally itself with the foreigner; Ziirich with France, the Union with Austria. The Swiss confederacy was thus broken up into two opposing camps. The Catholics were unable to accept the full principle of mutual tolerance; and Zurich also was aggressive and intolerant. The two armies faced each other at Kappel, but peace was patched up (June 1529). This was only a truce; they met again at Kappel, where Zwingli was defeated and slain (1531). The peace now made granted to each canton the choice of its own religion, and did much also to protect minorities. The country soon settled into much the same division which still obtains: Catholicism reigned mainly in the mountains and Protestantism in the more fertile lands and in the great cities.

Geneva. — Geneva (not yet in Switzerland) deserves separate mention: it owed everything to its neutral position and to the personality of John Calvin (*q.v.*). The Genevese had lived for centuries under a prince-bishop, though with a good deal of democracy in their civic constitution; thus State and Church were more closely interwoven here than in most other cities.

In 1530 the city rebelled against its bishop; in 1534 it entered into a contract for joint citizenship with Protestant Berne; in 1536 it formally committed itself to Protestantism, and two months later Calvin settled in the city. He was a man of precociously wide and exact scholarship, bred in the law, and touched with inspiration from Erasmus and Luther at the age of 24 (1533).

Calvin's "Institution."—Next year he fled from France; in 1535 he was at Basel, where he wrote in Latin his *Institution of Christian Religion,* which he afterwards turned into French. This epoch-making book has often been misrepresented. Calvin's insistence upon the torments of hell is merely the orthodox mediaeval doctrine, in a far milder form than we find it (for instance) in St. Bernardino of Siena. His insistence upon predestination does not go far beyond St. Thomas Aquinas, whose actual words are often softened down by his modern exponents. The great value of Calvin's book was that it gave a clear and logical structure to a hitherto formless and disorganized Protestant thought, much as St. Thomas and his fellows had constructed a logical synthesis from the heterogeneous mass of Catholic traditions.

In July of 1536 Calvin passed through Geneva, where the reformer Guillaume Farel persuaded him to stay. He introduced into the city, now an independent republic, a discipline which, like his *Institution,* may easily be misunderstood. His supervision of morals and expenses and amusements was no new thing; there is practically no detail in that field which had not been insisted upon by orthodox mediaeval theologians for centuries past, and written in town statute-books, and sometimes even enforced in practice. Here, Calvin's innovation was to substitute stern regularity for impulse and caprice. For the matter was now in the hands of business men; the bishop having been driven out, this enforcement of discipline devolved upon the town council as wielders both of ecclesiastical and of secular authority.

And behind that was another revival from the past. Anxious as Calvin was to revert to the Christianity of the earliest days, and finding as he did in the Lord's Supper the central Christian rite, he insisted on the rejection of unworthy communicants. This regulation proved too stringent for many others besides the "libertines"; and Calvin, with his two chief colleagues, was banished in 1538. The city recalled him in 1541, and he obeyed, most unwillingly, for the sake of what he regarded as a great public work. His *Ecclesiastical Ordinances* and his institution of the *Consistory,* became in one sense the parents of Presbyterianism (*q.v.*). The discipline which had always been advocated was now actually enforced; and nonconformists were punished, sometimes even to the death; the world will never forget how this rebel Calvin burned the Unitarian Servetus. But he saw that a Protestant ministry could never hold its ground without solid learning; therefore he wrote a catechism which should teach even children to give reasons for their faith; moreover, he founded a grammar-school and an academy which attracted able men from all lands, and which sent missionaries out in all directions.

FRANCE

In France, as in Switzerland, the germ of the Reformation is pre-Lutheran. The concordat of 1516 had put the French Church practically under royal authority; the Renaissance (*q.v.*) was rapidly sapping mediaeval conventions; and one very remarkable man devoted himself with equal enthusiasm to religious reform and to learning. This was Jacques Lefhvre (Faber Stapulensis), who in 1512, at the age of about 55, published a Latin translation of the Pauline epistles, with a commentary which roughly anticipated Luther's theory of grace and his denial of transubstantiation. In 1524 Lefhvre revised a French translation of the New Testament, as a foretaste of the whole Bible. He was now under the protection of his old pupil Briçonnet, bishop of Meaux, who had set his heart on the reformation of morals and religion within that diocese. With the help of other pupils, such as Guillaume Farel, Lefhvre created a whole school of students and evangelical preachers.

Meanwhile Luther's doctrines were spreading in France and had been formally condemned (1521); and in 1523 the bishop of

Meaux found himself obliged to fulminate against Luther by name, and against certain doctrines held by Farel and other extremists. Then the *parlement* took strong measures against the innovators: Lefèvre's Testament was burned, while he and his friends found safety in flight. Heresy spread rapidly, and Francis I. favoured or punished it according to the changes of the political weathercock. At the end of 1533 he decreed instant burning against any man convicted by two witnesses of being a Lutheran; but the next January he signed a secret treaty with the Protestant princes of Germany.

Then the excesses of the wilder reformers, who placarded Paris with an offensive broadside against the mass and the priests, caused a natural reaction among the people and at court. In two months, nearly 200 heretics were in the Paris prisons, and eight had been burned. When Lefèvre died (1536) "partly from the timidity of the leaders and partly from the rashness of the rank and file, the first or Evangelical phase of Protestantism in France had failed to bring about a reform of the Church" (A. A. Tilley in *Camb. Mod. Hist.*, vol. II.).

In that same year Calvin published his *Institution*, with which the second, or Calvinistic, phase began. The book supplied the Protestants with a clear and detailed theory of religion; on the other hand, it involved a considerable recoil from two most important principles: it set definite limits both to free enquiry and to individualism. Thenceforward French reformers shared the strength and the weakness of institutionalism. More truly in France than in any other great country, Geneva now became "the Protestant Rome."

The Waldensians.—After a lull, persecution became more severe again (1538–40). The theological faculty of Paris drew up 26 articles of faith in answer to the *Institution*, which Calvin had now published in French, and which was solemnly burned in 1544; meanwhile, many Calvinists were burned here and there. In 1530, the Waldensians (Vaudois) who had survived from mediaeval persecutions in a group of 30 remote mountain villages along the Durance, affiliated themselves to the Lutherans; therefore in 1545, after varying negotiations, an army was sent against them without warning; 22 villages were burned and 3,000 men, women and children were killed.

A still deeper impression was made by the *auto-da-fé* of Meaux (1546) because this was a solemn and judicial act. Sixty persons were here arrested for the crime of having celebrated the Lord's Supper in Protestant fashion; all but ten were punished; 14 were tortured and burned. Even this did not drive the new doctrines altogether underground; other executions took place elsewhere; but meanwhile missionaries and pedlars were secretly preaching and distributing forbidden pamphlets in every province except far-off Brittany. After ten years of this, Francis I. died, and Henry II. sharpened the persecution, by creating an anti-heretical committee of .the *parlement* of Paris, which became known as the *chambre ardente*. This condemned at least 100 persons to death in 3 years; and the provincial *parlements* followed suit.

Yet Protestantism still grew; and in 1555 it began to organize itself; churches were founded on the model which Calvin had framed for Strassburg, and in 1559 a General Synod met, representing from 40 to 50 churches. The Government now procured papal approbation for an Inquisition after the Spanish model; but the Paris *parlement* was not prepared to go so far. Meanwhile the new doctrines were taken up by some of the higher nobility; they thus acquired the advantage and the disadvantage of becoming both fashionable and political. The execution of a distinguished member of the *parlement*, Anne du Bourg, for merely protesting against persecution (1559), could be described by an eyewitness as "doing more harm to the Catholic Church than 100 ministers could have done." But the "tumult of Amboise," next year, redressed the balance. The Government, during the boyhood of Francis II., had fallen into the hands of the Guise family; and a number of Protestant nobles conspired at Amboise to arrest and imprison these unpopular rulers. The plot failed and brought natural discredit upon the religious cause.

A Political Party.— Protestantism was now becoming almost as definitely a political party in France as Catholicism: therefore, a council was held at Poissy, virtually representing the whole nation, to find a *modus vivendi* on the basis of mutual toleration. The Protestants were represented by 12 ministers and 20 laymen; the Catholics by six cardinals and 64 prelates or doctors; the king presided, with the queen mother and princes of the blood. The conference failed to effect a compromise between irreconcilable doctrines; but it was followed by an edict granting liberty of conscience within certain definite limitations. This, however, without fully satisfying the Protestants, was enough to exasperate the Catholics.

In March 1562, the former were holding a religious service in a barn at Vassy, in spite of the edict which forbade their worship in any walled town. The duke of Guise, passing through the town, sent his men to expel them. They resisted, and the soldiers stormed the barn, killing 63 of the worshippers and wounding 100 or more. The example of this "massacre of Vassy" was followed in many other places; henceforward the Wars of Religion begin, and we can no longer treat the French Reformation as a purely spiritual movement The massacre of St. Bartholomew was a natural sequel to the tumult of Amboise and the massacre of Vassy. But, before quitting this subject, we must note that the "Presbyterian" constitution owes even more, directly, to the French Protestants than to any other source. Their "confession of faith" and their "book of discipline," though founded essentially upon Calvin, have more directly influenced the Dutch, Scottish and American churches, than Calvin's own constitution at Geneva.

THE NETHERLANDS

When we have followed the German, Swiss and French Reformations, we find little that is new in other Continental countries. The Netherlands were well prepared for Protestantism by their busy civic life, their early welcome of the printing press, their vernacular translation of the Bible (1477), and the educational work of the *Brethren of the Common Life* or *Common Lot (see* BRETHREN OF THE COMMON LIFE; GROOT, GERHARD). Luther's writings were welcomed at once; and the Bible was frequently printed in Dutch, Flemish and French between 1513 and 1531.

Charles V. began with public burnings of Lutheran books *en masse*, and then established the Inquisition (1522). Burnings for heresy began early; but the emperor's edicts, though severe and frequently repeated, were difficult to enforce in face of the growing opposition. Special severity and peculiar tortures were reserved for the Anabaptists, who were intercepted and slaughtered in large numbers even when they attempted to emigrate. At last, in 1534, they were provoked to strike back, but with the natural result of severer persecution. Under Philip II., political and religious oppression were intertwined. When, in 1565, he insisted on the publication of the decrees of the Council of Trent, not in the pope's name but in his own, Holland and Brabant protested against this as an infringement of their constitutional liberties. Next year, a confederacy of nobles and leading citizens pledged themselves to resist the Inquisition, and adopted the nickname of *Gueux* (*q.v.*) which the courtiers had fastened upon them.

In July, Philip promised to withdraw the Inquisition and grant such tolerance as his conscience would permit; but the secret archives of Simancas show that he wrote simultaneously to the pope and explained this promise as a mere ruse to gain time. At that point, a series of iconoclastic outrages by the Protestant mob gave a legitimate handle to the Catholics. The duke of Alva was then made vicegerent by Philip II.; he proclaimed heresy as high treason and inaugurated a reign of terror (1567); from that time forth the struggle became political; religious discussion was merged in civil war.

DENMARK AND SWEDEN

In Scandinavia the revolution was comparatively bloodless. King Christian II. of Denmark imported a Lutheran preacher in 1519, and would have welcomed Luther himself; he published new codes of law which no pope could approve. But he became unpopular, fled from his kingdom in 1523, and was reconciled to the

pope in 1529. Meanwhile Frederick I., proclaimed as his successor, made peace with the clergy; but Lutheran doctrines still spread; and, Frederick believing himself to have been tricked by the pope in the matter of the archbishopric of Lund, was confirmed in his own growing inclinations towards Protestantism.

His son Christian and his son-in-law Albert of Brandenburg had already declared themselves and in 1527 Frederick met the solemn remonstrances of the bishops with the reply that faith is free, and that each man must follow his own conscience. In 1530, 21 Lutheran preachers, accused of heresy, offered to dispute publicly in Danish against the accusing bishops, who, however, refused to discuss religious questions in the vernacular. Frederick's son Christian III., in 1536, abolished the bishops' authority, seized their possessions, and imported a disciple of Luther, Bugenhagen, as his chief ecclesiastical adviser. Much of the ancient ritual was preserved; and, though there was inevitable friction between the two parties, this systematic and authoritative change of official religion avoided civil war, and brought Denmark higher in commerce and in learning than she had ever stood before. Frederick and Christian made corresponding changes in their subject lands of Norway and Iceland; but here the ancient abuses had been less crying; the people were less ready for change; so that the revolution thus forced upon them from above caused perhaps as much evil as that which it professed to remedy.

In Sweden also the royal initiative secured a bloodless change. Gustavus Vasa (1523–60) had made the acquaintance of Lutheran preachers before his accession; and political necessities led him to look towards disendowment of the Church. A public disputation in the king's palace (1524) went in favour of the reformers; between 1526 and 1541 the whole Bible was published in the vernacular; and men could henceforth judge better for themselves between the rival claims. The diet of 1527 decided in favour of Lutheranism and disendowment. The next king showed some preference for Calvinism; and John III. (1568–92) proposed reunion with Rome. John's son had adopted Catholicism; therefore the people resolved to secure themselves before his formal accession. A synod of lay folk and clergy was held at Uppsala; it decided to accept the Bible as the supreme authority, adopted the Augsburg confession, and restored Luther's catechism as the foundation of all religious teaching.

ITALY AND SPAIN

In Southern Europe, in Italy and Spain, Protestantism enjoyed no princely protection of any importance, nor (perhaps on that account) did it ever spread far enough to gain a hold upon the people. Here, as elsewhere, orthodox reformers constantly fell under suspicion because orthodoxy and radical reform were so difficult to reconcile in practice. The celebrated *Counsel for Amendment of the Church*, drawn up in 1537 by a papal commission of cardinals and other distinguished theologians, insisted that dispensations from Church law should not be so frequent, and should never be given for money. Yet one of these same cardinals, Caraffa, when raised to the papacy as Paul IV., condemned the document in 1559 to his Index of Prohibited Books, while three of the other cardinals (Sadoleto, Contarini and Pole) fell under suspicion of unorthodoxy in later years. Many Italian reformers were thus driven over the line; others protested their loyalty to the last.

The Triumph of Orthodoxy. — The Inquisition, in both countries, was a deciding factor. Into Italy it was reintroduced in 1542 by Cardinal Caraffa, who, when raised to the papacy, worked it with increasing severity. Although Naples and Venice refused to grant it full powers, yet, even there, it was strong enough to prevent any real organization of Protestantism; while in the principalities of Ferrara, Modena and elsewhere heresy was always struck down before it could mature; at Modena 14 persons were burned in the single year 1568 Many fled abroad; in Switzerland there grew up a considerable Italian community; some of these, persecuted by Calvin for their extreme radicalism, fled into Poland and contributed to the spread of Unitarianism.

In Spain, orthodoxy triumphed still more easily. Cardinal Ximenes (d. 1517) had, by the most drastic disciplinary action, raised the Spanish clergy far above the general European level of morals and learning: consequently there was a strong party which could accuse even Erasmus of wild exaggeration in his attack upon Church abuses; distinguished men were condemned for favouring "Erasmic" propositions. Secret communities of Protestants gradually formed at Seville (where we are told of nearly 1,000 members) and at Valladolid. But two *autos da fé* (1559–60) burned 24 men and women at Seville; two others (1559) burned 27 at Valladolid; there were other sporadic executions, and the Spanish non-conformists, like the Italian, could find safety only in flight. In Portugal, where the Inquisition was even more rigorous, we can scarcely guess what might have been the result if anything like private judgment had been possible for the people; what actually happened was that the country prodyced very few Protestants.

GREAT BRITAIN AND IRELAND

The English story is peculiar in one most important particular. In its beginnings, the Reformation was strongly political, yet not anti-Catholic; Henry VIII.'s ideal was "the papacy without the pope."

Here, as in Germany, the ground was well prepared. Lollardy had been driven underground; but it was still very far from complete extinction. The clergy were, on the whole, unpopular, especially in London. The bishop of London wrote to Wolsey in 1515: "Assured am I, if my chancellor be tried by any [jury of] 12 men in London, they be so maliciously set in favour of heretical pravity that they will cast and condemn any cleric, though he were as innocent as Abel." And Charles V.'s envoy, Chapuys, reported to his master from London in 1529: "Nearly all the people here hate the priests." Here. therefore, as in many other parts of Europe, the mediaeval concordat between Church and State was already breaking down.

And here also the Renaissance had already begun to undermine the old fabric. In 1516, More told Erasmus that the *Epistolae Obscurorum Virorum*, a bitter satire upon the monks and the traditional philosophy, was "read everywhere" in England. Erasmus's own writings had enjoyed great popularity; and Colet, dean of St. Paul's, supported the new learning against tradition with a boldness which naturally started other men upon still bolder courses; moreover, More's *Utopia*, published in 1516, was almost as revolutionary on the theological as on the social and political side. All religions are tolerated in Utopia, and almost all religious discussion. For in this country "nothing is seen or heard in the churches, but that which seemeth to agree indifferently with them all. If there be a distinct kind of sacrifice peculiar to any several sect, that they execute at home in their own houses." Wider knowledge of the universe was beginning to break down that mediaeval condemnation of all non-Christians to hell; and this breakdown must, sooner or later, involve a break with yet other mediaevai tenets.

The "Defender of the Faith." — Therefore, when Luther came forward, his works found an early welcome in England; and in 1521 Henry wrote a Latin treatise against the heresiarch which earned him from the pope the solemn title of "Defender of the Faith." Heretical books were burned in St. Paul's churchyard, and four heretics were burned in the diocese of Lincoln, while 50 more abjured their creed. But Lutheran groups began to form at the two universities, especially at Cambridge; which produced eight leaders of the new movement. Here, in 1525, the prior of the Austin Friars, Dr. Barnes, preached a sermon which caused his prosecution for heresy; he was compelled to abjure at St. Paul's, in company with four German merchants. But, a year later, the king was planning a divorce and remarriage, since it was politically necessary for him to have a definite heir to the throne.

This has often been represented as a mere piece of sensuality; but the facts speak plainly to the contrary. There was nothing to prevent Henry, if he had wished it, from keeping a harem like those of his contemporary Francis I. in France and his successor Charles II. in England. Moreover, before the question of Catharine's divorce came up, Henry was already taking very strong measures in another direction; he heaped honours upon his one

known illegitimate son, Henry Fitzroy, and planned, with the advice of his council, the proclamation of this six-year-old boy as heir to the throne. But the plan broke down and Henry's attachment to Anne Boleyn now contributed to suggest the other expedient of a divorce from Catharine. (In the strict technical sense it was not a *divorce,* but a *decree* of *nullity;* however, the briefer term was very commonly used then, as since.)

This complicated story may be reduced to a few simple issues. In the minds of all the principal actors except Catharine, the problem was mainly or wholly political. The king needed a male heir; he and his counsellors augured disaster to the kingdom from a female or a disputed succession. So also with Rome; Clement VII. himself was long in making up his mind as to the Catharine case; and, most significant of all, he actually suggested in 1530 that the problem might be solved without divorce, by allowing Henry two wives at once. (A. F. Pollard, *Henry VIII.* [1905], p. 207.) Even if, as some of Henry's advisers suggested, this was merely a diplomatic feint, it is no less significant in this present connection. Henry had thought of the proposal seriously at an earlier stage, and based it upon Old Testament precedents. As Pollard points out, Eugenius IV. had actually granted similar licence to Henry IV. of Castile, for similar political reasons, in 1437. For the pope's real difficulty was not in the moral problem of the Boleyn marriage but in the political problem of the divorce, since Catharine was aunt to the most powerful sovereign in Europe, and the one from whom Clement had most to fear personally. Therefore the pope evaded all definite decisions, shifting in response to the shifting political situation, for three years (1527–29), when at last he transferred the case to Rome.

Then, at Cranmer's advice, Henry appealed to the universities, and, apart from Oxford and Cambridge, eight of the greatest in Europe decided for him (Paris, Orléans, Bourges, Toulouse, Bologna, Ferrara, Pavia and Padua). However much we may discount these verdicts by royal pressure and other evidence which suggests bribery by both parties, yet on the whole '(these opinions must stand for the general opinion of the learned, unless the divines of France and Italy were more generally venal than is commonly supposed" (H. M. Gwatkin).

Supreme Head.—Already in 1529 Henry had begun to permit the circulation of anti-papal German pamphlets as a threat to the pope; and had even allowed his envoy to hint at further Lutheran developments. Next year, the bishop of Norwich complained of the impossibility of destroying heretical books so long as many folk believed the king to favour them. But at that very moment Henry was taking public measures against heresy, burning Tyndale's New Testament, and forbidding all English Bibles until a version should be made "by great, learned and Catholic persons." This last (as More confessed about the same time) was a great desideratum; yet no such orthodox version was made, or even attempted until long after England had broken finally with Rome (1582–1609).

Already, in 1529, Henry had begun an attack upon the clergy, probably upon the advice of his new minister, the adventurer Thomas Cromwell. Taking advantage of their notorious unpopularity, Henry considerably curtailed the clerical exactions of which lay folk were complaining, and restricted the evils of plurality and non-residence. It was made a penal offense to evade this statute by seeking dispensation from Rome.

Next year, came a still plainer step. Henry, under form of law and without real justice, condemned the clergy of England for having allowed the papal legate to set up his court in England, in violation of the Statute of Praemunire. He extorted not only an enormous fine, but also an acknowledgment in the convocation of Canterbury that the king is "only and supreme lord [of the clergy], and, as far as the law of Christ allows, even supreme head." But this weapon rested in its sheath until the parliament of 1532.

In this parliament, by means which cannot be palliated except on the plea that they were usual in the politics of that day, and that his adversaries were not more scrupulous, Henry first forced convocation, the parliament of the clergy, to accept three articles which definitely submitted Church to State in England. He then procured from parliament a statute abolishing "annates," one of the most lucrative sources of papal revenue from England: this, however, he held in his hand at first only as a menace to Rome, until he had procured papal bulls of approval for the election of Cranmer as archbishop of Canterbury. Next, he procured a statute declaring the king supreme head of Church and State, and forbidding all appeals to Rome. Then, by a capitulation even more humiliating than the previous "submission of the clergy," convocation, at Henry's demand, declared the nullity of Catharine's marriage. There was a mock-trial of the case at Dunstable, and Henry, who had already secretly married Anne Boleyn, was now free to make her his queen. How he then succeeded in defying papal excommunication, and in preventing any papal crusade being launched against him by the Catholic princes of Europe, is a purely political story. Before parliament dissolved. it passed a statute forbidding all further payments of any kind to "the bishop of Rome," and "an act for the submission of the clergy to the king's majesty."

The rest of Henry's reign was spent in ruthless warfare against heretics who believed in mediaeval Catholicism less than he did, and against others who believed more than he. His "six articles" of 1539 rehearsed nearly all the main points of the mediaeval creed; to deny transubstantiation was made heresy, and therefore punishable with burning; to deny any of the other five was felony. Consequently the king was burning heretics on the one hand, while on the other he was enforcing obedience to the royal supremacy by beheading Fisher and More.

The Monasteries.—Three causes led him to strike at the monasteries. They were pro-papal. wealthy, and not popular enough to find many defenders. Among the few points of importance upon which historians on both sides are agreed, are two which concern us here: that the monasteries necessarily considered their own cause bound up with the pope's and that one of the most remarkable features of Henry's despotic reign is the absence of organized or determined resistance on the part of the clergy, whether cloistered or not. Henry was extravagant; he wanted money; and here was a comparatively easy prey. Everywhere else in Europe, the civil authority had already been obliged to interfere in the cause of monastic reform.

The ardcles of reform for English monasteries, which Cromwell issued by Henry's orders, do not deserve the blame which has sometimes been cast upon them. Not only the majority of them, but the most important, were taken straight from the Benedictine rule or from the decrees of popes and other orthodox reformers in the past. When, for instance, Cromwell prescribes "that no monk, or brother of this monastery, by any means go forth of the precinct of the same," he is here only summarizing the plain prohibition in chapter 66 of St. Benedict's rule. When, again, he goes on to command that "women, of what state or condition soever they be, be utterly excluded," this is one of the most time-honoured and frequently repeated of monastic statutes. The only real novelties in this Cromwellian document are the command to accept and preach royal supremacy, and the freedom given to subject monks to complain against superiors who neglect or contravene any of this long list of injunctions.

But Cromwell's visitation of the monasteries is open to far more serious criticism. He chose base agents, who did their work in a base and hasty fashion. It is quite possible that they invented much of their evidence; yet we have irrefragable orthodox testimony to the fact that this unfavourable evidence did not violate probability. The spoils of the monasteries were devoted partly to public purposes, but mainly to pay Henry's courtiers: here England compares very unfavourably with Scotland and some of the German states, where the money went in a large measure to education. Yet, apart from all this which must be said against Henry's unjust and wasteful methods, his dissolution of the monasteries is justified by the experience of other European countries, all of whom, sooner or later, have been compelled to do the same. In Italy and Spain, where Protestantism has been virtually non-existent; in France, where Louis XIV. drove out thousands of Huguenots, and the pastor François Rochette was condemned and hanged in 1761 for exercising his pastoral office; in Austria, where

the small minority of Protestants was either driven into exile or submitted to the same leaden, crushing tyranny which England exercised over the Irish Catholics; in all these countries there has been a wholesale dissolution and disendowment.

The Tudor monasteries were probably in much the same state as that Oxford which Gibbon describes in his autobiography: and, if the universities of Gibbon's day had been entrenched behind all sorts of extra-legal privileges; if the students had been as numerous as the Tudor Religious were; and if they had successfully resisted, for at least three centuries, all serious efforts for reform, then we can hardly doubt that they also would have been disestablished and disendowed before now. The dissolution was one oi many causes for a rising in Lincolnshire, and for the "Pilgrimage of Grace," in the north, where the people were poorest and least educated, and the monasteries would most be missed. Henry showed himself a perfidious negotiator and took a cruel vengeance; but his cause had been supported by many of the higher nobility; and he had no difficulty in getting the shire levies oi the south to march against the northern rebels (1536).

Edward VI.—Under Edward VI. religious changes came far more rapidly. Henry VIII. had ended by not only permitting but enjoining the popular study of the vernacular Bible (1536–38) and, though the permission mas limited in 1543 to the higher classes of society, even this implied a freedom of private judgment quite incompatible with mediaeval tradition, and gave an enormous, if not intentional, impetus to Protestantism. Politics, however, played almost more of a part in the Reformation under Edward VI. than under his father. Reiormers were dominant on the council of regency which Henry had appointed; Edward's two tutors, Cheke and Cox, had both been reiormers. Under the protector Somerset the chantries were suppressed and confiscated; many of them had also been scholastic ioundations in a small way; and thus, though mediaeval England had never possessed an educational system in the modern sense, Edward VI. did iar more harm to the schools than he atoned for by a few ioundations of his own (1545).

Then, in 1548, came deliberate iconoclasm. The party which looked upon images as a hindrance to true religion was stronger now than those who found them edifying, and much regrettable violence was exercised; yet, when we take a wide view, we find that the Orthodox Catholic Montalembert is right in pointing out that a larger proportion of mediaeval Gothic architecture has survived in England than in France. Edward VI. introduced an English liturgy and a Protestant confession of faith in 42 articles (since reduced to 39); and he permitted marriage to the clergy.

A Return to Rome.— His early death put the Catholic Mary upon the throne, while the country in general was still halting between the rival creeds. She communicated immediately with Rome; Cardinal Pole was sent as papal legate; and both houses of parliament answered affirmatively to Mary's question whether they would return to papal obedience. They next rescinded all the anti-papal legislation of Henry VIII. and Edward VI., and revived the statutes against heresy. Mary was now free for all violent measures.

She had promised, and perhaps intended, leniency; but here was a death-struggle between two incompatible ideals, and, in an age when scarcely anybody believed in toleration, Mary had only one choice. She executed 210 Protestants in her last three years; and, at her death, this rate was rather rising than falling. This was fatal; her very first victim, John Rogers, had been so heartily cheered by the London crowd "that he seemed to be going to his marriage," so wrote the French ambassador to his master. This sympathy, strong from the first, grew in proportion as the queen's desperate efforts intensified. Moreover, a new generation was growing up which was far more widely educated than its ancestors; and this was especially noteworthy with the women.

Elizabeth.— The country welcomed Elizabeth; and, though she was not tolerant in the modern sense, she and her ministers carried through one of the most successful compromises in history, the "Reformation settlement." Elizabeth herself would possibly have preferred a moderate form oi non-papal Catholicism, though one of her earliest acts mas very significact; she forbade the bishop who said mass in her presence to elevate the Host, and went out of the chapel when he disobeyed. Many of her subjects were convinced and determined Catholics. But she recognized that Protestantism had come to stay; and she so managed that it should have far more freedom than in any Catholic land, while the Catholics, on the other hand, had as much liberty as the Protestant non-conformists.

Death mas the legal penalty for obstinate refusal to take the oath of royal supremacy; but in fact no Catholic who refrained from political plots needed to fear more than a shilling fine for each refusal to attend Sunday service, until after the pope had excommunicated her and decreed her deposition. Scarcely one-fiftieth of the Marian clergy were deprived of their livings for refusing the oath. Therefore the nation settled down rapidly; and the result was a more rapid national advance in learning, in literature and in commerce than at any period since the Conquest. One set of figures may be quoted as typical of the rest. The religious quarrels told very heavily upon the universities. The number oi degrees fell sadly at Oxford under Henry VIII, and rose again under Mary to the mediaeval average; at Cambridge, however, they fell under Mary. From 1555 to 1558 they averaged only 28 a year; but in 1570 they had risen to 170, and in 1583 to 277, or three times the mediaeval average.

Scotland and Ireland.— The Scottish Reformation went on side by side with the English; each assisted the other. John Knox and Elizabeth were far from complete agreement; but they had sufficient sense and self-control to work together. This religious Concordat went far to obliterate ancient enmities; "Knox included in his liturgy a prayer that there might nevermore be war between Scotland and England; and that prayer has been fulfilled" (F. W. Maitland in *Camb. Mod. Hist.*, vol. II). In 1560 the Scottish parliament did what the English had done a year before; mass and papal authority were formally rejected. Knox's *Book of Discipline*, founded mainly on Calvin's *Institution* and on the organization already adopted by French Protestantism, fixed Scotland in "presbyterianism."

The democratic character of the Scottish Reiormation, and Knox's own zeal for education, go far to explain the subsequent love of learning and the high level of general education in Scotland; though the greed of the barons irustrated the hope of endowing a whole system oi schools and colleges from confiscated Church property.

England's treatment of Ireland is a black page in Reformation history. The country was conquered, and the conquerors dealt with it aiter the brutal fashion of that time. Few Catholics lost their lives for religion pure and simple, as apart from political revolts; hut a series of unjust penal statutes were enacted, and these, although seldom enforced in their full theoretical strictness, were relaxed far too slowly in the face of advancing civilization; instead of weakening, they strengthened the attachment of the Irish to their religion.

GENERAL RESULTS

It has sometimes been argued that .the present religious equilibrium, or something better, might have been obtained without revolution. But this contention seems scarcely reconcilable either with previous or with subsequent history.

R e have seen how long this revolution had been brewing. It would be difficult to find any institution which has been so severely criticized by so many of its most devoted adherents, through so many centuries, as the mediaeval Church. At the very beginning of the 12th century, St. Bernard had emphasized weaknesses which, if not remedied, must necessarily bring disaster; yet orthodox churchmen of 1500 frequently quote St. Bernard's actual words as exactly applicable to the Church of their own day. Some scandals had been abated; but others were even more rampant. Such improvements as had taken place were mainly due to pressure from the laity; and friction between clergy and their flocks seemed increasing rather than decreasing.

Subsequent history, again, seems to point even more decisively in this same direction. We have seen that the real question at issue was that of private judgment. Nearly all reiormers had two fundamental points in common with the orthodox; they wanted to save souls and they believed in the inerrancy of the Bible. But on one fundamental point they differed; is the Bible to be interpreted by the individual for his own soul's sake, or by the Church for the individual's soul's sake? The reformers acted on the former principle; and this opened the floodgates ior the rest; so, although the full claim of private judgment was not the basis on which the reformers consciously took their stand, yet it was implicit in their original theories and actions.

Private Judgment.— Between authority and private judgment, no agreement seems possible except the agreement to differ; yet even that was essentially impossible under the mediaeval regime. To differ publicly irom any solemn pronouncement of the Church mas a crime; obstinately to differ was a capital crime. Therefore no orthodox mediaeval churchman could grant to others the right of nonconformity, or could really escape from the responsibility (however much he might personally shrink from it) of denouncing and punishing all dissenters. Yet, by 1500 at least, it was becoming quite obvious that considerable numbers oi Christians were trusting more to private judgment, confessedly or implicitly, than to the traditional teaching of their priests.

The Inquisition had driven the nonconformists underground for nearly three centuries, very much as early Christianity had been driven underground for nearly three centuries by imperial persecution; but it was now emerging with irresistible iorce. The pope could not now do what Constantine had done in 324, reversing at a single stroke the policy of his predecessors. To Constantine, this religious question had been only one of many debatable issues, and he may even have looked upon it as one of the least important of his political problems; therefore, a reversal at that point need not in the least imply reversal of the whole imperial machine. To the pope, on the other hand, this question of private judgment was absolutely fundamental.

Moreover, even the strongest of popes was always far more at the mercy of his predecessors' traditional policy, of his court and of his officials, than a strong emperor. The pope had no means of coming to terms with Protestantism but by accepting the basic tenet of Protestantism; the Protestants, again, could have come to terms only by abandoning a tenet which, implicitly at least, was absolutely necessary to their position. And the fact that, aiter a century of striie, Christendom was, and has since remained, pretty equally divided between these two irreconcilable principles, mould seem to prove that no human ingenuity could ,have kept the parties permanently within one fold.

And, indeed, this division of parties seems to have worked more

than any other factor towards that tolerance which is one of the greatest gains of modern civilization. The general mass of European society had improved greatly, in many important respects, between 1100 and 1500; but in this one matter of toleration there had been painful and continual retrogression. The Reformers, again, at their earliest stage, were compelled to plead for impunity; but, once in power, they probed as untrue to this principle as the Christian Church had proved when the emperors raised it from a persecuted minority to a persecuting majority.

Mutual Toleration.—Lord Acton, in one of his most plain-spoken essays', has insisted on the wickedness of this *volte-face,* and has pointed out that the innovators Martin Luther and John Calvin lacked that palliation which may be pleaded for persecutors who had persecuted in defense of tradition. But, whether we agree or disagree with him in condemning the individual persecuting Protestant more severely than the individual Catholic, the fact remains that the principle of private judgment is logically inseparable from the principle of toleration, and that no institution can survive, in the face of a powerful enemy, if it acts in public and systematic and continual violation of its own fundamental principle. There is a painful truth in the contention that both sides have learned toleration only under outside pressure; yet that pressure itself has resulted from the assertion of a principle irreconcilable with mediaeval theory and practice.

Private judgment brought half of Europe into conflict with the traditions of centuries; the resultant wars were indecisive; it became evident that neither side could exterminate the other; thenceforward both were obliged to seek some way of living together in the same world. The one party has never granted the individual's right to interpret Scripture otherwise than it was interpreted by the mediaeval hierarchy. Even Protestantism, for many generations, did not advance from the claim for individual interpretation of the Bible to the wider modern claim of rejecting, when necessary, some things that are plainly written in the Bible. But Catholics and Protestants and men of many other creeds live together in modern times in far less discord than that which often reigned in the middle ages among professing Catholics.

The Reformation thus becomes one of the most remarkable episodes in world history, whether we regard it in bulk or in detail. It is rich in striking incidents and in display of human character, both on the Catholic and on the Protestant side; we may find here the loftiest heroism and the lowest depths of turpitude. It exemplifies all the problems of daily life, magnified in proportion to the greatness of the issues here invoked. And from the heat of this conflict between two irreconcilable ideals one principle has slowly emerged, theoretically repudiated by one side and too often violated by the other in practice, yet finally victorious through the mere force of circumstances; the principle of religious toleration. The experience of centuries has now suggested that the main differences which separate many minds from the teaching of the mediaeval Church are rooted in human nature itself; and that, however near the two parties may dram to each other in the distant future, no such *modus vivendi* was possible in 1517.

REFORMATORY, an institution for the treatment, training and rehabilitation of youthful offenders. Institutions commonly referred to as reformatories for youth are basically of two types: (1) training schools for youths under 16 or 18 years; and (2) institutions for youthful offenders between the ages of 16 and 25 who have been convicted of criminal acts. Modern penologists have largely abandoned the term "reformatory" and replaced it with the more descriptive title of correctional training schools.

Viewed historically, institutions for the young offender were originally conceived of as "houses of refuge." The earliest institution of this nature was established in New York city in 1825. Neglected children as well as delinquents were detained there. On the other hand: the first reformatory for older youths was established in Elmira, N.Y., in 1876. In Great Britain the reformatory movement led to the establishment in 1908 of the Borstal system (*q.v.*).

Reformatories made a significant contribution to modern penology by introducing the indeterminate sentence concept whereby the length of incarceration is based upon individual needs rather than upon a fixed sentence. However, their rehabilitation programs were not successful.

Significant changes in treatment programs and architecture have occurred in individual states and in certain European countries. Whereas traditional training school programs accented rigid discipline and large-scale training and education, the leading youth correctional institutions are providing an increasing amount of individual treatment including psychotherapy. Such institutions are found in Sweden, Norway. England and Denmark and in California, New Jersey. Michigan. Ohio, New York and Minnesota, and in the U.S. federal youth correctional system.

While some progress has been made, the anachronistic reformatory programs of the early 1900s persist in most U.S. states and in many other parts of the world. Public apathy, lack of legislative support and uninspired administrative direction have perpetuated these conditions in youth training programs and impeded their development.

UNITED STATES

On any given day, approximately 40.000 minors are detained in more than 130 state and federal youth training schools and about 20 reformatories. Studies indicate the average youth remains in these institutions for approximately ten months and a significant proportion later continue their delinquent careers. This is attributable to two factors: (1) reformatory and correctional training schools, by and large, have failed to meet rehabilitation treatment needs; and (2) generally the more seriously involved. less amenable youthful offenders are committed to such institutions.

Experts largely agree that traditional reform school programs have not fulfilled their rehabilitative objectives, and that institutional programs, to be successful, must provide the following. (1) diagnosis and classification for each inmate: (2) an institutional program focused upon the individual with the ultimate objective of preparing him for return to the community; (3) a discipline program which develops self-control; (4) an academic and vocational training program which is adaptable to the needs of the inmates and which teaches healthful work habits and attitudes; and (5) postinstitutional or parole supervision which strengthens the child, his family and their community relationships

The leading correctional training programs in the United States and Canada and in Europe provide both institutional and aftercare services which meet these criteria in part. For example, in California where such institutions are under the administrative direction of the California Youth authority, a diversified institutional and parole program is offered. There are two reception-classification institutions where all newly admitted delinquent children are studied and processed. Following the completion of the diagnostic summary, each youth is then sent to an appropriate institution or forestry camp where individual and group counseling programs are provided under the direction of treatment specialists as well as academic. vocational training and religious programs. These programs are studied scientifically by trained social researchers. Following the minor's release, trained parole officers provide supervision, counseling and treatment to the child and his parents.

In New Jersey the Highfield School for Boys, a small institution housing 25 children, also provides intensive treatment and group counseling. Similar progressive programs can be found in several other states.

EUROPEAN PROGRAMS

Several European nations have also pioneered unique institutional treatment programs. Sweden has a program for deeply disturbed delinquent children at the Children's village near Stockholm, where an extremely permissive therapeutic environment is combined with intensive, individual psychotherapy. England's Borstal system has focused increasing emphasis upon treatment in small groups. Other experimental treatment programs are emerging in Norway and the Netherlands. However. the majority of European correctional schools, like those in most U.S. states. are generally deficient in basic psychiatric treatment programs for the disturbed child. Instead. they provide programs of vocational training and remedial teaching.

In summary, reformatories have not fulfilled the enthusiastic

promise responsible for their establishment in correctional systems. The most respected correctional specialists consider them junior prisons which are often secondary schools for crime. Discipline in most reformatories is excessively rigid and little treatment is provided.

Slowly a new type of correctional training school for youths is emerging. These are small institutions which have a fairly adequate clinical staff for treating delinquents, and which focus their rehabilitative programs upon meeting the delinquent's individual needs. Additional empirical research on the new institution awaits completion, but these changes in program emphases coupled with casework supervision of wards granted probation in lieu of confinement and also of those released from institutions hold greater promise for reducing recidivism.

REFORMED CHURCHES, THE, are those European churches which during the Reformation undertook to reform their faith and life, as they declared, "according to the Word of God," under the leadership of such men as Huldreich Zwingli, Martin Bucer, John Calvin, Heinrich Bullinger and John Oecolampadius. The movement first began in German-speaking Switzerland and in the Rhineland, spreading quickly to French-speaking Switzerland, France, the Netherlands, Hungary and other European countries. The churches are now world-wide in distribution. The Presbyterian Churches of Great Britain share, in part, these same origins, but are also distinctly British in other ways. The Presbyterians, however, classify themselves as Reformed Churches because of the common heritage. The Reformed Churches call their ecclesiastical polity the "presbyterian" system. The name "Reformed" was originally used by all the Reformation churches, as were the names "Evangelical" (*i.e.*, based on the Evangel, the Gospel) and "Lutheran." Only after the serious controversy over the Lord's Supper (after 1529) did the followers of Martin Luther become known distinctly as the Lutherans and the non-Lutheran Reformation bodies as the Reformed.

Though the term "Calvinistic Churches" has become synonymous with the name "Reformed Churches." John Calvin of Geneva was not the original leader of this phase of the Reformation. Rather he. coming after the first great leaders. Zwingli. Bucer, Oecolampadius, etc., took up their ideas, systematized them, adapted them and improved upon them. He is. therefore, the greatest figure in the history of these churches. Not all his distinctive ideas were adopted by all the Reformed Churches.

Switzerland. — The Reformation in Switzerland may properly be said to have been begun by Zwingli in 1519 at Zurich. Zwingli had been deeply influenced by Desiderius Erasmus, and stood closer to Renaissance Humanism than did any of the other great Reformation leaders. His outright break with the Roman Church did not come until 1522. It came then in a form which was to become virtually standard for the entire Swiss Reformation and which was to have consequences of the utmost importance. Switzerland had become a federation of cantons each of which had almost total autonomy in internal affairs. A democratically elected council, or other body, controlled all matters. Ecclesiastically episcopal authority had become vague in most cantons.

When controversy broke out between the reforming preachers and the Roman priests, the council of Ziirich assumed jurisdiction. Zwingli demanded that a public disputation be held between the reformers and the Roman clergy, and that thereafter the people themselves, through their officers, should decide which religion to follow. This pattern of debate followed by a vote of the people was used in almost every Swiss city or canton which became Evangelical (Protestant). The civil authorities were established in this manner as the heads of the churches, though they had actually controlled church affairs in great measure before. This control once established came to have serious consequences.

Zurich became fully Evangelical after a series of major disputations, 1523–25. Basle, following a similar pattern, led by Wolfgang Capito, Oecolampadius and Guillaume Farel, voted in the Evangelical faith the same year. Berne. the most powerful of all the cantons. followed suit in 1528. St Gallen, Biel and others also made the change in the same manner. Opposition from those cantons which remained Roman Catholic grew, and Zurich and Berne led in the formation of the Christian Civic league in defense of the Evangelical Reformation. Eventually even German cities such as Strasbourg joined, and Hesse and Wurttemberg became interested. The Roman forces now joined in the Christian union. In the t o wars which followed, the Evangelical forces were finally defeated, Zwingli was killed, and the Evangelical advance all but permanently halted. Moreover, political leadership in Swiss Protestantism passed from Zurich to Berne (1531). Evangelical and Roman groups agreed to recognize the right of the other to exist. Heinrich Bullinger succeeded Zwingli at Zurich.

Meanwhile, the controversy over the Lord's Supper (after 1529) had broken the Swiss reformers away from the German reformers led by Luther and had brought the Strasbourg reformers led by Bucer into the role of unsuccessful mediators. After Zwingli's death, Bullinger and the other Swiss reformers came to an understanding with Bucer and even with Philipp Melanchthon, but could not do so with Luther. Henceforth no one theological mind dominated the Reformation of the Swiss-German Rhineland, and a great area of tacit agreement came into existence. These reformers remained more Humanistic than Luther was or than Calvin was to be (though he was to be deeply influenced by them).

Berne took over and pushed the policy laid out by Zurich of advancing the Reformation by open debate and elections. In the furtherance of this policy it had as agents a number of Evangelical preachers who went everywhere, protected by Berne, preaching and debating in Roman Catholic areas. Guillaume Farel was one of the leaders of these preachers. So successful were their efforts that in 1532 it was possible to call a synod of 230 Evangelical preachers at Berne. Bucer was present as an adviser.

Farel turned his attention to Geneva in 1532 but found progress slow and hard Only after riots and threats of force by both Catholic and Protestant cantons did Geneva finally agree to hold a public disputation in 1532. The Catholic forces led by the prince-bishop besieged Geneva. Berne by coming into the war saved Geneva and crushed the house of Savoy's forces. This brought Geneva somewhat under Berne's tutelage, with Farel as the religious leader. Farel was unable to get an Evangelical church life established in any real measure at Geneva the first year.

Farel saved the situation by persuading John Calvin, a young French Evangelical refugee. to become his assistant. Calvin had been associated with the "group of Meaux," and perhaps also with the Strasbourg reformers. He had, in addition to great theological and pastoral gifts, unusual organizing abilities. Geneva had become Evangelical for political reasons and wished to do as Berne, Zurich and other Swiss cities had; namely, control, and use, the church. Calvin and the other Genevan pastors demanded independence for the church in religious matters and the right to criticize, on moral and religious grounds. the acts of the government and the moral life of the city. The church was, however, to have no authority in civil matters. After three years Farel and Calvin were dismissed by the civil authorities from their pastorates because of this clash of ideas (1538). Calvin became a pastor in Strasbourg.

Geneva dared not return to Roman Catholicism because it would mean the loss of its independence to the prince-bishop of the house of Savoy. Yet, religiously and politically the situation in the city deteriorated. The second year Calvin nas asked to return, but he refused. In 1541 Calvin's friends persuaded him to come back. He returned as pastor and teacher.

Work was now begun on the reforming of the church in Geneva. Calvin desired a church based on the Gospel and free to conduct its own affairs, including the right to discipline its members, if need

be, by excommunication. Also, he desired no civil office, but the right to preach and teach on civic issues. No civil officer was to have any hold on the church. The government, however, wished still to control, and to use, the church. In the end, the government temporized, leaving the pulpit free, with no civic office for ministers; but the government of the city constituted the government of the church, thus controlling it in the final analysis. Thus, the civil authorities hired the ministers also, whereas Calvin had wished the people to have this right. Because Geneva did have certain serious moral problems, the authorities gave the church large disciplinary power backed by civil penalties as well as religious. The mediaeval "blue laws" and many other regulations were imposed at once in order to reform the city.

Civil and religious authorities worked together well for a time. However, when the church attempted to discipline members of the upper, ruling class trouble came from the civil authorities. Also, Calvin's insistence upon making Geneva a centre for Evangelical refugees caused great resentment among the "old Genevese" party which resented the coming in of these "foreigners." The group in the city for which the religious change from Catholicism to Evangelicalism had been essentially a part of the move for civic independence made common cause with those who resented religious reform. In 1553 Calvin's cause seemed defeated.

Michael Servetus appeared in Geneva at that very time. He had just escaped from the Inquisition at Lyons, Fr., where he had been condemned for Unitarian views. He was an able and well-known freethinker. In Geneva he was arrested for heresy and tried before the civil authorities. At once this became the test case of the whole struggle between Calvin and his opponents. The trial lasted more than a month. Servetus eventually demanded that he be acquitted and that Calvin be put to death and Calvin's property awarded to himself. As other issues were interjected into the case, Calvin and several other ministers resigned and prepared to leave the city. The authorities now temporized and decided to circularize a number of other European churches asking for advice. The mediaeval idea that heretics were disrupters of society and dangerous prevailed, and all these churches recommended death for Servetus. The opposition now not only lost the Servetus test case but was in a hopeless strategic position. The city authorities burned Servetus, though Calvin and others urged a less cruel death.

Two years later (1555) the civil authorities gave up all control over the internal life of the church, but still held out on the issue of the refugees. When the leaders of the opposition to Calvin uere found to be in secret negotiations with the French king their whole cause collapsed. Calvin was then free to settle church affairs, found the University of Geneva. train refugee ministers for service all over Europe and make Geneva the Evangelical centre of Europe. He held no office other than that of pastor of the church, though his influence was enormous. Gradually leadership of the various Reformed Churches passed to Geneva. Calvin died in 1564, and his successor, Theodore Beza, was the acknowledged leader of French Protestantism. Under his successors Genevan leadership declined wholly. By the 18th century Geneva was dominated by the Enlightenment. German Switzerland came to greater prominence. French Reformed leadership was never again great.

During the Reformation most Swiss cantons had each its own state church. This pattern has never been dropped. During the 20th century most of the churches were disestablished in greater or lesser measure, without losing their character of national churches. The presbyterian form of government in general prevails in these churches. No particular creed is used by any of them, though, in general, they follow the Reformed tradition.

Switzerland has become the international cectre of world Protestantism, and the Reformed Churches have contributed much to this ecumenical work. During World Wars I and II the Swiss Churches did much to hold together Evangelical Churches in the warring world. In 1948 the Swiss Reformed Churches formed a federation which included roughly three-fifths the population of Switzerland.

Germany. — Matthew Zell, who had been influenced by Zwingli, began preaching Evangelical doctrine in Strassbourg as early as 1521. Soon he was joined by Capito from Basle, and others. Martin Bucer, who had become an Erasmian reformer, met Luther in 1518 and became an Evangelical. In 1524 he went to Strasbourg and shortly was made pastor. Subject now to influences from Ziirich, Basle and France. he gradually moved away from Luther. At the Diet of Augsburg, 1530, he led a small group of Germans and others who sought a middle ground between Luther's and Zwingli's groups. From then on he followed a policy of mediation, first between the various reforming groups, and then between the Reformed groups and the Roman groups. When the Interim was forced on Germany (1548), Strasbourg was compelled to become Roman Catholic, and the Reformed leaders were exiled. Bucer and others went to England, and some went to Switzerland. When the Interim was lifted Strasbourg was made exclusively Lutheran until 1789.

The course of the Reformed system in Strasbourg was, therefore, limited to the period 1521–49. However, during that period some decisive things took place. Strasbourg became the centre, within Germany, of Swiss Reformation thought. All down the Rhine valley Swiss-Strasbourg influences moved, even into the Netherlands. Calvin found refuge in Strasbourg 1538–41, and both gave and received lasting contributions. English Puritans before, during and after the "Marian exile" were permanently affected by this theology of the Rhineland, and Bucer eventually went to England. Without Strasbourg's role as a channel the influence of Zurich, Basle and Geneva upon the outside world might well have been rather small. The so-called Reformed Churches might have been limited to Switzerland and France.

Francis Lambert of Avignon, who had been at both Wittenberg and Strasbourg, led a brief attempt at a Reformed Church in Hesse. At the Synod of Homberg in 1526 the Reformed plan of pastors, elders and deacons elected by the people had been projected. The church soon became Lutheran, but the ideas set in motion by the synod continued to permeate other regions.

The city of Emden became Evangelical under Reformed leadership in 1526–29. Difficulties abounded until a Polish noble, Jan Laski the younger, who had become a Reformed minister took charge in 1542. He introduced a system which blended German Swiss-Rhineland views with those of Calvin. This form of Reformed thought had a wide influence, since Laski was twice a refugee pastor in England and later settled in the Rhineland.

Elector Frederick III of the Palatinate was, in many ways, the one who really gave the German Reformed Church its great opportunity. During the later years of Melanchthon's life, and for some time thereafter, grievous controversy raged among Lutherans between an ultra-Lutheran faction and a more moderate group of Melanchthon's followers. The latter were continually accused of being Calvinists, and Melanchthon was friendly toward Calvin and the Reformed groups. The violence of the controversy turned many minds toward Calvinism, or the Reformed views.

Frederick made Heidelberg university a centre of Reformed thought, bringing to it men such as Zacharias Ursinus and Kaspar Olevianus. Ursinus had been first a Melanchthonian Lutheran and had later come under Peter Martyr and Farel. Frederick commissioned these men to draft a constitution for the Palatinate which would more nearly express the Reformed views. The Heidelberg Catechism (1563) which they drew up quickly became the catechism (in many ways the creed) of all the Reformed Churches. In clarity, depth, simplicity and warmth it excelled any other Reformed confession or catechism. Theologically it was an able harmony of all current Reformed thought. Moreover, while it was not based on the then rising Federal theology, with which Olevianus was shortly to side, it could be fitted into that scheme. In view of its many virtues it is not surprising that it replaced, in time, all other Reformed catechisms.

Ursinus and Olevianus prepared also a directory for public worship for the Palatinate. It was definitely Reformed, being a guide to the right ordering of public worship and not a stated, required liturgy whose forms must be used. Altars and vestments were dispensed with, and the communion table was brought in. The pulpit became the focus of the church's public worship, because

from it the Gospel was proclaimed.

The Heidelberg Catechism was attacked fiercely by the ultra-Lutherans. Soon it was being asserted that those who held its views had no right to toleration under the terms laid down in the Peace of Augsburg, 1555. Frederick fought the issue to a successful conclusion at the Diet of Augsburg, 1566, thus gaining a clear-cut admission that the Reformed Churches had the right to exist parallel to the Lutheran Churches allowed by the diet of 1555. With a persuasive statement of faith, a great university, the legal right to exist and a powerful elector as their champion, the Reformed Churches enjoyed a period of growth and success.

Despite temporary or local losses, or both, the Reformed Churches spread down the Rhine. The Wetterau counties became Reformed, and at Herborn a famous Reformed university was founded. Bremen also became Reformed, and then Brandenburg (1613) with its capita1 Berlin. Other smaller areas scattered over the German states also became Reformed.

The Thirty Years' War brought the Reformed territories almost to ruin, and at the Peace of Prague, 1635, the Reformed groups were so wholly betrayed that the war was resumed. The Peace of Westphalia, 1648, recognized explicitly the Reformed Churches and restored the lands of the Reformed nobles. It also recognized Switzerland's independence of the empire. The war, therefore, had been an important event for the Reformed Churches. The revocation of the Edict of Nantes (1685) brought into Germany about 60,000 Huguenot refugees. These greatly strengthened the Reformed Churches. During this same period the French ravaged the Palatinate and greatly reduced the Reformed Churches, which were saved only by the intervention of Brandenburg. Yet, until 1802 serious hardship was their fate.

During the 18th century Pietism, coupled with the Federal theology, gained almost total allegiance among the German Reformed Churches. The form of Pietism was that of the Dutch Churches, and drew these two Reformed groups closer together. Pietism, in turn, was followed by the Enlightenment. (F. D. E. Schleiermacher was of the Reformed Church.)

Beginning in 1817, Prussia united, by three stages, the Reformed and Lutheran Churches in its territories. The first stage was federation, the second (1830) a common liturgy, and the third (1834) allowed each congregation the right to use whichever creed and liturgy it wished (Reformed or Lutheran). The territories were those where the Reformed groups had their greatest strength, Brandenburg. Prussia, Pomerania, Silesia, Posen, Westphalia and the Rhine provinces. Those provinces which joined Prussia after 1817, Hanover, Nassau and electoral Hesse, were not compelled to unite their churches, although Nassau had done so previously at its own order. Small local unions were made in these areas, however. Nonunion Reformed Churches remained in Bremen, Lippe, Alsace-Lorraine, Lower Saxony, etc. Generally speaking the Reformed tradition was overshadowed by the Lutheran in the union.

In 1861 Reformed leaders began to revive, but within the various union agreements, a greater appreciation for the Reformed tradition and ethic. Inner mission work among the poor, sick, etc., also was pushed, as were foreign missions, youth work, etc. A vigorous literature on the Reformed ideals began to appear. World War I and the years immediately following wrought havoc on all German Churches. Old cultural patterns disappeared, and the industrialized, modem secular society emerged. The close connections of all the churches with the German state had become a hindrance. and disestablishment under the Weimar republic was in itself good. However, it came when the churches could least afford the financial and other losses which it entailed.

Beginning in 1918–21 a vigorous theological renewal took place in Germany. The Reformed federation, led by August Lang, brought Karl Barth to Gottingen university. He quickly became the leading Reformed theologian of modern times. As the nazi regime took over, Barth and Otto Weber of the Reformed federation became leaders in the struggle of the German Churches against Hitler and neopaganism.

World War II brought serious losses to the Reformed Churches. Those regions of Germany where they were strongest fell into the soviet zone of occupation. Moreover, many Lutherans, pressed by the remembrance of the nazi persecutions, demanded unqualified adherence to (Lutheran) traditional creeds as a guarantee of future strength for the church. This meant the denunciation of the union in fact if not in law. In Hesse, the Ruhr and other regions of west Germany the Reformed Churches recovered slowly after the war, aided by United States Presbyterian and Reformed Churches.

Prior to World War I the German Protestant Churches, working through numerous missionary societies, had a vast foreign missionary work. After 1918 it was necessary, for financial reasons, that churches in other nations take over this work.

During the height of Germany's power, German Reformed groups spread out over a large part of Europe and also into Russia. Sizeable churches were established in Austria (Vienna), Yugoslavia, and Slovakia; smaller bodies were found among the German settlers in Russia, Lithuania and Latvia. In the territories which were alternately Polish and German in the 19th and 20th centuries there were large Reformed groups. The status of all these groups deteriorated seriously after World War II.

The Netherlands.--Reforming interest emerged in the Netherlands early in the Reformation era. Erasmus did much of his best work at Rotterdam. Moreover, the Brethren of the Common Life and other mystical groups had been active in these areas. From 1513 to 1531 about 25 different translations of the Bible, or parts of it, into Dutch, Flemish or French were published in the Netherlands. Much of the early English Reformation literature also was printed in the Low Countries.

Erasmian and mystical types of reform were soon followed by Zwinglian and Lutheran influences. Communications, and other interests also, bound the Rhineland and the Netherlands together. Hence the Swiss-Rhineland type of reform came to predominate. The Anabaptists and the other reform movements seldom if ever merged, and their influences were felt more at a later period. Charles V, who controlled the Ketherlands, instituted the Inquisition there against the Reformation as early as 1522.

The struggle for freedom from Spain was begun by the Dutch as a protest in demand of greater liberties, especially religious, within Charles's empire. Charles was determined to wipe out all heresy. and, while frustrated in Germany, he gave himself to the task in his own hereditary provinces, the Ketherlands, with the more fanatic zeal. Eventually, the Dutch nobles (c. 1566), led by William the Silent of Orange. turned against him. When he finally abdicated in defeat and despair, Philip II took over his father's crusade against heresy, but with even fewer prospects of success. One of Philip's generals, the duke of Alva, became a notorious symbol of blind and merciless despotism, William was murdered by a hired assassin in 1584, but by that time the Spanish-Roman Catholic cause had been defeated. The Netherlands became free, and the Reformed Church was established.

During the long struggle the religious situation had also become clarified. The leaders in the war for freedom had been deeply influenced by French Huguenot-Calvinist political and religious thought. Lutheran and Erasmian ideas had given way to a theology blended from Rhineland, Genevan Calvinist and French Huguenot influences and ideas drawn from Jan Laski's work. The Belgic Confession of 1561 became the standard creed. Church organization was patterned most nearly after the forms of Laski and the Huguenots, two forms of Calvinistic presbyterian polity. However, the church was not a national church. The Ketherlands was a federation of states with great local autonomy in each state. Each had its own church over which the local authorities had almost complete powers. National synods were provided for in the church's system but were seldom allowed by the various states.

Civic peace had scarcely been achieved before a theological revolution took place in the Dutch Church. Calvinists, in their controversies with Lutherans and Catholics, had carried their philosophical development of Calvin's religious view of predestination (which he shared with Luther) to great lengths. Some Reformed thinkers began to object, among them a Dutch theologian named Jacobus Arminius. Other issues also were involved. especially Dutch political issues. The leader of the ultrapredestinarian Calvinists in the Dutch Reformed Churches was Franz Gomarus.

To solve the issue a synod of representatives of Reformed Churches in all lands was called by the civil authorities. Representatives came from several European countries. James I of England took peculiar interest in the synod and sent representatives from the Church of England. The synod met at Dort in 1618, condemned Arminius' mild views, rejected Gomarus' extreme views and stated in more or less classical form the quasi-Calvinistic view which had become the badge of Calvinists in their poleniics with other theologians. The term "Arminianism" became a very broad designation in Europe for any deviation from any essential aspect of Calvinistic orthodoxy, whether or not connected with Arminius' followers or with the original points of controversy.

Though scholastic Calvinistic orthodoxy won the struggle with Arminius it failed to nurture the life of the Reformed Church. Dutch Pietism (anterior to and more churchly and theological than German Pietism) and the Federal theology soon dominated the Dutch scene. In these movements the Canons of Dort were always honoured but also made harmless in practice.

By the 19th century the extreme orthodox groups in the Dutch Church were disaffected by the influences of the Enlightenment upon the church. A series of schisms took place which eventually gave Holland three Reformed Churches, each professing to be the successor of historic Reformed Christianity in the Netherlands. The original church bears the name the Netherland Reformed Church. Two early secessionist groups were the Christian Reformed Church (1834) and the Low German Mourning Reformed Church (1886). These merged in 1892 as the Reformed Churches in the Netherlands. A minority of the early secession, however, constituted itself the Christian Reformed Church (Restored). None of these three churches is now a state church, although the original body is still regarded, in some measure, as the national church. During World War II and the German occupation of the Netherlands much progress was made toward healing these old schisms. After the peace most of this gain was lost.

On all matters of Dutch colonial policy the old original church became a leader of enlightened opinion in postwar times. Political parties and labour unions usually follow confessional lines in the Netherlands. Accordingly the various Reformed Churches have their corresponding political parties and labour unions. This structure has tended to fix the distance between the church and all degrees and forms of left-wing thought.

The Netherland Reformed Church had (in 1948) 1,500,000 members, 1,400 congregations and 2,500 additional preaching points, 1,550 ministers, 4,500 elders and 169 missionaries at 65 stations in the Netherlands Indies and Malaya.

The Reformed Churches in the Netherlands had (in 1948) 324,621 members, 810 congregations and 801 ministers. Missionary work was being done in the Netherlands Indies.

The Christian Reformed Church (Restored) had (in 1948) approximately 35,000 members.

The Dutch Churches followed the colonial expansion of the Netherlands. In the Union of South Africa they became the principal Christian Churches. This, together with the Dutch tendency to have political parties follow confessional lines, threw upon these churches a very large responsibility. With few exceptions, these churches reflected the views of the Dutch South Africans. The post-World War II premier, Daniel Malan, who led the campaign for the total segregation of the population and areas of South Africa on racial and colour lines, was an ordained Reformed minister. The South African Reformed Churches officially approved his policy.

Controversy over doctrinal issues divided the church in South Africa also. There were five distinct bodies in South Africa (in 1948) with an aggregate (white) membership of approximately 895,000 members. A mission church for nonwhite missionary converts had (in 1948) a membership of 132,096.

The Netherlands Indies, prior to its independence, had a Dutch Church of about 300.000 members.

France.— From the beginning the Reformation made slow progress in France. And yet, reforming movements within the Roman Catholic Church had been early in appearing. Before Luther had emerged as a reformer, French Humanists had created much interest in biblical studies and had aroused a concern for a purer type of Christianity. In time Marguerite d'Angoulême, the sister of Francis I, became the centre of a Humanistic group known as the "group of Meaux." While this group never broke with the Roman Church, and never became outright Evangelical, it did create great interest in reform. Also, members of it, such as Jacobus Faber, contributed much by their writings to biblical and theological studies which the Evangelicals could and did use. Again, a number of the group—Nicolas Cop, Guillaume Farel, etc.—as individuals, left the group and became outright Evangelicals. Moreover, because of her position and her influence, Marguerite was often of aid to all degrees of reforming interests.

Not until 1555 was any real attempt made to organize Evangelical congregations in France. Until that time some had hoped for reform from within the Roman Church, others had looked to the group of Meaux and others had thought the Evangelical cause too weak to organize. Calvin, Farel and Beza, all Frenchmen then active in Geneva, had maintained a deep interest in the French Reform movement. Hundreds of students had been sent from Geneva to evangelize France. By 1560 it was estimated that there were about 300,000 Evangelicals in France, and there were at least 49 organized congregations.

Geneva had indeed been the spiritual guide of these churches, but not their ruler. When, in 1559, these churches moved to draw up a confession of faith, Calvin had demurred, thinking the move too hasty. Nonetheless they proceeded, and informed him that they had used his brief confession of 1557 as a basis, although they had altered it somewhat. This pattern of relationships was to continue to the bitter end: Calvin urging patience, the French Reformed Churches (called the Huguenots) impetuous and often violent. In general the Huguenots followed Calvin's views, yet on many critical matters they made such changes as they wished and when they wished.

The Huguenot alterations on Calvin which became of greatest significance were two: in political theory and in church polity. Calvin had been resolute but cautious on the right of revolution against a civil government. He believed that when a tyrannical king or government attempted to force men to live contrary to the will of God, then, and then only, men might resist—but only through the next lowest, willing, legally constituted, official body or group (*i.e.*, usually a parliament against a king, or a league of cities against a king, etc.). The Huguenots urged that when men felt oppressed in any serious regard by a king, they might individually, or collectively in extralegally constituted groups, resist, revolt and even use tyrannicide.

The second alteration on Calvin's views made by the Huguenots was in the realm of church polity, or government. Calvin's adaptation of presbyterian church government had been worked out for the church of a small city-state. The Huguenots adapted it quite successfully to a national scale. The local congregation elected its minister and a body of elders and deacons who, with the pastor, formed the consistory. These consistories then constituted the provincial synod by electing members to it. The provincial synods again constituted by elected representatives the national synod. Nearly all subsequent forms of presbyterian church organization—European, British, U.S., etc., are directly or indirectly modelled on this Huguenot adaptation of Calvin's Genevan system (which in turn had not been original with Calvin).

Frances I had been no friend of the Huguenots, but under Frances II the Guises and their Roman Catholic followers harried the Huguenots. They in turn leaned, to their great loss, upon certain high nobles. Finally, against Calvin's objections, they organized as a political and military force. In a long series of civil wars (1562–94) which followed, they gained and lost as the fortunes of war came and went. Finally peace came when the Huguenot leader, Henry of Navarre, became King Henry IV of France as a Roman Catholic. This satisfied the Roman Catholic groups, and Henry promulgated the Edict of Nantes, 1598, which guaranteed the Huguenots virtual freedom of religion. During this era of strife had occurred the greatest horror of the Reformation, the massacre of thousands of Huguenots throughout France on St.

Bartholomew's night, 1572.

The French Reformed Churches recovered in great measure from these frightful persecutions after 1598. However, the Edict of Nantes was revoked in 1685. Untold sufferings preceded and succeeded this act by Louis XIV. Despite laws against emigration, more than 250,000 Huguenots fled to Germany, the Netherlands. England, Switzerland and the new world. Those who remained persisted as a virtual underground movement and did not regain their full rights until the Revolution of 1789.

Since the Revolution France as a nation has been quite indifferent to all religions. The French Reformed Churches have grown slowly under great handicaps. The theological upheavals of the 19th century broke these churches into two main bodies, the National Union of Evangelical Reformed Churches (conservative) and the National Union of Reformed Churches in France (liberal). In addition, the Reformed Churches of Alsace-Lorraine were grouped separately under that name. A union of the conservative and liberal unions was achieved in 1939, the Reformed Church of France. The churches of Alsace-Lorraine remained distinct and enjoyed state support, whereas the churches of France proper did not after 1905. A small group of the old conservative union continued under its old name.

The Reformed Church of France had (in 1948) approximately 150,000 members, 528 congregations, 600 ministers and 5,000 elders; missionary work was done through interdenominational bodies rather than through exclusive confessional agencies.

The Reformed Church of Alsace-Lorraine had (in 1948) 22,073 members, 50 congregations, 84 additional preaching points, 47 ministers and 280 elders; missionary work done as by the Reformed Church of France.

Hungary. — The influence of the Reformation was felt early in Hungary. A synod at Erdod adopted the Augsburg Confession in 1545. By 1567 Reformed views had become so well known that the Synod of Debrecen adopted the Heidelberg Catechism and the Second Helvetic Confession, thus becoming a Reformed Church. Except for minor reverses the Evangelicals made progress in Hungary until 1677. The Magyars had become almost all Reformed. The Counter Reformation era was one of severe persecution for all Evangelicals. Not until Joseph II promulgated the Edict of Toleration in 1781 did respite come. Nevertheless, the Reformed Church had not been destroyed by the persecution. Within the old Austro-Hungarian empire the Reformed Church was of two wings, the Magyar (the larger) and the German. The Magyar people spread rather widely through the old empire, carrying their church with them. Theologically the Reformed Churches were much influenced by German theological scholarship. Within the empire they built up a very large system of schools, elementary to university, and did much for Hungarian cultural life. Through state aid and through other sources the church became possessed of much landed property which was used for income purposes (a familiar pattern in Hungarian life).

World War I broke up the old Austria-Hungary, and the nation of Hungary which emerged after the peace of Versailles was approximately one-third the size of the old Hungary. The Hungarian Reformed Church was now shattered. Within the new nation of Hungary there remained about one-half the church. The other half was now minority groups in unfriendly or even hostile countries. The largest segment, 780,000 in Rumania, suffered grievously for both religious and cultural reasons. The 210,000 in Slovakia suffered less. The small group of 40,000 in Yugoslavia had a precarious existence.

The effect of this dismemberment in Hungary was to foster an extreme type of nationalism, to which the church in part fell prey also. Many of the upper middle class, the professional, the government and the military leaders were in the Reformed Church, Adm. Nicholas Horthy de Nagybanya among them. World War II brought a terrible defeat to Hungary and to all hopes of reuniting the Magyar people and their church. Moreover, it brought about a changed outlook among Reformed leaders. When the Communist government nationalized all church lands (Evangelical and Catholic), Reformed leaders urged that land reform must not be resisted; the church must give up its old privileges, etc. So, also, the church gave up its schools without strife wnen all church schools were nationalized. This reaction away from its pre-World War II upper-class nationalism and toward a better understanding with, and vigorous evangelism among, the Communist-controlled working classes caused much international comment. The war losses of the church in life and property were severe.

The Reformed Church in Hungary had (in 1948) 973,393 members, 1,203 congregations and 2,016 additional preaching points, 1,850 ministers (100 of whom were women) and 22,000 elders.

The Reformed Church in Rumania (Hungarian Magyar) had (in 1948) 380,000 members, 719 congregations, 686 ministers and 10,200 elders.

The Reformed Church in Slovakia (Hungarian Magyar) had (in 1948) 20,000 members, 31 congregations and 23 additional preaching points, 31 ministers and 588 elders.

Yugoslavia had approximately 40,000 Magyar Reformed Christians in 1948.

Czechoslovakia. — The Reformed Churches of Czechoslovakia are, as the nation itself, of varied origins. The Czech Reformed body is the Evangelical Church of Bohemian Brethren. The Slovak Reformed body is a wing of the Hungarian Magyar Reformed family (see above under Hungary).

John Huss's attempt at reforming the church ended at the stake in 1415. His followers were crushed in 1434, but underground the cause persisted. During the 16th-century reforming movement the Bohemian Brethren emerged again to flourish for a brief period. In 1547 they were again suppressed, and the Jesuits were given charge of religious affairs in Bohemia. A Bohemian revolt in 1618 began the Thirty Years' War in Europe, and thereafter the house of Habsburg and the Counter Reformation held sway in Bohemia. Thousands of Evangelicals fled the country, and the patriot and the Evangelical leaders were executed. During this Thirty Years' War the population of Bohemia was reduced from 3,000,000 to 800,000 by the frightful excesses of the conquest.

Not until 1781 were Evangelical groups again tolerated in Bohemia. Then only bodies holding either of the two German Protestant symbols (Augsburg or Heidelberg) were tolerated. The old native Czech Bohemian Church was still banned. It remained in existence, however, underground. Moreover, the cause of Czech independence and of the Bohemian Church became intertwined.

When the nation of Czechoslovakia was created by the peace of Versailles the Evangelical Church of Czech Brethren was freed. It became the leading Evangelical, or Protestant, Church in the nation. Its leadership in theological education, social work, etc., was marked. During the crises preceding World War II, Czech patriotism and the Bohemian Brethren again made common cause. When the nazi army seized Czechoslovakia the consequences for this Reformed Church were severe. Many of its leaders, Joseph Hromadka among them, had to flee. After the war the nation came under a Communist government and the church faced a new crisis. The church had been predominantly middle and upper class, with no great hold on the classes now influenced by communism. Under the leadership of Hromadka the church strove to come to an understanding with the government and with the proletariat in an effort to overcome its previous social stratification and isolation. Considerable criticism was directed at this move from other nations.

The church had (in 1948) 90,000 members, 218 congregations and 296 additional preaching points, 186 ministers and 2,616 elders.

Other European Countries. — Small Reformed Churches, often only a few scattered congregations, are found in Belgium, the Scandinavian countries, Greece, Spain and Portugal. Also, the ancient Waldensian Churches of Italy, together with their branches in Uruguay and Paraguay, have come within the orbit of the Reformed Churches, though preserving their own character.

United States. — The Reformed Church in America. — Dutch settlers were brought to the New York area in 1624 by the Dutch West India company. The first church was founded, subject to the church of the homeland, in 1628. When the English conquered the colony in 1664 they allowed the church of the Netherlands to continue in the area In 1629 a slight amount of power was granted by the home church to a local governing body of churches called a "classis."

Early in the 18th century new movements came, colonial self-

consciousness, the "Great Awakening" revival of religion, etc. The Dutch Church was divided into two groups, one favouring great freedom from the home church, supporting the revival, a local college and the free use of the English language. The other group was extremely conservative and wished to remain a part of the Dutch culture. The colonial group grew more rapidly, and founded Queen's college (later Rutgers university) in 1766.

The two factions reunited in 1771 under a plan which left ultimate authority in the Netherlands but gave great local autonomy. After the Revolutionary War the church became wholly independent under a constitution drafted 1784–92. By 1820 the Dutch language had ceased to be in use. The name Reformed Protestant Dutch Church was changed in 1867 to the Reformed Church in America.

A large migration of Dutch people into the United States about the middle of the 19th century added greatly to the church. Most of these settled in Michigan and other midwestern areas. The church had, therefore, two integrally related though rather distinct groups, one centred in New York and New Jersey, the other in Michigan.

The church had (in 1948) 181,299 members, 743 congregations, 899 ministers and 114 missionaries in Arabia, China, India, Japan and Mesopotamia.

The Christian Reformed Church. — *In* 1822 a small group withdrew from the Reformed Protestant Dutch Church because of doctrinal disagreements. When the mid-century migrations brought many Hollanders who were members of the Christian Reformed Church of the Netherlands into the United States, these united to form the Christian Reformed Church in America. A new secession from the Retormed Church in America in 1882 brought added strength.

The church had (in 1948) 74,778 members, 312 congregations, 268 ministers and 28 missionaries in China.

The Evangelical and Refornzed Church. — *(This* body was formed in 1934 by the union of the Reformed [German] Church in the United States, and the Evangelical Synod of North America. It maintains contact officially with the other Reformed Churches in the United States and elsewhere, although by the union it became both Lutheran and Reformed.)

Palatinate Germans, driven out by the wars between France and Germany, came to the American colonies early in the 18th century. The Reformed Church in the Netherlands aided them for a time. They settled in Pennsylvania and in the Valley of Virginia. Attempts to unite them to the Dutch Church and to the Presbyterian Church failed. Gradually they emerged as a self-sustaining church, 1791–93.

During the 19th-century migrations and the expansion of the American west, new German Reformed bodies arose only loosely connected with the eastern parent body. In 1863 these united in one. Efforts to unite with the Dutch Reformed Churches failed in 1891. Later attempts to unite with the Presbyterian Church in the U.S.A. failed also. Union with the Evangelical Church was achieved in 1934. In 1961 the church was united with the Congregational Christian Churches to form the United Church of Christ. *See* also CALVIN, JOHN; PRESBYTERIAN; REFORMATION.

REFORMED EPISCOPAL CHURCH, a Protestant community in the United States, dating from Dec. 1873. The influence of the Tractarian movement began to be felt at an early date in the Episcopal Church of the United States, and the ordination of Arthur Carey in New York, July 1843, a clergyman who denied that there was any difference in points of faith between the Anglican and the Roman Churches and considered the Reformation an unjustifiable act, brought into relief the antagonism between the evangelical Protestant clergy and those who sympathized with the position of Carey. The struggle went on for a generation and with increasing bitterness. The climax was reached when George D. Cummins (1822–76), assistant bishop of Kentucky, was angrily attacked for officiating at the united communion service held at the meeting of the sixth General Conference of the Evangelical Alliance in New York, Oct. 1873. This prelate resigned his charge in the Episcopal Church on Nov. 11, and a month later, with seven other clergymen and a score of laymen, constituted the Reformed Episcopal Church, and consecrated Charles E. Cheney (1836–1916), rector of Christ church, Chicago, Ill., to be bishop.

The church recognizes no "orders" of ministry; the episcopate is an office, not an order, the bishop being the chief presbyter, *primus inter pares. See* also ENGLAND. CHURCH OF.

REFORM MOVEMENT, the name given in history to that movement toward parliamentary electoral reform, active in England between 1769 and 1832, and in France between 1832 and 1848. Different as the two movements were in character, time (the principal phase of the English struggle was over in 1832, when the movement in France was, strictly, only beginning) and result (the ultimate desideratum of manhood suffrage was achieved in France in 1848 and in England only in 1918), the march of events in either country had a profound effect upon the movement in the other. The following article sketches the course of the movement in the two countries. (X.)

THE MOVEMENT IN ENGLAND

The ultimate, if long delayed, success of "reform," embodied in the great act of 1832 was due to an unanalysable blend of political theory and the logic of concrete fact. The political, social and economic structure of Great Britain had, in short, been revolutionized between 1780 and 1830 before the revolution was expressed in a decisive formative statute. The act of 1832 did not so much impose the new system of an ardent minority on an unprepared country as it translated into the organization of self-government the appropriate machinery for achieving what a majority had already accepted as inevitable.

The System in 1714.—The system of representation existing in 1714 was, like every other major organ of the national life, the deposit of a prolonged historic development of at least eight centuries. The House of Commons in 1714 consisted of 558 members, of whom 513 represented England and Wales and 45 represented Scotland. Ireland (with 100 members) was not included until the Act of Union of 1800, which abolished the separate Irish legislature. The Scottish representation had only been introduced in 1707 by the Act of Union. Of the 513 English representatives 94 represented counties, 415 boroughs and four the two universities of Oxford and Cambridge; 30 members represented Scottish counties and 15 Scottish boroughs. The English franchises for the counties, and the boroughs differed fundamentally. The county franchise, with trifling exceptions, was based on a 40s. freehold, assessed to the land tax. The borough franchise was amazingly varied and defied reduction to a single principle. Four groups can broadly be distinguished: (i.) The "Scot and lot" and "pot walloper" boroughs, where the voters, roughly, were residents rated to Church and poor rate; (ii.) the boroughs where every freeman, *i.e.,* enjoying the freedom of the borough, had a vote; (iii.) the burgage-boroughs with the franchise attaching to a certain holding or burgage, and (iv.) the corporation-boroughs, where a close corporation was the privileged electoral organ.

The county franchise dated back to 1430. The borough franchise was the haphazard result of five centuries of piecemeal development. The electoral map of 1714 emphasized the enormous preponderance of voting power in the borough representatives. The distribution of the boroughs roughly represented the distribution of population at the end of the 16th century. But by 1650 this distribution had altered, and since then had been altering rapidly, even before the radical redistribution and growth caused by the "Industrial Revolution" (*q.v.*). The "Reform of Parliament" embodied in "The Instrument of Government" of the Cromwellian period (1654), demonstrated very clearly by its redistribution the admitted hiatus between the existing system and the actual facts. The elaborate analyses made by the "Reformers" of the 18th century revealed these bewildering anomalies. Apart from the contradictions of the borough franchise, which allowed a vote in one borough that was denied in another, custom degenerating into caprice, or avowed manipulation, the distribution of seats resulted in the most astonishing paradoxes. Cornwall, for example, paying 16 out of 513 parts of the land-tax, returned 42 members (two county, 40 borough members); Lancashire, paying ten times as much, returned 14 (two county and 12 borough members). The City of London returned four, as did, also, the united boroughs of Weymouth and Melcombe Regis, with neither landed nor economic interests. In Yorkshire, York city and 13 boroughs, with a total of 7,000 voters, returned 28, while the county, with a total of 16,000 voters, returned two members.

The disabilities imposed by law severely restricted both the electors and the elected. Apart from women, children, lunatics, paupers or convicted criminals, the Nonconformists, the Roman

Catholics, the Quakers, the Jews and agnostics could neither vote nor be elected. In the counties neither leaseholders nor copyholders, however wealthy, could vote. Prosperous cities such as Birmingham or Manchester, which had come into existence since 1600, had no representation, while Old Sarum with seven, or Dunwich, half under the sea, with 14 voters, returned respectively two members apiece. Even in 1714 it was abundantly clear that members of parliament did not represent their constituencies, and that the constituencies still more did not represent the nation. It was estimated in 1793 that, with a population of some eight and a half millions, 257 members (*i.e.,* a majority of the House of Commons) were returned by 11,075 electors; that in 51 constituencies there were less than 50 voters, and that 130 boroughs had less than 300 electors apiece; and that whereas 92 county members were returned by 130,000 voters, 84,000 electors in the boroughs had 421 representatives. "The rotten boroughs," *i.e.,* those which were completely under the control of the Crown or a patron, were admittedly the most indefensible parts of this parody of principles and facts.

The Society of the Friends of the People undertook, in 1793, to prove that the lords of the Treasury, 71 peers and 82 commoners could together nominate 306 out of 558 members, *i.e.,* make a decisive majority. The influence of the Crown, *i.e.,* of the Government — through the patronage of the navy, army, Church, judiciary, civil and colonial services — was enormous, and secured the steady voting support in the Commons without which no administration considered itself safe or even possible. In 1770 there were 192 place-holders in the Commons. "Vested interests" in the whole system, indeed, were so strong and deeply-rooted that nothing short of a complete organic change in the social and economic structure could compel a House of Commons to accept "reform" which meant the extirpation of a half of those who sat in it, with the lucrative possibilities that membership offered. It follows from this brief summary that the would-be "reformer" of the 18th century, with so large and easy a target to attack, but which covered such a variety of interests, had really to prove that the "system" resulted in bad government, and that in the major issues of the national life the welfare of the unrepresented was more important than the welfare of the minority and was being continually sacrificed to it. Before the political theory of Locke, Blackstone and Burke could be dissolved a new political theory had to be created and absorbed. The Reform movement had by 1830 produced such a new theory, with a re-interpretation both of the ends and methods of popular government and civil society under a limited monarchy — but it was not until 1790 when Whiggism had been dissolved once and for all by the corrosive acids of the Industrial and French Revolutions that the school of Godwin, Priestley and Price, above all of Adam Smith and Bentham, had captured the best minds alike of the old gentry and the new individualists. In 1832 a true revolution was accomplished with less bloodshed and disturbance than "the glorious revolution" of 1688, and as in 1688 so in 1832, the monarchy entered on a new lease of life, influence and prestige.

The First Phase **(1714–65).**—In the Walpole and Bolingbroke era (1714–40) "reform" was the cry of the broken and discredited Tories or the schismatic Whigs, who denounced the corruption by which they asserted Walpole maintained his power, or who demanded the repeal of the Septennial Act and a return of the Triennial Act', or even to the annual parliaments of a "golden middle-age." The agitation, which had no support outside Westminster, had no effect on the general acquiescence in parliaments with a legal duration of seven years, and resulted only in a very limited Place bill, disfranchising a few hundreds of place-men. The elder Pitt gave a new life and a new power to the Reform movement, due to his prestige, his disinterestedness, the splendour of his achievements, and his criticism of effete or flabby government. But Pitt was neither a consistent political thinker nor a practical and constructive administrator, capable of creating and leading a party with a coherent and thought-out programme of internal reform. He accepted the Whig view that "representation was not of persons but of property," and that "the share of national burdens (*i.e.,* taxation of ***property)*** should decide the weight it ought to have in the political balance." He accepted "the rotten boroughs" (for one of which he had sat) as "the natural infirmity of the Constitution." "Amputation might be death." Pitt's sole remedy for "the corruption of the people and the ambition of the Crown" was to add a third member to the county representation, "the purest part of the system," and to revert to triennial parliaments. Neither of these remedies was seriously pressed, though they became a traditional formula for the Chathamite and Rockingham Whigs.

Cartwright, 1763–80.—John Wilkes, demagogue and the popular hero of the struggle against general warrants, for the rights of the electors in the Middlesex election and for the right to report debates in parliament, with John Cartwright, the brother of the inventor of the power-loom, were, in 1776, the joint but independent "fathers" of the real Reform movement, *i.e.,* a demand not merely to eliminate the rotten elements, but by an extension of the franchise and a redistribution of seats to secure "a just and equal representation of the people." Wilkes and Cartwright pinned reform down to these points-disfranchisement, enfranchisement and redistribution — on the basis of two democratic principles, that government was for the good of the governed and that rich and poor alike had equal rights and an equal interest in determining laws and government affecting their lives, fortunes and happiness. The Reform Act of 1832 was thus foreshadowed in embryo in 1776, the year of the Declaration of American Independence, of Adam Smith's Wealth of Nations, and Bentham's Fragment *on* Government. Cartwright, also, by founding The Society of the Supporters of the Bill of Rights was the parent of a new political method, the organized league for propaganda, education and consolidation of a group with a defined and agreed programme. Radicalism, in short, as a theory of political life and a constructive political machine, was born in 1776. Cartwright's society was the fruitful mother of many leagues, societies and federations down to the Free Trade League of 1837, the "Birmingham Caucus" of 1878, and the party organizations of to-day.

The Whigs and Economic Reform. — The Whigs, under the influence of Dowdeswell and of Burke, would have none of either Wilkes' and Cartwright's principles, or of "demagogic" methods. The genius of Burke, reverencing the Constitution as almost a Divine gift to a chosen people, dreading organic change as the betrayal of a mighty heritage, and already, in 1780, scenting in the political theory of the American rebels and of the English Radicals the Jacobinical poison which the French Revolution was to let loose, saw in "economic reform" the supreme remedy for purging a sound organism afflicted by a temporary but paralysing disease in the corrupting influence of the Crown. The Yorkshire Association and the famous Yorkshire Petition of 1780 were methods borrowed from the Radicals, but "the economic reform" for which they pressed kept clear of the Radical demand for organic reconstruction of the representative system. Burke and the Rockingham Whigs succeeded in disfranchising contractors and revenue officers, in abolishing sinecures and in reducing places and a swollen pension list, but in accomplishing this valuable result they had shot their bolt. They had not attempted to deal either with the legal disabilities which excluded whole classes from representation, or with the rotten boroughs which were far more demoralizing and far-reaching in their control of parliament than the "corrupt influence" of the Crown.

The Younger Pitt **(1780–1785).**—The mantle of Chatham fell, and the hopes of Radicalism concentrated on Chatham's son, the younger Pitt, who, in 1781, moved for "a Committee to enquire into the Present State of the Representation" and was defeated only by 20 votes — the best division the Reformers had between 1780 and 1831. As prime minister, in 1785, Pitt endeavoured to introduce a Reform bill, his intention being to disfranchise 36 rotten boroughs, establish a fund of £1,000,000 for compensating the owners of borough "property," and assign the 72 seats set free by the disfranchised 36 boroughs to the counties, London, Westminster and the chief unrepresented towns. "Leave to introduce" was, however, refused by a majority of 79 votes. Henceforward Pitt was lost to the Reform movement. It was his first and his

last effort as a constructive Reformer and the French Revolution shortly converted him into an obstinate antagonist to all or any change.

The Fourth Phase (1785–1807).—The movement really gained in the long run by this set-back. Had Pitt's milk-and-water proposals been carried the old system would have been given a new lease of existence. Pitt, equally with Burke, accepted the inherited past, and his acceptance of the rotten boroughs as a form of property, the disfranchisement of which required compensation, was rightly rejected as immoral and indefensible on any theory of national representation, by the Reformers of 1831. The Whigs had never really believed in reform, and it now became the monopoly of the "doctrinaire Radicals." For seven years the stars in their courses fought for Radicalism. The American War had given an immense stimulus to political thinking and a new school of political philosophy came into existence; the Industrial Revolution was steadily sapping the bases of 18th century society and of the economic fabric. In 1788 the centenary of 1688 was celebrated by the ardent Radicals and the young minds of the country outside politics. In 1789 the outbreak of the French Revolution galvanized all these currents into enthusiastic activity, and The London Revolution Society—the leading organization of the Reformers, of which Price and Godwin were vigorous members--entered into direct connection with the National Assembly in France and the Constitutional Revolutionists in Paris.

Fox, who hailed the French Revolution with joy, professed to be a Reformer, but he was in reality too deeply saturated with the old Whiggism to accept with conviction the new Radicalism. The real leaders in parliament were the young Charles Grey (the Earl Grey who carried the Reform Act in 1832) and Erskine. But all the ardent aspirations of 1789–91 were doomed to disastrous extinction, for which four main causes were responsible. First, the September massacres, the execution of Louis XVI. and Marie Antoinette, and the Reign of Terror not only paralyzed the moderate Reformers with a chill of disillusionment, but sent a series of waves of panic through Great Britain. Reform was promptly identified with revolution on the French model. Secondly, once Great Britain was at war with France (1793), reform was regarded as sedition and treason. Even the mildest critic of existing institutions was denounced as a Jacobin and a traitor. Thirdly, the opposition to reform found in Burke a thinker of genius whose "Reflections on the French Revolution" became the Bible, not only of Toryism, but of three-fourths of thinking or unthinking England. To Burke the new democratic philosophy of Price, Goodwin and Paine, even of Bentham and Mackintosh, was anathema, and the "Rights of Man" were exposed as the pseudo-scientific basis of a creed which would logically end in the downfall of the monarchy, a Jacobin Reign of Terror and a military dictatorship on the French model. The extremists on the Left of the Reform movement, with the bravado that extremists enjoy, were powerful allies of reaction. For 15 years Great Britain lived in the hurricane of a European convulsion, and Wyndham's phrase as to the folly "of repairing your house in the hurricane season," for all its shallowness, correctly summed up the mood of three-fourths of Great Britain, shown in the "loyalist" riots at Birmingham, Manchester and other industrial centres. Fourthly, the irreparable breach between Burke and Fox not only split the parliamentary opposition but drove one-half of the Whigs into coalition with Pitt and the Tory Party.

The war at first was popular; prosecutions for sedition followed, and the judiciary, especially in Scotland, where a great awakening of political activity had followed the French Revolution. were readv to strain the law of treason and to lav it down from the Bench that all criticism of existing institutions was calculated to bring the Government into contempt, and was, therefore, seditious treason. The proposal to hold at Edinburgh a British convention for the discussion of reform whetted the panic of the Government and the convention was dissolved. The trials and condemnation of "the Scottish martyrs," such as Tytler, Stewart, Callender, Muir, Palmer, Margarot, Gerrald, Watt and Downie, and, in England, of Frend, Frost, Eaton and Winterbotham, make a soiled page in the history of British law. Thanks to Erskine's splendid advocacy, the acquittal of Hardy and Horne Tooke brought some sanity into the supercharged atmosphere of indiscriminate terror and proscription. But until 1799 liberty of opinion ceased to exist in Great Britain, and in this valley of black shadows the numerous political societies, the chief of which were *The London Corresponding Society* and the *Society of United Scotsmen,* withered at the roots and were easily and finally suppressed by governmental action (1794–98). There would have been general and resentful astonishment could the memorial to "the Scottish Martyrs," on the Calton hill, at Edinburgh, erected by public subscription have been foreseen in 1800. Muir's "blasphemous" prediction that "the cause would ultimately prevail" was accepted as a platitude by a reformed and grateful Great Britain in 1844.

It "prevailed" for three reasons. First, the existing system of parliamentary representation provided its own condemnation when men could once more use their eyes, unblurred by panic and war. fever. Secondly, every five years of the changes made by "the Industrial Revolution" threw up a new and unrepresented population, creating a new wealth which paid three-fourths of the taxes but, under the old system, was not "property" with any political rights. Thirdly, the real Reformers retained their faith, and the new and abhorred creed of "democracy" was being hammered out by powerful minds, and could be proved to have a better scientific basis for the theory of a reborn, civilized and progressive society than the philosophy of Burke. To the England of 1807 and onwards the old Whig creed of 1688 was not to be regarded as a climax and a terminus, but simply a stage in an inexhaustible development.

The Fifth Phase (1807–1815).—A new point of departure was made in 1807. The Westminster election of that year brought Sir Francis Burdett, a wealthy and ardent Reformer, into the House of Commons to be the fearless and effective champion of the new Radicalism. The indefatigable Cartwright, who lived until 1824 and saw the dawn of the new day, was ready to join with Cobbett, "orator Hunt," Bentham, the stubborn and aristocratic Whig, Coke of Holkam, the "King of Norfolk," of whose respectability and place in the great gentry there could be no doubt. Reform had, in fact, its increasing adherents alike in the peerage, the intelligentsia and "the people." It only needed now two further acquisitions—the conversion of the official Whig Opposition and a first-rate organizer. The latter was found in Francis Place, the tailor of Charing Cross, whose career and gifts make a fascinating chapter in the history of British politics. Place, if any man, was the "organizer of victory." The conversion of the Whigs, led by Grey (who had succeeded to the earldom in 1807) was accomplished in 1820, when Lord Russell definitely associated the Whig party with the cause. Russell was ably supported by Brougham, and even more effectively by the aristocratic Radical, Lambton (later Lord Durham of the "Durham report"). Cartwright, in 1823, predicted that reform would "come suddenly." He did not live to see the passing of the Konconformist Emancipation Act in 1828, of Roman Catholic emancipation by a Tory minister in 1829, or the triumphant passage of the Reform **Act** of 1832, nine years after his prediction. It was, indeed, in the irony of history that the French Revolution of 1789 should have shattered "the cause," and that a second revolution in France in 1830 should convert Great Britain to enthusiastic support of the Whig Reform bill of 1831.

BIBLIOGRAPHY.—The reform movement is treated in all the general histories and text books, notably by W. E. H. Lecky, *A History of England in the Eighteenth century* (1878–90; new ed., 7 vols., 1892). The best special books are: E. and A. G. Porritt. *The Unreformed House of Commons. THE MOVEMENT IN FRANCE

If the political history of France be compared with that of England, it will be seen that the political system of both countries underwent similar changes, and arrived at approximately the same result—the main features of which were a responsible ministry and popular suffrage.

The political organization which was created both in France and in England was based on three essential elements: (1) an elected assembly capable of imposing an effective limitation on the power of the monarch; (2) a council of ministers subject to the control of the assembly; (3) an electorate capable of maintaining the control of the nation over the assembly. Three things were thus necessary in order to establish responsible government: the arbitrary power of the king must be restricted by an assembly independent of the court; the assembly must obtain effective control of the Government by transforming the king's ministers into agents for carrying out the will of the assembly; and the electoral system must be such as to ensure that the members of the assembly were representative of the will of the people.

In France the power of the king was so great that the people, who possessed no institutions through which they could exercise their action, were unable to impose any limitation on his authority. At a period when Great Britain already had a government responsible to an elected parliament, France had no political assembly, no franchise, and no check on the arbitrary power of ministers. The latter were simply the instruments through which the king exercised his personal authority.

It was impossible to modify this system, as had been done in England, by introducing successive improvements in the method of government, because there was no machinery in France through which control could be exercised. The change was made, without transition, by revolution; the old system of government was destroyed, and a new one had to be improvised. In devising a new system of government in this way it was of course necessary to proceed according to a general plan and to apply uniform rules of a legal and abstract character, whereas the British constitution was rather in the nature of a body of customs built up by a series of historical precedents. The difference in the method followed in the two countries has generally been attributed to a difference of national temperament, the Englishman being more phlegmatic, conservative and practical, and the Frenchman more passionate, revolutionary and fond of abstract ideas. It may however be more naturally explained by the different conditions under which the transformation of the political system was effected in the two countries. England already possessed an elected parliament which tended by gradual development to establish its control over the ministry; all that the English had to do was to reform their archaic electoral system. The French nation had to improvise an entire political system, and could only do so by the application of general rules.

The Revolution.—The French Revolution was initiated by the action of the royal Government itself in calling a meeting of the States General for the purpose of voting money. The meeting of the States General was not however, like the English parliament, an institution with the force of tradition behind it. The meeting called in 1789 under the old name of the States General was in reality a new assembly, summoned by a procedure created expressly for it.

Thus the question of the electoral system, which was the last to be settled in England, was in France the one which arose earliest. The system adopted was uniform for the whole country, and thus more logical than that of England. Voting was by secret ballot and by absolute majority. As the Government had extended the right to vote to all tax-payers, including the very numerous peasant class, the election of the deputies of the Third Estate was carried out by indirect suffrage. A system of indirect suffrage of two degrees, with a secret ballot and absolute majority, was applied to all elections of legislative bodies throughout the Revolution period.

The assembly, converted into a "National Assembly," declared that it would not separate until it had given France a Constitution; the royal power was thus limited by an elected body representing the nation as a whole. After the fall of Louis XVI. it became necessary to vest all powers in a single body, which was given the name of the Convention, a term borrowed from the United States. When the Convention desired to restore a regular political order conforming to the doctrine of the separation of powers, all that it could do was to replace the king by an executive Directory.

The third question, that of the qualifications and functions of ministers, had been settled under the pressure of practical necessities in 1789, when it had had to be decided whether ministers might also be members of the Assembly. The Constituent Assembly had been apprehensive of the influence which ministers might exercise over the legislative body; it feared the ambition of one of its members, Mirabeau. Ministers, as members of the executive, were therefore forbidden to be at the same time members of the Legislative Assembly; and this made it impossible to establish a system of responsible government in France.

The Restoration.—The institutions created by the Revolution were abolished by Napoleon, who reduced assemblies, elections and ministers to the position of instruments through which the absolute authority of the emperor was exercised. At the Restoration, however, a fresh attempt was made to create an organized political system. Louis XVIII. accepted the limitation of the royal power by a constitution and its control by an assembly. The three questions which had had to be considered in 1789 thus arose again in 1814; this time they were settled on lines directly copied from Great Britain.

Under the imperial regime there had been two chambers; Louis XVIII. maintained them under different names. The senate became a hereditary chamber of peers; the Legislative Assembly became the chamber of deputies, and the king had power to dissolve it, as in England. The chamber adopted a number of the practices of the British parliament, such as the King's speech, the voting of the Address, and the procedure for voting on ways and means.

The method of selecting ministers was not regulated by the Charter of 1814, just as there were no formal rules on the subject in England. Ministers were responsible, but only in the case of action contrary to the constitution, when they were liable to a procedure copied from the English system of impeachment. Thus France did not yet enjoy responsible government in the sense in which the term is understood in English-speaking countries at the present day. Louis XVIII. however generally followed the practice of forming the ministry in agreement with the majority of the chamber, and when Charles X., in 1829, appointed ministers who were definitely unpopular, the majority made an official protest, the "address of the 221," in which it enunciated the theory of responsible government.

The dispute led to an insurrection in Paris, and the Revolution of 1830 was the result. The new king, Louis Philippe, formally recognized the sovereign rights of the nation, and accordingly did not contest the principle of the responsibility of ministers to the Chamber. France thus adopted the principle of the political responsibility of ministers, according to which a minister is obliged to resign as soon as he is in disagreement with the elected Chamber.

"The Reform Movement."—The electoral system in France had been a constant subject of party controversy from 1814 onwards. The practice of holding elections had been introduced as a new departure in 1789; it was not a long-standing tradition as it was in England, and it had not struck deep root in the political life of the nation. The Charter of 1814, which was hastily drafted, only contained a single provision dealing with the electoral system; no one was entitled to vote unless he paid not less than 300 francs in direct taxes. This represented a much more limited franchise than that in force in England, and the result was to deprive the elections of their popular character.

It was not until later that legislation was adopted fixing the minimum tax payment constituting the electoral qualification and the procedure for elections. The act of 1831, which was passed after the Revolution, merely lowered the electoral qualification from 300 to 200 francs. This resulted in increasing the number

of electors from 87,000 to 166,000; a maximum of 249,000 was reached in 1847

One section of opinion in France regarded this reform as insufficient, since the large majority of citizens were still excluded from political life. Demands for the extension of the franchise were therefore put forward. At the time when in England the reform movement which had been initiated 60 years earlier was at last achieving success in the Reform Acts of 1832, agitation for the same object in France was only beginning. It is to the movement of 1832–48 that the term "reform" is applied in France.

Neither in France nor in England were the supporters of an extended franchise able to agree on the scope of the desired reform. Universal suffrage, which had been advocated in England as early as 1780, was not at first proposed in France except by a few isolated republicans. The *Société des Droits de l'Homme,* an association consisting mainly of young Parisian students and workmen, referred to universal suffrage in its manifesto of 1833 as an instrument for bringing about social revolution and improving the position of the proletariat; this attitude corresponded to that of the English Chartists.

The supporters of a less radical measure of reform put forward their demand for an extended franchise in the form of petitions to parliament, as had been done in England. The movement did not attain real political importance until 1838, when the National Guard of Paris, in which nearly the whole of the lower middle class population was enrolled, organized a petition asking that all members of the National Guard should be given the right to vote. A committee of deputies was formed to direct operations in the provinces; public manifestations were arranged, in which the National Guards marched in procession to greet the deputy with cries of "Vive la Réforme." The same cry was raised on June 14, 1840 at a review of the National Guard by Louis Philippe. The petition obtained about 240,000 signatures.

The opposition accused the Government of corrupting those deputies who were in the Government service by promises of promotion and the electors by granting them personal favours. As a remedy for the "corruption" of deputies it demanded "parliamentary reform," *i.e* , that civil servants should be forbidden to sit in the chamber. As a remedy for "electoral corruption" it demanded "electoral reform." These were the terms which had been employed in England in the time of George III.

Cniversal suffrage was at no time demanded by more than a very small minority, much less numerous than the Chartists in England. Almost its only champion in the chamber was the lawyer A. A. Ledru-Rollin. nho founded a journal entitled *La Réforme* in 1843, Ledru-Rollin represented political reform as a necessary condition for social reform. La *Réforme,* however, did not have a circulation of more than 2,000.

The campaign for reform was carried on in the chamber principally by the party nhich was opposed to the dynasty. For some years the question formed the subject of debates which led to no practical result. François Guizot, the virtual head of the ministry, always replied that the introduction of reform measures was inexpedient. Louis Philippe himself took part in the dispute. "There will be no reform." he said in Jan. 1848; "I will not have it If the Chamber of Deputies votes for it. I have the Chamber of Peers to reject it. Even if the Chamber of Peers adopted it. I have my veto."

The restrictions imposed on the press by the legislation of 1835 made it difficult for the opposition to state its views in the newspapers. A means of expression was found in the organization of a series of public dinners by opposition deputies and journalists; about 70 such dinners were held in 1847 and 1848, and toasts were drunk in honour of reform. The Government. by prohibiting a public dinner in Paris, provoked the revolt which led to the Paris insurrection of Feb. 23 and the overthrow of the monarchy. The provisional Government, composed of deputies representing the small republican minority, at once introduced universal male suffrage. Thus electoral reform, which was only begun in England after half a century of agitation, was consummated in France in a few days in its most radical form. (C. SE.)

REFRACTION. When waves of any kind traveling in one medium enter another, in nhich their velocity is difierent. their direction is. in general, changed, the rays, i.e , the lines perpendicular to the wave surfaces (in isotropic media) along nhich the energy travels, being bent or refracted at their point of incidence on the second medium. The change in direction is such that the sine of the angle formed by the incident ray and the normal to the surface of separation bears the same ratio to the sine of the angle formed by the refracted ray and this normal. as the velocity of the waves in the first medium to their velocity in the second. This ratio, known as the refractive index, may depend on the frequency of the wave vibrations If such be the case, each frequency in the incident disturbance gives rise to a separate refracted ray—a phenomenon known as dispersion. (*See* OPTICS.)

Mirage is due to the refraction of light by layers of air of gradually varying temperature and density. A similar variation. due to convection currents, is responsible for the flickering appearance seen above asphalt and sand on a hot day, and also for the twinkling of the stars. The refraction of rays of light entering the earth's atmosphere from heavenly bodies is knonn as astronomical refraction; it has the effect of making such bodies appear higher above the horizon than they really are. See REFRACTORIETER. *See* also Index references under "Refraction" in vol. 24.

REFRACTOMETER, an optical instrument for measuring refractive index. The refractive index, n, of a substance is equal to the speed of light. V_m, in that substance divided into the speed, V_s, in a standard medium: $n = V_s/V_m$. The standard medium is usually air or, in the case of gases. vacuum. Each pure substance has a unique value of n under standard conditions of temperature. pressure and wave length.

Refractometers are generally either of the deviation type or interference type, depending on the utilized change in light waves passing from one medium into another. These changes are caused by the different speeds of light in the two media and consist of: (1) a change in direction when the light strikes the boundary surface obliquely; and (2) a change in the phase of vibration of the light wave. A third. less common, type of refractometer makes use of the ratio between the intensities of light reflected and incident on an interface between two media. Sensitive photoelectric cells allow the rapid detection of small changes in refractive index by the photometric method.

A number of variables must be accurately controlled in precision refractometry. These are mainly temperature. nave length of light. and optical alignment of parts. An increase in temperature of 1° C. causes, for most liquids, a decrease in n by several units in the fourth decimal. The refractive index of a colourless substance measured with red light may be as much as several units in the second decimal smaller than when measured with violet light. The most widely used monochromatic light source is the sodium lamp; unless otherwise stated. values of n refer to the average wave length of the yellow sodium spectral lines (5.893 Å) Electric-discharge tubes containing such elements as helium, hydrogen, cadmium or mercury provide a series of well-defined wave lengths that are often used to determine optical dispersion.

Instruments designed to give fourth- or fifth-decimal accuracy require the highest quality workmanship in their optical and mechanical construction and adjustment. Reliable refractometric measurements require frequent calibrations of the instrument with known standards. The greatest accuracy is obtained by a direct comparison of the unknown with a similar knonn substance. The critical-angle and interference-type refractometers allow this kind of technique. knonn as the differential method. Easily purified liquids. such as water. serve as convenient standards of comparison; glass test plates are also used. In 1944 the U.S. National Bureau of Standards made available a series of pure hydrocarbons with refractive indices certified to the fifth decimal.

Deviation-Type Instruments. — Optical Principles. — Basic to

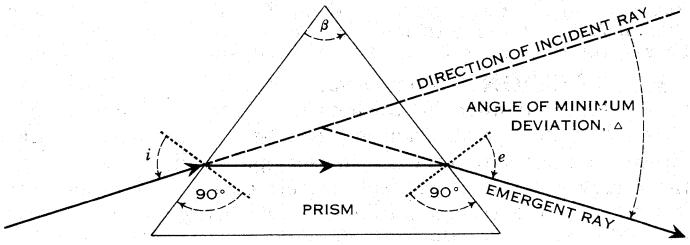

FIG. 1.— PRINCIPLE OF MINIMUM DEVIATION. USED WITH SPECTROMETER TO DETERMINE REFRACTIVE INDEX n OF PRISM: $n = \text{SIN } [(\beta + \Delta)/2] / \text{SIN } (\beta/2)$

all such instruments is Snell's law of refraction: $n = \sin i / \sin r$. The angle of incidence i and the angle of refraction r are the angles made with the normal, *i.e.*, perpendicular, to the boundary surface by the rays in the first and second media, respectively. The angles i and r are usually found indirectly from the deviations of rays which traverse not only the sample but one or more prisms and lenses of the refractometer as well. In the spectrometer type of instrument the incident rays come from a narrow slit so that, with a proper lens system, the refracted rays can be located precisely with the aid of a telescope. The spectrometer is ordinarily used with the principle of minimum deviation, which states that the angle between incident and emergent rays (fig. 1) can be made a minimum, Δ, by a unique orientation of the prism. Under these conditions, $i = e$, and the refractive index of the prism is $n = \sin \frac{1}{2}(\beta + \Delta) / \sin \frac{1}{2} \beta$, where β is the angle between the refracting faces of the prism.

Critical-angle refractometers make use of particular incident and refracted rays. The critical angle of refraction, C, is the greatest value of r which can be attained by any ray passing from a less to a more refracting medium (fig. 2). According to Snell's law, C corresponds to an incident ray that grazes the intersurface between the two media ($i = 90°$). All other refracted rays come closer than C to the normal direction. In critical-angle refractometers a prism of known refractive index n_p is used as the more refracting medium. A beam of nonparallel rays passes through the sample into the prism. On viewing the light refracted through the prism by means of a telescope, one finds a sharp critical boundary between a dark and a light region (fig 2) which very precisely defines the rays having the angles $i = 90°$ and $r = C$. The refractive index of the sample is given by the equation $n = n_p \sin C$.

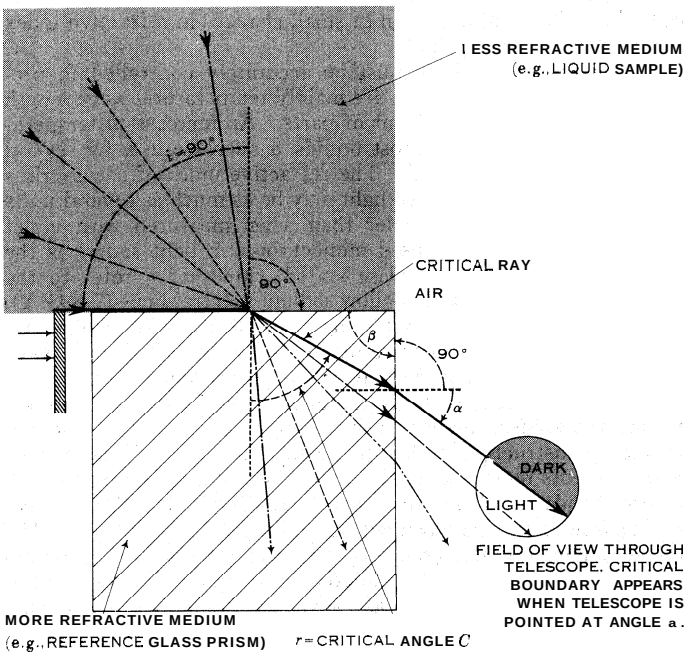

FIG. 2.— CRITICAL ANGLE OF REFRACTION. RAYS HAVING AN ANGLE OF INCIDENCE OF EXACTLY 90° APPEAR IN THE VIEWING TELESCOPE AT THE SHARP BOUNDARY BETWEEN A LIGHT AND A DARK REGION. HENCE THEIR ANGLE OF REFRACTION CAN BE MEASURED ACCURATELY

Abbe *Refractometer*.—This instrument is perhaps the most widely used critical-angle instrument. The ordinary model is rugged, compact (about the size of a microscope) and is capable of fourth-decimal accuracy. Only a few drops of a liquid sample are required, and a determination may be completed in less than five minutes. Liquid samples are confined to a thin film between the surfaces of the refracting prism P (fig. 3), $\beta = 60°$, and an adjacent auxiliary prism P'. The latter prism serves to send light into the sample in the direction required for the critical boundary. If white light is used, the critical boundary is not sharp because of the different refraction of rays of different wave length.

Most Abbe models are provided with a pair of compensating prisms, mounted in the barrel of the telescope, which remove nearly all of the boundary colour and sharpen the boundary. The amount of rotation of one compensating prism relative to the other, required to achromatize the boundary, provides a rough measure of the dispersion of the sample. The compensating system is designed to give refractive indices corresponding to a wave length near that of the sodium lines. The prisms holding the sample can be rotated with respect to the telescope about an axis passing through the point R (fig. 3). With a solid or liquid sample on the lower face of the prism P, the critical boundary can be made to coincide with the cross hairs in the telescope by rotating the prism by means of the alidade arm and a slow-motion screw. A pointer attached to the arm indicates the degree of rotation on a circular scale attached to the telescope. The scale may read directly in terms of refractive index n or, as desired, in terms of concentration of some solute. The range of each instrument is limited by the refractive index of the prism. Usually refractive indices from 1.3 to 1.7 can be covered.

Dipping *or* Immersion *Refractometer*.—This instrument resembles the Abbe instrument without the auxiliary prism P'. The refracting P is directly immersed in liquid samples, and the critical boundary is located with respect to a movable eyepiece scale. The dipping refractometer is widely used to check the concentration of solutions. The use of interchangeable prisms gives it a greater range than the Abbe type.

Other Types.— Deviation-type instruments, such as spectrometers, cover an unlimited range of refractive indices and, when appropriately designed, can be used with ultraviolet or infrared light. The material under investigation must be in the form of an accurately shaped prism. Liquid samples are placed in a prismatic cell. Monc-hromatic or polychromatic light from a narrow slit is made parallel by a collimating lens before traversing the prism. For each wave length an image of the slit is located by means of a telescope mounted on a graduated circle. The many necessary careful adjustments make the spectrometer inconvenient for routine use. Its principle is employed, however, in a number of simplified image-displacement refractometers. Some of these'are designed for rapid measurement of small liquid samples. The sample is made into a tiny prism by placing a drop between a pair of glass surfaces. If an illuminated slit is viewed through such a prism, its apparent position is shifted from its true position by an amount that depends on the refractive index of the sample and the angle of the prism. The amount of image displacement can be observed on a scale mounted behind the prism. A variation of this principle is found in the Nichols refractometer, which uses a microscope to observe the image displacement. The ordinary microscope can be adapted for use as a simple refractometer of this type.

Interference-Type Instruments.— Interference refractometers are indispensable for finding the refractive indices of gases; they can also be used for liquids and some solids. The interferometric method offers the most convenient means for determining the concentration of a substance in an extremely dilute solution.

Differences in refractive index of one part in a million may be detected easily, and still higher sensitivities have been attained. Such small differences may be of practical importance, as in the industrial analysis of air. Portable interference refractometers have been used to detect traces (0.1%) of methane (marsh gas) in coal-mine air as a means of preventing explosions.

Optical Principles.—In the interference-type refractometer a set of interference bands is produced by the superposition of two light beams originating at the same slit source. When a transparent substance having a refractive index n is placed in the path of one of the beams while the other beam travels a comparable distance in a material of index n_o, there is a displacement of the interference bands that depends on the difference n − n,.

The relation between refractive index and band displacement can be understood by considering the superposition of two converging trains of wave fronts. If they originate at the same slit source, there is a series of locations along the wave fronts where the waves are in the same phase of vibration and reinforce each other to produce a maximum light intensity. At intervening places the waves will be out of phase and tend to annul each other. One then sees alternately bright and dark areas in the field of view. These interference bands usually appear as narrow vertical fringes. If one of the wave trains is slowed down somewhat by passing through a more refracting medium than the other, the locations of the maxima and minima will be displaced laterally.

A relative retardation by one wave length causes the bands to shift laterally by one fringe interval. The band displacement, in number of fringe intervals N, is consequently related to the refractive index n by the formula $n - n_o = \lambda N/t$, where λ is the wave length of the light and t is the thickness of the interposed sample.

Rayleigh *Refractometer.*—The basic elements of the Rayleigh interference refractometer (fig. 4) are two achromatic lenses of long focal length, the first for obtaining parallel rays from a narrow slit source, the second for bringing together two beams, B_I and B_{II}, emerging from two broad slits in front of the first lens. The resulting interference bands are' observed with the aid of a cylindrical lens focused on the focal plane of the second achromatic lens. Adjacent cells C_1 and C_2, each in the path of one of the beams B_I and $B_{,,}$. contain the reference substance and the sample.

Commercial instruments are usually of the Rayleigh-Haber-Löwe type (fig. 4), which uses the Jamin method of determining the band displacement. B_I and B_{II} are so divided that there are actually four beams: B_I, B_{II}, b_I and b_{II}. The lower beams, b_I and b_{II}, pass through air and the lifting prism (Pr). The upper beams, B_I and B_{II}, pass through cells C_1 and C_2 and movable plate P_1 and fixed plate P_2, respectively. Instead of counting the bands, the path in the glass is increased by tilting the plate P_1 to produce a retardation just equal to that produced by the sample in the other beam. The effective thickness of P_1 is adjusted by the tilting lever L and a graduated micrometer screw. The micrometer scale may be calibrated to read values of $n - n_o$. The screw M is turned until the central interference band is brought back into the position it had before the sample was introduced. The central band in white light can be recognized because it is the only one having a pure white colour. See also INTERFEROMETER; LIGHT; OPTICS.

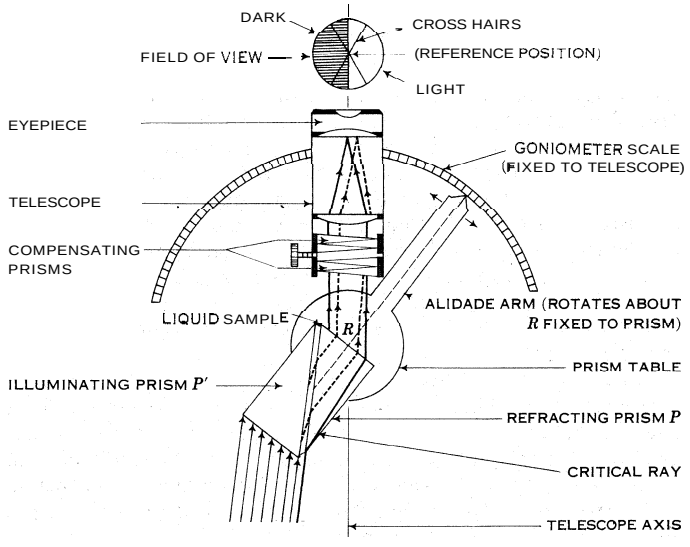

FIG. 3.— SCHEMATIC DIAGRAM OF ABBE REFRACTOMETER

REFRIGERATION. Refrigeration is the process of extracting heat from the interior of an insulated enclosure and rejecting it to the surroundings or some other external medium of higher temperature, thereby lowering the temperature inside the enclosure. Heat will not flow spontaneously from a region of low temperature to one of higher temperature, and so mechanical work or heat energy from an external source must be expended to move the heat from the enclosure to be refrigerated.

In the following article the applications of refrigeration are treated first. Then follow discussions of the working principles of refrigeration systems, the mechanical compression and absorption systems of refrigeration, and the history of liquefaction of gases.

APPLICATIONS OF REFRIGERATION

Household Refrigerators and **Freezers.**—With the achievement of reliability in modern, hermetic, mechanical refrigeration systems of fractional horsepower size, the main emphasis in household refrigerators was placed on improved appearance, utility and convenience.

The greatly increased use of frozen foods resulted in the need for refrigerators with much larger and colder frozen-food storage compartments. In a variety of models the freezing compartments run the full width across the top or bottom of the food compartment. The evaporator is operated at the low temperatures required for proper food storage but at the same time maintains temperatures above freezing in the regular food storage compartment, an insulated baffle being placed beneath the evaporator. Some manufacturers provide separate cooling for the freezer and the food storage compartments with separate evaporators. In larger refrigerators a two-door design is introduced, where the freezer and food storage compartments are completely separated from each other and each has its own exterior door. The volume of the frozen-food compartment may vary from 20% to 100% of the food storage compartment volume. Those in the latter category are normally classified as combination refrigerator-

freezers.

The trend toward specialized interior designs has become a common practice. Meat storage compartments maintained at temperatures slightly above freezing, with relative humidities around 90%, special high-humidity compartments for leafy vegetables, shelves on the inner panel of the door for storage of small bottles, containers, eggs, etc., and compartments with provisions for maintaining butter at suitable spreading temperatures are common. Another important feature in modern household refrigerators is the rapid automatic defrosting of the evaporator. With defrosting cycles ranging from 5 to 30 minutes in duration no substantial rise occurs in the frozen-food temperature or in the normal food compartment temperature.

The use of household freezers in urban homes and on farms can be considered to have assumed commercial importance in 1937, and their acceptance and use have been constantly increasing since that year. The functions of the household freezer are to provide a storage space at a temperature of 0° F. or below and a fast-freezing zone where limited quantities of fresh food may be frozen in a reasonably short time with minimum disturbance of the stored load temperature. Modern freezer cabinets are made in two general styles, namely, the upright freezer and the chest-type freezer. Upright freezers have followed the pattern of household refrigerators, with interior locker doors used to reduce air spillage and to form convenient loading shelves when the main door is opened. Tests comparing chest and upright types indicate no significant difference in operating costs with a door-opening frequency of two per day. The frost accumulation in the upright type may become objectionable when more frequent door openings are necessary, but in household use this objection is not experienced.

Cold-Storage Warehouses.— Cold-storage warehouses vary in capacity from 1,000,000 to 6,000,000 or more cubic feet of storage space devoted, on the average, two-thirds to freezer space and one-third to cooler space. Unless special provisions are made for quick freezing, the minimum temperatures maintained in these spaces usually are: sharp freezers, −15° to −10° F.; carrying freezers, −10° to 0° F.; and coolers, 30" F. The actual refrigeration capacity necessary to take care of a cold-storage warehouse is not always easy to estimate as the load requirements vary appreciably with the nature of products stored and many other operating variables, including the size of the plant. To give an idea of the order of magnitude involved. one can say that an average cold-storage warehouse of 6,000,000 cu ft. storage capacity requires the installation of the order of 300 tons of refrigeration.

The cooling systems used in cold-storage applications come under three main classifications, namely: (1) the direct application, where the refrigerant proper circulates in pipe coils in the space to be cooled; (2) the indirect application, where the refrigerant cools a brine (a solution of water and calcium chloride or sodium chloride having a freezing point temperature as low as −60" F., depending on the salt concentration) in a heat exchanger, and the cold brine circulates in pipe coils in the space to be refrigerated; (3) the indirect application, where air, cooled either by a brine spray or direct expansion coils, is circulated through diffusers in the refrigerated space. Of the three methods mentioned, the brine and the forced-air circulation methods are the most extensively used because of their greater flexibility and safety features. It is common practice to use several refrigeration compressors to handle the total load of a cold-storage installation, a number of the units supplying refrigeration for the freezer rooms and others for the coolers, with at least one unit kept as a stand-by or spare to be used in the event one of the operating units breaks down.

Another type of installation somewhat similar to the cold-storage warehouse but much smaller in capacity and more specialized in function is the frozen-food locker plant, where foods are frozen and held in storage for families and other groups of a community.

Refrigerated Food Transportation.— *Trucks and Trailers.*— The distribution of refrigerated foods from major storage centres to retailers and even the long-distance hauling from farms and food processing centres to cities is handled to a large extent by refrigerated trucks and trailers. In the main, two types of truck bodies are constructed: those maintaining 35° to 40° F. for carrying fresh meat, vegetables and dairy products; and those holding about 0° F. for ice cream and frozen foods. Numerous types of mechanical refrigeration systems are used in both trucks and trailers, the source of power being obtained either by a separate internal-combustion engine or from the truck engine itself. either by a crankshaft extension at the front end or by a power take-off from the transmission. Besides mechanical refrigeration, water ice and dry ice (solid carbon dioxide) are extensively used in refrigerated transportation, where these are charged in conveniently located bunkers either at the end or near the ceiling of the truck body, and air is circulated past them and through the body by means of a small blower. The use of dry ice in refrigerated transportation (truck, trailer and rail) was steadily increasing in the 1960s despite its much higher cost per pound. Because of its low temperature it is ideal for frozen-food transportation. When dry ice is used in the shipment of fresh foods, the carbon dioxide gas in the atmosphere immediately surrounding the product serves as a means of reducing the oxygen content of the air, thus minimizing possible deterioration resulting from oxidation. Also, it inhibits the growth and development of bacteria and various molds which cause spoilage. It is often the practice to precool the interior of the truck, as well as the fresh produce, prior to or at the time of loading.

Refrigerated Railway Cars.— Despite the tremendous volume of perishables transported by trucks and trailers and their increasing competition nith the railways, the main bulk of long-distance refrigerated transportation was handled by rail in the 1960s. The earliest known use of refrigeration by the railroads was in July 1851. when several tons of butter were shipped from Ogdensburg, N.Y., to Boston, Mass., in a wooden boxcar insulated with sawdust and stocked with ice. More than a century later, water ice was still more or less the universal cooling medium in refrigerated freight and express cars. The modern standard refrigerator car in the U.S. is 40 ft. long and of the end-bunker type, equipped with fans and having about 4 in. insulation. Some cars, 50 ft. long and with 6 in, insulation, using 30% by weight sodium chloride salt with water ice giving a bunker temperaturt of −3° F., are used in the transportation of frozen foods. The use of mechanical refrigeration on railways was still more or less in the developmental stage in the early 1960s. Considerations of high first cost and high maintenance costs were expected to delay wide-scale mechanical installations. The few mechanically refrigerated freight cars in operation were mostly equipped with Freon-12 compressors run by diesel-electric drives. Each of these cars had a refrigeration capacity of about seven tons, and they were used mainly by the frozen-food and frozen-concentrate industry.

Marine Refrigeration.— The early history of mechanical refrigeration as applied to food transportation finds its origin in marine refrigeration. In the summer of 1880 the steamer "Strathleven" brought to England the first successfully carried refrigerated meat cargo. Early shipboard installations were equipped with dense-air machines, later being replaced by carbon dioxide and ammonia systems. In modern installations Freon refrigerants are used extensively. Design conditions and other basic principles are not greatly different in marine refrigeration from those in cold-storage warehouse practice. All equipment and installations must be specified as complying with the rules and regulations of the classification societies (American Bureau of Shipping or Lloyd's Register or both, etc.).

Manufacture of Water Ice.— Despite the tremendous increase in the use of fractional-horsepower mechanical refrigeration units for household and other commercial refrigeration uses, the manufacture of water ice remained a major industry. The method most extensively used is the can method, using treated or untreated raw (tap) water. Galvanized steel ice cans, usually of about 320 lb. capacity, 11 x 12 in. at the top and 50 in. in depth, with an overall taper of $\frac{1}{4}$ in, in their length. are submerged in a well-insulated (10 to 12 in. granulated cork) tank in which cold brine is circulated. Tank depths are usually about 52 in. for 320-lb. ice cans, and width and length seldom exceed 40 and 120 ft. The brine is cooled by direct-expansion evaporator coils normally placed be-

tween rows of cans. The velocity of the brine flowing past the cans and the brine temperature determine the time required for freezing. Brine velocities should not exceed about 35 ft. per minute, and variations of temperature should be kept less than 1° F. For a given brine velocity, the time required to freeze a given thickness of ice is determined first by the brine temperature. As most raw waters, treated or untreated, crack upon freezing at temperatures below 10° F., the freezing temperatures are in general somewhat above this figure. The rate of freezing drops rapidly as the ice becomes thicker. An 11 x 12-in. can holding 320 lb. of water in 12° F. brine takes 24 hours to freeze the first 280 lb. of ice and requires an additional 14 hours to freeze the last 40 lb. When raw water is used in the manufacture of ice it is necessary to agitate the water in the cans during freezing to obtain clear ice. This is done by bubbling dry air, usually at about 15 to 18 lb. per square inch (p.s.i.) gauge pressure, at the centre of each can, thus rejecting most of the dissolved minerals into the unfrozen centre core. Near the completion of freezing, the concentrated core, consisting of about three to four gallons, is sucked out and replaced with chilled fresh water to complete the freezing of the complete block. The refrigeration reauired to manufacture ice depends on many factors, such as initial water temperature, brine temperature, insulation of brine tank, efficiency of refrigeration compressors, size of plant, etc. A good figure for a well-constructed plant of 30- to 50-ton daily ice capacity using 60° F. water and 12° F. brine is 1.52 tons of refrigeration per ton of ice.

Despite the large amount of ice consumption in all countries of the world, the methods for handling and processing ice have not changed significantly over the years. Only in the decade following World War II did mechanization of ice making become widespread. There was then a definite trend toward increased sales of ice in small sizes (cubed, crushed and sized and shaved) aside from the manufacture of block ice. Installation of scoring machines, cubing machines, sizing machines and packing machines for automatic vending stations expanded rapidly.

Comfort Air Conditioning. — In its strictest definition, comfort air conditioning must incorporate the following features: control of temperature, humidity, air distribution (ventilation), odour, air cleanliness and in some instances air sterilization. All comfort conditioning applications are functionally similar whether the space under consideration be a residential dwelling, large building, hotel or restaurant. In large installations, involving sometimes 1,000 or more tons of refrigeration capacity, the central system design is adapted. However, the majority of installations run in sizes starting from ½ ton for window air-conditioning units to 5, 10 or 25 tons for small retail shops, restaurants, etc. *(See* AIR CONDITIONING.)

Other Applications. — The following constitutes only a partial illustrative list of the many diverse applications where refrigeration is used extensively: food processing and manufacturing: dairy products (butter, ice cream, cheese), beverages (beer, wine and other alcoholic and carbonated beverages), bakery goods, etc.; industrial and engineering applications: liquefied storage and transportation of industrial gases (oxygen, nitrogen, hydrogen), manufacture of dry ice, textile industry (synthetic and natural yarn processing and weaving), petroleum refining and chemical processes, metallurgical processes, engineering construction (freezing of sliding silty soils in the construction of dams, tunnels, shaft sinking, curing of large masses of poured concrete), low-temperature testing facilities, wind-tunnel cooling. etc.; industrial air conditioning: printing and paper manufacture, precision machining and assembly of metal machine parts, confectionery processing, deep-mine cooling, preservation of valuable books, paintings, tapestries, etc., in libraries and museums, etc. See also AIR CONDITIONING; HEATIKG AKD VENTILATION.

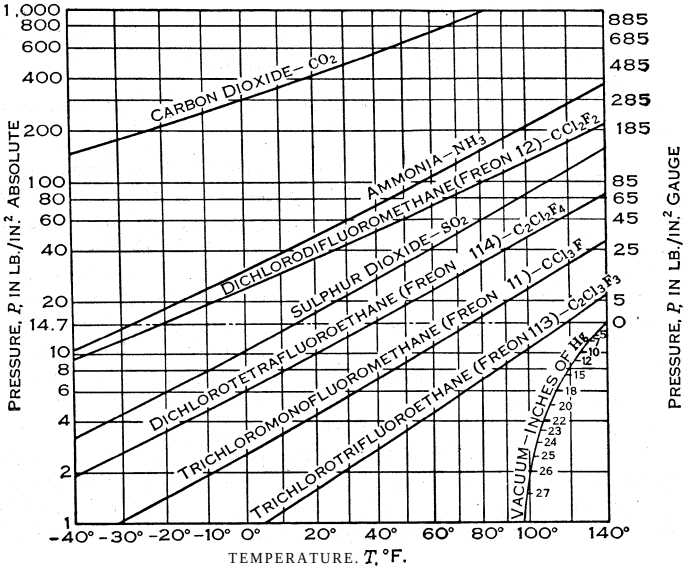
WORKING PRINCIPLES OF REFRIGERATION SYSTEMS

Refrigeration technology draws its basic knowledge from three interrelated yet distinct areas of science, namely, thermodynamics, heat transfer and fluid flow. In the following sections the underlying principles of operation of major refrigeration systems are discussed, drawing on the basic sciences only to the extent necessary to achieve understanding and clarity.

In all refrigeration systems the working fluid used to carry away the heat from the region to be cooled is known as the refrigerant. The boiling temperature of refrigerants, as that of any other liquid, depends on the pressure at which the boiling takes place, the boiling temperature decreasing with decreasing pressure. This boiling temperature *v.* pressure characteristic of refrigerants is used to advantage in all refrigeration systems and can be said to constitute the main principle of operation. Fig. 1 illustrates the boiling temperature v. pressure characteristics of some commonly used refrigerants. It is to be noted that, at a given pressure, the phenomena of boiling and condensation take place at the same temperature, one process being the reverse of the other.

MECHANICAL COMPRESSION REFRIGERATION SYSTEMS

The most widely used refrigeration cycle is the mechanical compression refrigeration cycle which is schematically illustrated in fig. 2. Referring to fig. 2, high-pressure refrigerant vapour is discharged from the compressor (point 1) in a superheated state (a



REPRINTED FROM THE DESIGN VOLUME OF THE 1942 "ASRE DATA BOOK" BY COURTESY OF THE AMERICAN SOCIETY OF REFRIGERATING ENGINEERS

FIG. 1. — PRESSURE AND TEMPERATURE RELATIONSHIP OF SOME REFRIGERANTS

state having a temperature higher than the boiling temperature at that pressure) and enters a heat exchanger known as the condenser. In the condenser the refrigerant vapour is condensed, essentially at constant pressure, by giving up its latent heat to the cooling water flowing through coils or tubes, as shown in the figure. or to the surrounding atmosphere, as is often the case in small-sized machines. The saturated liquid refrigerant (liquid at the boiling temperature corresponding to the condensing pressure) is collected into a receiver tank which in the case of water-cooled condensers may consist of the lower portion of the condenser shell itself as indicated in fig. 2. At point 2 the saturated liquid refrigerant at high pressure enters the expansion valve, also known as the throttling valve or reducing valve, and its pressure is reduced to a much lower value at point 3. Simultaneous with the reduction in pressure an associated reduction in temperature takes place, the new temperature corresponding to the boiling temperature at this lower pressure. The actual mechanism which accounts for this lowering of the liquid refrigerant temperature consists of the flashing into vapour of a portion of the liquid, and as there exists no external source of heat, the energy for this evaporation is supplied by the liquid refrigerant itself, thus causing its temperature to drop. At point 3 in fig. 2 the low-temperature liquid refrigerant, with a small fraction of its vapour, is admitted to a heat exchanger known as the evaporator. Within the evaporator (which may be constructed in a variety of designs) the liquid

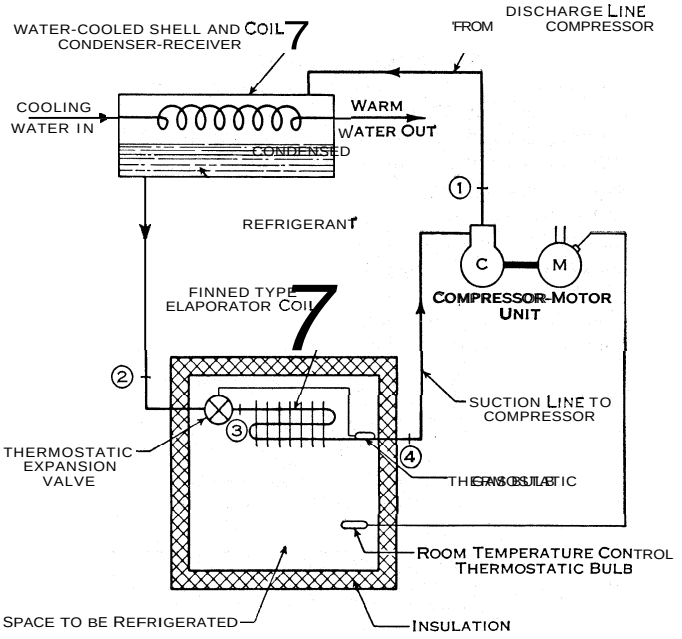


FIG. 2.— SCHEMATIC FLOW DIAGRAM OF A MECHANICAL REFRIGERATION SYSTEM

refrigerant is evaporated by heat transferred to it from the comparatively warmer space to be refrigerated. The flow rate of the refrigerant is so adjusted by the thermostatic expansion valve that at the exit of the evaporator, at point 4 in the system, all the liquid refrigerant is in the saturated vapour state (vapour at the boiling temperature corresponding to the evaporator pressure). The vapour leaving the evaporator enters the suction side of the compressor and is compressed to a higher pressure. The work *of compression raises both the pressure and temperature of the refrigerant vapour* which *is discharged in the superheated vapour state and ready to repeat the entire cycle over again.*

A cycle of the type described above is known as a steady flow thermodynamic cycle because at any one point in the cycle refrigerant conditions (i.e., flow rate, temperature, pressure, etc.) do not change with *time,* while *heat and* work *are received by the refrigerant in the evaporator and compressor, respectively, and heat is rejected in the condenser. It is to be noted that the cycle discussed above operates between* two *levels of pressure and* two *corresponding levels of* temperature. *The high-pressure half of the cycle extends from the dis rge of the compressor to the inlet of the expansion valve, and the low-pressure side extends from the discharge of the expansion valve to the inlet of the compressor.*

Thermodynamic Analysis of Compression Refrigeration Cycles.— The evaluation of the performance of the various components of the refrigeration cycle discussed above requires a knowledge of some of the laws of thermodynamics which govern the interconversion of heat and work *and enable the calculation of the thermal properties of substances. It sufficesto state here that extensive tables of thermodynamic properties of all commonly used refrigerants have been prepared and are available in tabular or graphical form readily usable in engineering calculations (see* HEAT; THERMODYNAMICS).

From the principle of conservation of energy it can be stated that for a fluid *in steady flow the summation of all its energy* quantities *(its total energy) entering a system (compressor, heat exchanger, etc.) must be equal to the summation of all its energy quantities leaving the system. For a unit mass* flowing *in and out of a system per unit time this principle can be written in symbolic form as:*

$$u_1 + A(P_1v_1) + A(V_1^2/2g) + AZ_1 + {}_1Q_2 = u_2 + A(P_2v_2) + A(V_2^2/2g) + AZ_2 + A({}_1Wk_2) \quad (1)$$

In the above relation subscripts 1 and 2 refer, respectively, to the magnitudes of the various quantities as the fluid enters and leaves the system. The magnitude of the various quantities can be expressed in any consistent set of units such as the British system of engineering units employed here. The above symbols are defined as follows: u = internal energy of the fluid, its value depending on the temperature and pressure of the fluid, expressed in the units of B.T.U. per pound (one B.T.U. [British thermal unit] is the quantity of heat required to raise the temperature of one pound of water by one degree Fahrenheit [from 63° F. to 64" F.]); P = pressure of the fluid, in pounds per square foot; v = specific volume of fluid, in cubic feet per pound; V = velocity of the fluid, in feet per second; Z = elevation of the inlet to the system measured from an arbitrary reference level, in feet; ${}_1Q_2$ = heat transferred to or away from the fluid from the time it enters to the time it leaves the system, in B.T.U. per pound of fluid flowing (by convention, ${}_1Q_2$ is taken as positive if the fluid receives heat and negative if it gives up heat); ${}_1Wk_2$ = external work done by the fluid or on the fluid from the time it enters to the time it leaves the system, in foot-pounds per pound of fluid flowing (by convention, ${}_1Wk_2$ is taken as positive if it is performed *by the fluid and negative if it is performed on the fluid); g = gravitational acceleration whose standard value is 32.2 ft. per square second; A = the mechanical equivalent of heat, a universal constant used to convert units of work into units of heat and vice versa ($A = \frac{1}{778}$ ft.-lb. per B.T.U.).*

Examining equation (1) further, the term (Pv), the product of the pressure by the volume, represents the magnitude of the flow work necessary to set the fluid in motion; the term $V^2/2g$ represents the kinetic energy caused by motion; and Z represents the potential energy of the moving fluid measured above a given arbitrary reference datum plane. In thermodynamics, because of the frequent simultaneous occurrence of the terms u and (Pv), a new *term called enthalpy is defined as $h = u + Pv$. Hence, the quantity $(u_1 + AP_1v_1)$ can be written as h_1 and $(u_2 + AP_2v_2)$ as h_2. Making these substitutions and transposing some of the terms, equation (1) can be rewritten in the form*

$$(h_2 - h_1) = {}_1Q_2 - A({}_1Wk_2) + A(V_1^2 - V_2^2)/2g + A(Z_1 - Z_2) \quad (2)$$

Equations (1) and (2), which are identical, are known as the general energy equations for steady flow and are used extensively in engineering calculations involving the interchange of heat and work. *For reasons of simplicity, in the analysis of refrigeration cycles it is common practice to neglect the last two terms on the right-hand side of equation (2), since their magnitude is either zero or negligible compared with the others. Indeed, the difference in elevation between the inlet and outlet openings or the difference in velocity between the inlet and outlet of compressors or heat exchangers is either nil or negligible. On the basis of this simplifying assumption equation (2) reduces to the form*

$$(hz - h_1) = {}_1Q_2 - A({}_1Wk_2) \quad (3)$$

Equation (3) may be applied to any one of the components that make up the refrigeration system shown in fig. 2. Considering the condenser, the refrigerant receives no external or shaft work *and delivers none as it enters and leaves this equipment, and only heat is exchanged between the condensing refrigerant and the cooling water. Therefore in equation (3) the quantity ${}_1Wk_2$ is zero, and the decrease in enthalpy of the refrigerant $(h_2 - h_1)$ is equal to the heat it rejects to the cooling water, ${}_1Q_2$. The evaporator is a similar piece of equipment and again there is no work involved; therefore, the heat absorbed from the space to be refrigerated is equal to the increase of enthalpy of the evaporating refrigerant, ${}_3Q_4 = (h_4 - h_3)$. The* flow *through the expansion valve involves neither the exchange of heat nor work, hence, in this instance, equation (3) yields the result $h_3 - h_2 = 0$, indicating that the refrigerant undergoes no change of enthalpy. In the case of the compressor a definite amount of work, ${}_4Wk_1$, is delivered to the refrigerant vapour being compressed.* While *some heat, ${}_4Q_1$, is dissipated from the compressor* cylinder *head to the surrounding atmosphere by convection and radiation, this quantity is usually a small fraction of the total* work *input and may be neglected in most instances without causing serious error. Where more exact*

calculations are desired or, in the case of jacketed water-cooled compressors, where the heat loss from the compressor cylinder is appreciable, in applying equation (3) either the quantity ${}_4Q_1$ must be known or a different expression should be used to evaluate the work required for compression. Such an expression has the general form

$$Wk_{comp.} = [n/(n-1)]P_4v_4[1 - (P_1/P_4)^{(n-1)/n}] \quad (4)$$

where all symbols are as defined before and n is a constant which depends on the nature of the refrigerant, the type of compression (the extent of heat loss during compression) and the pressure range over which the compression takes place. Values of n are determined experimentally and are reported in reference works on refrigeration. An important observation to be made in equation (4) is the fact that the work of compression depends primarily on the pressure ratio of compression and not on the absolute values of the inlet or discharge pressures.

The Thermodynamic Diagram. — In the solution of refrigeration problems it is most helpful to trace the processes the refrigerant undergoes on a chart of thermodynamic properties of the refrigerant. Such a chart most frequently used in refrigeration work is the pressure v. enthalpy chart shown in skeletal form in fig. 3, where the interrelationship between three of the most frequently

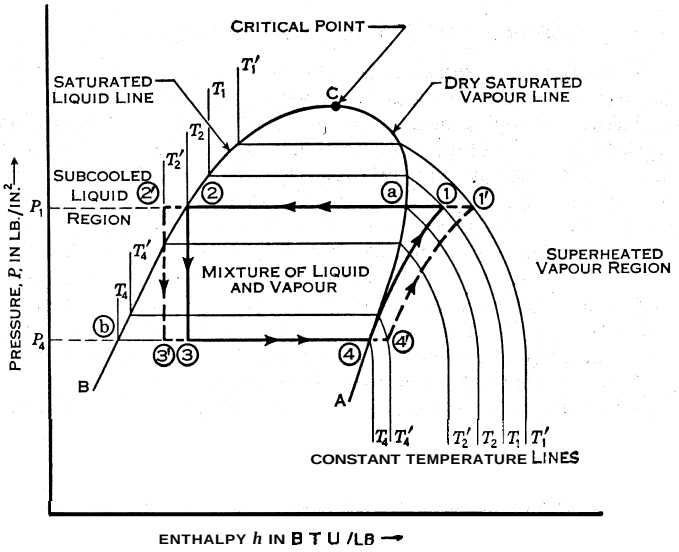

FIG. 3.— SKELETAL THERMODYNAMIC DIAGRAM ILLUSTRATING THE REFRIGERANT CYCLE FOR THE SYSTEM SHOWN IN FIG. 2 (NUMBERS CORRESPOND TO POINTS IN FIG. 2)

used properties of refrigerants (pressure, enthalpy and temperature) is graphically depicted. The properties pressure and enthalpy are chosen as the co-ordinates for the figure, and their variation with temperature is represented by the family of constant temperature lines T_4, T_4', T_2', T_2, T_1, T_1', in order of increasing temperature. The dome A-C-B is known as the saturation dome. Points along the curve A-C represent states of dry saturated vapour and along B-C states of saturated liquid. The saturated vapour and saturated liquid curves meet at point C, which is known as the critical point. At this unique temperature and pressure the liquid and vapour phases of the refrigerant are indistinguishable and therefore possess identical properties known as the critical properties of the refrigerant. The region to the right of the saturated vapour curve A-C represents states of superheated vapour and that to the left of the saturated liquid curve B-C represents states of subcooled (or compressed) liquid (liquid at a temperature lower than the condensation temperature corresponding to the same pressure). The region within the dome A-C-B (wet vapour region) represents states of mixtures of liquid and vapour refrigerant. The per cent*by weight of vapour in the mixture at any point within the dome is obtained by taking the ratio of the horizontal distance between the saturated liquid curve and the point in question to the total distance between the two saturation curves (measured at the same pressure). For example, at point 3 (fig. 3) the per cent of vapour in the mixture is given by the ratio of distances (b to 3)/(b to 4) or $(h_3 - h_b)/(h_4 - h_b)$. This fraction is called the quality of the wet vapour and is designated by the symbol x. On this basis, the vapour at point 4 on the saturated vapour curve would have a quality x = 100%. At a given pressure or temperature, the difference in enthalpies between the saturated vapour and saturated liquid is known as the latent heat of evaporation (or condensation) representing the quantity of heat required to evaporate completely a unit mass of refrigerant from the saturated liquid state to saturated vapour state (at constant temperature and pressure). It should be noted that within the saturation dome A-C-B the constant temperature lines are horizontal and coincide with the corresponding saturation constant pressure lines.

The Thermodynamic Cycle. — The cycle of the refrigerant corresponding to the simple refrigeration system of fig. 2 is traced on this thermodynamic chart, with corresponding points on the flow diagram being labeled by matching numbers on fig. 3. Referring to fig. 3, the trace 1–2–3–4 represents this cycle. At point 1 the compressed and superheated refrigerant vapour (at temperature T_1 and pressure P_1) leaves the compressor and enters the condenser. As heat is transferred in the condenser to the cooling water the superheated vapour is cooled at constant pressure and its temperature drops from T_1 to T_2 (same as T_a). At point a the saturated vapour begins to condense and upon further heat transfer condensation continues between points a and 2, the vapour giving up its latent heat of condensation until at point 2 all of the vapour is completely liquefied and is collected in the lower part of the condenser (or a receiver) as saturated liquid. At point 2 the saturated liquid refrigerant enters the expansion valve and its pressure is reduced from P_1 (same as P_2) to P_3 $(P_3 = P_4)$. As shown earlier, the enthalpy of the refrigerant entering and leaving the expansion valve is the same; *i.e.*, $h_2 = h_3$. As a result of this pressure drop the temperature of the refrigerant is reduced to T_3 (same as T_4) at the expense of some of the liquid flashing into vapour. The fraction of the liquid flashed (the quality) is given by the ratio $x_3 = (h_3 - h_b)/(h_4 - h_3)$. At point 3 the refrigerant (mixture of liquid and vapour) enters the evaporator and as it absorbs heat from the refrigerated space and its contents it continues to evaporate at constant pressure and temperature until at point 4 all of the refrigerant is completely evaporated and leaves the evaporator as saturated vapour. The dry saturated vapour enters the compressor at point 4, and by means of external work it is compressed along the path 4–1 and is discharged at 1 to repeat the cycle. The cycle just described is known as the simple saturation ideal cycle because the refrigerant entering the expansion valve and the compressor consists of saturated liquid and saturated vapour, respectively. It is called ideal because of the simplifying assumption that no pressure drop takes place in any of the piping, the heat exchangers, or at the inlet and outlet of the compressor.

In actual practice it is nearly always the case that the liquid refrigerant leaving the condenser is somewhat subcooled and the vapour leaving the evaporator is somewhat superheated. Such a cycle is shown in fig. 3 by the trace 1'–2'–3'–4'. All other things being the same, the effect of subcooling is to increase the refrigeration effect per pound of refrigerant circulated in the system and is therefore desirable. On the other hand, superheating of the vapour entering the compressor increases the work of compression and should be kept to a minimum.. A slight amount of superheating is encouraged in practice as a safety measure to protect the compressor by preventing any liquid from entering the compressor cylinder.

All previous discussion and analysis have been based on one pound of refrigerant circulating in the system. In the design and analysis of actual systems certain information and requirements are given the engineer at the outset. For instance, the refrigeration load (demand) is specified, and the temperature at which this refrigeration effect is desired is stated. The temperature of the available condenser cooling water (or ambient air) is also specified. Starting with this information, the first step is to determine the condensation and evaporation temperatures and pres-

sures for the refrigeration cycle. In practice, it is customary to assume an average temperature difference between the cooling medium and the condensing refrigerant of the order of 10° F. A similar figure is taken for the temperature difierence between the evaporating refrigerant and the refrigerated medium. The smaller the temperature differential, the larger becomes the required size of the heat exchanger needed to accomplish a given heat transfer. Hence. the actual selection of temperature differentials to be used is based on both engineering and economic considerations. In general, therefore, one can write

$$T_c = (T_{c.w})_{av.} + (\Delta T)_c \text{ and } T_e = T_r - (\Delta T)_e \qquad (5)$$

where T_c, T, and T_r are the temperatures of the condensing and evaporating refrigerants and refrigerated medium, respectively; (T, ₃)$_{av}$ is the average cooling nater or air temperature; (AT), and (AT), are the design temperature differentials between the cooling water and condensing refrigerant and between the refrigerated medium and evaporating refrigerant, respectively, all temperatures being expressed in degrees F.

At this point the choice of a refrigerant must be made. The proper refrigerant selection is dependent primarily on the condenser and evaporator temperatures. A desirable refrigerant should not give rise to either unduly high condenser pressures or very low evaporator pressures. Some of the characteristics of refrigerants are discussed in a later section. Having decided on the refrigerant to be used and having determined the condensing and evaporating temperatures, the respective pressures are directly obtained by looking up the saturation pressures corresponding to these two temperatures. The next step in the analysis is the determination of the flow rate of refrigerant necessary to provide the desired refrigeration. Refrigeration load is commonly expressed in the unit of tons of refrigeration. In the U.S., 1 ton of refrigeration is equal to a cooling rate of 288,000 B.T.U. per 24-hour day or 200 B.T.U. per minute. The ton as the unit of refrigeration derives its name from the fact that to freeze 1 ton of water per day (1 U.S. ton equals 2,000 lb.) from 32° F. liquid to 32° F. solid requires approximately 288,000 B.T.U. In Great Britain and Europe the ton of refrigeration is sometimes defined either on the basis of the long ton (2.240 lb.) or taken equal to a cooling rate of one kilocalorie per second. These units are larger than the C.S. ton by 12% and 18.8%, respectively. Referring to the cycle 1–2–3–4 of fig. 3, the refrigeration performed per pound of refrigerant is given by $(h_4 - h_3)$, in B.T.U. per pound; hence, the required refrigerant flow rate, w, is

$$w = (\textit{tons of refrigeration})\ 200/(h_4 - hs),\ \textit{pounds per minute}$$

The work necessary for compression is obtained from the relation

$$Wk_{comp.} = w(h_1 - h_4)/42.42,\ \text{h.p.}$$

where 42.42 is a conversion factor between heat units and horsepower (1 h.p. = 42.42 B.T.U. per minute).

A final quantity of interest in the analysis of refrigeration cycles is the efficiency of performance of the cycle. The efficiency of refrigeration cycles. which is known as the coefficient of performance (C.O.P.), is defined as the ratio of the refrigeration effect produced in the evaporator to the compressor work necessary to bring about this refrigeration effect. In symbolic form this may be expressed as

$$\text{C.O.P.} = w(h_4 - h_3)/w(h_1 - h_4) = (h_4 - h_3)/(h_1 - h_4)$$

The C.O.P. of all mechanical refrigeration cycles is greater than 1. Since the magnitude of the C.O.P. is not directly indicative of the degree of perfection attained by an actual refrigeration system, it is often compared with the C.O.P. of an ideal cycle operating between the same condensing and evaporating temperatures. Such an ideal cycle is the Carnot cycle, named after its originator, Nicolas Léonhard Sadi Carnot, the French engineer. It can be shown in thermodynamics that a refrigeration system operating on the Carnot cycle requires the least amount of work per unit of refrigeration. It can further be shown that the C.O.P. of the Carnot cycle is independent of the type of refrigerant used and is fixed solely by the two temperatures at which heat is rejected and received. The C.O.P. of the Carnot cycle is defined as

$$(\text{C.O.P.})_{\text{Carnot}} = T_c/(T_c - T_e) \qquad (6)$$

where T, and T_c are the evaporation and condensation temperatures. respectively, expressed in degrees Rankine. Temperatures in degrees Rankine are obtained by adding 460 to Fahrenheit degrees (see THERMOMETRY).

Properties of Refrigerants.—Since the early days of mechanical refrigeration the number of available refrigerants has increased steadily as a result of the consistent efforts of chemists and physical chemists searching for new fluids possessing suitable thermal, physical and chemical characteristics to meet demands of new applications and equipment design. The most striking example of such research is the development of the series of refrigerants known under the trade name of Freons. With rapid advances in the understanding of the structure of matter it has become possible to synthesize almost any type of refrigerant suitable for a specific application. However, even scientific progress has not been able to produce the ideal refrigerant having simultaneously optimum thermodynamic. physical and chemical properties. Therefore, in the final analysis. refrigerant suitability for a specific application is determined as a result of both engineering and economic considerations, and compromises must be made among the most important factors involved in a particular situation.

ABSORPTION REFRIGERATION SYSTEMS

Absorption refrigeration systems use heat energy directly through the medium of a generator-absorber-pump circuit which replaces the complex mechanical compressor. In some absorption refrigerators a small liquid pump constitutes the only moving part in the entire system, and in others even this is eliminated, resulting in a system with no moving parts whatsoever. Two of the most prominent types of absorption systems are discussed below.

The Ammonia-Water Absorption Refrigeration Cycle.— The most common absorption system is the two-fluid, water-ammonia (also known as aqua-ammonia) system. The operation of this system is based on the particular relationship between the temperature, pressure and concentration of a mixture of two fluids, such as ammonia and water, while it undergoes a change of phase. When a mixture of ammonia and water boils at a given pressure, the vapour phase is much richer in ammonia (the more volatile of the two components) than the liquid phase in contact with it. Conversely, when condensing a mixture of ammonia and water vapour the condensate is poorer in ammonia than the vapour mixture in contact with it. It is also observed that at a given pressure the boiling point temperature of the mixture decreases with increasing concentration of ammonia. This behaviour can be interpreted to mean that at low temperatures the mixture can hold more ammonia in solution than at high temperatures Increasing the pressure on the mixture at constant temperature has the same effect. Finally, as is the case with single-component liquids, at a given concentration the boiling temperature of the mixture increases with increasing pressure. These basic behaviour characteristics of binary (two-component) mixtures will help in the understanding of the operation of the absorption system schematically shown in fig. 4 (see SOLUTIONS). Liquid ammonia (point 2) at about 85° F. and 160 p.s.i. is expanded through the expansion valve to about 22 p.s.i. and 15° F. and enters the evaporator where it evaporates, absorbing heat from the space to be refrigerated. This ammonia vapour is discharged into the absorber (point 3), where it meets a shower (point 8) of weak liquor (about 30% ammonia), which absorbs the ammonia vapour into solution as it trickles down successive trays, thus forming a solution stronger in ammonia (about 38%). This strong liquor is pumped from the absorber to the top of the analyzer (point 5), being partly heated on its way as it passes through the heat exchanger. In the analyzer this strong liquor trickles down trays against a current of vapour of ammonia and water rising from the boiling solution in the generator below it. The heater (electric, gas or low-pressure condensing steam) boils the ammonia-water liquor, and the hot vapour (about 220° F.) rises up the analyzer counterflow to the cold strong liquor. As a result of this distilla-

tion process the vapour at the top of the analyzer (point 9) reaches a concentration of about 94%. This concentration is further increased as the vapour continues its way through the rectifier, where partial condensation takes place, and the vapour is enriched

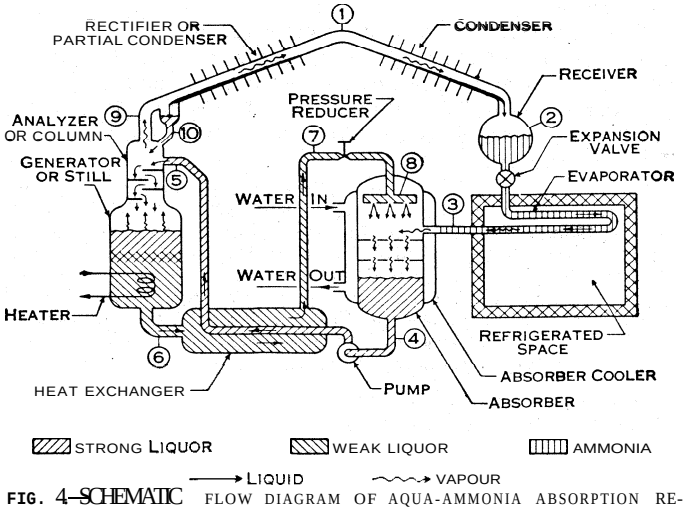

FIG. 4.—SCHEMATIC FLOW DIAGRAM OF AQUA-AMMONIA ABSORPTION REFRIGERATION CYCLE

to about 99.5% ammonia as it enters the condenser at about 125° F. (point 1). The small amount of condensate (about 60% ammonia) formed in the rectifier flows back to the top of the analyzer (point 10). As the liquor boils in the generator the part weak in ammonia gravitates to the bottom of the generator, from where it is taken to the absorber through a pressure reducer (point 7). On its way to the absorber this weak liquor is partly cooled in the heat exchanger as it heats up the strong liquor. The C.O.P. of absorption systems is much lower than that of mechanical refrigeration systems (about 0.5); however, this disadvantage is offset by the fact that they can be made to operate on inexpensive, low-grade energy. Also, the fact that they have no major moving parts makes for quiet and vibration-free operation, a feature desirable in some applications.

Electrolux Absorption Refrigeration System.—An ingenious modification of the absorption cycle shown in fig. 4 is the Electrolux absorption system in which the refrigerant is taken around the refrigeration cycle without employing any machinery with moving parts. This system was invented by two Swedish engineers, Carl Munters and Baltzar von Platen, while they were still undergraduates at the Royal Institute of Technology in Stockholm. The Electrolux system is in all respects identical to the ammonia-water absorption system with the exception that the strong-liquor pump, the expansion valve and the pressure-reducer valve are all eliminated. In the Electrolux system the ammonia is transported from the absorber to the generator by going into solution in water and the aqua ammonia being circulated by gravity and thermal siphon effect. The functions of the expansion and pressure-reducer valves are performed by an inert atmosphere of hydrogen gas (insoluble in water or ammonia) which circulates between the evaporator and the absorber, transporting the ammonia vapour with it. Heat is supplied to the generator. forcing slugs of strong aqua-ammonia solution and its vapour into the standpipe and lifting the liquid in the same way a coffee percolator operates. As this stream discharges into the top of the generator the liquid and vapour separate and the concentrated ammonia vapour enters the rectifier, where the concentration is increased by partial liquefaction prior to entering the condenser. The small amount of condensate formed in the rectifier returns to the top of the generator. The ammonia vapour is liquefied in the condenser and is discharged as a liquid into a flash chamber at the head of the evaporator. Hydrogen gas released in the absorber also enters the evaporator at this point, and as a result ammonia evaporates into this hydrogen, thus undergoing a drop in temperature. The evaporation of the ammonia is caused by its drop in pressure, say, from 180 p.s.i. in the condenser to a partial pressure of 30 p.s.i. in the evaporator. This is explained by a physical law discovered by John Dalton which states that the total pressure of a mixture of gases is equal to the sum of the pressures that each gas in the same volume and at the same temperature would exert if the other gases were absent. Therefore, when the ammonia which is liquefied at 180 p.s.i. in the condenser enters the evaporator, where the partial pressure of the hydrogen is only 150 p.s.i., it evaporates at a rate to make up the difference between the two pressures; *i.e.*, 30 p.s.i. The mixture of hydrogen gas and ammonia vapour leaves the evaporator and enters the absorber where it meets a spray of weak aqua ammonia. Within the absorber the ammonia vapour is readily absorbed into solution by the weak aqua ammonia as it trickles down successive perforated trays and leaves the absorber at the bottom as strong liquor while the inert hydrogen gas free of ammonia vapour rises up the absorber and leaves at the top to repeat its cycle. An absorber cooling jacket, in which water is circulated, is provided to remove the heat of solution generated by the absorption of ammonia vapour by the weak liquor. The strong liquor leaving the absorber proceeds to the generator, being partially heated on its way in the heat exchanger by the hot weak liquor coming from the generator on its way to the absorber. It is seen that in this system the total pressure in all its parts is the same (except for minor friction losses). While the partial pressure of the refrigerant varies from a minimum in the evaporator to a maximum in the condenser, a compensating variation in the partial pressure of the hydrogen gas enables the maintenance of the same total pressure throughout.

HISTORY OF LIQUEFACTION OF GASES

The exact date of the conception to liquefy gases is not known; however, Antoine L. Lavoisier certainly seems to have expressed this idea concerning the Earth's atmosphere, but it remained to his associates Gaspard Monge and Louis Clouet to first liquefy sulfur dioxide in a glass tube cooled with a mixture of ice and salt. About the same time, Van Marum and Paets van Troostwyk (1790) compressed ammonia to corroborate the validity of Boyle's law and found that when a certain pressure was reached drops of liquid ammonia appeared.

In 1799 Louis Guyton de Morveau also liquefied gaseous ammonia by cooling it to the temperature of a mixture of ice and salt. In 1805 Northmore compressed a number of gases mechanically and seems to have succeeded in liquefying chlorine.

In 1823 Sir Humphry Davy and his assistant Michael Faraday presented papers before the Royal society, describing experiments conducted at the Royal institution on chlorine and sulfureted hydrogen. Davy's paper is of historical importance because it shows that in 1823 he had already installed apparatus for the compression liquefaction of gases.

In 1834 Thilorier developed a method already in vogue for the manufacture of soda water and applied it to the condensation of carbon dioxide in large quantity. In his experiments Thilorier observed that a snowlike solid was formed when the liquid was allowed to escape through an orifice into a well-insulated chamber. His observation that solid carbon dioxide mixed with ether was a much more efficient refrigerant than the solid alone was a valuable contribution to the experimental side of the subject.

The first to apply Thilorier's work to scientific investigations was Faraday, who by using carbon dioxide and ether in the presence of vacuum was able to obtain a temperature of −166° F. Faraday then took up the work of Davy in the determination of the vapour pressure of all the gases which could be liquefied at temperatures above −166° F. and at pressures up to 50 atmospheres.

Faraday was unable to liquefy hydrogen, oxygen, nitrogen, nitric oxide and carbonic oxide, and the failure of others to succeed by using even higher pressures gave rise to the idea that these gases were permanent, the term being still used, with recognized qualifications.

Among the many investigators who attempted, but failed, to liquefy the so-called permanent gases was Thomas Andrews, who

in 1860 repeated in more extended form the nearly forgotten work of Cagniard de la Tour performed as early as 1822. Andrews discovered that for each gas there exists a critical temperature above which it cannot be liquefied. This discovery threw considerable light on the general problem of the liquefaction of gases and explained the reason for his own failures and those of Faraday and other investigators to liquefy the permanent gases.

Andrews' studies gave rise to a number of theoretical investigations and important contributions to the understanding of the liquid-vapour relationship of substances. Among those who contributed in a major way between 1850 and 1916 were: William Thomson (Lord Kelvin), Johannes D. van der Waals, Heike Kamerlingh Onnes, Rudolf Clausius, P. E. Marcelin Berthelot, Witkowski and Conrad Dieterici.

The next experimental work of importance following the work of Andrews is that of Louis Cailletet. He first partially liquefied acetylene and then nitrous oxide by means of compression followed by expansion through a jet, thus obtaining a liquid mist. Following his success, Cailletet proceeded to attack the problem of liquefying the so-called permanent gases. Methane, carbon monoxide and oxygen were in turn compressed to 300 atmospheres, cooled to −20° F. in a bath of sulfur dioxide boiling under reduced pressure and then allowed to expand by releasing the pressure. In each case a dense mist was observed, indicating that liquefaction had taken place although no liquid was actually collected in static condition.

Almost simultaneously with Cailletet, Raoul Pictet was also able to obtain a jet of liquid oxygen, surrounded by a white mist, by allowing compressed and cooled oxygen to expand through an expansion valve.

In 1883 Zygmunt Wroblemski and Olszewski repeated Cailletet's experiments in a much improved manner and attained not only the lowest temperature (−213° F.) until then obtained but were the first to produce liquid oxygen in a static condition. Two years later they were able to reach a temperature of −242° F., and both nitrogen and carbon monoxide were liquefied. Improving his apparatus even further, in 1885 Olszewski reached a temperature of −373° F., the lowest temperature recorded until much later, and liquefied much larger quantities of oxygen, nitrogen, carbon monoxide and small amounts of hydrogen.

It was not until 1886 that James Dewar obtained liquid oxygen under static conditions. At this point it is worth while to note that perhaps Demar's greatest contribution to the field of low-temperature production was his invention of the method of vacuum insulation which constitutes the basis for design of all low-temperature systems. The Dewar flask or bottle (popularly known as the Thermos bottle) is named in his honour.

The work of Olszewski was followed in rapid succession by major achievements in the design of continuously operating gas-liquefaction installations. Carl von Linde in Germany in 1895 and William Hampson in England in 1896 used the Joule-Kelvin cooling effect to liquefy air in large quantities. These first commercially feasible systems were further improved in 1902 by Georges Claude, who, using a suggestion originally made by Lord Rayleigh, succeeded in building a machine to liquefy air by adiabatic expansion of the air in an expansion engine.

The mechanical difficulties encountered in producing liquid air in the expansion engine were removed by a modification of the system which became known as the Claude-Heylandt liquefier. The Claude-Heylandt and Linde cycles, with certain mechanical and thermal improvements, are used in producing nearly all the liquid gases consumed in industry.

Once oxygen, air and hydrogen were liquefied in quantity, it became possible to liquefy helium by precooling it to −432° F. by using liquid hydrogen boiling under vacuum.

Kamerlingh Onnes was the first to liquefy helium in 1908. He immediately proceeded to attempt to solidify helium by further reducing the pressure to 0.013 mm., using a battery of condensation pumps, thus obtaining an estimated temperature of −458.2° F.

Kamerlingh Onnes, however, was not successful in solidifying helium, and the final triumph was to be achieved by his colleague and successor P. H, Keesom. Keesom reversed Kamerlingh Onnes' approach, and by increasing the pressure on the helium he brought the melting point in the range of temperature already obtained. It was on July 26, 1926, that Keesom solidified helium, and thus every known substance had been liquefied and solidified by that date.

Others followed Keesom's original successes with further improvements of techniques in the production of liquid helium and detailed studies of the properties of helium. Notable among the early workers were F. Simon (1927) and P. Kapitza (1934). See LOW-TEMPERATURE PHYSICS. See also Index references under "Refrigeration" in vol. 24.

REFUGEES. Refugees result in the main from wars and political upheavals. Discriminations against particular racial, religious or political groups have historically developed into threats to life and liberty, precipitating the flight of refugees in many instances across national boundaries and without guarantee of asylum. Thereafter they have sought to re-establish their lives as opportunity afforded. Changes in national boundaries, postwar agreements and the actions of aggressor states have also resulted in transfers or exchanges of populations, generally of minority groups, with or without the transfer of possessions.

In the early history of European civilization wars and conquests were often followed or accompanied by considerable movements of population. For a long period this aspect of warfare had disappeared, but with World Wars I and II it recurred. In some cases. these movements, though large, were only temporary. For example, although the Belgian refugees who fled from the German invaders in 1914 were very numerous, they did not attempt to create a new life or to establish new homes outside their native land; their migration was only temporary, like that of the refugees who fled from the invaded provinces of France, Italy and Rumania, and to a smaller extent from all the territories occupied by enemy troops during World War I.

But in other cases, great masses of war refugees had little prospect of ever returning to their homes or of recreating their previous life there. This was the situation, for example. of a considerable proportion of the inhabitants of the Balkan peninsula.

MOVEMENTS IN VARIOUS COUNTRIES, WORLD WAR I

Excluding such temporary movements as those of the Belgians, the emigrations of war refugees of different nationalities were roughly as follows:

Russians.—Between 1917 and 1920 nearly 1,500,000 political refugees from Russia were thrown upon the charity of Europe. Some of these refugees were prisoners taken by the Germans and Austrians during the war, who refused to return to Russia. A great number were members of the defeated armies of Roltchak, Wrangel, Denikin and others. Many of the refugees mere women and children who fled from the bolshevist revolution. In the earlier days of their exile they were dispersed as follows: Germany 300,000, Poland 400,000, France 400.000, Constantinople 100,000, Yugoslavia 50,000, Bulgaria 30,000, Czechoslovakia 26,000, Rumania and Greece 50,000, Baltic states 100,000. In addition a large number, at least 100,000, fled eastward into China.

Greeks.—As the result of warlike operations there fled into Greece between 1915 and 1922 1,250,000 Greek refugees from Asia Minor and eastern Thrace and 50,000 from Bulgaria. In addition there came under treaties for the exchange of population from Bulgaria a further 50,000; from Asia Minor approximately 100 000.

Armenians.—From the year 1915 onward there were expelled from their dwellings in Asia Minor some hundreds of thousands of Armenians. Great numbers of them perished in their wanderings in the mountains; some thousands succeeded in mak-

ing journeys on foot as far as Mesopotamia; others sought protection in the Russian empire. In 1921 the independent Armenian republic of Erivan, with an Armenian population of 800,000, adopted the soviet régime and became part of the Union of Soviet Socialist Republics. To its original population, 300,000 to 400,000 additional refugees from Turkish Armenia were shortly added, and in spite of-their great suffering, they were absorbed with remarkable rapidity into the economic system of the country. It was further estimated that more than 300,000 other Armenians were scattered more or less in destitution over Russia and the near east, particularly Bulgaria and Greece. In 1921 100,000 fled to Syria, many of whom became Syrian subjects in the territory then under French mandate; more than 60,000 fled in the following year to Greece, 35,000 to Bulgaria and 20,000 to 30,000 more fled to the republic of Erivan.

Bulgars.—From 1918 onward a large number of minorities of Bulgarian or quasi-Bulgarian race and language fled from their homes in the Dobruja, in Macedonia and in eastern and western Thrace. It was calculated by the Bulgarian government that their total number amounted to almost 500,000. In addition, about 75,000 Bulgars voluntarily emigrated to Bulgaria from Greece under the terms of the Greco-Bulgarian Exchange of Populations treaty.

Turks.—Approximately 50,000 Turks fled from eastern Thrace and Smyrna when these territories were occupied by Greek forces in 1919, but returned to their homes in 1922. In addition approximately 350,000 to 400.000 Turks were moved from Greece (most of them from Macedonia, Crete and western Thrace) to Asia Minor under the terms of the Exchange of Populations treaty made at Lausanne in 1923.

Effects.—Broadly speaking, the general features of these movements of population during and following World War I may be summarized as follows:

The great emigration of Russian political refugees was, in the first instance, regarded as an almost unmixed evil both for Europe and for the refugees themselves. Their great suffering was not, in the early stages, compensated by any considerable political or economic gain. This is not equally true, however, of the movement of population in the Balkans and in the near east. These movements at least accomplished a great deal toward effective unmixing of the populations in these areas. The mixture of populations had led to so much political trouble in modern times that this unmixing process must be regarded as a very considerable advantage.

Further, in certain countries the influx of refugees, while at first it appeared to be a disaster, in the long run proved to be a source of strength. This was particularly true of Greece, where, thanks to arrangements which will be mentioned shortly, the refugees were absorbed very quickly into the economic system of the country, where they immensely increased the agricultural production and imported industries formerly unknown. There is no doubt that they thus improved the political position of Greece by giving it a homogeneous and vigorous new population and by increasing the economic wealth of the ration as a whole.

In Bulgaria, however, the process was much slower, as the refugees showed less inclination to accept their exile as definitive and to settle down in new homes, than did those who went from Asia Minor to Greece.

Another result of general importance which followed the movement of population caused by World War I was that Asia Minor was left almost exclusively to the Turks. Hitherto inhabited by a very mixed population, including elements which continued the traditions of the ancient civilization of Byzantium, there were now few of these elements left. Furthermore it should be noted that the Russian emigration, which, as already stated, was regarded as an unmixed evil for the refugees and for the countries offering them hospitality began under the guidance of the League of Nations and the International Labour office, in certain countries, especially France, to constitute an important reconstructive economic factor.

Treaties **of** Exchange.—Under these treaties, the most important of which were the Greco-Turkish and the Greco-Bulgarian, impartial committees consisting of one representative from each government and two or three impartial experts appointed by the League of Nations supervised or actually carried out the transportation of the persons moved from one country to the other, valued their property, kept an exact record of it and established their claim for this value against the government of the country to which they went. These treaties of exchange worked with varying success.

So far as the Greco-Turkish treaty was concerned, its principal and most necessary effect was to make room in Greece, by the removal of 350,000 Turks, for a great part of the incoming flood of refugees, who found in the evacuated Turkish properties fields and houses ready for their use. Without this treaty of exchange, and without a refugee settlement loan floated under the auspices of the League, the absorption of the Greek refugees into productive employment in their motherland could never have been done.

On the other hand, the fate of the Turks transported under the treaty from Greece into Turkey and in the absence of such a loan, appears to have been less happy. Official information was not disclosed, but it is obvious that the arrival of 350,000 refugees in a country whose total population did not exceed 5,000,000, necessarily imposed a heavy burden on its resources already straitened by many years of war.

Of the Greco-Bulgarian treaty of exchange, it is enough to say that while the working of its machinery was slow, it laid the foundation for an unmixing of the population in Greek Macedonia and in parts of Bulgaria.

Work **of the** League **of** Nations.—The other personal and economic problems which were raised by the refugee movements above described were dealt with partly by individual governments and partly by the League of Nations. To take the Russians first, many governments throughout Europe accorded them particular privileges and gave them much state help, estimated at £2,000,000 per annum—in particular Yugoslavia, Czechoslovakia and Bulgaria deserve mention. The League of Nations and the International Labour office also played a considerable part through the action of the delegations established in Constantinople and in the Baltic states, Rumania, China, Bulgaria, Greece, Serbia, Germany, Poland, France and other countries, in breaking up the most disastrous congestions of refugees in places where no employment could be found, for example, in Constantinople and Greece; in placing some hundreds of thousands in employment in no fewer than 50 different countries; in securing for the refugees in many countries legal protection, freedom of movement in search of employment and a new form of so-called "League of Nations passport" which secured the recognition of over 50 governments, under which they were enabled to travel from one country to another; and even in securing for a small number who desired it, repatriation to their native land. Cnder the auspices and with the help of these League offices, large movements of Russian refugees were carried out to France, where some thousands were settled as tenant farmers and in industry, to the United States, to Canada, to South America and to other countries where employment could be found.

For the Greek refugees the League did still more. Through its machinery a loan of £12,000,000 for their settlement in agricultural and other employment was obtained, and under the international control of a League commission this settlement was carried out with remarkable success. For the Armenians, who did not enjoy the protection of the government of the Turkish republic, the same passport privileges and legal protection were obtained through the machinery of the League as had previously been obtained for the Russians. (F. NA.; X.)

CONDITIONS BETWEEN WARS

The death of Fridtjof Nansen in May 1930 was a distinct loss to the refugees whose problems had absorbed his attention during the last ten years of his life. After a year of study and uncertainty the League of Nations established in 1931 the Nansen International Office for Refugees to carry on the work which Dr. Nansen had initiated.

The League, while accepting responsibility for the legal pro-

tection of refugees, had always considered its interest in refugee problems to be of a temporary nature. Consequently the new Nansen office was established as an autonomous body under the authority of the League of Nations with mandates to conclude its affairs by 1938 and to restrict its humanitarian activities to the co-ordination of the efforts of private organizations engaged in administering relief to refugees.

In order that the legal protection of refugees might be assured after the closing of the Nansen office, the League of Nations provided, through the medium of the convention of Oct. 28, 1933, for the issuance of Nansen identity certificates by the governments signing the convention and for rights of residence and employment and other benefits for Russians, Armenians and assimilated refugees then under the protection of the Nansen office. In 1938, after the Nansen office had concluded its activities, the League constituted a new high commissioner to deal with refugees hitherto coming under the Nansen office and the office of the high commissioner for refugees coming. from Germany.

Saar.—After the plebiscite in the Saar in 1935 approximately 7,000 former residents of the Saar left that territory, most of them to settle in France. This new group of refugees was added by League action to those already under the protection of the Nansen office and a recommendation was made to the governments that Nansen identity certificates be issued to them.

China.— The war in China beginning in 1937 precipitated one of the largest internal migrations in modern history. It was estimated that approximately 30,000,000 Chinese fled before the Japanese armies in two substantial movements from the coast areas to the agricultural hinterland— one from central China and the southeast to the southwest and the other from the northeast to the north est. Apart from the problem of internal displacement in China the Chinese government was later concerned, at the end of the war, with accomplishing the return of 135,000 overseas Chinese driven back to China by the war to their former homes in countries of southeast Asia. These overseas Chinese had played an important role in the economy of China and the resumption of their trading activities was a matter of importance to China's economic recovery.

Germany.—When the nazi party assumed control of the German government in 1933, thousands of new refugees were dispersed over central and western Europe in the beginning of a movement which later gained momentum during World War II. Those in Germany who opposed the nazi political philosophy— non-Aryans according to the Nürenberg laws, scientists, intellectuals, authors, artists, the members of other liberal professions and labour leaders— were first removed from government posts and later from private positions in the universities, publishing houses and business, were arrested and confined in concentration camps, deprived of their property and citizenship and finally driven from Germany, to find new places of livelihood as best they could in other countries.

Neighbouring countries— Austria. Hungary, Poland, Czechoslovakia. Switzerland, Belgium, the Netherlands and France—accepted the refugees, often in flight over their borders at night, in the expectation of extending hospitality to them for a temporary period until they could emigrate to places of permanent residence overseas. Approximately half of the Jewish refugees who left Germany in the early days of the persecution migrated to Palestine.

The German *Anschluss* with Austria in March 1938 added new thousands to the stream of central European refugees, who were already taxing the capacities of the countries of temporary refuge of western Europe. In an effort to substitute planned migration for the chaotic dispersion of refugees, President Franklin D. Roosevelt summoned 32 governments to the Evian conference of July 1938.

Offers to receive refugees for permanent settlement were not forthcoming at Evian. however, with the exception of the Dominican Republic, which 'offered to accept 100,000 for settlement in agriculture.

The Intergovernmental Committee on Refugees, composed of the governments which had met at Evian in July was organized in London in Aug. 1938. It was believed at that time that the committee, lacking refugee-producing countries in its membership and free, in comparison with the high commissioners of the League of Nations, to negotiate on behalf of refugees who had not yet left their countries of origin but were under pressure to do so, would soon be able to resettle the refugees from Germany and Austria and an additional 185,000 from Czechoslovakia on a pro rata basis in receiving countries. This expectation was not realized.

Spain.— On the collapse of the loyalist army in Spain in Feb. 1939 some 340,000 refugees burst over the border into France. While at first there was indecision in France with respect to admitting the refugees, the final decision was to intern them in refugee camps at Argelès-sur-Mer and Cyprien. Since many of the refugees were fleeing primarily from military action, repatriation to Spain started immediately after the end of the war. However, some 40.000 were political refugees who could not return to Spain with safety and they eventually were placed in labour camps and absorbed in French industry. Others migrated to North Africa, Mexico, the Dominican Republic and Latin and South American countries. (J. G. McD.; X.)

REFUGEES IN WORLD WAR II

Poland.— The German invasion of Poland in Sept. 1939 precipitated an eastward movement of refugees far larger in volume and more rapid and violent in action than the westward movement which had been in process since 1933. Poland's population of 3,000,000 Jews constituted the majority of those affected by the advance of the German armies eastward, but as the war was fought more bitterly, distinctions between the treatment of Jews and Poles at the hands of the Germans became less marked. Fewer than 100,000 refugees from Poland escaped into the Baltic countries and southward into Rumania, Hungary and Bulgaria. More than 1,175,000 Jews became subject to German control in the area of former Poland that was incorporated into the German reich and in Government-General Poland.

Unknown numbers of Polish and Jewish refugees who resided in or fled into the area of former Poland which was occupied by the forces of soviet Russia were moved eastward to Siberia and southeastern Asiatic Russia.

The conquest of Poland also created numerous cross currents of population movements. The policy of the German reich was to repatriate German minorities in eastern and southwestern Europe to the *Altreich.* A treaty concluded with Italy in the fall of 1939 providing for the return of some 270,000 Germans from the south Tirol was the first effort to implement this policy. Later similar treaties were signed with Latvia and Estonia for the return of approximately 75,000 Baltic Germans.

Some 300,000 Germans were also repatriated from Bukovina, Bessarabia and Rumania.

As the members of these German minorities in other countries returned to Germany they crossed the paths of the 300,000 to 400.000 Jewish refugees from Germany, Austria and Czechoslovakia who were constantly being deported eastward to the ghettos established in Warsaw, Lublin and Lwów. These constituted the remainder of the refugees who had been unable to escape from central Europe before the outbreak of the war. The last to escape had gone by boat to Shanghai or through Poland and across Siberia to Harbin and Vladivostok and thence on to the Philippines or to the western hemisphere through Kobe and Yokohama.

As western Poland was incorporated into the reich both Poles and Jews were driven eastward into Government-General Poland. It was estimated by Polish sources that more than 1,200,000 Poles had been moved into Government-General Poland by Germany by the end of 1939. Germans in Government-General Poland were returned to Germany. Germans were also moved from southern and eastern Poland occupied by soviet Russia to Germany.

From this area Poles and Jews were evacuated far eastward into Russia to be replaced by a Russian infiltration westward.

Finland.— Finns from the Karelian isthmus, ceded to Russia by the peace treaty between Russia and Finland after the winter

war of 1939–40, were resettled in the diminished area of that hard-pressed country. More than 400,000 people had to be placed on the land or in industry at a time when the resources of the Finnish government were exhausted by the war.

Some assistance was provided by private funds raised in the United States.

Norway — Norway faced a similar problem of internal resettlement after the German invasion. Approximately 400.000 people were moved from the coast defense areas into the interior of the country, including many who had resisted the invasion in the short-lived defense of their country.

Low Countries and France. — The advance of the German armies into the Low Countries of western Europe in the spring of 1940 uprooted civilian populations on a scale comparable to that precipitated but a few months earlier by the invasion of Poland. This movement of about 3,000,000 Dutch, Belgian and French people in flight to southern France in advance of the German armies was joined by some 140,000 refugees from central Europe who had found temporary respite in the Netherlands, Belgium and France.

The great majority who had fled to safety from military actions returned to their homes after the signing of the armistice between France and Germany, which illustrated the generally temporary character of such war refugee movements.

England after the flight of its defeated army from Dunkerque found itself harbouring some 70,000 central European refugees in addition to the members of the military forces of its allies who had escaped with its own forces. The threat of an impending German invasion from the continent and the fear of "fifth columnists" among the refugees, understandably resulted in the internment of all. Later, when the defenses against invasion were strengthened, the great majority of the refugees were released.

Balkans. — In the late summer and fall of 1940, Germany in its efforts to bind allies in the Balkan countries more closely to the axis cause did not hesitate to utilize minority groups as pawns in its strategy. In Vienna in Aug. 1940, Hungary was awarded part of the coveted area of Transylvania and approximately 2,500,000 people. The fact that many Rumanians were included in the transfer demonstrated again the difficulties involved in legislating boundaries in order to achieve racial homogeneity in the confused pattern of racial strains in southeastern Europe.

South Dobruja was allotted to Bulgaria, which agreed to repatriate 65,000 Bulgarians from north Dobruja. The transfer to Rumania of Rumanians in south Dobruja was also planned. Slovakia undertook to repatriate Slovaks from the protectorate of Bohemia and Moravia.

Luxembourg and Lorraine. — In the west, Luxembourg and Lorraine were incorporated as provinces into the German reich. Again non-Aryan refugees, members of the government of Luxembourg and political refugees were forced to flee. Some 20,000 of the French population of Lorraine were expelled without warning into France and only vigorous protest by the Vichy government prevented the expulsion of larger numbers from their homes. In Nov. 1940, 10,000 Jewish refugees were driven from Baden and the Palatinate into southern France.

U.S.S.R.—The advance of the German armies into soviet Russia in the summer and fall of 1941 drove before it the greatest migration of a decade in which the history of uprooted populations had exceeded in stark tragedy all previous records of modern history. No authentic figures were available, but conservative estimates placed the numbers driven eastward as between 10,000,000 and 20,000,000. More than 2,000,000 inhabitants of the invaded soviet areas survived the hardships and cruelties of the labour camps in which they were confined during the war in eastern Europe. Similar numbers were estimated to have succumbed under the conditions of work which could only result in exhaustion and death.

German Forced Labour. — Apart from the dispersal and flight of political refugees, the transfers of German minorities in pursuit of concepts of racial purism, the transfer of minority groups as political pawns and the flight of masses of civilians from military action, the most outstanding movement of people during World War II was the draft into Germany of more than 8,500,000 workers from countries occupied by the German armies. One-fifth of these slave labourers were women. In addition, 4,000,000 workers were employed away from their homes and often outside their own countries in industrial or military labour in the occupied countries of Europe. Included in this group were many former Polish and French prisoners of war whose status under the Geneva prisoner of war convention was violated by one device or another.

After the occupation of western Europe efforts were made to enlist such labour voluntarily by inducements of high wages and promises of food rations. French prisoners of war were in the first instance returned from Germany to France and released from custody only to be confronted by various pressures to return to Germany immediately as labourers. As the demands of the German war machine increased, legal and proper methods of recruiting were abandoned for more forceful methods.

The conditions of work of the labourers from the east, chiefly Russians and Poles, were deplorable in the early years of the war. On the other hand, efforts were made by the Germans to provide better conditions of work and wages for workers from the western European countries. Finally as the sources of forced labour were exhausted, food, wages and working conditions were equalized for all in desperate efforts to secure maximum production. This policy continued until toward the end of World War II, when deterioration in German organization and control became evident and conditions in the labour camps degenerated to those prevailing in the concentration camps, where the policy appeared to be to drive the inmates to exhaustion by long hours of heavy work with inadequate provisions for food and shelter.

Included among the 8,500,000 workers drawn into Germany were approximately 2,000,000 Russians, 2,000,000 French, 1,500,000 Poles, 500,000 Belgians, 500,000 Dutch, 600,000 Italians and smaller numbers of Czechs, Balts, Hungarians, Rumanians, Danes and Norwegians.

As the German armies disintegrated in the spring and early summer of 1945 these millions of slave labourers were released by the Allied armies as were also the inmates of the concentration camps. In the early days of liberation they provided a problem for the Allied armies intent upon the final destruction of all German resistance. Food and means of care and transport were lacking. The liberated workers trekked homeward as best they could, living on the land; many were in such advanced stages of malnutrition that even hospital care which was soon organized could not save their lives.

POSTWAR PROBLEMS OF DISPLACED PERSONS

Gradually as the occupying armies stabilized conditions within Germany and Austria, orderly means of repatriation were developed. The displaced persons were removed to their home countries by train, truck and air.

Their eagerness to reach home was matched by the necessity of the Allied armies to repatriate them or to organize supply lines to feed them where they were. It proved more practical to repatriate them quickly than to move food and clothing to them in central Europe. Within six months after the cessation of hostilities in the summer of 1945 between 6,500,000 and 7,000,000 United Nations nationals had been returned to their home countries in Europe.

Repatriation slowed down substantially in the winter months of 1945 and 1946 owing to the lack of heated transportation equipment and inadequate reception facilities in the receiving countries. Efforts to re-establish the flow of repatriation in the spring and summer months of 1946 proved unavailing. By that time it appeared that many among the former workers and concentration camp victims were unwilling to return to their countries of origin because of the political changes which had taken place in those countries during the war. More than 1,000,000 displaced persons, including approximately 600,000 Poles, 75,000 to 100,000 Yugoslavs, 250,000 former Baltic nationals and 50,000 Ukrainians, were unwilling to return. They were maintained in displaced persons

assembly centres in Germany, Austria and Italy provided by the occupying military authorities and administered by the personnel of the United Nations Relief and Rehabilitation administration (UNRRA) which in 1946 undertook the responsibility for further repatriations.

The Jewish refugees included among the foregoing total constituted a special group. They had suffered particularly at the hands of the nazis and were reluctant to return to home areas where so many of their relatives and coreligionists had perished during the war. At the end of the war it was estimated that no more than 1,250,000 Jews remained out of a prewar population of approximately 5,500,000 in Europe excluding soviet Russia.

The numbers of Jewish refugees in central Europe was slightly under 100,000 at the end of hostilities in 1945. However, these numbers were swollen by postwar infiltrations from Poland, Hungary and Rumania to 200,000 by the end of 1946. More than 90% expressed the desire for emigration to Palestine.

The displacements of German and Austrian nationals in Germany and Austria at the end of the war were substantial. These had resulted from the dispersion of industry during the war, evacuations from bombed areas and the flights of civilians from final military action. One of these general movements was westward from the Baltic countries, Poland and East Prussia to Denmark and southwestward toward Austria and Switzerland. Some 200,000 Germans in this movement remained interned in Denmark because of the overcrowding and lack of housing facilities in Germany until late 1948.

Following the cessation of hostilities, political pressures and hatreds aroused by the war resulted in the expulsion from Poland, Czechoslovakia and Hungary under the Potsdam agreement (1945) of more than 8,000,000 members of the German prewar minorities in those countries. This substantial movement severely strained the limited housing facilities in Germany resulting from the destruction in the final stages of the war. There were similar expulsions of German minorities totalling 200.000 persons into Austria from Yugoslavia and Rumania which were not covered by the Potsdam agreement.

The presence in Germany, Austria and Italy of more than 1,500,000 United Nations refugees and displaced persons who were unwilling to accept repatriation to their home countries was disturbing to the peace and order of central Europe and a cause of political friction between friendly allied governments. The eastern European governments took the position that their nationals should return to their countries.

The position of the western democracies was that the individual should have complete freedom of choice with respect to repatriation. This principle was formally adopted by the general assembly of the Cnited Nations in its resolution of Feb. 12, 1946 on the subject.

International Refugee Organization.—Between July 1947 and Dec. 1951 the International Refugee organization (IRO), a temporary specialized agency of the UN, which took over the responsibilities in this field of UNRRA and other wartime agencies, assisted over 1,500,000 refugees and displaced persons in camps in Europe for varying periods of time by providing medical care, hospitalization, vocational training, food and clothing. Eighteen government members provided approximately $430,000,000 for these purposes and for the resettlement in overseas countries of 1,040.000 persons; 73,000 were repatriated to their home countries.

Upon the termination of IRO in 1951, the office of the high commissioner for refugees was established by the United Nations to provide legal protection for refugees and to assist governments and voluntary agencies to find permanent solutions for refugee problems. The convention relating to the status of refugees promulgated by the United Nations in 1951 had been ratified by 21 governments by March 1957.

In 1951 the Intergovernmental Committee for European Migration consisting of 27 governments was established to facilitate the movement out of the overpopulated countries of Europe of migrants and refugees who would not otherwise be moved. Between Feb. 1952 and June 1957 over 600,000 persons, including 280,000 refugees, were assisted to resettle in overseas countries.

Germany. — The steady flow of refugees from eastern Germany to western Germany, which began prior to 1952, reached a peak of 340,000 in 1953 and continued at an annual rate of over 200,000 to account for more than 1,500,000 in total by Dec. 1956.

Palestine. — United Nations efforts to resolve the problem of 875,000 Arab refugees resulting from the conflict in Palestine in 1948 persisted between 1949 and 1957. The refugees were housed and fed in camps in Lebanon, Syria, Iraq, Jordan and the Gaza strip. The repatriation of the refugees to Palestine or their permanent resettlement on the land in Arab countries was delayed by the continuing political conflicts in the area.

China.—As a result of the communization of mainland China in 1950 the situation of some 20,000 European refugees remaining in China at that time seriously worsened. Over 8,000 were granted exit permits from China between 1950 and 1957. During the same period approximately 1,000,000 Chinese refugees entered Hong Kong and many other thousands succeeded in reaching Formosa. Severe conditions of overcrowding developed in both areas of asylum.

India, Pakistan.—One of the largest exchanges of populations in recent history resulted from the division of British India into the new nations of India and Pakistan in 1947. Soon thereafter 5,000,000 Hindus and Sikhs moved out of West Pakistan into India and a similar number of Moslems moved out of India into West Pakistan. Additionally, after 1950, 3,000,000 Hindus moved out of East Pakistan into India and approximately 1,500,000 Moslems from India moved into East Pakistan. These movements resulted from political motivations within the populations rather than from agreements between the two governments.

Japan.—Japanese infiltration into other countries of the far east prior to and during World War II was substantial. More than 2,000,000 Japanese were in China at the end of the war, larger numbers in Manchuria, 800,000 in Korea, 500,000 in southeast Asia and 200,000 in Australia and New Guinea. The total of displacement in Japan proper was estimated at 12,000,000 including 2,000,000 Korean labourers and their families. The repatriation of these large numbers of Japanese and Koreans began before the war was over and continued under the direction of the Allied military forces. These infiltrations and later repatriations had their respective effects on the economies of the areas involved and left serious problems of reconstruction which complicated the task of postwar economic and political reorganization.

Apart from the death and destruction resulting from World Wars I and II and from the political events which preceded and followed them, more than 50,000,000 people were uprooted from the areas in which they had resided for generations. Governments were challenged as never before to find places of settlement for the displaced.

Korea and Vietnam. — The war in Korea in 1950 uprooted more than 5,500,000 civilians most of whom took refuge in southern Korea. Over 900,000 refugees from north Vietnam were resettled in south Vietnam after the Asian Conference in Geneva in 1954.

Hungarian Refugees.—As a result of the Hungarian revolution in Oct. 1956, approximately 174,000 Hungarian refugees had fled into Austria by June 30, 1957 and 19,000 into Yugoslavia. Over 140,000 of the Hungarian refugees in Austria and 7,000 of those in Yugoslavia had been resettled in other countries by that date. *See* MIGRATION. *See* also Index references under "Refugees" in vol. 24.

REFUSE DISPOSAL is the term employed in the United States and Canada for the collection and disposal of the solid wastes of a community, including garbage, rubbish and ashes. In Great Britain this type of refuse is called dry or town refuse, as differentiated from wet refuse (fecal matter) and mixed refuse (a mixture of town refuse and fecal matter).

Garbage is the waste matter resulting from the preparation and consumption of food; rubbish is all nonputrescible solid wastes, except ashes, including both combustible and noncombustible material such as paper, rags, wood, plastic and metals.

Sanitary refuse disposal is essential to community health. Refuse has been shown to be important as a breeding ground or food source for rats, flies and other potential carriers of diseases of man. It has been demonstrated to-be of importance in the transmission of trichinosis of man and vesicular exanthema, foot-and-mouth disease, cholera and other diseases of swine. Rubbish has been found to be a significant factor in the incidence of building fires in the United States. Particulate matter and smoke from the burning of refuse can be a significant source of atmospheric pollution. while improper disposal has sometimes resulted in surface- and ground-water pollution. Potential nuisance factors, such as smoke and odours resulting from open dumps, are well recognized.

Refuse disposal consists of three phases: storage on the premises, collection for transport to the final disposal site and final disposal.

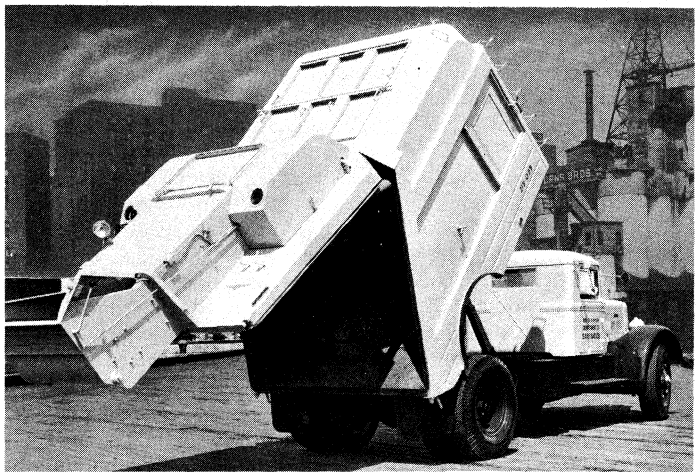
Quantity of Refuse.—A household of four people in an American community may be expected to produce an average of 70 lb. of refuse each week, or about 23 lb. per capita per day. If commercial garbage and rubbish, incinerator ash and solid industrial wastes are included, over 4 lb. of refuse per capita per day may be expected from a community-wide collection system. In England about 672 lb. per capita per annum is considered average. In U.S. and Canadian communities where the refuse has a negligible ash content, garbage has been found to comprise as little as 20%–25% of the refuse by weight, with the remainder rubbish. Garbage has a moisture content of 60%–70%. The moisture content of rubbish usually approximates 25%–35% of its over-all weight.

Premises Storage.—Most cities require that household garbage be well wrapped and stored in durable, easily cleaned containers with tight-fitting covers. Glass or metal food containers should be stored in similar receptacles. Other rubbish may be tied in easily handled bundles or so placed in boxes that it will not cause littering or fire hazard. Ashes should be stored in metal containers. In most U.S. cities household refuse containers ordinarily are not permitted to exceed 26–30 gal. in capacity.

Collection of Refuse.—Methods of collection vary. Garbage may be collected separately from the other refuse; in mixed collection, garbage and rubbish—or sometimes garbage, rubbish and ashes—are collected at one time and from a common receptacle. The trend is toward mixed collection. Separate collection is utilized when garbage is used for feeding to swine or is ground and disposed of in the sewerage system, or when cheaper methods are at hand to dispose of the less objectionable components of the refuse.

Where garbage is collected separately, it is the usual practice to collect it twice a week in the summer and once or twice a week in the winter. A few cities collect more frequently. Most make daily collections in the business sections. Most of the large cities and about half the smaller ones in the U.S. employ municipal collection, contract or private collection being used otherwise.

Collection Equipment.—There is nothing that could be called a standard type of refuse collection vehicle. In America municipal garbage-hauling vehicles are usually custom-designed. Enclosed mixed-refuse collection vehicles are equipped with mechanically or hydraulically operated packing devices to compress



BY COURTESY OF THE CITY OF NEW YORK, DEPARTMENT OF SANITATION

FIG. 1.—ENCLOSED REFUSE COLLECTION VEHICLE. WITH BODY IN DUMPING POSITION. SUCH TRUCKS ARE EQUIPPED WITH MECHANICAL OR HYDRAULIC COMPACTING DEVICES TO COMPRESS REFUSE

the voluminous refuse and thereby increase the amount the vehicle can accommodate. Many industries, and other concentrated production areas use large portable containers which when full are transported to the disposal site by a vehicle equipped with a special hoist.

Disposal.—There are five methods of refuse disposal: reclamation for re-use (although this disposes only of certain components in the refuse); disposal into the sewerage system; incineration; dumping in water; and disposal on land.

Reclamation.—In its simplest form reclamation is the removal of such items as paper or heavy metals for salvage. In Great Britain this is practised in many cities in separation plants constructed for the purpose. In America reclamation is usually carried on as private enterprise, either by the individual householder or by contract arrangement at the disposal site. Metals from incinerator ash and the ash itself are often used for salvage or reclamation purposes.

Feeding waste food to pigs has long been a popular method of garbage disposal because it is relatively cheap and often can be carried on by private enterprise at a profit, thus relieving the authorities of the responsibility and expense of garbage disposal. In Great Britain and Canada it has been required for many years that garbage fed to swine be cooked to disinfect it and to prevent possible spread of disease. In the United States, vesicular exanthema, a disease of swine similar to foot-and-mouth disease and spread primarily by the practice of feeding raw garbage, became epizootic in the early 1950s. By 1960 all of the states had adopted legislation or regulations requiring the disinfection (usually by cooking) of garbage fed to pigs. Although the use of residential garbage in the U.S. for pig food has declined substantially, use of commercial garbage from hotels and restaurants is widespread.

Composting is the biochemical alteration of refuse from a noxious to an innocuous usable humus. During the first half of the 20th century a number of anaerobic and aerobic processing schemes were offered under various proprietary names. None was successfully employed in the United States on a continuing basis, primarily for economic reasons.

Composting of refuse has been successfully carried on in the Netherlands and the Jersey Islands for many years. The method has also been used with some success in Great Britain, France, New Zealand and India.

Reduction, or the cooking of garbage to remove salvable greases and fats for industrial use and to produce tankage usable as an

animal food base, was a recognized method of reclamation in the United States in the first quarter of the 20th century. The introduction of detergents, which reduced the demand for fats in soap manufacture, together with increased labour costs, made this method uneconomical, and the last municipal garbage reduction plant ceased operation in the early 1950s.

Disposal Into Sewerage System.—If garbage is ground into minute particles it can be discharged into the community sewerage system. Millions of household grinder units were installed in the United States following their introduction in the early 1930s. Little difficulty is encountered in a properly designed sewer system as a result of this practice, and household water consumption will increase only 1% to 2% with the installation of a grinder. Increases in solids handling capacities are needed at the sewage treatment plants in cities where large numbers of grinders have been placed in service, however, and for this reason some communities with already overloaded treatment plants had to forbid their use. A few cities having separate garbage collection systems used central grinding stations at which truckloads of garbage could be handled at one time.

Most newly constructed food-handling establishments in the United States, particularly hospitals and other institutions, have kitchens equipped with food waste grinders. The grinding of garbage is an important sanitation device since it eliminates the need for storage and collection of the most noisome and potentially hazardous portion of community refuse.

Incineration.—The burning of community refuse is one of the safest and most efficient methods of disposal, provided it is properly done. The special equipment and methods essential to this process are described in the article INCINERATOR.

Dumping in Water.—For many years the disposal of refuse in large bodies of water was an accepted practice. The refuse from a number of large cities was taken to sea on barges and dumped. Unfortunately, much of the lighter material found its way back to the beaches with the wind and the tides.

New York city was prohibited from continuing this practice in 1936 as the result of a ruling by the U.S. supreme court. Very few cities in North America or Europe resort to this method of refuse disposal.

Disposal on Land.—The indiscriminate dumping of refuse on land is an age-old practice still widely followed, particularly in small communities. However, the unsightliness of dumping grounds and the unavoidable presence cf flies, rats, smoke and odours led to the development of more efficient and sanitary methods.

The method of controlled tipping, known in the U.S. as sanitary land fill, was introduced in England in 1912; it makes use of the natural fermentation brought about by microorganisms in the putrescible portion of the refuse. Usually the refuse is deposited in shallow layers, compacted, and covered within 24 hours with compacted earth or other chemically inert material to form an effective seal. Mechanical equipment such as a bulldozer mounted on a heavy tractor is used to grade, compact and cover the refuse. The method often is employed to reclaim otherwise useless land and by the early 1960s was used by over 1,400 American communities. See also SEWAGE DISPOSAL.

BIBLE REGAL, A PORTABLE ORGAN WHICH FOLDS UP LIKE A BOOK

REGAL, a small late-medieval portable organ, furnished with beating reeds and having two bellows like a positive organ; also in Germany the name given to the reed stops (beating reeds) of a large organ, and more especially the *vox* humana stop. During the 16th and 17th centuries the regal was a very great favourite, and although, because of the civil wars and the ravages of time, few specimens now remain, the instruments are often mentioned in old wills and inventories.

RÉGENCE STYLE is the designation for the French art of the period from 1715 to 1730; it did not quite coincide with the regency of Philippe d'Orléans, duc d'Orléans (1715–23), between the reigns of Louis XIV and Louis XV. The *régence* style marked the transition from the massive, serious baroque art (*q.v.*) to the more elegant. lighthearted rococo style (*q.v.*). The term should not be confused with the English Regency (1811–20) during the latter part of the reign of George III. (WM. F.)

REGENERATION is the process by which organisms replace structures or organs which have been lost by accident or mutilation. This definition is not quite adequate because it does not cover two phenomena which belong undoubtedly to the category of regeneration phenomena. In some invertebrates, such as the fresh-water polyp Hydra, the planarian flatworm Dugesia and the starfish, a small fragment of the body can restore a complete, whole organism rather than merely an organ. Furthermore, many animals can restore structures lost in the normal course of life rather than by accident. The periodic molting of feathers in birds, the shedding of fur in mammals, of the exoskeleton in arthropods and of the epidermal scales in reptiles are followed by regeneration of the discarded structures. The uppermost cornified skin layers in mammals including man are constantly worn off in small bits and replaced by active, proliferating cell layers in the deeper layers of the skin. The same holds for the continuous replacement of hair, nails and claws. The teeth are replaced only once in mammals, including man, but there is a continuous succession of teeth in lower forms, such as the dogfish and shark. The antlers of deer are shed at regular intervals and then regenerated. The periodic changes in the genital tracts of female mammals during menstruation and oestrus also should be included here. All these instances in which replacements are part of the normal life functions are called physiological or repetitive regeneration, in distinction to restorative or reparative regeneration which follows injury. The present article deals primarily with the latter type.

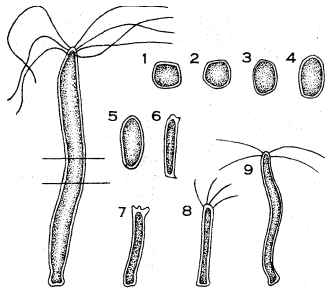
There are wide differences in the regenerative capacity of different animals. The one extreme is represented by the above-mentioned invertebrates, in which a part of the body can restore a whole organism. In higher organisms, as for instance the salamanders among the vertebrates, and many crustaceans and insects, only single organs, such as limbs, can regenerate; mammals cannot restore entire organs, but they can repair damage to tissues, such as bone fractures, skin and muscle injuries and peripheral nerve loss. These phenomena of tissue repair are, of course, included under the general heading regeneration.

General Types.—Regeneration can be accomplished in two ways: (1) by outgrowth of new tissue from the wound surface or (2) by the transformation and reorganization of the remaining parts, without an outgrowth of new material.

Where new tissue is produced, a regeneration bud, or blastema, is formed at the wound surface (see below, Regeneration Process: *Blastema* Formation). It is usually cone-shaped and consists of an embryonic type of cells which gradually form the adult struc-

tures by processes of cell differentiation and growth, much in the fashion of embryonic development. The regeneration of limbs and tails in salamanders is an example of this type of regeneration, which T. H Morgan termed epimorphosis.

The second type of regeneration. the remodeling of old parts, is called morphallaxis (fig. 1). Very small fragments of a freshwater or marine polyp, or of a planarian, undergo a change in shape instead of growing blastemas; they break down old structures, and build in their place new ones of a smaller proportion. All regeneration processes in protozoans are of this type. Occasionally, both types of regeneration take place simultaneously, and there may be no fundamental difference between them. The term regeneration is almost universally adopted as the all-inclusive term, with "epimorphosis" and "morphallaxis" as subheadings. C. M. Child (1941) proposed "reconstitution" as the general term to cover all related phenomena. He used the term regeneration in a narrow sense, synonymously with epimorphosis, as reconstitution by outgrowth, and the term reorganization as reconstitution by internal changes.



FROM E KORSCHELT AFTER T H MORGAN

FIG 1—REGENERATION IN THE FRESH-WATER POLYP HYDRA. THE SHORT PIECE BETWEEN THE TWO LINES (AT LEFT) REGENERATES INTO A NEW POLYP I TO 9 ARE STAGES IN THE REGENERATION PROCESS

The aim of regeneration is to maintain or restore the fitness of an organism after the loss of parts. This aim is best accomplished by a replacement of precisely those structures nhich were lost. However, a number of cases are known in which more than, or less than, the lost part is regenerated, and other cases in which the regenerate is structurally different from the lost part. The term heteromorphosis covers all types of atypical regeneration. The term homeosis is used for those atypical regenerations in nhich the regenerate represents an organ different from the original. For instance. in crabs, an amputated eyestalk, under certain conditions, will be replaced by an antenna. Another type of atypical regeneration has been given special attention; namely, those instances in which the polarity of the regenerate is changed. For example, the posterior cut surface of a piece of planarian, under certain conditions mill regenerate a head instead of a tail. This type of polarity change is called polar heteromorphosis.

Theoretical Considerations.— When a regeneration blastema differentiates into the head of a planarian or into the limb of a salamander, the processes which go on in the blastema are fundamentally of the same nature as the embryonic developmental processes which created these organs originally. Although the regeneration processes are rarely exact replicas of the corresponding developmental processes, they are alike in some fundamental aspects. Both require a building material of plastic, undifferentiated, embryonic-type cells, and a set of specific organizing factors which direct and control the molding and differentiation of such building materials In this sense, regeneration can be defined as the revival, or reactivation. of developmental potencies in organisms which have passed the embryonic stages of development.

If this point of view is adopted, then the close affinity of regeneration processes with asexual reproduction becomes evident. In fact, in some instances it is difficult to draw the line betneen the two. For instance, most protozoans reproduce asexually, by fission. The daughter individuals restore by regeneration those structures which they do not contain at the start of the fission. If a protozoan is cut in tno by a fine instrument, the result is the same—each half regenerates the missing structures. In this instance. fission and regeneration differ primarily in the factors which set the processes in motion. Similarly, some flatworms and annelids (segmented norms) which possess high regenerative powers reproduce regularly by transverse fission or by a budding process at their posterior ends. Their regenerative potencies are placed, so to speak, in the service of reproduction. Budding is a mode of asexual reproduction particularly common among colonial forms. It is practised by coelenterates and tunicates among animals and by plants. A bud is an outgrowth on an adult organism which is an expression of the revival of growth potentialities at a localized area of the body. The parallel to regeneration is obvious. In many marine coelenterates a lateral regeneration bud can be produced easily by making a cut in the body wall. Again, the main difference between regeneration and spontaneous budding lies in the initiating stimuli.

If the ability for regeneration is considered as a residual developmental capacity nhich a number of organisms retain throughout adult life, it is implied that regeneration is the manifestation of a universal property of all organisms; namely, the capacity for gronth and development. This point of view, now generally adopted, did not always prevail. It was seriously contested during the second half of the 19th century. Under the influence of the theory of natural selection, another theory of regeneration mas strongly advocated by August Weismann and others. This theory emphasized the usefulness and adaptive value of regeneration; it stressed the point that regeneration was apparently limited to those organs and structures which are particularly in danger of being injured or mutilated by enemy attacks. It was assumed, therefore, that regeneration is not part of a basic equipment of all organisms, but is acquired secondarily as a special adaptation wherever the ability to regenerate is of crucial survival value in the struggle for existence. It was held that natural selection is instrumental in creating and improving the regenerative capacity. A just objection has been raised against this theory, namely. that in many instances inner organs regenerate which are not liable to injuries, as for instance, the crystalline lens of the amphibian eye, or the liver. For this and other reasons, Weismann's theory in its extreme form is untenable. However, its valid element, the emphasis on natural selection as a mechanism for increasing preexisting limited regenerative capacity, can be readily incorporated in the residual growth theory of regeneration.

Generally speaking, lower organisms have a better regenerative power than do higher organisms, but the regenerative capacity is distributed sporadically among animals and in many instances closely related forms differ nidely in their regenerative capacity. A theory of regeneration has to explain this scattered distribution of regeneration. Natural selection cannot account for it, because there is apparently no close correlation between liability to injury and the regenerative power. The residual growth theory. which assumes that regeneration is a manifestation of a universal property of all organisms, has to account for the fact that this potentiality is lost in a great many forms.

Two prerequisites must be fulfilled if a successful regeneration is to occur: there must be available the necessary building material in the form of unspecialized cells, capable of growth and differentiation; and the necessary organizing factors must be present which direct the development of these cells. Regeneration may be prevented by the loss of either one or of both. The necessary building material may be lost in the normal course of development, during which embryonic cells undergo a differentiation into highly specialized tissues. This differentiation is undoubtedly irreversible in most instances. and the transformation of all cell materials into an irrevocably differentiated form is probably one reason for the lack of regeneration in highly organized animals. Some authors maintain that in some instances a differentiated tissue can dedifferentiate and rejuvenate under certain conditions, and thus become available as a source of regeneration material. Furthermore. in a number of invertebrates and lower chordates. certain embryonic cells remain in an undifferentiated embryonic condition and form a reservoir for regeneration and asexual reproduction (see below). It is obvious that regeneration is impossible in all those organisms which possess neither reserve cells nor tissues capable of de- and redifferentiation. The organizing or "field" factors for regeneration are discussed below. Their loss, in the course of embryonic development, may be an alternative cause for a lack of regenerative power. Finally. an amputation stump may be potentially capable of regenerating but be prevented from doing so either by a de-

ficiency in one of the many subsidiary agents necessary for regenerative growth, such as hormones or nerve-produced agents, or by a block from a rapidly overgrowing skin or wound scar which prevents the outgrowth of the blastema cells. An appropriate treatment of the stump can call forth a regeneration where it would not occur under ordinary conditions.

REGENERATION IN DIFFERENT ANIMAL GROUPS

Invertebrates

Protozoa. — Most Protozoa (acellular or one-celled animals) reproduce asexually by longitudinal or transverse fission, or by other modes of division. Fission requires a reorganization and new formation of structures in the daughter individuals, and this process can be considered as a physiological regeneration. The power to rebuild structures is therefore inherent in all protozoans, and it is not surprising to find that most Protozoa can regenerate parts which were lost by accident or removed in an experiment. In all instances, the presence of nuclear material is a necessary prerequisite for successful regeneration. In ciliates which possess a macro- and a micronucleus, the former is essential; the latter is not. In forms such as *Stentor,* in which the macro-nucleus is represented by a beadlike chain, small segments of the chain are sufficient to enable a fragment to regenerate. In Amoeba, which has no highly specialized organelles, a non-nucleate fragment can grow and survive up to 30 days, but it cannot divide. The most highly differentiated Protozoa, the ciliates, have been the subject of extensive studies on regeneration; Paramecium and *Stentor* are the favourite materials. Their regenerative power is excellent. Fragments as small as $\frac{1}{64}$ of an individual can form a complete new organism. The new organelles are formed either by remodeling of the remnants of the old ones or by breakdown of the latter and rebuilding of entirely new structures. In parasitic Protozoa the regeneration capacity seems to be poor or entirely missing.

Sponges. — The regeneration of amputated parts in Porifera, or sponges, does not seem to be very extensive. However, a series of interesting experiments revealed a remarkable capacity of the sponge cells to reorganize themselves into a whole organism, following a complete breakup of their organization. Sponges were strained through bolting silk and thus completely dissociated. Following this treatment, small cell groups reunited into larger aggregates which reorganized themselves and eventually formed a typical sponge.

Coelenterates. — These occur in the forms of polyps and medusae (jellyfish). The well-known fresh-water form Hydra takes its name from the mythological nine-headed monster which was believed to regenerate two heads in the place of each amputated head. The regenerative power of Hydra is at least as startling as that of its namesake. It was in this form that the Swiss naturalist Abraham Trembley made the first planned regeneration experiments (1744), which aroused a tremendous interest and were soon followed by those of R. A. F. de Réaumur, Lazzaro Spallanzani and others. Small fragments of the body can regenerate a whole individual (see fig. 1). One tentacle with a small portion of the mouth region is capable of forming a new individual. The regenerative power of other hydroids differs in different species. *Tubularia* and other marine forms have been widely used for experiments on the physiology of regeneration.

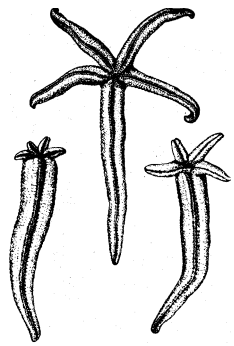
FIG 2.— REGENERATIONIN THE PLANARIAN FLATWORM DUGESIA. THE THREE ROWS SHOW REGENERATION OF (A) ANTERIOR SECTION, (B) MIDSECTION AND (C) POSTERIOR SECTION OF THE ANIMAL AT THE LEFT

The regenerative capacity of the medusae (jellyfish) is much restricted. The Anthozoa (sea anemones and corals) have a considerable regenerative capacity.

Flatworms. — This phylum, Platyhelminthes, includes the planarians, which have an exceedingly high regenerative capacity, and which have therefore been used more than any other form for regeneration experiments. A planarian (Dugesia) may be cut in any direction by one or more transverse, longitudinal or oblique sections, and each fragment will regenerate a whole, though smaller, individual (see fig. 2). Planarians possess complex structures such as eyespots, brain and pharynx. Any or all of these can be rebuilt from a fragment not containing them. Of three closely related groups of Turbellaria (free-living flatworms), distinguished mainly by differences in the shape of the intestine, only the triclads, or planarians, have a high regenerative power, and even within this group there are great differences with respect to the ability to regenerate.



FROM E KORSCHELT

FIG. 3.—REGENERATION IN THE STARFISH, ONE ARM REGENERATES A WHOLE STARFISH (CENTRE)

The entirely parasitic flukes (Trematoda) and tapeworms (Cestoda) have not been thoroughly investigated. They seem to lack regenerative power.

Annelids. — Regeneration in the common earthworm is well known. It can regenerate many segments at the posterior part of the body, but regeneration of the anterior part is limited. Up to five segments can be completely restored, but if more are removed, fewer than the normal number are rebuilt; no regeneration takes place if 15 or more anterior segments are amputated. Some relatives of the earthworm can do better. For instance, the fresh-water worm Criodrilus regenerates as many as 25 anterior segments. In another fresh-water form. *Nais,* two isolated segments can regenerate a whole worm. One of the remarkable features in these annelid regenerations is the formation of gonads in the regenerated segments, although the stumps which give rise to the regenerates may not contain a trace of gonad material. The regenerative power of the more highly specialized marine polychaetes is, in general, lower than that of the earthworm and its relatives (oligochaetes). It is very low in the leeches (Hirudinea).

Echinoderms. — The arms of starfish (Asteroidea) and brittle stars (Ophiuroidea) can regenerate a whole individual in some instances, even if the amputated arm contains no trace of the central disc. Occasionally, there may be found on the seashore an odd-looking starfish with one or two normal-sized and several very short arms (see fig. 3); the latter are in the process of regeneration. Sea urchins can repair damage in the skeleton and restore tube feet and spines. Sea urchin and starfish larvae (plutei) have little regenerative power.

Mollusks. — Parts of the shells of snails (Gastropoda) and valves of clams and relatives (Lamellibranchia) can be replaced. Damage can be repaired at the margin, at which the shell is formed, and also in central parts. The mantle and the foot likewise can regenerate. Some snails have highly complex eyes at the tips of tentacles. The amputation of a tentacle at its base results in its regeneration, including the eye. However, the entire head of a snail cannot be regenerated. Squid, octopus and cuttlefish (Cephalopoda) can regenerate amputated arms.

Arthropods. — The body of an arthropod has many appendages such as legs, wings, antennae, stalked eyes, mandibles and tail. These are all readily exposed to accidental damage, and most of them can be regenerated when lost. This holds particularly for the best-known and most thoroughly investigated groups, the crustaceans (crayfish, crab, lobster, etc.) and the insects. All arthropods molt periodically; that is, they shed the chitinous exoskeleton. Its replacement may be considered a type of physiological regeneration. The regenerative power of insects is high during larval and pupal stages but greatly reduced in the adult. The regeneration of structures such as wings or legs of adult insects is either limited and incomplete or entirely impossible. On the other hand, crustaceans continue to molt throughout adult stages, and they are capable of regenerating complex organs such as legs or eyes.

Sea Squirts. — High regenerative power is found in the seden-

tary ascidians. A small part of the body can regenerate a whole individual.

VERTEBRATES

Fishes.—In the bony fishes the regenerative capacity is limited. They can regenerate the tail fins and the other paired and unpaired fins. A few other structures are known to be capable of regeneration, such as the gill cover, parts of the gills and of the lower jaw.

Amphibians.— The tailed Amphibia, salamanders and newts (Caudata), have by far the most extensive regenerative potency of all vertebrates and have therefore been the favourite subjects for experiments on vertebrate regeneration. ,In particular, limb regeneration of salamanders has been analyzed in many respects, ever since it was discovered by Spallanzani in 1768. Any part of a foot or hindlimb can be regenerated; one of the remarkable features is the precision with which the missing part is restored. If the foot is amputated (fig. 4[B]), only this part is replaced; if the leg is removed at its base (fig. 4[A]), it will be replaced in its entirety. Other organs can regenerate equally well, among them the tail, parts of the snout and eyes and parts of inner organs such as lungs and gonads. The regenerative capacity of salamander larvae and of young specimens exceeds even that of full-sized specimens.

FIG. 4.—ARM REGENERATION IN A SALAMANDER. 1–6 ARE REGENERATION STAGES, FOLLOWING AMPUTATION AT A; BLASTEMA AT 1 AND 2. (SEE TEXT)

In the tailless Amphibia, frogs and toads (Salientia). the regenerative capacity is limited to larval stages. The tadpoles can readily regenerate a tail which is clipped at the tip or even near the base. The hindleg regeneration proceeds rapidly and efficiently in young tadpoles, but this capacity subsides when the larva approaches metamorphosis. Adult frogs do not regenerate limbs, contrary to a common belief. Usually the stumps heal without regenerating. If the arm of an adult frog is amputated and the wound surface is bathed repeatedly in a saturated sodium chloride solution, the stump will proceed to form a regenerate. However, the regenerated arm is never complete and normal. It is assumed that in untreated adult frogs the thick skin closes up rapidly over the wound surface and suppresses regeneration.

Reptiles.— Vertebrates higher than Amphibia have greatly reduced regenerative potentialities. The tail of a lizard is the only highly specialized structure in reptilians which can regenerate. The animal makes occasional use of this capacity: when captured by its tail. it shakes the tail off and leaves it behind. Lizards with regenerated tails are occasionally encountered in the field. However. tail regenerates are never complete; their inner structures are atypical. Amputated limbs of lizards do not regenerate.

Birds.—The regeneration of fragments of beaks has been reported in several birds. The periodic renewal of the plumage after each molt is a type of physiological regeneration, and the growth of a feather from a feather rudiment resembles other regenerative processes.

Mammals.— These present numerous instances of tissue regeneration, but very little, if any. evidence for the regeneration of complex structures. The change of hair, of teeth and of red blood cells and the regeneration of antlers in deer illustrate physiological regeneration. Reparative regeneration, following an amputation, is limited to tissues, such as bone, muscle, liver, skin and peripheral nerves. Whole organs cannot be regenerated.

GENERAL CONCEPTS

What general concepts can be derived from this survey? In the first place, it brings into proper relief a point which has been emphasized by students of regeneration since the early days, that there is a correlation between regeneration potentiality and level of organization; *i.e.,* lower organisms have a high regenerative power, and this power decreases with increase in complexity. Mammals, including man, pay for their high organization with an almost complete loss of regenerative capacity. The relation between regenerative power and level of organization, however, holds only in a general way and breaks down in numerous special instances. For example, some planarian species have an exceptionally high regenerative power, but closely related species have none. The same holds for Annelida. The regenerative ability of the fishes is lower than that of the more highly organized tailed amphibians. The regeneration of the crystalline lens of the eye of salamanders is perfect in one genus and absent in another. These examples could be multiplied easily. They show that factors other than the general level of organization of the animal often play a decisive role.

It has also been asserted that since regeneration is a developmental process, embryos, larvae and young animals, in general, should be more readily capable of regeneration than adult stages of the same animal. This expectation is fulfilled in many instances. but again it is not a rigid rule. It is true that salamander larvae regenerate limbs and tails more rapidly and more perfectly than adults do, and lens regeneration in some salamander species is limited to larvae; frog tadpoles can regenerate a hindlimb, but an adult frog cannot. On the other hand, sea urchin and starfish larvae do not regenerate, while the adults do. The same holds for annelids and for tunicates. Again, factors other than age determine the limitation of regenerative power in these forms. Finally, one would expect that external organs and appendages which are readily exposed to injury and loss would show a higher regenerative capacity than inner organs. This, again, holds in a general way. However, several examples have been mentioned of the regeneration of inner organs which are rarely subject to injury during the normal course of life.

AUTOTOMY

A number of animals, when attacked and caught by a leg or tail, save their lives by casting off this appendage. The organ which is sacrificed can usually be restored by regeneration. This act of self-amputation is called autotomy. Instances of autotomy are found in a number of different animal groups, such as coelenterates mollusks. echinoderms, annelids, arthropods and others, although this means of escape is used only by a few representatives of these phyla and by no means by all of them. The only case of autotomy in vertebrates, and perhaps the best known of all, is that of the autotomy of the tail in lizards. The facility with which the tail breaks off is astounding. This is because of a special structural adaptation. A breaking plane is prepared at the base of the tail along which it is severed when grasped. Several vertebrae are split across the middle. The halves are held together by cartilage which ruptures readily. The regeneration usually begins at the breaking plane. The regenerated tail is not quite typical. It contains no vertebrae but merely a cartilaginous skeletal axis; the muscle and nerve distribution is likewise atypical. Nevertheless, such a regenerated tail can regenerate a second time.

Many crabs, insects and spiders have a similar device to facilitate autotomy, namely, a preformed breaking plane at the base of legs or antennae. The chitinous exoskeleton is soft and thin at certain levels, and the muscle arrangement expedites self-amputation. It is not always the same segment of the leg at which such a breaking plane is prepared, but the mechanism is apparently similar in all species. In the walking stick, or stick insect, all three pairs of legs are adapted for autotomy. Quite frequently, special care is taken to avoid an excessive loss of blood: the skin contracts over the wound and closes it off. A few other instances of autotomy may be mentioned: some sea anemones release a tentacle when it is strongly stimulated; starfishes cast off an arm voluntarily, and some annelids can autotomize the hindmost body segments and regenerate them subsequently.

One of the most startling instances of autotomy is the self-evisceration in sea cucumbers, which, when strongly stimulated, cast off their anterior ends, including tentacles, mouth parts and the water-vascular system, and at the same time discard through the anus the intestine and attached structures, such as gonads.

The discarding of the inner organs is accomplished by strong muscle contraction. The nearly empty hull composed of skin and muscles is capable of regenerating the autotomized organs. *Thione* can accomplish this feat within a month.

There is only one step from spontaneous autotomy to spontaneous fission for the purpose of asexual reproduction. For instance, certain starfishes and certain sea cucumbers break apart at more or less regular time intervals and the fragments regenerate a whole individual. Likewise, in certain annelids and flatworms posterior parts of the body are constricted off and the fragments regenerate into new individuals. This performance has been established as a regular mode of reproduction. The close affinity of regeneration and reproduction in lower animals is thus again affirmed.

FIG. 5.— REGENERATION OF A DOUBLE HEAD IN A PLANARIAN (SEE TEXT). A REGENERATE; TISSUE IS UNSTIPPLED

HETEROMORPHOSIS

A regenerate is ordinarily a replica of the original structure, but a number of cases are known in which regeneration is atypical in that either more or less than was lost is regenerated. Occasionally, the regenerate represents an organ entirely different from the one it replaces. All forms of atypical regeneration are called heteromorphosis. The last-mentioned category of heteromorphic regenerations is called homeosis.

Incomplete Regeneration.— This type of heteromorphosis is common both in naturally occurring and in experimentally induced regeneration. Regenerated tails of lizards invariably show certain structural deficiencies, such as the absence of normal vertebrae. Regenerated salamander limbs frequently have a reduced number of digits or even greater deficiencies. Those of arthropods may have a reduced number of segments. Several species of annelids can regenerate only a limited number of head segments. If more are amputated, the total segment number of the worm after completed regeneration will be subnormal. Planarians occasionally regenerate a head with two fused eyes, or only one eye, or eyeless heads, instead of the normal head with two separate eyes.

Such atypical head regenerates can be produced experimentally by exposing the regenerating animals to any one of a number of chemical agents which are known to impair developmental processes in a general, nonspecific way.

Superregeneration.— Of greatest interest among the superregenerations are those in which a single organ is replaced by a duplicated or multiple formation. Instances of such monstrosities have been observed in practically all regenerating animal forms, as, for instance. in hydranths of Hydra and of its marine relatives, in heads and tails of planarians and annelids, in tails of lizards and limbs or digits of amphibians and particularly frequently in appendages of arthropods. Double claws of crabs or lobsters, double legs and antennae of beetles and of other insects have been described. Starfishes with bifurcated arms and sea cucumbers with duplicated body parts also have been observed. Triplicate appendages are commonest in arthropods and occasionally are found in other forms. They originate probably in most instances in the following way: a leg, claw or antenna ruptures at a joint without breaking off completely. As a result, two wound surfaces are exposed, each of which begins to regenerate the distal parts. The two new formations, together with the persisting original structure, form the triple monstrosity. It was found that such triplicate structures follow a definite rule of symmetry relations (Bateson's rule): two adjacent components, namely, the middle one and one of the marginal components, are mirror images of each other, whereas the two marginal parts have the same symmetry pattern.

It is often difficult or impossible to decide whether double or triple monstrosities found in nature have been brought about by regeneration or whether the duplication occurred in early embryonic development. Therefore, experimental methods were devised that make it possible to study the origin of duplications by regeneration under controlled conditions. An expedient way of accomplishing this is to create a wound surface which will produce two separate blastemas instead of one. For instance, if the tail of a tadpole is amputated by two oblique cuts, in the form of an arrowhead (instead of by one transverse cut), then two blastemas and tails will grow out, each with its main axis perpendicular to the oblique, cut surface (Barfurth's rule). Multiple digits in salamander legs were produced in the same fashion, by making two oblique transections. Two-headed planarians can be obtained by making a longitudinal fission in the median plane through the anterior part of the animal, and a subsequent amputation of the two halves of the head (fig. 5[A]). Each separate anterior body half then regenerates the missing lateral parts and, in addition, a whole head at the anterior surface (fig. 5[B]). By repeating this procedure, animals with multiple heads (up to ten) have been obtained. In the same way, planarians with double tails can be produced experimentally.

Homeosis.—This category of atypical regenerations includes all those instances in which the regenerate represents a structure different in type from the original. Homeosis occurs mainly in arthropods. It is a characteristic of this phylum that most of the numerous body segments bear appendages which are of different types in different body regions (*e.g.*, antennae, mandibles, claws, thoracic legs. abdominal appendages). In homeosis, the appendage of one type substitutes for another type. A few examples may serve as illustrations: in crustaceans (crayfish, lobster. crab), a thoracic leg with claws was regenerated in place of a maxilliped; in other cases an abdominal leg was found in place of a thoracic leg. A leg may be regenerated in place of an antenna or of a mandible, and vice versa. An anterior wing of a butterfly or moth may replace a posterior wing. Of particular interest is the regeneration of an antenna in place of a stalked eye, which was observed in marine decapod crustaceans of the genus *Palinurus, Palaemon* and in others (fig. 6). Curt Herbst discovered that if the optic ganglion, which is located at the base of the eyestalk, is removed along with the eye, an antenna grows out, but if the optic ganglion is left intact and the eye alone is amputated. a normal eyestalk and eye regenerate. The ganglion, then, determines the quality of the regenerate.

REGENERATION PROCESS

ORIGIN OF REGENERATION MATERIAL

Blastema Formation.— Regeneration, as noted above, can be performed by reorganization of the old piece (morphallaxis) or by outgrowth of new tissue at the cut surface (epimorphosis). Only the latter mode of regeneration is discussed in the following. In limb and tail regeneration of salamanders, in head and tail regeneration of planarians and in many similar instances, a regeneration bud or blastema is formed at the amputation surface. The blastema is at first a slight elevation which grows to a cone-shaped structure and then begins to differentiate into tissues or organs. The blastema is an accumulation of cells of embryonic type, whose origin has been the topic of numerous investigations. The material that builds up the regenerate may be derived from three different sources. In several invertebrate phyla, including coelenterates, annelids and flatworms. a special type of undifferentiated cells, the so-called reserve cells or neoblasts, are stored in different parts of the body. When the need for regeneration arises they are mobilized and migrate to the site of injury. Tissue out-

growth is a second source. The differentiated tissues at the cut surface (for instance, skin or muscle) may simply grow out and each form tissue of its own kind. Finally, the blastema cells may be derived from formerly differentiated tissues of the amputation stump which have dedifferentiated and returned to an embryonic-type condition. It is conceivable that when the blastema proceeds to develop, such cells may differentiate into a type of tissue different from the one from which they mere derived. For example. in salamander limb regeneration, a former muscle cell may become a bone cell, or vice versa. This transformation is referred to as metaplasia.

Tissue **Outgrowth.**—This mode of regeneration is characteristic of tissue repair such as bone regeneration following a fracture, restitution of a muscle injury or liver regeneration. Peripheral nerves regenerate in this fashion, by outgrowth from the cut end. In amphibian limb regeneration. apparently only nerves and skin regenerate in this way. The skeletal elements of the regenerate do not originate from old skeletal tissue at the cut surface. This was demonstrated by an experiment in which the upper arm bone (humerus) mas carefully removed and the limb then amputated across the upper arm. The regenerated forearm and digits contained all typical skeletal elements, although no bone tissue was present at the amputation surface.

Reserve Cells **(Neoblasts).**—A glance at some of the extensive regenerations in lower animals shows that in these cases tissue outgrowth cannot be the primary source of the new formations. For example, a narrow piece from the middle of a planarian can regenerate a new individual, with such organs as brain, eyes, pharynx and reproductive organs, no trace of which was present in the original piece. In flatworms, annelids, coelenterates and tunicates the reserve cells or neoblasts are the major source of the building material for new organs. These cells have been set aside in the embryo for this purpose, and have never undergone any specialized differentiation. In the common coelenterate Hydra, which is famous for its regenerative capacity, a type of connective tissue or mesenchyme cell, the so-called interstitial cell. is found scattered throughout the body; these cells migrate to a cut surface and form the chief or even exclusive source of the blastema. In some annelids the neoblasts can be identified as particularly large cells, stored in different parts of the body. However, it seems that tissue outgrowth and metaplasia also contribute to regeneration in annelids, and there is a great deal of variation in details in this group.

Different species of flatworms vary greatly in their capacity for regeneration, and a correlation seems to exist between the degree of regenerative power and the quantity of reserve cells present in the body. The role of these reserve cells in planarian regeneration was firmly established by the use of a modern tool, irradiation. It was found that reserve cells are more sensitive than ordinary body cells to X-rays and other radiation. If the whole animal is exposed to a mild dosage, the neoblasts can be destroyed nithout destroying the animal, which survives for at least several weeks; these individuals have no capacity for regeneration. A modification of this experiment gave evidence that reserve cells can migrate over long distances to reach the amputation surface. If the anterior part of a flatworm is irradiated and the posterior part shielded, and then the head removed by a transverse cut within the irradiated region, head regeneration occurs uith a considerable delay because the reserve cells in the intact posterior region have to migrate across the irradiated band to reach the amputation surface. The wider the band, the longer the delay, but eventually a head is regenerated.

Metaplasia.—The question of whether metaplasia, as defined above, exists is of great theoretical interest: it goes to the heart of the problem of cellular differentiation. Is the process of differentiation of an embryonic cell into a highly specialized cell, such as a muscle or bone cell, reversible? Can a full-fledged muscle cell revert to an embryonic state and then, under certain conditions, differentiate in a new direction and become a bone cell? The origin of the limb-regeneration blastema in salamanders has always been in the centre of this discussion, without, however, yielding crucial evidence one way or the other. First, the question had to be settled whether the blastema cells come from the amputation stump or from more distant parts of the body, or perhaps even from formed elements of the blood. Irradiation experiments gave the answer: if part of a salamander limb is irradiated and the rest of the body shielded, and an amputation is then performed in the irradiated region, regeneration fails to occur; conversely, irradiation of the whole animal, except for the limb, does not interfere with limb regeneration. Contrary to what happens in planarians, then, the blastema cells do not come from distant parts but derive from the cells near the amputation surface.

Microscopic study of the events following the amputation of a limb reveals that a dedifferentiation of differentiated muscle and cartilage or bone actually occurs near the cut surface during the few days preceding the formation of the blastema. The multinuclear muscle fibres break up into fragments forming small cells with single nuclei, which have the appearance of embryonic cells or fibroblasts. There seems to be agreement that these cells, together with similar cells of skeletal origin and with ordinary fibroblasts, contribute materially to the blastema. If by metaplasia is meant merely the loss of highly specialized structure and the transformation into a fibroblastlike embryonic-looking cell, then this is a case in point. But this is not metaplasia in the strictest sense. The crucial question is still open: Have these cells actually lost all their biochemical and metabolic specifications? Have they reverted to a true embryonic pluripotential state which would enable them to differentiate into a cell type different from the one they represented before? A definitive answer to this question awaits new techniques.

There is, however, one clear case of true metaplasia. This is the regeneration of the crystalline lens of the salamander eye, often referred to as Wolffian lens regeneration in recognition of one of the co-discoverers and most active students of this very remarkable phenomenon. If the lens is carefully removed with fine instruments, it is replaced by a new lens that originates at the upper margin of the iris; the latter is the pigmented part of the eye, enclosing the pupil. The first change, following lens extirpation, is the disappearance of the pigment in the upper iris; that is, a process of dedifferentiation. Next, the two tissue layers that comprise the iris separate and expand at the rim where they are continuous, and form a small vesicle. This vesicle grows downward to assume the normal position of a lens; eventually it becomes detached from the iris and differentiates into a typical lens. Here may be observed directly the transformation of pigmented iris cells into lens cells. Another case of true metaplasia, the regeneration of brain tissue from epidermis in annelids, is well documented.

Analysis

Initial Stimulus. — The regeneration process is ordinarily initiated by the injury that accompanies the loss of a part. The trauma seems to play an activating role similar to that of fertilization in the egg. The physiological and metabolic equilibrium at the wound surface is undoubtedly disturbed, and it is likely that the injured tissues produce a chemical agent or agents that set the process in motion. However, the actual loss of a part is not a necessary prerequisite for regeneration. An injury such as an incision in the stem of a coelenterate or in the body of a planarian is sufficient to initiate a new growth process. If ultraviolet irradiation is applied to the elbow region of a salamander limb, a local injury ensues, and an accessory, well-formed forearm with digits may grow out at this place. Duplications of limbs and other organs encountered occasionally in amphibians, arthropods and other groups, may have originated in this fashion, by local injury.

In some instances not even an injury is necessary for activation of the regeneration process. The above-mentioned lens regeneration in the salamander eye is initiated simply by removal of the old lens, which can be done without injury to the upper iris, from which the regenerating lens is derived. What is the stimulus in this instance? Experiment has shown that the lens produces a chemical agent that holds the upper iris in check. If this inhibitor is removed, along with the lens, the regeneration process is set in

motion. The coelenterate *Tubularia,* a marine relative of the common Hydra, which has been widely used for regeneration experiments, consists of stolon, stem and hydranth, the latter containing the mouth opening surrounded by two rows of tentacles (fig. 8). The stem is sheathed in a transparent coat. the perisarc. If a small area of the stem tissue is exposed to sea water by cutting a hole in the perisarc. a bud grows out at that place and forms eventually a new hydranth. In this instance, the local increase in oxygen tension serves as the activating stimulus. This experiment again illustrates the close relationship between regeneration and asexual reproduction by budding.

Regeneration Fields in Amphibians. — Once a blastema is formed, it is possible to inquire into the organizing factors that so direct the further development of the blastema that exactly the missing parts are replaced. The problems faced here are similar to those the embryologist encounters when he tries to analyze the factors that determine the origin of an embryonic organ primordium (*see* EMBRYOLOGY, EXPERIMENTAL). The regeneration blastema can be considered as equivalent to an organ primordium; the same types of organizing and determining factors probably are in operation in both, and the same kinds of experimental methods, such as extirpation and transplantation. are applied for their analysis. However, it should be stated that analysis of the regeneration process is much less advanced than that of embryonic processes.

The concept of regeneration fields has been found useful for an understanding of regeneration phenomena; the field concept also has been applied to embryonic development. The capacity for regeneration of an organ such as limb. tail or snout in salamanders is limited to a well-circumscribed area. For instance, limb regeneration after amputation can be obtained at any level down to the base, but if a still larger area, including the limb girdle, is removed, no regeneration occurs. By this type of extirpation experiment, regeneration fields for different organs have been demarcated. The fields are the units of regeneration; therefore. it is not quite correct to say that the salamander regenerates a limb; rather, the limb regeneration field restores its wholeness when it has been impaired. The field concept conveys another notion: the organizing factors for regeneration are distributed over the whole field in such a fashion that if the field district is injured at two separate points, two regenerates of the same type can be formed In this nay duplicate limbs or tails can originate by experiment or by accidental injury. An example is an experiment mentioned above in uhich local irradiation at the elbow of a salamander called forth the formation of an extra limb. If a field can give rise to more than one organ. then part of a field should be able to produce a whole organ This expectation is fulfilled in the following experiment: if the salamander hand is amputated and the forearm split lengthwise, each half of the cross section can regenerate a whole hand with four digits. The regeneration field shares this remarkable regulative property uith the embryonic fields.

Determination. — Very young limb or tail blastemas apparently resemble early embryonic structures in that they are not yet irreversibly determined but show a certain plasticity. If a few-days-old blastema of a salamander forelimb is transplanted onto the stump of an amputated hindlimb, the regenerate is a hindlimb. However, if the blastema is a week old. or older, it forms a forelimb in a foreign position; that is, its fate has been determined in the meantime. Obviously. the blastema acquires gradually its specific characteristics. It must get its "instructions" from the underlying stump tissue, but the determinative mechanisms are unknonn.

Organizers and Induction. — The discoveries of inductors and organizers were landmarks in experimental embryology. Transplantation experiments showed that certain embryonic areas, called inductors, produce chemical agents that stimulate the formation of an organ, such as inner ear, nose, lens. in an adjacent embryonic area. The organizer, discovered by H. Spemann in early amphibian embryos. is a complex inductor that. when transplanted to another embryo, induces in the latter not merely a single organ but a more or less complete secondary embryo. Similar phenomena were discovered in the regeneration of lower forms. If a small piece from the mouth region of a coelenterate polyp (fig. 8) is transplanted into the stem of another individual, a secondary individual grows out, composed largely of host material; the transplant contributes the organizing factors but little material. Similarly, if a piece of the head of a planarian is transplanted to the middle of the body of another planarian, a secondary individual is induced. If individuals of different colour are used in this experiment. it is possible to establish clearly the share of the graft and of the host in the new formation, and it can be seen that the graft forms only a small part of the outgrowth. Obviously, it is important to distinguish between organizing factors and building material.

Organ induction also has been demonstrated. In certain species of planarians, the brain produces a diffusible substance that induces eye regeneration. In the above-mentioned case of lens regeneration in the salamander eye from the upper iris. it is not enough to remove the lens-produced inhibitor; in addition an inductive substance, produced by the retina of the eye, must be present.

Role of the Nervous System. — The presence of nerves at the cut surface has long been recognized as a necessary prerequisite for amphibian limb regeneration. No regeneration takes place if simultaneously with limb amputation all limb nerves are transected in the region of the limb girdle. However, the nerves themselves can regenerate. and as soon as the regenerating nerves reach the amputation level a belated blastema formation begins. Limb regeneration can be prevented permanently by repeated nerve transections. If this is done in larval salamanders, not only is there no regeneration, but the amputation stump begins to regress and is eventually completely resorbed. The nerves apparently produce a trophic (nutritive) agent of unknown chemical nature that promotes the blastema formation. Once the blastema has reached a certain size, it becomes independent of the nerve influence. This trophic factor should be counted among the general, nonspecific metabolic conditions for regeneration, and not in the category of specific organizing factors. because the nerves do not determine the specific quality of the regenerate; they do not decide whether it is to be a forelimb or a hindlimb. The question of nhether any special nerve fibre type, such as sensory, motor or sympathetic. is responsible for the production of this trophic agent was a matter of controversy for a long time, the issue being finally settled by M. Singer, who found that the requirement for nerves is quantitative, not qualitative; a certain minimum number must be present at the amputation surface, but the source from which they are derived is immaterial.

The nervous system also plays a role in the regeneration of certain invertebrates. For instance, head regeneration of the earthworm seems to be dependent on the presence of the ventral nerve cord at the amputation surface. Eye regeneration in some marine decapod crustaceans presents a particularly interesting case.

A normal eye regenerates if the eye and eyestalk are removed but the optic ganglion at the base of the stalk is left intact; if the latter is also removed, then an antenna is formed in the place of the eye (fig. 6; homeosis).

In other arthropods antennae and legs can regenerate in the absence of nerves.

Hormones in Regeneration. — Hormones (*q.v.*) play an important role as agents controlling a great variety of body functions. Their influence on growth and development is illustrated by the well-known cretinism, which results from deficiency of the thyroid hormone, and by the control of amphibian metamorphosis by .the thyroid gland. The pituitary body (*q.v.*) produces a growth hormone; its underproduction results in dwarfism and its overproduction in gigantism. Since regeneration is a special type of growth and development. similar hormonal influences on regeneration would be expected, and this is indeed the case. The regeneration of limbs in adult newts (tailed amphibians) is inhibited when the entire pituitary is removed. This effect is exerted only on the very first phase of the regeneration process, following amputation, namely the breakdown of tissue (dedifferen-

tiation) near the cut surface. Instead of formation of the blastema, a thick pad of skin grows over the wound and blocks further outgrowth.

Regeneration proceeds in a normal fashion if the regeneration process is allowed to get a start of five or six days before the gland is removed. It is assumed that the hormone is involved in the breakdown of proteins. Thyroid hormone has a similar effect on amphibian limb regeneration, and hormonal effects on regeneration in insects also have been reported.

Polarity; Gradient Theory. — The familiar distinction between head. trunk and tail, or anterior and posterior end, calls attention to the axial organization, or polarity. of most animals. In the polyps of coelenterates, polarity is expressed in the formation of a tentacle-bearing hydranth with mouth opening at the apical end of the stem and a stolon at the basal end (fig. 8). One of the striking phenomena in the regeneration of lower animals is the retention of polarity even in small fragments.

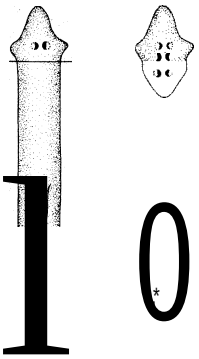

FIG 7 —POLAR HETEROMORPHOSIS (REVERSAL OF POLARITY) IN A PLANARIAN. AN AMPUTATED HEAD OR A SHORT POSTERIOR BODY PIECE MAY REGENERATE A HEAD WHERE A TAIL WOULD BE EXPECTED REGENERATED TISSUE IS UNSTIPPLED

A slice of a planarian taken from any part of the body regenerates a head at the anterior cut surface and a tail at the posterior cut surface. However. exceptions do occur; reversal of polarity is referred to as polar heteromorphosis (fig. 7).

How can the maintenance of polarity in regenerates be explained? Older theories that postulated specific cell types or specific morphogenetic substances for head or tail formation have been abandoned. The axial gradient theory of C. M. Child offers a more dynamic interpretation. According to this theory, polarity is the manifestation of a gradient of physiological activities along the main axis. the head end representing the highest activity and the tail end the lowest. Each section of the body or stem shares in this axial gradient. The theory assumes further that a head, or hydranth in coelenterates. regenerates at the anterior surface of an isolated piece because this is the region of relatively highest metabolic activity in the fragment; and the tail or stolon forms at the level of relatively lowest activity. In other words. the fate of a regeneration blastema is determined by its relative position in the whole gradient system.

Polar heteromorphoses, which occur predominantly in very short pieces (fig. 7), are explained by assuming that in such pieces the activity at the two surfaces is nearly equal and the differential too small to determine two different types of structures.

The nature of the physiological activity postulated by the theory has never been clearly defined, and efforts to demonstrate single gradient systems of oxygen consumption or of other general metabolic activities, consistent over a wide range of eggs, embryos and lower animals, have failed. However, there are some indirect methods that give indications of rather widespread gradients, for instance in the susceptibility of lower animals, eggs and embryos to toxic agents. In this context, gradients of regeneration capacity are of special interest. In the stem of the coelenterate *Tubularia* the rate of regeneration, measured by the amount of tissue regenerated per hour. decreases gradually from the apical to the basal regions; this is attributed to the gradient concentration of a catalyst. Likewise, if a planarian is cut in six or eight transverse pieces of equal size, the quality of head regeneration is highest in the anteriormost piece and declines from there in a graded fashion.

The concept of physiological dominance is an integral part of the axial gradient theory It is postulated that the region of highest physiological activity not only forms a head or a hydranth but at the same time suppresses head or hydranth formation at any other part of the regenerating piece. It sets itself up as a "dominant region" and thus guarantees the unity in the regenerating system. One experiment, selected from many others, may illustrate dominance. As illustrated in fig. 8. a piece of the stem of the coelenterate *Tubularia* would normally regenerate a hydranth at the apical end, at surface 1, and a stolon at surface 2. If regeneration at the apical end is prevented by a ligature, then the basal end regenerates a hydranth. In terms of the theory, the ligature has eliminated all influences of the apical region; thus, the basal end has been released from the inhibitory effect of the original dominant region and set itself up as a new dominant region. Incidentally, a polar heteromorphosis has been produced in this way.

Nerve Regeneration. — The great practical importance of nerve regeneration following nerve injury in man justifies a brief special consideration of this process. Only peripheral nerves can regenerate; the nerve cells, or neurons, that make up the tissue of the brain and spinal cord, and the ganglia, cannot be replaced once they are destroyed. The peripheral nerves are actually bundles of nerve fibres embedded in connective tissue. Each fibre is a delicate protoplasmic thread spun out in early development by one of the nerve cells in the central nervous system or ganglion. The fibre remains part of its cell of origin and depends on its cell body for nutriment throughout life. This fact is important for an understanding of nerve fibre regeneration. When a nerve is transected, regeneration starts from the so-called proximal stump of the fibre (that is. the part that remained connected with its cell body), whereas the disconnected, distal or peripheral stump dies off. The fibres at the proximal stump begin to sprout new threads that penetrate the gap between the two cut ends.

How do these fine processes bridge this gap? How do they find their uay to the peripheral organs they are supposed to reinnervate? They obtain substantial aid from a special type of companion cells, the so-called Schwann cells. These very versatile small cells serve several important functions. They are lined up all along the nerve fibre, forming a continuous. very delicate coat around it During development, they produce an insulating coat around the fibre, the so-called myelin sheath, which gives the nerve its white, glistening appearance. In nerve regeneration, they play a major role in reconstructing the peripheral pathway for the regenerating fibres. The peripheral parts of the nerve fibres themselves that were severed from their cell bodies break down and disappear; not so the Schuann cells that surround them. These become very active. They multiply and form long dense strands, or cords, in the peripheral nerve stump.

These cords are then invaded by the newly regenerating fibres from the proximal stump and serve the outgrowing fibres as a substrate and a guide, from the cut end all the way to their destination at the periphery.

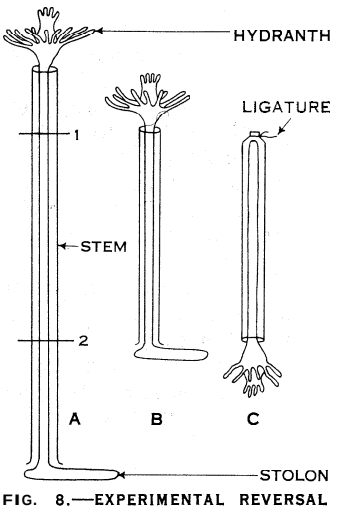

FIG. 8.—EXPERIMENTAL REVERSAL OF POLARITY IN THE MARINE POLYP TUBULARIA ILLUSTRATING PHYSIOLOGICAL DOMINANCE. (A) PIECE 1–2 REGENERATES NORMALLY (B) A HYDRANTH AT 1 AND A STOLON AT 2. (C) IF A LIGATURE IS MADE AT 1, A HYDRANTH REGENERATES AT 2

The greatest hazard for the regenerating nerve fibres is the crossing of the gap between the two cut ends of the nerve. In this they are also aided by the Schwann cells; the latter, together with fibroblasts, form between the two cut ends a bridge of parallel strands which is then used as a track by the outgrowing fibres. In this phase of nerve regeneration, the surgeon can lend a helping hand by facilitating the crossing of the gap. Particularly if the gap is wide, the two ends may be connected with sutures, or fitted together with a sleeve made of a piece of artery or other material. Growth of the regenerating nerve fibre proceed~at the rate of several millimetres per day. In man. functional recovery takes several months, the time depending, of course, on the distance between

the cut end and the peripheral end organ.

REGENSBURG (RATISBON), a city and episcopal see of Germany, in the *Land* of Bavaria. Pop. (1959 est.) 123,476. It is on the right bank of the Danube, opposite the influx of the Regen, 86 mi. by rail N.E. from Munich, and 60 mi. S.E. of Nuernberg. The pre-Roman settlement of *Radespona* was chosen by the Romans, who named it *Castra Regina*, as the centre of their power on the upper Danube. It afterward became the seat of the dukes of Bavaria and was the focus from which Christianity spread over southern Germany. St. Emmeran founded an abbey there in the middle of the 7th century, and St. Boniface established the bishopric about 100 years later. Regensburg acquired the freedom of the empire in the 13th century, and was for a time the most flourishing city in southern Germany. It became the chief seat of the trade with India and the Levant, and the boatmen of Regensburg are frequently heard of as expediting the journeys of the crusaders. Numerous imperial diets were held there in the middle ages, and after 1663 it became the regular place of meeting of that body. The Reformation found only temporary acceptance at Regensburg and was met by a counter-reformation inspired by the Jesuits. Before this period the city had almost wholly lost its commercial importance because of the changes in the great highways of trade. Regensburg is said to have suffered in all no fewer than 17 sieges. In 1810 the town and bishopric were ceded to Bavaria. In 1809 the French reduced a great part of the city to ashes.

Across the river is Stadt-am-Hof, connected with Regensburg by a stone bridge of the 12th century. One of the most characteristic features in its architecture is the number of strong loop-holed towers attached to the more ancient dwellings.

The cathedral, though small, is an interesting example of pure German Gothic. It was founded in 1275 and completed in 1634, with the exception of the towers, which were finished in 1869. Adjoining the cloisters are two chapels of earlier date than the cathedral itself, one of which, known as the "old cathedral," goes back perhaps to the 8th century. The church of St. James —also called Schottenkirche—a plain Romanesque basilica of the 12th century, derives its name from the monastery of Irish Benedictines ("Scoti") to which it was attached. The old parish church of St. Ulrich is a good example of the Transition style of the 13th century. Examples of the Romanesque basilica style are the church of Obermünster, dating from 1010, and the abbey church of St. Emmeran, built in the 13th century, and remarkable as one of the few German churches with a detached belfry. The cloisters of the ancient abbey, one of the oldest in Germany, are still in fair preservation. In 1809 the conventual buildings were converted into a palace for the prince of Thurn and Taxis. The town hall, dating in part from the 14th century, contains the rooms occupied by the imperial diet from 1663 to 1806. Among the chief manufactures are pottery, parquet flooring, musical instruments, furniture, sugar, chemicals, tobacco and lead pencils.

REGENT, one who rules or governs, especially during the absence, minority or incapacity of the sovereign. William I of England appointed *ad hoc* administrators whenever he left for Normandy, and in the course of the 12th century it became customary for the justiciar to act as regent when the king was abroad In 1216 the barons chose the earl of Pembroke to be *rector regis et regni* ("guide of king and kingdom") for the boy king. Henry III. By the statute of 28 Henry VIII c 7, advance provision was made for the selection of a regent upon Henry's death to serve until the new sovereign should attain the age of 18 if a male or 16 if a female. Although it was always subsequently assumed that a regent could be appointed only by or pursuant to an act of parliament, it was not until the Regency act, 1937, that permanent provision was made for the selection of a regent if the sovereign is under 18 or is found by a commission composed of his or her spouse, the lord chancellor, the speaker of the house of commons. the lord chief justice and the master of the rolls to be infirm of body or mind.

At the universities of Oxford and Cambridge the term regent was applied to a resident master who presided over disputations in the schools, and Cambridge once called the upper house of the university senate Regent house. In the Scottish universities the term designated a tutor for undergraduates; in France it designated a teacher of elementary arts or sciences in a secondary school. The term nas occasionally used in Europe and elsewhere to refer to the governing board of a city, and in some Moslem states for the chief of state. In Java it was the title given to a native chief through whom the Dutch colonial officials governed a residency. In the United States the term is little used except by some educational institutions, especially state universities, for a member of the governing board; *e.g.*, the regents of the University of California. (J. A. C. G.)

REGER, MAX (1873–1916), German composer, was born at Brand, Bavaria, on March 19, 1873. He studied at Weiden, Sondershausen and Wiesbaden, and taught at the Royal academy, Munich, from 1905–07, when he became a teacher at the Leipzig conservatorium, a post which he retained until his death, on May 11, 1916. His early piano works, Variations on a Theme from Bach, Variations on a Theme from Beethoven, the passacaglia and Fugue, and later the violin sonata in F sharp minor, which show already his individuality and remarkable technical powers, were followed by his first orchestral work, *Sinfonietta* (1906). After moving to Leipzig he wrote the violin concerto and piano concerto, with the powerful Symphonie Prologue to a Tragedy and the Comedy Overture, a number of choral pieces including *Die Nonnen, Der romische Triumphgesang* and *Die Weihe der Nacht*, the fine motets written for the Thomaner-Chor and the *Schlichte Weisen* sonatinas. From the period 1911–13, when he was also director of the court orchestra at Meiningen, there dates the Romantische Suite, Bocklin Suite, Ballet Suite, and later, Variations on a Theme from Mozart. From 1914 onwards his numerous compositions include many chamber works, pieces for choir and orchestra, for the piano and for the organ, and songs.

Reger was one of the most prolific and, in some respects, remarkably gifted composers of his day. His fertility was extraordinary, and he turned out work after work, often on the largest scale and in the most complex forms, with astonishing ease. His powers as a contrapuntist were especially noteworthy, and the fugue was one of his favourite forms. But as to the value of his immense output critical opinion is sharply divided.

A list of Reger's works is given in Grove's *Dict. of Music* (3rd ed., 1928). *See* also K. Hasse, *Max Reger* (Leipzig, 1921); E. Segnitz, *Max Reger* (Leipzig, 1922); and R. Würz, *Max Reger* (Munich, 1920).

REGGIO DI CALABRIA (anc. Regium, *q.v.*), a town and archiepiscopal see of Calabria, Italy, capital of the province of Reggio Di Calabria. on the Strait of Messina, 248 mi. S.S.E. from Naples by rail. Pop. (1957) 148.970 (commune). It is the terminus of the railways from Naples along the west coast, and from Metaponto along the east coast of Calabria. The straits are there about 7 mi. wide, and the distance to Messina nearly 10 mi. The ferryboats to Messina therefore cross by preference from Villa S Giovanni, 8 mi. N. of Reggio, now included within its communal boundary, whence the distance is only 5 mi. In 1894 the town suffered from an earthquake, though less severely than in 1783. It nas totally destroyed however, by the great earthquake of Dec. 1908; in the centre of the town about 35.000 out of 40 000 persons perished The cathedral, which dated from the 17th century, and the ancient castle which rose above it. were wrecked. Great damage was done by n seismic wave following the shock. The town was heavily bombed in 1943.

REGGIO NELL'EMILIA, a city and episcopal see of Emilia-Romagna. Italy, the capital of the province of Reggio Nell'Emilia (till 1859 part of the duchy of Modena), 38 mi. by rail N.W. of Bologna. Pop. (1906) 19,681; (1957 est.) 110.923 (commune). The town is in the shape of a diamond. The cathedral, originally erected in the 12th century, was reconstructed in the 15th and 16th; the façade shows traces of both periods, the Renaissance work by Prospero Spani (1516–84) being complete only in the lower portion. The Madonna della Ghiara, built in 1597–1619 in the form of a Greek cross. is beautifully proportioned and finely decorated in stucco and with frescoes of the Bolognese school of the early 17th century. S. Prospero has a good façade of 1753. There are several good palaces of the early Renaissance, a fine theatre (1857) and a museum containing important paleethnological collections. ancient and medieval sculptures, and the natural history collection of Lazzaro Spallanzani.

Lodovico Ariosto, the poet (1474–1533), was born in Reggio, and his father's house is still preserved. The industries embrace the making of railway locomotives and carriages and streetcars, and of cheese.

Regium Lepidi was probably founded by M. Aemilius Lepidus during the construction of the Via Aemilia (187 B.C.), on which it lay half-way between Mutina and Parma. It was during the Roman period a flourishing town. The bishopric dates perhaps from the 4th century A.D. Under the Lombards the town was the seat of dukes and counts; in the 12th and 13th centuries it formed a flourishing republic, busied in surrounding itself with walls (1229), controlling the Crostolo and constructing navigable canals to the Po. About 1290 it first passed into the hands of Obizzo d'Este, and the authority of the Este family was finally recognized in 1409.

REGICIDE, the name given to anyone who kills a sovereign (Lat. *rex,* a king, and *caedere,* to kill). Regicides is the name given in English history at the Restoration of 1660 to those persons who were responsible for the execution of Charles I. The number of regicides was estimated at 84, this number being composed of the 67 present at the last sitting of the court of justice, 11 others who had attended earlier sittings, four officers of the court and the two executioners.

The trial of the regicides before a court of 34 commissioners took place in Oct. 1660. Twenty-nine were condemned to death, but only ten were actually executed, the remaining 19 with six others being imprisoned for life. The ten who were executed at Charing Cross or Tyburn, London, in Oct. 1660, were Thomas Harrison, John Jones, Adrian Scrope, John Carew, Thomas Scot and Gregory Clement, who had signed the death-warrant; the preacher Hugh Peters; Francis Hacker and Daniel Axtel, who commanded the soldiers at the trial and the execution of the king; and John Cook the solicitor who directed the prosecution.

In Jan. 1661 the bodies of Cromwell, Ireton, and Bradshaw were exhumed and hanged at Tyburn, but Pride's does not appear to have been treated in this way. Of the nineteen or twenty regicides who had escaped and were living abroad, three, Sir John Barkstead, John Okey and Miles Corbet, were arrested in Holland and executed in London in April 1662; and one, John Lisle, was murdered at Lausanne. The last survivor of the regicides was probably Edmund Ludlow, who died at Vevey in 1692.

BIBLIOGRAPHY.—Ludlow's Memoirs, edited by C. H. Firth (Oxford, 1894), give interesting details about the regicides in exile. See also D. Masson, Lije oj Milton, vol. vi. (1880), and M. Noble, Lives *of* the English Regicides (1798); L. E. Welles, *History* of the Regicides (1927).

REGILLUS, an ancient lake of Latium, Italy, famous in the legendary history of Rome as the lake in the neighbourhood of which occurred (496 B.C.) the battle which finally decided the hegemony of Rome in Latium. Of the various sites proposed, the best is Pantano Secco. some 2 mi. N. of Frascati.

REGIMENT. In European and U.S. armies, the regiment is a body of troops headed by a colonel and organized into companies, battalions, or squadrons for tactical control. French cavalry units were called regiments as early as 1558 The word is derived from the Latin *regimen,* a rule or system of order, and describes the regiment's functions of raising, equipping and training troops. As a regiment developed individuality, through its name or number, colours, coat of arms, distinctive uniform and insignia, and achievements in battle, it also became a central object of loyalty, pride and esprit *de corps* of its soldiers.

In early U.S. service, as in European armies up to that time, the usual number of companies in a regiment was ten, forming a single battalion in battle. Early in the 19th century, Napoleon Bonaparte organized the regiments of the French army into three battalions or squadrons, of which two were in the field and one was in quarters recruiting and training additional troops. Later, Lord Cardwell reorganized the British infantry into two-battalion regiments, each having one battalion at the regimental depot at home and one stationed overseas. The U.S. army adopted a three-battalion infantry regimental organization in 1901, and incorporated regiments of this type in the divisions employed in World Wars I and II and Korea. In the late 1950s, the U.S. army inaugurated a system of organizing, out of each historic regiment selected for retention, a variable number of tactical units in proportion to the size of the army. (E. SR.)

REGINA, the capital and largest city of the province of Saskatchewan, Can., is located in the south central part of the province, 357 mi. W. of Winnipeg. Founded in 1822 as Pile O' Bones and renamed Regina, it was capital of the Northwest Territories from 1882 to 1905, having been chosen because of its central location on the Canadian Pacific railway, and was selected as capital city when Saskatchewan became a province in 1905.

Regina is a busy distribution centre serving a rich agricultural area. Both major Canadian railway systems serve the city and five main highways converge on it, one of these the Trans-Canada. Regina is on the main Trans-Canada Air line and has regular air service with. most other Saskatchewan cities. It has good daily newspaper service, a television station on a national hookup and three radio stations. It obtains abundant natural gas from provincial sources and uses local artesian and Saskatchewan river water for domestic and industrial needs.

Regina experienced rapid physical expansion and economic development after World War II and became an important prairie manufacturing centre. Its industry includes two large oil refineries, one co-operatively owned; extensive assembly plants; a cement plant; a brewery; and various services to the petroleum and agricultural industries. A steel production and fabricating industry was established in the early 1960s.

Regina is the provincial government seat, with its legislative and administration buildings, various government and educational institutions including a provincial university college. several affiliated colleges and the provincial natural-history museum. It is the headquarters for Canada's largest co-operative, the Saskatchewan Wheat Pool. and has been an important centre in the growth of the co-operative movement in Canada. Pop. (1961) 112.141. (C. S. BR.)

REGINON (REGINO OF PRÜM), medieval chronicler, was born at Altripp near Spires, and was educated in the monastery of Prüm. There he became a monk, and in 892, just after the monastery had been sacked by the Danes, he was chosen abbot. In 899, however, he was deprived of this position and he went to Trier, where he was appointed abbot of St. Martin's. He died in 915, and was buried in the abbey of St. Maximin at Trier, his tomb being discovered there in 1581.

Reginon wrote a Chronicon, dedicated to Adalberon, bishop of Augsburg (d. 909), which deals with the history of the world from the commencement of the Christian era to 906, especially with the affairs in Lorraine. The chronicle was first published at Mainz in 1521; another edition is in Band I. of the *Monumenta Germaniae* historica. Scriptores (1826); the best is the one edited by F. Kurze (1890); German trans. by W. Wattenbach (1890). Reginon also drew up at the request of his patron, Radbod, archbishop of Trier (d. 915), a collection of canons, Libri duo de *synodalibus causis* et disciplinis ecclesiasticis; this is published in Migne's Patrol. Lat. t. 132.

REGIOMONTANUS: *see* MÜLLER, JOHANN (REGIOMONTANUS).

REGIONALISM. The clustering of men into areas and regions of all kinds is one of the enduring facts of history. Specific regions, such as Kashmir or Scandinavia. England's black country

or the Donetz basin, the Tirol or Texas, often mirror a more faithful palimpsest of history than does history itself. Regionalism, that is, the doctrine and practice of geographic grouping according to selected criteria of cohesiveness. prevails among mankind simply because human beings are gregarious yet spacebound. Even nomads have to delimit the region over which they roam. The most extended domain in history previous to that of modern Russia was Genghis Khan's Mongol empire, stretching from Peking to Vienna; but even his dynamic hordes had to fall back upon their own grazing regions on the Asian steppe.

Social and Geographic Factors. — Regionalism, as a concept expressing spatial relationship, is to the social sciences what ecology is to the biological sciences and what the newer field theory is to the physical sciences. In defining regions, two classes of criteria are employed: the physical factors of geography, climate or natural resources; and the social phenomena of culture, economics or government. For a region must not only have a geographic framework; it must also possess sufficient cohesion among its occupants and homogeneity in conditions to allow it to deal with common concerns and to differentiate itself from other regions. It is hard to tell where to draw the boundary line. But, by concentrating on the regional core instead of the margins, it is possible to delimit a region or set of regions.

The most tenacious type of region known to man is the resource-based region administered by the political arm of society. The ancient river basins, for example, with their irrigated alluvial lands, were the sites of the original city-states and the riverine societies of Mesopotamia, Egypt, India and China. Associated with their origins were such concrete regional devices as the irrigation province. Indeed, the Egyptian hieroglyphic for "province" was a pictograph denoting irrigation. It is no wonder that 20th-century reconstruction programs in these ancient countries stress river-basin development and regional administrative authorities; *e.g* , the Damodar Valley corporation in India, a nation which in the second half of the 20th century was trying to reconcile its older, cultural regions with its newer, political ones.

Regionalism was also being fostered by means of technical assistance programs sponsored by the more developed countries and the United Nations. The UN charter specifically recognizes international "regional arrangements" (art. 52), and those UN agencies that were concerned with economic and social development on a broad regional basis, such as the UN Economic Commission for Latin America (ECLA), were vigorously supported. Other operating regional undertakings of international scope were found in western Europe, where the Benelux customs union, European Coal and Steel Community (E.C.S.C.) and Euratom co-ordinated the resources and productivity of blocs of nations with a long history of mutual antagonism. *(See* PAN-EUROPEAN MOVEMENT.)

The most genuine forms of regionalism have appeared within individual nations, with their greater homogeneity. although the cultural and class cleavages which cut across the most cohesive political regions should not be underestimated. All modern nations subdivide their territory into counties, states, provinces or other regions; and often these are not merely convenient administrative districts for the central authority but possess a distinct autonomy as do, for example. the cantons of the Swiss confederation. However, the degree of regionalism does not depend on whether a government is federal or unitary in character, since regions appear under various guises in different nations.

United States and Great Britain. — The United States of America has produced some of the richest forms of regional differentiation and decentralization, despite its national stereotypes and standardized economy. Its politically powerful states, although often artificially bounded by straight lines, established unique regional patterns. True, this led to the traumatic experience of civil war, and an anachronistic racial discrimination persisted in the south into the second half of the 20th century. But there also was established the Tennessee Valley authority, an inspiring regional experience more copied abroad than at home A whole series of other inventive American devices were contrived, involving river-basin development and regional resources administration, interstate compacts and intergovernmental agencies. federal decentralization and metropolitan reorganization. These changes were accompanied by detailed researches of particular regions and scientific studies about regionalism unmatched anywhere in the world.

British regionalism was particularly instructive. Centrally guided by Whitehall, Britain's spreading conurbations and parochial countryside were diligently administered by counties, boroughs. county boroughs and by urban, rural and special districts. But a nostalgic regionalism continued to prevail, and there mas even a tenacious nationalism in the form of separate cabinet ministries for Scottish affairs and Welsh education. Under the stress of World War II a dozen defense regions were established with certain civil functions. but these lapsed in peacetime.

Europe. — With its roots in the power-centred Roman empire, modern Italy originally rejected a system of regional autonomy advocated by its founders, Cavour and Mazzini. Following World War II, Italy revised its centralized arrangement in favour of a partial system of regional devolution. Spain exhibited more widespread agitation for regional independence to its "small fatherlands." but in practice Spanish regionalists exacted little from their rulers.

Regionalism has long stalked through French history under the banners of recalcitrant Burgundians and revolutionary Girondists Napoleon, himself a little corporal from Corsica. erased at one stroke three dozen historic provinces in favour of 90 administrative *départements,* which governed 19th- and 20th-century France. But fiery French poets and provincial intellectuals, who coined the very word "regionalism" in the 1870s, restored the regional spirit.

Modern Germany curbed its regional particularism, without entirely destroying the pride of Bavaria or Hanover, by combining Prussian centralization with joint authorities for special purposes. After defeat in World War II, the German Federal Republic mas compelled to decentralize and to reconstitute its *Lander,* enhancing the movement toward regional "rationalization." Less rational but more experimental was Russian regionalism. Like the tsars. the Communists struggled with the administration of their vast Eurasian expanses and their profusion of nationalities. But Russian enthusiasm for autonomous republics. federated regions, economic development areas and other deviations from "democratic centralism" could not hide the fact that the U.S.S.R. was still struggling to free itself from a top-heavy administration at the monolithic centre in order to release human talent at the regional periphery.

Speedier communications and wider-ranging administration had in the second half of the 20th century enabled man to expand his regional influence until he was tampering with interstellar space. But modern technology also had a distinctly decentralizing and regionalizing impact upon economic development and especially upon the devolution of governmental power. The urge of human intimacy continued to tie man to his sense of place. and modern complexity compelled him more than ever to seek the coherent community and the balanced region.

For a discussion of literary regionalism, *see* the various articles on national literatures. The principal regions of the U.S. are discussed in NEW ENGLAND; SOUTH, THE; MIDDLE WEST, THE; and WEST, THE. For the U.S. frontier as a region with a distinctive outlook and culture, *see* AMERICAN FRONTIER. (A. LY.)

REGIONAL PLANNING, a term used by political scientists. engineers, sociologists. geographers and others to describe the process of considering systematically the functional organization of the natural and human resources of an area of the earth. Regional planning may involve extensive areas that include one or more nations or more limited areas such as drainage basins or metropolitan areas. The objectives may be general or specific. Examples of international regional planning include the European common market and the Colombo plan (*q.v.*), involving whole nations, the St. Lawrence seaway (*q.v.*) and the Nile valley and Amur river schemes, involving parts of two or more nations. In many instances a regional plan involves the creation of a new organization for its particular purpose as, for example, the Tennessee Valley authority, the boundaries of whose area coincide

with those of no general political jurisdiction but which in its operation involves the co-operation of several to their mutual advantage.

Regional planning is essentially a process of orderly and systematic anticipation of the future of a region, involving recommendations of the necessary remedial and constructive actions by public and private agencies to achieve the objectives of the plan. In one sense it is as old as society. In modern times. significant contributions to knowledge of planning principles have been made by geographers who are concerned with the nature of man's occupancy of the earth and of its regional similarities and differences; by economists whose concerns include the flows of goods, money and credit to, from, and within regions as well as theories relating to the location of economic activity; by sociologists who are concerned with the regional aspects of the organization of society and of social action; by political scientists whose concern includes the institutional means by which plans are made and effected; by psychologists, philosophers and others concerned with motivation and the setting of social goals; by engineers, architects and others concerned with the physical structures and forms involved in man's utilization of resources; and by specialists in many other fields.

Planning does not set goals or objectives within a society; it rather points out the consequences of alternative decisions relating to the utilization of resources and the organization of society in space and recommends programs of action considered most appropriate and effective in the light of the objectives which the particular society sets for itself.

The Nature of Regions.— Regions are human creations for the purpose of analysis, synthesis and planning. The extent and character of a region will depend upon the purpose or purposes for which it is created and the number of possible regions is infinite. Geographers recognize two types: homogeneous and nodal. Homogeneous regions are areas nithin which, for the purposes for which the region is being defined, the similarities from place to place are considered to be more significant than the differences. Such similarities may be in a single element, such as climate, soils, population density, drainage characteristics, religion or language. For multipurpose planning or comprehensive planning a combination of elements is employed in defining a region; two or more of these may exhibit coincidences in their variations or may on the other hand show no significant variations from place to place within the region. The second type of region is the nodal region, which is an area of concentration of elements or activities, such as an urban or metropolitan area or the intensively developed core of a more extensive homogeneous region.

A major difficulty in preparing and especially in effecting a regional plan is that most appropriate real units very rarely coincide with a governmental jurisdiction. Metropolitan areas such as New York. Chicago, London. Tokyo and Paris involve many municipalities and other units of local government; river basins seldom are included entirely within individual states or provinces and many of them such as the Rhine, Rio Grande, Columbia and Congo, are international. The co-ordination of capital improvement programs of a multiplicity of units of government presents a challenge to the planner. In some instances the problem can be solved by the creation of new units of government, such as the metropolitan municipality of Toronto and the various types of special-function authorities such as the Port of New York authority. the metropolitan sanitary district of Greater Chicago and the Tennessee Valley authority.

The Process Of Regional Planning.— Whether the planning is for a homogeneous or a nodal region. whether comprehensive or special-purpose, and whether undertaken by a regular governmental unit, a special public agency or a private organization, it involves several steps: (1) inventory and survey of the resources or other elements relative to their character, quantity, quality, availability and distribution within and without the area; (2) analysis of the relationships among the natural and human resources of the region and of their significance; (3) making of the plan. including proposals for maximizing the effectiveness of utilization of the resources in terms of the plan objectives, and recommendations as to the staging or timing of the various proposed steps; and (4) effectuation of the plan, including the carrying out of the responsibilities of the various bodies and agencies concerned with each aspect of the regional development. The first three steps generally involve the planning agency directly; most planning agencies do not have the responsibility of effectuation but rather recommend the necessary steps to the appropriate agencies and at times may suggest the creation of new agencies for specific purposes. Inventory, analysis and the making of the plan involve the efforts of many specialists, and the professional planner is essentially a co-ordinator. Once a plan is prepared and adopted, it is essential, in most instances, that it be subjected to continuous or periodic review and revision in the light of subsequent developments. The continuity of operation of planning agencies is therefore important. The nature of the process of effectuation, of course, varies with the nature of the government and other institutional operations in the region or for the objectives of the particular plan. In some countries, as in the Soviet Union, effectuation of a plan is by a central authority with absolute powers; in democratic countries the authorities are responsible directly to the public and in many instances the plan or major elements of it may be subject to referendum. In most instances, legislative bodies within areas of appropriate jurisdiction adopt either total plans or the individual proposals contained within the plans. Educational programs and information services on the nature of planning and the objectives and content of specific plans are therefore essential aspects of planning in democratic countries. Most regional planning involves multiple purposes and the regions are demarcated in such a way as to serve the maximum number of purposes with the maximum effectiveness. The conservation movement in the United States in the early 20th century was an important incentive to regional planning; later the multipurpose development of water resources, as in the Tennessee valley and the Columbia basin, constituted an important type of regional planning. Meanwhile, the spread of cities beyond the boundaries of municipalities and the development of metropolitan areas and conurbations became important incentives for another type of regional planning, typified in the United States by the Burnham plan of Chicago, published in 1909, the Regional plan of New York city and its environs, in the 1920s, and the creation of many metropolitan planning agencies in the 1950s, and in Great Britain by the numerous regional planning schemes of the period during and shortly after World War II.

Aspects of Regional Planning.— Much of the concern of regional planning relates to two aspects of man's relations to regional resources. The first may be termed the static aspect, and it includes those features, tangible and intangible, which have fixed locations at any point in time, such as land uses, buildings, population distribution and other features of culture; the second may be termed dynamic and refers to the interchange of people, goods and ideas within and among regions and places. as expressed by transportation facilities and the flows of traffic as well as by communication. No place or region can be completely self-sufficient; each has innumerable bonds with other regions and places. The strength and relative importance of these bonds vary with the size. distance and complexity of the various regions and places and are subject to change with the existence and utilization of alternative opportunities represented by competing regions and places, the possibility of substitution of resources of other places or of other types. changes in the material or intangible cultures of the respective regions, and the competition among alternative routes and forms of transportation. Transportation makes regional specialization possible, and the planning of facilities for the handling of movement to, from, and within regions has become an important aspect of regional planning. In many regions of the world where economic development has been retarded by inadequate transportation facilities. a major concern of regional planning is the selection of appropriate forms of transportation, as between railnays, highways. airways and inland and coastal waterways, and the determination of the amount and routes of transportation to be recommended. In the United States, the Federal Highway act of 1956, which provided for a

new 41,000 mile interstate highway system, was a stimulus for the organization of regional planning in many areas, as was the focusing of the highway networks upon urban centres and the stimulation of peripheral expansion of population and development within and beyond metropolitan areas as a result of the increased availability of motor transportation.

Regional planning on the one hand is an extension of local planning at the municipal and county level and on the other hand is a part of national and international planning. In the United States regional planning was stimulated in the 1930s by the National Resources Planning board, which was terminated with the advent of World War II. In the second half of the 20th century, however, numerous state planning agencies were in operation, as well as a number of metropolitan and *ad hoc* regional planning agencies.

REGIUM, a city of the territory of the Bruttii in south Italy, on the east side of the strait between Italy and Sicily *(see* REGGIO DI CALABRIA). A colony, mainly of Chalcidians, partly of Messenians from the Peloponnesus, settled at Regium in the 8th century B.C. About 494 B.C., Anaxilas, a member of the Messenian party, made himself master of Regium (apparently with the help of the Samians; *see* MESSINA) and about 488 joined with them in occupying Zancle (Messina). In 433 Regium made a treaty with Athens and in 427 joined the Athenians against Syracuse, but in 415 it remained neutral. An attack which it made on Dionysius I of Syracuse in 399 was the beginning of a great struggle which in 387 resulted in its complete destruction and the dispersion of its inhabitants as slaves, but it soon recovered its prosperity. In 280 Pyrrhus invaded Italy, and the Regines admitted within their walls a Roman garrison of Campanian troops; these mercenaries revolted, massacred the male citizens, and held the city till in 270 they were besieged and put to death by the Roman consul Genucius. The city remained faithful to Rome throughout the Punic Wars, and Hannibal never succeeded in taking it.

It took the name Regium Iulium under Octavius (Augustus); and the pedestal of a statue erected in his honour (as Augustus) has been found there. It continued to be a Greek city even under the empire. Toward the end of the empire it was made the chief city of the Bruttii.

REGIUM DONUM or ROYAL GIFT, an annual grant formerly made from the public funds to Presbyterian and other Nonconformist ministers in Great Britain and Ireland. In 1690 William III made a grant of £1,200 a year to the Presbyterian ministers in Ireland as a reward for their services during his struggle with James II. Because of the opposition of the Irish house of lords, the money was not paid in 1711 and some subsequent years, but it was revived in 1715 by George I, who increased the amount to £2.000 a year. Further additions were made in 1784 and in 1792, and in 1868 the sum granted to the Irish Presbyterian ministers was £45,000. The Regium Donum was withdrawn by the act of 1869 which disestablished the Irish church. Provision was made, however, for existing interests therein, and many Presbyterian ministers commuted these on the same terms as the clergy of the church of Ireland.

In England the Regium Donum proper dates from 1721, when Dr. Edmund Calamy (1671–1732) received £500 from the royal bounty "for the use and behalf of the poor widows of dissenting ministers." Afterward this sum was increased to £1,000 and was made an annual payment "for assisting either ministers or their widows," and later it amounted to £1,695 per annum. It was given to distributors who represented the three denominations, Presbyterians, Baptists and Independents, enjoying the grant.

Among the Nonconformists themselves, however, or at least among the Baptists and the Independents, there was some objection to this form of state aid. and it was withdrawn in 1857.

See J. Stoughton, *History of Religion in England* (1901); J. S. Reid, *History of the Presbyterian Church in Ireland* (1867); and E. Calamy, *Historical Account of My Own Life,* ed. *by* J. T. Rutt (1829–30).

REGNARD, JEAN FRANÇOIS (1655–1709), French dramatist, one of the most successful of Molière's immediate successors. Baptized in Paris on Feb. 8, 1655, he inherited a fortune and traveled widely in his youth (he was a prisoner of the Algerian corsairs for seven months, 1678–79). He held a post in the financial administration in Paris, but from 1688 devoted himself almost entirely to the theatre. writing first for the Italian comedians, then, from 1694, for the Comédie Française. He 'also published accounts of his travels. Of his numerous plays, the best-known are *Le Joueur* (1696) and *Le Légataire universel* (1708). but *La Sérénade* (1694), *Le Distrait* (1697), *Démocrite* (1700), *Les Folies amoureuses* (1704) and *Les Ménechmes, ou les Jumeaux* (1705) also helped to make his reputation. He imitated both the Italians and Molière quite openly. Regnard died on his estate of Grillon, in Normandy, on Sept. 4, 1709.

There are collected editions of his works by E. Fournier, 2 vol. (1854) and by A. Michiels (1875) and selections ed. by G. d'Heylli, 2 vol. (1886).

See P. Toldo, "Études sur le théâtre de Regnard," *Revue d'histoire littéraire de la France* (1903–04); *H.* C. Lancaster, *History of French Dramatic Literature in the 17th Century,* part iv (1940).

(W. G. ME.)

REGNAULT, (ALEXANDRE GEORGES) HENRI (1843–1871), French painter of allegorical and historical subjects, was born at Paris on Oct. 31, 1843, the son of the scientist Henri Victor Regnault (*q.v.*). He studied successively under Antoine A. Montfort, Lamothe and Alexandre Cabanel, and in 1864 exhibited two portraits at the Salon. In 1866 he won the Grand Prix with "Thetis Bringing the Arms Forged by Vulcan to Achilles." In Rome Regnault came under the influence of the modern materialistic Hispano-Italian school. His paintings include an imaginative portrait of the Spanish soldier Marshal Prim at the head of his troops, inspired by a glimpse of his subject received when traveling in Spain; "Judith" (1870), "Salome" and the realistic "Execution Without Hearing Under the Moorish Kings," painted at Tangiers. Regnault was killed in the Franco-German War on Jan. 19, 1871. There is a monument to his memory at the École des Beaux-Arts.

REGNAULT, HENRI VICTOR (1810–1878), French chemist and physicist, who worked on the problem of the expansion of gases by heat, was born on July 21, 1810, at Aix-la-Chapelle. His early life was a struggle with poverty. He worked in a textile establishment in Paris until 1829 and then entered the École Polytechnique, passing in 1832 to the École des Mines. After studying under Justus von Liebig (*q.v.*) at Gressen, Ger., he was appointed to a professorship at Lyons. His most important contribution to organic chemistry was a series of researches, begun in 1835, on the halogen and other derivatives of unsaturated hydrocarbons. He also studied the alkaloids and organic acids, introduced a classification of the metals and effected a comparison of the chemical composition of atmospheric air from all parts of the world. In 1840 he became professor of chemistry in the École Polytechnique in succession to Gay-Lussac and was elected a member of the Académie des Sciences; in 1841 he succeeded Pierre Louis Dulong (*q.v.*), professor of physics in the Collège de France. In 1847 he published a four-volume treatise on chemistry which was translated into many languages. Regnault's work in physics was remarkably accurate and painstaking. He designed standard types of apparatus for a large number of measurements.

Regnault executed a careful redetermination of the specific heats of many solids, liquids and gases. *(See* CALORIMETRY.) He

investigated the expansion of gases by heat. and showed that, contrary to previous opinion, no two gases had precisely the same coefficient of expansion. By delicate experiments he proved that Boyle's law is only approximately true for real gases. He studied the subject of thermometry (*q.v.*) critically; he introduced the use of an accurate air-thermometer. and compared its indications with those of a mercurial thermometer, determining the absolute expansion of mercury as a step in the process. He also paid attention to hygrometry and devised Regnault's hygrometer.

In 1854 he was appointed director of the porcelain manufactory at Sèvres. He carried on his great research on the expansion of gases in the laboratory at Sèvres. but all the results of his latest work were destroyed during the Franco-German War, in which also his son Henri (*q.v.*) was killed. Regnault never recovered from the double blow. and. although he lived until Jan. 19, 1878, his scientific labours ended in 1872. Regnault's most important work is collected in vol. 21 and 26 of the *Mdmoires de l'Académie des Sciences*.

RÉGNIER, HENRI FRANÇOIS JOSEPH DE (1864–1936). the foremost French poet of the first decade of the 20th century, was born at Honfleur on Dec. 28, 1864. of an old Norman family. Going to Paris to study law, he came under the influence of the Symbolist poets there. His first books of poems, *Lendemains* (1885), was followed by several other minor collections, eventually reprinted in two volumes, *Podmes 1887–1892* (1895) and *Premiers podmes* (1899). In 1896 he married the poet J. M. de Heredia's daughter Marie, herself later well-known as a poet under the pseudonym Gérard d'Houville.

By this time Régnier showed a preference for themes from classical antiquity or from the Renaissance, so that while the personal quality of his approach and certain metrical licences still reflected the Symbolist influence, his subject matter came to be more like that of his Parnassian father-in-law. His most characteristic poems in this style appeared in *Les Jeux rustiques et divins* (1897), *Les Médailles d'argile* (1900). *La Cite' des eaux* (1902), mainly about Versailles, *La Sandale ailée* (1906) and *Le Miroir des heures* (1910). His aristocratic manner distinguished him from his more bohemian contemporaries, and he became the favourite poet of *la belle époque*. He was elected to the Académie Française in 1911 (received 1912). He published some patriotic verse in *1914–1916* (1918), but his only major collections of poems after World War I were *Vestigia flammae* (1921) and *Flamma tenax, 1922–1928* (1928). From 1894. however, Régnier had been publishing also novels and short stories, in which he combined realism with a hedonistic attitude to morality. These include *Contes à soi-même* (1894; reprinted in *La Canne de jaspe,* 1897), *La Double Maîtresse* (1900), *La Peur de l'amour* (1907), *L'Amphisbène* (1912), *Romaine Mirmault* (1914). *La Pkcheresse* (1920), *Le Divertissement provincial* (1923) and *Le Voyage d'amour* (1930). Henri de Régnier died in Paris on May 23, 1936.

RÉGNIER, MATHURIN (1573–1613), French satirist, was born at Chartres on Dec. 21, 1573, the son of Jacques Regnier, and Simone Desportes, sister of the poet. Little is known of his youth, except that he received the tonsure at eight years old, and it is chiefly conjecture which fixes the date of his visit to Italy in a humble position in the suite of the cardinal, François de Joyeuse, in 1587. Régnier found his duties irksome, and when, after many years of constant travel in the cardinal's service, he returned definitely to France about 1605, he took advantage of the hospitality of Desportes. In 1606 Desportes died and Régnier obtained a pension of 2,000 livres, chargeable upon one of Desportes' benefices. He was also made in 1609 canon of Chartres through his friendship with the lax bishop, Philippe Hurault, at whose abbey of Royaumont he spent much time in the later years of his dissipated life. The death of Henry IV. deprived him of his last hope of great preferments. He died at Rouen, Oct. 22, 1613.

His undoubted work falls into three classes: regular satires in alexandrine couplets, serious poems in various metres, and satirical or jocular epigrams and light pieces, which often, if not always, exhibit considerable licence of language. The real greatness of Régnier consists in the vigour and polish of his satires, contrasted and heightened as that vigour is with the exquisite feeling and melancholy music of some of his minor poems. He was an acute critic. and the famous passage (Satire ix., *À Monsieur Rapin*) in which he satirizes Malherbe contains the best denunciation of the merely "correct" theory of poetry that has ever been written. All Régnier's merits are displayed in the masterpiece entitled *Macette ou l'Hypocrisie déconcertée,* which does not suffer even on comparison with *Tartufe;* but hardly any one of the 16 satires which he has left falls below a very high standard.

REGNITZ, a river of Germany, 42 mi. long, and a left-bank tributary of the Main. It rises in the Jurassic rocks of the Frankish Jura, but its course is along the Trias. through an undulating vine-clad country, past Fiirth, Erlangen, Baiersdorf and Forchheim, from which point it is navigable, and joins the blain at Bischberg. below Bamberg. The Ludwigs canal connects it with the Main and the Danube. Its main tributaries are the Pegnitz, on which is Nurnberg, the Gründlach and the Wiesent (right) and the Zenn, the Aurach and the Aisch (left). *(See* MAIN and RHINE.)

REGULATORY AGENCIES. Administrative regulation is a basic feature of 20th-century government that sharply distinguishes it from government in the 19th century. Formerly governmental regulation was provided for almost entirely by statutes, whose prescriptions were enforced through the traditional machinery of the courts. Such legislative regulation proved inadequate to deal with the complexities of a modern industrial economy. In its place, there developed a system of administrative regulation. Under it, the legislature provides only the broad principles of a particular regulatory scheme, leaving their detailed implementation to the agency charged with administering the law. The latter is vested with the power to prescribe regulations having the force of law, to police those subject to its authority to ensure that such regulations are not violated, and to decide cases involving alleged particular violations. The administrative agency is able to furnish the continuous supervision and expert knowledge that cannot, as a practical matter, be expected of the legislature.

United States.—The need for administrative regulation first became apparent in the United States in the railroad industry. and it was out of the attempts to deal with the railroad problem that the first modern U.S. administrative agency, the Interstate Commerce commission (ICC), was developed. Established by the Interstate Commerce act of 1887 and with its power expanded by the Hepburn act of 1906 and subsequent statutes, it is composed of 11 members appointed by the president, and confirmed by the senate, who serve for staggered terms of seven years. The commissioners may be removed only for cause and have, in practice, been able to function free from direct presidential control. This has led some to characterize them as a "headless fourth branch" of the government.

ICC is the classic example of a quasi-judicial regulatory agency. As such, it applies the broadly stated legislative policies to concrete cases by a procedure patterned upon that of the courts. The commission fixes reasonable rates and ensures that they are observed. It grants licences to those seeking to engage in interstate transportation. It exercises injunctive power over discriminatory practices. The commission also performs important nonjudicial functions. It promulgates safety and other regulations. It controls railroad financing and planning. It is the commission which gives specific form and content to the congressional policies expressed in the Interstate Commerce act as amended. Its position has been compared to that of a superboard of directors of the railroad industry. It also has extensive authority over motor carriers. *(See* also INTERSTATE COMMERCE)

The assertion of governmental control in other economic fields led to the creation of many other regulatory agencies modeled upon the ICC, chief among these being the Federal Trade commission (FTC; 1914), Federal Power commission (FPC; 1920), Federal Communications commission (FCC; 1934), Securities and Exchange commission (SEC; 1934) and Civil Aeronautics board (CAB; 1938). *(See* COMMISSION.) In addition, regulatory powers were conferred upon the ordinary executive departments; *e.g.,* the department of agriculture under the Packers and Stock-

yards act, 1921, and the Agricultural Adjustment act, 1938. As traditional legal devices proved inadequate to cope with economic abuses. they were superseded by administrative controls. This was especially true of the period following the depression of the early 1930s. The New Deal program was largely carried out through administrative regulation. During the same period, a comparable development took place in the states.

Other Countries. — Administrative regulation is not a purely U.S. phenomenon. Similar problems have given rise to the creation in other countries of some analogous regulatory agencies. In England the starting point was the setting up of the Railway and Canal commission in 1888. In 1921 the Railway Rates tribunal was established to fix railroad rates. With the nationalization of British railways in 1947, these bodies were superseded by the Transport tribunal. which determines the rates to be charged by the governmental operator of the nationalized industry, English motor transport is regulated by licensing authorities, which grant licences and control road service. Similar regulation is provided for in other areas, such as the marketing of agricultural products.

There is, however, an important difference between administrative authority in the United States and that in other countries. Administrative regulation is basically of two kinds. In certain fields the normal rules of free competition are recognized to be inapplicable. In them, the state tolerates the existence of virtual monopolies, but by regulation it ensures that the monopolistic power shall not be abused. This is the usual practice regarding public utilities. In other areas, free competition governs but the state intervenes to prevent abusive practices conceived deleterious to the working of a free competitive system. Thus, the FTC was established in the United States to prevent unfair trade practices.

In other countries. there is less room for these types of administrative regulation than in the United States. In the field of public utilities the dominant theme is not regulation but operation. Toward abusive practices other governments also tend to adopt more of a hands-off policy than does the U.S. This applies in both Britain and in continental European countries, though less so in the former in view of the specific types of British regulation already mentioned, as well as the setting up in 1948 of a Monopolies and Restrictive Practices commission patterned upon the U.S. Federal Trade commission.

Abuses **of** Administrative Power. — Administrative regulation enables government to cope with the need to control economic power in the public interest. But at the same time raises the basic problem of whether the regulator himself is adequately controlled for the executive and legislature are responsible to the people whereas the administrator has no analogous responsibility. In democratic countries, he is, it is true, responsible to the law, but this "rule of law" becomes less effective under statutes delegating wholesale discretion. Under such "skeleton" legislation, the flesh and the blood (not to mention the soul) of regulation are left to the administrator. Excessive discretion opens the door to administrative arbitrariness.

The growth of administrative regulatory power was accompanied by the development of safeguards to ensure against administrative abuses. In the U.S. the emphasis is upon procedural devices and judicial review. Due process (*q.v.*) requires that, before administrative action adversely affects an individual, he be given notice and a full opportunity to be heard. Such hearings must include the essentials (though not the forms) of judicial procedure. The fundamentals of fair administrative procedure were prescribed in the Federal Administrative Procedure act, 1946, and in similar laws in many states. Those aggrieved by administrative action can obtain review in the courts. In Anglo-American countries such review is in the ordinary courts. In France and many civil-law countries there is a special administrative-court system to review the legality of administrative action. There is also legislative control. This is most fully developed under parliamentary systems; *e.g.,* in Britain, where administrative regulations are subject to direct annulment by parliament. In the United States, control by the congress did not prove effective in practice, though attempts were made to remedy the situation in the Legislative Reorganization act, 1946, by giving standing congressional committees direct responsibility over administrative agencies. This did not prove workable because of the preoccupation of such committees with other matters and their lack of adequate expert staffs.

REGULUS, MARCUS ATILIUS, Roman general and consul (for the second time) in the ninth year of the First Punic War (256 B.C.). He was one of the commanders in the naval expedition which shattered the Carthaginian fleet at Ecnomus, and landed an army on Carthaginian territory *(see* PUNIC WARS).

The other consul was recalled, Regulus being left behind to finish the war. After a severe defeat at Adys near Carthage, the Carthaginians were inclined for peace, but the terms proposed by Regulus were so harsh that they resolved to continue the war. In 255 Regulus was completely defeated and taken prisoner by the Spartan Xanthippus. There is no further trustnorthy information about him. According to tradition, he remained in captivity until 250, when after the defeat of the Carthaginians at Panormus he was sent to Rome on parole to negotiate a peace or exchange of prisoners. On his arrival he strongly urged the senate to refuse both proposals and, returning to Carthage, was tortured to death (Horace, *Odes,* iii, 5). The story is insufficiently attested; it may have been invented to excuse the treatment of Carthaginian prisoners at Rome but it served to make Regulus the type of heroic endurance to the later Romans.

REHABILITATION, MEDICAL AND VOCATIONAL. Rehabilitation has been defined as the ultimate restoration of the disabled person to his maximum physical, emotional, social and vocational capacity. This article will discuss first the medical and then the vocational aspects of rehabilitation.

MEDICAL REHABILITATION

Medical rehabilitation frequently has been termed the third phase of medicine and surgery, following preventive medicine and curative medicine and surgery. Its objectives are: first, to eliminate the physical disability if that is possible; second, to reduce or alleviate the disability to the greatest extent possible; and third, to retrain the person with a residual physical disability to live and work within the limits of his disability and to the extent of his capabilities.

Much of the interest in expanding rehabilitation opportunities and services for the handicapped resulted from World Wars I and II, when attention was drawn to the problems of disabled servicemen. Interest also was heightened later by the increase in the age of the population in many parts of the world. In the developed parts of the world, rehabilitation services for the handicapped became a part of an expanding consciousness of social welfare that was reflected in similar advances in all educational, health and social services.

Except in a few isolated instances, the physically handicapped person must be retrained to walk and travel, to care for his daily needs, to use normal methods of transportation, to use ordinary toilet facilities, to apply and remove his own prosthetic devices and to communicate orally or in writing. These are such simple things that they are frequently overlooked, but the personal, vocational and social success of the handicapped person is dependent upon them.

Outstanding rehabilitation programs in various parts of the world have demonstrated that rehabilitation to the point of self-care and even to full or limited employment is possible for many persons who have been hospitalized for long periods.

Information about the number of persons who require rehabili-

tation world-wide is meagre and inexact because of a lack of reporting facilities, such as exist in some local and state health departments for collecting data on communicable diseases, and varying definitions of physical disability., It was estimated that on an average day in the U.S. in 1954 there were approximately 2,900.000 persons of ages 14–64 who were unable to work or follow other normal activities because of physical or mental disease or impairments. .When persons under age 14 and over age 64 were included, the total number became 5,300,000 or about 3.3% of the civilian population. Of these persons, 1,200,000 were in institutions. The office of vocational rehabilitation of the U.S. department of health, education and welfare estimated that about 2,000,000 men and women in the United States need vocational rehabilitation in order to engage in suitable employment. Each pear about 250.000 disabled persons are added to the list of those needing vocational rehabilitation. The office of vocational rehabilitation also estimated the total homebound population of the U.S. (*i.e.*, persons of all ages confined to their homes for at least one year but excluding persons in institutions) to be approximately 1,000,000.

Four of the disabling conditions in which medical rehabilitation is used frequently are hemiplegia, paraplegia, cerebral palsy and multiple sclerosis. all of which are discussed below.

Hemiplegia.—One of .the 'major causes of disability throughout the world, and particularly in the northern European and North American countries, is hemiplegia, or paralysis of one side, which is caused by a stroke. Stroke formerly was believed to be a hopeless situation and the patient was relegated to a chronic disease hospital or to a back bedroom to wait until a fatal second, third or fourth attack came. This concept, however, was proved to be invalid.

In a study reported in 1949, it was noted that 90% of the strokes suffered by individuals in the older age groups were caused by thrombosis. or a blocking of the blood supply. For persons who survive six to eight weeks after the initial stroke, life expectancy is about the same as for others of their age who have not had strokes. Thus, even a severe stroke need not mean the end of a productive, useful life. In a study made at Bellevue hospital, New York city. 900 (90%) of 1,000 patients who underwent modern rehabilitation training after strokes were able to walk, meet all the needs of daily living and live noninstitutional lives; 40% were able to return to gainful work.

A program of rehabilitation for the hemiplegic patient has six goals: (1) to prevent deformities; (2) to treat deformities if they occur; (3) to retrain the patient in walking and in going up and down stairs; (4) to teach the patient to perform the activities of daily living and working with the unaffected arm and hand; (5) to retrain the affected arm and hand to their maximum capacity; and (6) to treat facial paralysis and speech disability if they are present.

If treatment of the hemiplegic is started early, *i.e.,* as soon as the patient becomes conscious, there will be no limitation of motion at the joints, and the affected arm and leg can be moved passively through their normal range. If, however, the patient is not given early rehabilitation, contractures usually result, especially at the shoulder. One of the most difficult problems in the medical rehabilitation of the hemiplegic is aphasia (speech impairment'), which may occur in varying degrees and may be permanent or temporary, depending on the type of lesion.

Most patients with hemiplegia caused by a stroke can be rehabilitated within two months.

Paraplegia. — Paraplegia results from the severing of the spinal cord, the patient being left without the power of motion or feeling below the level of the severance. Formerly, most patients suffering such disabilities died within a relatively short time from kidney infections, decubitus ulcers (bedsores) or other complications. Of the 400 Cnited States veterans of World War I thus disabled, only 2 were alive 20 years later. With the 2,503 United States paraplegic veterans of World War II, however. the story was different. More than 80% of them were alive in the early 1950s.

The advances in paraplegic rehabilitation for disabled veterans in Great Britain and the United States were extended to the far greater number of civilians who suffer the same condition as a result of automobile accidents, surf and diving accidents and disease. Although paralyzed from the waist down. these people have demonstrated that with proper rehabilitation they can once again take their places in society as self-sufficient, productive citizens.

When medical and surgical care are completed, the paraplegic is placed on the following program of rehabilitation: General conditioning exercises are performed on a mat on the floor; these include strengthening exercises for the muscles of the upper extremities, abdomen and trunk. Particular attention is paid to development of the latissimus dorsi muscles. which help move the shoulder and upper arm, since they will be important in the use of crutches. The patient is taught to balance while sitting erect. Short crutches may be used to practise push-ups while sitting on a mat. General exercises are followed by a workout in the ambulation room. The patient. who is fitted with braces, is taught to do a swing-to gait and eventually a swing-through on the parallel bars. As he becomes more proficient and his sense of balance improves, he is started on crutches within the parallel bars, after which he is allowed to walk outside the parallel bars with an attendant. and finally alone. Patients are instructed in the necessity for standing in braces and crutches at least one hour a day in order to increase calcium metabolism in the long bones and to prevent formation of kidney and bladder stones. Even if he does not eventually walk to any great extent. the patient is urged to stand up at least one hour a day for the rest of his life.

Cerebral Palsy. — Cerebral palsy (*q v.*) was an almost totally neglected disability for many years but beginning in the late 1940s it gained attention throughout the world. Cerebral palsy is a neuromuscular disability that is caused by congenital or early postnatal damage to the motor centres of the brain. It causes varying disturbances of motor function, such as spasticity, weakness, incoordination. athetosis, rigidity or tremors These dysfunctions may be accompanied by mental retardation, sensory disorders, convulsions, ear and eye disabilities and disorders of behaviour.

Each palsied child must be considered individually He must be provided with the specialized medical. rehabilitation and educational services he needs and then his mental capacities must be evaluated to determine his ability to profit by these services.

Multiple Sclerosis. — This is a chronic, crippling disease of the nervous system that occurs most frequently in persons between the ages of 20 and 40; it also was once considered a hopeless disease. There is no specific diagnostic test; its cause and cure are unknown and the disease is progressive and unpredictable The myelin surrounding the nerves is destroyed in patches and replaced by scar tissue. As a result, nerve impulses do not pass properly from the brain to the muscles and other organs that they activate. Although the disease is progressive and crippling, the life span of most multiple sclerosis patients is not much less than that of persons who do not have the disease.

In rehabilitation, the problems of multiple sclerosis are the same as those of any other chronic. progressive. crippling disease. Progression of the disease. however, must be evaluated: if it outstrips training, the training is obviously wasted. Medical evaluation of the patient must include, in addition to general diagnostic studies muscle and joint range of motion tests.

Other Disabilities. — Medical rehabilitation also can produce good results in patients with chronic arthritis. pulmonary diseases. epilepsy, the chronic degenerative neurologic diseases, and in those patients who hsve hypertensive, arteriosclerotic and rheumatic myocardial and vascular lesions.

Regardless of the disease that causes the disability and regardless of the degree of disability within the individual, experience has shown that there are fen., if any, disabled persons for whom something cannot be done through medical rehabilitation to assist them in reaching a higher level of physical, social or emotional adjustment.

VOCATIONAL REHABILITATION

After World War I, the U.S. federal government and the individual states worked together to provide vocational rehabilitation

services for persons who could be made employable, Studies showed that the federal government recouped in income taxes alone ten dollars for each dollar invested in such services; this program rehabilitates and returns to employment approximately 90,000 persons yearly. The state-federal program of vocational rehabilitation in the U.S., as authorized by federal vocational rehabilitation legislation enacted in 1954, is characterized by its primary concern for disabled persons who can become economically independent. Its objective is to help physically and mentally impaired persons, through the provision of substantial rehabilitation services, to be placed in gainful employment, including sheltered workshop or home employment. These services also are extended to persons who can contribute to the national economy in other ways; for example, homemakers.

The program is organized and administered as a state-federal partnership. Federal responsibilities are discharged by the office of vocational rehabilitation in the department of health, education and welfare. Matching federal grants are made to states for providing rehabilitation services to the disabled and for encouraging them to offer new services and to cover new geographical areas. The office also makes studies, conducts investigations and disseminates information on the needs and capabilities of the handicapped. It provides consultation on specialized aspects of rehabilitation and assists the states in interpreting their programs to the public. Most technical and consultative services reach state agencies through the federal regional representatives.

Actual services to the disabled are provided by public agencies in all of the states. Each agency operates its own program in accordance with a state plan developed in co-operation with the federal office of vocational rehabilitation. A state plan describes the organization of the program, standards of personnel administration and the policies governing program operations. To insure flexibility, a state plan may provide for a decentralization of administration to county or municipal agencies.

Disabled persons are referred to a state rehabilitation agency from many sources—private medical practitioners, hospitals, health departments, public employment offices, public assistance agencies and crippled children's administrations.

Generally, the criteria for eligibility for vocational rehabilitation are these: an individual must have a physical or mental disability that is a substantial handicap to employment; he must be of, or near, working age; and there must be a reasonable expectation that the services will render him fit to engage in remunerative employment. The actual determination of eligibility in each case, however, is a responsibility of the state agency.

The individual receives a thorough examination in which all factors influencing the course and outcome of rehabilitation are evaluated. To the degree needed, this study embraces the individual's personality, intelligence, educational status, work experience. vocational aptitudes, personal and social adjustment, and employment opportunities. On the basis of these data an individual plan of vocational rehabilitation is formulated; the plan sets forth a vocational objective and names the services necessary to attain the objective.

Comprehensive services are available to the disabled under the U.S. program. These include medical diagnosis, individual counseling and guidance. physical restoration, training for a job, transportation, maintenance, occupational tools, initial stocks of goods for small business enterprises, job placement and follow-up. The use of public funds for services other than medical diagnosis, counseling, placement and follow-up depends on the economic status of the client.

In its early years, vocational rehabilitation consisted largely of attempts to "get around" the disability by specialized job training and by helping the disabled to find work. Federal-state action to eliminate or reduce a handicap through medical services first was authorized by federal legislation in 1943. Since that time. emphasis on medical services has increased; in the early 1960s physical restoration services were received by more than half of the persons being rehabilitated and accounted for more than 40% of the expenditures for case services. Among the services included in the term "physical restoration" are medical and surgical treatment; psychiatric treatment; dentistry, nursing, hospital and clinic services; convalescent or nursing home care; drugs; prosthetic devices; physical therapy; occupational therapy; and medically directed speech or hearing therapy. These services are made available only in instances where (1) the clinical status of the individual's condition is stable or slowly progressive (*i.e.*, not acute or transitory); (2) where a favourable outcome may be expected within a reasonable period of time; and (3) where the individual's financial need has been demonstrated.

REHAN, ADA (ADA CREHAN) (1860–1916), U.S. actress, for 20 years star of Augustin Daly's company, whose special gift was for comedy, was born in Limerick, Ire., on April 22, 1860. The family moved to the United States when she was five years old. She made her acting debut in 1873, in *Across the Continent,* a melodramatic potboiler written by her brother-in-law. Oliver Doud Byron. Miss Rehan—who changed her name from Crehan after a printer's error produced it thus on a theatre program—next joined Mrs. Drew's company at the Arch Street theatre in Philadelphia. In 1879. after six years of acting experience in various companies, she joined Daly's company at the Olympic theatre in New York city, remaining Daly's star until his death in 1899. She retired from the stage in 1905, when the artificial 19th-century acting style was giving way to the new naturalism, and died in New York on Jan. 8, 1916. (S. W. H.)

REHOBOAM, last king of the united kingdom of Israel and first king of the southern kingdom of Judah, son and successor of Solomon, began to reign c. 931 B.C. The events are related in I Kings xi–xiv and II Chron. x–xii. Rehoboam was not acceptable to the northern tribes, who recalled Jeroboam (*q.v.*) from his exile in Egypt and made Rehoboam's contemptuous refusal of their demands the occasion for instituting a rival kingdom under Jeroboam (I Kings xii). It is probable that this was done with the encouragement of Egypt. Sheshonk I (Shishak) of Egypt attacked the kingdom of Judah c. 930, and despoiled the temple at Jerusalem of its treasures. Rehoboam's reign mas marked by constant conflict with the northern kingdom of Israel. An unfavourable judgment is pronounced on him by the editor of Kings because he favoured customs connected with Baal worship. The fact that his mother was an Ammonite woman may in some measure account for this. He was succeeded after a reign of 17 years by his son Abijah (in I Kings, Abijam), of whom little is known save a victory over Jeroboam.

REICHENAU, a picturesque island in the Untersee or western arm of the lake of Constance, Baden-Württemberg, Ger., 3 mi. long by 1 mi. broad, and connected with the east shore by a causeway $ mi long. It had 2,034 inhabitants in 1950. The soil is fertile, and excellent wine is produced in sufficient quantity for exportation. The Benedictine abbey of Reichenau, founded in 724, was long celebrated for its wealth and for the services rendered by its monks to the cause of learning. In 1540 the abbey, previously independent. was annexed to the see of Constance. and in 1799 it was secularized. The abbey church. dating in part from the 9th century, contains the tomb of Charles the Fat id. 888), who retired to this island in 887, after losing the empire of Charlemagne.

REICHENBACH, GEORG VON (1772–1826), German

astronomical instrument maker, was born at Durlach in Baden on Aug 24, 1772. By 1796 he mas engaged in the construction of a dividing engine In 1804 he was one of the founders of an nstrument making business in Munich; and in 1809 he helped establish an optical works at Benedictbeuren nhich was later moved to Munich. He withdrew from both enterprises in 1814, and was instrumental in establishing a new optical business, from nhich he retired in 1820. He died at Munich on May 21. 1826

Reichenbach built for F. W. Bessel in 1819 an instrument in which he introduced the meridian or transit circle, combining the transit instrument and the mural circle into one instrument This combination had been introduced earlier, but aith the exception of the transit circle constructed by Edward Troughton in 1806. had not been adopted. Reichenbach's form of instrument came into general use. (S. C HR.)

REICHENBACH, a town of Germany. in the district of Karl-Marx-Stadt, situated in the Vogtland 11 mi S IS'. of Znickau Pop. (1959 est.) 29,937. The earliest mention of the town occurs in a document of 1212. Woolen manufacture was introduced in the 15th century, and took the place of the mining industry. Industries include the manufacture of textile goods and machinery.

REICHSTADT, NAPOLEON FRANCIS JOSEPH CHARLES, DUKE OF (1811–1832), known by the Bonapartists as Napoleon II, was the son of the emperor Napoleon I and Marie Louise. archduchess of Austria. He was born on March 20, 1811, in Paris at the Tuileries palace. He was at first named the king of Rome. after the analogy of the heirs of the emperors of the Holy Roman empire. By his birth the Napoleonic dynasty seemed to be finally established; but in three years it crumbled in the dust. At the time of the donnfall of the empire (April 1814) Marie Louise and the king of Rome were at Blois with Joseph and Jerome Bonaparte, who aished to keep them as hostages. This design, however, was frustrated. Napoleon abdicated in favour of his son; but events prevented the reign of Napoleon II from being more than titular.

While Napoleon repaired to Elba. his consort and child went to Vienna; and they remained in Austria during the Hundred Days (181j), despite efforts made by the Bonapartists to carry off the prince to his father at Paris.

In the settlements of 1814 and 1815 *(see* MARIE LOUISE) the powers opposed all participation of the prince in the affairs of his mother's duchy of Parma. He therefore remained at Vienna.

From this time onward he became, as it were, a pawn in the complex game of European politics, his claims being put forward sometimes by Metternich, sometimes by the unionists of Italy, while occasionally malcontents in France used his name to discredit the French Bourbons. In Nov. 1816 the court of Vienna informed Marie Louise that her son could not succeed to the duchies. This decision was confirmed by the treaty of Paris of June 10, 1817. The title of "duke of Reichstadt" was conferred on him on July 22, 1818. by way of compensation. The upheaval in France in 1830 and the disturbances which ensued led many Frenchmen to turn their thoughts to Napoleon II; but though Metternich dallied for a time with the French Bonapartists, he had no intention of inaugurating a Napoleonic revival. The duke died on July 22, 1832.

REICHSTEIN, TADEUSZ (1897–), Swiss chemist, was born at Wloclawek, Pol . on July 20, 1897. He shared with E. C. Kendall and P. S. Hench the 1950 Nobel prize for medicine "for their discoveries concerning the suprarenal cortex hormones, their structure and biological effects." His family acquired Swiss citizenship in 1914, and he was educated at Zurich. where he obtained his first degree, in chemical engineering (1920), and his doctorate, in organic chemistry (1922). For several years he was engaged in industrial chemical research, but from 1930 onward he held in succession the posts of instructor. assistant to Leopold Ruzicka. assistant professor and associate professor in the department of organic chemistry at the State Technical college, Zurich. In 1938 he was appointed head of the department of pharmacology and director of the Pharmacological institute of the University of Basle, where in 1946 he became head of the organic division and director of the organic laboratories. His investigations were mainly concerned with steroids, particularly uith the hormones of the adrenal cortex. 26 of nhich he and his associates isolated. One of these hormones. isolated and described by Reichstein in 1936 and named by him "Substance Fa," proved to be identical with Kendall's "Compound E," and was later renamed cortisone. Apart from these researches. Reichstein's best-known work is the synthesis of ascorbic acid (vitamin C), which he carried out independently of Sir Norman Haworth and his coworkers. in 1933. (W. J. BP.)

REID, THOMAS (1710–1796), Scottish philosopher, was the critic of David Hume's sceptical empiricism and the first exponent of the so-called philosophy of common sense continued by the "Scottish school." He was born on April 26, 1710, at Strachan, Kincardineshire, the son of a minister and of his wife Margaret Gregory, who belonged to the famous family of mathematicians. He was educated at Marischal college, Aberdeen. where he had as tutor George Turnbull who left an influence on his philosophy, particularly in the use of the appeal to language. After studying theology and being licensed for the ministry in 1731. Reid remained at Marischal college as librarian from 1733 to 1736. From 1737 he held the living of New Machar for 14 years, during which period he was aroused by his study of Hume's *Treatise of Human Nuture* (1739) and began his lifelong task of examining its doctrines. In 1751 he was elected to the chair of philosophy in King's college, Aberdeen, where he remained until in 1764 he succeeded Adam Smith as professor of moral philosophy in the University of Glasgow. During the tenure of his post at Aberdeen he devoted himself to the problems of epistemology raised by Hume, offering the preliminary results of his examination in four graduation addresses delivered to the university (*Philosophical Orations*, 1st ed., by W. D. Humphries. Aberdeen, 1937), which were more fully developed, with special reference to problems of perception, in his first book, *An Inquiry Into the Human Mind, on the Principles of Common Sense* (1764). Further deliberation at Glasgow (where in 1780 he ceased to lecture, in order to devote himself wholly to research) resulted in the *Essays on the Intellectual Powers of Man* (1785; new ed. by 4. D. Woozley, London, New York, 1941), their scope being uider than that of the earlier work, and in the *Essays on the Acttve Powers of Man* (1788), in which he upheld a rationalist theory of ethics against the current subjectivism of Francis Hutcheson and Hume. His only other publications were "An Essay on Quantity" (in the *Transactions* of the Royal society. 1748), *A Brief Account of Aristotle's Logic* (1774) and the posthumous *Statistical Account of the University of Glasgow* (1799). He died on Oct. 7, 1796, four years after the death of his wife and cousin Elizabeth Reid, whom he had married in 1740.

Brought up himself on the theory of ideas (the theory that ideas alone are the direct objects of the mind's awareness) and starting out as a Berkeleian, Reid was shaken out of his acceptance of this orthodoxy by realizing, as he thought, the sceptical lengths to which the theory led in Hume; for it appeared to deprive us of the possibility of knowing almost all that Reid felt convinced that we do know. Finding himself unable to accept Hume's conclusions or to refute the arguments by which they were reached, he set himself to examine the premisses from uhich the arguments started, namely the theory of ideas, and came to the conclusion (at the time bold and original) that the theory was based on no better ground than the prejudices and confusions of philosophers. Against the supposition that the immediate data of perception are ideas or in any way peculiarly mental he argued (1) that it is pure hypothesis. unsupported by evidence; and (2) that it does not perform the function for which it was introduced, since its only result is to leave all questions about the veracity of any perception in principle unanswerable. The latter objection would apply only to a representationalist theory such as Locke's; the former would apply to Berkeley and Hume as well, if Reid's interpretation of them was correct. Reid himself propounded a view of perception which might be called indirect realism. According to this, our senses provided us with immediate sensations (which are neither veridical nor nonveridical), plus a noninf erential belief in the existence of corresponding material objects which cause the sensa-

tions, such a belief being liable—but not committed—to error; the function of sensation is to "suggest" the material objects. Thus Reid attempted to retain what seemed the common-sense elements in Locke's account, without the ideas and inferences from them which appeared both unjustified and fatal to it. As on many other topics, Reid's account of perception is tantalizingly incomplete and, without further explication of the notion of "suggestion," appears liable to criticisms similar to those which he had brought against Locke.

Reid rejected the orthodox representationalist theory of memory on similar grounds. In the first place, he denied the existence of the images which the theory held to be likenesses of the event or situation remembered; in effect he was protesting against being misled by the use of the noun "image" into the supposition that there was a special kind of mental entity of which it was the name. Secondly, the supposition that remembering consists of having images, related in a certain way to their originals, would preclude us from any justification of our memory beliefs. An acceptable theory of memory must be such as would entitle us (1) to claim that at least some remembering is reliable (although not infallible); and (2) to provide criteria for distinguishing correct remembering from misremembering or imagining. In general Reid was objecting, although not with entire clarity or consistency, against the "picture" model which seemed the fatal error of the theory of ideas. While all thought requires an object of thought, this does not necessitate that the object shall exist, even mentally. At times, indeed, Reid advances to a view more in accord with 20th-century thought: namely, that a concept is the meaning of the appropriate word or expression, that to have a concept is to know the meaning of the expression (*e.g.,* to have a concept of circle is to know the meaning of the word "circle") and that to know the meaning of a word, expression or sentence is to know how they are used.

As the founder of the philosophy named after it, Reid may appear to say disappointingly little directly about common sense, but his practice makes his principles reasonably clear. He was claiming, not that common sense is an oracle of truth (this was the view which Kant contemptuously but ignorantly attributed to him), but that there is such a thing as common-sense knowledge, as evidenced partly by the structure of language (which he held, without producing any evidence for it, to be to a high degree uniform from one natural language to another) and partly by the uniformity of our practical conduct.

The business of philosophy is not to challenge what each of us perfectly well knows to be true: for example, that there are material objects of whose existence and character we are aware by perception; that he is a continuing and identical person at least as far back as he can remember; that there are other persons like himself possessing life and intelligence; that he has some freedom of decision and of action; that expectatioh of the future based on experience of the past may be reasonable; and so on. To question such pieces of knowledge as these, as though they were empirical hypotheses to be tested, is to misconceive the philosopher's task, which is rather to attempt to understand more fully and clearly than is required for the unreflective, practical purposes of life the meanings of the propositions concerned. If philosophers had paid more attention to the basic facts and functions of language, they would have avoided the extravagances of scepticism and irrationalism into which they plunged. In emphasizing that the typical philosophical problem is not whether we know that something is the case, but what exactly it is that we do know when we know that something is the case, Reid was pointing the way which much British philosophy followed in the 20th century under the more immediate and more stimulating influence of Ludwig Wittgenstein and of G. E. Moore.

REID, THOMAS MAYNE (1818–1883), better known as MAYNE REID, British novelist, was born at Ballyroney, County Down, Ire., on April 4, 1818. His own early life was as adventurous as any boy reader of his novels could desire. When 20 years old he went to America in search of adventure. He traded on the Red river, studying the ways of the Indian and the white pioneer; he made acquaintance with the Missouri in the same way. In Philadelphia, where he was engaged in journalism from 1843 to 1846, he met Edgar Allan Poe. When the war with Mexico broke out in 1846 he obtained a captain's commission, was present at the seige and capture of Vera Cruz and led a forlorn hope at Chapultepec, where he sustained severe injuries. In one of his novels he says that he believed theoretically in the military value of untrained troops, and that he had found his theories confirmed in actual warfare. He offered his services to the Hungarian insurgents in 1849, raised a body of volunteers and sailed for Europe, but arrived too late.

He then settled in England, and began his career of **a** novelist with the publication, in 1850, of the *Rifle Rangers.* This was followed next year by the *Scalp Hunters.* He never surpassed his first productions, except perhaps in *The White Chief* (1859) and *The Quadroon* (1856); but he continued to produce tales of self-reliant enterprise and exciting adventure in great number. He died in London on Oct. 22, 1883.

See Memoir (1890) by his widow, Elizabeth Mayne Reid.

REID, WHITELAW (1837–1912), U.S. journalist and diplomat, ambassador to Great Britain prior to World War I, was born near Xenia, O., on Oct. 27, 1837. He graduated from Miami university, Oxford, O., in 1856, and spoke frequently in behalf of John C. Frémont, the Republican candidate for the presidency in that year. In 1860 he became legislative correspondent at Columbus for several Ohio newspapers, including the *Cincinnati Gazette,* of which he was made city editor in 1861. He was war correspondent for the *Gazette* in 1861–62, serving also as volunteer aide-de-camp to Gen. Thomas A. Morris and to Gen. William S. Rosecrans in West Virginia, and was Washington' correspondent of the *Gazette* in 1862–68. In 1868 he became a leading editorial writer for the *New York Tribune,* in the following year was made managing editor, and in 1872, upon the death of Horace Greeley, became the principal proprietor and editor in chief. In 1905 Reid relinquished his active editorship of the *Tribune,* but retained financial control. He served as minister to France in 1889–92, and in 1892 was the unsuccessful Republican candidate for vice-president on the ticket with Benjamin Harrison. In 1897 he was special ambassador of the United States on the occasion of Queen Victoria's jubilee; in 1902, special ambassador of the United States at the coronation of King Edward VII; and in 1905 he became ambassador to Great Britain. He died in London on Dec. 15, 1912.

His publications include *After the War* (1867); *Our New Duties* (1899); *Later Aspects of Our New Duties* (1899); *Problems of Expansion* (1900); *The Greatest Fact in Modern History* (1906); and, posthumously, *American and English Studies* (1913).

See Royal Cortissoz, *The Lije of Whitelaw Reid* (1921).

REIGATE, a municipal borough (1863) in the Reigate parliamentary division of Surrey, Eng., 22 mi. S.S.W. of London bridge by road. Pop. (1951) 42,248. Area 16 sq.mi. Reigate (Cherchefelle was the Saxon village; Regate, the "roe gate," is mentioned in 1203), at a crossroad on the Pilgrim's way, at the foot of the North Downs, had a castle, a stronghold of the Warennes in the 12th–14th centuries. The manor of Cherchefelle was granted by William Rufus to Earl Warenne, through whose family it passed in 1347 to the earls of Arundel. It was held by the Somers family from 1697 until 1922, when it was conveyed to the corporation by deed of gift. Reigate priory, originally an Augustinian foundation, was purchased by the corporation in 1948. Of the castle (destroyed *c.* 1648), there remains only the entrance to a sandstone cave beneath. The grounds are laid out as a public garden.

The old town hall (1708, presented to the corporation in 1922) is on the site of an ancient chapel dedicated to St. Thomas Becket. In the chancel of the parish church of St. Mary (Transitional Norman to Perpendicular) is buried Lord Howard, the commander of the English navy against the Spanish Armada. The boys' grammar school was founded in 1675, but the Girls' County

school is a modern foundation (1905). The borough, largely residential, which was considerably extended in 1933, includes the town of Redhill (aith a growing industrial area on its outskirts) and Merstham, part of which is now a London County council housing estate.

REIMARUS, HERMANN SAMUEL (1694–1768), German' philosopher and man of letters, was born at Hamburg, on Dec. 22, 1694 He aas educated by his father and by the famous scholar J. A. Fabricius. whose son-in-law he became, and later at Jena. He uas professor of Hebrew and oriental languages in the high school of his native city from 1727 till his death. His house was the centre of the highest culture. and a monument of his influence in that city remained in the *Haus der patriotischen Gesellschaft,* where the learned and artistic societies partly founded by him continued to meet. He died on March 1, 1768.

Reimarus' reputation as a scholar rests on the valuable edition of Dio Cassius (1750–52) which he prepared from the materials collected by J. A. Fabricius. He also published *Abhandlungen von den vornehmsten Wahrheiten der natürlichen Religion* (Hamburg, 1754; 6th ed.. 1791); *Vernunftlehre* (Hamburg and Kiel, 1756; 5th ed., 1790); *Betmchtztngen über der Kunsttriebe der Thiere* (Hamburg, 1762; 4th ed., 1798). But his best-known work is his *Apologie oder Schutzschrift fur die vernünftigen Verehrer Gottes* (kept back during his lifetime) from which, after his death, Lessing published certain chapters under the title *Wolfenbüttel Fragments (see* LESSING, GOTTHOLD *EPHRAIM).* Other portions were published by "C. A. Schmidt" (1787) and D. W. Klose (1850–52).

The standpoint of the *Apologie* is that of pure naturalistic deism. Miracles and mysteries, with the exception of the Creation, are denied, and natural religion is put forward as the absolute contradiction of revealed. The essential truths of the former are the existence of a wise and good Creator and the immortality of the soul. These truths are discoverable by reason, and are such as can constitute the basis of a universal religion and lead to happiness. A revealed religion could never obtain universality, as it could never be intelligible and credible to all men.

See the "Fragments" as published by Lessing, reprinted in vol. xv of *Lessing's Werke,* Hempel's edition; *D.* F. Strauss, H. S. *Reimarus und seine Schutzschrift fur die verndnftigen Verehrer Gottes (1862;* 2nd ed., 1877); C. Voysey, *Fragments from Reimarus* (1879) *(a* translation of Strauss's book, with the second part of the seventh fragment, on the "Object oi Jesus and his Disciples").

REIMS (RHEIMS), a city of northeastern France, chief town of an *arrondissement* of the *département* of Marne, 98 mi. E.N.E. of Paris, on the Eastern railway. Pop. (1954) 114,682. Reims stands in a plain on the right bank of the Vesle, a tributary of the Xisne, and on the canal which connects the Aisne with the Marne. South and west rise the "montagne de Reims" and vine-clad hills.

Before the Roman conquest Reims, as Durocortorum, was capital of the Remi, from whose name that of the town was subsequently derived. The Remi made voluntary submission to the Romans. and by their fidelity secured the special favour of their conquerors. Christianity was established in the town by the middle of the 3rd century, at which period the bishopric was founded. The consul Jovinus, an influential supporter of the new faith, repulsed the barbarians who invaded Champagne in 336; but the Vandals captured the town in 406 and slew St. Nicasus, and Xttila afterward put it to fire and sword. Clovis, after his victory at Soissons (486), was baptized at Reims in 496 by St. Remigius. Later kings desired to be consecrated at Reims with the oil of the sacred phial which was believed to have been brought from heaven by a dove for the baptism of Clovis and was preserved in the abbey of St. Remi. Meetings of Pope Stephen III with Pippin the Short, and of Leo III with Charlemagne, took place at Reims; and there Louis the Debonair was crowned by Stephen IV. Louis IV gave the town and countship of Reims to the archbishop Artaldus in 940. Louis VII gave the title of duke and peer to William of Champagne. archbishop from 1176 to 1202, and the archbishops of Reims took precedence of the other ecclesiastical peers of the realm.

In the 10th century Reims had become a centre of intellectual culture. Archbishop Adalberon, seconded by the monk Gerbert (afterward Pope Silvester 11), having founded schools where the "liberal arts" were taught. Adalberon was also one of the prime authors of the revolution which put the Capet house in the place of the Carolingians. The most important prerogative of the archbishops was the consecration of the kings of France — a privilege which was exercised, except in a few cases, from the time of Philip Augustus to that of Charles X. Louis VII granted the town a communal charter in 1139. The treaty of Troyes (1420) ceded it to the English, who had made a futile attempt to take it by siege in 1360; but they were expelled on the approach of Joan of Arc, who in 1429 caused Charles VII to be consecrated in the cathedral. A revolt at Reims, caused by the salt tax in 1461, was cruelly repressed by Louis XI. The town sided with the League (1585), but submitted to Henry IV after the battle of Ivry. In the foreign invasions of 1814 it was captured and recaptured; in 1870–71 it was made by the Germans the seat of a governor general and impoverished by heavy requisitions.

Reims suffered severely during World War I. The town was heavily bombarded by the Germans in Sept. 1914, and the population took shelter in the huge subterranean wine cellars, occupying old chalk quarries, where dormitories were made, schools were held and a daily paper was published. In 1917 the civilian population which remained was evacuated; in 1918 the town was one of the objectives of the Germans, but it was held until freed by the Allied offensive in October. Reims was then in ruins, and the cathedral was severely damaged, especially on the southwest side. The work of restoration of the cathedral, to the cost of which there was a large U.S. contribution, took many years to complete. The cathedral and other famous buildings were not damaged during World War II, although the town again suffered wartime destruction. The statue of St. Joan of Arc, which stood in front of the cathedral, was removed during World War I for safety and replaced in 1921; many of the art treasures, tapestries, etc., were also saved.

The oldest monument in Reims is the Mars gate (so called from a temple to Mars in the neighbourhood), a triumphal arch 108 ft. in length by 43 ft. in height, consisting of three archways flanked by columns. It is popularly supposed to have been erected by the Remi in honour of Augustus when Agrippa made the great roads terminating at the town, but probably belongs to the 3rd or 4th century. In its vicinity a curious mosaic, measuring 36 ft. by 26 ft., with 3 j medallions representing animals and gladiators, was discovered in 1860. To these remains must be added a Gallo-Roman sarcophagus, said to be that of the consul Jovinus and preserved in the archaeological museum in the cloister of the abbey of St. Remi.

The cathedral of Notre Dame, where the kings of France used to be crowned, replaced an older church (burned in 1211) built on the site of the basilica where Clovis was baptized by St. Remigius. The cathedral, with the exception of the west front, was completed by the end of the 13th century. That portion was erected in the 14th century after 13th-century designs — the nave having in the meantime been lengthened to afford room for the crowds that attended the coronations. In 1481 fire destroyed the roof and the spires. The facade was one of the most perfect masterpieces of the middle ages. The three portals are laden with statues and statuettes. The central portal, dedicated to the Virgin, was surmounted by a rose window framed in an arch itself decorated with statuary. The rose window, the statue of the smiling angel, the still more famous "Beau Dieu" statue were all severely damaged in World War I. The gallery of the kings above the rose window survived but the angel spire was destroyed.

The archiepiscopal palace, built between 1498 and 1509 and in part rebuilt in 1675, was almost completely destroyed. The church of St. Remi (11th, 12th, 13th and 15th centuries) retained intact its facade and two Romanesque towers; the nave and choir were ruined, and the mausoleum of St. Remigius (1847), containing the reliquary of the saint, behind the high altar, had to be reconstructed.

Reims became the seat of an archbishop, a court of assize and

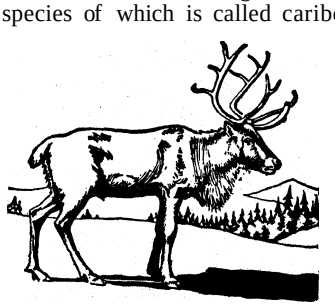
a subprefect, and a tribunal and a chamber of commerce. It also became an important centre for the combing, carding and spinning of wool and the weaving of woolen goods of all kinds. The manufacture of and trade in champagne are also very important. The wine is stored in large cellars tunneled in the chalk. The town also became well known for its cakes and biscuits.

REINACH, JOSEPH (1856–1921), French author and politician, who is remembered chiefly for his defense of Alfred Dreyfus, was born in Paris on Sept. 30, 1856. After leaving the Lycée Condorcet he was called to the bar in 1887. He attracted the attention of Gambetta by articles on Balkan politics published in the *Revue bleue,* and in Gambetta's *grand ministère* Reinach was his secretary. In the *République française* he waged a steady war against General Boulanger which brought him three duels, one with Edmond Magnier and two with Paul Déroulède. Between 1889 and 1898 he sat for the chamber of deputies for Digne. He brought forward many reform bills, advocated complete freedom of the theatre and the press, the abolition of public executions, and denounced political corruption. But he is best knoun as the champion of Dreyfus. At the time of the original trial he attempted to secure a public hearing of the case, and in 1897 allied himself with Scheurer-Kestner to demand its revision. He denounced in the *Siècle* the Henry forgery, and Esterhazy's complicity. His articles aroused the fury of the anti-Dreyfusard party, especially as he was himself a Jew and therefore open to the charge of bias. He lost his seat in the chamber of deputies and, having refused to fight Henri Rochefort, eventually brought an action for libel against him. Finally, the "affair" being terminated and Dreyfus pardoned, he undertook to write the history of the case, the first four volumes of which appeared in 1901. This was completed in 1905. In 1906 Reinach was re-elected for Digne. He died in Paris on April 18, 1921.

SALOMON REINACH (1858–1932), born at St. Germain-en-Laye on Aug. 29, 1855, brother of Joseph Reinach, was educated at the École Normale Supérieure, and joined the French school at Athens in 1879. He made valuable archaeological discoveries at Myrina near Smyrna in 1880–82, at Cyme in 1881, at Thasos, Imbros and Lesbos (1882), at Carthage and Meninx (1883–84), at Odessa (1893) and elsewhere. He received in 1886 an appointment at the National Museum of Antiquities at St. Germain; in 1893 he became assistant keeper, and in 1902 keeper of the national museums. In 1903 he became joint editor of the *Revue archdologique,* and in the same year officer of the Legion of Honour. The lectures he delivered on art at the École du Louvre, 1902–03, were published by him under the title of *Apollo.*

REINCARNATION: *see* METEMPSYCHOSIS.

REINDEER, a large arctic and subarctic deer, the American species of which is called caribou. The reindeer constitutes the genus *Rangifer,* characterized by the possession of antlers by both sexes, though those of the male are larger and more complex. Reindeer are clumsily built animals, with large lateral hoofs, hairy muzzles and a curious type of antler with the brow tine directed downward. The compact, dense coat is clove brown in colour above and white below, with a white tail patch. The ears and tail are short and the throat is maned. A tarsal gland is present. The lateral metacarpal bones are represented only by their lower extremities *(see* DEER).



BY COURTESY OF THE N Y. ZOOLOGICAL SOCIETY

REINDEER (RANGIFER TARANDUS) It inhabits arctic and subarctic regions

The type of the genus *(R. tarandus)* is the Scandinavian wild form. In America the barren ground caribou are forms of the old world species. The woodland caribou *(R. caribou* and *R. novaterrae)* are other species. All caribou move around and many herds undertake great migrations in the spring and autumn. A small species *(R. platyrhynchus)* inhabits Spitzbergen and Novaya Zembla.

The reindeer has been domesticated by the Lapps and introduced as a domestic animal into arctic Canada and Alaska. Reindeer feed largely on lichens. one species of which is the so-called "reindeer moss." The brow tine is not used to scrape away snow; this is done with the hoofs, the horns being shed before spring.

See also Index references under "Reindeer" in vol. 24.

REINDEER LAKE, in northern Canada, straddles the Saskatcheaan-Manitoba border in Pre-Cambrian rock terrain near the northern limit of the coniferous forest. At an altitude of 1.150ft., it is 2,444sq mi. in area, 152 mi. long and up to 35 mi. wide, irregularly shaped and island-dotted. Fed by numerous streams. it drains southward over a control dam into the Churchill river via the Reindeer. In fur trade days the lake was a transport link and tno small settlements formed near its extremities. More recently, commercial and sport fishing produced a third settlement on the east shore connected by truck road with the railhead at Lynn Lake. Manitoba. (C. S. BR.)

REINDEER MOSS *(Cladonia rangiferina),* a species of lichen found in great abundance in arctic lands. It is an erect, many-branched plant, a few inches in height, which covers immense areas somewhat in the manner of pasture grasses in the temperate regions. In many districts it forms the chief food of the reindeer. and it also provides forage for the barren-ground caribou and the musk ox. *See* LICHENS.

REINECKE, KARL (HEINRICH CARSTEN) (1824–1910). German composer. pianist and conductor who was regarded as the best interpreter of the piano music of Mozart of his time. was born at Altona, June 23, 1824. He appeared in public as a child, toured Scandinavia at the age of 18 and in 1843 settled in Leipzig. where his close contact with Mendelssohn and Schumann was of decisive influence in his development. He conducted the Leipzig Gewandhaus concerts from 1860 to 1895. Of his numerous works, which include operas, symphonies, concertos, overtures and chamber music, those written for educational purposes are the most valuable and his pieces for children are still fresh and alive. He died at Leipzig, March 10. 1910. (H. GA.)

REINFORCED CONCRETE: *see* CONCRETE.

REINHARDT, MAX (1873–1943), Austrian theatrical producer and director, the most influential and productive theatre figure of his generation, directed many kinds of plays in many types of theatres and introduced new concepts of design and production to audiences in Berlin Vienna. London and New York. He was born at Baden, near Vienna, on Sept. 9, 1873. From 1893 to 1903 he studied acting, chiefly under Otto Brahm. but spent the rest of his career as a play director and teacher, principally in Berlin.

Reinhardt popularized classical plays such as *Oedipus Rex, Everyman, Faust* and those of Shakespeare by giving them a contemporary flavour through the appeal of spectacle, a new translation or novel staging. He brought together young artists who successfully realized in their costume and scenic designs many of the revolutionary ideas of E. G. Craig and Alexander Tairov. He broke the convention of the proscenium wall and staged his plays in circuses, cathedrals, Greek-style theatres and on cathedral steps. In addition to his spectacles for large audiences, he staged light operas and modern plays with clean precision in ballrooms (the Redoutensaal in Vienna) and intimate theatres and cabarets.

From the time of his first popular success with *Sumurun,* an oriental pantomine, to his last spectacle, *The Eternal Road* in New York in 1937. Reinhardt worked on the development of his artistic theories. Chief among his beliefs was that the function of the director was to realize the specific atmosphere of a play and that every play, whether new or old. must be made to live for a contemporary audience. Occasionally his zeal for theatrical effect and publicity caused him to distort the fundamental dramatic values in a script. but those cases are exceptions and insignificant in relation to his total record. He believed in careful preparation of a production before beginning rehearsals, and his director's manuscript or *Regiebuch* for any play, with its detailed annotations and diagrams, is a legendary document.

Reinhardt left Germany in 1933. In Hollywood he directed films and established a school for actors and directors. He became

a U.S. citizen in 1940 and died in New York on Oct. 31, 1943.

See Huntley Carter, *The Theatre of Max Reinhardt* (1914); Oliver M. Sayler (ed.), *Max Reinhardt and His Theatre (1924).* (*E. P. K.*)

REINKENS, JOSEPH HUBERT (1821–1896), German Old Catholic bishop, was born at Burtscheid, near Aix-la-Chapelle, on March 1, 1821. He became professor of ecclesiastical history at Breslau (Wroclaw), and in 186j rector of the university. In 1870. Reinkens opposed the proclamation of the dogma of papal infallibility. He signed the Declaration of Niirnberg in 1871, and took a conspicuous part in the Bonn conferences with the orientals and Anglicans in 1874 and 1875. The Old Catholics having decided on secession, Reinkens was chosen their bishop in Germany at Cologne in 1873 *(see* OLD CATHOLICS). His best-known theological work is his treatise on Cyprian and the unity of the church (1873). In 1881 Reinkens visited England, and in 1894 he defended the validity of Anglican orders against the Old Catholics of Holland. He died at Bonn on Jan. 4, 1896.

REINMAR VON HAGENAU (REINMAR DER ALTE) (d. *c.* 1205), was the most notable exponent of *Minnesang* toward the end of the 12th century (*see* MINNESINGERS). His birthplace was probably in Alsace but he moved early to Vienna where he became court poet of the Babenberg dukes. Among his pupils was Walther von der Vogelweide (*q.v.*), who later became his rival. Reinmar was considered by his contemporaries to be the "nightingale" of the poets of his day. In matters of form he sought purity of rhyme and smoothness of rhythm and rejected any phrase or emotion which might have offended courtly susceptibilities. The modern reader. however, may find his songs stereotyped as he sang mostly of unrequited love. The volume of songs attributed to him is considerable but modern scholarship doubts the authenticity of all but some 30 of them, assigning the rest to his pupils.

See K. von Kraus (ed.), *Des Minnesangs Frühling* (1939).

(W. W. Cs.)

REINSCH, PAUL SAMUEL (1869–1923), U.S. political scientist, who was a pioneer in the field of serious study by Americans of world affairs. was born in Milwaukee, Wis., June 10, 1869. Graduated (A.B., LL.B. and Ph.D.) at the University of Wisconsin, Madison, after studying in Europe, he taught there until 1913. Gifted, ambitious, perceptive and dynamic, he excelled in the social sciences and soon achieved repute as an authority on international relations.

He was active in the founding of the American Political Science association (president in 1920), served as a U.S. delegate at several conferences in Central and South America and lectured as Roosevelt exchange professor (1911–12) in Germany. In 1913 Pres. Woodrow Wilson appointed him U.S. minister to China. He contended brilliantly, emphatically and prophetically for proficient attention to matters far eastern. His *An American Diplomat in China* (1922) is an illuminating memoir. He resigned in 1919, became an adviser to the Chinese government and, traveling in that capacity, died in Shanghai on Jan. 24, 1923. Outstanding among Reinsch's many books were his *World Politics at the End of the Nineteenth Century, as Influenced by the Oriental Situation* (1900), *Colonial Government* (1902), *Colonial Administration* (1905), *Public International Unions* (1911) and *Intellectual and Political Currents in the Far East* (1911). (S. K. H.; S. G. L.)

REINSURANCE. Reinsurance is the term used to denote the transaction whereby a person who has insured a risk insures again a part or the whole of that risk with another person. The purpose of reinsurance is to relieve the original insurer from a liability which is too heavy for him to carry. There is no privity of contract between the reinsurer and the original insured, so that the latter could not sue the former to recover any part of a loss. but the insured could recover in respect of a loss against the original insurer up to the full amount of the policy, notwithstanding that part of it had been reinsured.

In a reinsurance transaction the company which reinsures is called the ceding company, the accepting company is called the reinsurer and the transaction itself is termed a cession.

It is not known when reinsurance was first practised. though there is evidence of its existence at least as early as the first half of the 18th century. In the early days of insurance, insurers did not, as a rule, insure for greater amounts than they were prepared to keep for themselves, and, even when this rule began to be relaxed, the arrangements whereby they relieved themselves of heavy commitments partook more of the nature of co-insurance than of reinsurance. Under such arrangements the original insured was in contractual relationship with each of the insurers.

However, in marine business reinsurance was known nearly 200 years ago, for in 1746 an act of parliament made it illegal. a prohibition which was not raised until 1864. It is thought by some that the act of 1746 really prohibited double insurance; *i.e.,* where the insured covered his property twice, but the word used in the act is "reassurance." However this may be, it is certain that the growth of reinsurance in various sections of the business was slow until well into the 19th century.

Facultative Reinsurance.—This was the original form. By this method each risk is offered for reinsurance separately and the ceding company has a free choice as to where it will offer the business. Similarly the reinsurer has freedom to accept or decline. The term facultative is derived from the power of choice, which this method implies. This system of reinsurance is cumbersome. as each risk reinsured has to be handled separately. The particulars of the risk are first shown to the reinsurer on a slip, which it initials for the share it is prepared to accept. This is followed by a request note; *i.e.,* a formal demand issued by the ceding company to the reinsurer for the specified reinsurance. Upon this the reinsurer issues its "take" note, which is its official acceptance given pending the issue of a reinsurance policy,

Reinsurance by Treaty.—A treaty is an obligatory arrangement, under which the ceding company binds itself to cede, and the reinsurer binds itself to accept, a fixed share of every risk, of a nature as defined in the contract, which the ceding company has to reinsure. A treaty, therefore, provides not for the reinsurance of an individual risk, but for all the risks of a given class. The power of choice is here eliminated. The two parties are reciprocally bound, one to cede and the other to accept.

This is an advantage to both, since the ceding company knows in advance that it can place the reinsurances and the reinsurer can rely on receiving a regular flow of business under the treaty. It is a condition of all treaties that, as soon as a reinsurance is placed thereunder, the reinsurer's liability commences from the same moment as the liability of the ceding company, while the obligation to cede prevents the ceding company placing some of its reinsurances with one reinsurer and some with another, or favouring one at the expense of another. It is customary to arrange a treaty so that a number of reinsurers share in it, each accepting only a proportionate part of the business ceded.

Quota-Share Treaty.—A quota-share treaty is one under which the ceding company agrees to cede a fixed share of every risk which it accepts from its clients. There is a necessary tendency for reinsurance business to comprise risks of a second class nature, since the better the risk the more the ceding company keeps. But in a quota-share treaty this feature is not present. Every risk must be reinsured. For this reason the quota-share treaty is not greatly used, except by small companies, which can obtain sound cover only by offering attractive terms.

Surplus Treaty.—The surplus treaty is that in common use. Under this the ceding company first fixes the amount it will keep, which is called its retention, and the remainder of the amount insured constitutes the surplus. This is divided amongst the treaty reinsurers according to their due proportion. The whole surplus is usually divided into percentages, each reinsurer taking 1% or more as agreed of every surplus. But the amount which can be ceded is governed by the ceding company's retention.

Excess of Loss Treaty.—An excess of loss treaty is an agreement under which no part of any individual risk is reinsured, but the ceding company arranges to cover only the excess of any one loss over and above an agreed figure. This is a treaty to guard against catastrophe. A ceding company may arrange to cover itself by reinsurance against the excess of loss over £50,000 in respect of any one fire, the cover to run, say, up to £100,000; *i.e.,* a further £50,000. Then if one fire results in a loss to that company of £50,000, or less, the reinsurers pay nothing, but if the

cost of the fire exceeds that figure the reinsurers pay the amount of the excess, according to their agreed proportions. This kind of treaty is largely used in motor insurance; but in fire insurance its use is a modern development. In that branch it is operated independently of and in addition to the surplus treaty. The ceding company must still use its surplus treaty to limit its liability on individual risks. taking out an excess of loss cover only to protect itself against heavy conflagrations.

Conditions of Reinsurance. — The conditions applying to a reinsurance are, as a rule, the same as those which apply to the original insurance. Thus the reinsurer receives the same rate of premium and must pay its proportionate share of any claim. There are. however. exceptions to this rule. Under an excess of loss treaty the reinsurer receives no specific premium, but is paid a percentage of the total premium income derived by the ceding company from the class of business to which the treaty applies. In marine reinsurance there is a practice to reinsure risks which are affected by a possibility of loss, and in such cases much higher premium may be paid than under the original policy.

The share of premium payable to the reinsurer is subject to a deduction of commission, which varies from 20% to 35% or, in rare cases, 40% or 45%. Reinsurance commission has to cover not only the agent's commission paid on the original insurance but also a part of the ceding company's expense of obtaining and dealing with the business. The rate of reinsurance commission depends partly on the level of the expense of dealing with the business and partly on the quality of the treaty. Treaties giving consistently good results can command better terms than poor treaties. As well as commission deducted from premium. the reinsurer has to pay a commission — usually 10% — on the profits. In this way the profitable treaty automatically receives better terms than the bad one. The profit on a treaty is computed after making due provision for all claims and liabilities outstanding at the end of the year. The commission is payable on the average of the profit of the year of account, and of the two preceding years, so that a reinsurer shall not be required to pay away part of its profits in a year which follows a year showing a heavy loss.

The reinsurer, being liable to pay its share of all losses, is entitled to a like share of any amounts recovered as salvage. The ceding company has the control of all loss settlements and may settle a loss or contest a claim as it thinks fit. The reinsurer is bound to follow the fortunes of the ceding company in this matter.

Disputes arising between the parties to a reinsurance treaty, as to any matter coming thereunder, are almost invariably settled by arbitration.

Bordereaux. — Particulars of cessions made under a treaty are advised by the ceding company to the reinsurer by means of bordereaux. A bordereau is a statement giving the name and address of the insured, the nature of the risk, the sum insured, the premium. the amount reinsured and the reinsurance premium. No reinsurance policies are issued under treaties, as the reinsurance cover operates under the treaty contract. In marine business, however, properly stamped policies have to be issued even for reinsurance, under the provisions of the Stamp Act, 1891, and the Marine Insurance Act, 1906.

Retrocession. — A reinsurer, receiving particulars of its cessions by bordereaux, will itself deal with the business so received, and will in its turn arrange treaties to cede off its own surplus lines. A reinsurance of a reinsurance is called a retrocession. Retrocession is an important part of reinsurance business because where a reinsurer has a share of many treaties it will frequently receive a share of the same risk under many of its different treaties and must needs relieve itself by retrocession of the accumulation of risk. (C. E. G.)

United States. — The U.S. reinsurance business grew rapidly during the 20th century. As in the European countries facultative and the three kinds of treaty insurance are used, but the percentage of facultative is rapidly diminishing because of delay and uncertainty.

What may be called a variation of the fixed treaty is the "pool" or "syndicate." Here as many as 3j companies will enter into an agreement to share all insurance in a given territory on a basis of certain agreed proportions both in regard to premiums and losses.

In order to facilitate the placing of reinsurance and to bring about greater uniformity of practice, reinsurance clearing houses or exchanges were established. Here the detailed reinsurance agreement is subscribed to by the member companies who are all represented by a manager.

Many of the life insurance companies continued to use the facultative plan of reinsurance.

There are two ways of reinsuring. The smaller companies will reinsure the amount at risk with term insurance. Most of the larger companies use the coinsurance plan, whereby the reinsurance company receives a proportionate part of the premium and guarantees a proportionate part of all payments including expenses and taxes.

There are many insurance companies whose business is entirely reinsurance. (R. RET.; X.)

REISKE, JOHANN JAKOB (1716–1774), German philologist, who surpassed all his predecessors in the range and quality of his knowledge of Arabic literature, was born on Dec. 25, 1716, at Zorbig in electoral Saxony. From the orphanage at Halle he passed in 1733 to the University of Leipzig, and there spent five years. He bought Arabic books, and when he had read all that was then printed he thirsted for manuscripts. He qualified as a doctor. but failed to secure any medical practice at Leipzig, and lived, as before. on ill-paid literary hack work. Although the electoral prince gave him the title of professor he was not permitted to lecture. At length in 1758 the magistrates of Leipzig rescued him from poverty by giving him the rectorate of St. Nicolai. and, though he still met with hostility in the university, he enjoyed the esteem of Frederick the Great, of Lessing, Karsten, Niebuhr and many foreign scholars. Reiske died on Aug. 14, 1774, and his manuscript remains are now in the Copenhagen library.

In the *Adnotationes historicae* to his *Abulfeda Annales Moslemici,* 5 vol. (1789–91), Reiske collected a veritable treasure of original research: he knew the Byzantine writers as thoroughly as the Arabic authors, and was alike at home in modern works of travel in all languages and in ancient and medieval authorities. In Greek his corrections are often hasty and false, but a surprisingly large proportion of them have since received confirmation from manuscripts. He was interested too in numismatics, and his letters on Arabic coinage form the basis of that branch of study.

REITH, JOHN CHARLES WALSHAM REITH, 1ST BARON OF STONEHAVEN (1889–), one of the principal British architects of the modern pattern of publicly owned but independent utility corporations, was born at Stonehaven, Kincardineshire, Scot., on July 20, 1889. He mas educated at Glasgow academy, Gresham's school. Holt, Norfolk, and the Royal Technical college, Glasgow. Trained as a civil engineer, in 1916–17 he was engaged in the United States on the supply of munitions to the United Kingdom. As general manager of the British Broadcasting company from 1922, and director general of the corporation, as it became. from 1927 to 1938, he was responsible for the creation and development of broadcasting throughout the British Isles, and also for the inauguration of the empire short-wave broadcasting service and the first regular service of high-definition television in the world (1936). He had been knighted in 1927. In 1938 he became chairman of Imperial Airways and in the following year was responsible for its merger with British Airways and the creation of the British Overseas Airways corporation, of which he became chairman. He was made a peer in 1940. After holding a number of ministerial and other appointments in World War II, Lord Reith was responsible in 1946 for a reordering of the cable and wireless system of the commonwealth. becoming chairman of the new Commonwealth Telecommunications board (1946–50). He was chairman of the New Towns committee (1946). the Hemel Hempstead Development corporation (1947–50) and the National Film Finance corporation (1948–51). From 1950–59 he was chairman of the Colonial Development corporation and served on

other commercial and industrial boards. Lord Reith published his autobiography, *Into the Wind*, in 1949. (G. R. M. G.)

RÉJANE (GABRIELLE CHARLOTTE RÉJU) (1857–1920), French actress, regarded as the queen of the comedy stage, was born on June 6. 1857, in Paris, where she made her debut at the Vaudeville in 1875. Her first big success was in Henri Meilhac's *Ma Camarade* in 1883. She became a favourite, playing in many of the Parisian theatres and also in England and America, where she was very popular. On her first appearance in London, in 1894, Bernard Shaw. then a dramatic critic, paid her a great tribute. She did not attempt tragedy or classical roles, but was unequaled in light comedy. She had great emotional powers, which she displayed in *Madame Sans-Gêne*, in which she attained world renown. She was also extremely successful in *Zaza* and *La Passerelle.* In 1905 she opened the Théâtre Réjane in Paris under her own management. and in 1906 she took over the Royalty theatre in London, intending to make it a French repertory theatre. She toured South Africa in 1909 and retired in 1915, dying in Paris on June 14, 1920. Réjane had great beauty, charm and remarkable clarity of diction, and she was also a typical Parisienne.

(W. J. M.-P.)

REJERIA, the Spanish form of openwork screens made from combinations of wrought- and cast-iron work. The word *reja* is used for a screen, individually; *rejeria* properly signifies this whole class of ironwork. A magnificent example is the *reja* of the Capilla Mayor of Seville cathedral (1518–33). Many beautiful examples of this type are found as window guards in Spanish Renaissance houses. *See* IRONWORK.

REJUVENATION, or the restoration of youthfulness, has long been an aspiration of mankind. To stop the inevitable march toward senile decline, to turn the clock back, countless generations of men from philosophers to explorers have sought the elixir of life. the source of eternal youth. Although the causes of aging have been little understood, a most obvious change occurs in the reproductive capacities of men and animals as they approach the twilight of their mature years. It is not unnatural, therefore, that the genital powers and the genital organs have been the centre of preoccupation by those who have sought the secret of rejuvenation.

Early historical records indicate that the elders and priests of ancient China and India. 3,000 years ago, consumed the sexual organs of wild animals in order to improve their vigour and acuity and thus to offset the decline of old age. Long before the Christian era, roughly 1400 B.C., the testicles of sacrificial animals were employed to counteract sexual weakness. Such fancy and such practices have not waned during the intervening centuries, since some primitive societies still indulge in these crude attempts at rejuvenation.

The achievement of rejuvenation was claimed during the early 20th century by several surgeons of Europe and the U.S. who maintained that operations on the genital organs or transplantation of young testicular tissue into elderly men brought about a new feeling of well-being, physiological youthfulness and, in some instances, a renewal of sexual potency. This era stemmed from the accounts of the physiologist Charles Edouard Brown-Séquard (*q.v.*) who in 1889, at the age of 70, injected himself with testicular material from dogs and guinea pigs and claimed a renewal of vigour, mental alertness and the "enjoyment of life." Twenty-five years later Jiirgen W. Harms believed that he had accomplished the same thing in senile guinea pigs and, further, that he had regenerated sexual activity by the transplantation of testicles from young, healthy animals.

The foremost names in the field of induced rejuvenation were those of the Viennese scientist Eugen Steinach who experimented mostly with rats, and Serge Voronoff, a French surgeon who combined animal and human experimentation. The Steinach operation consisted merely of ligation and severance of the male seminal duct. Voronoff transplanted young human or monkey testicular tissue into the testicular sacs of elderly men. In both procedures, the operation was regarded as increasing the secretion of the testicular hormone androgen thereby giving new vigour to the organism (*see* HORMONES). In the most dramatic cases of rejuvenation of 65- to 83-year-old men, the results claimed were long-lasting improvement in mental alertness, sense of well-being, visual acuity, muscle tone, blood pressure, hair growth, skin elasticity, libido and sexual potency.

Although loudly proclaimed, these procedures were not well founded in theory and have not withstood the tests of time and confirmation. No evidence has been discovered that aging of the body as a whole is dependent on either the activity or the failure of the sexual glands per se. These glands have their own characteristic functional life span, just as do other organs and tissues in the organism. Both the spermatozoa-forming and the hormone-secreting functions of the testis are mainly devoted to reproduction of the species and not to growth, differentiation and maintenance of the body against the ravages of old age.

Voronoff's transplantations of monkey glands in men could not possibly have persisted as active, growing tissues and could at best only have supplied a temporary exogenous source of androgenic substance. The apparent results were probably mainly responses to the sudden and temporary flood of androgen throughout the system, combined with readjustment in subjective and psychological attitudes. and improvement in nutritive and constitutional factors. It has been well recognized among clinical circles that some cases of human infertility in both men and women have responded to improved conditions of diet, rest, relaxation and peace of mind when previous medical therapy had been of no avail.

With the chemical identification and synthesis of the male hormone testosterone there was ample opportunity to test its capacity to induce true rejuvenation as well as to study its general physiological effects on the organism. Its administration to elderly men followed in some instances by feelings of well-being. sexual interest, improved circulation and increased muscle tone, but analogous results also have been obtained with other stimulants and strengthening methods. The effects are temporary and did not offset the slow decline of old age. Indeed, some danger is involved in such a one-sided stimulation since the organism as a whole may not be physically constituted to withstand the sudden and abnormal stress.

The systemic effects of testosterone administered to experimental animals under controlled conditions were found to include a multitude of physiological responses: modification in blood pressure, red blood cell count, muscle tone, glycogen storage, electrolyte and water retention, enzyme activity, carbohydrate and protein metabolism. oxygen and carbon dioxide exchange and brain wave pattern. Moreover, it is known that through the intricate integration of the endocrine system androgen administration has an important action on the all-powerful pituitary gland and on the adrenals as well. Obviously then. a sudden change of disturbance in the androgen balance might have profound effects throughout the system. A practical example of the effect of androgen stimulation may be found in the annals of horse racing: a run-down and over-aged horse was able, after testosterone administration, to perform well with his younger competitors. The response was temporary, however, and not devoid of some risk.

Attempts to induce the revitalization by surgical means have been confined to the male. Apparent rejuvenation, however, has been frequently described in women suffering from ovarian tumours and reproductive disorders. This misuse of the term in these instances has resulted from the effects of excessive secretion of the female hormone estrogen. Although estrogen may seem to offset some of the appearances of aging—thus its widespread incorporation into facial creams—the effect on rejuvenescence is relatively superficial. As in the male, the sexual hormones may alter the background of physiological reactions and modify the structural integrity of the cells and tissues, but they have little lasting effect on the primary causes of aging and senility.

A kind of "rejuvenescence" has been acknowledged as occurring among certain types of single-celled animals. These Protozoa undergo various forms of sexual recombination (conjugation or endomixis) which add new life to the organism or to the strain (*see* REPRODUCTION). This phenomenon, however, is analogous in the higher animals not to rejuvenation of the individual but to procreation of a new being. Life continues uninterruptedly from gen-

eration to generation, with the germ plasm manifesting signs of immortality. Thus, while the germinal elements become the source of posterity, the body seems predestined to weaken, grow old and die, and no means have been found to seriously alter this decline.

RELANDER, LAURI MRISTIAN (1883–1942), president of Finland, born May 31, 1883, and educated at Helsinki university. He was a member of the central committee of the agrarian party in 1909, sat in the diet from 1910 to 1913 and 1917–19, when he became its speaker. From 1925 to 1931, he was president of the republic. He died Feb. 9, 1942.

RELAPSING FEVER (FEBRIS RECURRENS) is an infectious disease characterized by recurring febrile symptoms and caused by spirochetes that have been given a number of conflicting genus and species designations: Borrelia (*Treponema*) recurrentis (obermeieri, duttoni, etc.). The spirochetes are transmitted from man to man by lice of the genus Pediculus, and from animals to man by ticks of the genus *Ornithodoros*. The human disease is characterized by sudden onset with violent febrile symptoms, which persist for about a week in cases contracted from lice, and usually for a shorter period in the tick-transmitted disease. The attack ends by crisis with profuse sweating. followed after about a week, during which time the patient is fairly well, by a return of the febrile symptoms. Additional relapses may follow—rarely more than one or two in the louse-borne disease, but up to 12 (usually decreasing in severity) in cases contracted from ticks. The mortality is variable. ranging from nil in some tick-transmitted varieties to 6% or as high as 30% in some recorded louse-borne epidemics associated with famine conditions. The spirochetes may invade the central nervous system and cause a variety of neurological symptoms, although these usually are not severe.

Relapsing fever spirochetes were the first microscopic organisms to be associated clearly with serious human disease. Otto Obermeier observed these organisms in the blood of relapsing fever patients in 1867–68 and published his observations in 1873 The organisms are corkscrew-shaped spiral threads, which rotate rapidly in performing forward, backward and twisting movements.

They are easily observed in dark-field microscopic preparations of the patient's blood collected during the height of a febrile attack, but disappear from the blood during the intervals between attacks. These observations, as well as the relapsing symptoms, have been related to changes in the immunological (antigenic) characteristics of the spirochetes, which cause each attack and relapse. As the patient develops immunity to the prevailing immunological type and recovers from the attack, a new (mutant) immunological type of the spirochete develops and produces the relapse. Louse-borne relapsing fever has tended to occur in extensive epidemic outbreaks when human populations live under conditions which are conducive to louse infestation. Since neither the bite nor the excreta of the louse is infectious, human infections usually result from crushing the louse on the skin while scratching. Tick-transmitted relapsing fever does not occur in extensive epidemics. Cases usually are related to tick-infested human or animal habitats, because the ticks tend to engorge rapidly, detach and hide about the premises while digesting their meal, mating and laying eggs. The adult ticks may live and remain infectious for as long as five years without feeding. The spirochetes frequently invade the eggs of infected female ticks and survive in the body of the developing lawae and nymphs. Therefore, all developmental stages of the tick may transmit the infection by bite or otherwise.

Arsphenamine and related arsenical drugs have been used extensively in the treatment of relapsing fever. However, many treatment failures with these drugs have been recorded. Penicillin has proved effective in curing many cases of the disease. Other antibiotics such as aureomycin, terramycin and related compounds also have proved to be effective therapeutic agents. Inadequate therapy commonly results in relapse after treatment, probably due to the persistence of live spirochetes in the brain, where the drug concentration does not reach curative levels. After treatment these protected spirochetes may reinvade the blood stream and start a relapse. (V. T. S.)

RELATIVITY. Since the time of Galileo the concept of relativity, in its broadest sense, has always been present in physics. Loosely speaking, this concept can be expressed simply as a question: Do the laws of nature. and hence the physical situations described by them, always appear to be the same to different observers, even though the state of motion of the observers is not identical? It is with this question that we will be concerned in the following discussion.

GALILEAN RELATIVITY

If we wish to describe a physical event, a system of reference is needed to specify its position. The reference system can be formed by a co-ordinate system in space and by clocks which are fixed to this co-ordinate system to indicate the time. Also, we need a noncommittal word to describe experience. We will consider the experiences as a succession of events, each of which happens at a given point in space at a given time. Mechanical experimentation has shown that there are systems of reference such that a body in them, not acted upon by external forces, moves with constant speed along a straight line, and the laws of mechanics take a very simple form; to wit, if forces are acting upon the body, the acceleration will be proportional to the acting force. Such frames of reference are called inertial. (The name originates from the way the laws were visualized. We may assume that an innate property. inertia. keeps the body moving on a straight line in the absence of external forces, while the acceleration arises via an interplay of the external forces and inertia.) Is there more than one inertial frame? If so, then all these inertial frames will be equivalent, since in all of them the laws of mechanics (and, we hope, the laws of physics as well) will be the same. If we survey our everyday experiences we can observe immediately that such equivalent systems of reference do indeed exist. For example, consider the fact that experiments performed upon the earth, involving only observations relative to the earth. tell us nothing about the motion of the earth around the sun. not to mention' the motion of the solar system through space. Similarly, observations performed in a smoothly moving railway car, without looking out the window, do not enable us to decide whether the car is at rest or in uniform motion. Of course, if the car proceeds with jolts we realize that it is not at rest, or not moving with a constant velocity.

Thus we may tentatively announce this statement: if a system of reference S is inertial, and if another system S′ moves with a constant velocity relative to S, S' will also be an inertial system of reference. However, this does not enable us to specify completely the relations between the description of events in S and S. To do this we have to answer the following question: If in S′ an event took place at the point x' at time t', what will be the place x and time t of the same event in system S?

To fix the ideas with an example let us consider a simple case. Brown is traveling in a railway train which moves with a uniform velocity of 60 m.p.h. along a straight line. This moving train is system S'; the distances x' can be measured, say, by numbering the cars. The time Y is the time shown on the clocks in each car. While Brown is walking to the dining car, he slips and breaks his leg. This is the event we will discuss. This event happened in the first car, and we can specify x' by measuring it along the train and tracks. The time when the event happened was just two hours after the train's departure, according to the clocks in the train. This specifies Y, to wit t'= 2 hr. Vow, shifting to another frame of reference, S, the frame in which the railway stations are at rest. what are the values of x and t? Here classical mechanics makes the following assumptions: the time of the event is the same in both frames (the clock at the railway station shows the same time as the ones in the train); lengths measured in both frames are the same. Consequently, in frame S, $t = t' = 2$ hr.

In turn, x can be calculated this way: The train has traveled for two hours, and during each hour the distance covered was 60 mi.; hence, the total distance traveled is 120 mi. If we measure distances in S from the point of departure, $x=120$ mi. Formally, this relationship between the co-ordinates x, y, z, t and x', y', z', t' gives the following transformation equations:

$$\begin{aligned} x &= x' + ut' \\ y &= y' \\ z &= z' \\ t &= t'. \end{aligned} \qquad (1)$$

Here we have assumed that the co-ordinate axes in S and S' are parallel, that their origins coincide and that the motion takes place in the x direction; u is the velocity of the primed co-ordinate system S', relative to the unprimed one, S. A transformation based on these assumptions bears the name Galilean transformation.

Thus the principle of special relativity takes the following form in classical mechanics: if S is an inertial system of reference, and S' is a system of reference which moves with a constant velocity relative to S, then the laws of mechanics must have the same form in S and S', provided x, y, z, t and x', y', z', t' are connected by a Galilean transformation. Briefly. we may say the laws of Newtonian mechanics are invariant under Galilean transformations.

Of course, the next question is whether the rest of the physical laws are also invariant under this transformation. In other words, this would mean that such experiments which do not rely exclusively on the laws of mechanics should also be unable to tell the observer whether he is at rest or in uniform motion, using the connections given by equations (1) between the primed and unprimed quantities. We encounter such experiments in electrodynamics where we deal with the behaviour of the electric and magnetic fields; *e.g.*, the propagation of light. However, we very soon realize that such is not the case. The simplest way to see this is perhaps the following. The Galilean transformations, equations (1), give rise to a certain addition law of velocities, the one we commonly use in everyday life. For example, if a man walks along a moving train with a velocity of 2 m.p.h. relative to the train, in the direction of motion of the train, and if the train moves with a velocity of 60 m.p.h. along the tracks, then the velocity of the man relative to the tracks will be, we say, 62 m.p.h. If in place of the walking man we think of a light signal traveling along the train, emitted from a source on the train, we would expect that its velocity also would be different if it is measured relative to the train or relative to the tracks. However, experiments show that the speed of light is the same in all inertial systems of reference. (The experiment performed by Michelson and Morley will be discussed later.) Consequently, the Galilean principle of relativity applies only to mechanics, and not to electrodynamics. Putting it in another way, the Galilean principle of relativity and the constancy of the light velocity in an inertial frame of reference seem to be logically incompatible.

SPECIAL THEORY OF RELATIVITY

The resolution of this paradox was accomplished by Albert Einstein in 1905. He clearly realized the three assumptions underlying the Galilean principle of relativity and the different roles the constancy of light velocity plays in each. The three assumptions were the following: there are inertial systems in which the laws of physics are identical; if one system is inertial, any system of reference which moves with a constant velocity relative to the first one is also inertial; the transcription of space and time data from one inertial system to another has to be done according to the Galilean transformations as given by equations (1). The first two assumptions assert that it is the relative configurations of bodies which determine the physical phenomena (and not their configurations and motions relative to some external frame of reference), while the last one indicates how we have to translate the results we have obtained in one inertial frame to get the results observed in any other inertial frame. Experiments indicate that in electrodynamics, as well as in mechanics, all phenomena depend on relative configurations and motions only. Thus the first two assumptions should be valid no matter what assumptions we make about the velocity of light. What about the third one? As we have seen in the discussion preceding equations (1), the Galilean transformations assume tacitly that the position and time of occurrence of an event are the same in all inertial frames. The question arises uhether or not this assumption is sensible if the velocity of propagation of signals (light signals) is not infinite. This would question, then, in our example of the train, whether it is sensible to assume that the clock at the railway station shows the same time as the one in the moving train. We can see that this is not a valid assumption. To show this, let us try to achieve simultaneous operation of the clocks. We could start two identical clocks, one in the railway station and one in the car when the train is at rest at the railway station. If the rate of the clock would not change when the train is set in motion we would have accomplished our task. However we do not know this, and we either have to test this hypothesis or proceed in a different fashion. What we inevitably will do is the following: we take two identical clocks, put one on the train and leave the other one at the railway station. Now, when the train is in motion we send a signal from the station to the train, say exactly at noon. If this signal would travel with an infinite speed we simply would set the clock in the train to indicate noon, and the synchronization would be accomplished. However, if the signal travels with a finite speed we must take into account the time which is needed for the signal to reach the train. It is just this delay which is ambiguous. The conductor, knowing that the stationmaster is to send the signal at the time t later than the train was at the station, says that the distance is ut, where u is the velocity of the train, and if the signal velocity is c, the delay is $(u/c)\ t=\beta t$, where $\beta=u/c$. He will then expect to receive the signal at $t'=t\ (1+\beta)$. The stationmaster will say that, since the train is receding during the signal's flight, the distance traveled by the signal is $u\ (t+\Delta t)$ and the delay time is given by $\Delta t=\beta\ (t+\Delta t)$ or $t'=t+\Delta t=t\ (1-\beta)^{-1}$.

The difference in the two computations is exactly that in the naive Galilean reference it is impossible that the signal velocity, c, can take the same numerical value in two reference systems moving with a velocity u with respect to each other. Since both conductor and stationmaster observe, in the train and in the station, respectively, that light velocity has the same numerical value, c, each computes the delay time as though the other is moving away from him. The conflict between the computations of conductor and stationmaster is resolved if each believes that the other's clock runs slow by the factor $\sqrt{1-\beta^2}=\sqrt{(1+\beta)(1-\beta)}$. The conductor will then say that his clock should register $t'=t\ (1+\beta)/\sqrt{1-\beta^2}=t\sqrt{(1+\beta)/(1-\beta)}$, whereas the stationmaster will compute $t'=t(1-\beta)^{-1}\sqrt{1-\beta^2}=t\sqrt{(1+\beta)/(1-\beta)}$. They will still disagree about whose clock runs slow. and still disagree about the delay in the signal, but they will agree in the computation of the relation between t' and t, an agreement that is verified experimentally.

To sum up this important step, we can say that the constancy of the velocity of light in different frames. and the existence of equivalent frames, are logically compatible if we modify the transcription of space and time data from one inertial system to another. This means that we must find another set of transformations which will take the place of the Galilean transformations. Moveover, this modification is not only permissible but required, from a physical standpoint. since it is the mathematical description of the empirical procedure to set up synchronous clocks in different inertial systems of reference. It was the brilliant achievement of Einstein to realize that this modification of our space and time concepts (to achieve the logical compatibility of equivalent frames with the existence of a constant velocity of light) is required if we analyze carefully how a finite signal velocity influences the meaning of time in a system of reference, if time is defined in terms of operations such as the indications of clocks which are situated in the immediate neighbourhood of the event, moving with the same velocity as the observer.

Our next step is then to find that set of transformations which will replace the Galilean ones. This will furnish us with the rela-

tions which tell us how to correlate space and time data in two different systems of reference, moving with a constant velocity relative to each other, in such a fashion that the velocity of light should be the same in both. If we try to satisfy chis last condition we find the transformations to be of this form:

$$\begin{aligned} x &= (x' + ut')\gamma \\ y &= y' \\ z &= z' \\ t &= (t' + \tfrac{x'u}{c^2})/\gamma \end{aligned} \qquad (2)$$

where c is the speed of light, $\beta = u/c$ and $\gamma = \sqrt{1-\beta^2}$

The relative arrangement of the co-ordinate systems is the same as for equations (1). These equations describe the so-called Lorentz transformations, named for Hendrik Antoon Lorentz, a Dutch physicist who investigated them for the first time before Einstein.

We have then a framework which is based on three postulates: that inertial systems of reference exist; that inertial systems differ from each other at most by the fact that they may move with a constant velocity relative to each other; and that the transcription of space and time data from one inertial system to another is done according to the Lorentz transformations, equations (2). The physical description of the external world which satisfies these conditions is called Lorentz invariant and forms the Special Theory of Relativity.

The experimental confirmation of this theory is so extensive that we can give only a few examples. First let us discuss the special implications of the Lorentz transformations. Naturally, we will expect that some interesting consequences arise from the fact that we no longer have an absolute time, the same in all frames of reference. This means that both the spatial distance between points and the duration of a process will change as we change systems of reference. For example, a metre rod, if at rest relative to us, has the length one metre. Set it in motion in the direction of its axis, measure its length again, and the new measurement will be less by a factor $\sqrt{1-\beta^2}$. For ordinary velocities this factor is practically one; for large velocities, however, it may be much less than one. For example, if the metre rod is flying by an observer with a velocity of about 0.85 times the velocity of light ($\beta = 0.85$), the observer will measure its length to be only a half metre.

With time indications it is just the other way around. The seconds indicated by a moving clock will be longer by a fraction $1/\sqrt{1-\beta^2}$ (longer, since this factor is bigger than one). This is very dramatically confirmed by recent experiments on elementary particles. In nature we encounter elementary particles, the mesons, which have a rather short lifetime. In principle this lifetime could be used as a time measure, and so the meson could function as a clock. Accordingly. the lifetime of a moving meson ought to be longer than the lifetime of a meson at rest. In cosmic rays the mesons move practically with the velocity of light, and thus the life of a moving meson should be much longer than that of the meson at rest. Indeed, mesons which are stopped in an absorber have a lifetime of about 1.5×10^{-6} sec. On the other hand, in cosmic radiation a meson travels a distance of about 50 km. before it decays. From this fact we find that the speed of such a meson is about $(1 - 1/5{,}000)$ times the velocity of light. and the lifetime of a meson in our reference frame is increased by the enormous factor of 50.

As far as electrodynamical experiments are concerned, they naturally will agree nith the Special Theory of Relativity, since the latter was created just to incorporate these experiments. Consequently, the success of Maxwell's electrodynamics means automatically the success of the relativity theory as well. For historical reasons we mention the famous Michelson and Morley experiment which showed conclusively that the velocity of light is the same in all inertial systems of reference. The idea of the experiment, which is due to James Clerk Maxwell, is very simple. Suppose that the velocity of light does depend on the state of motion of the observer; then. test the consequences of this hypothesis. We send outa light signal in the direction of motion of the earth, and another signal in the opposite direction. In one case the observer travels in the same direction as the light, which, under the hypothesis, would make the observed light velocity less than if the observer had been at rest. In the other case the velocity of light as observed should be larger than the velocity observed by an observer at rest. The difierence between these two velocities could be observed interferometrically. This task was performed first by A. A. Michelson (1881), and later in improved form by Michelson and E. W. Morley (1887) (see MICHELSON-MORLEY EXPERIMENT). The result was negative; no difference in the velocity of light was found. Naturally, there were attempts to explain this before establishment of the Special Theory of Relativity.

In 1893 G. F. Fitzgerald, an Irish physicist, and in 1895 Lorentz proposed independently the following explanation. Suppose that the velocity of light does vary with the state of motion of the observer. But suppose as well that the linear dimension of a body in the direction of the motion contracts in the ratio $\sqrt{1-u^2/c^2}$. Then, the observed velocity would be the same, independent of the velocity of the observer. Moreover? this supposition conformed with the theory of electrodynamics, since Lorentz showed that if matter consisted only of charged particles held together by electromagnetic forces, then, if set in motion, the relative positions of the particles would adjust themselves in such a fashion that the contraction would take place.

We know now that this contraction does not depend on the special nature of the forces which keep matter together. but is a simple consequence of the Lorentz transformations, as we have seen in the discussion of equations (2).

Let us turn now to the mechanical experiments. First, a remark. While electrodynamics was born Lorentz-invariant, though its creator. Maxwell, did not realize it, mechanics was made to be Lorentz-invariant. This happened in two steps. First, modifications were introduced in the definitions of mechanical quantities so that the Newtonian equations of motion would conform to the Special Theory of Relativity. The classical concepts of mechanics, such as inertia and force. were retained, however. Finally, with the advent of the General Theory of Relativity, even these concepts were modified or removed. In this section we will discuss the first stage of development, while the next stage will form the content of the description of the General Theory.

The reformulation of dynamics in a Lorentz-invariant form, while retaining the classical concept of force, brought some beautiful results. Classical dynamics contained three most important laws concerning the conservation of energy, momentum and mass. These laws were essentially independent. and we would have been able (in principle) to drop one and retain the others. In the Lorentz-invariant formulation this freedom no longer exists. Here, the three conservation laws are fused into one: and the violation of one entails the violation of all. Moreover, because the conservation of energy is linked to the conservation of mass. processes are permitted which would change energy into mass, or mass into energy (if the amount of mass which disappears in a given physical event is m, there will appear an amount of energy $E = mc^2$, c being the speed of light). Indeed, the last of these processes is the one which provides us with prodigious amounts of energy in nuclear reactions.

In other respects, the differences between the classical and relativistic dynamics are most pronounced in the description of fast particles. This is natural, for we know that the difference in the classical and relativistic descriptions arises from the fact that in the classical theory there is no limiting velocity. If a particle moves slowly, it cannot make any difference, as far as the result is concerned, whether we consider a limiting velocity which is very large, or actually infinite. Expressing it in another way, classical Newtonian mechanics must be a limiting case of relativistic mechanics. This limiting case can be reached from the relativistic formulation by placing the velocity of light equal to infinity. and it can be applied in cases where the actual velocities of the bodies under description are much less than that of light. (This is a good example of the growth of physical theories. Each theory describes a part of our experiences correctly. However, the conditions under which this description is correct are usually

less general than was originally thought. With the arrival of new facts this is realized, and a new, more general theory is created which, though it may be based on entirely different concepts. contains the mathematical formalism of the old one as a limiting case. Thus a new physical theory does not replace the old one but generalizes it.)

There are numerous examples showing that the proper description of fast-moving particles is the relativistic one. In modern research, physicists often experiment with very fast particles, which are accelerated in machines by electromagnetic fields. In the design of these machines (cyclotrons, betatrons, etc.) the physicist uses relativistic dynamics with the same confidence that an engineer feels when he uses Newtonian mechanics to design motorcars. The successful operation of particle-accelerating machines shows how correct the relativistic description of fast particles is.

The mathematical description of the Special Theory of Relativity and its content was greatly simplified by the geometrica! interpretation given to it by Hermann Minkowski, a German mathematician. This interpretation had the most far-reaching significance, since geometrization provided the clues which finally enabled Einstein to generalize the theory so as to embrace gravitational forces as well. Moreover, Minkowski's interpretation suggested the proper mathematical tools, tensor calculus and differential geometry, which gave the theory great elegance.

The underlying idea is the following. Every observer must specify four data (x, y, z, t) to describe an event. The first three of these will specify the location of the event relative to a co-ordinate system, while the last one specifies the time relative to a clock at rest in this co-ordinate system. In those cases where there are only three (or two) quantities to be specified. it is quite customary to draw a graph to represent the totality of these measurements at one glance. Even if in practice we cannot draw a four-dimensional graph (plot four quantities at once), we can think about it. To facilitate our understanding we will now contemplate only situations where the position can be given by two data only. So, let us suppose that we are aboard an ocean liner and we want to have a graphical record of our journey. The simplest thing to do is to take the map and at each hour, say, put a point at the proper latitude and longitude where the boat is, and write next to it the time, It is much more revealing, however. if we make a three-dimensional model, and put the dot not on the map, but above the intersection of the proper longitude and latitude. The perpendicular distance from map to point should be proportional to the time elapsed from the departure. If we do this each hour and finally connect all these points with a thin wire. the wire will contain in a graphical form all the information about the journey.

This information shows not only the location of the boat at a given time, but much more. If the wire is straight, it tells us that the boat has traveled on a straight line with constant speed. If the wire lies in one plane (normal to the map), but describes a curve in this plane, the boat was traveling on a straight line, though the speed did change during the course, etc.

Now if we take a particle instead oi the boat and note mentally in a four-dimensional space its position (x, y, z) at time t for each instant of time, we will get a similar plot. Each point on the plot specifies an event. and the resulting curve is called the world line of the particle; it describes the history of this particle. The four-dimensional continuum in which the plotting takes place is called space-time (*q.v.*). The immense importance of this concept is as follows: suppose that several different observers, each using a different inertial system of reference, are observing the motion of a particle, and each is asked to construct a space-time diagram of the motion. According to the Special Theory of Relativity, each observer will construct exactly the same curve in space-time for the history of the particle. The different states of motion of the observers (since they use different inertial systems of reference) will manifest themselves by the fact that the co-ordinate axes in space-time, x, y, z, t (which localize an event in space-time relative to the inertial system of reference used by the observer): will be different for different observers. The relations between these axes is that given by equations (2); thus, we can pass from one set of axes in space-time to another set by a Lorentz transformation.

This is the great moment of geometrization. In geometry we are dealing with the description of objects and the relations among them. Such objects can be points, lines, planes, surfaces, bodies, etc. We describe them by giving the co-ordinates of the corresponding points relative to a co-ordinate system. If we change the co-ordinate system we change the description, but we do not change the configuration of the points we describe. In relativity theory the histories, the configurations of points describing events, are objective. Their description relative to an observer depends, however, on the co-ordinate system in space-time that the observer uses and the co-ordinate system in turn depends on the state of motion of the observer. A Lorentz transformation corresponds to a change of co-ordinates in space-time. As a co-ordinate transformation leaves the configuration of points unchanged, so a Lorentz transformation does not change the histories. Also, in a co-ordinate transformation the new co-ordinates, in general, will be given combinations of the old co-ordinates. In a Lorentz transformation the new space-time co-ordinates will be a combination of the old space-time co-ordinates. The mixing of space and time co-ordinates in a Lorentz transformation is then no more mysterious than the mixing of co-ordinates in an ordinary co-ordinate transformation. Moreover. the physical laws will now be geometrical propositions concerning world lines. In this way our geometrical intuition can come into play again, and can furnish help in the formulation of theories and problems. We will at once expect that the significant geometrical properties, such as curvature, torsion and straightness, will also describe physically significant properties. Indeed, this is so. For example: a curved world line shows that the particle was accelerating, and thus we know that a force was acting on the particle whose history is described by this world line. The place and time of the action can be determined by locating the curved section of the world line relative to a system of reference in space-time. The magnitude of the curvature will be simply proportional to the magnitude of the force and the work done by the force. As a corollary we see that if no forces are acting on a particle its history is a straight line in space-time.

In geometry it is the distance between two points which has an intrinsic significance: while the projections of this distance upon the co-ordinate axes depend on the co-ordinate system, and vary as the co-ordinates change. A similar thing happens in relativity theory.

The distance between events, which we will call an interval, is something absolute, represented by a line segment connecting the two events. Each observer will split this interval into a space part and a time part., relative to his own inertial system of reference; the spatial part will be the projection of the interval upon the spatial co-ordinates (x, y, z), while the time part will be the projection of the interval upon the time axis. This splitting into spatial and time parts will depend on the orientation of the co-ordinate system x, y, z, t in space-time.

For example, take as one event the Great Fire in London. and for the other event the outburst of the nova Persei. The observer who is at rest relative to the earth (and so, relative to London) will split space-time with his co-ordinate axes and find that the outburst took place a century before the Great Fire and many millions of miles away from London. An observer who travels with a constant velocity relative to the earth may conclude that for him the distance and time elapsed is different. There will even be an observer with a certain velocity such that for him the two events took place simultaneously. Each observer slices up space-time into a space part and a time part, and the slicing depends on the orientation of the co-ordinate system. Thus, as Minkowski has put it: "Space in itself and time in itself sink to mere shadows, and only a kind of union of the two retains an independent existence."

GENERAL THEORY OF RELATIVITY

The Special Theory of Relativity has not only solved problems,

but has posed some new questions. As is usual in physical theories. the advent of new viewpoints forces us to re-examine the concepts which we used freely before. With the advent of the Special Theory of Relativity these questions were abundant. In discussing the Special Theory we have learned that the histories in space-time have some permanent significance, at least so far as Lorentz transformations are concerned. Now, if the geometrical interpretation makes sense, we would think that the other, more general transformations should be also of significance. (A geometrical figure remains the same, irrespective of the co-ordinates we use to describe it.) At firs; sight the introduction of general transformations is clearly nonsensical. Such transformations in space-time correspond physically to the use of noninertial coordinate systems. Now, it is a familiar story that in noninertial systems of reference we have fictitious forces acting. Such forces are the centrifugal and Coriolis forces, which manifest themselves in rotating systems of reference. They are called fictitious because we can make them disappear by changing back into an inertial frame of reference. Consequently, we can distinguish between these frames of reference and inertial frames, and thus the simple principle of relativity cannot hold. However, our geometrical intuition insists that there must be something behind this idea. So let us analyze what happens if we observe a physical system from an accelerated system of reference. The fictitious forces we encounter have two important characteristics. First! they impart the same acceleration to every body, irrespective of its mass; second, these forces can be transformed away by the simple device of transferring ourselves to an inertial system of reference. As an example, consider what happens when we ride in a railway train. As long as the train moves in a straight line with a uniform velocity, everything inside the train behaves as if the train were at rest. Now the train makes a turn; the luggage in the train starts to slide, the water surface in a pitcher is no longer horizontal. Sitting inside the train, we conclude that a force is acting on these objects. The acceleration imparted by this force is the same for each body, and it disappears as soon as the train runs in a straight line with constant velocity. However, we can also say that, after all, the objects in the train wanted to continue to travel on a straight line with a uniform velocity on account of their inertia, and only we, the observers (and our system of reference, the train), were accelerating; hence, it is natural that all objects should have the same acceleration, since after all this is just the observer's acceleration in the opposite direction. Thus, the inertia of the body is essentially what we see as a fictitious force. Also. it is obvious that if we cease to be in an accelerated frame of reference, we will see the other objects travel along straight paths with constant velocities (if they are not acted on by other forces), thereby transforming away the fictitious forces. If we say all that, we are correct. The puzzling thing, however, is that there is another force, the gravitational force, which has these two properties. A falling apple undergoes the same acceleration as a falling cherry. though their masses differ. Also, if we fall together with the apple, it will appear to be at rest relative to us. apparently with no force acting on it.

This suggests that there must be an equivalence between noninertial systems of reference and gravitational fields, in the sense that an observer performing observations locally cannot distinguish between gravitational forces and forces which arise on account of accelerated systems of reference. Consequently, the admission of noninertial systems is necessary to construct a theory of the gravitational forces. But if accelerated systems are equivalent to gravitational forces, then gravitational forces should be in all respects similar to the fictitious forces. We have seen that these fictitious forces are essentially the manifestations of the inertia of bodies. The gravitational forces then must be similar manifestations.. How could we formulate this?

We have learned in the Special Theory that the world lines of particles not acted upon by any forces are straight lines. These world lines have the important geometrical property of being as "straight" as possible. In geometry such lines are called geodesics. This we will consider as the proper characterization of inertia, and we can say that the world line of a particle subjected only to its own inertia is the straightest line in space-time; it is a geodesic. Then, if we exclude any other forces, except gravitational and other fictitious forces which should be the manifestations of the inertia of the bodies, we should be able to say the following: there are no forces acting on bodies; bodies always move freely under the influence of their own inertia. Consequently, their motion is such that their world lines are geodesics in space-time.

This space-time, of course. cannot be the space-time of the Special Theory, for there, we have just learned, the geodesics correspond to the motion of bodies which are not subjected to gravitational forces in the ordinary Newtonian usage of the word. The space-time continuum of the General Theory of Relativity must have additional properties. What are they? Again, our geometrical intuition comes to help. We know that the properties of geodesics depend on the curvature of the geometrical space. As a simple example let us take a two-dimensional space, a surface. If.this surface is flat, the geodesics on it are ordinary straight lines (in the sense of Euclidean geometry); if the surface is curved, *e.g.,* if it is part of the surface of a sphere, the geodesics are not "straight" any longer in the Euclidean sense. On the surface of a sphere the geodesics are great circles! and their projections onto a plane will appear as curves. Thus, our analogy will lead us to believe that, in general, space-time will be curved. while the space-time of the Special Theory was flat. The history of a particle will be described by a geodesic in this curved space-time. If we would project this geodesic onto the flat space-time used in the Special Theory, we would get a curve which is not a geodesic in this flat space-time. The deviation from a geodesic in flat space-time will become larger as the curvature of space-time increases. However, our considerations must embrace the fact that in Newtonian mechanics gravitational forces exist only in the neighbourhood of masses. This must find its counterpart in the geometrical picture. The reasoning is very simple. If gravitational forces find their expression in the curvature of space-time, and these gravitational forces were caused by masses in the Newtonian theory, then, in the General Theory, the masses must cause the curvature of space-time. Indeed, this seems to be the solution.

The structure of the Newtonian theory of gravitation is the following. Space and time are the stage upon which physical processes are displayed. In these processes the masses are acting directly upon each other. In the General Theory of Relativity, space and time are first fused together into a continuum called space-time. The geometrical properties of this space-time determine the evolution of the physical processes in space and time. The geometrical properties of the space-time continuum in turn are determined by the masses (and physical processes) present in space and time. Thus in the latter theory we do not have anything external or uninfluenced. and the series of causes of mechanical phenomena is closed. (Observe, however, that this is not so for phenomena caused by electromagnetic and nuclear forces.)

These ideas and their mathematical formulation were finally given by Einstein in 1916. The geometrical properties of space-time are characterized by ten functions, which form the so-called "metric tensor" of this four-dimensional continuum. (Knowing the metric tensor, we can compute the separation of any two events in space-time.) Einstein formulated the field equations which relate these ten functions and their derivatives to ten other functions which describe the material content of space-time. These second ten functions form the "energy-momentum tensor," and they are the measure of the amount of energy (hence also mass) and momentum present in a portion of space at a given time.

The relationship mentioned has a very simple physical significance and is the mathematical expression of the idea that the curvature of space-time is caused by the masses and their motion. From the metric tensor and the derivatives of its components we can form another tensor which is the measure of the curvature of space-time at a given point in space-time. Einstein's equations state essentially that the curvature of space-time at a given point in space-time is proportional to the amount of energy and momentum present at that point in space-time. Moreover, from the

geometrical picture we can see that there always will be such a system of reference in which events in the immediate neighbourhood of the observer (local events) can be described according to the Special Theory. This follows from the fact that any curved space can be approximated locally by a flat space which is tangential to the curved space at that point. (For example. think of the curved space as the surface of a sphere, and the tangential flat space as the tangential plane.) Physically this corresponds to an accelerated frame of reference which has the same acceleration as caused by the gravitational forces at that point. (Thus again we can see how a more general theory embraces the special one as a limiting case.)

For any given material content, we can solve. in principle, the field equations and obtain from them the metric tensor. From the metric tensor we can compute the geodesics of space-time, which describe the history: and thereby the motion, of matter in the universe. The history of light rays can also be obtained, since they iorm a special class of geodesics, the "null geodesics." (These have no simple geometrical analogies from ordinary geometry, so we will omit discussion of them.)

Logically, then, the theory rests in its present form on two different postulates. First, the metric tensor shall satisfy the field equations; second, the history of a particle is given by a geodesic in space-time having the aforementioned metric tensor. Although we have seen that the second postulate played an important role in the formulation of the theory, the question arises whether we should not be able to discard it and extract all the information from the field equations only. Indeed, this proves to be the case. In a beautiful set of papers, Einstein and his coworkers attacked the problem in this fashion during the years 1938–49. Let us assume that mass points can be represented by singularities of the metric tensor. If, then. we want to have a solution for the field equations, the singularities must satisiy certain conditions. These conditions turn out to be just the equations of motions of mass points.

Sow what about the experimental verification of the theory? The theory was subjected to three important tests. First. we can compute the orbits of planets from the General Theory. Barring the planet Mercury, the difference between the Newtonian orbit and the relativistic one is negligibly small for practical purposes. However, for Mercury. the Newtonian theory predicted the orbit incorrectly. Since the time of U. J. Leverrier, the French astronomer, it was known that there is a discrepancy between the observed motion of the Mercury perihelion and the one predicted by Newton's theory, even if we take into account the perturbations caused by the other planets. The first big success of the General Theory came when Einstein showed that this discrepancy disappears if we perform the calculations relativistically.

There are two other effects predicted by the General Theory, both concerning the propagation of light. According to the General Theory the world lines of light rays must also be geodesics (null geodesics). Consequently the propagation of light will also be influenced by the presence of masses. For this reason light rays will be deflected from their original path if they pass in the neighbourhood of bodies. If these bodies are very large, the effect can be observed. (Actually; rays which pass the object near enough will circle around it a few times before they go off to infinity!) The most suitable large mass at our disposal is the sun. The measurements can be performed in the following fashion. First we take a photograph of a part of the sky when the sun is not in that neighbourhood. Sext we take one when the sun is there. Saturally, the latter picture has to be taken during a total eclipse; otherwise, we will not see the nearby stars at all. If the sun deflects the light rays, the angular distance between two stars lying at diametrically opposite sides of the sun must be larger on the second picture than on the first one. There have been five attempts to measure the effect precisely. All measurements have shown the effect to be present. The precise evaluation of the numerical magnitude. however, is very difficult on account of experimental complications. The theoretical value is 1.74 sec. The five experimental observations scatter around this value, and each observation has a probable error large enough to embrace the theoretical value. (Two of the five observations took place in 1919, and one each in 1922, 1929 and 1951.)

The third experiment concerns the frequency shift of spectral lines emitted by atoms located in a gravitational field. We have already mentioned in discussing the Special Theory that atoms can be considered as clocks, since the radiation emitted by them has a periodicity· the frequency, which can be used to measure time. One of the predictions of the General Theory is that clocks in a gravitational field run slower than the same clock would run if the gravitational field were not present. Consequently, the slowing down of an atomic "clock" will mean the emission of light with a smaller period and thus a frequency shift in the spectral lines toward the red. All investigations have confirmed the existence of this effect. However, for atoms located on the surface of the sun, there are so many other disturbing factors which modify the effect that we hardly can attach great significance to the numerical values obtained for the red shift caused by the sun. On the other hand, measurements performed on light emitted by the companion to Sirius give the same order of magnitude as that predicted by the theory.

In our discussion which led up to the formulation of the General Theory we have reduced the concept of gravitational force to that of inertia, eliminating the idea of force (at least the idea of gravitational force). We have done this by agreeing that the world line of a particle should be a geodesic in space-time. The action of other bodies manifests itself only by changing the geometrical properties of space-time.

However, we can now think of this in another fashion. If gravitation could have been conceived as a sort of mutual interaction of bodies (and of course we now have reduced the idea of gravitation to that of inertia) then could we perhaps conceive that inertia is actually a manifestation of a mutual action between bodies? As far as the histories of particles are concerned, we have already done that. But the inertial properties of matter find their expression also in the mass of bodies. So the question arises whether the concept of mass does not depend essentially on the existence of other bodies in the universe. Ernst Mach, an Austrian physicist, first posed this problem, before the advent of relativity theory. It seems that the General Theory answers the question in the affirmative. It follows from the theory that (1) the mass of a body increases when ponderable masses approach it; (2) if neighbouring masses are accelerated there is a force acting on the body (in the same direction as the acceleration) ; and (3) a rotating hollow body creates a field of force inside itself! a field which acts on particles inside the hollow body. These effects are much too small (for ordinary bodies) to be observed. However, it might be possible that if the rotating masses are of cosmic magnitude. of the size of galaxies, for example, the effects on light rays could be detected.

Another interesting inierence we can draw from the General Theory is the way gravitational disturbances are traveling. This is of great interest, since one of the chief objections to Newton's theory was the instantaneous action of gravitational forces; *i.e.*, their infinite speed of propagation. The results are the following. Moving bodies, on account of their motion, emit a weak gravitational field in the form of waves. These waves travel with the velocity of light. At a large distance from the source the waves are transverse and polarized. The energy loss of the source due to this radiation is very small, being proportional to the inverse fifth power of the velocity of light. For double stars the energy loss per year would be about 10^{-12} part of the total energy.

Until now we have discussed how individual masses influence the geometry of space-time. The result has shown that in the main the Newtonian conclusions were good approximations, though the concepts invoked were of an entirely different nature. This was connected with the smallness of the masses, distorting only a little the flatness of space-time. If this be the case, we may reasonably expect that great differences may arise if we consider problems which entail the universe as a whole, considering all the masses in the universe. In other words we may expect that the cosmological theories stemming from the General Theory of Relativity can

be of an entirely different nature than the Newtonian ones. Relativistic cosmologies vary in scope and importance, and though some of them describe part of our experiences correctly, none can be singled out as the best. (*See* COSMOLOGY; COSMOGONY.)

UNIFIED THEORIES

The General Theory of Relativity has eliminated the concept of gravitational forces. The "guidance" of particles does not take place by a direct interaction between them, but is accomplished by the geometrical structure of space and time. Gravitational forces, in the Newtonian sense, arise only if we refuse to interpret properly the geometry of space-time.

Naturally this makes us wonder whether the other existing forces, electromagnetic and nuclear, are also merely misinterpretations of the geometry of space-time. Our aesthetic sense would be greatly pleased if these forces were found to stem from the same origin as the gravitational forces.

There were numerous attempts to endow space-time with such a geometrical structure from which the existence of the other forces would follow. However, while nature gave us a guide in the case of the gravitational forces, to wit, the similarity between fictitious and gravitational forces, we do not see any simple or suggestive relation between the gravitational forces and electromagnetic and nuclear forces. In addition to this, it is also possible that unification cannot be achieved in this fashion. We know now that the description of the microscopic properties of matter and its interaction with radiation brings entirely novel features to physics, features which are dealt with in quantum theory (*see* QUANTUM MECHANICS). These features are not present in the General Theory; and it is quite possible that unification has to proceed via a theory which embodies the quantum aspects. (There were attempts to introduce the quantal aspects by formal manipulations in the General Theory [quantization of the gravitational field]. The nonlinearity of the gravitational field equations makes this approach somewhat ambiguous. For weak gravitational fields the quantization is mathematically unambiguous; the results would indicate that the gravitational field has a particlelike aspect where the particles have a spin two. [Compare this with the electromagnetic field, which, upon quantization, also acquires a particlelike aspect. The particles there are called photons.])

The general trend toward constructing a unified field theory is somewhat as follows: the Riemannian geometry of four dimensions, which described the geometry of space-time in the General Theory of Relativity, has no available functions which could be used to describe other fields of forces. Consequently we have to enlarge this geometry in such a fashion that just the sufficient number of functions appears.

If the unification extends over the gravitational and electromagnetic fields there will be at least 14 functions needed, 10 to describe the gravitational fields as in the General Theory and at least 4 to characterize the electromagnetic field, as in Maxwell's equations. Of course the unification may bring in some additional functions, too, just as in the General Theory ten functions are needed to characterize the gravitational field completely, while in the Newtonian theory one was enough.

Suppose we have some ideas about what this geometry should be; what will then be the essential features of the theory? First, it must furnish a sufficient number of equations from which we can determine the functions describing the fields. Next, it should furnish in some fashion the equations of motions of charged and uncharged particles. If possible, it also ought to furnish a good definition for particle (as, for example, in the General Theory a mass point was a singularity of the gravitational field). Finally, we would expect that the fields will be, in general, tangled up (otherwise we would have only a formal unification), and will reduce to distinct electromagnetic and gravitational fields only under certain conditions, which, loosely speaking, would correspond to weak fields. The theory also should furnish the condition for weakness. If we want to incorporate the nuclear forces, we have to include in our program the description of additional fields, called meson fields.

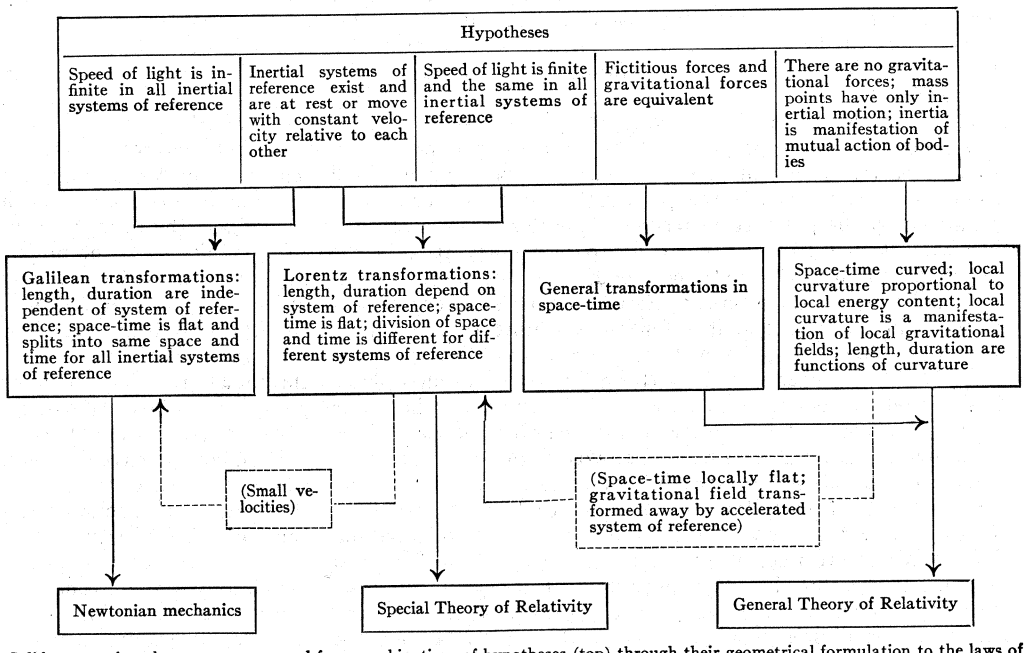
This alone is already a formidable program. However, it is aggravated by the following problem. Suppose we have established tentatively a system of geometrical field equations. The functions, or field components, which are connected in this way have to be identified now with physical quantities, and the equations must be identified with physical field equations. This is not at all so simple as it may sound, and ambiguities may arise. This difficulty of interpretation is a rather novel feature of our unification problem, and it is intimately linked with the fact that our generalization proceeds from mathematical considerations and not from physical ones, which immediately would have given a meaning to the mathematical quantities used to represent the physical observables entering these considerations.

The loosening up of the geometrical structure to accommodate the additional field variables was pursued in two rather different ways. One way retained the idea of a four-dimensional continuum as the playground of physical phenomena, but used a non-Riemannian geometry in place of the Riemannian geometry which described space-time in the General Theory. The other way used a higher-dimensional continuum and projective or conformal geometries (*see* UNIFIED FIELD THEORY).

It is not easy to tell how far these attempts will prove successful. On the one hand, we cannot see clearly the conclusions which can be drawn because of the mathematical complications. On the other hand, as we have mentioned, the physical interpretation is in general far from being evident, and for this reason the interpretation and the mathematical development must proceed together. This complicates both the mathematical understanding and, thereby, the hope of experimental verification or refutation.

However, there is in both theories one prediction, obtained by

Outline of Hypotheses and Their Interrelationships



Solid arrows show how we may proceed from combinations of hypotheses (top) through their geometrical formulation to the laws of Newtonian mechanics and the Special and General theories of relativity. Dotted arrows show ways of passing from one theory to another by using the approximations shown in the dotted boxes.

Erwin Schroedinger, which in principle makes possible an experimental test. Alas, the effect is too small to be measured. This effect is the following: if in a region of space-time gravitational and electromagnetic fields are present simultaneously, an electric current field must be present in the same region, in general. On the surface of the earth, where gravitational and magnetic fields are simultaneously present, this mould correspond to a small additional magnetic field, the strength of which is of the order of r/R times the primary magnetic field strength (the latter being about one-third gauss). The factor r/R is fantastically small, r being the gravitational radius of the earth (a few centimetres) while R is the actual radius of the earth (about 6.4×10^8 cm.).

It is much more difficult to give a coherent and simple account of the unified theories which use higher dimensional geometries. In all these cases the additional dimensions have no physical significance and their introduction is purely formal. The additional dimensions simply enable us to obtain enough functions to describe the different kinds of fields. At some stage or another we have to eliminate, by some assumption, the explicit appearance of the variables describing the additional dimensions (but not, of course, the additional fields), since these dimensions have no physical significance.

Apart from the formal nature of these considerations the principal difficulty is that most of these theories give only a formal unification of the electromagnetic and gravitational fields: both fields remaining clearly separated, irrespective of their strength.

Synge, *Relativity: the Special Theory* (1555). The important original articles of Einstein, Lorentz, Minkowski and Weyl were collected in the book entitled *The Principle of Relativity* (1923). The history of relativity is covered by E. T. Whittaker, *A History of the Theories of Aether and Electricity,* vol. ii (1553). (N. L. B.)

RELATIVITY: PHILOSOPHICAL CONSEQUENCES. The most important philosophical consequence of the theory of relativity is the clarification it has brought into the relations between science and philosophy. The position may be briefly summarized as follows. Up to the 17th century the subject matter of these studies formed a unity, the rudiments of that which we now call science being simply a part of a larger whole. A rift then appeared and gradually widened until, by the beginning of the 20th century, science and philosophy had become quite distinct and a person expert in one was usually very inexpert and ill-informed in the other. The effect of the relativity theory was to re-establish physics on a philosophical basis and thereby to elucidate certain bewildering implications of current research.

More particularly, the position was this. The general problem of philosophy is to give a rational account of experience with the minimum of presuppositions. Consequently it was not originally presupposed that physical experience must be regarded as an effect on our senses of an objectively existing external world having certain definite and ascertainable properties: that was a matter for discussion, and both affirmative and negative answers were given. Modern science, however, originated in the determination to ignore the metaphysical question and to accept experience as an object of study, whether or not it was "real." Thus Galileo discovered the law of falling bodies by measuring how the space covered varied with the time of fall. By carrying out certain processes of measurement he obtained results which stood in a certain relation to one another, and this relation remained true whatever metaphysical status one assigned to motion.

This became the origin and type of a large body of investigation which. by reason of its distinctive character and its rapid growth and success. came to be regarded as something other than traditional philosophy and was given the name "science." Nevertheless. it was still an attempt to give a rational account of experience with the minimum of presuppositions. Moreover, although it needed no supplement. it was in fact coupled from the beginning with a particular view of what the measurements signified. Galileo, for instance. supposed that they represented the magnitudes of certain characteristics of the external world which he regarded as possessing only mechanical properties such as size, shape, position. motion; other qualities (*e.g.*, colours. sounds, temperatures) he thought were not properties of the bodies which seemed to possess them but were contributed by the observing subject. This view was tenable in his day since he was unable to measure such things; but after the invention of thermometers, spectroscopes. etc.. there remained no reason for distinguishing these so-called secondary qualities so fundamentally from motions and shapes. and they were gradually put back into the external world and included among the objectively existing properties of bodies. which science investigates.

The progress of physics from Galileo's time up to the beginning of the 20th century had therefore a t ofold aspect: in practice it was a faithful prosecution of the program of carrying out certain operations of measurement and finding relations between their results; in theory it mas an investigation of the metrical properties of an external world. While the latter view was of almost indispensable assistance in pointing the way to the most profitable operations of measurement to perform. the achievements of physics can clearly stand in their own right if it is abandoned and if no suppositions at all are made about the metaphysical status of the measurements performed. So instinctive. however, had this particular metaphysical interpretation of physics become that when. in 1887, the Michelson-Morley experiment (*q.v.*) gave an incredible result, it occurred to no one for nearly 20 years to inquire whether the root of the anomaly might not lie in the invalidity of that interpretation. That this was actually so is the essential point of Albert Einstein's special relativity theory of 1905.

In the Michelson-Morley experiment a comparison was made between the passage of light along material bars in different states of uniform motion. The bars. when relatively at rest, were equal in length, and since, according to the metaphysical view just described, its length is an objective property of a bar, they were equal in length when in uniform relative motion. for uniform motion, according to Newtonian mechanics, can have no mechanical effect. But if that view is rejected. the "length of a bar" is not an objective property but simply the result obtained when a particular operation of measurement is made. Now the operation for measuring length was well-known, but it required that the body measured must be at rest with respect to the measuring scale; it was inapplicable if the body was moving along the scale. Hence one had no right to speak of the "length" of a moving bar. This was not because the length, an objectively existing property. could not. because of practical difficulties. be ascertained. It was because one had no right to use the word until one had the result of a particular operation to which to apply it, and no such operation had been devised for a moving body.

The theory of relativity prescribed an appropriate operation, and the experiment was then satisfactorily explained. This belongs to physics, but one aspect of it has philosophical implications. The reason why the ordinary operation for measuring length was inapplicable to a moving body was that the scale readings for the two ends of the bar varied with time when the body was moving. To get a definite result, therefore, they had to be taken simultaneously. Hence one had to know how to determine that two events at different places occurred at the same time, and on analysis it appeared that this was impossible without some arbitrary stipulation. Here again, then. the idea of something existing objectively which physical measurement revealed had to be given up. It was not that, because of practical limitations. we could not determine which of a number of spatially separated events were simultaneous. There was no meaning in speaking of the simultaneity of such events until one had prescribed a process for determining it, and there was a wide degree of liberty in prescribing such a process.

Physics was thus thrown back on the unadorned description of itself as the discovery of relations between the results of chosen operations of measurement. This description adequately covered

the whole of physics from Galileo's basic discoveries onward; but the metaphysical accompaniment that had provided the imagination with a model and the experimenter with a guide was now proved misleading. The philosopher must henceforth interpret physics in terms of operations and their results alone, leaving external existences out of account. But the physicist, finding a picture of an external world indispensable, began to devise a better one. In the old picture the world consisted of pieces of matter, measured essentially by their mass, moving about, without thereby becoming changed, in an infinite extension called space and an independent extension called time. According to the revised picture, matter, space and time are no longer independent but merge into a single continuum, space-time—a device made possible by the fact that, according to the definitions adopted for the length of moving bodies and the time relations of separated events, a certain combination of the space and time separations of events is independent of the state of motion which we choose to assign to any one of the bodies concerned. We can thus suppose that this combination of our measurements measures some absolute quality of events, just as we previously thought that the measurement of length indicated some absolute quality of a body. The masses of bodies, however, still change with motion; but going farther in the same direction, the general theory of relativity succeeds in prescribing a combination of space, time and mass measurements that is independent of motion altogether and so—for the time being, at any rate—can pose as an aspect of an external world of which physical measurements provide a quantitative description. From the philosophical point of view, however, it would be exceedingly unwise to forget, as pre-relativity physics did, that all such pictures are but an aid to investigation and have no fundamental significance whatever. It has been shown, indeed, that when the phenomenon of radiation is treated in the same manner as the phenomenon of motion, an "entropy-time" emerges which is of precisely similar character to the space-time of mechanics. Neither of these concepts is to be regarded as objective in the way that space and time were formerly thought to be.

The general effect of all this on the philosophy of science has been to emphasize the distinction between the empirical and the rational. It was the theory of relativity that chiefly inspired the Vienna circle, later known as the logical positivist school, to formulate their verification principle, according to which the meaning of any statement is determined by the empirical steps necessary to verify it. Statements that are not susceptible of empirical verification (or falsification) are either rational (*i.e.*, tautological) or nonsensical. The absolute simultaneity of separated events is a typical example of a nonsensical concept since it is neither empirically determinable nor a rational necessity.

Precisely the same classification was made by Sir Arthur Eddington, who also was inspired primarily by the relativity theory: but whereas the logical positivists have developed their views in the direction of an analysis of language in general, without special reference to physics, Eddington undertook the detailed examination of physical theory. He was led to the conclusion that the whole scheme of physical law mas rational in nature and could have been derived without any experience at all of actual events. In other words, although, as a historical fact, the laws have been derived by studying the results of measurements, they are actually so abstract that they characterize only the nature of the processes of measurement and are therefore independent of the particular results that applications of those processes have yielded.

Eddington's views on this point are not generally accepted. but it must be acknowledged that they are either not understood or misunderstood by the majority of critics—a fact for which Eddington himself is not entirely blameless. His mathematical work is not without error, and his gift for picturesque language led him at times to sacrifice rigour of expression for the sake of a vivid metaphor. He himself advanced, as the crucial argument for his view, the claim that he had derived all the dimensionless constants of physical theory from purely rational considerations; but the derivation involved such a wealth of little-known mathematical processes that a lengthy analysis was required before it could be finally appraised. One common misunderstanding, however, can here be removed: he did not claim that the whole course of physical experience could have been predicted; on the contrary, he held that none of it could. The laws of physics, he believed, were not the laws of behaviour of observed bodies but those of postulated entities. Only when observed bodies were identified with such entities were the laws applicable to them, and any lack of agreement mould indicate, not a failure of the laws, but false identification.

RELAXATION PHENOMENA, in physics, are phenomena associated with the approach of a system to equilibrium. If a force is suddenly applied to a system and thereafter maintained constant, some time may elapse before the system settles down to a new state of equilibrium. For instance, gas contained in a vessel contracts immediately the pressure applied to it is increased, and becomes warmer in the process; subsequently, as the gas cools to the surrounding temperature, a further slow contraction occurs. A more extreme example of relaxation is to be found in a substance like pitch, which reacts as a solid to forces of short duration, but as a liquid to prolonged stress. In such cases one may consider the system to require a certain characteristic time to stabilize itself, and to exhibit different behaviour according as the duration of the stress is much longer or much shorter than this. If the duration is comparable with the characteristic time, or if the stress is periodic with a comparable period, the failure of the system to achieve internal stability shows itself in hysteresis behaviour of the sort which commonly leads to the degradation of mechanical energy into heat. Some of these typical properties mav be examined in more detail with the help of a simple electrical circuit, which serves as a useful model of a relaxing system.

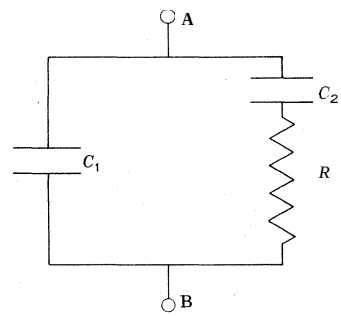

FIG. 1.— SIMPLE ELECTRICAL CIRCUIT ILLUSTRATING A RELAXING SYSTEM (SEE TEXT)

The circuit is shown in fig. 1 and consists of two capacitances, C, and C_2, and a resistance R. If a voltage V is applied suddenly (at time $t = 0$) across the terminals AB, the charge which flows will be as represented by the graph in fig. 2; there is an initial immediate flow of C_1V, charging up the condenser C_1, and a slower charge flow amounting in all to C_2V as current flows through R to charge the condenser C_2. This second process is described by an exponential law, the charge on C_2 being given by $C_2V\ (1 - e^{-t/\tau})$. in which the characteristic time τ (called the "relaxation time") is equal to C_2R. Now consider the application of an alternating voltage across AB. If the angular frequency ω is low, so that $\omega\tau \ll 1$, the voltage will change sufficiently slowly that there is time for C_2 to receive very nearly as much charge as if the voltage were steady, and under these conditions the circuit will behave like a condenser of capacity $C_1 + C_2$. If however the frequency is high. so that $\omega\tau \gg 1$, there will be insufficient time for C_2 to receive any charge before a reversal the voltage tends to remove it again and therefore C_2 will remain virtually uncharged; thus the circuit will behave like a condenser of capacitance C_1. At intermediate frequencies, when $\omega\tau \sim 1$, the effective value of the capacitance will take intermediate values and there will also be significant heat production by the currents flowing in the resistance. Fig. 3

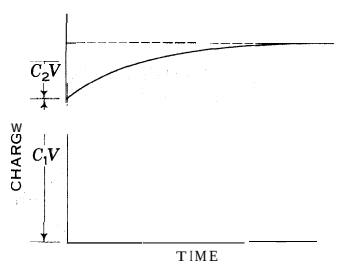

FIG 2.—CHARGE FLOW WHEN VOLTAGE IS APPLIED TO TERMINALS AB OF FIG. 1

shows on a logarithmic frequency scale the variation of the effective capacitance and the heat production per cycle; the latter varies in proportion to the frequency at low frequencies, and in inverse proportion at high frequencies. Two points may be particularly observed about the behaviour of this model. The first is that the transition is extended over a wide band of frequencies, *i.e.*, values of $\omega\tau$ ranging between $\frac{1}{10}$ and 10; the second is that the height of the peak representing resistive losses is directly related to the difference between low- and high-frequency capacitances. This is particularly clearly shown by a graph of the (complex) effective capacitance of the circuit. If the impedance Z between A and B is used to define formally the effective capacity C_{eff} by the equation $Z = 1/i\omega C_{\text{eff}}$ the two curves in fig. 3 represent the real and imaginary parts of C_{eff}; the imaginary part is resistive and determines the heat production per cycle. In fig. 4 is shown a representation of C_{eff} on a complex diagram, where the whole variation is described by a semicircle. As the frequency is increased the value of C_{eff} for the circuit moves anticlockwise from $C_1 + C_2$ to C_1; the parts reached at various frequencies are indicated on the diagram. Analogues of this complex diagram are observed in many physical systems, which may be inferred therefrom to exhibit relaxation effects governed by a simple exponential law. The examples given below are of this type, but it should be remembered that there are many more complicated examples showing qualitatively similar, but not identical, behaviour, for which a more elaborate theory is needed.

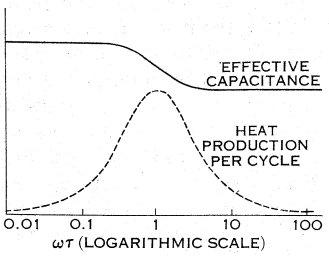

FIG. 3.—VARIATION OF EFFECTIVE CAPACITANCE AND HEAT PRODUCTION PER CYCLE

Alternating voltage across AB of fig. 1

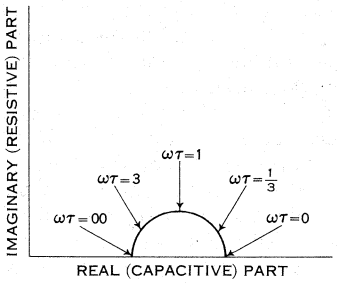

FIG. 4.—EFFECTIVE CAPACITANCE OF THE SYSTEM IN COMPLEX PLANE

Data in Fig. 3 have been replotted with $\omega\tau$ entering as a parameter

Systems of which the above circuit is a helpful model are to be found in almost all branches of physics, but perhaps particularly in the fields of elasticity and acoustics. One of the most famous examples concerns the propagation of ultrasonic waves in gaseous carbon dioxide (CO_2). The velocity of sound in a gas is expressed by the formula $\bar{v}\sqrt{\gamma/3}$, in which $\bar{v}$ is the root mean square velocity of the molecules and γ is the ratio of the principal specific heats C_p/C_v; since $C_p - C_v$ is equal to R, the gas constant, γ may also be related to C_v by the formula $C_v = R/\gamma - 1$. Now it is found experimentally that sound waves of a frequency less than 2 kc. per second travel at a velocity of 268 m. per second in pure CO_2, while if the frequency is greater than 200 kc. per second the velocity is increased to 280 m. per second. Since $\bar{v}$ does not depend on the frequency this result may be interpreted to mean that the effective value of γ, or C_v, depends on the frequency. In fact the low-frequency value of C_v determined by this argument is 6.85 cal. mole^{-1} degrees^{-1} and the high-frequency value 4.95 cal. mole^{-1} degrees^{-1}. The latter value is almost precisely that predicted by Boltzmann's Equipartition law (*see* CHEMISTRY: *Physical Chemistry: The Kinetic Theory of Gases*) for a gas molecule having five degrees of freedom, and herein is an interpretation of the experiment. When a portion of the gas is alternately compressed and expanded by the passage of the wave, kinetic energy is transmitted to or extracted from the molecules by collisions—in other words, on adiabatic compression the gas is heated. This kinetic energy is taken up immediately in translational energy of the molecules, and by collision is shared almost as quickly with the rotational motions of the molecules. If enough time is allowed, ultimately some of this energy will be transmitted to the vibrational motions of the atoms constituting the molecule, but this takes much longer. The main reason is that the vibrational motions are quantized and energy can be exchanged only in units of $h\nu$, where ν is the vibrational frequency involved; in CO_2 all the quanta $h\nu$ of the various vibrations are several times higher than the mean kinetic energy of the molecules, so that only the rare collisions between exceptionally energetic molecules are effective in transferring energy. There is thus a characteristic relaxation time τ, about 10^{-5} sec. in pure CO_2 at room temperature, for imparting energy to the vibrations. If the angular frequency ω of the wave motion is such that $\omega\tau \ll 1$, the vibrational modes are able to come into thermal equilibrium with the external (translational and rotational) modes, and the value of C_v reflects about seven degrees of freedom. But if $\omega\tau \gg 1$, the vibrational modes are unable to exchange energy and C_v has a value corresponding to only the five external modes. The analogy between the internal and external modes in this example, and the capacitances C_1 and C_2 in the model analyzed above, should be obvious. At a frequency of 20 kc. per second, when $\omega\tau \sim 1$, the peak of resistive loss in the model is paralleled by a peak of attenuation of the sound wave; the energy in the sound wave is halved in a distance of only $5\frac{1}{2}$ wave lengths, or $7\frac{1}{2}$ cm.

Many other examples of this type of relaxation have been studied, as well as a similar type associated with structural rearrangements, particularly in liquids and solids. Detailed discussions of many will be found in the references below, but one example must suffice here, elastic relaxation of certain cubic metals containing dissolved impurities. When carbon dissolves in tantalum, the atoms occupy interstitial sites which may be said to be of three kinds, according as the nearest tantalum atom lies in the x, y or z direction, these three directions defining the cube axes of tantalum. So long as the tantalum is unstrained, there is no preference between sites, which are all equally likely to be occupied; but if the tantalum be compressed along the x-axis, the x-sites are deformed differently from the y- and z-sites, and in equilibrium the two types of site will become differently occupied by the migration of carbon atoms toward the preferred sites. The deformation resulting from a given compressional force now depends on whether enough time is given for migration to occur. In fact fig. 2 may be interpreted as a schematic graph of the deformation due to a constant force, while the curves of fig. 3 serve to represent the variation of compressibility and elastic loss with frequency when a periodic force is applied. The relaxation time τ is related to the time taken by carbon atoms to diffuse from site to site and is highly temperature-dependent according to the law $\tau \propto e^{H/RT}$, where H is a heat of activation. Thus if the frequency is kept constant and the temperature varied, $log\ (\omega\tau) =$ constant $+ H/RT$ and a plot of elastic behaviour against $1/T$ should look like fig. 3. This is shown in fig. 5, from the scale of which it may be immediately deduced that H for this diffusion process is 25,000 cal. per molecule. Relaxation peaks of this nature are found in many solids and are often the most sensitive way of detecting the presence of certain impurities; *e.g.*, it is pos-

sible to trace one part in a million of carbon in iron. Finally it should be mentioned that exactly analogous phenomena are observed when sound waves pass through mixtures of substances in chemical equilibrium, when oscillatory electric fields are applied to metals and to many dielectric substances and when oscillatory magnetic fields are applied to many paramagnetic substances. Detailed study of these provides information on the rate at which equilibrium is attained and hence may suggest the mechanisms which are operative in establishing the state of equilibrium.

RELEASE, in law, the term applied to the discharge of some obligation. by which it is extinguished (see DEBTOR AND CREDITOR LAW). and to the conveyance of an estate or interest in real or personal property to one who has already some estate or interest therein. For the special form of conveyancing known as "lease and release," see LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS: Leases.

RELICS, any objects once connected with the person of a departed saint, especially the body or parts of the body. Veneration of the relics of saints, especially of martyrs, appears at an early date both in the Eastern and in the Western Church. St. Thomas Aquinas formulates the doctrinal principles thus: "It is clear . . . that he who has a certain affection for anyone, venerates whatever of his is left after death, not only his body and the parts thereof, but even external things, such as his clothes and such-like. Now it is manifest that we should show honour to the saints of God. as being members of Christ. and children and friends of God, and our intercessors. Wherefore in memory of them we ought to honour any relics of theirs in a fitting manner: principally their bodies, which were temples, and organs of the Holy Spirit dwelling and operating in them, and are destined to be likened to the body of Christ by the glory of the resurrection. Hence God Himself fittingly honours such relics by working miracles at their presence." (*Summa* Theol., iii, *q.* 25, art. 6.)

The council of Trent, in its 25th session, solemnly affirmed the same doctrine. while condemning those who hold the practice in contempt, and modern canonical legislation was framed in accordance with these principles (Codex *Iuris Canonici,* especially canons 1276–89). It is noted expressly that relics are to be honoured with a veneration that looks beyond the relics to the saints themselves, whom the relics commemorate (canon 1255 § 2). Further prescriptions attempt to assure the authenticity of relics exposed for public veneration (canons 1283–86); the fabrication of false relics. their sale or distribution, or their exposition for public veneration involves *ipso* facto excommunication (canon 2326). The Old Testament refers to the cult of relics, in the religious character of the burial of saintly persons (Gen. xxxv, 19, 20; l, 2j, 26; Exod. xiii, 19), in the miraculous power of Elijah's mantle (IV [11] Kings, ii, 13, 14) and the bones of Elisha (ibid., xiii, 21); but the practice assumes its definitive form in the New Law (see Matt. ix, 20–22; Acts xix, 11, 12). St. John Chrysostom refers frequently to the relics of the martyrs as sources of divine favours (Eulogy of St. Eustathius, in J. P. Migne, Patrol. Graeca, 1, 600; Homily on the Martyrs, ibid., 648, 649; Eulogy of St. Julian, ibid., 670–672). St. Augustine makes clear reference to the practice (for example in De Civitate Dei, in Migne, Patrol. Lat., xli, 255), and indeed all the great doctors of early Christianity extolled the veneration of the relics of the saints. Inevitably, the insatiable demand of churches and of private persons led to a traffic in relics, both genuine and spurious, and to other abuses, which ecclesiastical authority constantly strove to hold in check. Already in 386, the Theodosian code legislated against the traffic in relics of the martyrs, and the sale of relics was forbidden by the fourth Lateran council in 1215 (canon 62) and by the council of Trent.

The veneration of relics is a practice rooted in ecclesiastical tradition and in human psychology. It is to be understood and judged by reference to its doctrinal foundations, rather than to its abuses.

See article "Reliques," by P. Sejourne, in the *Dictionnaire de théologie catholique,* ed. *by A.* Vacant *et al.,* vol. xiii (Paris, 1937); and the article "Reliques et reliquaires," by H. Leclercq, in the *Dirtionnaire d'archéologie chrétienne et de liturgie,* ed by F. Cabrol and H. Leclercq, fasc. clx–clxi (Paris, 1947).

RELIEF. The term "relief" is used in sociology and social work to denote aid given to needy persons who would otherwise suffer without it. It is contrasted with work relief and social insurance. Relief as a generic term is used to cover all forms of aid, in cash and in kind, public and private, to needy persons. As a specific term it is sometimes used in the United States to distinguish aid given on a noncategorical undifferentiated and emergency basis from the types of public assistance far which federal funds are given under the Social Security act. In both Great Britain and the United States, the term relief was being replaced in the 1950s by the word "assistance."

Relief has been provided in ancient as well as modern forms of society. Helping one another in a time of emergency such as sickness, orphanhood or old age was practised in simpler and early societies. (For early history, see PHILANTHROPY.) Private forms of relief exist through individuals and voluntary institutions.

UNITED STATES

Responsibility for providing relief was, in accordance with the tradition and statutes of Great Britain, accepted by the American colonists as a local governmental responsibility. (See POOR LAW.) During the period 1910–30 state governments in the United States began to take financial and administrative responsibility to assist the localities for various categories of needy persons such as the aged, the blind, and dependent children. In 1932–33 the federal government began to assume responsibility for aid in the relief of human need and suffering. An important and far-reaching development was the enactment in 1935 of the Social Security act, which provided for the establishment of federal old-age insurance and state programs of unemployment insurance which greatly reduced the need for relief. (See SOCIAL SECURITY.) In addition the federal government made grants to the states lor "assistance" to the needy aged, blind, and dependent children. In 1939 the federal old-age insurance program was broadened to include survivors insurance and in 1950 to add a fourth category of assistance to needy persons who are permanently and totally disabled. In 1954 the federal old-age and survivors insurance program was expanded to cover virtually all persons who work for a living. As a result of these legislative changes, the increase in the aged and child population, and the relatively high levels at which the economic system operated, the role of relief in the American economy changed in important respects after 1932.

Relief Programs in 1932.—There was no system of federal relief in existence when the depression began in the United States in 1929 Public relief was provided under state "poor laws," and was usually limited to almshouse care, medical care, burial and small amounts of relief, financed by towns and counties. In structure. social theory and method of administration, this system of local public relief had remained practically unchanged from the days of Elizabethan England. This kind of public relief was supplemented by private charity.

For three years after 1929, notwithstanding the rapid growth of unemployment (which rose from an estimated 2,000,000 to 15,000,000), the federal government held that the relief of unemployment was a local problem. to be handled by state and local governmental resources supplemented by private charity. Two successive committees were set up by Pres. Herbert Hoover to co-ordinate private and local governmental relief efforts—the president's emergency committee for employment, and the president's organization on unemployment relief

Appeals for federal relief, however, became more and more insistent. The Reconstruction Finance corporation, a new federal agency which was making loans to distressed banks, railroads and businesses, was authorized by congress in July 1932 to make loans for relief purposes to states and municipalities. Because of the various restrictions imposed on such relief loans, only $80,000,000 was disbursed by Jan. 1, 1933.

Federal Emergency Relief Administration, 1933–35.—With the inauguration of Franklin D. Roosevelt as president in

March 1933, the principle of federal participation in relief was immediately broadened. Instead of a financial agency making loans to states and municipalities in distress, a new social agency, the Federal Emergency Relief administration, was created to undertake a program of federal grants-in-aid to states. While the grants were made to the state governments, the actual administration of relief was primarily in the hands of the local communities to which the state government granted the available federal funds. together with state appropriations where such had been made. The FERA assumed a major share of the cost, the rest being borne by states and local communities.

The FERA attempted to set up minimum standards for relief administration, under penalty of withholding the federal grants. It also had authority, which it exercised only in exceptional circumstances, of, administering federal relief directly in those states where it met with no co-operation. In addition, the FERA earmarked a portion of the grants to the states for a number of special programs. for classes of persons whose needs could not be met effectively by the general relief program. These included transient relief. education, college student aid and rural rehabilitation.

One of the objectives of the FERA from the beginning was the development on a national scale of the system of work programs for employable persons that had been initiated by some state relief administrations. During the first six months, however, comparatively little was accomplished along that line because of the pressure of the more elementary needs of the unemployed for food, shelter and clothing. The early state work projects were in some cases poorly conceived, for it took time to realize that there was certain work the unemployed could do that would be socially useful and not compete with private industry. There was generally a shortage of funds for materials since only local funds—not federal moneys—could at the beginning be used for that purpose.

Civil Works Administration, 1933–34.—The deficiencies of the local work relief programs. the critical unemployment situation and the need of stimulating business recovery by large scale governmental expenditures prompted President Roosevelt to start a new works program in the fall of 1933. This was the program of the Federal Civil Works administration. instituted within two weeks after the creation of the agency on Nov. 9, 1933. While the civil works program was directly administered by the federal government through a nationwide organization, most of the projects were initiated and sponsored by local governments.

Workers were paid on the basis of the work performed rather than on the "budgetary deficiency" basis which characterized local work relief projects.

Within two months of its organization, the civil works program reached a peak employment of 4,200,000, roughly half of the workers being taken from the relief rolls. The greater part of the program was terminated at the end of March 1934. The program resulted in total expenditures of $951,600,000, of which the federal government contributed $860,400,000, the local communities $85,000,000, and the states the remainder.

Though hastily organized, the civil works program for the first time revealed the large variety of socially useful projects that could be operated with unemployed labour. Its field of activity embraced the repair and construction of roads and streets, the rehabilitation and new construction of school buildings, recreational facilities, the building of new sanitation works, and a wide array of white-collar and service projects.

During the period of the CWA program, the FERA continued to function as an agency subsidizing the state relief agencies, although local work relief programs were very much curtailed. With the discontinuance of the CWA, the FERA, in co-operation with the states, set out to develop a more adequate work relief program than had been in operation in 1933. Those CWA projects which had not been finished were taken over and completed. New projects were developed on the same principles. Thus, federal funds were made available for the purchase of materials; better supervision of projects was instituted.

Wages in the FERA work program were based on the principle of "budgetary deficiency." A relief family's sources of available private income were determined by the social service staff and deducted from the estimated budgetary needs. The principal breadwinner was given as many hours of work as would yield the requisite income deficiency.

In the case of large families, work relief earnings were. often supplemented by direct relief. In addition, surplus foods were sometimes furnished to general relief cases through the Federal Surplus Relief corporation, which was largely financed with FERA funds. (It later became an agency in the G.S. department of agriculture.)

In 1935 congress and the administration made an important change in the method of dealing with the problem of unemployment relief. This new method involved, first, the turning over of direct relief to the states and local communities and. second. the setting up of a large federal works program to provide emergency employment, particularly to employable heads of families on relief rolls.

The decision to take the federal government "out of the business of relief'! was made at the moment a comprehensive social security system was set up. This system made provision not only for unemployment and old-age insurance, but for old-age assistance, aid to the blind and aid to dependent children, to be administered by the states with matching grants by the federal government. It was felt that once these three categories of destitution were taken care of, and once the federal government assumed responsibility for the employment of employables on relief, the remaining direct relief problem could be handled by the states and local communities with their own resources.

WPA, 1935–39.—The new feature in the reoriented programs of 1935 was the introduction of a broad program of project work, comprising locally planned and sponsored undertakings that were, however, to be federally directed and in large measure federally financed. Workers were to be removed from the relief rolls and paid fixed monthly security wages. The security wages represented a compromise between the CWA principle of regular wages and the FERA principle of budgetary needs. Monthly wages were fixed at the same level for the same type of work regardless of family diversities, but the wages for the different classifications of skills and different regions of the country represented less than the corresponding normal earnings in private industry. Most of the work projects were directed by the newly created Works Progress (later Work Projects) administration, which was originally intended to serve as a co-ordinating agency for the entire works program but which became the principal operating agency as well.

In addition to the system of work projects, the works program of 1935 continued the emergency employment programs on heavy public works carried on by the bureau of public roads and the Public Works administration. These phases of the work program were carried on by the contract method. At first these agencies were required to see to it that contractors selected their crews as far as possible from the relief rolls—a requirement that proved difficult to enforce and was later dropped. The 1935 works program also continued the program of the Civilian Conservation corps, which provided employment and training to needy youths between 18 and 25. A National Youth administration was established within the WPA, which, in addition to providing aid for high school, college and graduate students, developed work projects for needy youths between 16 and 2j.

The cost of WPA operations was borne largely by the federal government. But since the work projects concentrated on local needs, it was felt desirable that local communities should suggest and sponsor the projects that were put in operation and should at the same time pay part of the cost. Sponsors' contributions varied with the financial resources of the community, the character of the public improvements it desired to carry out and the gravity of the local unemployment problem. Contributions averaged about 20% for the nation as a whole after July 1937. Beginning Jan. 1, 1940, the average of sponsors' contributions for each state was required by law to be 25% of the total cost of projects subsequently approved and initiated.

A few federal projects (notably the arts projects) were operated by the WPA on a nationwide basis with relatively small contributions from co-sponsors. The Emergency Relief Appropriation act of 1939 provided that the WPA could not itself sponsor projects.

Thereafter the arts projects were continued where state and local governments were interested in sponsoring and sharing in the cost of the work. The theatre projects were entirely discontinued on July 1, 1939, by act of congress.

About 80% of WPA activities were in the construction field, while 20% represented goods projects (canning projects and sewing rooms for women) and white-collar projects.

Surplus Farm Commodity Distribution. — Surplus farm commodities were first distributed to needy persons in 1933 under emergency relief legislation. Nearly 13,000,000 received such surplus farm commodities in 1939. The department of agriculture was assigned the responsibility for delivering the commodities in carload lots to state and local welfare agencies which distributed them in accordance with state or local eligibility standards. At the end of 1954, about 2,500,000 needy persons were receiving such commodities. of whom about one-fourth were persons on the public assistance rolls. Schools and charitable institutions were also made eligible for surplus farm commodities.

Public Assistance Under the Social Security Act, **1935–54.** — The provisions of the public assistance titles of the Social Security act of 1935 were designed to overcome some of the major limitations of the earlier relief programs. The selection of the term "assistance" instead of "relief" was intended by those who drafted the act to distinguish the categorical forms of aid as a more liberal, humane and modern form of aid in contrast with restrictive, harsh and haphazard forms of relief. The Dill-Connery bill for federal aid to needy aged persons. which was favourably considered by the house of representatives in 1934, used the terms "relief" and "assistance." But the proposal recommended to the congress by Pres. Roosevelt's committee on economic security in 1935 adopted the term "assistance:" which was accepted by the congress and written into the federal law without debate or controversy.

The Social Security act also included the specific language that assistance meant "money payments" to the needy individuals. This limited the federal funds to cash payments and was intended to limit and discourage payments in kind such as grocery orders and direct distribution of commodities. The unrestricted cash payment was intended to eliminate the restrictive control exercised by local authorities in the granting of aid. In 1950 congress made an exception to the principle of unrestricted money payments to the individual by amending the federal act to permit payment of federal funds within certain maximums in cases where states paid medical bills directly to the doctor, hospital or to others providing medical care. The special characteristics of medical care — particularly irregularity and unpredictability — distinguish it from other types of needs.

The Social Security act of 1935 also required as a condition of receipt of iederal aid that the state make a financial contribution to the program, a single state agency administer each program, the state have a "state plan" in effect in political subdivisions of the state, and the individual be given th portunity for a fair hearing if his claim for assistance is denie ach of these requirements was aimed at eliminating certair incial and discriminatory methods of administering relief tc persons.

Congress also provided that no al funds could be used to pay assistance to any adult in a public institution or to any child in any institution. This was the outgrowth of dissatisfaction with county homes, almshouses, orphan asylums and other large institutions. (*See* POOR LAW.) As a result, the assistance program encouraged aiding persons in their own homes and in practically eliminating almshouses. In 1950, however, congress amended the law to permit iederal funds for payment of assistance to adults in certain types of public medical institutions. A growing number of chronically-ill aged persons came to be cared for in public and private nursing homes operating under standards established and maintained by the states. The 1950 amendments also required the states to establish and maintain standards for private or public institutions if the state plan includes payments to individuals in such institutions.

In 1939 congress amended the law to require the states to select and promote their personnel in accordance with a merit system so that the programs would be administered on a professional basis. Another requirement added to the law by the congress in 1939 provided that the states establish safeguards which restrict the use or disclosure of information concerning applicants and recipients to purposes directly connected with administration of assistance. This provision was the subject of much controversy in 1951 and congress amended the law to permit states to enact legislation prescribing any conditions under which public access might be permitted to records of disbursements if such legislation prohibited the use of any list of names for commercial or political purposes.

Enactment of the federal assistance programs and the requirement for the establishment of a single state agency for the administration of each program helped accelerate the trend toward the establishment of state departments of welfare and the co-ordination of all state welfare functions in one state agency. The result was an improvement in welfare programs through the leadership, standard-setting. research and community organization and planning undertaken by the state welfare departments. While conditions continued to vary widely in the various states, there was a substantial measure of progress. Since in many states the state departments of public welfare also help finance or administer the general assistance or relief programs, there has been a tendency for standards in the general relief programs to be administered to some extent along the same lines as the categorical programs for which federal funds are received and federal standards maintained. However, in the states which left the entire general assistance problem to the localities. there still remained in the 1950s a great deal of the same type of inadequacies which existed prior to the enactment of the social security program.

Numerous groups which studied the assistance, relief and related programs in the United States made recommendations for changes in the federal and state legislation. Perhaps the most important in helping reduce the need for assistance and relief was the expansion and liberalization of the federal old-age and survivors insurance program in 1950, 1952 and 1954, and of the federal and state provisions for unemployment insurance. Increased coverage under private pension. health and welfare plans. particularly as a result of collective bargaining, also aids in reducing the need for assistance and relief. The number of aged persons receiving old-age insurance became larger than the number of aged persons receiving assistance for the first time in 1951. The year 1953 was a turning point in the history of public assistance. The number receiving old-age and survivors insurance benefits at the end of 1953 was larger than the number receiving all four types of public assistance (including general assistance). At the end of 1954, there were about 6,800,000 persons receiving insurance benefits compared with 5,700,000 receiving assistance.

General Assistance. — General assistance. often called general relief in the United States, is supported by the localities and the states with no participation by the federal government. It is the only recourse of needy persons in want who are ineligible for one of the four federal-state assistance programs. General assistance also is provided to some extent to recipients of the special types of public assistance when the maximum amounts of categorical aid they can get are insufficient to meet their needs.

In some states the general assistance program is integrated with all or some other assistance programs at the local level. In other states general assistance is administered separately. The amount of financial aid and supervision supplied by the state welfare departments to the local units varies greatly from state to state. In 10 states in 1954, the state paid the entire bill for general assistance. At the opposite extreme were 16 states where the localities met the full cost. In the other states, the localities and the state shared the cost in varying degrees. Total expenditures for general assistance in the mid-1950s were shared approximately 50% by the localities and 50% by the states.

In most states with little or no state financial participation, each locality decides for itself who shall be eligible for aid and how much assistance in cash or kind he shall get. Thus the place where a needy person lives is likely to be a primary determinant of the adequacy with which his needs are met. In many places throughout the nation a needy person deemed employable can get assistance only if he is in the direst straits — and then only for a tempo-

rary period. In such places in most cases the breadwinner is suffering from acute illness or disability that is not sufficient in degree to qualify him for aid to the permanently and totally disabled. Some states still have local settlement laws which originated before the days of modern transportation and high mobility of population. On the other hand, in some states general assistance is available at substantially the same standard as the special types of public assistance for any needy person for whom there is no other provision.

Consideration has been given from time to time to providing federal funds and federal standards for general assistance. In 1948, an Advisory Council on Social Security recommended such legislation and the congress considered such a proposal in 1949. Congress did not adopt the proposal but did add a fourth category of assistance to the Social Security act in 1950 for persons permanently and totally disabled, thus narrowing the scope of general assistance. A large number of the disabled persons were transferred from general assistance to the disabled category. General assistance tended to decline in terms of its role in the total assistance picture. In 1940 expenditures for general assistance represented about 40% of expenditures for all forms of public assistance; but by 1950, they had dropped to about 13% and by 1954 they were only about 7%.

Medical Care.—A large proportion of the number of persons receiving public assistance are disabled or chronically ill and require medical care. The states vary in the extent to which they provide medical care to needy persons. This variation depends upon the availability of funds, and the extent of available hospital care and services from physicians. About $200,000,000 was paid annually in the mid-1950s by public assistance agencies directly to doctors, hospitals and other suppliers of medical care for medical services for assistance recipients. About one-quarter of all expenditures for general assistance at that time was for payments directly to such suppliers of medical care. Medical care to public assistance recipients improved slowly in both coverage and scope after 1950 when the Congress earmarked a limited amount of federal funds for this purpose. However, because of the many inadequacies, Pres. Dwight D. Eisenhower in 1955 recommended that the Congress earmark additional federal funds for medical care for public assistance recipients.

Status of Relief and Assistance Programs.—Total relief and assistance expenditures in the United States reached a peak of $300,000,000 a month in 1938–39. Expenditures for these purposes declined sharply during the World War II years 1942–45. As a result of increased population—particularly aged persons and children—increased prices and more adequate standards of assistance, expenditures began to increase after World War II. Nevertheless, measured as a per cent of the national income, relief and assistance expenditures were substantially below the proportions for the years immediately prior to 1940. During the fiscal year ending June 30, 1954, nearly $2,800,000,000 was expended for all five forms of public assistance and their administration. This amount was equivalent to about 1% of all personal incomes in the nation, or $16 per capita for the year. The federal government assumed about 52% of total assistance payments made under all five programs; the states 37%; and the localities 11%.

Approximately 5,700,000 persons were receiving public assistance at the end of 1954. Of this number about 2,500,000 were receiving old-age assistance, 2,000,000 persons were receiving aid to dependent children, 100,000 aid to the blind, 300,000 aid to the permanently disabled and about 800,000 general assistance.

OTHER COUNTRIES

Programs of public assistance or relief for the general population or for some categories of needy people are in operation in many countries. Although there are some common features, there are notable differences among the countries in such matters as the method of determining need, the extent of local and national administrative and financial responsibility, and the age, residence and other requirements.

While in most of western Europe social welfare functions are delegated to the provincial and local governments, in some countries of the British Commonwealth relief is a function of the central government. Thus, in the United Kingdom a national assistance board administers the principal assistance programs, which, except for certain institutional and welfare services, are nationally financed and have standardized payments.

Australia and Canada, which have a federal form of government like the United States, employ some different methods than either Great Britain or the United States. In Australia, the Commonwealth Department of Social Services administers social security and relief for needy persons not eligible for any of the categorical payments. In Canada, the general relief function remains in the hands of the local governments. The provinces pay mothers' pensions and administer and share the financing with the national government of the system of old-age assistance for persons aged 65–69, inclusive.

RELIEF, literally, the projection of forms from a ground; in sculpture, a work in which figures or ornaments are shown as projecting from a ground. The height of elevation may vary. In a low relief (*basso-rilievo* or bas-relief) the design is more or less of a piece with the ground, projecting but slightly and with little, if any, undercutting of outlines. In a high relief (*alto-rilievo*) the forms are made to stand out more detachedly and may in parts be completely disengaged from the ground, so as to approximate sculptures in the round. But a reference to and, in most cases, physical connection with the ground must be taken to be a constituent feature of all representations in relief, in contrast to statuary which is not related to any ground and can be viewed from all sides. The 19th century tendency to employ the term "bas-relief" indiscriminately for all kinds of relief, high as well as low, is unjustified linguistically and seems now to be subsiding.

Rarer forms of relief are the "sunk reliefs," especially of ancient Egypt, where the forms are carved in and beneath the surrounding ground rather than rising from it. Intaglio, likewise, is a hollow relief, but carved as a negative image like a mold instead of a positive form. Actually the most common use of intaglio is in engraved seals of precious stones or metal, designed to produce a positive imprint when pressed into a plastic material such as heated wax. However, intaglio techniques may also be used without such a purpose; *e.g.,* in the decoration of transparent materials such as glass.

Modes of representation and composition in relief are always determined by their dependence on the ground plane from which the forms emerge, or on which they are superimposed. In this important respect reliefs are more nearly related to painting than to the detached roundness of statuary. Ancient Egyptian art, which differentiated the various branches of art in the most systematic manner, from the beginning applied the same basic principles of representation to reliefs as to painting. Usually the design stands out from the ground in very low relief, however carefully modeled. Figures are shown sidewise, standing on base lines, and precisely outlined in conformity to the plane surface from which they are carved. As to their methods of representation, and regardless of their materials—wood, soft stones, hard stones or metal—they must therefore be classified with painting. Similar observations are true of other early arts, like those of Mesopotamia and the ancient near east.

High reliefs first became common in Greek art; notable examples are the Attic tomb reliefs, with individual figures or family groups shown almost in the round, of the 4th century B.C. On the whole the Greek reliefs, also, follow rather closely the development of contemporary painting. Sculptured friezes were often used in architectural decoration. A doubt may arise regarding the famous pedimental sculptures of Greek classical temples which are composed of large figures worked singly, and not physically connected with the ground, thus resembling free statues. (*See* GREEK ART; OLYMPIA; PARTHENON; etc.)

However, since these figures were placed in the pediments and consequently not seen freely but against a background wall, their compositions must in effect be regarded as a kind of high reliefs. Likewise in Roman art (*q.v.*), the pictorial character of the reliefs is undeniable. A rich field of study for the relation between ground and figures in classical reliefs can be found in the numerous sculptured sarcophagi which constitute one of the most representative achievements of Roman art during the 2nd and 3rd centuries A.D. Excellent examples of ancient relief are also available in the minor arts, both of Greece and Rome, especially

in silver and ivory. (See SILVERSMITHS' AND GOLDSMITHS' WORK.) Moreover the rapid expansion of the classical style in and beyond the Mediterranean area after the Hellenistic period gave rise to a flowering art of relief sculpture in the far east, first of all in the religious art of India.

It appears as a natural consequence of the classical tradition that during the early middle ages, a period which generally exhibits a marked preference for painting over statuary, the emphasis in sculpture was definitely on relief work. This statement holds good of Byzantine no less than western art. Not only does a wealth of very fine reliefs appear in the minor arts, Byzantine as well as western medieval, but French Romanesque art, especially, reached a new height of relief sculpture in architectural decoration. Some of the most outstanding examples of medieval art are among the Romanesque portals ("tympana"), sculptured capitals of columns and other reliefs decorating the ecclesiastic buildings of France, England and other European countries. (See SCULPTURE; SCULPTURE TECHNIQUE.)

The Gothic period continued this tradition, often preferring a higher relief than the Romanesque, in accordance with the renewed interest in statuary typical of the later middle ages. Reliefs were much in demand also for funeral monuments of bronze or stone, a number of which include some of the finest works of the period. The latest examples of Gothic relief art are the frequent carved altars, mostly of wood, and other church furniture of the "international style" shown in churches all over western and central Europe from Spain to Poland. (See WOOD CARVING: European and American.)

During the Italian Renaissance period the status of relief work among the total output of art begins to change. Between painting and statuary the number of reliefs decreases, except perhaps in the minor arts. No longer are certain places traditionally reserved for decoration in relief, as was true of the medieval church buildings. On the other hand the condition of representations in relief now became subjected to new studies and experimentation with a revisory intent, as a task of art different from both painting and statuary. The first striking results of the new trend are the bronze doors which Ghiberti created for the famous baptistery of Florence. Characteristic is the free play between high and low relief, from which a strikingly illusionistic style of composition can be derived, supporting the new interest in space as a subjective, visual experience.

Donatello further exploited these experiments, adding to the interplay of high and low relief the contrasts between rough and smooth surfaces, as well as between forms shown fully modeled and others only indicated in an almost painterly, impressionistic state of incompleteness. As a result, Florentine artists after Donatello pursued for a while two rather different trends regarding the treatment of reliefs. Typical of the one are the delicate and low reliefs in marble and terra cotta, for which Desiderio da Settignano and Mino da Fiesole became best known. The other, more contrasting trend became incorporated in the relief style of Bertoldo and later, Michelangelo.

Baroque art continued these experiments, often on a very large scale. Characteristic are large compositions—a kind of marble painting—of which the Roman churches, especially, hold many excellent specimens. These compositions, because of their large size and high relief, often approach the effect of tableaux vivants shown in deep boxlike frames and special, stagelike conditions of lighting. L. Bernini's "Ecstasy of Sta. Theresa," with figures carved almost fully in the round but encased in a marble altar, in the church of Sta. Maria della Vittoria, Rome, offers a most impressive example.

Neoclassic art of the early 19th century, following a more puritan attitude toward artistic principles, temporarily revived experimentation with low reliefs, relying for effect on fine surface modeling and clarity of design. The works of Antonio Canova and Bertel Thorwaldsen are typical. However, on the whole the Renaissance concept of relief prevailed. Its dramatic and impressionistic possibilities were sensed keenly and employed vigorously by subsequent sculptors of the 19th century such as F. Rude ("The Marseillaise," decorating the Arc de Triomphe in Paris) and later, most famously, Auguste Rodin ("Portal of Hell" and other reliefs). In continuation of these trends relief techniques came to be used in modern art. not only for representational but also for abstract compositions which exploit freely the spatial element as well as the contrasts of light and shade, in reliefs conceived as a succession of overlapping planes. The latter concept, by its nature, often leads to a greater emphasis of the pictorial qualities inherent in relief art. It is typical of this situation that modern painters not infrequently show an interest in the art of relief as did Picasso, among others, during the evolution of his Cubism. See also SCULPTURE; SCULPTURE TECHNIQUE; etc.

RELIGION (AND THEOLOGY), ARTICLES ON.

For the purpose of enumerating the main articles in this section, a division will be made into Christian and Non-Christian.

CHRISTIAN

The number of articles on the different aspects of Christian doctrine, faith and church is so great that nothing beyond a casual selection of titles can be made here. Anything approaching a complete guide to the separate religious divisions would be a lengthy index of titles of differing merit. To begin with, all the prophets of the Old Testament, all the disciples of the New Testament, and all the books of the Bible have separate articles under their own headings. Special terms occurring in the Scriptures, such as ALPHA AND OMEGA; ARMAGEDDON; APOSTLE; ANGEL. etc.. have articles to themselves, where their meaning and connection with other passages in Holy Writ are given in some detail. The article BIBLE is divided. for convenience of reference, into sections and subsections, with appropriate subheads and sideheads to mark out the main points of interest. CONCORDANCE is exhaustively treated, and the article JESUS CHRIST deals with the life of the Founder of Christianity and all his activities and influences. JOSEPH (husband of Mary) and MARY (the Mother of Jesus), are important articles, and those such as REVELATION, BOOK OF and PASTORAL EPISTLES are deserving of attention. VULGATE; ATHEISM; DEISM; IMMORTALITY; MIRACLE; MYSTICISM; ESCHATOLOGY; APOLOGISTS, EARLY CHRISTIAN; DOGMA; ABSOLUTION; ANTICHRIST; ATONEMENT; BAPTISM, CHRISTIAN; BENEDICTION; CATECHISM; CATHOLIC; CHURCH; CONFESSION; CONFIRMATION; CREED; EXCOMMUNICATION; EXTREME UNCTION; FASTING; GRACE; MARTYRS. EARLY CHRISTIAN; PREACHING; RELICS; SACRAMENT; SIN and WORSHIP. are all important articles well worthy of special attention. The different sects and divisions of Christian practice and worship are treated under their own headings.

Some of the major councils (*e.g.*, BASEL. COUNCIL OF, etc.) are treated in separate articles apart from the main article COUNCIL. Some of the major synods, too, have special articles under the names they usually bear, as is also the case with the different courts. The famous heresies are also treated under their separate names. There is also a large article PAPACY.

The chief saints of the Church Calendar are noted and details are given under their respective names. The popes have biographies. and are also treated in connection with their special work in separate articles where there is historical mention of their times. The reader should refer to CONSTITUTIONS. APOSTOLIC; APOSTOLIC FATHERS, etc., for the Christian documents required.

There are comprehensive articles on the religious orders. (See for example, BENEDICTINES; CAPUCHINS, etc.) In addition to the main article ROMAN CATHOLIC CHURCH, all important subdivisions of this aspect of Christian worship have articles under their own headings, *e.g.*, IMMACULATE CONCEPTION; INDULGENCE; PENANCE. etc.

All the main Eastern Churches have articles devoted specially to them. All relationships of the Church of England and the modern Continental churches, their special forms of worship and attitude to problems of belief and practice, are treated under their own headings.

Ecclesiastical offices are treated under separate headings, *e.g.*, ABBOT; ACOLYTE; ARCHBISHOP; ARCHDEACON, etc. The ecclesiastical seasons have all their own headings, and this is also the case with Ecclesiology and its subdivisions: Bible and Biblical criticism is a section which contains important articles on the prophets and books of the Old Testament, and the Apostles and books of the New.

NON-CHRISTIAN

In this section appear such major articles as BABYLONIA AND ASSYRIA: *Religion;* GREEK RELIGION; ROMAN RELIGION; HINDUISM; ANCESTOR WORSHIP; ZOROASTER (for Zoroastrianism); ASCETICISM. etc. Apart from the main articles on Greek and Roman religion, there are numerous short articles on the gods and goddesses of the ancient classical world. Such articles as ANIMISM; ANTHROPOMORPHISM; DEMON; DIVINATION; EXORCISM; FETISHISM; FCNERARY RITES AND CUSTOMS; IDOLATRY, LYCANTHROPY: MYTHOLOGY; PRIEST; RITUAL and WITCHCRAFT are the main supports of the non-Christian religious program.

In addition to these there are numerous accounts, each under its own heading, of the gods and spirits of Brahmanism, Buddhism, etc, and the early faiths of Scandinavia, Europe, and the two divisions of America.

RELIGION. The treatment of this subject will fall into two distinct sections, *A. Primitive Religion* and *B. The Higher Religions.*

A. PRIMITIVE RELIGION

I. Definition of Primitive Religion.—Amongst the numberless definitions of religion that have been suggested, those that have been most frequently adopted for working purposes by anthropologists are Tylor's and Frazer's. Sir E. B. Tylor in *Primitive Culture* (1), i. 424, proposes as a "minimum definition" of religion "the belief in spiritual beings." Objections to this definition on the score of incompleteness are, firstly, that, besides belief, practice must be reckoned with (since, as W. Robertson Smith has made clear in his *Lectures on the Religion of the Semites, 18 sqq*, ritual is in fact primary for primitive religion, whilst dogma and myth are secondary); secondly, that the outlook of such belief and practice is not exclusively towards the spiritual, unless this term be widened until it mean next to nothing, but is likewise towards the quasi-material, as will be shown presently. The merit of this definition, on the other hand, lies in its bilateral form, which calls attention to the need of characterizing both the religious attitude and the religious object to which the fornner has reference. The same form appears in Sir J. G. Frazer's definition in *The Golden Bough* (3rd ed), i. 222. He understands by religion "a propitiation or conciliation of powers superior to man which are believed to direct and control the course of nature and of human life" He goes on to explain that by "powers" he means "conscious or personal agents." It is also to be noted that he is here definitely opposing religion to magic, which he holds to be based on the (implicit) assumption "that the course of nature is determined, not by the passions or caprice of personal beings, but by the operation of immutable laws acting mechanically" His definition improves on Tylor's in so far as it makes worship integral to the religious attitude. By regarding the object of religion as necessarily personal, however, he is led to exclude much that the primitive man undoubtedly treats with awe and respect as exerting a mystic effect on his life. Further, in maintaining that the powers recognized by religion are always superior to man, he leaves unclassed a host of practices that display a bargaining, or even a hectoring, spirit on the part of those addressing them *(see* PRAYER). Threatening or beating a fetish cannot be brought under the head of magic, even if we adopt Frazer's principle (*op. cit.* i. 225) that to constrain or coerce a personal being is to treat him as an inanimate agent; for such a principle is quite inapplicable to cases of mere terrorism, whilst it may be doubted if it even renders the sense of the magician's typical notion of his mode of operation. viz., as the bringing to bear of a greater *mana* or psychic influence *(see* below) on what has less, and must therefore do as it is bidden. Such definitions, then, are to be accepted, if at all, as definitions of type, selective designations of leading but not strictly universal features. An encyclopaedic account, however, should rest rather on an exterior definition which can serve as it were to pigeon-hole the whole mass of significant facts. Such an exterior definition is suggested by E Crawley in *The Tree of Life*, 209, where he points out that "neither the Greek nor the Latin language has any comprehensive term for religion, except in the one ἱερά and in the other *sacra*, words which are equivalent to 'sacred.' No other term covers the whole of religious phenomena, and a survey of the complex details of various worships results in showing that no other conception will comprise the whole body of religious facts." It may be added that we have here no generalization imported from a higher level of culture, but an idea or blend of ideas familiar to primitive thought. An important consequence of thus giving the study of primitive religion the wide scope of a comparative hierology is that magic is no longer divorced from religion, since the sacred will now be found to be coextensive with the magico-religious, that largely undifferentiated plasm out of which religion and magic slowly take separate shapes as society comes more and more to contrast legitimate with illicit modes of dealing with the sacred. We may define, then, the religious object as the sacred, and the corresponding religious attitude as consisting in such manifestation of feeling, thought and action in regard to the sacred as is held to conduce to the welfare of the community or to that of individuals considered as members of the community.

II. Aspects of the Nature of the Sacred.—To exhibit the general character of the sacred as it exists for primitive religion it is simplest to take stock of various aspects recognized by primitive thought as expressed in language. If some, and not the least essential, of these aspects are quasi-negative, it must be remembered that negations—witness the Unseen, the Unknown, the Infinite of a more advanced theology—are well adapted to supply that mystery on which the religious consciousness feeds with the slight basis of conceptual support it needs. (1) *The sacred as the forbidden.* The primitive notion that perhaps comes nearest to our "sacred," whilst it immediately underlies the meanings of the Latin *sacer* and *sanctus,* is that of a *taboo,* a Polynesian term for which equivalents can be quoted from most savage vocabularies. The root idea seems to be that something is marked off as to be shunned, with the added hint of a mystic sanction or penalty enforcing the avoidance. Two derivative senses of a more positive import call for special notice. On the one hand, since that which is tabooed is held to punish the taboo-breaker by a sort of mystic infection, taboo comes to stand for uncleanness and sin. On the other hand, since the isolation of the sacred, even when originally conceived in the interest of the profane, may be interpreted as self-protection on the part of the sacred as against defiling contact, taboo takes on the connotation of ascetic virtue, purity, devotion, dignity and blessedness. Primary and secondary senses of the term between them cover so much ground that it is not surprising to find taboo used in Polynesia as a name for the whole system of religion, founded as it largely is on prohibitions and abstinences. (2) *The sacred as the mysterious.* Another quasi-negative notion of more restricted distribution is that of the mysterious or strange, as we have it expressed, for example, in the Siouan *wakan,* though possibly this is a derivative meaning. Meanwhile, it is certain that what is strange, new or portentous is regularly treated by all savages as sacred. (3) *The sacred as the secret.* The literal sense of the term *churinga,* applied by the Central Australians to their sacred objects, and likewise used more abstractly to denote mystic power, as when a man is said to be "full of *churinga,*" is "secret," and is symptomatic of the esotericism that is a striking mark of Australian, and indeed of all primitive, religion, with its insistence on initiation, its exclusion of women, and its strictly enforced reticence concerning traditional lore and proceedings. (4) *The sacred as the potent.* Passing on to positive conceptions of the sacred, perhaps the most fundamental is that which identifies the efficacy of sacredness with such mystic or magical power as is signified by the *mana* of the Pacific or *orenda* of the Hurons, terms for which analogies are forthcoming on all

sides. Of *mana* R. H. Codrington in ***The*** *Melanesians,* 119 *n.,* writes: "It essentially belongs to personal beings to originate it, though it may act through the medium of water, or a stone or a bone. All Melanesian religion consists . . . in getting this *mana* for oneself, or getting it used for one's benefit." E. Tregear's *Maori-Polynesian Comparative Dictionary* shows how the word and its derivatives are used to express thought, memory, emotion, desire, will—in short, psychic energy of all kinds. It also stands for the vehicle of the magician's energy—the spell; which would seem likewise to be a meaning, perhaps the root-meaning, of *orenda (cf.* J. *N. B.* Hewitt, *American Anthropologist,* N.S., iv. 40). Whereas everything, perhaps, has some share of indwelling potency, whatever is sacred manifests this potency in an extraordinary degree, as typically the wonder-working leader of society, whose *mana* consists in his cunning and luck together. Altogether, in *mana* we have what is *par excellence* the primitive religious idea in its positive aspect, taboo representing its negative side, since whatever has *mana* is taboo, and whatever is taboo has *mana.* (5) *The sacred as the animate.* The term "animism," which embodies Tylor's classical theory of primitive religion, is unfortunately somewhat ambiguous. If we take it strictly to mean the belief in ghosts or spirits having the "vaporous materiality" proper to the objects of dream or hallucination, it is certain that the agency of such phantasms is not the sole cause to which all mystic happenings are referred (though ghosts and spirits are everywhere believed in, and appear to be endowed with greater predominance as religious synthesis advances amongst primitive peoples). Thus there is good evidence to show that many of the early gods, notably those that are held to be especially well disposed to man, are conceived rather in the shape of magnified non-natural men dwelling somewhere apart, such as the Mungan-ngaur of the Kurnai of S.E. Australia *(cf.* A. Lang, *The Making of Religion,* x. *seq.).* Such anthropomorphism is with difficulty reduced to the Tylorian animism. The term, however, will have to be used still more vaguely, if it is to cover all attribution of personality, will or vitality. This can be more simply brought under the notion of *mana.* Meanwhile, since quasi-mechanical means are freely resorted to in dealing with the sacred, as when a Maori chief snuffs up the sanctity his fingers have acquired by touching his own sacred head that he may restore the virtue to the part whence it was taken (R. Taylor, Te *Ika* a *Maui,* 165), or when uncleanness is removed as if it were a physical secretion by washing, wiping and so forth, it is hard to say whether what we should now call a "material" nature is not ascribed to the sacred, more especially when its transmissibility after the manner of a contagion is the trait that holds the attention. It is possible, however, that the savage always distinguishes in a dim way between the material medium and the indwelling principle of vital energy, examples of a pure fetishism, in the sense of the cult of the purely material, recognized as such, being hard to find. (6) *The sacred as the ancient.* The prominence of the notion of the *Alcheringa* "dreamtime," or sacred past, in Central Australian religion illustrates the essential connection perceived by the savage to lie between the sacred and the traditional. Ritualistic conservatism may be instanced as a practical outcome of this feeling. Another development is ancestor-worship, the organized cult of ancestors marking, however, a certain stage of advance beyond the very primitive, though the dead are always sacred and have *mana* which the living may exploit for their own advantage.

III. The Activity of the Sacred.—The foregoing views of the sacred, though starting from distinct conceptions, converge in a single complex notion, as may be seen from the many-sided sense borne by such a term as *wakan,* which may stand not only for "mystery," but also for "power, sacred, ancient, grandeur, animate, immortal" (W. J. McGee, *15th Report of U. S. Bureau of Ethnology,* 182). The reason for this convergence is that, whereas there is found great difficulty in characterizing the elusive nature of the sacred, its mode of manifesting itself is recognized to be much the same in all its phases. Uniform characteristics are the fecundity, ambiguity, relativity and transmissibility of Its activity. (1) *Fecundity.* The mystic potency of the sacred is no fixed quantity, but is big with possibilities of all sorts. The same sacred person, object, act, will suffice for a variety of purposes. Even where a piece of sympathetic magic appears to promise definite results, or when a departmental god is recognized, there would seem to be room left for a more or less indefinite expectancy. It must be remembered that the meaning of a rite is for the most part obscure to the participants, being overlaid by its traditional character, which but guarantees a general efficacy. "Blessings come, evils go," may be said to be the magico-religious formula implicit in all socially approved dealings with the sacred, however specialized in semblance. (2) *Ambiguity.* Mystic potency, however, because of the very indefiniteness of its action, is a two-edged sword. The sacred is not to be approached lightly. It will heal or blast, according as it is handled with or without due circumspection. That which is taboo, for instance, the person of the king, or woman's blood, is poison or medicine according as it is manipulated, being inherently just a potentiality for wonder-orking in any direction. Not but what primitive thought shows a tendency to mark off a certain kind of mystic power as wholly bad by a special name, *e.g.,* the *arungquilta* of Central Australia; and here, we may note, we come nearest to a conception of magic as something other than religion, the trafficker in *arungquilta* being socially suspect, nay, liable to persecution, and even death (as amongst the Arunta tribe, *see* Spencer and Gillen, *The Arunta,* ii. 414 *n.),* at the hands of his fellows. On the other hand, wholly beneficent powers seem hardly to be recognized, unless we find them in beings such as hfungan-ngaur ("father-our"), who derive an ethical character from their association with the initiation ceremonies and the moral instruction given thereat *(cf.* Lang, *l.c.).* *(3) Relativity.* So far we have tended to represent the activity of the sacred as that of a universal force, somewhat in the style of our "electricity" or "mind." It remains to add that this activity manifests itself at numberless independent centres. These differ amongst themselves in the degree of their energy. One spell is stronger than another, one taboo more inviolable than another. W. H. R. Rivers *(The Todas, 448)* gives an interesting analysis of the grades of sanctity apparent in Toda religion. The gods of the hill-tops come first. The sacred buffaloes, their milk, their bells, the dairies and their vessels are on a lower plane; whilst we may note that there are several grades amongst the dairies, increase of sanctity going with elaboration of dairy ritual *(cf. ibid.* 232). Still lower is the dairyman, who is in no way divine, yet has sanctity as one who maintains a condition of ceremonial purity. (4) *Transmissibility.* If, however, this activity originates at certain centres, it tends to spread therefrom in all directions. F. B. Jevons (in *An Introduction to the History of Religion,* vii.) distinguishes between "things taboo," which have the mystic contagion inherent in them, and "things tabooed." to which the taboo-infection has been transmitted. In the former class he places supernatural beings (including men with *mana* as well as ghosts and spirits), blood, new-born children with their mothers, and corpses; which list might be considerably extended, for instance, by the inclusion of natural portents, and animals and plants such as are strikingly odd, dangerous or useful. Any one of these can pass on its sacred quality to other persons and objects (as a corpse defiles the mourner and his clothes), nay to actions, places and times as well (as a corpse will likewise cause work to be tabooed, ground to be set apart, a holy season to be observed). Such transmissibility is commonly explained by the association of ideas, that becoming sacred which as it were reminds one of the sacred; though it is important to add, firstly, that such association takes place under the influence of a selective interest generated by strong religious feeling, and, secondly, that this interest is primarily a collective product, being governed by a social tradition which causes certain possibilities of ideal combination alone to be realized, whilst it is the chief guarantee of the objectivity of what they suggest.

IV. The Exploitation of the Sacred. **A.** Methods.—It is hard to find terms general enough to cover dealings with the sacred that range from the manipulation of an almost inanimate type of power to intercourse modelled on that between man and man. Primitive religion, however, resorts to either way of ap-

proach so indifferently as to prove that there is little or no awareness of an inconsistency of attitude. The radical contrast between mechanical and spiritual religion, though fundamental for modern theology, is alien to the primitive point of view, and is therefore inappropriate to the purposes of anthropological description. (1) *Acquisition.* Mystic power may be regarded as innate so far as skill, luck or queerness are signs and conditions of its presence. On the whole, however, savage society tends to regard it as something acquired, the product of acts and abstinences having a traditional character for imparting magico-religious virtue. An external symbol in the shape of a ceremony or cult-object is of great assistance to the dim eye of primitive faith. Again, the savage universe is no preserve of man, but is an open field wherein human and non-human activities of all sorts compete on more or less equal terms, yet so that a certain measure of predominance may be secured by a judicious combination of forces. (2) *Concentration.* Hence the magico-religious society or individual practitioner piles ceremony on ceremony, name of power on name of power, relic on relic, to consolidate the forces within reach and assume direction thereof. The transmissibility of the sacred ensures the fusion of powers drawn from all sources, however disparate. (3) *Induction.* It is necessary, however, as it were, to bring this force to a head. This would appear to be the essential significance of sacrifice, where a number of sacred operations and instruments are made to discharge their efficacy into the victim as into a vat, so that a blessing-yielding, evil-neutralizing force of highest attainable potency is obtained *(see* H. Hubert and M. Mauss, "Essai sur la nature et la fonction du sacrifice" in *L'Année sociologique,* ii.). *(4) Renovation.* An important *motif* in magico-religious ritual, which may not have been without effect on the development of sacrifice, is, as Frazer's main thesis in *The Golden Bough* asserts, the imparting of reproductive energy to animals, plants and man himself, its cessation being suggested by such phenomena as old age and the fall of the year. To concentrate, induce and renovate are, however, but aspects of one process of acquisition by the transfusion of a transmissible energy. (5) *Demission.* Hubert and Mauss show in their penetrating analysis of sacrifice that after the rite has been brought to its culminating point there follows as a pendant a ceremony of re-entry into ordinary life, the idea of which is preserved in the Christian formula *Ite, missa est. (6) Insulation.* Such deposition of sacredness is but an aspect of the wider method that causes a ring-fence to be erected round the sacred to ward off casual trespassers at once in their own interest and to prevent contamination. We see here a natural outcome of religious awe supported by the spirit of esotericism, and by a sense of the need for an expert handling of that which is so potent for good or ill. (7) *Direction.* This last consideration brings to notice the fact that throughout magico-religious practice of all kinds the human operator retains a certain control over the issue. In the numberless transitions that, whilst connecting, separate the spell and the prayer we observe as the accompaniment of every mood from extreme imperiousness to extreme humility an abiding will and desire to help the action out. Even "Thy will be done" preserves the echo of a direction, and, needless to say, this is hardly a form of primitive address. At the bottom is the vague feeling that it is man's own self-directed mysterious energy that is at work, however much it needs to be reinforced from without. Meanwhile, tradition strictly prescribes the ways and means of such reinforcement, so that religion becomes largely a matter of sacred lore; and the expert director of rites, who is likewise usually at this stage the leader of society, comes more and more to be needed as an intermediary between the lay portion of the community and the sacred powers.

V. Results. — Hitherto our account of primitive religion has had to move on somewhat abstract lines. His religion is, however, anything but an abstraction to the savage, and stands rather for the whole of his concrete life so far as it is penetrated by a spirit of earnest endeavour. The end and result of primitive religion is, in a word, the consecration of life, the stimulation of the will to live and to do. This bracing of the vital feeling takes place by means of imaginative appeal to the great forces man perceives stirring within him and aboat him, such appeal proving effective doubtless by reason of the psychological law that to conceive strongly is to imitate. Meanwhile, security against any clashing of conceptions to inhibit the tendency of the idea of an acquired "grace" to realize itself in action, is assured by the complete unanimity of public opinion, dominated as it is by an inveterate custom. To appreciate the consecrating effect of religion on primitive life we have only to look to the *churinga*-worship of the Central Australians (as described by Spencer and Gillen in *The Native Tribes of Central Australia,* [1] *The Northern Tribes of Central Australia* and *The Arunta).* Contact with *these* repositories of mystic influence "makes them glad" (*Nat. Tr.* 165); it likewise makes them "good," so that they are no longer greedy or selfish *(North. Tr.* 266); it endows them with second sight *(ibid.);* it gives them confidence and success in war (*Nat. Tr.* 135); in fact, there is no end to its "strengthening" effects *(ibid. n.).* Or, again, we may note the earnestness and solemnity that characterize all their sacred ceremonies. The inwardness of primitive religion is, however, non-existent for those who observe it as uninitiated strangers; whilst, again, it evaporates as soon as native custom breaks down under pressure of civilization, when only fragments of meaningless superstition survive: for which reason travesties of primitive religion abound.

It remains to consider shortly the consecration of life in relation to particular categories and departments. (1) *Education.* Almost every tribe has its initiation ceremonies, and in many tribes adult life may almost be described as a continuous initiation. The object of these rites is primarily to impart mystic virtue to the novice, such virtue, in the eyes of the primitive man, being always something more than social usefulness, amounting as it does to a share in the tribal luck by means of association with all it holds sacred. Incidentally the candidate is trained to perform his duties as a tribesman, but religion presides over the course, demanding earnest endeavour of an impressionable age. (2) *Government.* Where society is most primitive it is most democratic, as in Australia, and magico-religious powers are possessed by the whole body of fully initiated males, age, however, conferring increase of sacred lore and consequently of authority; whilst even at this stage the experts tend to form an inner circle of rulers. The man with *mana* is bound to come to the top, both because his gifts give him a start and because his success is taken as a sign that he has the gift. A decisive "moment" in the evolution of chiefship is the recognition of hereditary *mana,* bound up as this is with the handing on of ceremonies and cult-objects. Invested, as society grows more complex, with a sanctity increasingly superior to that of the layman, the priest-king becomes the representative of the community as repository of its luck, whilst, as controller of all sacred forces that bear thereon, he is, as Frazer puts it, "dynamical centre of the universe" (*The Golden Bough* [3rd ed.], iii. 1). Only when the holy man's duty to preserve his holiness binds him hand and foot in a network of taboos does his temporal power tend to devolve on a deputy. (3) *Food-supply.* In accordance with the principle of Renovation *(see* above), the root-idea of the application of religion to economics is not the extorting of boons from an unwilling nature, but rather the stimulation of the sources of life, so that all beings alike may increase and multiply. (4) *Food-taking.* Meanwhile, the primitive meal is always more or less of a sacrament, and there are many food-taboos, the significance of which is, however, not so much that certain foods are unclean and poisonous as that they are of special virtue and must be partaken of solemnly and with circumspection. (5) *Kinship.* It is hard to say whether the unit of primitive society is the tribe or the group of kinsmen. Both are forms of union that are consolidated by means of religious usages. Thus in Australia the initiation ceremonies, concerned as they partly are with marriage, always an affair between the kin-groups, are tribal, whilst the totemic rites are the prime concern of the members of the totem clans. The significance of a common name and a common blood is immensely enhanced by its association with mystic rights and duties, and the pulse of brotherhood beats faster. (6) *The Family.* Side by side with the kin there is always found the domestic group, but the latter

institution develops fully only as the former weakens, so that the one comes largely to inherit the functions of the other, whilst the tribe too in its turn hands over certain interests. Thus in process of time birth-rites, marriage-rites, funeral-rites, not to mention subordinate ceremonies such as those of name-giving and food-taking, become domestic sacraments. *(7) Sex.* Woman, for certain physiological reasons, is always for primitive peoples hedged round with sanctity, whilst man does all he can to inspire awe of his powers in woman by keeping religion largely in his own hands. The result, so far as woman is concerned, is that, in company with those males who are endowed with sacredness in a more than ordinary degree, she tends as a sex to lose in freedom as much as she gains in respect. *(8) Personality.* Every one has his modicum of innate *mana,* or at least may develop it in himself by communicating with powers that can be brought into answering relation by the proper means. Nagualism, or the acquisition of a mystic guardian, is a widely distributed custom, the essence of which probably consists in the procuring of a personal name having potency. The exceptional man is recognized as having *mana* in a special degree, and a belief thus held at once by others and by himself is bound to stimulate his individuality. The primitive community is not so custom-bound that personality has no chance to make itself felt, and the leader of men possessed of an inner fund of inspiration is the wonder-worker who encourages all forms of social advance.

VI. Psychology of the Primitive Attitude Towards the Sacred.—We are on firmer ground when simply describing the phenomena of primitive religion than when seeking to account for these in terms of natural law—in whatever sense the conception of natural law be applicable to the facts of the mental life of man. One thing is certain, namely, that savages stand on virtually one footing with the civilized as regards the type of explanation appropriate to their beliefs and practices. We have no right to refer to "instincts" in the case of primitive man, any more at any rate than we have in our own case. A child of civilized parents brought up from the first amongst savages is a savage, neither more nor less. Though race may count for something in the matter of mental effectiveness—and at least it would seem to involve differences in weight of brain—it clearly counts for much less than does *milieu,* to wit, that social environment of ideas and institutions which depends so largely for its effectiveness on mechanical means of tradition, such as the art of writing. The outstanding feature of the mental life of savages known to psychologists as "primitive credulity" is doubtless chiefly due to sheer want of diversity of suggestiveness in their intellectual surroundings. Their notions stick fast because there are no competing notions to dislodge them. Society suffers a sort of perpetual obsession, and remains self-hypnotized as it were within a magic circle of traditional views. A rigid orthodoxy is sustained by means of purblind imitation assisted by no little persecution. Such changes as occur come about, not in consequence of a new direction taken by conscious policy, but rather in the way that fashions in dress alter amongst ourselves, by subconscious, hardly purposive drifting. The crowd rather than the individual is the thinking unit. A proof is the mysterious rapid extinction of savages the moment that their group-life is broken up; they are individually so many lost sheep, without self-reliance or initiative. And the thinking power of a crowd—that is, a mob, not a deliberative assembly—IS of a very low order, emotion of a "panicky" type driving it hither and thither like a rudderless ship. However, as the students of mob-psychology have shown, every crowd tends to have its *meneur,* its mob-leader, the man who sets the cheering or starts the running-away. So too, then, with the primitive society. Grossly ignorant of all that falls outside "the daily round, the common task," they are full of panicky fears in regard to this unknown, and the primary attitude of society towards it is sheer avoidance, taboo. But the mysterious has another face. To the mob the mob-leader is mysterious in his power of bringing luck and salvation; to himself also he is a wonder, since he wills, and lo! things happen accordingly. He has *mana,* power, and by means of this *mana,* felt inwardly by himself, acknowledged by his fellows, he stems the social impulse to run away from a mystery. Not without nervous dread—witness the special taboo to which the leader of society is subject—he draws near and strives to constrain, conciliate or cajole the awful forces with which the life of the group is set about. He enters the Holy of Holies; the rest remain without, and are more than half afraid of their mediator. In short, from the standpoint of lay society, the manipulator of the sacred is himself sacred, and shares in all the associations of sacredness. An anthropomorphism which is specifically a "magomorphism" renders the sacred powers increasingly one with the governing element in society, and religion assumes an ethico-political character, whilst correspondingly authority and law are invested with a deeper meaning.

VII. The Abuse of the Sacred.—Lest our picture of primitive religion appear too brightly coloured, a word must be said on the perversions to which the exploitation of the sacred is liable. Envy, malice and uncharitableness are found in primitive society, as elsewhere, and on their behalf the mystic forces are not infrequently unloosed by those who know how to do so. To use the sacred to the detriment of the community, as does, for instance, the expert who casts a spell, or utters a prayer, to his neighbour's hurt, is what primitive society understands by magic (cf. *arungquilta,* above), and anthropology has no business to attach any other meaning to the word if it undertakes to interpret the primitive point of view. On the other hand, if those in authority perpetrate in the name of what their society holds sacred, and therefore with its full approval, acts that to the modern mind are cruel, silly or revolting, it is bad science and bad ethics to speak of vice and degradation, unless it can be shown that the community in which these things occur is thereby brought nearer to elimination in the struggle for existence. As a matter of fact, the earlier and more democratic types of primitive society, uncontaminated by our civilization, do not present many features to which the modern conscience can take exception, but display rather the edifying spectacle of religious brotherhoods encouraging themselves by mystical communion to common effort. With the evolution of rank, however, and the concentration of magico-religious power in the hands of certain orders, there is less solidarity and more individualism, or at all events more opportunity for sectional interests to be pursued at other than critical times; whereupon fraud and violence are apt to infect religion. Indeed, as the history of the higher religions shows, religion tends in the end to break away from secular government with its aristocratic traditions, and to revert to the more democratic spirit of the primitive age, having by now obtained a clearer consciousness of its purpose, yet nevertheless clinging to the inveterate forms of human ritual as still adequate to symbolize the consecration of life—the quickening of the will to face life earnestly.

BIBLIOGRAPHY.—The number of works dealing with primitive religion is endless. The English reader who is more or less new to the subject is recommended to begin with Sir E. B. Tylor, *Primitive Culture* (4th ed., Lond. 1903), and then to proceed to Sir J. G. Frazer, *The Golden Bough* (3rd ed., Lond. 1911–15), together with his other works *The Belief in Immortality* 1913; *Folk-Lore in the Old Testament,* 1919; *The Worship of Nature,* 1926. Only second in importance to the above are W. Robertson Smith, *Lectures on the Religion of the Semites* (3rd ed. with Introd. and additional notes by Dr. S. A. Cook, Lond. 1927); A. Lang, *Myth, Ritual and Religion* (2nd ed., Lond. 1899), and *Magic and Religion* (Lond. 1902); E. S. Hartland, *The Legend of Perseus* (Lond. 1894–96); F. B. Jevons, *An Introduction to the History of Religion* (2nd ed., 1902); E. Crawley, *The Tree of Life* and *The Mystic Rose* (2nd ed. Lond. 1927). The two last-mentioned works perhaps most nearly represent the views taken in the text, which are also developed by the present writer in *The Threshold of Religion* (2nd ed., 1909) and *Psychology and Folk-Lore,* 1920. *See* also H. Hubert and M. Mauss, "Essai sur la nature et la fonction du sacrifice," *L'Année sociologique,* ii.; and "Esquisse d'une théorie générale de la magie," *ibid* vii.; E. Durkheim, *Les formes élémentaires et la vie religieuse,* Paris, 1912; L. Levy-Bruhl, *Les fonctions mentales dans les sociétés inférieures,* Paris, 1912; R. H. Lowie, *Primitive Religion,* 1925, E. Westermarck, *Ritual and Belief in Morocco,* 1926; R. Briffault, *The Mothers,* 1927.

Side by side with works of general theory, first-hand authorities should be freely used. To make a selection from these is not easy, but the following at least are very important: R. H. Codrington, *The Melanesians* (Oxford, 1891); W. B. Spencer and F. J. Gillen, *The*

Native **Tribes** *of Central Australia* (Lond. *1899*); *The Northern Tribes of Central Australia* (Lond. 1904); *The Arunta* (Lond. 1927); A. W. Howitt, *The Native Tribes of South-Eastern Australia* (Lond. 1904); A. C. Haddon, *Reports of the Cambridge Anthropological Expedition to Torres Straits* (Cambridge, 1904, vol. v.); A. B Ellis, *The Tshi-Speaking Peoples of the Gold Coast* (Lond. 1897); *The Ewe-Speaking Peoples of the Slave Coast* (Lond. 1890); *The Yoruba-Speaking Peoples of the Slave Coast* (Lond. 1894); Miss M. H. Kingsley, *Travels in West Africa* (Lond. 1898), and *West African Studies* (Lond. 1899); R. S. Rattray, *Ashanti* (1923); *Religion and Art in Ashanti* (1927); E. Westermarck, *Ritual and Belief in Morocco* (1926); A. C. Hollis, *The Masai* (1905); W. Crooke, *The North-West Provinces of India* (Lond. 1897); W. H. R. Rivers, *The Todas* (1906) An immense amount of valuable evidence is to be obtained in the *Reports of the Bureau of Ethnology*, Smithsonian Institution, Washington *See* Nos. 2, 5, 6, 7, 8, 9, 11, 13, 14, 15, 16, 18, 19, 21, 22, 23, and specially J. O. Dorsey, *A Study of Siouan Cults*, in No. 11; A. C. Fletcher, *The Hako*, in No. 22; and M. C. Stevenson, *The Zuñi Indians*, in No. 23. Though dealing primarily with a more advanced culture, J. J. M. de Groot, *The Religious System of China* (1892–1901), will be found to throw much light on primitive ideas Finally let it be repeated that there is offered here no more than an introductory course of standard authorities suitable for the English reader. **(R. R. M.)**

B. THE HIGHER RELIGIONS

No attempt can here be made to deal in detail with the Higher Religions. These are treated elsewhere under their respective headings. The different Higher Religions will only be considered in so far as they exhibit general principles. The main object of this section will be to show the lines on which the higher religious consciousness has developed, the broad features which it discloses, and the way in which it gives expression to human needs.

I. THE BASIS OF HIGHER RELIGION

Higher religions have developed on a pre-existing basis, in response to an impulse of the religious spirit seeking better self-expression. They have grown out of primitive religion, and all of them exhibit traces of their lineage. The survival of primitive traits in developed religion is a recurring phenomenon.

Evidently a higher religion can only emerge from a lower by a process of selection ana development. Certain elements in early religion were intractable to development, while others were capable of it. To the former must be reckoned the strongly local character and particularist tendency of primitive religion. Spirits or powers attached to a definite spot, or embodied in a specific object are not easily elevated or expanded. Sentiment is conservative, and the being reverenced is too much lacking in individual quality to be readily transformed into a personal god. On the other hand, though the feeling of the clan that its objects of worship belong to it resists absorption in a larger cult, the strong sense of affinity with divine powers is capable of being elevated to a higher religious relationship. The same holds of primitive rites of communion. So too primitive ideas of Tabu and Interdiction have naturally passed into conceptions of the sacred and not-sacred, the pure and the impure, ideas that play a great part in developed religion. Again the cult of the dead, passing into that of family ancestors (see ANCESTOR WORSHIP) easily expands with the enlargement of society: it has contributed important elements to national religion as in the case of China and ancient Rome. There are then higher possibilities in primitive religion, but they can only come to fruition with the emergence of new needs and a wider outlook.

II. THE RISE AND GROWTH OF POLYTHEISM

Higher religions emerge after the tribal has been superseded by the national culture. The transition to the more developed stage was the outcome of social changes which were reflected in the growth of man's inner life. This enrichment of personal life carried with it the need of a revised idea of the objects of worship and of the religious relation. The old spiritism, with its multitude of indefinite powers and capricious daemons. no longer corresponded to man's better ordered life and his varied and specialized interests. The larger and more constant values of a social order based on agriculture required divine beings capable of responding to its wants, and the rise of polytheism was the answer to these religious demands. The polytheistic system was the expression of man's vision of the world, a world of diverse departments and manifestations though not a real unity. But polytheism marks an advance. For it helped (a) to liberate religion from its bondage to purely local associations. And (b), it replaced the colourless powers or *numina* of older belief by a number of divine beings of more specific character and with more or less definite spheres of activity. A god, as distinguished from a spirit, is a being with determinate qualities which embody the values of which men are conscious.

(1) *The* Emergence of Gods.—The formless spirits supply only a shifting and uncertain basis on which to evolve a god. It has been suggested that the Greek deities Hermes and Artemis were developed in this way, and the Roman goddess Juno has been construed as the general personification of the fertility *numen* or Juno of every woman. In any case such a process is infrequent. And the instances in which a totem has grown into a god, if they do occur at all, are extremely rare. What is clear is, that many of the greater gods have a connection with the phenomena of nature, and show traces of this relationship. Sometimes the connection is quite definite. Thus the Egyptian Ra and the Babylonian Shamash are sun-gods. The Greek Zeus, to whom corresponds the Vedic Dyaus, is a sky-god, and Ushas of the Vedic Hymns is a dawn-goddess. But there are many instances where the connection of a deity with nature cannot be precisely stated, though the general fact is not in doubt. Thus it remains uncertain what the natural basis of the Egyptian Osiris is; and we cannot say more of the Vedic Varuna and Vishnu than that they are connected with light and the heaven. The later development of a deity usually furnishes a very slender clue to his real origin. Moreover when the identification of a deity with a phenomenon of nature is transparent and precise, it is difficult for the god to develop by assuming new and higher qualities.

But while the greater phenomena of nature, by the fact that they possess a kind of physical universality, were a means of helping the mind to rise to the conception of deities of wider range and power, all gods are not to be explained thus. For some of them have their origin in the cult. The Hindu Soma is the power of the sacrificial libation, and Brahma the power of the sacrificial prayer personified. The Greek Hestia and the Roman Vesta (*q.v.*) have grown out of the sacred hearth as the centre of family life. Again, aspects of the cultural life, such as war and agriculture, have suggested deities who preside over them. In some cases men remarkable for their power and deeds have been exalted to the rank of divine, or semi-divine beings, *e.g.*, the Greek Herakles and Asklepios. (See ASCLEPIUS and HERCULES.) The motives which develop polytheism are complex.

(2) The Characterization *of* the Gods.—As social Life expands, its values become more varied, and the representations of the gods gain correspondingly in content. A god takes on new qualities and aspects in response to the needs and desires of his worshippers, and this process appears in all religions. Few gods have acquired so varied qualities and offices as the Greek Apollo. His identification with the sun is comparatively late, and his original character obscure. But he came to figure as the lord of flocks and herds, the master of oracles and prophecy, the god of healing, of purification, and of poesy. The imaginative process which predicated diversified attributes to a deity at the same time expressed the interests and aspirations of his worshippers. And the cultus was the chief medium by which these tendencies were developed and took concrete form.

The problem of organization is urgent where a religion arises out of the fusion of different cultures Conspicuous instances are Babylonian and Greek religion. The Semitic invaders of Babylonia absorbed the older Sumerian culture, and found a place for Sumerian deities within their own pantheon. Greek civilization, as we now know, was the result of a fusion of two races, a race of Aryan invaders with the "Helladic" race. And it is almost certain that some of the Hellenic deities, e.g Athene, Artemis, and Aphrodite, were adopted by the Greeks from the older culture. Yet it is always hard to achieve organization in the religious complex of polytheism even when a fusion of cultures seems to render it essential. The local associations and the cult-interests of the dei-

ties of the conquered race resist absorption. This difficulty may be overcome by fitting them into the enlarged pantheon as sons or servants of greater gods. Even then the older cults and beliefs will linger on. Homeric religion is no doubt an example of organisation; but it is artificial and literary. it does not fairly represent the actual beliefs and cult-practices in Greece. Still, however imperfectly the process may work itself out, there is behind polytheistic religion an impulse towards order and system. The development of social life, with its well-marked departments and functions, prompted the mind to conceive the divine world after the pattern of the human. The needs of worship, where not dominated by magical ideas, led in the same direction. For worship at the higher level cannot be easily apportioned among a number of divine beings whose mutual relations are quite indefinite. Some order and gradation are necessary.

III. THE CULTUS IN HIGHER RELIGIONS

The cultus is the focus of a religion: here it is concentrated and symbolized. As the focus of religious life the cultus becomes the point at which the sense of the sacred is most concentrated and intense. Radiating from this centre the sacred suffuses associated elements, investing with religious significance things and persons, places and times.

(1) The *Sacred* Place.—In early religion a place or thing became sacred through the presence in it of a spirit or power: *numen inest.* But when men began to build houses, when the house became the centre of family life, the thought lay to hand that there must be a house for the deity to be the focus of his worship. So the temple arose, reared often on sacred spots or "high places," hallowed by immemorial associations. As the deity was supposed to be more intimately present in his temple, it often became a centre of oracles and prophecy.

(2) *Sacred Men: tire Priesthood.*—To holy places correspond holy men. The priest has his precursor in the wizard of the lower culture. The priest is a man endowed with a special knowledge of the cultus, is possessed of ritual purity, and embodies in his person the power of the sacred. At first priestly functions were not the exclusive privilege of a class. The head of the family, or the king as head of the people, offers sacrifice, so in the old Hebrew and Roman religions. But with the growing value attached to sacred functions there was the tendency to assign the priestly office to a particular class, as in the Hebrew, Persian and Hindu religions. Nowhere have the priests formed a more strict and exclusive caste than in Brahmanism.

(a) Prayer.—Perhaps nowhere does the spirit of a religion reveal itself more intimately than in its prayers. Yet even in the higher religions the idea of prayer as the free outpouring of the soul to the divine comes late. Primitive prayer is closely allied to the spell, and it must take a fixed form of words to be effective. The elevation of prayer comes with the development of inner life and an enhanced sense of ethical and spiritual values. Some knowledge of the kind of prayers offered in the cultus may be gathered from liturgical forms, *e.g.* from the sacrificial hymns of the Gathas and the Vedas. Prayer as petition to the gods is universal. But only in a few religions do we find prayers containing confessions of sin *e.g.* in the penitential psalms of the Hebrew and the Babylonian religions. Nowhere is the mysterious potency of prayer so exalted as in Brahmanism. Here prayer becomes a cosmic power which constrains the gods, and is finally construed as the divine principle of things. But wherever prayer ceases to be the expression of a fundamental dependence on the Divine, it loses its essential meaning and value. An intrinsically efficacious form of words is really a reversion to the magic spell. (See PRAYER.)

(b) *Sacrifice.*—Sacrifice springs from a deep-rooted impulse of the religious nature. It plays a part in early religion, and is present in some form in all the higher religions. The purpose of sacrifice is to maintain and strengthen. or to restore. fellowship with divine powers. and it takes a central place in the cultus. In the burnt-offering the sacrifice is wafted to the gods. In the bloody offering the victim, through contact with the altar, becomes charged with the sacred, and its sprinkled blood has atoning virtue. The idea of substitutionary atonement is later and is due to reflection. In sacrifices of purification and atonement there is an ethical element which may lead to the higher development of religion. Just as with prayer, however, sacrifice may evolve in a way which is detrimental to the religious relation. What lifts sacrifice to an ethical and spiritual level is the conception of the righteousness of God. Where this obtains it is the inner side of the sacrificial act which is emphasised, the offering of the contrite heart and the obedient will. (See SACRIFICE.)

IV. RELIGIONS OF OBSERVANCE AND PROPHETIC RELIGIONS

The ritual aspect of religion tends to grow with the increasing complexity of the social order. When this tendency prevails religion takes on the specific character of legal observance.

(1) Religions of Observance *and* Law.—The idea of fixed observances or rules binding on the faithful develops where the idea of ritual purity is emphasised. The roots of the conception of the clean and unclean go back to primitive ideas of the sacred and of the dangerous with the associated apotropaic rites of expulsion. The growth of a sacral system leads to the fuller definition of the clean and unclean, and rules and forms are prescribed to preserve purity and remove impurity. In many higher religions there are detailed methods and a ritual of cleansing. In Roman religion we have lustration, which combined cathartic and apotropaic rites, and in Greece cathartic rites were specially connected with Apollo, the god of ritual purity. It is, however, in later Persian religion that rites of purification receive the most comprehensive and detailed expression, and nowhere is the notion of purity so dominant and pervasive. To all the numerous defilements that are possible correspond stated cleansings, and the Vendidad itself has been described as a kind of sin-codex. With this we may compare the laws of purity and impurity in the book of Leviticus, a book which embodies the cathartic ritual of post-Exilic Judaism. When a higher religion has developed a complicated system of ritual observance it brings the sense of the sacred into close and constant relation with the varied details of life. On the other hand, the religion itself is exposed to great dangers. The magical beliefs, which are a heritage of older religion, always tend to reassert themselves, and the religious rites readily degenerate to a mechanical performance which has intrinsic efficacy. When this happens the way to spiritual development is closed, and the later Persian and Jewish religions did not wholly escape the danger.

(2) Prophetic Religion.—Religion as piety has its centre within. The prophetic spirit proclaims this principle, and is itself the issue of personal and moral conviction. The prophet turns from the formal and external side of religion to emphasize its inner life, and when such a movement appears within a national religion it involves a loosening of religion from the social and political system. Great religious reforms and renewals arise from an individual or individuals for whom religion has become an intense and personal concern. Such a prophetic figure was Zarathustra. As we picture him from the Gathas he was a man of burning conviction, for whom Ahura Mazda was a supreme and moral deity whose cause is the right as against the lie. In this conflict the prophet calls men to fight and freely to choose the good. A like intense moral conviction and faith in the righteousness of Jahveh appears in the eighth century prophets of Israel linked with an even greater stress on the inner side of piety. The same note recurs in the teaching of Jèsus that the vision of God is for the pure in heart.

It is curious to find an emphasis on the inner side of religion appearing within Hinduism. It emerges in the doctrine of Bhakti which has its classical expression in the Bhagavad Cita. Here we have the doctrine that trust and devotion, faith and love, to the divine power are a means of salvation. Religion assumes a personal colour. With Buddha this principle appears in the form of an extreme subjectivism. Within man himself lies the secret of salvation.

The work of the prophetic spirit makes possible the high stages of spiritual religion. Apart from its vivifying influence institu-

tional religion tends to grow formal and fixed, and its inner life to ebb. "Where there is no vision the people perish." The uprising of the prophet is a token that a religion which seems dead has still within it the springs of life.

V. REDEMPTIVE RELIGIONS

The prophetic movement is one symptom of the enhanced sense of personal and religious values, and the emergence of religions of salvation or redemption is another. Both indicate a slackening of the tie which binds religion to the national and political structure. For the official religion which men share simply as citizens of the state, a religion concerned with external observance rather than inner spirit and motives, no longer satisfies the more personal needs of which men are becoming aware. Corresponding to this increasing self-consciousness there grows up a craving for a more intimate and individual relation with the divine Power, a craving which the traditional religious forms cannot meet. And this feeling is deepened by the personal sense of the evils and sufferings of life. This longing for deliverance finds no fulfilment in the customary and external religion that a man inherits from his social group. Some better way is necessary; and the personal consciousness of the need of salvation carries with it a sense of responsibility for realizing it. So men seek some mode of expressing the religious spirit which shall embody their choice and preference, for religion must be in a more intimate sense their own. As the new movement takes its rise from broadly human needs. the form of religion which meets these needs cannot be merely local and particular: in its meaning at least it mill be universal. This implies that the form of the religious relation is reconstituted. and this carries with it a differentiation of the religious community from political society. There now come into being religious associations or churches, where membership is based on a voluntary adherence to a particular religion or cult. This principle of a sacred society or church. clearly distinguished from secular society, is of great significance in the evolution of religion. For only under such conditions can the other-worldly or transcendent element in faith come to its due, and religion itself be delivered from bondage to political and secular interests. The idea of the sacred gains spiritual significance: the sacred community is united not merely in the observance of sacred rites but by a common disposition of the mind and will toward a religious good. And this good is not mundane but supramundane.

The new tendency finds expression in different ways. It appears as a movement which. without deliberately breaking with existing religion, takes form in religious associations which minister to felt religious wants. Again it appears as a philosophic gospel which offers spiritual deliverance to elect souls. Finally it manifests itself in the birth of a new religion, a religion which originates with a personal founder who proclaims a message of salvation. To the first class belong the various forms of mystery religions which were common in Creek and Mediterranean lands for a period of eight centuries B.C. One of the best known is the Orphic mysteries, a cult open at least to all Hellenes who underwent initiation. This cult held out the prospect of immortality and union with the divine. The body was a kind of tomb (σῶμα, σῆμα) from which the soul had to win deliverance. The way of salvation was by purification, abstinence and sacramental rites. The idea of something peculiarly sacred, in which the initiated participate, is common to mystery religions. The later mystery cults. like those of Attis, Isis and Mithras. which were widespread in eastern Mediterranean lands in the post-Alexandrian period, set in the foreground the spectacle of the dying and reviving god. Their votaries, through baptism, purification and a sacramental meal, somehow shared in the being of the god and with him rose to new life.

In the philosophic sphere, Neoplatonism proclaims the deliverance of the soul through an ecstatic union with the One that transcends rational thinking. Philosophic Brahmanism likewise has a doctrine of salvation, but a salvation through knowledge of the identity of the self with the Absolute or Brahman.

In Buddhism and in Christianity the spirit of redemptive religion is most fully expressed. In Buddhism the principle is seen taking an extreme subjective form. Buddha discards the metaphysics of Brahmanism, though he shares with it the idea that salvation comes through knowledge. The Enlightened, the Arahat, knows that thirst, with its attendant desire and suffering, is the evil of life, and by following the Noble Eightfold Way he advances to that indefinable goal, Nirvana. Redemption is thus a negative process: it is a gospel for the monk who breaks with the world rather than for the ordinary man who has to live in the world. Christian redemption is a richer and more positive conception. The deliverance sought is from moral evil or sin, and it is conditioned by repentance and faith. The end is not the extinction of personality but its enrichment through the power of a divine life, and it has corporate expression in life in the Kingdom of God which overcomes the evil in the world. Christian redemption is marked by its theistic basis, its sense of personal values and its positive character. The religious society of Buddhism is a monkish community: that of Christianity is the church, or the fellowship of the faithful united in the service of God.

VI. PANTHEISM, MYSTICISM AND MONOTHEISM

These are features found only in the higher religious culture. They all claim to be an advance on some existing religious system.

(1) *Pantheism.*

Pantheism is in the main a result of the development of reflective thinking. In the many it finds merely the passing appearances of the One. If pantheism is a late development, it was at least foreshadowed at earlier stages of religious evolution. Men soon became dimly conscious of a unity pervading the cosmic order and everywhere operative throughout it. In the Hindu conception of Rita and of Karma we have the idea of a power behind all things working by inflexible law. The ancient Chinese Tao conveys a sense of the eternal order and way of the universe. The Greek Moira and the Persian Asha contain the same ideas. This belief in a universal principle, when applied to polytheism, leads to the notion of a common power behind the gods and suggests that the various gods are only forms of the one Reality. Thus during the middle kingdom in Egypt reflective thinking treated the various gods as manifestations of Ra, and among the priesthood there was an esoteric pantheism.

The trend toward pantheism works itself out more readily when the gods are not sharply defined in their specific character and attributes. This was the case with the Vedic gods, since the qualities of one were often transferred to another. In the avatars of Vishnu one god assumes many divine forms. So by an easy process of transition the pantheism of the Upanishads and the Vedanta is reached. Here pantheism is thoroughgoing. All cosmic and psychical phenomena are unified in the one real Being: Brahman-Atman, the soul and the Absolute, are identical. Tat *tvam asi:* "that art thou." The multiplicity of the phenomenal world is only Maya or illusion; it disappears with knowledge. In contrast the clear-cut gods of Greece resisted a process of fusion. The Stoic pantheism, which identified Zeus with the universal and immanent reason or Logos, was rather an independent speculative theory than a development of Greek religion.

Religious pantheism is in the main a reflective development resulting from rational demands. If consistent, it is not a working religious creed, for it abolishes the religious relation by reducing it to an identity. (See PANTHEISM.)

(2) *Mysticism.*

Mysticism. like pantheism, in the strict sense is a phenomenon of highly developed religion. Individualistic in character, it is the outcome of a longing for intimate communion with the Divine. The mystery religions show a mystic tendency in their doctrine of union with the god through the sacramental meal. The same is perhaps true of Hindu Yoga which is a method of inducing religious ecstasy by concentration and absorption of mind. The Yogin became for others a kind of supernatural being. But mysticism proper is a conscious reaction against the externality of a merely intellectual knowledge of God: its goal is a perfect union with the Deity in which the element of difference implied in thinking is overcome. The Neoplatonic union of the

soul with the One is a purely mystical experience. The same spiritual movement appeared within Islam in Sufism, which no doubt was influenced by Neo-Platonism. The sufi sought to purge his mind of all that was not God, and the perfect man attained to absorption in God. The great mediaeval mystics sought the same consummation. an *unio mystica* achieved by transcending the form of thinking. Mysticism is loosely related to official and institutional religion. Possessing a "more excellent way," it can dispense with the recognized means of mediation. But if it invests religion with a new warmth and intimacy, it is deficient as a social power. And mysticism is always exposed to the danger of falling into pantheism. *(See* MYSTICISM.)

(3) Monotheism.

Monotheism is a late phenomenon of religion. The hypothesis of a primitive monotheism lacks foundation, and is intrinsically improbable. Beyond doubt the spirit and meaning of religion attain their fullest and best expression in some form of monotheistic faith. Polytheism disperses the religious interest: intimacy of worship and the confidence of trust are only possible when there is one, and only one, object of religious devotion. The trend towards monotheism was gradual, and it had preparatory stages. The first stage was what is called monarchianism. After the analogy of human society one deity is exalted above the rest, and becomes the king of the gods. A familiar example is the Homeric Zeus who stands supreme over all the gods and looks down on the conflicts of mortals among whom his will is accomplished. (Διὸς δ' ἐτελείετο βουλή.) The Babylonian Marduk and the Egyptian Ra are illustrations of the same phenomenon of one deity attaining a position of undisputed sovereignty. A rather more advanced stage is that of monolatry, where other gods are admitted to exist, but worship is reserved for one. This we find in Hebrew religion in the pre-prophetic period.

The earliest attempt—an abortive one—to introduce a pure monotheism, in this case a solar monotheism, is that of the Egyptian Amenhotep IV. in the XIVth century B.C. More impressive is the monotheism of Zarathustra, perhaps some eight hundred years before our era. This monotheism rests on a comprehensive view of the world. The physical and moral order derive from the one God, his will is right, and all the pure elements of life belong to his kingdom. The pronounced dualism of the later Avesta is absent from the prophet's teaching. With the eighth century prophets of Israel the earlier monolatry became a true monotheism. This monotheistic universalism finds its clearest utterance in the work of Deutero-Isaiah. From this heritage of Hebrew religion Christianity derived its pure monotheism, and the same influence is manifest in the monotheism of Islam.

Monotheism is the ripest expression of the religious consciousness. It rests on the conviction that the ethical and religious values must have a sufficient ground, and this is the one God on whom all existence and value depend.

VII. REVELATION AND THEOLOGY

Belief in the communication of truth to man from a divine source is common in religions. This kind of communication usually concerns the future, and may be subject to a process of interpretation. Hence the practices of divination, the reading of omens and auspices, and star-lore. But the communication may be in and to the individual, for instance through visions and dreams.

(1) *Revelation.*

More especially is revelation thought to come through inspiration or "possession" by a divine power. The words spoken by the individual thus "possessed" are identified with the utterances of the god The Greek Xpollo was the god of prophecy, and the words spoken by his inspired priestess at Delphi were deemed to be the authentic voice of the god himself. The religious value of revelation depends on the character of the deity who is believed to reveal; and it is the consciousness of ethical values leading to an ethical idea of deity which purifies the content of revelation. Revelation in the large and comprehensive sense is linked with monotheistic religion. So Zarathustra proclaimed the message communicated to him by Ahura Mazda, and Mohammed in his visions had the truth revealed to him by Allah. The divine word came to the prophets of Israel, and the preface to their message was, "Thus saith the Lord." What they spoke Jahveh had caused them to know. At this level revelation centres in an experience or illumination within. But these inspired utterances were afterwards written down and collected: in the form of sacred books they came to be regarded as objective statements of divine truth. Hence the claims made for the Avesta, the Veda, the Koran, and the Old and New Testaments. Books which were accepted as statements of revealed truth naturally became authoritative, and as expressing authoritatively the content of a religion they furnished a basis for theology.

(2) *Theology.*

Theology grows out of the beliefs contained in an historic religion: it is an endeavour to state what is involved in a definite religious type of experience in general propositions or doctrines. The earliest anticipation of this is the myth framed to explain the meaning of something done in the cult. Theology is not detached like speculation, it is a natural and necessary outgrowth from the life of religion itself. It is the product of a mature religion, and commonly has its basis in the sacred books which record its religious experience. We find theological developments in Judaism and Buddhism, but in a more complete form in Islam and in Christianity. The Islamic and the Christian theologies claim to interpret the authoritative revelation contained in their sacred scriptures. In both instances the growth of theology was stimulated by the presence of beliefs judged to be heretical. The Mutazalite movement, with its doctrines of faith and free-will and its criticism of tradition, impelled the orthodox party in Islam to define the true doctrine of Allah and his attributes. In a like way the Gnostic heresies provoked the growth of a Christian theology which sought to expound the doctrines involved in Christian faith and practice. The Islamic conception of religion, however, is too much interwoven with what is external and political to furnish a favourable field for theological development. Christianity, on the other hand, has developed a body of religious experience of a wealth and amplitude capable of sustaining an impressive body of doctrine.

The function of theology is primarily to interpret. As contrasted with speculation it leans on authoritative revelation, and stands in organic relation to a specific historic religion. *(See* THEOLOGY.)

VIII. ETHICS AND ESCHATOLOGY

The ethical element is of fundamental importance in determining the quality of a religion: it is a powerful factor in elevating the object of worship, the religious relation, and the religious life. At the pre-deistic stage the sacred is interpenetrated with magical beliefs, and ethical principles have their lowly precursor in the sanctity of tribal custom. When through the growth of social culture the moral virtues are recognized as values, they are made to qualify the character of the gods.

(1) *Ethics.*

The process may not be easy when the deity has a pronounced natural basis, but still it does occur, as in the case of the Vedic Varuna and the Babylonian Shamash. On the other hand, the Persian Ahura Mazda became a definitely ethical god who demands pure living and right thinking. At a later date Mithra was revered as the god of truth and loyalty. The Greek Zeus acquired moral functions, and Δικη, or Justice, was proclaimed to be his daughter. The feeling for the moral element in religion appears in the saying of Euripides: "If the gods do aught that is shameful, they are no gods." A profound appreciation of the moral values is seen in the Hebrew prophets who passionately declared that Jahveh is a righteous God who demands righteousness in his people And when men cherish the conviction that the divine Power is righteous, the efficacy of sacrifice is made to depend on moral conditions.

Through the interpenetration of ethics with religion the sphere of the sacred is enlarged, and the moral life becomes an aspect of the religious vocation. Moral laws rank as divine commands, and ethical duty as a religious obligation. On the other hand, when the notion of divine personality is weak or lacking, ethics inevi-

tably assume a worldly or a negative character. Chinese religious ethics, for instance, founds on the idea of Tao or world-order, and man's duty is to reflect this order in his life. The ethical ideal is one of conformity, propriety and measure. A like utilitarianism is present in the Roman *pietas,* the knowledge of the *jus divinum* which enables a man to keep on profitable terms with the divine powers. The negative conception of ethics is strongly marked in Buddhism, which, in its original form, had no deity. The ideal of the Arahat is merely an ascetic discipline by which the dominion of desire and sense may be extinguished and Nirvana attained. In strong contrast is Christian ethics which rests on an ethical monotheism. Here the ideal is positive, the development of man's ethical life as a member of the Kingdom of God.

(2) Eschatology.

The problem of eschatology is the ultimate destiny of man and the world. It is a problem which lies in the background of the religious consciousness, though eschatological motives may powerfully affect the working of religion. Thus eschatology looms large in the old Egyptian, the Christian and the Islamic religions, but it plays a feeble part in the Babylonian, the old Hebrew and the early Greek religions. There is no side of religion where the survival of old ideas is more apparent, or where the presence of inconsistent elements is more conspicuous. This is intelligible; for eschatological ideas do not lend themselves to verification in religious experience, and they offer an ample field for religious imagination.

Primitive eschatological ideas gather round the fate of the dead, and are unleavened by ethical elements. Two factors promote the growth of eschatology in higher religions, a quickened moral consciousness and the sense of the value of the individual. If ethical ideas, however, be cast in a utilitarian mould, the eschatological interest may be slender; and even though they are of a higher order, as in Hebrew Prophetic religion, the merging of the individual in the people as the religious unit has the same result. Post-Exilic Judaism gained a new sense of the value of the individual, and felt the need of retribution, and this led to decided eschatological developments. In Buddhism, where ethics are negative and personality an obstruction rather than a value, eschatological doctrine is nebulous in the extreme.

Of the ethical ideas which promote eschatology the most prominent is that of justice, for it directly suggests the notion of future rewards and punishments. Justice, it is felt, is only imperfectly done on earth. The Osiris-Religion of Egypt figured the soul of the dead man ushered into the judgment-hall of Osiris, where his deeds were weighed in a balance. Those who pass the test go to serve Osiris in the fields of Earu. In the Avesta, Shraoshi, the guide of souls, is said to lead the just over the heavenly bridge to the gate of paradise. Orphism taught that the initiated were rewarded by a happy life in the Elysian Fields, while the wicked were cast into Tartarus. In the Persian, Christian, and Islamic religions, along with the judgment of the individual there is conjoined the idea of a world-judgment and the final separation of the good from the wicked.

The fuller development of eschatological doctrines belongs to the ethical and redemptive religions. But no religion has done this consistently, and eschatology remains the most backward aspect of religion. Here the material and the ethical, the sensuous and the spiritual, are often incongruously blended, and old beliefs survive in an alien environment. The Islamic eschatology, for instance, is on a lower level than that of a religion of salvation. And Christian eschatology, at least in its traditional form, is only imperfectly spiritualized. The problem of a consistent eschatology is a difficult one. *(See* ESCHATOLOGY; IMMORTALITY.)

IX. CLASSIFICATION OF RELIGIONS

Various attempts have been made to classify religions, but with only partial success, and there is no generally accepted scheme. Every religion is a complex of many elements, and there is no one specific feature which adequately characterizes it. One of the earlier classifications is that of Hegel into Nature-Religions, Religions of Spiritual Individuality, and Absolute Religion. But he arbitrarily groups together very disparate materials, and in the light of modern knowledge the scheme is unworkable. Edward Caird's revision into Objective, Subjective, and Absolute or Universal Religion is less open to this objection, but it is too vague and too much dependent on a particular philosophic construction of religion. Tiele adopts a very broad classification into Nature-Religions and Ethical Religions, while Siebeck groups religions into Primitive Religions, Morality-Religions, and Redemptive Religions. The latter scheme is certainly suggestive, though the distinction between ethical religions and redemptive religions can hardly be carried out consistently. Even the broad distinction between natural and ethical religion would have to be applied rather arbitrarily.

In the classification of religions into Tribal, National, and Universal, the line of demarcation is much more distinct and can be more easily used. But it may be objected to this classification that it is based on a principle which gives no clue to the character and content of the religions. Moreover it may be said that no religion is *de facto* universal. And from an evolutionary standpoint it is a defect in a classification that it ignores the principle of valuation.

The complexity and variety of the materials render a complete and consistent classification impracticable. But it is always possible to apply different criteria in surveying the religious field. Religions may be grouped according to their conception of the Divine, according to the types of piety they foster, or according to the ideal after which they strive. But such classifications will be merely provisional: though suitable for the purpose on hand, they cannot claim to be comprehensive and final.

BIBLIOGRAPHY.—Monographs dealing with particular religions will be found under the respective headings. The literature on religion is vast, and only a few of the works likely to be useful are noted here.

(a) *Histories of Religion.*

The most compact and complete history, embodying the results of recent research, is the *Lehrbuch der Religionsgeschichte,* edited by Bertholet and Lehmann, 2 vols. 1925. G. F. Moore, *History of Religions,* 2 vols., 1914, 1920. A. Menzies, *History of Religion* (1st ed., 1895, and later editions). Toy, *Introduction to the History of Religions* (1913). The *Religionsgeschichtliche Lesebuch* (1908), ed. by Bertholet, gives a translation of extracts from the chief religious classics. A new edition is appearing. There is also the *Textbuch zur Religionsgeschichte* (1912), by E. Lehmann.

(b) *The General Development of Religion.*

E. Caird, *The Evolution of Religion* (1894). Tiele, *Elements of the Science of Religion* (2 vols., 1897 & 1899). Bousset, *Das Wesen der Religion* (1904); Galloway, *Principles of Religious Development* (1909). King, *The Development of Religion* (1910). Farnell, *Greece and Babylon* (1911), and *Attributes of God* (1925). Wundt, *Mythus und Religion* (1909). G. F. Moore, *The Birth and Growth of Religion* (1923). Some works of more restricted scope are valuable for the light they cast on religious development, *e.g.* W. R. Smith's *Religion of the Semites* (3rd ed. 1927), Nilsson's *History of Greek Religion* (1925), and Warde Fowler's *Religious Experience of the Roman People* (1911).

(c) *Psychology and Philosophy of Religion.*

For the Psychology of Religion James's *Vnneties of Religious Experience* (1902), Stratton's *Psychology of the Religious Life* (1911), Pratt's *The Religious Consciousness* (1923), will he found useful, and other works equally deserve mention.

Hegel's *Philosophie der Religion* (1840) is historically important. Among other works on the subject are those of J. Caird, Rauwenhoff, Hoffding, Siebeck, Pfleiderer, Galloway and Ladd. (G. GA.)

RELIGIOUS ARCHITECTURE. This article is concerned with the development of western religious architecture in the 20th century. After a brief introductory account, the countries that have contributed most to this development are examined. For earlier religious architecture of the western world, *see:* BYZANTINE ARCHITECTURE; ROMANESQUE ARCHITECTURE; GOTHIC ARCHITECTURE; RENAISSANCE ARCHITECTURE; BAROQUE ARCHITECTURE; MODERN ARCHITECTURE. For the religious architecture of other parts of the world, *see* appropriate headings; *e.g.,* CHINESE ARCHITECTURE; IBERO-AMERICAN ARCHITECTURE; INDIAN ARCHITECTURE; ISLAMIC ARCHITECTURE. *See* also PAGODA; TEMPLE ARCHITECTURE.

Historical Background. — When Constantine recognized Christianity by the edict of Milan in A.D. 313 a pattern of church architecture as such did not exist. The earliest Christians had worshiped in the houses of wealthier members or in the catacombs,

which in Rome were particularly extensive. A converted house in Doura-Europos (now Salihiyah) in eastern Syria is held to be the first-known Christian church, dating from 232. In both the eastern and western halves of the Roman empire. however, a certain amount of unco-ordinated church building took place.

As Christianity became established throughout the Roman empire a basic building type for sheltering a large congregation was the basilica (*q.v.*), found in Rome and Roman north Africa. This was a sizable rectangular building the interior of which was divided by two rows of columns into a large central hall with side aisles. It was easily roofed in mood. By putting the altar at one end, preferably in a niche with room for suitable circulation in front, and by locating the entrance at the opposite end, a basic church pattern was established. The basilica-inspired old St. Peter's in Rome, which Constantine built in c. 326 and which was substantially replaced by the present St. Peter's in the 16th century, was one of the first of these. The same plan was used later in the 4th century in Rome in S. Clemente. Sta. Maria Maggiore, St. John Lateran and St. Paul's Outside the Walls, to name only the finest extant examples. The long basilica nave was suited to church processionals and produced a stunning spatial impression as, well. At the sanctuary end was a slightly raised platform, or bema, with a semicircular apse, often gloriously covered with mosaics, directly behind.

In the formative days of the Christian church, however, plans other than the basilica were used. The circular church and baptistery. undoubtedly inspired by Greek and Roman temples and tombs, were common. S. Stefano Rotondo in Rome (c. 475) is the largest and best known of these. In the 6th century the Byzantines explored an even more complex geometry. SS. Sergius and Bacchus in Constantinople (523–527) is a domed octagon enclosed in a square. while its contemporary, the sublime Hagia Sophia: is square outside, domed and counterdomed within. Charlemagne's mausoleum chapel at Xix-la-Chapelle (*c.* 790–805) has 16 sides. The opulent St. Mark's in Venice, finished in 1073, has four arms of equal length. making a Greek cross. The geometry that characterized church planning until the beginning of the Romanesque had an ingenious variety.

From the fall of Rome in A.D. 475 to the Romanesque beginnings around 1000. very little building of any type was done in Europe with the exception of the Byzantine work centred around Ravenna and Venice. The golden age of church building, beginning with the Romanesque style and continuing through the Gothic until the 15th and 16th centuries, covered western Europe with some of the greatest monuments to God ever built. It is significant that almost all of these were adaptations of the long-armed Latin cross in plan. Indeed it is this Latin plan, largely as developed in the middle ages. which determined church planning, both Roman Catholic and Protestant. to modern times.

During the baroque and rococo periods of the 17th and 18th centuries, a revolt against the rigid Latin-cross plan occurred, particularly in Italy and southern Germany where a number of extremely interesting freely planned churches evolved. A more intimate atmosphere was wanted, and it is pertinent to note that many of these flowing geometric shapes were revived in modern German churches. But after the late 18th century and particularly during the age of architectural revivals from the 19th century onward. the familiar Latin plan again dominated church design.

20th-Century Developments. — Beginning in the early 20th century. when architects everywhere increasingly questioned the copybook styles that had stultified building for almost 200 years, a new freshness was evident. This was primarily the result of two factors: a reassessment of the basic relationship between clergy and congregation; and revolutionary new materials of steel and reinforced concrete, both of which were introduced in the mid-19th century.

The long nave of the Latin cross isolates much of the congregation from the priest or minister and the sanctuary. Not only is it difficult to hear the sermon throughout many attenuated churches — as the presence of amplifying systems testihes — it is also difficult to feel in touch with the altar and sanctuary, As church processionals largely disappeared, virtually altogether in Protestant churches, the liturgical necessity for a long nave likewise diminished. As a result a more compact planning, evolving toward a one-room ambiance. became evident. The customarily precise divisions of nave, transept. chancel and sanctuary gave way to a more open and intimate interior with the congregation arranged in closer contact with the clergy and altar. Enhanced by the general developments of 20th-century architecture. a general simplification and unity in church architecture of all faiths evolved.

Although the changes in liturgical relationships brought obvious changes to the appearance of modern churches. even greater changes occurred through the use of new materials, such as reinforced concrete, steel, processed (*e.g.*, laminated) wood and new forms of glass.

Concrete had been used in churches since the end of the 19th century, *e.g.*, by Anatole de Baudot in his St. Jean de Montmartre in Paris (1894), but always as a structural means within a largely stylistic framework. It was not until 1923. when Auguste and Gustave Perret built their superb Notre Dame, Le Raincy, near Paris, that reinforced concrete was fully used and expressed in a church. The design for this church, chosen for its economy. not its aesthetics, revolutionized European religious architecture. The interior has few peers.

The first steel and glass church. the Stahlkirche, was built by Otto Bartning in Cologne in 1928. Modeled to a large extent after the famous 13th-century Ste. Chapelle in Paris: this church, later destroyed, had a maximum amount of stained glass and a minimum of structure.

Industrialized or processed wood was another new material that markedly affected the structural design of 20th-century churches. New forms and uses were given to man's most venerable building material. Church architects, especially in the United States, made frequent use of prefabricated laminated wood arches which became readily available. Handsome and economical, wood has a visual and tactile warmth, plus excellent acoustic qualities; which make it well suited for religious work.

Another old material in new guise that had an interesting role in 20th-century religious architecture is a glass technique called *Betonglas* (*i.e.*, "concrete glass") or mosaic glass. It is made from faceted bits of brilliantly coloured glass, approximately an inch thick. Instead of the various sections being supported and separated by lead dividers, as in stained glass (*q.v.*), the thick glass chunks are laid and composed. like a mosaic, on the fat, with wire reinforcing rods laced between and fine concrete poured in the interstices. When the concrete has set the panel is polished; it then forms a self-supporting, weatherproof unit ready to be raised in place.

Betonglas has a depth and richness, a glowing quality, which is almost jewellike in its changing intensities. It became popular in France, where it first evolved in the late 1920s and early 1930s. and its use has spread to much of the continent and to North and South America. One of its most impressive single installations is in Wallace Harrison's First Presbyterian church (1958) in Stamford, Conn.

Through the combination of external forces that have changed all aspects of western life and through the evolution in liturgical thinking and new technical means, nerr church forms irresistibly evolved. The Perrets with Notre Dame. Le Raincy, awakened clergy and architects all over Europe with their fresh approach toward religious architecture. The movement spread throughout the continent. then the world.

France. — France. which had nurtured the Gothic style and taken it to its greatest heights, was also to a large degree instrumental in establishing the classic revival both in architecture and art. France won the cultural dominance of Europe from Italy in the 17th century and established itself in a long-term position of aesthetic authority. The extraordinary archeological discoveries of the late 18th century (particularly J. J. Winckelmann's work in Greece) and Napoleon's imperial leanings set the stage for this neoclassical idiom. The search for ancient prototypes was far more of an architectural atavism at this time than it had been during the Renaissance. Renaissance architects sought inspiration in the glories of Greece and Rome; the neoclassicists sought ancient

models, or authentic ancient elements for new buildings. The movement was epitomized in France by Napoleon's *temple de* la *Gloire,* the Madeleine (1806), by Pierre Vignon.

Interest in the neoclassical style in France, as elsewhere, waned. however. and toward the middle of the 19th century interest revived in the Gothic. E. E. Viollet-le-Duc was the continent's chief champion of the Gothic revival and his *Dictionnaire raisonné* de *l'architecture française* (1854–68). along with his many restorations, including that of Ste. Chapelle, sparked wide enthusiasm throughout Europe. In France more neo-Gothic restoration—in some cases violation—was executed than new construction. but several prominent churches were built, such as. Ste. Clotilde in Paris by F. C. Gau and T. Ballu (begun in 1846); St. Nicolas in Kantes by L. A. Piel and J. B. A Lassus (1854–59); and St. Epvre in Nancy (1864–79). by M. P. Morey.

Following the Gothic revival, architectural uncertainties for almost a century resulted in a combination of styles. The most prominent Parisian example of this period is the Sacré Coeur, begun in 1875 by Paul Abadie and continued by Pierre Daumet and L. Magne The neoclassical and neo-Gothic had a certain "authenticity," although generally cold and lifeless. but the church architecture that folloued in France and elsewhere until after World War I was almost totally undistinguished. Little of the wonderful vitality, originality and daring, which had marked Christian church building almost continually since its beginnings were apparent Little effort was made to use the revolutionary new structural means of the 19th century—cast iron, steel and reinforced concrete. When the Perrets built their Kotre Dame, Le Raincy, in 1923 it was a milestone in the rejuvenation of Christian church architecture. It was the first church to utilize and express fully one of the most important materials of modern times: reinforced concrete The roof is supported by slender concrete columns: the outside walls are pierced panels of concrete. each panel being laced with a series of geometric openings in which are set panes of coloured glass. The interior effect of this small church (it measures only 184 by 66 ft) is one of reverent simplicity and timeless grace It has few equals.

The effect of Kotre Dame, Le Raincy permeated all Europe. The Perrets themselves built Ste. Thérèse, a somewhat similar church at Montmargny (1925), and projected several others. Karl Moser in Snitzerland was inspired to design his excellent St Antonius in Basel (1926–27), and a whole school of new church architecture arose in Germany under Dominikus Bohm, Otto Bartning and Rudolf Schn arz.

After this church renascence, however, a curious and unfortunate mediocrity characterized most French architecture, religious and secular (excluding, of course, the work of the Swiss-born Le Corbusier). After the Perrets' work at Le Raincy and Montmargny, few churches of real architectural merit were built in France until a second church-building movement was initiated after World War II. The revolution that the Perrets began in 1923 was rightly concerned with a fresh sweep in architecture; the new postwar direction was primarily toward employing the finest contemporary artists in the church. As in past centuries of great church building. architect and artist worked hand in hand.

Father M. A. Couturier, O.P., was largely responsible for initiating this movement. and under his aegis a number of the greatest artists in France were invited to work on the church of Notre Dame de Toute Grâce at Assy, near Chamonix (Maurice Novarina, architect). This church was consecrated in 1950. Fernand Léger composed an enormous mosaic for the entrance, Jean Lurçat created a superb tapestry for the chancel. Georges Rouault and Henri Matisse designed the windows, while Jacques Lipchitz. Pierre Bonnard. Marc Chagall. Georges Braque and Henri Laurens were among the other contributors. It is pertinent that many were not religious or even Christian.

The architectural form of the church at Assy, which is somewhat neo-Romanesque, is rather heavy and in no way equal to its art, and there is a lack of co-ordination in the art itself. This church, however. has had an extremely important influence throughout France and Europe, Architecture unaided by art can rarely reach the spiritual heights sought in a church because of its concern with the technrcal requirements of shelter.

After Assy a number of new churches, in which architect and artist actively co-operated, were built in France. One of these is Notre Dame des Pauvres at Audincourt (Doubs). Designed by Novarina. the church proper (dedicated in 1951) is simple and undistinguished. However the continuous band of 17 stained glass windows by Léger and the entrance mosaic and baptistery glass by Jean Bazaine lend importance to this church, in a modest workers' village. The Léger windows are brilliant examples of contemporary thematic glass (they trace the Passions of Christ) while the abstract glass in the baptistery, with its warm, glowing colours, is a superb statement of nonobjective art.

A small semi-private chapel of charm is that of Notre Dame du Rosaire. at Vence near Nice (1948–51), by Matisse. Although the church is of secondary importance architecturally. Matisse decorated it with superb tiles and glass and continued his lovely colours and motifs in the design of the vestments themselves. Thus a complete integration of the visual arts, some fixed, some in motion, was achieved. The chapel at Vence is near the interesting old church at Villefranche-sur-Mer which Jean Cocteau redecorated.

It is generally held that the greatest masterpiece of contemporary French, indeed world, religious architecture is Notre Dame du Haut at Ronchamp (Doubs) (1955), by Le Corbusier. This startlingly original building is thought by many to be the most important church of the past several centuries, so profound is its impact and so creative its force. Although its architecture is almost completely nonderivative, recalling little of the past, the atmosphere within is intensely and very personally religious. It is an interesting contrast to the great Gothic cathedrals which, though incomparable monuments to God, tend to humble the worshiper.

The church exterior is dominated by the enormous upturned eave of the roof which r -ts far over the approach or south side and on the east sic ver the outdoor pulpit and altar. The massive south wal s 12 ft. thick at the bottom and 5 at the top, command! oach with a series of openings of various rectangular sha rsed irregularly across the front. Although these windov appear! both from without and from within, to have be d haphazardly, their total effect is one of careful orchestra

The interior of the ch s likewise dominated by the roof. which according to the ar ct was inspired by the shape of the shell of a crab; it swoops c n toward the middle like the underside of a great tent. The roof is not directly attached to the supporting walls, but rests lightly on blocks atop them so that the feeling of space, flowing over and out, is intensified. Although the physical dimensions of Ronchamp are modest, a mere 84 by 40 ft., with seats for only 50 people, it gives an impression of a very great space. This effect is intensified by the subtle relation of three chapels subsidiary to the nave and by the deeply splayed windows: only a few of which are visible from any one spot. It is necessary to move about the church to appreciate its features. since they cannot be grasped from a fixed position.

Other important postwar churches in France are: a Dominican friary at d'Eveux (Lyons) (1960), by Le Corbusier; St. Rémy, Baccarat (1957), by Nicolas Kazis, with very interesting sculpture and glass; St. Julien, Caen, by Henry Bernard; Kotre Dame. Royan (1958), by Guillaume Gillet; a startling "tower" church (St. Joseph): by Auguste Perret and R. Audigier at Le Havre (1959); St. Agnits Fontaines-les-Grits (Aube) (1956); by Michel Marot; Kotre Dame de Grâce, Morsang-sur-Orge, by Roger Faraut: Ste. Thérèse. Roubaix (1957), by Hermann Baur; and the extraordinary underground basilica for 20.000 at Lourdes (1958) by Pierre Vago (Eugène Freyssinet, engineer).

Germany. — In tracing the background of contemporary German religious architecture the 19th century requires brief mention. Karl Friedrich Schinkel's St, Nicholas in Potsdam. completed in 1849. is the finest neoclassic example, although obviously inspired by J. G. Soufflot's Panthéon in Paris. St. Nicholas in Hamburg (1845–63), by the Englishman Sir George Gilbert Scott. is outstanding among the neo-Gothic. The nave was coinpletely

destroyed in World War II. The Gothic revival also added a top to the ancient tower of Ulm cathedral in 1877–90, making it the highest stone tower in the world (528 ft.).

Church architecture at the opening of the 20th century in Germany was stirring uneasily under the changing styles then prevalent. In the first years of the century several German architects, notably Theodor Fischer, made a tentative effort toward less derivative religious building. primarily by simplifying old clichés rather than attempting a genuinely fresh approach.

The first positive move was by Otto Bartning whose book *Vom neuen Kirchenbau* ("Toward a New Church Architecture") in 1919 was followed three years later by a model of his projected Star church. Although never built, it was a highly original and stimulating design which, together with the Perrets' church at Le Raincy, did much to awaken Germany to new church-building possibilities.

By 1926 several exciting new German churches had been constructed. These were Martin Weber's St. Boniface in Frankfurt am Main, and Dominikus Bohm's War Memorial church in Neu-Ulm and his bold Catholic church at Bischofsheim. Bohm, in the latter church, took the reinforced concrete that the Perrets had confined to rigid boxlike frames and made it dramatically plastic. He built several other distinguished churches, among them St. Joseph at Hindenburg-Oberschlesien (1929) and St. Engelbert in Cologne-Riehl (1931).

Bartning's Protestant Steel church for the Cologne Press exhibition of 1928, the great pioneer in steel, was followed with two larger examples: the Round church at Essen (1930), and the Gustav Adolf church in Berlin-Charlottenburg (1934), later destroyed.

Rudolf Schwarz, who was to become Germany's most impressive church architect, designed a series of starkly simple but notable Catholic churches. The first was his Corpus Christi in Aachen, completed in 1930. Unquestionably one of the greatest religious architects of the 20th century, Schwarz in this, his first mature work (he was 33 at the time), showed promise of the Spartan directness and religious intensity that marked his subsequent designs.

After Hitler came to power in 1933 progressive thinking in architecture was muzzled. Schwarz, Böhm and Bartning were largely inactive for 15 years; during which each thought deeply and maturely on the manifold problems of church building in the mid-20th century. Schwarz, probably the most profoundly religious of the three, published his *Vom* Bau der *Kirche* (1938) in which his architectural-religious concepts are set forth and illustrated by beautiful geometric diagrams.

When conditions finally permitted, all three set to work so actively and so successfully that Germany in a relatively few years became the leader in European religious architecture. Bartning designed a series of 48 emergency churches (*Notkirchen*), made from rubble and standardized salvaged material, while Bohm and Schwarz produced a number of new churches together with many reconstructions. Bohm's son, Gottfried, boldly carries on the church work launched by his father. Postwar German churches are characterized by a daring, a willingness to experiment and a directness which is very powerful.

Among the most impressive examples are: Maria Konigin, Cologne-Marienburg (1954), by D. Bohm; St. Konrad, Neuss (1955), and St. Albert, Saarbrucken (1956), by G. Bohm; St. Mauritius, Saarbrucken (1956), by Albert Dietz; St. Matthews, Pforzheim (1953), by Egon Eiermann; Christ church, Leverkusen-Burig (1958), by Hentrich and Petschnigg; St. Martin, Hanover (1957), and Christ church, Bochum (1959), by Dieter Oesterlen; St. Joseph, Hasloch-am-Main (1958), by Hans Schadel; St. Rochus, Diisseldorf (1955), by Paul Schneider-Esleben; the following by Rudolf Schwarz—St. Joseph, Cologne-Braunsfeld (1954), with Joseph Bernard, St. Michael, Frankfurt am Main (1954). St. Anna, Düren (1956), Holy Cross, Bottrop (1957), and Maria Konigin, Saarbrucken (1959); Trinity church, Mannheim (1959), by Helmut Striffler.

Switzerland. — The contemporary church movement in Switzerland is. after the German and French, the most interesting in Europe. Starting with Karl Moser's superb St. Antonius in Basel (1927) and continuing through the 1930s and '40s when Germany and France built little of merit the Swiss built an impressive number of fine new churches. Having, like Germany, slightly more Protestants than Catholics, Switzerland profited from the stimulating reaction the religious architecture of each group had upon that of the other.

Following the Catholic initiative in Moser's St Antonius, the Protestants, after a competition in 1931, launched their contemporary church building with St. Johannes in Basel (1936). by E. F. Burckhardt and Karl Egender. There followed a number of sensitively designed, handsomely detailed and constructed churches, both Protestant and Catholic.

The outstanding church in the country is the Reformed church at Zurich-Altstetten (1941), by Werner Moser, the son of Karl. Other churches of particular interest are All Saints. Basel (1953), and Bruderklausen, Basel-Birsfelden (1959), by Hermann Baur; Bruderklausen, St. Gall-Winkeln (1959), by Ernest Brantschen; the Chbtelaine church. Geneva (1958), by André Gaillard; First Church, Christ Scientist. Zurich (1938), by Adolf Kellermuller and Hans Hofmann; Liebenfels Cemetery chapel, Baden (1957), by Edi and Ruth Lanners and Res Wahlen; St. Francis, Basel-Riehen (1950), by Fritz Metzger; Village church, Thayngen (1952). and Blessed Virgin (Muttergottes), Solothurn (1954), by Josef Schutz.

Great Britain. — England, combining great scientific and technical progress with conservatism in the arts, produced little religious architecture of outstanding merit in the first half of the 20th century. The intellectual climate was favourable and several promising beginnings were made, but few churches of international merit mere built.

During the 19th and early 20th centuries architecture in England followed the cultural pattern of France. Neoclassicism was strong in England until the mid-19th century, but primarily influenced banks, clubs and public buildings, not church architecture. Even in these it was less purified and more humanized than abroad, as English stylistic adaptations of foreign models have generally been. The Gothic revival enjoyed a more active popularity in England than in any other European country. Because of its almost continuous use in religious work, notably interrupted by Sir Christopher Wren who considered Gothic barbaric, the English Gothic revival has been referred to as the "Gothic survival." Neoclassicists and Gothicists in England fought so heatedly that their controversy was dubbed the "battle of the styles." A compromise of sorts was effected whereby most public buildings were designed in a watered-down classical or Renaissance tradition, while most churches were Gothic.

Few churches built in England in the 19th and early 20th centuries were not inspired by the Gothic. The tuo most imposing examples are John Bentley's large Roman Catholic cathedral in Westminster, London (1895–1903), a curious pseudo-Byzantine edifice. and Sir Giles Gilbert Scott's enormous Liverpool cathedral, begun in 1903.

The contemporary church-building movement of the 1920s which took such an exciting hold of the continent had little effect in the British Isles. A number of semitraditional churches were built, but none with either the daring or conviction typical of the religious work in France and Germany.

After World War II English church architecture received a decided stimulus from Basil Spence's winning design for the rebuilding of Coventry cathedral. Several other progressive churches should be mentioned, primarily C. C. Handisyde and D. R. Stark's Trinity church at Poplar, London, done in conjunction with the 1951 Festival of Britain; St. Paul's, Bow Common. London (1960), by Robert Maguire; and Edward Mills' fine Methodist church, Mitcham, Surrey (1959).

Scandinavia. — The development of architecture in Scandinavia before the 20th century followed at a discreet distance the fashions of the continent. Few buildings of international distinction were to be found. After Gunnar Asplund's Stockholm exposition of 1930, however. Sweden, Finland, Denmark and Norway contributed greatly to the richness and vocabulary of contemporary architectural thought. In some respects. such as land usage and housing, Scandinavia, and Sweden in particular, led the

world.

The religious architecture after 1930 was also significant. Erik Bryggman's cemetery chapel in Åbo, Fin. (1941), is one of the loveliest churches in Europe with its sensitive proportions and its wall of glass opening onto the parklike setting. Other notable Finnish churches are: Technical University chapel, Otaniemi, (Helsinki) (1957), by Kaija and Heikki Siren; Alppila church, Helsinki (1957), by Keijo Ström and Olavi Tuomisto; Cemetery chapel, Jarvenpaa (1958), by Tarja and Esko Toiviainen; and the famous Vuoksenniska church, Imatra (1958), by Alvar Aalto.

In Sweden, although relatively few distinguished urban churches were built in the 20th century, Ivar Tengbom's Hogalid church in Stockholm (1923) being an exception, the Swedes designed several of the world's most beautiful crematoriums. The three most impressive are Asplund's Woods crematorium in Stockholm (1940), one of the great monuments of modern architecture, S. Lewerentz's crematorium in Malmo (1945) and Borje Blomé's St. Michael's chapel in Mora (1954). Some fine churches are: Cyrillus Johansson's ingratiating wood church in Nikkaluokta (1942) and Hakon Ahlberg's semitraditional church at Malmberget (1945), both along the Arctic circle in Lapland; the cemetery chapel in Sater (1954), by Sven Soderholm; Vasterort church at Vallingby, Stockholm (1956), by Carl Nyrén; and St. Botvids at Oxelosund (1957), by Rolf Bergh.

Architecture in Norway has always lagged behind that in the rest of Scandinavia. The most brilliant facet of Norway's contribution to architecture lies in its churches of the middle ages. From the 11th through the 13th centuries there were built, largely in the more remote regions of Norway, 500 to 600 stave churches. Intensely personal and highly carved and painted, these almost pagan wooden churches are unique in ecclesiastical architectural history. Only 22 were extant in modern times. The village church at Gravberget (1955), by Magnus Poulsson is the finest recent example.

Of the 20th-century churches in Denmark, P. V. J. Klint's Grundtvig church in Copenhagen (1913–40) is the most nationalistic in flavour (it recalls the traditionally Danish stepped gables) its façade suggesting a gigantic series of organ pipes in brick. Three other Copenhagen churches should be mentioned: Frits Schlegel's crematorium chapel in Mariebjerb (1937), Erik Moeller's pleasant Church of the Advent and St. Knud Lavard (1957), by Carl R. Frederiksen.

Italy.— The Italians, having the most magnificent inheritance of fine churches in the world, were little disposed to construct more until the unparalled devastation of World War II. Although several churches were built in contemporary style in Italy in the 1930s, none compared to the advanced work done by that time in Germany, Switzerland and France. There are fewer fine new churches in Italy than in the northern countries, but both quantity and quality have improved steadily and the climate for progressive religious architecture is excellent.

Among the impressive postwar churches are: S. Antonio Abate, Recoaro Terme (Vicenza) (1950), by Giuseppe Vaccaro; churches at Matera, and Francavilla al Mare, Pescara (1953, 59), by Ludovico Quaroni; several new churches near Ferrara (1952, 1954), by Pierluigi Giordani; Madonna of the Poor, Milan (1953), by Luigi Figini and Gino Pollini; San Luca, Rome (1956), by V., F. and L. Passarelli, and the stimulating Matri Misericordiae at Baranzate, Milan (1958), by Angelo Mangiarotti and Bruno Morasutti.

Elsewhere in Europe.—Of the remaining countries of Europe few contributed significantly to religious architecture in the 20th century, although some good work was done in most of them. After World War I Czechoslovakia produced several excellent churches, notably St. Wenceslaus in Prague (1930), by Josef Gočár, but after 1939 little work of merit was done.

The Dutch Reformed Church in the Netherlands after World War II constructed a series of good churches. Among the most successful are: Cross church, Amstelveen (1951), by Marius Duintjer; Cross church, Geleen (1956), by B. van Kasteel; church of the Good Shepherd, Oosterbeek (1952), by F. A. Eschauzier; the Resurrection church, Amsterdam, by M. Duintjer; and the Reformed church, Aerdenhout (1958), by Karel L. Sijmons.

The most fantastic church of the 20th century is the church of the Holy Family in Barcelona, Spain (1852–1926). by Antonio Gaudi. Although begun late in the 19th century the church was never completed. Its lofty towers and facade are original and imposing; they recall a child's seaside castle of wet sand drippings. Eduardo Torroja, the brilliant Spanish architect and engineer, built several unusual churches in the Pyrenees, the most striking of which is that at Pont de Suert (1952). The entire nave of this church is built of thin (7-in.) superimposed and staggered cuplike shells of concrete, whose bulbous forms are fully revealed both inside and out. The church of the Holy Rosary, Vallodolid (1954), by Miguel Fisac is also of interest.

Ibero-America.— In spite of the great growth of all Latin-American countries in the 20th century only a few significant churches were built. The best of these are found in two countries, Brazil and Mexico. These two countries also have the richest architectural heritage from their colonial eras. One of the most brilliant churches in the western hemisphere is Oscar Niemeyer's San Francisco in Belo Horizonte, Braz. (1943).

The development of contemporary architecture in Mexico was vigorous. and several churches there had influence beyond Mexico itself. One of these is Enrique de la Mora's Church of La Purisima in Monterrey (1947), constructed of intersecting paraboloids of concrete. Although details and lighting are clumsy, the structure is good. Much more successful is Felix Candela's church of the Virgin of the Miraculous Medal in Mexico City (1954). Candela, one of the world's great experts in thin-shell warped concrete surfaces, or hyperbolic paraboloids, helped pioneer highly promising developments in reinforced concrete. Candela tended to free reinforced concrete from rigid boxlike shapes, rectangular beams and flat slabs like wood and steel, and used it instead in thin very strong curved planes. like eggshells and folded pieces of paper. The church of the Virgin is so refined structurally that the roof is only $1\frac{1}{2}$ in. thick. The aesthetic potential of concrete is enormous and Candela made bold use of it in this church, particularly on the interior. Other churches by Candela's staff, using this material, are La Capilla de Nuestra Señora de la Soledad, outside Mexico City (1957), and San Antonio de las Huertas, Mexico City (Enrique de la Mora. architect).

United States.—The United States has an architectural heritage of some of the loveliest and most appealing small churches ever built. Outstanding among these are the 17th- and 18th-century village churches and meeting houses, primarily Congregational and Unitarian, scattered throughout much of New England and eastern New York state. These simple white wood structures, with their tall spires, have an inherent rightness. a sense of belonging architecturally, which make them one of the country's finest cultural contributions.

The colonists in the south brought to Virginia an established liturgy and church-building program. The program was of necessity modified somewhat by local conditions, but the 17th- and 18th-century churches of southern colonial and Georgian inspiration reflected the old world far more than the churches and meeting houses of New England. Equally reminiscent of Europe were the buildings that the Spaniards built from Florida to California. Their churches, missions and public buildings stem in large part from Iberian models.

As the American Colonies coalesced under English dominance, religious building increasingly reflected the fashions and developments of the British Isles. Sir Christopher Wren and James Gibbs inspired churches from Boston (Christ church, 1723) to New York city (St. Paul's chapel, 1764–66) to Charleston (St, Michael's, 1752–61).

Following the Revolution a self-consciously nationalistic federal architecture arose, strongly abetted by Jefferson's enthusiasm. It evolved directly from the classical revival then sweeping Europe, particularly France, the new nation's important friend. The general classical revival was followed by the specific Greek revival; at mid-19th century came the Gothic revival and after this a potpourri. The cycle of styles was the same as in Europe.

Richard Upjohn's Trinity church (1839–46), James Renwick's Grace church (1845–6) and St. Patrick's cathedral (1858–79), all

in New York city, are among the country's outstanding Gothic revival churches. External form, however, not structural purity, was predominant. St. Patrick's vaults are not self-supporting; its flying buttresses receive no load.

At the end of the 19th century the two largest churches in the U.S. were projected: St. John the Divine, New York (begun in 1892), and the cathedral of SS. Peter and Paul, Washington, D.C. (begun in 1907). Both of these are genuinely in the medieval Gothic, stone-by-stone tradition (although St. John was originally planned as Romanesque-Byzantine). Churches of such enormous size take years to build, and both of these Episcopal churches were put into use before completion.

U.S. architecture in most of the first half of the 20th century lagged far behind that of Europe, except in skyscraper construction. Notable buildings were built, but they were few in number and not widely accepted. After World War II however, the U.S. produced a great many excellent structures in all categories and public acceptance of new work was widespread.

The contemporary tradition in U.S. church building has distinguished roots in Unity temple, Oak Park, Ill., built in 1907 by Frank Lloyd Wright, and in the First Church of Christ Scientist, Berkeley. Calif. (1910), by Bernard Maybeck. Although neither constituted the architectural revolution which the Perrets' church at Le Raincy occasioned, they are unquestionably landmarks in the evolution of contemporary church architecture. Wright maintained his high standard in his chapel at Florida Southern college, Lakeland (1941), the First Unitarian church in Madison. Wis. (1951), and the striking Beth Sholem synagogue in Elkins Park, Pa. (1958). His son. Lloyd Wright, built one of the country's memorable churches in the beautifully situated Wayfarer's chapel at Palos Verdes, Calif. (1951). The design is composed basically of frames of redwood and sheets of clear glass so that the sea and surroundings seem to become an intimate part of the service itself.

Pietro Belluschi, who went from Italy to the U.S. in 1923. designed a number of churches which are models of elegant simplicity, sympathetic scale and carefully considered natural lighting. His Zion Lutheran, Portland, Ore. (1951), First Presbyterian, Cottage Grove, Ore. (1951), First Lutheran church, Boston (1957), Church of the Redeemer, Baltimore (1958), with Rogers. Taliaferro and Lamb, and his Portsmouth Priory, Portsmouth, R.I. (1959), uith Anderson, Beckwith and Haible, greatly encouraged and enriched the U.S. church-building scene.

Eliel Saarinen and his son, Eero, both born in Finland, were among the pioneers in contemporary U.S. church design. Their Tabernacle Church of Christ in Columbus. Ind. (1942), was one of the important earlier ones built in the U.S. They collaborated even more successfully in Christ Lutheran church in Minneapolis, Minn. (1950), which was Eliel Saarinen's last work. The younger Saarinen then designed the nonsectarian cylindrical Kresge chapel at Massachusetts Institute of Technology in Cambridge (1956), a brilliant example of religious architecture, and several college chapels, notably at Stephens college in Columbia, Mo. (1956), and the chapel at Concordia college, Fort Wayne, Ind. (1958). Another university chapel of note is at the Illinois Institute of Technology, Chicago (1952), by the German-born Ludwig Mies van der Rohe.

Two striking religious buildings of large size are the Air Force academy chapel at Colorado Springs, Colo. (1961), and the First Presbyterian church in Stamford, Conn. (1958). The Air Force academy chapel is of aluminum skinned tetrahedral frames. graphically suggesting the daring spirit of the air age. Skidmore, Owings and Merrill (called S.O.M.) were the architects, and Gordon Bunshaft and Walter Netsch the designers. Wallace Harrison's Stamford church is one of the most powerful modern churches in the world. Its exterior is of canted, angular planes, resembling some great fish, with a soaring colour-drenched nave within. A dazzling flood of light fills the interior from windows that rise from the floor to the ceiling ridge. These windows are filled with 20,000 pieces of inch-thick *Betonglas*, designed by Harrison and executed by Gabriel Loire of Chartres, France. The Crucifixion is depicted in abstract style on the north side and the Resurrection on the warmer. south side.

Harrison and his partner, Max Abramovitz, also designed an Interfaith centre for Brandeis university, Waltham, Mass. (1955). Instead of a single convertible building for the three faiths represented. there are three separate, individual chapels. Jewish, Protestant and Catholic, sensitively grouped around a common pool and landscaped setting.

Synagogue architecture in the U.S. is of a very high level. Eric Mendelsohn, who lived in the U.S. after 1942, designed several fine temples, among them Congregation B'nai Amoona, St. Louis (1952), Congregation Emanuel, Grand Rapids, Mich. (1951), Mount Zion temple, St. Paul, Minn., and the Cleveland Park synagogue, Cleveland, O. (1954).

Percival Goodman also designed splendid synagogues: Congregation Beth El, Springfield, Mass. (1953), Temple Beth El. Providence, R.I. (1953), Fairmount temple, Beechwood village, Ohio (1957) and Temple Mishkan Tefila, Newton, Mass. (1958). They are further distinguished by their excellent use of art by some of the finest artists in the country. The co-operation of architect and artist from the beginning achieved superior results.

Two of the handsomest synagogues in the U.S. are the Temple Emanu-el, Dallas. Tex. (1957), by Howard R. Meyer and Max Sandfield. and Philip C. Johnson's elegantly beautiful Kneses Tifereth Israel synagogue in Port Chester, N.Y. (1956). This clean, geometrically precise temple is a sharp contrast to the freer, more rugged design of Wallace Harrison's First Presbyterian church in Stamford, less than ten miles away. Though poles apart architecturally, they are two of the finest religious buildings in the country.

In contrast to its magnificent accomplishments in Europe, the Catholic Church in the U.S., as in Latin America, espoused relatively traditional church forms for new building. In the first half of the 20th century there were few Catholic churches of distinctive contemporary design. Among the most notable Catholic buildings are Robert Anshen and W. S. Allen's Chapel of the Holy Cross, Sedona, Ariz. (1956), and Marcel Breuer's Benedictine Abbey of St. John in Collegeville, Minn. (1961).

Two Protestant churches are of interest in that they illustrate the problems of the automobile age: St. Clement's Episcopal church. Alexandria, Va. (1948), by J. H. Saunders and the former rector, Darby Betts; and the Venice-Nokomis Presbyterian church, Venice, Fla. (1953), by Victor A. Lundy. The first, being flanked by roads with noisy traffic is of nindowless, soundproofed design, artificially lit and air conditioned. The Florida chapel is just the reverse: it is an open-air, drive-in church. *See* also Index references under "Religious Architecture" in the Index volume.

REMAGEN, a town in Rhineland-Palatinate. Germany. on the left bank of the Rhine, 12 mi. above Bonn, by the railway from Cologne to Coblenz. and at the junction of the railway to Adenau. Pop (1959 est.) 7.132. Its Roman name was Rigomagus and many Roman remains have been found here. It passed to Prussia from the duchy of Jülich. The (Roman Catholic) parish church is remarkable for a gate dating from the 12th century. Below the town. on a height overlooking the Rhine, stands the Apollinaris church, built 1839–53 on the site of a chapel formerly dedicated

to St. Martin.

The Ludendorff railway bridge across the Rhine, built at Remagen during World War I, played a dramatic part in World War II. On March 7. 1945, elements of the U.S. 1st army captured it intact—the only Rhine bridge to be so taken—and established the first enemy bridgehead on the eastern bank since the time of Napoleon. Ten days later, on March 17. the 1,200-ft. span. weakened by earlier German demolition attempts and a heavy volume of Allied vehicular traffic. collapsed. During its ten days of use, however, five U.S. divisions and thousands of tons of supplies had crossed over it.

REMAINDER, REVERSION. In the view of English law a remainder or reversion is classed either as an incorporeal hereditament or, with greater correctness, as an estate in expectancy. That is to say, it is a present interest subject to an existing estate in possession called the particular estate, which must determine before the estate in expectancy can become an estate in possession. A remainder or reversion is in strictness confined to real estate, whether legal or equitable, though a similar interest may exist in personalty. The particular estate and the remainder or reversion together make up the whole estate over which the grantor has power of disposition. Accordingly a remainder or reversion limited on an estate in fee simple is void. The difference between a remainder and a reversion, stated as simply as possible. is that the latter is that undisposed-of part of the estate which after the determination of the particular estate mill fall into the possession of the original grantor or his representative, while a remainder is that part of the estate which under the same circumstances will fall into the possession of a person other than the original grantor or his representative. The subject is too technical for further treatment, for which reference must be made to legal textbooks.

The state laws of the U.S. affecting remainders will be found in Washburn. Real Property, ii. bk. 2. As a general rule contingent remainders have been rendered of little practical importance by enactments that they shall take effect as executory devises or shall not determine on determination of the particular estate.

REMAINDER THEOREM, a theorem of particular value in the study of polynomials and equations. If we divide

$$2x^2 + 3x + 6 \text{ by } x - 2,$$

for example, the quotient is $2x + 7$ and the remainder is 20. The remainder. however, can be found by substituting 2 for x in the polynomial. This gives:

$$2.2^2 + 3.2 + 6 = 8 + 6 + 6 = 20.$$

More generally, to find the remainder arising from dividing $f(x)$ by $x - r$, substitute r for x in $f(x)$. This evidently amounts simply to evaluating $f(x)$ for some special value (r) of x. This is conveniently done by following the plan shown at the right. This work reveals not only the remainder (20) but also the coefficients $(2 + 7)$ of the quotient $(2x + 7)$. When used for this latter purpose it is known as synthetic division. This method of dividing is very helpful in finding the roots of numerical higher equations.

$2+3+6$		2
	4	14
$2+7;$		20

REMAND, a term of English law meaning the return of a prisoner by order of a court to the custody from which he came to the court. Where trials or indictments are not concluded at a single sitting the court of trial has poner to remand the accused into proper custody during any necessary adjournment. If the remand is for more than three days the order must be in writing (Indictable Offences act 1838). Similar poners of remand or committal to prison during adjournments are given to justices in the exercise of their summary criminal jurisdiction (Summary Jurisdiction acts 1848 and 1879). In the case of charges against children or young persons the remand must be to a "place of detention" unless released on bail or certified unfit for such a place of detention (Children act 1908). For this purpose homes have been established under the act.

In the U.S. the term is used in two senses The first is where a prisoner is returned to custody to await the resumption of the preliminary hearing or the commencement of the trial. The second is where a cause of action is returned to the original court after the same had been transferred or appealed.

REMARQUE, ERICH MARIA (1898–), German novelist, was born on June 22, 1898, in Osnabriick. He achieved world fame as author of *Im Westen* nichts Neues (1929; Eng. trans. by A W. Wheen, All *Quiet* on the *Western* Front, 1929), a vehement antiwar novel which, because of its sensational realism, caused a considerable controversy in Germany. Its sequel Der *Weg zurück* (1931: Eng trans. by A. W. Wheen, The Road Back, 1931) describes the collapse of Germany in 1918 and the subsequent political disorders. Remarque fought in World War I and was later a teacher and journalist. He left Germany in 1932 for Switzerland, but in 1939 went to New York where he became a U S citizen. After World War II he returned to Switzerland. Of his many other novels only Arc de *Triomphe* (1946; Eng trans. by W. Sorell and Denver Lindley, 1946) was a world success.

(H. S. R.)

REMBRANDT (REMBRANDT HARMENSZ [or HARMENSZOON] VAN RIJN [or RYN]) (1606–1669), the outstanding genius of the Dutch school of painting in the 17th century, was born in Leiden on July 15. 1606. His father, Harmen Gerritsz van Rijn, was a miller, while his mother, Neeltgen (Cornelia), was the daughter of a baker, Willemsz van Zuytbrouck, and they appear to have been simple, industrious and deeply pious folk, typical of the Dutch lower-middle class of this period. They originally intended him for a scholastic career and at about the age of seven he entered the Latin school in Leiden. In 1620, when not quite 14, he was enrolled in the university but he did not stay there long. In the following year his parents recognized that his talents as well as his inclinations lay in the direction of painting and he was apprenticed for three years to Jacob Isaacsz van Swanenburgh, a minor painter of architectural subjects. Rembrandt can have learned little from Swanenburgh beyond the basic elements of technique, for there is not the least trace of his first master's style in any of his work.

In 1624, having completed his apprenticeship, he went to Amsterdam for six months as a pupil of the historical painter Pieter Lastman, a far more talented artist than Swanenburgh. Lastman was a capable painter, but his somewhat theatrical style lacked any kind of profundity and he cannot have played an important part in developing that depth of human sympathy which is perhaps Rembrandt's most personal and valuable quality. However, at the more superficial level of subject matter and imagery—the visual vocabulary of Rembrandt's art—the influence of Lastman was powerful and enduring. Lastman was one of a small group of Dutch artists who had worked in Italy during the first decade of the century and were associated with the German master Adam Elsheimer (*q.v.*). The work of this group was strongly influenced by the 16th-century masters of Venice, notably Tintoretto, and in this they are quite distinct from the Dutch followers of Caravaggio, such as Gerard van Honthorst, Hendrick Terbrugghen and the other Utrecht painters, who were the principal channel of Italian influences in Holland at the time when Rembrandt was reaching maturity. Tintoretto and Caravaggio were both masters of chiaroscuro. using violent contrasts of light and shade for dramatic effect, but their methods were almost diametrically opposed, and the fact that Rembrandt's early contacts were not with the Utrecht school but with Elsheimer's followers in Amsterdam may well have been an important factor in the formation of his onn chiaroscuro style. The contrast of searching light and deep shadow is one of the central elements of Rembrandt's art, and his employment of it approaches more closely to the spirit of Tintoretto—emotional, mysterious, nonnaturalistic and even arbitrary in treatment of the play of light and its source—than to the almost brutal naturalism and the quasi-scientific handling of light that characterize Caravaggio and his followers The link with Tintoretto via Elsheimer can be traced more clearly through the works of the Pynas brothers (*e.g*, Jan Pynas' "Raising of Lazarus," in Philadelphia) than through Lastman himself, for whom the major Venetian influence

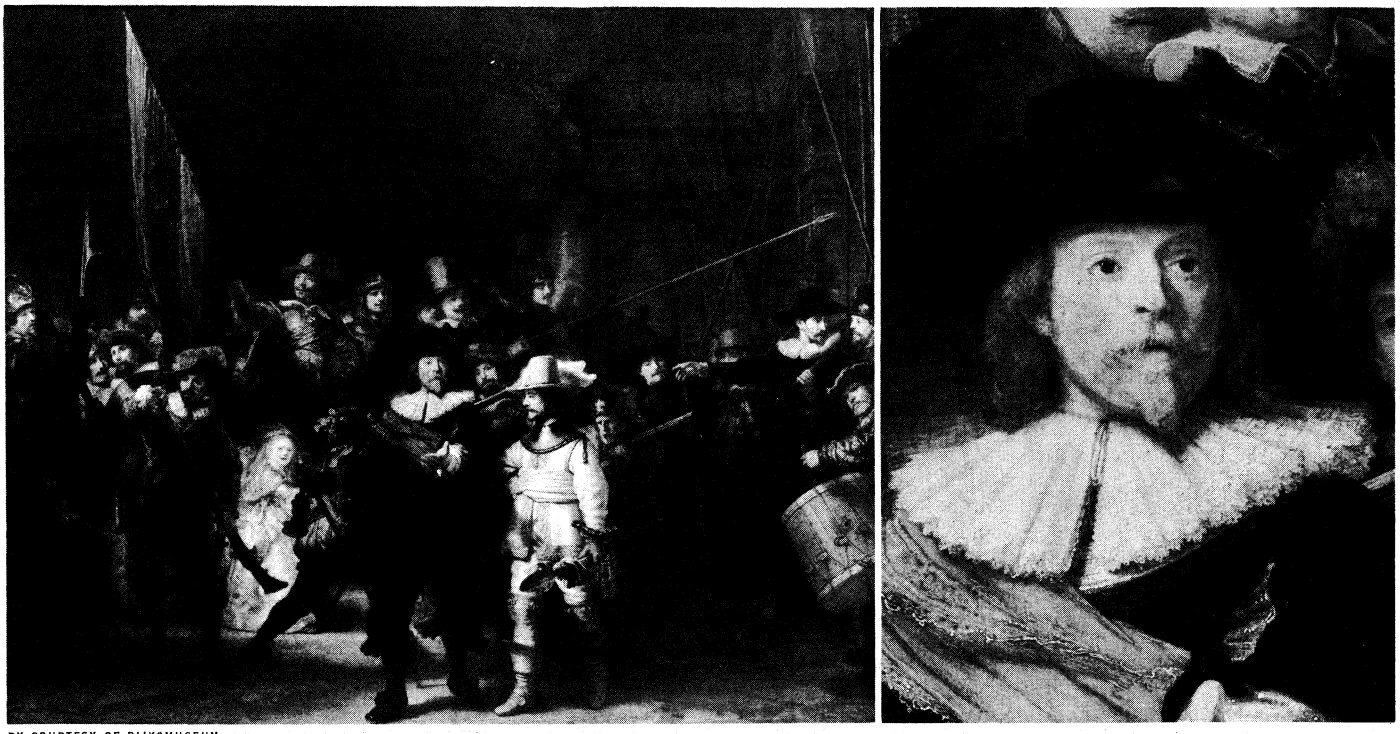
was that of Veronese. In Lastman's biblical and historical compositions the delicate daylight of Veronese takes on a cruder glare, and the cultured urbanity of Veronese's poses and gestures becomes pompous and provincial, but none the less the youthful Rembrandt found Lastman worth imitating and there are many echoes of his master in the historical pictures which he painted in Leiden between 1625–31. Examples of these are: "The Prophet Balaam" (1626; Cognacq-Jay museum, Paris) and "David Presenting the Head of Goliath to Saul" (1627?; Smidt van Gelder collection, Amsterdam), of which the latter is virtually a Lastman in miniature. Other works of these years, such as "The Tribute Money" (1629; Beit collection, London) show his growing interest in the use of expressive chiaroscuro. Rembrandt was naturally very much alive to influences other than the Italianism of the Lastman school. In addition to occasional hints borrowed from such contemporaries as Frans Hals and Adriaen Brouwer (*qq.v.*) one can detect the persistence of the northern genre tradition of the previous century, with its love of elaborate still-life details, in such a picture as "Tobit, His Wife and the Kid" (1626; in the private collection of Baroness Bentinck von Thyssen).

So far Rembrandt has been considered only as a painter of classical and biblical themes, but already in this early period a large proportion of his work consisted of portraits and studies of single figures and he was also making his first experiments in etching, a medium in which he was later to achieve unsurpassed results. The sitters for the portrait studies were frequently members of his own family, the most frequent being himself. These are not portraits in the fashionable sense, but studies in character, expression and lighting that could be (and often were) used in his subject pictures. The borderline between portraiture, genre and historical art is often a shadowy one, as when he paints "The Artist's Mother as the Prophetess Hannah" (1631; Rijksmuseum, Amsterdam), or develops a study of an old man into "The Apostle Paul" (Museum, Nürnberg). Often his homely sitters are given an exotic look by being made to wear some piece of extravagant headgear—a colourful turban, a helmet or a curiously plumed hat—as an exercise in the rendering of textures and effects of light. Most of the pictures of this period are painted on panel, with a predominance of cool, greyish monotone in the colouring, and the technique, though vigorous, is tighter and more constrained than the broad, loose brushwork of his later years. He soon became known in Leiden, where he shared a studio with the almost equally promising Jan Lievens, and before his removal to Amsterdam he was already taking pupils, among whom the most notable was Gerard Dou. More important for his subsequent career, he had roused the interest and admiration of Constantijn Huygens, with whose remarkable family he appears to have remained in contact throughout his life.

In the latter part of 1631 Rembrandt moved from Leiden to Amsterdam, the city which by this time had risen to be the foremost mercantile and artistic centre in Holland. Since he had already received a number of commissions from patrons in Amsterdam, he no doubt felt reasonably assured of a successful future there, and in fact the next ten years were to be—in terms of material reward—the most successful period of his life. He quickly gained a lion's share of the market in middle-class portraiture, in competition with such established and competent masters as Thomas de Keyser, and was commissioned (c. 1633) to paint a series of scenes of the Passion for the stadholder, Frederick Henry, prince of Orange, probably through the good offices of Constantijn Huygens, who was the stadholder's secretary. In 1634 he married Saskia van Uylenburch, a relative of his landlord and business associate, the art dealer Hendrick van Uylenburch. Saskia brought a considerable property of her own as marriage portion, for her family was both wealthy and well connected, and the rise in Rembrandt's fortune and social status is fully reflected in the confident and extrovert mood of much of his aork of the 1630s. In his art as in his life this was a period of growth and expansion, and the centre of both life and art was the personality of his attractive young wife. In the "Self-Portrait With the Artist's Wife" (Dresden museum) Rembrandt, jovial and resplendent in "cavalier" costume, is seated at a richly garnished table, one hand raising a drinking glass while the other clasps the waist of Saskia, who sits perched, rather demurely, on his knees. It would be foolish to regard this as a literal glimpse into their home life, but it is, in its somewhat vulgar exuberance, Rembrandt's most joyful testimony of his own pleasure in the good things of life.

Doubtless he did enjoy life, but he worked hard also, enlarging his achievement as well as his ambition in a splendid succession of portraits, historical pieces, etchings and drawings. He painted on a larger scale than in his Leiden years, with an increasing preference for canvas rather than panel. His colouring grew warmer, with brown and golden tones predominating, and his brushwork began to develop toward the unrivaled breadth and expressiveness of his fullest maturity. His first big portrait commission was in 1632 for the Surgeons' guild in Amsterdam—"The Anatomy Lesson of Professor Nicolaes Tulp" (Mauritshuis, The Hague). The official group portrait, depicting the officers of a guild, civic guard or other corporate body, was an established and important genre in Holland (as nowhere else) and "anatomies" had already been painted by De Keyser and others, although before Rembrandt's time such pictures had tended to be somewhat rigid assemblages of individual portraits, without psychological or pictorial unity in any marked degree. Hals in his earlier groups of the Haarlem civic guards moved toward a more pictorial solution, but Rembrandt penetrates far more deeply into the human situation. Without false overemphasis his "Tulp" reveals the inherent drama of the moment. contriving at the same time to convey the humane and compassionate motives which underlie an otherwise macabre operation, and it was an important step forward in the direction of his own "Night Watch" and "Syndics." In many of his portraits of this period Rembrandt aimed at the neat and highly finished effects which characterized the work of most of his rivals, as can be seen in such pictures as the pair of oval bust-length figures (Boston Museum of Fine Arts) of an "Unknown Man" (1634) and a "Lady in a Lace Collar," or the splendid pair of full-lengths (in the private collection of Baron Robert de Rothschild) also painted in 1634, which were thought to be portraits of Maerten Daey and his first wife Machteld van Doorn, but which more probably represent Marten Soolmans and his wife Oopjen Coppit, who after the death of her husband married Maerten Daey as his second wife. Among many other fine portraits of this phase are: the undated companion pieces of "Jan Pellicorne With His Son" and of Pellicorne's wife "Susanna van Collen With Her Daughter" (Wallace collection. London); "The Shipbuilder and His Wife" (1633; Royal collection at Buckingham palace, London); "The Preacher Eleazar Swalmius" (1637; Antwerp museum); "The Mennonite Preacher Cornelis Anslo and His Wife" (1641; Berlin); "Saskia as Flora" (1634; Hermitage, Leningrad); and the "Self-Portrait" of 1640 (National gallery, London), which shows the artist at the height of his fame and prosperity. In addition Rembrandt continued to produce many studies of a more personal kind, such as heads and single figures of old men, or Jewish types in turbans or colourful robes, that could be of use in his historical paintings.

The biblical subject pictures of these early years in Amsterdam are richly varied and provide evidence that Rembrandt studied almost every contemporary current in European painting. "Christ Appearing to Mary Magdalene" (1638; Buckingham palace) and the "Visitation" (1640; Detroit Institute of Arts) continue and enrich the Elsheimer tradition. The "Sacrifice of Abraham" (1635; Hermitage) is a fully baroque design of spiraling movement. Three illustrations of the story of Samson contrast with the pictures mentioned above and with each other: "Samson Threatening his Father-in-Law" (1635; Berlin) is a straightforward scene of comedy in which the painter's own features can be recognized in the guise of the irate hero; "The Blinding of Samson" (1636; Stadelsches Kunstinstitut, Frankfurt-on-Main) is a piece of savage melodrama and perhaps the most Caravaggesque of all Rembrandt's pictures; while "Samson's Wedding Feast" (1638; Dresden museum) is a sumptuous banqueting scene, in which the composed and charming figure of Saskia (Delilah) forms the central key of the composition. "The Sacrifice of Manoah" (1641; Dresden) gives a foretaste of the simplicity and the depth



BY COURTESY OF RIJKSMUSEUM

LEFT. "NIGHT WATCH" BY REMBRANDT: RIGHT. DETAIL OF CENTRAL FIGURE. IN THE RIJKSMUSEUM. AMSTERDAM

of feeling of Rembrandt's later religious paintings. In spite of the stylistic diversity of these works, they are all deeply impressed with the stamp of Rembrandt's individuality and humanity. Jakob Rosenberg observed that Rembrandt was never inclined to separate the human point of view from the pictorial. In this lies the peculiarly moving quality of his art that no imitator could approach His paintings testify to an intimate and loving knonledge of the Bible stories and he presents their characters always as samples of common humanity, not as remote and superhuman protagonists of legend or fairy tale. For Rembrandt the Bible was simple fact—and to be treated as such. The five pictures of the Passion cycle (1633–39; Altere Pinakothek, Munich) contain all these elements of style and character. In them can be traced echoes of Tintoretto. Caravaggio. Lastman and of Rubens' great "Descent From the Cross" in Antwerp cathedral, but all are fused in the concentrated and forthright power of Rembrandt's own manner, which owes nothing crucial to any of them. All are imbued with the painter's profound compassion, and in the first of the series ("The Raising of the Cross") he painted his own troubled face among the soldiery who heave the cross into position—and who shall be forgiven because "they know not what they do."

From about 1636 onward Rembrandt produced a small number of landscapes, most of them on panel and small, or fairly small, in size. Representative examples are: "Landscape With a Stone Bridge" (1637–38; Rijksmuseum); "Landscape With an Obelisk" (1638; Isabella Stewart Gardner museum. Boston); the comparatively large "River Landscape With Ruins on a Hill" and the tiny "Winter Landscape" (1646; both in the museum, Cassel. Ger.). These pictures strike one almost as being occasional relaxations of the artist from the hard discipline of figure painting, for they are free and spontaneous in design and technique. In general they follow the tradition of such landscape masters as Pieter Molijn, the early Jan van Goyen and Hercules Seghers. painted almost in monochrome but enlivened by spirited brushwork and dramatic tonal contrasts. Rembrandt delighted in painting an overcast or stormy sky, pierced by a single brilliant shaft of sunlight which illumines a building, a bridge or a clump of trees. producing a "spotlight" effect parallel to that of his figure and interior subjects. There is not the space here for a detailed consideration of Rembrandt's etchings, but among the more important plates of this phase are "The Raising of Lazarus" (c. 1632), "Christ Before Pilate" (1636) and "The Death of the Virgin" (1639).

The celebrated picture known as "The Night Watch" (Rijksmuseum), which was completed in 1642, may be regarded with some truth both as the culminating masterpiece of this decade of successes and as representing the transition to Rembrandt's later and less prosperous years. It might more accurately (though less succinctly) be called "The Civic Guard Under Captain Frans Banning Cocq and Lieutenant Willem van Ruytenburch." for the thorough cleaning which it received in 1946–47 proved that it nas not a night scene at all. but that the crowd of figures are emerging into sunlight from the shadows of an arched gateway. It is a huge canvas, about 12 ft. high by 14½ ft. wide, and was originally even larger. Early copies show that the painting has since been cut donn on all sides and especially drastically at its left edge, where two figures have been entirely lost. The composition has suffered from this curtailment, but it remains one of the supreme achievements of European art, baroque in its surging yet unified movement and its dramatic yet unified chiaroscuro, but a baroque which Rembrandt keeps under firm control by the strength of his design. "The Night Watch" also provides a foretaste of the brighter colouring that was to appear in his late style though, characteristically, it is used sparingly and effectively against a dark background. The captain's bright red sash and the lieutenant's yellow uniform provide the principal chord of colour. ahich is echoed in more muted tones in the reds and orange-browns of the figures on each side of them and in the paler yellow of the little girl's dress, nhile in the background and at the sides cooler greenish and yellowish tints predominate. To achieve the splendid unity of this complex composition Rembrandt subordinated the claims of portraiture to those of his own imaginative genius. This may well have dissatisfied some of the sitters nho are placed in such deep shadow as to be almost invisible, but it is surely too much to assume, as many have done, that the decline in his popularity from about this time is directly attributable to the cool reception of this masterpiece. As a body the shooting company of Captain Banning Cocq can hardly have been displeased at acquiring a work of such evident splendour.

From 1640 onward a series of misfortunes overtook Rembrandt. In 1640 his mother died and in 1642 he suffered a still more

grievous loss in the death of Saskia, a few months after the birth of their one surviving child, a son. This boy, christened Titus, was thenceforth the apple of his eye and he painted many portraits of him in childhood and as a young man. His popularity as a painter was on the wane, for patrons were turning their attention to the glossier and more readily comprehensible style of the younger generation, a style to which Rembrandt made no concessions. On the contrary, he followed undeviatingly the path of his genius toward ever broader and less "finished" effects. In 1639 he had bought a large and imposing house in the Jodenbreestraat, which contributed to his troubles for he could not really afford its upkeep, and for several years he sank deeper and deeper into financial difficulties. In 1656 he was declared bankrupt, and by 1660 the fine house and almost all of his possesuions, including valuable pictures and a vast assortment of armour and other curiosities, had been sold to pay what could be paid of his debts and he had moved into a humble lodging in a poorer quarter of the city. With him went Titus, now a youth of about 18, and Hendrickje Stoffels, who had entered his household as a servant girl in about 1645 and remained with him in his years of adversity as his mistress and loyal helper. Hendrickje and Titus formed a business partnership as dealers in works of art, with Rembrandt nominally their employee, bound to hand over to them all that he produced in return for his food and lodging. This ingenious device afforded him some protection from his creditors and permitted him at least to work unmolested as old age drew nearer. But his misfortunes were not ended. Hendrickje died in 1662, and in 1668 Titus died, only a few months after his marriage to Magdalena van Loo. Rembrandt did not long outlive his son. He died on Oct. 4, 1669, and was buried in the Westerkerk on Oct. 8. He was survived by his daughter Cornelia, born to Hendrickje Stoffels in 1654. The hardships of Rembrandt's old age have been much exaggerated by some writers, who have pictured him as almost entirely neglected after his brief period of prosperity. This was not really the case. Although no longer a successful painter in the material sense, he was far from being forgotten, as contemporary accounts fully prove. As late as 1662 he executed an important commission, the superb groups of "The Syndics." The failure of contemporary taste to accept the ultimate achievements of his late style was a fate that other great artists have endured in old age. For Rembrandt, as for them, the fulfillment of his art was more important than the applause that he might gain from it, and his triumph was that he spurned any ignoble compromise.

It is no easy task to single out individual pictures for mention from the wealth of masterpieces which Rembrandt produced in the final phases of his career. The self-portraits, which stretch in an unbroken series from his youth to the end of his life to form an artistic autobiography of the most fascinating and moving kind, take on a more sombre and troubled look. In such examples as the half-length "Self-Portrait" of 1652 (in Vienna) and the magnificent "Self-Portrait With a Palette" (Iveagh bequest, Kenwood house, London), painted about ten years later, he analyzes his own moral and physical progress with the same objective compassion as is seen in his studies of other humble sitters, such as the "Old Man in an Armchair" (which entered the National gallery in 1957 from the duke of Devonshire's collection). Other outstanding single portraits are the "Jewish Merchant" (National gallery), the "Jan Six" (1654; in the possession of the sitter's family) and the hauntingly romantic "Polish Rider" (Frick collection, New York). Among the later portrait groups mention must be made of the superb painting of "The Board of the Clothmakers' Guild" (1662; Rijksmuseum). This group, known usually as the "Staalmeesters," or in English "The Syndics," stands supreme in its own category of Dutch group portraiture, as does "The Night Watch." Perhaps the crowning achievement of his career in portraiture was the even later "Family Group" (Herzog Anton Ulrich museum, Brunswick, Ger.). This displays all the qualities of his last manner—rich yet subdued colour harmonies, firm yet unobtrusive compositional structure, vigorous yet subtle brushwork—and is at the same time a tender expression of all that is meant by the family relationship. The same human understanding is to be found in the biblical subjects of this period. Some recall his style of about 1630, for instance "The Woman Taken in Adultery" (1644; National gallery) and the Elsheimer-like "Susanna and the Elders" (Berlin); but in the 1650s and 1660s he produced works of such unique depth of feeling that they elude comparison with any earlier master. Such are the "Peter Denying Christ" (1660; Rijksmuseum) and the profoundly moving "Return of the Prodigal Son" (Hermitage). Parallel with the development in his painted work is a similar deepening of human values in his etchings, of which the famous large plate of "Christ Healing the Sick" (the "Hundred Guilder Print"), of about 1642–45 is possibly his supreme achievement in the medium. Finally, only the barest mention can be made of Rembrandt's incomparable drawings in pen or brush, or both, of which there are numerous examples in the principal collections on both sides of the Atlantic. *See* PAINTING: *The Netherlands: Rembrandt.* *See* also Index references under "Rembrandt" in the Index volume.

REMEMBRANCER, the name of certain officials who compiled the memoranda rolls and prepared the business for the barons of the exchequer, and so "reminded" them of the matter with which they must deal. There were at one time three clerks of the remembrance, styled king's remembrancer, lord treasurer's remembrancer and remembrancer of first-fruits. The latter two offices have become extinct. At the present moment (1929) the King's remembrancer is required to be a master of the court of exchequer, and by the Supreme Court of Judicature (Officers) act, 1879, he is a master of the supreme court. The office is usually filled by the senior master.

The king's remembrancer still assists at certain ceremonial functions. His duties are set out in the *Second Report of the Legal Departments Commission* (1874).

"Remembrancer" is also the title of an official of the corporation of the City of London, whose principal duty is to represent that body before parliamentary committees and at council and treasury boards.

REMI (REMY, REMIGIUS), **SAINT** (d. c. 530), bishop of Reims and friend of Clovis (*q.v.*), whom he converted to Christianity, was appointed to his see in 459. Clovis, pagan king of northern Gaul, had married Clotilda (daughter of Chilperic, Christian king of Burgundy), whose attempts to convert him he resisted. According to legend, however, during his war against the Alamanni, he promised that he would be converted if Clotilda's God would grant him the victory. He was successful, and Clotilda, therefore, summoned Remi, who with St. Vaast instructed Clovis and baptized him on Christmas day, 506; later his sisters and 3,000 men of his army also were baptized. Sources for Remi's life include only scattered references in Gregory of Tours and a few letters written by Remi and some contemporary bishops. Stories such as that of the dove that brought Remi a vial of oil from heaven for the baptism of Clovis, which was kept at Reims and used at the coronation of French kings, are later legends.

His feastday is Oct. 1.

See A. Van de Vyver, "La victoire contre les Alamans et la conversion de Clovis," *Revue Belge de philologie et d'histoire*, 15:859–914 (1936), 16:35–94 (1937). (J. N. G.)

REMINGTON, ELIPHALET (1793–1861), U.S. fire-arms manufacturer and inventor, was born at Suffield, Conn., on Oct. 28, 1793. In 1800 he traveled with his parents to the Mohawk valley, where they settled 20 mi. from Utica, N.Y. The elder Remington built a smithy and forge powered by a water wheel where he made horseshoes and agricultural implements. In 1816 young Remington built himself a flintlock rifle at his father's forge. It embodied no new inventions, but it was so remarkably accurate that the neighbouring sportsmen ordered similar guns from him, and within two years manufacture of sporting guns and rifle barrels became the main business of the forge. In 1828 Remington built a sizable factory beside the Erie canal at the present site of Ilion, N.Y., and expanded his production. He and his son Philo pioneered many improvements in arms manufacture, including the reflection method of straightening gun barrels, the lathe for cutting gunstocks, and the first successful cast-steel, drilled rifle barrel in the U.S.

In 1847 Remington supplied the U.S. navy with its first breech-loading rifle (Jenks carbine). In 1861, at the beginning of the American Civil War, the federal government placed large orders for small arms with Remington. He died on Aug. 12, 1861 in Ilion.

The Remington Arms company is still a large manufacturer of sporting arms and ammunition. During the American Civil War and World Wars I and II it was an important supplier of small arms and ammunition to the U.S. government.

See Alden Hatch, *Remington Arms in American History (1956).* (AL H.)

REMINGTON, FREDERIC (1861–1909), U.S. painter and sculptor, noted for his realistic portrayals of the American west, was born at Canton, N.Y., on Oct. 4, 1861. He was a pupil of the Yale art school and of the Art Students league, New York, and became known as an illustrator, painter and sculptor. Having spent much time in the west, where he went for his health, and having been with United States troops in warfare, he made a specialty of rendering the Indian and the soldier as seen on the western plains. In the Spanish-American War he was with the army under General Shafter as war correspondent. He died Dec. 26, 1909, near Ridgefield, Conn. His statuettes of soldiers, Indians, cowboys and trappers are full of character, while his paintings have been largely reproduced. He wrote several volumes of stories, including Pony Tracks (1895), Crooked Trails (1898), Sundown *Leflare* (1899) and *John* Ermine of the *Yellowstone* (1902).

REMIREMONT, a town of eastern France, in the *département* of Vosges, 17 mi. S.S.E. of Epinal by rail, on the Moselle, below its confluence with the Moselotte. Pop. (1954) 8,887. Remiremont (*Romarici Mons*) is named after St. Romaric, a companion of St. Columban of Luxeuil, who in the 7th century founded a monastery and a convent on the hills above the present town. In 910 an invasion of the Hungarians drove the nuns to Remiremont, which had grown round a villa of the Frankish kings, and in the 11th century they settled there. Enriched by dukes of Lorraine, kings of France and emperors of Germany, the ladies of Remiremont attained great power. The abbess was a princess of the empire, and received consecration at the hands of the pope. The fifty canonesses were selected from the nobility. On Whit-Monday the neighbouring parishes paid homage to the chapter in a ceremony called the "Kyrioles"; and on their accession the dukes of Lorraine, the immediate suzerains of the abbey, had to come to Remiremont to swear to continue their protection. The "War of the Scutcheons" (Panonceaux) in 1566 between the duke and the abbess ended in favour of the duke, and terminated the abbess's power. The monastery and nunnery were both suppressed in the Revolution. Remiremont is surrounded by forest-clad mountains. The 13th century abbey church has a crypt of the 11th century. The abbatial residence (which now contains the *mairie*, the court-house and the public library) has been twice rebuilt in the original plan in modern times. Some of the houses of the canonesses (17th and 18th centuries) remain Remiremont has a board of trade-arbitrators and a chamber of arts and manufactures.

The town's industries include cotton-spinning and weaving. the manufacture of embroidery, iron and copper founding and the manufacture of brushes.

REMIZOV, ALEXEI (1877–1957), Russian novelist. whose work influenced the modern Russian novel, was born June 24. 1877, in Moscow and brought up amid factory surroundings and in the strict observance of Orthodox Church rites, with frequent pilgrimages to monasteries. He thus gained an intimate knowledge of national habits, monastic life and old religious legends. He studied natural science and economics at Moscow university, took part in revolutionary activities, and was imprisoned and spent years of exile in Vologda.

Remizov subsequently went to live in Paris. The influences of his varying surroundings contributed to the formation of his fantastic personality, uniting the whimsical mischievousness of some fairy-tale sprite with a deep spirit of pity.

The most remarkable of Remizov's works are The Pond (1907), a powerful and gloomy picture of vulgarity, vice and crime among the Moscow bourgeoisie and the monasteries; The Clock (1908, Eng. trans. 1924); The *Fifth* Pestilence, two stories of provincial life (Eng trans. by A. Brown. 1927); *The* Sisters of the Cross (1910), a novel of St. Petersburg life; and The Story of Ivan *Semenovich* Stratilatov (1909). He also wrote stories relating to the revolution of 1905, and several plays. He died in Paris on Nov. 26, 1957.

REMONSTRANTS, those Dutch Protestants who, after the death of Jacobus Arminius, maintained the views associated with his name, and in 1610 presented to the states-general a "remonstrance" formulating their points of departure from stricter Calvinism. The Remonstrants were assailed both by personal enemies and by the political weapons of Maurice, prince of Orange, and in 1618–19 the synod of Dort expelled them and declared Remonstrant theology contrary to Scripture. The movement remains, however, and its liberal school of theology has reacted powerfully on the state church and on other Christian denominations. See ARMINIANISM; DORT, SYNOD OF.

REMORA, a name given generally to fishes of the family Echeneidae, which are remarkable for having the spinous dorsal fin developed into a transversely laminated sucking disc, placed on top of the head; in a more restricted sense the name refers to a particular species, *Remora* remora, other species being given common names such as sharksucker (Echeneis naucrates), slender suckerfish (Plztheirichthys *lineatus*), whalesucker (Remora *australis*), etc. There are about 12 species, found in all tropical and temperate seas.

Remoras attach themselves to whales, porpoises, sharks. sea turtles and large fish; they are not, however, parasitic on these animals but are merely transported by them. They detach themselves and swim when searching for food, frequently bits that fall from the mouths of their "hosts." Each plate in the sucking disc can be elevated to produce a partial vacuum when it is attached to a flat surface.

Attempts to dislodge a remora by pulling merely make the attachment more firm; the fish can be detached, however, by sliding it forward. In some parts of the tropics fishermen have used remoras with a line attached to their tails to catch larger fish and sea turtles. (C. HU.)

REMPHAN (in A.V., *Rephan* in R.V.) a word found in Acts vii. 43 (Ῥομφά, Westcott and Hort). The writer is quoting the Septuagint of Amos v. 26 (Ῥαιφάν), where the Hebrew has *Kiyyùn* (כִּיּוּן). This is probably a mistake for *Kewan*, the Babylonian name for the planet Saturn. The Greek form may be an error of the transliterator.

REMSCHEID, a town in North Rhine-Westphalia, Germany, 6 mi. by rail S. of Barmen, in an industrial area heavily bombed in World War II. Pop. (1959 est.) 123.276. It is a centre of the hardware industry, and makes large quantities of tools, scythes, drills and other small articles in iron, steel and brass.

REMSEN, IRA (1846–1927), U.S. chemist and university president, co-discoverer of saccharin, was born in New York city

on Feb. 10, 1846. He was educated at the Free academy (College of the City of New York; B.A., 1865), College of Physicians and Surgeons, Columbia university (M.D., 1867), and at the universities of Munich and Gottingen (Ph.D., 1870). At the University of Tiibingen (1870–72), where he was the assistant of Rudolph Fittig, he began the investigations into pure chemistry upon which his later fame was chiefly based. He became professor of chemistry at Williams college, Williamstown, Mass. (1872), and was one of the original faculty of Johns Hopkins university, Baltimore, Md., where he was professor of chemistry 1876–1913, director of the chemical laboratory 1876–1908, secretary of the academic council 1881–1901 and president of the university 1901–13 As president of Johns Hopkins he continued to emphasize the primary function of the university as a centre of research. He was president emeritus and professor emeritus 1913–27, during which time he traveled widely and worked on government pure food commissions. Remsen brought to Johns Hopkins many of the German laboratory methods and as a teacher he had many widely scattered and influential students.

He founded the *American Chemical Journal* in 1879. in which most of his papers appeared, and continued to edit it almost to the time of his death. In the first volume he described the preparation and properties of a new compound, subsequently to become widely known as saccharin, which he and a pupil discovered. Another long series of studies led to the discovery and enunciation of Remsen's law, concerning the prevention of oxidation in methyl and other groups. His writings included *Principles of Theoretical Chemistry* (1876), which passed through five editions and has been translated into German, Russian and Italian; *An Introduction to the Study of the Compounds of Carbon* (1885; jth rev.. 1922); *Elements of Chemistry* (1888); *Inorganic Chemistry* (1889); and *A College Text-book of Chemistry* (1901). He died at Carmel, Calif., on March 5, 1927.

BIBLIOGRAPHY.—B. Harrow, *Eminent Chemists of Our Time* (1920); "Impressions of Ira Remsen," *Johns Hopkins Alumni Magazine,* **xvi,** 215–26 (1928); "Ira Remsen," *Science,* n.s, lxvi, 243–46 (1927)

RÉMUSAT, CHARLES FRANÇOIS MARIE, COMTE DE (1797–187j), French politician and man of letters, was born in Paris on March 13, 1797. He was called to the bar, and became an active journalist. He signed the journalists' protest against the ordinances of July 1830, and in October was elected deputy for Haute-Garonne. He then ranked himself with the *doctrinaires,* and supported measures of restriction on popular liberty. Rémusat held office in the reign of Louis Philippe. He took no part in politics under the empire until 1869. In Aug. 1871 he became minister of foreign affairs. He died in Paris on Jan. 6, 187j.

His works include: *Abélard,* 2 vol. (1845); *Saint Anselme de Cantorbéry* (1854); *L'Angleterre au XVIII*ème *siècle* (1856; 2nd ed. enl., 1865); *Bacon, sa vie, son temps* (1858); *Channing,...* (1862); *Histoire de la philosophie en Angleterre depuis Bacon jusqu'à Locke* (1875).

RÉMUSAT, JEAN PIERRE ABEL (1788–1832), French Chinese scholar, was born in Paris on Sept. 5, 1788. He was educated for the medical profession, but a Chinese herbal in the collection of the Abbé Tersan led him to study Chinese. His *Essai sur la langue et la littérature chinoises* (1811) won him the patronage of Silvestre de Sacy, and in 1814 he was appointed to the chair of Chinese founded in that year at the Collège de France. His contributions from Chinese sources to the history of the Tatar nations claims special notice. Rémusat became an editor of the *Journal des savants* in 1818, and founder and first secretary of the Paris Asiatic Society in 1822; he also held various Government appointments. He died at Paris on June 4, 1832. A list of his works is given in Quérard's *France littéraire* s.v. Rémusat.

RENAISSANCE, THE. The "Renaissance" or "Renascence" is a term used to indicate a well-known but indefinite space of time and a certain phase in the development of Europe. On the one hand it denotes the transition from that period of history which we call the middle ages (*q.v.*) to that which we call modern. On the other hand it implies those changes in the intellectual and moral attitude of the Western nations by which the transition was characterized. If we insist upon the iiteral and etymological meaning of the word, the Renaissance was a re-birth; and it is needful to inquire of what it was the re-birth. The metaphor of Renaissance may signify the entrance of the European nations upon a fresh stage of vital energy in general, implying a fuller consciousness and a freer exercise of faculties than had belonged to the mediaeval period. Or it may mean the resuscitation of simply intellectual activities, stimulated by the revival of antique learning and its application to the arts and literatures of modern peoples. Upon our choice between these two interpretations of the word depend important differences in any treatment of the subject. The former has the disadvantage of making it difficult to separate the Renaissance from other historical phases—the Reformation for example—with which it ought not to be confounded. The latter has the merit of assigning a specific name to a limited series of events and group of facts, which can be distinguished for the purpose of analysis from other events and facts with which they are intimately but not indissolubly connected. In other words, the one definition of Renaissance makes it denote the whole change which came over Europe at the close of the middle ages. The other confines it to what was known by our ancestors as the Revival of Learning. Yet, when we concentrate attention on the recovery of antique culture, we become aware that this was only one phenomenon or symptom of a far wider and more comprehensive alteration in the conditions of the European races. We find it needful to retain both terms, Renaissance and Revival of Learning, and to show the relations between the series of events and facts which they severally imply. The Revival of Learning must be regarded as a function of that vital energy, an organ of that mental evolution, which brought into existence the modern world, with its new conceptions of philosophy and religion, its reawakened arts and sciences, its firmer grasp on the realities of human nature and the world, its manifold inventions and discoveries, its altered political systems, its expansive and progressive forces. Important as the Revival of Learning undoubtedly was, there are essential factors in the complex called the Renaissance with which it can but remotely be connected. When we analyse the whole group of phenomena which have to be considered, we perceive that some of the most essential have nothing or little to do with the recovery of the classics. These are, briefly speaking, the decay of those great fabrics, church and empire, which ruled the middle ages both as ideas and as realities; the development of nationalities and languages; the enfeeblement of the feudal system throughout Europe; the invention and application of paper, the mariner's compass, gunpowder, and printing; the exploration of continents beyond the ocean; and the substitution of the Copernican for the Ptolemaic system of astronomy. Europe in fact had been prepared for a thorough-going metamorphosis before that new idea of human life and culture which the Revival of Learning brought to light had been made manifest. It had recovered from the confusion consequent upon the dissolution of the ancient Roman empire. The Teutonic tribes had been Christianized, civilized and assimilated to the previously Latinized races over whom they exercised the authority of conquerors. Comparative tranquillity and material comfort had succeeded to discord and rough living. Modern nationalities, defined as separate factors in a common system, were ready to co-operate upon the basis of European federation. The ideas of universal monarchy and of indivisible Christendom, incorporated in the Holy Roman empire and the Roman Church, had so far lost their hold that scope was offered for the introduction of new theories both of state and church which would have seemed visionary or impious to the mediaeval mind. It is, therefore, obvious that some term, wider than Revival of Learning, descriptive of the change which began to pass over Europe in the 14th and 15th centuries, has to be adopted. That of Renaissance, Rinascimento, or Renascence is sufficient for the purpose, though we have to guard against the tyranny of what is after all a metaphor. We must not suffer it to lead us into rhetoric about the deadness and the darkness of the middle ages, or hamper our inquiry with preconceived assumptions that the re-birth in question was in any true sense a return to the irrecoverable pagan past. Nor must we imagine that there was any abrupt break with the middle ages. On the contrary, the Renaissance was rather the last stage of the middle ages emerging

from ecclesiastical and feudal despotism, developing what was original in mediaeval ideas by the light of classic arts and letters, holding in itself the promise of the modern world. It was, therefore, a period and a process of transition, fusion, preparation, tentative endeavour. And just at this point the real importance of the Revival of Learning may be indicated. That rediscovery of the classic past restored the confidence in their own faculties to men striving after spiritual freedom; revealed the continuity of history and the identity of human nature in spite of diverse creeds and different customs; held up for emulation master-works of literature, philosophy and art; provoked inquiry; encouraged criticism; shattered the narrow mental barriers imposed by mediaeval orthodoxy. Humanism', a word which will often recur in the ensuing paragraphs, denotes a specific bias which the forces liberated in the Renaissance took from contact with the ancient world—the particular form assumed by human self-esteem at that epoch —the ideal of life and civilization evolved by the modern nations. It indicates the endeavour of man to reconstitute himself as a free being, not as the thrall of theological despotism, and the peculiar assistance he derived in this effort from Greek and Roman literature, the *litterae humaniores*, letters leaning rather to the side of man than of divinity.

In this article the Renaissance will be considered as implying a comprehensive movement of the European intellect and will toward self-emancipation, toward reassertion of the natural rights of the reason and the senses, toward the conquest of this planet as a place of human occupation, and toward the formation of regulative theories both for states and individuals differing from those of mediaeval times. The Revival of Learning will be treated as a decisive factor in this process of evolution on a new plan. To exclude the Reformation and the Counter-Reformation wholly from the survey is impossible. These terms indicate moments in the whole process of modern history which were opposed, each to the other, and both to the Renaissance; and it is needful to bear in mind that they have, scientifically speaking, a quite separate existence. Yet, if the history of Europe in the 16th century of our era came to be written with the brevity with which we write the history of Europe in the 6th century B.C., it would be difficult at the distance of time implied by that supposition to distinguish the Italian movement of the Renaissance in its origin from the German movement of the Reformation. Both would be seen to have a common starting-point in the reaction against long dominant ideas which were becoming obsolete, and also in the excitation of faculties which had during the same period been accumulating energy.

Chronology. — The Renaissance, if we try to regard it as a period, was essentially the transition from one historical stage to another. It cannot therefore be confined within strict chronological limits. There is one date, however, which may be remembered with advantage as the starting-point in time of the Renaissance, after the departure from the middle ages had been definitely and consciously made by the Italians. This is the year 1453, when Constantinople, chosen for his capital by the first Christian emperor of Rome, fell into the hands of the Turk.[2] One of the survivals of the old world, the shadow of what had been the Eastern empire, now passed suddenly away. Almost at the same date that visionary revival of the Western empire, which had imposed for six centuries upon the imagination of mediaeval Europe, hampering Italy and impeding the consolidation of Germany, ceased to reckon among political actualities; while its more robust rival, the Roman Church, seemed likely to sink into the rank of a petty Italian principality. It was demonstrated by the destruction of the Eastern and the dotage of the Western empire and by the new papal policy which Nicholas V. inaugurated, that the old order of society was about to be superseded. Nothing remained to check those centrifugal forces in state and church which substituted a confederation of rival European Powers for the earlier ideal of universal monarchy, and separate religious constitutions for the previous Catholic unity. At the same time the new learning introduced by the earlier humanists awakened free thought, encouraged curiosity, and prepared the best minds of Europe for speculative audacities from which the schoolmen would have shrunk, and which soon expressed themselves in acts of cosmopolitan importance. If we look a little forward to the years 1492–1500, we obtain a second date of great importance. In these years the expedition of Charles VIII. to Naples opened Italy to French, Spanish and German interference. The leading nations of Europe began to compete for the prize of the peninsula, and learned meanwhile that culture which the Italians had perfected. In these years the secularization of the papacy was carried to its final point by Alexander VI., and the Reformation became inevitable. The same period was marked by the discovery of America, the exploration of the Indian seas, and the consolidation of the Spanish nationality. It also witnessed the application of printing to the diffusion of knowledge. Thus, speaking roughly, the half-century between 1450 and 1500 may be termed the culminating point of the Renaissance. The transition of the mediaeval to the modern order was now secured if not accomplished, and a rubicon had been crossed from which no retrogression to the past was possible. Looking yet a little farther to the years 1527 and 1530 a third decisive date is reached. In the first of these years happened the sack of Rome, in the second the pacification of Italy by Charles V. under a Spanish hegemony. The age of the Renaissance was now closed for the land which gave it birth. The Reformation had taken firm hold on northern Europe. The Counter-Refomation was already imminent.

'To the humanists themselves "humanitas" meant nothing more nor less than "culture."

[2] Most scholars now deny that the fall of Constantinople had any appreciable influence on the culture of Western Europe. For Symonds' date of 1453 they would substitute the date of the invention of printing about 1440.

THE MIDDLE AGES

It must not be imagined that so great a change as that implied by the Renaissance was accomplished without premonitory symptoms and previous endeavours. In the main we mean by it the recovery of freedom for the human spirit after a long period of bondage to oppressive ecclesiastical and political orthodoxy — a return to the liberal and practical conceptions of the world which the nations of antiquity had enjoyed, but upon a new and enlarged platform. This being so, it was inevitable that the finally successful efforts after self-emancipation should have been anticipated from time to time by strivings within the ages that are known as dark and mediaeval. It is, therefore part of the present inquiry to pass in review some of the claimants to be considered precursors to the Renaissance.

First of all must be named the Frank in whose lifetime the dual conception of universal empire and universal church, divinely appointed sacred and inviolable, began to control the order of European society. Charles the Great (Charlemagne) lent his forces to the plan of resuscitating the Roman empire at a moment when his own power made him the arbiter of Western Europe, when the papacy needed his alliance, and when the Eastern empire had passed under the usurped regency of a female. He modelled an empire, Roman in name, but essentially Teutonic, since it owed such substance as its fabric possessed to Frankish armies and the sinews of the German people. As a structure composed of divers ill-connected parts it fell to pieces at its builder's death, leaving little but the incubus of a memory, the fascination of a mighty name, to dominate the mind of mediaeval Europe. As an idea, the Empire grew in visionary power, and remained one of the chief obstacles in the way of both Italian and German national coherence. Real force was not in it, but rather in that counterpart to its unlimited pretensions, the Church which had evolved it from barbarian night, and which used her own more vital energies for undermining the rival of her creation. Charles the Great, having proclaimed himself successor of the Caesars. was obscurely ambitious of imitating the Augusti also in the sphere of letters. He caused a scheme of humanistic education to be formulated, and gave employment at his court to rhetoricians of whom Alcuin was the most considerable. But very little came of the Revival of Learning which Charles is supposed to have encouraged; and the empire he restored was accepted by the mediaeval intellect in a crude theological and vaguely mystical spirit. We should, how-

ever, here remember that the study of Roman law, which was one important precursory symptom of the Renaissance, owed much to mediaeval respect for the empire as a divine institution. This, together with the municipal Italian intolerance of the Lombard and Frankish codes, kept alive the practice and revived the science of Latin jurisprudence at an early period.

Speculation and Heresy. — Philosophy had tried to free itself from the trammels of theological orthodoxy in the hardy speculations of some schoolmen, notably of Scotus Erigena and Abelard. These innovators found, however, small support, and were defeated by opponents who used the same logical weapons with authority to back them. Nor were the rationalistic opinions of the Averroists without their value, though the Church condemned these deviators from her discipline as heretics. Such mediaeval materialists, moreover, had but feeble hold upon the substance of real knowledge. Imperfect acquaintance with authors whom they had studied in Latin translations made by Jews from Arabic commentaries on Greek texts, together with almost total ignorance of natural laws, condemned them to sterility. Like the other schiomachists of their epoch, they fought with phantoms in a visionary realm. A similar judgment may be passed upon those Paulician, Albigensian, Paterine and Epicurean dissenters from the Catholic creed who opposed the phalanxes of orthodoxy with frail imaginative weapons, and alarmed established orders in the state by the audacity of their communistic opinions. Physical science struggled into feeble life in the cells of Gerbert and Roger Bacon. But these men were accounted magicians by the vulgar; and, while the one eventually assumed the tiara, the other was incarcerated in a dungeon. The schools meanwhile resounded still to the interminable dispute upon abstractions. Are only universals real, or has each name a corresponding entity? From the midst of the Franciscans who had persecuted Roger Bacon because he presumed to know more than was consistent with human humility arose John of Parma, adopting and popularizing the mystic prophecy of Joachim of Flora. The reign of the Father is past; the reign of the Son is passing; the reign of the Spirit is at hand. Such was the formula of the Eternal Gospel, which as an unconscious forecast of the Renaissance, has attracted retrospective students by its felicity of adaptation to their historical method. Yet we must remember that this bold intuition of the abbot Joachim indicated a monastic reaction against the tyrannies and corruptions of the Church, rather than a fertile philosophical conception. The Fraticelli spiritualists, and similar sects who fed their imagination with his doctrine, expired in the flames to which Fra Dolcino Longino and Margharita were consigned. To what extent the accusations of profligate morals brought against these reforming sectarians were justified remains doubtful; and the same uncertainty rests upon the alleged iniquities of the Templars. It is only certain that at this epoch the fabric of Catholic faith was threatened with various forms of prophetic and Oriental mysticism, symptomatic of a widespread desire to grasp at something simpler, purer and less rigid than Latin theology afforded. Devoid of criticism, devoid of sound learning, devoid of a firm hold on the realities of life, these heresies passed away without solid results and were forgotten.

Naturalism. — We are apt to take for granted that the men of the middle ages were immersed in meditations on the other world, and that their intellectual exercises were confined to abstractions of the schools, hallucinations of the fancy, allegories, visions. This assumption applies indeed in a broad sense to that period which was dominated by intolerant theology, and deprived of positive knowledge. Yet there are abundant signs that the native human instincts, the natural human appetities, remained unaltered and alive beneath the crust of orthodoxy. In the person of a pope like Boniface VIII. those ineradicable forces of the natural man assumed, if we may trust the depositions of ecclesiastics, well acquainted with his life. a form of brutal atheistic cynicism. In the person of an emperor, Frederick II., they emerged under the more agreeable garb of liberal culture and Epicurean scepticism. Frederick dreamed of remodelling society upon a mundane type, which anticipated the large toleration and cosmopolitan enlightenment of the actual Renaissance. But his efforts were defeated by the unrelenting hostility of the Church, and by the incapacity of his contemporaries to understand his aims. After being forced in his lifetime to submit to authority, he was consigned by Dante to hell. Frederick's ideal of civilization was derived in a large measure from Provence, where a beautiful culture had prematurely bloomed, filling southern Europe with the perfume of poetry and gentle living. Here, if anywhere, it seemed as though the ecclesiastical and feudal fetters of the middle ages might be broken. and humanity might enter on a new stage of joyous and unimpeded evolution. This was, however, not to be. The Church preached Simon de Montfort's crusade, and organized Dominic's Inquisition; what Quinet calls the "Renaissance sociale par l'Amour" was extirpated by sword, fire, famine and pestilence. Meanwhile the Provencal poets had developed their modern language with incomparable richness and dexterity, creating forms of verse and modes of emotional expression which determined the latest mediaeval phase of literature in Europe. The naturalism of which we have been speaking found free utterance now in the fabliaux of jongleurs, lyrics of minnesingers, tales of trouvères, romances of Arthur and his knights — compositions varied in type and tone, but in all of which sincere passion and real enjoyment of life pierce through the thin veil of chivalrous mysticism or of allegory with which they were sometimes conventionally draped. The tales of Lancelot and Tristram, the lives of the troubadours and the Wachtlieder of the minnesingers, sufficiently prove with what sensual freedom a knight loved the lady whom custom and art made him profess to worship as a saint. We do not need to be reminded that Beatrice's adorer had a wife and children, or that Laura's poet owned a son and daughter by a concubine, in order to perceive that the mystic passion of chivalry was compatible in the middle ages with commonplace matrimony or vulgar illegitimate connections. But perhaps the most convincing testimony to the presence of this ineradicable naturalism is afforded by the Latin songs of wandering students, known as Carmina Burama, written by the self-styled Goliardi. In these compositions, remarkable for their facile handling of mediaeval Latin rhymes and rhythms, the allegorizing mysticism which envelops chivalrous poetry is discarded. Love is treated from a frankly carnal point of view. Bacclius and Venus go hand in hand, as in the ancient ante-Christian age. The open-air enjoyments of the wood, the field, the dance upon the village green are sung with juvenile light-heartedness. No grave note, warning us that the pleasures of this earth are fleeting, that the visible world is but a symbol of the invisible, that human life is a probation for the life beyond, interrupts the tinkling music as of castanets and tripping feet which gives a novel charm to these unique relics of the 13th century. Goliardic poetry is further curious as showing how the classics even at that early period were a fountain-head of pagan inspiration. In the taverns and low places of amusement haunted by those lettered songsters, on the open road and in the forests trodden by their vagrant feet, the deities of Greece and Rome were not in exile, but at home within the hearts of living men. Thus, while Christendom was still preoccupied with the Crusades, two main forces of the Renaissance, naturalism and enthusiasm for antique modes of feeling, already brought their latent potency to light, prematurely indeed and precociously, yet with a promise that was destined to be kept.

The Mediaeval Attitude. — When due regard is paid to these miscellaneous evidences of intellectual and sensual freedom during the middle ages, it will be seen that there were by no means lacking elements of native vigour ready to burst forth. What was wanting was not vitality and licence, not audacity of speculation, not lawless instinct or rebellious impulse. It was rather the right touch on life, the right feeling for human independence, the right way of approaching the materials of philosophy, religion, scholarship and literature that failed. The courage that is born of knowledge, the calm strength begotten by a positive attitude of mind, face to face with the dominant over-shadowing sphinx of theology, were lacking. We may fairly say that natural and untaught people had more of the just intuition that was needed than learned folk trained in the schools. But these people were rendered licentious in revolt or impotent for salutary action by ignorance, hy terror, by uneasy dread of the doom declared for heretics and rebels.

The massive vengeance of the Church hung over them, like a heavy sword suspended in the cloudy air. Superstition and stupidity hedged them in on every side, so that sorcery and magic seemed the only means of winning power over nature or insight into mysteries surrounding human life. The path from darkness to light was lost; thought was involved in allegory; the study of nature had been perverted into an inept system of grotesque and pious parablemongering; the pursuit of truth had become a game of wordy dialectics. The other world, with its imagined heaven and hell, haunted the conscience like a nightmare. However sweet this world seemed, however fair the flesh, both world and flesh were theoretically given over to the devil. It was not worth while to master and economize the resources of this earth, to utilize the good and ameliorate the evils of this life, while everyone agreed, in theory at any rate, that the present was but a bad prelude to an infinitely worse or infinitely better future. ' To escape from these preoccupations and prejudices except upon the path of conscious and deliberate sin was impossible for all but minds of rarest quality and courage; and these were too often reduced to the recantation of their supposed errors no less by some secret clinging sense of guilt than by the Church's iron hand. Man and the actual universe kept on reasserting their rights and claims, in one way or another; but they were always being thrust back again into Cimmerian regions of abstractions, fictions, visions, spectral hopes and fears, in the midst of which the intellect sornnambulistically moved upon an unknown way.

THE REVIVAL OF LEARNING IN ITALY

At this point the Revival of Learning intervened to determine the course of the Renaissance. Mediaeval students possessed a considerable portion of the Latin classics, though Greek had become in the fullest sense of the phrase a dead language. But what they retained of ancient literature they could not comprehend in the right spirit. Between them and the text of poet or historian hung a veil of mysticism, a vapour of misapprehension. The odour of unsanctity clung around those relics of the pagan past. Men bred in the cloister and the lecture room of the logicians, trained in scholastic disputations, versed in allegorical interpretations of the plainest words and most apparent facts, could not find the key which might unlock those stores of wisdom and of beauty. Petrarch first opened a new method in scholarship and revealed what we denote as humanism. In his teaching lay the twofold discovery of man and of the world. For humanism, which was the vital element in the Revival of Learning, consists mainly of a just perception of the dignity of man as a rational, volitional and sentient being, born upon this earth with a right to use it and enjoy it. Humanism implied the rejection of those visions of a future and imagined state of souls as the only absolute reality, which had fascinated the imagination of the middle ages. It involved a vivid recognition of the goodliness of man and nature, displayed in the great monuments of human power recovered from the past. It stimulated the curiosity of latent sensibilities, provoked fresh inquisition into the groundwork of existence and strengthened man's self-esteem by knowledge of what men had thought and felt and done in ages when Christianity was not. It roused a desire to reappropriate the whole abandoned provinces of mundane energy, and a hope to emulate antiquity in works of living loveliness and vigour. The Italians of the 14th century, more precocious than the other European races, were ripe for this emancipation of enslaved intelligence. In the classics they found the food which was required to nourish the new spirit; and a variety of circumstances among which must be reckoned the pride of a nation boasting of its descent from the *populus Romanus,* rendered them apt to fling aside the obstacles that had impeded the free action of the mind through many centuries. Petrarch not only set his countrymen upon the right method of studying the Latin classics, but he also divined the importance of recovering a knowledge of Greek literature. To this task Giovanni Boccaccio addressed himself; and he was followed by numerous Italian enthusiasts, who visited Byzantium before its fall as the sacred city of a new revelation. The next step was to collect manuscripts, to hunt out, copy and preserve the precious relics of the past. In this work of accumulation Guarino da Verona and Francesco Filelfo, Giovanni Aurispa and Poggio took the chief part, aided by the wealth of Italian patricians, merchant princes and despots, who were inspired by the sacred thirst for learning. Learning was then no mere pursuit of a special and recluse class. It was fashionable and it was passionate, pervading all society with the fervour of romance. For a generation nursed in decadent scholasticism and stereotyped theological formulas it was the fountain of renascent youth, beauty and freedom, the shape in which the Helen of art and poetry appeared to the ravished eyes of mediaeval Faustus. It was the resurrection of the mightiest spirits of the past. "I go," said Cyriac of Ancona, the indefatigable though uncritical explorer of antiquities, "I go to awake the dead!" This was the enthusiasm, this the vitalizing faith, which made the work of scholarship in the 15th century so highly strung and ardent. The men who followed it knew that they were restoring humanity to its birthright after the expatriation of ten centuries. They were instinctively aware that the effort was for liberty of action, thought and conscience in the future. This conviction made young men leave their loves and pleasures, grave men quit their countinghouses, churchmen desert their missals, to crowd the lecture rooms of philologers and rhetoricians. When Greek had been acquired, manuscripts accumulated, libraries and museums formed, came the age of printers and expositors. Aldus Manutius in Italy, Joannes Froben in Basle, the Étiennes in Paris committed to the press what the investigators had recovered. Nor were there wanting men who dedicated their powers to Hebrew and Oriental erudition, laying, together with the Grecians, a basis for those biblical studies which advanced the Reformation. Meanwhile, the languages of Greece and Rome had been so thoroughly appropriated that a final race of scholars, headed by Politian, Jovianus Pontanus, Lorenzo Valla, handled once again in verse and prose both antique dialects, and thrilled Europe with new-made pagan melodies. The Church itself at this epoch lent its influence to the prevalent enthusiasm. Nicholas V and Leo X, not to mention intervening popes who showed themselves tolerant of humanistic culture, were heroes of the classical revival. Scholarship became the surest path of advancement to ecclesiastical and political honours. Italy was one great school of the new learning at the moment when the German, French and Spanish nations were invited to its feast.

It will be well to describe briefly, but in detail, what this meeting of the modern with the ancient mind effected over the whole field of intellectual interests. In doing so, care must be taken to remember that the study of the classics did but give a special impulse to pent-up energies which were bound in one way or another to assert their independence. Without the Revival of Learning the direction of those forces would have been different; but that novel intuition into the nature of the world and man which constitutes what we describe as Renaissance must have emerged. As the facts, however, stand, it is impossible to dissociate the rejection of the other world as the sole reality, the joyous acceptance of this world as a place to live in and act in, the conviction that "the proper study of mankind is man," from humanism. Humanism as it actually appeared in Italy was positive in its conception of the problems to be solved, pagan in its contempt for mediaeval mysticism, invigorated for sensuous enjoyment by contact with antiquity, yet holding in itself the germ of new religious aspirations, profounder science and sterner probings of the mysteries of life than had been attempted even by the ancients. The operation of this humanistic spirit has now to be traced.

Dante, Petrarch, Boccaccio and **Villani.**—It is obvious that Italian literature owed little at the outset to the Revival of Learning. The *Divine* Comedy, the *Canzoniere* and the *Decameron* were works of monumental art, deriving neither form nor inspiration immediately from the classics but applying the originality of Italian genius to matter drawn from previous mediaeval sources. Dante showed both in his epic poem and in his lyrics that he had not abandoned the sphere of contemporary thought. Allegory and theology, the vision and the symbol, still determine the form of masterpieces which for perfection of workmanship and for emancipated force of intellect rank among the highest products of the

human mind. Yet they are not mediaeval in the same sense as the song of Roland or the Arthurian cycle. They proved that, though Italy came late into the realm of literature, her action was destined to be decisive and alterative by the introduction of a new spirit, a firmer and more positive grasp on life and art. These qualities she owed to her material prosperity, to her freedom from feudalism, to her secularized church, her commercial nobility, her political independence in a federation of small states. Petrarch and Boccaccio, though they both held the mediaeval doctrine that literature should teach some abstruse truth beneath a veil of fiction, differed from Dante in this, that their poetry and prose in the vernacular abandoned both allegory and symbol. In their practice they ignored their theory; Petrarch's lyrics continue the Provençal tradition as it had been reformed in Tuscany, with a subtler and more modern analysis of emotion, a purer and more chastened style than his masters could boast; Boccaccio's tales, in like manner, continue the tradition of the fabliaux, raising that literary species to the rank of finished art, enriching it with humour and strengthening its substance by keen insight into all varieties of character. The *Canzoniere* and the *Decameron* distinguish themselves from mediaeval literature, not by any return to classical precedents, but by free self-conscious handling of human nature. So much had to be premised in order to make it clear in what relation humanism stood to the Renaissance since the Italian work of Dante, Petrarch and Boccaccio is sufficient to indicate the re-birth of the spirit after ages of apparent deadness. Had the Revival of Learning not intervened, it is probable that the vigorous efforts of these writers alone would have inaugurated a new age of European culture. Yet, while noting this reservation of judgment it must also be remarked that all three felt themselves under some peculiar obligation to the classics. Dante, mediaeval as his temper seems to us, chose Virgil for his guide, and ascribed his mastery of style to the study of Virgilian poetry. Petrarch and Boccaccio were, as we have seen, the pioneers of the new learning. They held their writings in the vernacular cheap, and initiated that contempt for the mother tongue which was a note of the earlier Renaissance. Giovanni Villani, the first chronicler who used Italian for the compilation of a methodical history, tells us how he was impelled to write by musing on the ruins of Rome, and thinking of the vanished greatness of the Latin race. We have, therefore, to recognize that the four greatest writers of the 14th century, while the Revival of Learning was yet in its cradle, each after his own fashion acknowledged the vivifying touch upon his spirit of the antique genius. They seem to have been conscious that they could not give the desired impulse to modern literature and art without contact with the classics; and, in spite of the splendour of their achievements in Italian, they found no immediate followers upon that path.

Scholarship and Literature.— The fascination of pure study was so powerful, the Italians at that epoch were so eager to recover the past, that during the 15th century we have before our eyes the spectacle of this great nation deviating from the course of development begun in poetry by Dante and Petrarch, in prose by Boccaccio and Villani, into the channels of scholarship and antiquarian research. The language of the *Canzoniere* and *Decameron* was abandoned for revived Latin and discovered Greek. Acquisition supplanted invention; imitation of classical authors suppressed originality of style. The energies of the Italian people were devoted to transcribing the codices, settling texts, translating Greek books into Latin, compiling grammars, commentaries, encyclopaedias, dictionaries, epitomes and ephemerides. During this century the best histories—Bruni's and Poggio's annals of Florence, for example—were composed in Latin after the manner of Livy. The best dissertations, Landino's *Camaldunenses,* Valla's *De Voluptate,* were laboured imitations of Cicero's *Tusculans.* The best verse, Pontano's elegies, Politian's hexameters, were, in like manner Latin; public orations upon ceremonial occasions were delivered in the Latin tongue; correspondence, official and familiar, was carried on in the same language; even the fabliaux received, in Poggio's *Facetiae,* a dress of elegant Latinity. The noticeable barrenness of Italian literature at this period is referable to the fact that men of genius and talent devoted themselves to erudition and struggled to express their thoughts and feelings in a speech which was not natural. Yet they were engaged in a work of incalculable importance. At the close of the century the knowledge of Greece and Rome had been reappropriated and placed beyond the possibility of destruction; the chasm between the old and new world had been bridged; mediaeval modes of thinking and discussing had been superseded; the staple of education, the common culture which has brought all Europe into intellectual agreement, was already in existence. Humanism was now an actuality. Owing to the uncritical veneration for antiquity which then prevailed, it had received a strong tincture of pedantry. Its professors, in their revolt against the middle ages, made light of Christianity and paraded paganism. What was even worse from an artistic point of view, they had contracted puerilities of style, vanities of rhetoric, stupidities of wearisome citation. Still, at the opening of the 16th century, it became manifest what fruits of noble quality the Revival of Letters was about to bring forth for modern literature. Two great scholars, Lorenzo de'Medici and Politian, had already returned to the practice of Italian poetry. Their work is the first absolutely modern work—modern in the sense of having absorbed the stores of classic learning and reproduced those treasures in forms of simple, natural, native beauty. Boiardo occupies a similar position by the fusion of classic mythology with chivalrous romance in his *Orlando Innamorato.* But the victor's laurels were reserved for Ariosto whose *Orlando Furioso* is the purest and most perfect extant example of Renaissance poetry. It was not merely in what they had acquired and assimilated from the classics that these poets showed the transformation effected in the fields of literature by humanism. The whole method and spirit of the mediaeval art had been abandoned. That of the *cinque cento* is positive, defined, mundane. The deity, if deity there be, that rules in it, is beauty. Interest is confined to the actions, passions, sufferings and joys of human life, to its pathetic, tragic, humorous and sentimental incidents. Of the state of souls beyond the grave we hear and are supposed to care nothing. In the drama the pedantry of the Revival which had not injured romantic literature made itself perniciously felt. Rules were collected from Horace and Aristotle. Seneca was chosen as the model of tragedy; Plautus and Terence supplied the groundwork of comedy. Thus in the plays of Rucellai, Trissino, Sperone and other tragic poets, the nobler elements of humanism, considered as a revelation of the world and man, obtained no free development. Even the comedies of the best authors are too observant of Latin precedents, although some pieces of Machiavelli, Ariosto, Aretino, Cecchi and Gelli are admirable for vivid delineation of contemporary manners.

Fine Arts.—The relation of the plastic arts to the Revival of Learning is similar to that which has been sketched in the case of poetry. Cimabue started with work which owed nothing directly to antiquity. At about the same time Niccola Pisano (d. 1278) studied the style of sculpture in fragments of Graeco-Roman marbles. His manner influenced Giotto, who set painting on a forward path. Fortunately for the unimpeded expansion of Italian art, little was brought to light of antique workmanship during the 14th and 15th centuries. The classical stimulus came to painters, sculptors and architects chiefly through literature. Therefore there was narrow scope for imitation; and the right spirit of humanism displayed itself in a passionate study of perspective, nature and the nude. Yet we find in the writings of Ghiberti and Alberti, we notice in the masterpieces of these men and their compeers Brunelleschi and Donatello, how even in the 15th century the minds of artists were fascinated by what survived of classic grace and science. Gradually, as the race became penetrated by antique thought, the earlier Christian motives of the arts yielded to pagan subjects. Gothic architecture, which had always flourished feebly on Italian soil, was supplanted by a hybrid Roman style. The study of Vitruvius gave strong support to that pseudo-classic manner which, when it had reached its final point in Palladio's work, overspread the whole of Europe and dominated taste during two centuries. But the perfect plastic art of Italy, the pure art of the *cinque cento,* the painting of Raphael, Da Vinci, Titian and Correggio the sculpture of Donatello, Michel-

angelo and Sansovino, the architecture of Bramante, Omodeo, and the Venetian Lombardi, however much imbued with the spirit of the classical revival, take rank beside the poetry of Ariosto as a free intelligent product of the Renaissance. That is to say, it is not so much an outcome of studies in antiquity as an exhibition of emancipated modern genius fired and illuminated by the masterpieces of the past. It indicates a separation from the middle ages, inasmuch as it is permanently natural. Its religion is joyous, sensuous, dramatic, terrible, but in each and all of its many-sided manifestations strictly human. Its touch on classical mythology is original, rarely imitative or pedantic. The art of the Renaissance was an apocalypse of the beauty of the world and man in unaffected spontaneity, without side thoughts for piety or erudition, inspired by pure delight in loveliness and harmony for their own sakes.

Science and Philosophy. — In the fields of science and philosophy humanism wrought similar important changes. Petrarch began by waging relentless war against the logicians and materialists of his own day. With the advance made in Greek studies scholastic methods of thinking fell into contemptuous oblivion. The newly aroused curiosity for nature encouraged men like Alberti, Da Vinci, Toscanelli and Da Porta to make practical experiments, penetrate the working of physical forces, and invent scientific instruments. Anatomy began to be studied, and the time was not far distant when Titian should lend his pencil to the epoch-making treatise of Vesalius. The middle ages had been satisfied with absurd and visionary notions about the world around them, while the body of man was regarded with too much suspicion to be studied. Now the right method of interrogating nature with patience and loving admiration was instituted. At the same time the texts of ancient authors supplied hints which led to discoveries so far-reaching in their results as those of Copernicus, Columbus and Galileo. In philosophy, properly so called, the humanistic scorn for mediaeval dullness and obscurity swept away theological metaphysics as valueless. But at first little beyond empty rhetoric and clumsy compilation was substituted. The ethical treatises of the scholars are deficient in substance, while Ficino's attempt to revive Platonism betrays an uncritical conception of his master's drift. It was something, however, to have shaken off the shackles of ecclesiastical authority; and, even if a new authority, that of the ancients, was accepted in its stead, still progress was being made toward sounder methods of analysis. This is noticeable in Pomponazzo's system of materialism, based on the interpretation of Aristotle, but revealing a virile spirit of disinterested and unprejudiced research. The thinkers of southern Italy, Telesio, Bruno and Campanella, at last opened the two chief lines on which modern speculation has since moved. Telesio and Campanella may be termed the predecessors of Bacon. Bruno was the precursor of the idealistic schools. All three alike strove to disengage their minds from classical as well as ecclesiastical authority, proving that the emancipation of the will had been accomplished. It must be added that their writings, like every other product of the Renaissance, except its purest poetry and art, exhibit a hybrid between mediaeval and modern tendencies. Childish ineptitudes are mingled with intuitions of maturest wisdom and seeds of future thought germinate in the decaying refuse of past systems.

Criticism. — Humanism in its earliest stages was uncritical. It absorbed the relics of antiquity with omnivorous appetite and with very imperfect sense of the distinction between worse and better work. Yet it led in process of time to criticism. The critique of literature began in the lecture-room of Politian, in the printing house of Aldus, and in the school of Vittorino. The critique of Roman law started under Politian's auspices, upon a more liberal course than that which had been followed by the powerful but narrow-sighted glossators of Bologna. Finally, in the court of Naples arose that most formidable of all critical engines, the critique of established ecclesiastical traditions and spurious historical documents. Valla by one vigorous effort destroyed the False Decretals and exposed the Donation of Constantine to ridicule, paving the way for the polemic carried on against the dubious pretensions of the papal throne by scholars of the Reformation. A similar criticism, conducted less on lines of erudition than of persiflage and irony, ransacked the moral abuses of the Church and played around the foundations of Christianity. This was tolerated by men who repeated the witty epigram, attributed to Leo X, "What profit has not that fable of Christ brought us!" The same critical and philosophic spirit working on the materials of history produced a new science, the honours of which belong to Machiavelli. He showed, on the one side, how the history of a people can be written with a recognition of fixed principles, and at the same time with an artistic feeling for personal and dramatic episodes. On the other side, he addressed himself to the analysis of man considered as a political being, to the anatomy of constitutions and the classification of governments, to the study of motives underlying public action, the secrets of success and the causes of failure in the conduct of affairs. The unscrupulous rigour with which he applied his scientific method, and the sinister deductions he thought himself justified in drawing from the results it yielded, excited terror and repulsion. Nevertheless a department had been added to the intellectual empire of mankind, in which fellow-workers, like Guicciardini at Florence, and subsequently Sarpi at Venice, were not slow to follow the path traced by Machiavelli.

Education. — The object of the foregoing paragraphs has been to show in what way the positive, inquisitive, secular, exploratory spirit of the Renaissance, when toned and controlled by humanism penetrated the regions of literature, art, philosophy and science. It becomes at this point of much moment to consider how social manners in Italy were modified by the same causes, since the type developed there was in large measure communicated together with the new culture to the rest of Europe. The first subject to be noticed under this heading is education. What has come to be called a classical education was the immediate product of the Italian Renaissance. The Universities of Bologna, Padua, and Salerno had been famous through the later middle ages for the study of law, physics and medicine; and during the 15th and 16th centuries the first two still enjoyed celebrity in these faculties. But at this period no lecture-rooms were so crowded as those in which professors of antique literature and language read passages from the poets and orators, taught Greek, and commented upon the systems of philosophers. The mediaeval curriculum offered no defined place for the new learning of the Revival, which had indeed no recognized name. Chairs had therefore to be founded under the title of rhetoric, from which men like Chrysoloras and Guarino, Filelfo and Politian expounded orally to hundreds of eager students from every town of Italy and every nation of Europe their accumulated knowledge of antiquity. One mass of Greek and Roman erudition, including history and metaphysics, law and science, civic institutions and the art of war, mythology and magistracies, metrical systems and oratory, agriculture and astronomy, domestic manners and religious rites, grammar and philology, biology and numismatics, formed the miscellaneous subject-matter of this so-styled rhetoric. Notes taken at these lectures supplied young scholars with hints for further exploration; and a certain tradition of treating antique authors for the display of general learning, as well as for the elucidation of their texts, came into vogue, which has determined the method of scholarship for the last three centuries in Europe. The lack of printed books in the first period of the Revival, and the comparative rarity of Greek erudition among students, combined with the intense enthusiasm aroused for the new gospel of the classics, gave special value to the personal teaching of these professors. They journeyed from city to city, attracted by promises of higher pay, and allured by ever-growing laurels of popular fame. Each large town established its public study, academy or university—similar institutions under varying designations—for the exposition of the *literae humaniores*. The humanists, or professors of that branch of knowledge, became a class of the highest dignity. They were found in the chanceries of the republics, in the papal curia, in the council chambers of princes, at the headquarters of condottieri, wherever business had to be transacted, speeches to be made and the work of secretaries to be performed. Furthermore, they undertook the charge of private education, opening schools

which displaced the mediaeval system of instruction and taking engagements as tutors in the families of despots, noblemen and wealthy merchants. The academy established by Vittorino da Feltre at Mantua under the protection of Gian Francesco Gonzaga, for the training of pupils of both sexes, might be chosen as the type of this Italian method. His scholars who were lodged in appropriate buildings met daily to hear the master read and comment on the classics. They learned portions of the best authors by heart, exercised themselves in translating from one language to another and practised composition in prose and verse. It was Vittorino's care to see that while their memories were duly stored with words and facts their judgment should be formed by a critical analysis, attention to style and comparison of the authors of a decadent age with those who were acknowledged classics. During the hours of recreation suitable physical exercises, as fencing, riding, and gymnastics, were conducted under qualified trainers. From this sketch it will be seen how closely the educational system which came into England during the reign of the Tudors, and which has prevailed until the present time, was modelled upon the Italian type. English youths who spend their time at Eton between athletic sports and Latin verse, and who take a first class in Literae Humaniores at Oxford are pursuing the same course of physical and mental discipline as the princes of Gonzaga or Montefeltro in the 15th century.

The humanists effected a deeply penetrating change in social manners. Through their influence as tutors, professors, orators and courtiers, society was permeated by a fresh ideal of culture. To be a gentleman in Italy meant at this epoch to be a man acquainted with the rudiments at least of scholarship, refined in diction, capable of corresponding or of speaking in choice phrases, open to the beauty of the arts, intelligently interested in archaeology, taking for his models of conduct the great men of antiquity, rather than the saints of the Church. He was also expected to prove himself an adept in physical exercises and in the courteous observances which survived from chivalry. The type is set before us by Castiglione in that book upon the courtier which went the round of Europe in the 16th century. It is further emphasized in a famous passage of the *Orlando Innamorato* where Boiardo compares the Italian ideal of an accomplished gentleman with the coarser type admired by nations of the north. To this point the awakened intelligence of the Renaissance, instructed by humanism, polished by the fine arts, expanding in genial conditions of diffused wealth, had brought the Italians at a period when the rest of Europe was comparatively barbarous.

Defects of the Renaissance. — This picture has undoubtedly a darker side. Humanism in its revolt against the middle ages was, as we have seen already, mundane, pagan, irreligious, positive[1]. The Renaissance can, after all, be regarded only as a period of transition in which much of the good of the past was sacrificed while some of the evil was retained, and neither the bad nor the good of the future was brought clearly into fact. Beneath the surface of brilliant social culture lurked gross appetites and savage passions, unrestrained by mediaeval piety, untutored by modern experience. Italian society exhibited an almost unexampled spectacle of literary, artistic and courtly refinement crossed by brutalities of lust, treasons, poisonings, assassinations, violence. A succession of worldly pontiffs brought the Church into flagrant discord with the principles of Christianity. Steeped in pagan learning, desirous of imitating the manners of the ancients, thinking and feeling in harmony with Ovid and Theocritus, and at the same time rendered cynical by the corruption of papal Rome, the educated classes lost their grasp upon morality. Political honesty ceased almost to have a name in Italy. The Christian virtues were scorned by the foremost actors and the ablest thinkers of the time, while the antique virtues were themes for rhetoric rather than moving springs of conduct. This is apparent to all students of Machiavelli and Guicciardini, the profoundest analysts of their age, the bitterest satirists of its vices, but themselves infected with its incapacity for moral goodness. The Italians were not only vitiated; they had also become impotent for action and resistance. At the height of the Renaissance the five great Powers in the peninsula formed a confederation of independent but mutually attractive and repellent states. Equilibrium was maintained by diplomacy, in which the humanists played a foremost part, casting a network of intrigue over the nation which helped in no small measure to stimulate intelligence and create a common medium of culture, but which accustomed statesmen to believe that everything could be achieved by wire-pulling. Wars were conducted on a showy system by means of mercenaries, who played a safe game in the field and developed a system of bloodless campaigns. Meanwhile the people grew up unused to arms. When Italy between the years 1494 and 1530 became the battlefield of French, German and Spanish forces, it was seen to what a point of helplessness the political, moral and social conditions of the Renaissance had brought the nation.

Spread of the New Learning. — It was needful to study at some length the main phenomena of the Renaissance in Italy, because the history of that phase of evolution in the other Western races turns almost entirely upon points in which they either adhered to or diverged from the type established there. Speaking broadly, what France, Germany, Spain and England assimilated from Italy at this epoch was in the first place the new learning as it was then called. This implied the new conception of human life, the new interest in the material universe, the new method of education, and the new manners, which we have seen to be inseparable from Italian humanism. Under these forms of intellectual enlightenment and polite culture the renascence of the human spirit had appeared in Italy, where it was more than elsewhere connected with the study of classical antiquity. But that audacious exploratory energy which formed the motive force of the Renaissance as distinguished from the Revival of Learning took, as we shall see, very different directions in the several nations who now were sending the flower of their youth to study at the feet of Italian rhetoricians.

The Renaissance ran its course in Italy with strange indifference to consequences. The five great Powers, held in equilibrium by Lorenzo de' Medici, dreamed that the peninsula could be maintained in *statu quo* by diplomacy. The Church saw no danger in encouraging a pseudo-pagan ideal of life, violating its own principle of existence by assuming the policy of an aggrandizing secular state, and outraging Christendom openly by its acts and utterances. Society at large was hardly aware that an intellectual force of stupendous magnitude and incalculable explosive power had been created by the new learning. Why should not established institutions proceed upon the customary and convenient methods of routine, while the delights of existence were augmented, manners polished, arts developed and a golden age of epicurean ease made decent by a state religion which no one cared to break with because no one was left to regard it seriously? This was the attitude of the Italians when the Renaissance, which they had initiated as a thing of beauty, began to operate as a thing of power beyond the Alps.

GERMANY

Germany was already provided with universities, seven of which had been founded between 1348 and 1409. In these haunts of learning the new studies took root after the year 1440, chiefly through the influence of travelling professors, Peter Luder and Samuel Karoch. German scholars made their way to Lombard and Tuscan lecture-rooms, bringing back the methods of the humanists. Greek, Latin and Hebrew erudition soon found itself at home on Teutonic soil. Like Italian men of letters, these pioneers of humanism gave a classic turn to their patronymics: unfamiliar names, Crotus Rubeanus and Pierius Graecus, Capnion and Lupambulus Ganymedes, Oecolampadius and Melanchthon, resounded on the Rhine. A few of the German princes, among whom Maximilian, the prince cardinal Albert of Mainz, Frederick the Wise of Saxony, and Eberhard of Wiirttemberg deserve mention, exercised a not insignificant influence on letters by the foundation of new universities and the patronage of learned men. The cities of Strasbourg, Nuremberg, Augsburg, Basle, became centres of learned coteries which gathered round scholars like Wimphel-

[1] But there was also a great school of Christian humanists intent upon reconciling the gospel with the Greek philosophers.

ing, Brant, Peutinger, Schedel, and Pirckheimer, artists like Diirer and Holbein, painters of the eminence of Froben. Academies in imitation of Italian institutions came into existence, the two most conspicuous named after the Rhine and the Danube, holding their headquarters respectively at Heidelberg and Vienna. Crowned poets, of whom the most eminent was Conrad Celtes Protucius (Pickel!) emulated the fame of Politian and Pontano. Yet though the Renaissance was thus widely communicated to the centres of German intelligence, it displayed a different character from that which it assumed in Italy. Gothic art, which was indigenous in Germany, yielded but little to southern influences. Such work as that of Durer, Vischer, Cranach, Schongauer, Holbein, consummate as it was in technical excellence, did not assume Italian forms of loveliness, did not display the paganism of the Latin races. The modification of Gothic architecture by pseudo-Roman elements of style was incomplete. What Germany afterwards took of the Palladian manner was destined to reach it on a circuitous route from France. In like manner the new learning failed to penetrate all classes of society with the rapidity of its expansion in Italy, nor was the new ideal of life and customs so easily substituted for the mediaeval. The German aristocracy, as Aeneas Sylvius had noticed, remained for the most part barbarous, addicted to gross pleasures, contemptuous of culture. The German dialects were too rough to receive that artistic elaboration under antique influences which had been so facile in Tuscany. The doctors of the universities were too wedded to their antiquated manuals and methods, too satisfied with dullness, too proud of titles and diplomas, too anxious to preserve ecclesiastical discipline and to repress mental activity, for a genial spirit of humanism to spread freely. Not in Cologne or Tübingen but in Padua and Florence did the German pioneers of the Renaissance acquire their sense of liberal studies. And when they returned home they found themselves encumbered with stupidities, jealousies and rancours. Moreover the temper of these more enlightened men was itself opposed to Italian indifference and immorality; it was pugnacious and polemical, eager to beat down the arrogance of monks and theologians rather than to pursue an ideal of aesthetical self-culture. To a student of the origins of German humanism it is clear that something very different from the Renaissance of Lorenzo de' Medici and Leo X. was in preparation from the first upon Teutonic soil. Far less plastic and form-loving than the Italian, the German intelligence was more penetrative, earnest, disputative, occupied with substantial problems. Starting with theological criticism, proceeding to the stage of solid studies in the three learned languages, German humanism occupied the attention of a widely scattered sect of erudite scholars; but it did not arouse the interest of the whole nation until it was forced into a violently militant attitude by Pfefferkorn's attack on Reuchlin. That attempt to extinguish honest thought prepared the Reformation; and humanism after 1518 was absorbed in politico-religious warfare.

Humanism and the German Reformation. — The point of contact between humanism and the Reformation in Germany has to be insisted on; for it is just here that the relation of the Reformation to the Renaissance in general makes itself apparent. As the Renaissance had its precursory movements in the mediaeval period, so the German Reformation was preceded by Wycliffe and Huss, by the discontents of the Great Schism, and by the councils of Constance and Basel. These two main streams of modern progress had been proceeding upon different tracks to diverse issues, but they touched in the studies stimulated by the Revival, and they had a common origin in the struggle of the spirit after self-emancipation. Johann Reuchlin, who entered the lecture-room of Argyropoulos at Rome in 1482, Erasmus of Rotterdam, who once dwelt at Venice as the house guest of the Aldi, applied their critical knowledge of Hebrew and Greek to the elucidation and diffusion of the Bible. To the Germans, as to all nations of that epoch, the Bible came as a new book, because they now read it for the first time with eyes opened by humanism. The touch of the new spirit which had evolved literature, art and culture in Italy sufficed in Germany to recreate Christianity. This new spirit in Italy emancipated human intelligence by the classics; in Germany it emancipated the human conscience by the Bible. The indignation excited by Leo X.'s sale of indulgences, the moral rage stirred in Northern hearts by papal abominations in Rome were external causes which precipitated the schism between Teutonic and Latin Christianity. The Reformation, inspired by the same energy of resuscitated life as the Renaissance, assisted by the same engines of the printing-press and paper, using the same apparatus of scholarship, criticism, literary skill, being in truth another manifestation of the same world-movement under a diverse form, now posed itself as an irreconcilable antagonist to Renaissance Italy. It would be difficult to draw any comparison between German and Italian humanists to the disparagement of the former. Reuchlin was no less learned than Pico; Melanchthon no less humane than Ficino; Erasmus no less witty and far more trenchant than Petrarch; Ulrich von Hutten no less humorous than Folengo; Paracelsus no less fantastically learned than Cardano. But the cause in which German intellect and will were enlisted was so different that it is difficult not to make a formal separation between that movement which evolved culture in Italy and that which restored religion in Germany, establishing the freedom of intelligence in the one sphere and the freedom of conscience in the other. The truth is that the Reformation was the Teutonic Renaissance. It was the emancipation of the reason on a line neglected by the Italians, more important indeed in its political consequences, more weighty in its bearing on rationalistic developments than the Italian Renaissance, but none the less an outcome of the same ground-influences. We have already in this century reached a point at which, in spite of stubborn Protestant dogmatism and bitter Catholic reaction, we can perceive how the ultimate affranchisement of man will be the work of both.

The Counter-Reformation. — The German Reformation was incapable of propagating itself in Italy, chiefly for the reason that the intellectual forces which it represented and employed had already found specific outlet in that country. It was not in the nature of the Italians, sceptical and paganized by the revival, to be keenly interested about questions which seemed to revive the scholastic disputes of the middle ages. It was not in their external conditions, suffering as they were from invasions, enthralled by despots, to use the Reformation as a lever for political revolution. Yet when a tumultuary army of so-called Lutherans sacked Rome in 1527, no sober thinker doubted that a new agent had appeared in Europe which would alter the destinies of the peninsula. The Renaissance was virtually closed so far as it concerned Italy, when Clement VII. and Charles V. struck their compact at Bologna in 1530. This compact proclaimed the principle of monarchial absolutism, supported by papal authority, itself monarchially absolute, which influenced Europe until the outbreak of the Revolution. A reaction immediately set in both against the Renaissance and the Reformation. The Council of Trent, opened in 1545 and closed in 1563, decreed a formal purgation of the Church, affirmed the fundamental doctrines of Catholicism, strengthened the papal supremacy, and inaugurated that movement of resistance which is known as the Counter-Reformation. The complex onward effort of the modern nations, expressing itself in Italy as Renaissance, in Germany as Reformation, had aroused the forces of conservatism. The four main instruments of the reaction were the papacy, which had done so much by its sympathy with the revival to promote the humanistic spirit it now dreaded, the strength of Spain, and two Spanish institutions planted on Roman soil — the Inquisition and the Society of Jesus. The principle contended for and established by this reaction was absolutism as opposed to freedom — monarchial absolutism, papal absolutism, the suppression of energies liberated by the Renaissance and the Reformation. The partial triumph of this principle was secure, in as much as the majority of established powers in Church and State felt threatened by the revolutionary opinions afloat in Europe. Renaissance and Reformation were, moreover, already at strife. Both, too, were spiritual and elastic tendencies toward progress, ideals rather than solid organisms.

SPAIN

The part played by Spain in this period of history was deter-

mined in large measure by external circumstance. The Spaniards became one nation by the conquest of Granada and the union of the crowns of Castile and Aragon. The war of national aggrandizement being in its nature a crusade, inflamed the religious enthusiasm of the people. It was followed by the expulsion of Jews and Moors, and by the establishment of the Inquisition on a solid basis, with powers formidable to the freedom of all Spaniards from the peasant to the throne. These facts explain the decisive action of the Spanish nation on the side of Catholic conservatism, and help us to understand why their brilliant achievements in the field of culture during the 16th century were speedily followed by stagnation. It will be well, in dealing with the Renaissance in Spain, to touch first upon the arts and literature, and then to consider those qualities of character in action whereby the nation most distinguished itself from the rest of Europe. Architecture in Spain, emerging from the Gothic stage, developed an Early Renaissance style of bewildering richness by adopting elements of Arabic and Moorish decoration. Sculpture exhibited realistic vigour of indubitably native stamp; and the minor plastic crafts were cultivated with success on lines of striking originality. Painting grew from a homely stock, until the work of Velasquez showed that Spanish masters in this branch were fully abreast of their Italian compeers and contemporaries. To dwell here upon the Italianizing versifiers, moralists and pastoral romancers who attempted to refine the vernacular of the *Romancero* would be superfluous. They are mainly noticeable as proving that certain coteries in Spain were willing to accept the Italian Renaissance. But the real force of the people was not in this courtly literary style. It expressed itself at last in the monumental work of *Don Quixote,* which places Cervantes beside Rabelais, Ariosto and Shakespeare as one of the four supreme exponents of the Renaissance. The affectations of decadent chivalry disappeared before its humour; the lineaments of a noble nation, animated by the youth of modern Europe emerging from the middle ages, were portrayed in its enduring pictures of human experience. The Spanish drama, meanwhile untrammelled by those false canons of pseudo-classic taste which fettered the theatre in Italy and afterwards in France, rose to an eminence in the hands of Lope de Vega and Calderon which only the English, and the English only in the masterpieces of three or four playwrights, can rival. Camoens in the *Lusiad,* if we may here group Portugal with Spain, was the first modern poet to compose an epic on a purely modern theme, vying with Virgil, but not bending to pedantic rules, and breathing the spirit of the age of heroic adventures and almost fabulous discoveries into his melodious numbers. What has chiefly to be noted regarding the achievements of the Spanish race in arts and letters at this epoch is their potent national originality. The revival of learning produced in Spain no slavish imitation as it did in Italy, no formal humanism, and, it may be added, very little of fruitful scholarship. The Renaissance here, as in England, displayed essential qualities of intellectual freedom, delight in life, exultation over rediscovered earth and man. The note of Renaissance work in Germany was still Gothic. This we feel in the penetrative earnestness of Diirer, in the homeliness of Hans Sachs, in the grotesque humour of *Eulenspiegel,* and the *Narrenschiff,* the sombre pregnancy of the Faust legend, the almost stolid mastery of Holbein. It lay not in the German genius to escape from the preoccupations and the limitations of the middle ages, for this reason mainly that what we call mediaeval was to a very large extent Teutonic. But on the Spanish peninsula, in the masterpieces of Velasquez, Cervantes, Camoens, Calderon, we emerge into an atmosphere of art definitely national, distinctly modern, where solid natural forms stand befcre us realistically modelled, with light and shadow on their rounded outlines, and where the airiest creatures of the fancy take shape and weave a dance of rhythmic, light, incomparable intricacy. The Spanish Renaissance would in itself suffice, if other witnesses were wanting, to prove how inaccurate is the theory that limits this movement to the revival of learning. Touched by Italian influences, enriched and fortified by the new learning, Spanish genius walked firmly forward on its own path. It was crushed only by forces generated in the nation that produced it, by the Inquisition and by despotic Catholic absolutism.

In the history of the Renaissance, Spain and Portugal represent the exploration of the ocean and the colonization of the other hemisphere. The voyages of Columbus and Vespucci to America, the rounding of the Cape by Diaz and the discovery of the sea road to India by Vasco da Gama. Cortés's conquest of Mexico and Pizarro's conquest of Peru, marked a new era fo- the human race and inaugurated the modern age more decisively than any other series of events has done. It has recently been maintained that modern European history is chiefly an affair of competition between confederated states for the possession of lands revealed by Columbus and Da Gama. Without challenging or adopting this speculation, it may be safely affirmed that nothing so pregnant of results has happened as this exploration of the globe. To say that it displaced the centre of gravity in politics and commerce, substituting the ocean for the Mediterranean, dethroning Italy from her seat of central importance in traffic, depressing the eastern and elevating the western Powers of Europe, opening a path for Anglo-Saxon expansiveness, forcing philosophers and statesmen to regard the Occidental nations as a single group in counterpoise to other groups of nations, the European community as one unit correlated to other units of humanity upon this planet, is truth enough to vindicate the vast significance of these discoveries. The Renaissance, far from being the re-birth of antiquity with its civilization confined to the Mediterranean and the Hercules' Pillars beyond which lay Cimmerian darkness, was thus effectively the entrance upon a quite incalculably wider stage of life on which mankind at large has since enacted one great drama. While Spanish navies were exploring the ocean, and Spanish paladins were overturning empires, Charles V headed the reaction of Catholicism against reform. Stronger as king of Spain than as emperor, for the Empire was little but a name, he lent the weight of his authority to that system of coercion and repression which enslaved Italy, desolated Germany with war, and drowned the Low Countries in blood. Philip II, with full approval of the Spanish nation, pursued the same policy in an even stricter spirit. He was powerfully assisted by two institutions in which the national character of Spain expressed itself, the Inquisition and the Society of Jesus. Of the former it is not needful to speak here. But we have to observe that the last great phenomenon of the Spanish Renaissance was Ignatius Loyola, who organized the militia by means of which the Church worked its Counter-Reformation. His motto. *Perinde ac cadaver,* expressed that recognition of absolutism which papacy and monarchy demanded for their consolidation. (*See* JESUS, SOCIETY OF and LOYOLA, ST. IGNATIUS OF.)

FRANCE

The logical order of an essay which attempts to show how Renaissance was correlated to Reformation and Counter-Reformation has necessitated the treatment of Italy, Germany and Spain in succession; for these three nations were the three main agents in the triple process to be analysed. It was due to their specific qualities, and to the diverse circumstances of their external development that the re-birth of Europe took this form of duplex action on the lines of intellectual and moral progress, followed by reaction against mental freedom. We have now to speak of France, which earliest absorbed the influence of the Italian revival, and of England which received it latest. The Renaissance may be said to have begun in France with Charles VIII.'s expedition to Naples, and to have continued until the extinction of the house of Valois. Louis XII. and Francis I. spent a considerable portion of their reigns in the attempt to secure possession of the Italian provinces they claimed. Henry II.'s queen was Catherine of the Medicean family; and her children, Charles IX. and Henry III., were Italianated Frenchmen. Thus the connection between France and Italy during the period 1494–1589 was continuous. The French passed to and fro across the Alps on military and peaceful expeditions. Italians came to France as courtiers, ambassadors, men of business, captains and artists. French society assumed a strong Italian colouring, nor were the manners of the court very different from those of an Italian city, except that

externally they remained ruder and less polished. The relation between the crown and its great feudatories, the military bias of the aristocracy, and the marked distinction between classes which survived from the middle ages, rendered France in many vital points unlike Italy. Yet the annals of that age, and the anecdotes retailed by Brantôme, prove that the royalty and nobility of France had been largely Italianized.

Architecture. — It is said that Louis XII. brought Fra Giocondo of Verona back with him to France and founded a school of architects. But we need not have recourse to this legend for the explanation of such Italian influences as were already noticeable in the Renaissance buildings on the Loire. Without determining the French style, Italian intercourse helped to stimulate its formation and development. There are students of the 15th century in France who resent this intrusion of the Italian Renaissance. But they forget that France was bound by inexorable laws of human evolution to obey the impulse which communicated itself to every form of art in Europe. In the school of Fontainebleau, under the patronage of Francis I., that Italian influence made itself distinctly felt; yet a true French manner had been already formed, which, when it was subsequently applied at Paris, preserved a marked national quality. The characteristic of the style developed by Bullant, De l'Orme and Lescot, in the royal or princely palaces of Chenonceaux, Chambord, Anet, Écouen, Fontainebleau, the Louvre and elsewhere is a blending of capricious fancy and inventive richness of decoration with purity of outline and a large sense of the beauty of extended masses. Beginning with the older castles of Touraine, and passing onward to the Tuileries, we trace the passage from the mediaeval fortress to the modern pleasure-house, and note how architecture obeyed the special demands of that new phenomenon of Renaissance civilization, the court. In the general distribution of parts these monumental buildings express the peculiar conditions which French society assumed under the influence of Francis I. and Diane de Poitiers. In details of execution and harmonic combinations they illustrate the precision, logic, lucidity and cheerful spirit of the national genius. Here, as in Lombardy, a feeling for serene beauty derived from the study of the antique has not interrupted the evolution of a style indigenous to France and eminently characteristic of the French temperament.

Painting and Sculpture. — During the reign of Francis I. several Italian painters of eminence visited France. Among these Del Rosso, Primaticcio, Del Sarto and Da Vinci are the most famous. But their example was not productive of a really great school of French painting. It was left for the Poussins and Claude Lorraine in the next century, acting under mingled Italian and Flemish influences, to embody the still active spirit of the classical revival. These three masters were the contemporaries of Corneille, and do not belong to the Renaissance period. Sculpture, on the contrary, in which art, as in architecture, the mediaeval French had been surpassed by no other people of Europe, was practised with originality and power in the reigns of Henry II. and Francis I. Ponzio and Cellini, who quitted Italy for France, found themselves outrivalled in their own sphere by Jean Goujon, Cousin and Pilon. The decorative sculpture of this epoch, whether combined with architecture or isolated in monumental statuary, ranks for grace and suavity with the best of Sansovino's. At the same time it is unmistakably inspired by a sense of beauty different from the Italian — more piquant and pointed, less languorous, more mannered perhaps, but with less of empty rhythmical effect. All this while the minor arts of enamelling, miniature, glass-painting, goldsmith's work, jewellery, engraving, tapestry, wood-carving, pottery, etc., were cultivated with a spontaneity and freedom which proved that France, in the middle point between Flanders and Italy, was able to use both influences without a sacrifice of native taste. It may indeed be said in general that what is true of France is likewise true of all countries which felt the artistic impulses of the Renaissance. Whether we regard Spain, the Netherlands, or Germany at this epoch, we find a national impress stamped upon the products of the plastic and the decorative arts, notwithstanding the prevalence of certain forms derived from the antique and Italy. It was only at a later period that the formalism of pseudo-classic pedantry reduced natural and natronal originality to a dead unanimity.

Literature. — French literature was quick to respond to Renaissance influences. De Comines, the historian of Charles VIII.'s expedition to Naples, differs from the earlier French chroniclers in his way of regarding the world of men and affairs. He has the perspicuity and analytical penetration of a Venetian ambassador. Villon, his contemporary, may rather be ranked, so far as artistic form and use of knowledge are concerned, with poets of the middle ages, and in particular with the Goliardi. But he is essentially modern in the vividness of his self-portraiture, and in what we are wont to call realism. Both De Comines and Villon indicate the entrance of a new quality into literature. The Rhétoriqueurs, while protracting mediaeval traditions by their use of allegory and complicated metrical systems, sought to improve the French language by introducing Latinisms. Thus the Revival of Learning began to affect the vernacular in the last years of the 15th century. Marot and his school reacted against this pedantry. The Renaissance displayed itself in their effort to purify the form and diction of poetry. But the decisive revolution was effected by Ronsard and his comrades of the Pléiade. It was their professed object to raise French to a level with the classics, and to acclimatize Italian species of verse. The humanistic movement led these learned writers to engraft the graces of the antique upon their native literature, and to refine it by emulating the lucidity of Petrarch. The result of their endeavour was immediately apparent in the new force added to French rhythm, the new pomp, richness, colouring and polish conferred upon poetic diction. French style gradually attained to fixity, and the alexandrine came to be recognized as the standard line in poetry. D'Aubigné's invective and Régnier's satire, at the close of the 16th century, are as modern as Voltaire's. Meanwhile the drama was emerging from the mediaeval mysteries; and the classical type, made popular by Garnier's genius, was elaborated, as in Italy, upon the model of Seneca and the canons of the three unities. The tradition thus formed was continued and fortified by the illustrious playwrights of the 17th century. Translation from Greek and Latin into French progressed rapidly at the commencement of this period. It was a marked characteristic of the Renaissance in France to appropriate the spoils of Greece and Rome for the profit of the mother tongue. Amyot's *Plutarch* and his *Daphnis and Chloe* rank amongst the most exquisite examples of beautiful French prose. Prose had now the charm of simplicity combined with grace. To mention Brantôme is to mention the most entertaining of gossips. To speak of Montaigne is to speak of the best as well as the first of essayists. In all the literary work which has been mentioned, the originality and freshness of the French genius are no less conspicuous than its saturation with the new learning and with Italian studies. But the greatest name of the epoch, the name which is synonymous with the Renaissance in France, has yet to be uttered. That, of course, is Rabelais. His incommensurable and indescribable masterpiece of mingled humour, wisdom, satire, erudition, indecency, profundity, levity, imagination, realism, reflects the whole age in its mirror of hyper-Aristophanic farce. What Ariosto is for Italy, Cervantes for Spain, Erasmus for Holland, Luther for Germany, Shakespeare for England, that is Rabelais for France. The Renaissance cannot be comprehended in its true character without familiarity with these six representatives of its manifold and many-sided inspiration.

The Reformation. — The French Renaissance, so rich on the side of arts and letters, was hardly less rich on the side of classical studies. The Revival of Learning has a noble muster-roll of names in France: Turnebus, the patriarch of Hellenistic studies, the Étiennes of Paris, equalling in numbers, industry and learning their Venetian rivals; the two Scaligers; impassioned Dolet; eloquent Muret; learned Cujas; terrible Calvin; Ramus, the intrepid antagonist of Aristotle; De Thou and De Bèze; ponderous Casaubon; brilliant young Saumaise. The distinguishing characteristics of French humanism are vivid intelligence, critical audacity and polemical acumen, perspicuity of exposition, learning directed in its applications by logical sense rather than by artistic ideals of

taste. Some of the names just mentioned remind us that in France, as in Germany and Holland, the Reformation was closely connected with the revival of learning. Humanism has never been in the narrow sense of that term Protestant; still less has it been strictly Catholic. In Italy it fostered a temper of mind decidedly averse to theological speculation and religious earnestness. In Holland and Germany with Erasmus, Reuchlin and Melanchthon it developed types of character, urbane, reflective, pointedly or gently critical, which left to themselves would not have plunged the north of Europe into the whirlpool of belligerent reform. Yet none the less was the new learning, through the open spirit of inquiry it nourished, its vindication of the private reason, its enthusiasm for republican antiquity, and its proud assertion of the rights of human independence, linked by a strong and subtle chain to that turbid revolt of the individual consciousness against spiritual despotism draped in fallacies and throned upon abuses. To this rebellion we give the name of Reformation. But while the necessities of antagonism to papal Rome made it assume at first the form of narrow and sectarian opposition, it marked in fact a vital struggle of the intellect towards truth and freedom, involving future results of scepticism and rationalistic audacity from which its earlier champions would have shrunk. It marked, moreover, in the condition of armed resistance against established authority which was forced upon it by the Counter-Reformation, a firm resolve to assert political liberty, leading in the course of time to a revolution with which the rebellious spirit of the Revival was sympathetic. This being the relation of humanism in general to reform, French learning in particular displayed such innovating boldness as threw many of its most conspicuous professors into the camp at war with Rome. Calvin, a French student of Picard origin, created the type of Protestantism to which the majority of French Huguenots adhered. This too was a moment at which philosophical seclusion was hardly possible. In a nation so tumultuously agitated one side or the other had to be adopted. Those of the French humanists who did not proclaim Huguenot opinions found themselves obliged with Muret to lend their talents to the Counter-Reformation, or to suffer persecution for heterodoxy like Dolet. The Church, terrified and infuriated by the progress of reform, suspected learning on its own account. To be an eminent scholar was to be accused of immorality, heresy and atheism in a single indictment; and the defence of weaker minds lay in joining the Jesuits as Heinsius was fain to do. France had already absorbed the earlier Renaissance in an Italianizing spirit before the Reformation made itself felt as a political actuality. This fact, together with the strong Italian bias of the Valois, serves to explain in some degree the reason why the Counter-Reformation entailed those fierce entangled civil wars, massacres of St. Bartholomew, murders of the Guises, regicides, treasons and empoisonments, that terminated with the compromise of Henry IV. It is no part of the present subject to analyse the political, religious and social interests of that struggle. The upshot was the triumph of the Counter-Reformation, and the establishment of its principle, absolutism, as the basis of French government. It was a French king who, when the nation had been reduced to order, uttered the famous word of absolutism, *"L'État,* c'est *moi."*

THE NETHERLANDS

The Renaissance in the Low Countries, as elsewhere, had its brilliant age of arts and letters. During the middle ages the wealthy free towns of Flanders flourished under conditions not dissimilar to those of the Italian republics. They raised miracles of architectural beauty, which were modified in the 15th and 16th centuries by characteristic elements of the new style. The Van Eycks, followed by Memling, Metsys, Mabuse, Lucas van Leyden, struck out a new path in the revival of painting and taught Europe the secret of oil-colouring. But it was reserved for the 17th century to witness the flower and fruit time of this powerful art in the work of Porbus, Rubens and Vandyck, in the Dutch schools of landscape and home-life, and in the unique masterpieces of Rembrandt. We have a right to connect this later period with the Renaissance, because the distracted state of the Netherlands during the 16th century suspended, while it could not extinguish, their aesthetic development. The various schools of the 17th century, moreover, are animated with the Renaissance spirit no less surely than the Florentine school of the 15th or the Venetian of the 16th. The animal vigour and carnal enjoyment of Rubens, the refined Italianizing beauty of Vandyck, the mystery of light and gloom on Rembrandt's panels, the love of nature in Ruysdael, Cuyp and Van Hooghe, with their luminously misty skies, silvery daylight and broad expanse of landscape, the interest in common life displayed by Ter Borch, Van Steen, Douw, Ostade and Teniers, the instinct for the beauty of animals in Potter, the vast sea spaces of Vanderveldt, the grasp on reality, the acute intuition into character in portraits, the scientific study of the world and man, the robust sympathy with natural appetites, which distinguish the whole art of the Low Countries, are a direct emanation from the Renaissance.

The vernacular in the Netherlands profited at first but little by the impulse which raised Italian, Spanish, French and English to the rank of classic languages. But humanism, first of all in its protagonist Erasmus, afterwards in the long list of critical scholars and editors, Lipsius, Heinsius and Grotius, in the printers, Elzevir and Plantin, developed itself from the centre of the Leyden university with massive energy, and proved that it was still a motive force of intellectual progress. In the fields of classical learning the students of the Low Countries broke new ground chiefly by methodical collection, classification and comprehensive criticism of previously accumulated stores. Their works were solid and substantial edifices, forming the substratum for future scholarship. In addition to this they brought a philosophy and scientific thoroughness to bear on studies which had been pursued in a more literary spirit. It would, however, be uncritical to pursue this subject further; for the encyclopaedic labours of the Dutch philologers belong to a period when the Renaissance was overpast. For the same reason it is inadmissible to do more than mention the name of Spinoza here.

The Netherlands became the battlefield of Reformation and Counter-Reformation in even a stricter sense than France. Here the antagonistic principles were plainly posed in the course of struggle against foreign despotism. The conflict ended in the assertion of political independence, as opposed to absolute dominion. Europe in large measure owes the modern ideal of political liberty to that spirit of stubborn resistance which broke the power of Spain. Recent history, and, in particular, the history of democracy, claims for its province the several stages whereby this principle was developed in England and America, and its outburst in the frenzy of the French Revolution. It is enough here to have alluded to the part played by the Low Countries in the genesis of a motive force which may be described as the last manifestation of the Renaissance striving after self-emancipation.

ENGLAND

The insular position of England combined with the nature of the English has allowed the country to feel the vibration of European movements later and with less of shock than the continental nations. Before a wave of progress has reached its shores there has been the opportunity of watching it as spectators, and of considering how to receive it. Revolutions have passed from the tumultuous stages of their origin into some settled and recognizable state before we have been called upon to cope with them. It was thus that England took the influences of the Renaissance and Reformation simultaneously, and almost at the same time found herself engaged in that struggle with the Counter-Reformation which, crowned by the defeat of the Spanish Armada, stimulated the sense of nationality and developed the naval forces of the race. Both Renaissance and Reformation had been anticipated by at least a century in England. Chaucer's poetry, which owed so much to Italian examples, gave an early foretaste of the former. Wycliffe's teaching was a vital moment in the latter. But the French wars, the Wars of the Roses and the persecution of the Lollards deferred the coming of the new age; and the year 1536, when Henry VIII. passed the Act of Supremacy through parliament, may be fixed as the date when England entered definitely upon a career of intellectual development abreast

with the foremost nations of the continent. The circumstances just now insisted on explain the specific character of the English Renaissance. The Reformation had been adopted by consent of the king, lords and commons; and this change in the state religion, though it was not confirmed without reaction, agitation and bloodshed, cost the nation comparatively little disturbance. Humanism, before it affected the bulk of the English people, had already permeated Italian and French literature. Classical erudition had been adapted to the needs of modern thought. The hard work of collecting, printing, annotating and translating Greek and Latin authors had been accomplished. The masterpieces of antiquity had been interpreted and made intelligible. Much of the learning popularized by the poets and dramatists was derived at second hand from modern literature. This does not mean that England was deficient in ripe and sound scholars. More, Colet, Ascham, Cheke, Camden were men whose familiarity with the classics was both intimate and easy. Public schools and universities conformed to the modern methods of study; nor were there wanting opportunities for youths of humble origin to obtain an education which placed them on a level with Italian scholars. The single case of Ben Jonson sufficiently proves this. Yet learning did not at this epoch become a marked speciality in England. There was no class corresponding to the humanists. It should also be remembered that the best works of Italian literature were introduced into Great Britain together with the classics. Phaer's *Virgil,* Chapman's *Homer,* Harrington's *Orlando,* Marlowe's *Hero and Leander,* Fairfax's *Jerusalem Delivered,* North's *Plutarch,* Hoby's *Courtier* —to mention only a few examples — placed English readers simultaneously in possession of the most eminent and representative works of Greece, Rome and Italy. At the same time Spanish influences reached them through the imitators of Guevara and the dramatists; French influences in the versions of romances; German influences in popular translations of the Faust legend, *Eulenspiegel,* and similar productions. The authorized versions of the Bible had also been recently given to the people — so that almost at the same period of time England obtained in the vernacular an extensive library of ancient and modern authors. This was a privilege enjoyed in like measure by no other nation. It sufficiently accounts for the richness and variety of Elizabethan literature, and for the enthusiasm with which the English language was cultivated.

Art, Letters, and the Drama. — Speaking strictly, England borrowed little in the region of the arts from other nations, and developed still less that was original. What is called Jacobean architecture marks indeed an interesting stage in the transition from the Gothic style. But, compared with Italian, French, Spanish, German and Flemish work of a like period, it is both timid and dry. Sculpture was represented in London for a brief space by Torrigiani; painting by Holbein and Antonio More; music by Italians and Frenchmen of the Chapel Royal. But no Englishman rose to European eminence in these departments. With literature the case was very different. Wyat and Surrey began by engrafting the forms and graces of Italian poetry upon the native stock. They introduced the sonnet and blank verse. Sidney followed with the sestine and terza rima and with various experiments in classic metres, none of which took root on English soil. The translators handled the octave stanza. Marlowe gave new vigour to the couplet. The first period of the English Renaissance was one of imitation and assimilation. Academies after the Italian type were founded. Tragedies in the style of Seneca, rivalling Italian and French dramas of the epoch, were produced. Attempts to Latinize ancestral rhythms, similar to those which had failed in Italy and France, were made. Tentative essays in criticisms and dissertations on the art of poetry abounded. It seemed as though the Renaissance ran a risk of being throttled in its cradle by superfluity of foreign and pedantic nutriment. But the natural vigour of the English genius resisted influences alien to itself, and showed a robust capacity for digesting the varied diet offered to it. As there was nothing despotic in the temper of the ruling classes, nothing oppressive in English culture, the literature of that age evolved itself freely from the people, It was under these conditions that Spenser gave his romantic epic to the world, a poem which derived its allegory from the middle ages, its decorative richness from the Italian Renaissance, its sweetness, purity, harmony and imaginative splendour from the most poetic nation of the modern world. Under the same conditions, the Elizabethan drama, which in its totality is the real exponent of the English Renaissance, came into existence. This drama very early freed itself from the pseudo-classic mannerism which imposed on taste in Italy and France. Depicting feudalism in the vivid colours of an age at war with feudal institutions, breathing into antique histories the breath of actual life, embracing the romance of Italy and Spain, the mysteries of German legend, the fictions of poetic fancy and the facts of daily life, humours of the moment and abstractions of philosophical speculation, in one homogeneous amalgam instinct with intense vitality, this extraordinary birth of time, with Shakespeare for the master of all ages, left a monument of the Renaissance unrivalled for pure creative power by any other product of that epoch. To complete the sketch, we must set Bacon, the expositor of modern scientific method, beside Spenser and Shakespeare, as the third representative of the Renaissance in England. Nor should Raleigh, Drake, Hawkins, the semi-buccaneer explorers of the ocean, be omitted. They, following the lead of Portuguese and Spaniards, combating the Counter-Reformation on the seas, opened for England her career of colonization and plantation. All this while the political policy of Tudors and Stuarts tended towards monarchial absolutism, while the .Reformation in England, modified by contact with the Low Countries during their struggles, was narrowing into strict reactionary intolerance. Puritanism indicated a revolt of the religious conscience of the nation against the arts and manners of the Renaissance, against the encroachments of belligerent Catholicism, against the corrupt and Italianated court of James I., against the absolutist pretensions of his son Charles. In its final manifestation during the Commonwealth, Puritanism won a transient victory over the mundane forces of both Reformation and Renaissance, as these had taken shape in England. It also secured the eventual triumph of constitutional independence. Milton, the greatest humanistic poet of the English race, lent his pen and moral energies during the best years of his life to securing that principle on which modern political systems at present rest. Thus the geographical isolation of England, and the comparatively late adoption by the English of matured Italian and German influences, give peculiar complexity to the phenomena of Reformation and Renaissance simultaneously developed on our island. The period of our history between 1536 and 1642 shows how difficult it is to separate these two factors in the re-birth of Europe, both of which contributed so powerfully to the formation of modern English nationality.

THE NEW EUROPE

It has been impossible to avoid an air of superficiality and the repetition of facts known to every schoolboy in this sketch of so complicated a subject as the Renaissance — embracing many nations, a great variety of topics, and an indefinite period of time. Yet no other treatment was possible upon the lines laid down at the outset, where it was explained why the term Renaissance cannot now be confined to the Revival of Learning and the effect of antique studies upon literary and artistic ideals. The purpose of this article has been to show that, while the Renaissance implied a new way of regarding the material world and human nature, a new conception of man's destiny and duties on this planet, a new culture and new intellectual perceptions penetrating every sphere of thought and energy, it also involved new reciprocal relations between the members of the European group of nations. The Renaissance closed the middle ages and opened the modern era — not merely because the mental and moral ideas which then sprang into activity and owed their force in large measure to the revival of classical learning were opposed to mediaeval modes of thinking and feeling, but also because the political and international relations specific to it as an age were at variance with fundamental theories of the past. Instead of empire and church, the sun and moon of the mediaeval system, a federation of peoples, separate in type, and divergent in interests, yet bound

together by common tendencies, common culture and common effortscame into existence. For obedience to central authority was substituted balance of power. Henceforth the hegemony of Europe attached to no crown, imperial or papal, but to the nation which was capable of winning it, in the spiritual region by mental ascendancy, and in the temporal by force.

That this is the right way of regarding the subject appears from the events of the first two decades of the 16th century, those years in which the humanistic revival attained its highest point in Italy. Luther published his thesis in 1517, 64 years after the fall of Constantinople, 23 years after the expedition of Charles VIII. to Naples, ten years before the sack of Rome, at a moment when France, Spain and England had felt the influences of Italian culture but feebly. From that date forward two parties wrestled for supremacy in Europe, to which may be given the familiar names of Liberalism and Conservatism, the party of progress and the party of established institutions. The triumph of the former was most signal among the Teutonic peoples. The Latin races championed by Spain and supported by the papacy fought the battle of the latter, and succeeded for a time in rolling back the tide of revolutionary conquest. Meanwhile that liberal culture which had been created for Europe by the Italians before the contest of the Reformation began continued to spread, although it was stifled in Italy and Spain, retarded in France and the Low Countries, well-nigh extirpated by wars in Germany and diverted from its course in England by the countermovement of Puritanism. The *autos da fé* of Seville and Madrid, the flames to which Bruno, Dolet and Paleario were flung, the dungeon of Campanella and the seclusion of Galileo, the massacre of St. Bartholomew and the faggots of Smithfield, the desolated plains of Germany and the cruelties of Alva in the Netherlands, disillusioned Europe of those golden dreams which had arisen in the earlier days of humanism, and which had been so pleasantly indulged by Rabelais. In truth the Renaissance was ruled by no *Astraea redux* but rather by *a* severe spirit which brought no peace but a sword, reminding men of sternest duties, testing what of moral force and tenacity was in them, compelling them to strike for the old order or the new, suffering no lukewarm halting between two opinions. That, in spite of retardation and retrogression, the old order of ideas should have yielded to the new all over Europe — that science should have won firm standing-ground and political liberty should have struggled through those birth-throes of its origin — was in the nature of things. Had this not been, the Renaissance or re-birth of Europe would be a term without a meaning. (J. A. S.)

While Symonds' article on the Renaissance, originally contributed to the 9th edition of the *Encyclopædia Britannica* remains the classical exposition of a certain view of the subject, more recent research has brought out other aspects of the matter. It is noteworthy, however, that in some important points the very latest investigators have returned to Symonds' conception of the Renaissance, from which historians of the generation immediately following him had departed.

Our continually growing knowledge of the middle ages has thrown the Renaissance into a very different perspective from that in which it was once viewed. Less and less are the centuries preceding the 15th seen as the "Dark Ages" in contrast to the sudden sunrise of modern times. Indeed, many scholars now speak of a Carolingian Renaissance in the 8th century, an Ottonian Renaissance in the 10th, and of the Renaissance of the 12th century, in order to emphasize the constant stream of light and progress throughout the millennium once regarded as a long night of gloom and decadence. On the other hand, many scholars have emphasized even more than did Symonds the extreme gradualness of the efflorescence of the Italian Renaissance and the long persistence in it of mediaeval and Germanic elements. The extreme position is taken by Mr. Henry O. Taylor, who is so impressed by the slowness of the transition from mediaeval to modern times that he would abolish the term "Renaissance" altogether. This proposal, however, has commended itself to few other scholars; there *was* a re-birth of the human mind in the 11th century, though it was not so sudden and decisive as once thought.

In another way our view of the Renaissance has been greatly modified by the economic historians who have stressed the material antecedents of the great political and intellectual movements of the 14th, 15th and 16th centuries. Symonds, like nearly all his contemporaries, wrote almost as if the change in the mental habit of the race were a first cause, unexplained by any alteration in social conditions. But it is now generally accepted that the intellectual change was but the natural result of material conditions altered by the growth of wealth, of commerce, and of city communities. The humanists and artists were dwellers in the cities and in the marts of trade; their patrons were largely found in the newly powerful bourgeoisie of the Italian and German cities. Of course the Renaissance had its intellectual as well as its material antecedents; it was produced by the happy creation in the commercial revolution of a wealthy and leisured class just at a time when discoveries and inventions were thrilling the mind of Western Europe with interest and curiosity. It was no accident that individualism, humanism, and Italian painting attained their majority in the age which saw the invention of printing and the great geographical discoveries of Diaz, of Vasco da Gama, and of Columbus.

Of all the positions taken by Symonds that most subject to attack has been his assertion of the close connection and similar purpose of the Renaissance and Reformation. Like most historians of the 19th century, Symonds regarded them both as liberal movements, emancipations of reason so nearly alike that the Reformation might be called "the Teutonic Renaissance." Just as he was writing, however, Friedrich Nietzsche, basing his opinion on Janssen's *Geschichte des deutschen Volkes seit dem Ausgang des Mittelalters*, which represented the Reformation as a blight on German Catholic civilization, proclaimed that "the Reformation was a reaction of backward minds against the Italian Renaissance": and this view gained ground until it was adopted by Catholic historians like Lord Acton, Protestant historians like Ernst Troeltsch, and generally by the majority of scholars. They have pointed out that the humanists and Reformers came to blows, that the spirit of the Renaissance was largely secular and that of the Reformation intensely religious, that the former was tolerant and often indifferent and sceptical and that the latter was usually intolerant, devout, and sometimes superstitious, that the humanists were aristocratic and the Reformers democratic in method, and that Puritanism proved hostile to and often destructive of the artistic and pleasure-seeking interests of the Renaissance. In criticism of this view, however, it has been contended that the Renaissance was not, any more than the Reformation, consciously progressive; rather did both movements find their ideal in the past, the one in the golden age of Rome and the other in the primitive age of Christianity. It has been further shown that the humanists did little in principle to emancipate the reason from authority; they were closely bound by their own authorities in the classical poets and orators, and could only attack the schoolmen on the basis of the ancient pagans as the Reformers attacked them from the standpoint of the ancient Fathers. In conclusion one may say that neither movement was a conscious appeal to reason or an intentional step forward and away from the past, but that each accomplished, undesignedly, a great work of emancipation and that each created new cultural values.

BIBLIOGRAPHY.—The special articles on the several arts and literatures of modern Europe, and on the biographies of the great men mentioned in this essay, will give the details of necessity here omitted. Of general works, with bibliographies, may be mentioned Jakob Burckhardt, *Die Cultur der Renatssance in Italien*, called by Lord Acton, "the most penetrating and subtle treatise on the history of civilization that exists in literature" (Leipzig, 1st ed. 1860; 20th ed., revised by L. Geiger, 1919; Eng. trans. by S. G. C. Middlemore, 1875); W. H. Pater, *Studies in the History of the Renaissance* (1873); *J. A.* Symonds, *The Renaissance in Italy* (1875–88); *Cambridge Modern History*, vol. 1, "The Renaissance" (1902); A. Tilley, *The Literature of the French Renaissance* (1904); J. E. (P. S.)

RENAISSANCE ARCHITECTURE. The Renaissance style of architecture originated in Florence, Italy, during the early 15th century and from there spread throughout most of the Italian peninsula; by the 16th century the new style pervaded almost all of Europe, gradually replacing the Gothic style of the middle ages. The name Renaissance *(rinascimento* in Italian) dates from the period itself, whose goal was the rebirth or re-creation of ancient classic culture.

In architecture there was a revival of classic forms and ornament, such as the column and round arch, the tunnel vault and dome; but from this classic vocabulary the Renaissance architects made a completely original architecture.

This article is organized as follows:

The periods of European architecture before the Renaissance are discussed in BYZANTINE ARCHITECTURE; ROMANESQUE ARCHITECTURE; and GOTHIC ARCHITECTURE. European architecture after the Renaissance is discussed in BAROQUE ARCHITECTURE and MODERN ARCHITECTURE. The classic antecedents of Renaissance architecture are treated in GREEK ARCHITECTURE and ROMAN ARCHITECTURE. *See* also ARCHITECTURE.

I. INTRODUCTION

The Renaissance knowledge of the classic style was derived chiefly from two sources: (1) the ruins of ancient classic buildings, particularly in Italy, but some in France and Spain, and (2) the treatise, *De architectura,* by the ancient Roman architect Vitruvius from the late 1st century B.C. The theory of Vitruvius was drawn to a great extent from Hellenistic Greek architectural theory, although this was not realized during the Renaissance and it was assumed that the theory was purely Roman. As a result the Renaissance architects were often disturbed by the apparent discrepancies between Vitruvius and the actual Roman ruins.

The Orders.—The Renaissance architects considered the classic orders one of the basic elements of their architecture; the orders were organized on a system of proportions, and proportion was the essence of their theory of beauty. *(See* ORDER.) During the Renaissance five orders were used, the Tuscan. Doric, Ionic, Corinthian and Composite, but various ones were prevalent in the different periods of the Renaissance. For example. the ornate, decorative quality of the Corinthian order was embraced during the early Renaissance. while the masculine simplicity and strength of the Doric was preferred during the Italian High Renaissance. Following ancient Roman architecture (*e.g.,* the Colosseum or the Theatre of Marcellus) Renaissance architects often superimposed the orders, that is, used a different order for each of the several stories of a building, commencing with the heavier, stronger Tuscan or Doric order below, then rising through the lighter, more decorative Ionic, Corinthian and Composite.

For all the Renaissance arts proportion tended to be the most important predetermining factor of beauty. The great Italian humanist and architect, Leon Battista Alberti, defined beauty in architecture as "a Harmony of all the Parts in whatsoever Subject it appears, fitted together with such Proportion and Connection, that nothing could be added, diminished or altered, but for the Worse" (*Ten Books on Architecture,* trans. by J. Leoni, book vi, ch. 2, 1755).

The Renaissance architect worked from a fixed unit of proportion, the module, which was usually half the diameter of the column of the order and which determined the size and location of the various parts of his elevation or plan. There was even a relationship between architectural proportions and the leading Renaissance device of perspective (*q.v.*); the Italian painter Piero della Francesca said that perspective represented objects seen from afar "in proportion according to their respective distance." In fact. it was an Italian Renaissance architect. Filippo Brunelleschi, who apparently was the first to formulate perspective. Many Renaissance architects were as concerned with perspective as the painters were, for most Renaissance architecture was meant to be seen from a fixed visual viewpoint, like a painting in perspective, and not from a moving viewpoint as were baroque and modern architecture.

Architecture as a Liberal Art.—It was during the Renaissance that architecture was raised to the level of a liberal art (or a fine art), in part because of the interest in proportion. During the preceding middle ages, architecture, along with the other arts, was simply a mechanical art and the artists and architects were basically anonymous craftsmen, their anonymity only occasionally dispelled by the fortunate preservation of building accounts. For the Renaissance the varying systems of proportion were dependent on a knowledge of geometry. Architecture became the materialization in space of the principles of geometry and, thereby, an equal of geometry, which had been a liberal art during the middle ages.

Renaissance architecture was produced no longer by craftsmen but by educated men of some social standing. In Italy during the 15th and 16th centuries the architect gradually acquired this social standing through his knowledge and education which were concerned with the theory and principles of design more than with the craft of building. The Renaissance architect was, therefore, known as an individual. His life and his ideas have been preserved, and he is not merely another name in a building record.

Architectural Theory.—The Renaissance was the great moment in the history of architecture for the expression of architectural theory. Inspired by the rediscovery or re-evaluation of the ancient Roman treatise by Vitruvius, many architects recorded their theories of architecture; some were preserved in manuscript, (*e.g.,* those of the architects Francesco di Giorgio and Antonio Filarete), but most were published. In the middle of the 15th century the humanist and architect Alberti wrote his treatise, *De re aedificatoria* (published 1485), modeled on Vitruvius. However, it was during the last three-quarters of the 16th century, the period of Mannerism, that architectural theory flourished. The Italians Serlio, Vignola and Palladio published famous books on architecture at that time. Elsewhere, works were published by the Frenchmen Androuet du Cerceau, Delorme and Jean Bullant; the Fleming Vredeman de Vries; the German Wendel Dietterlin; and John Shute in England.

II. ITALY

Renaissance architecture commenced in Italy about 1420 and flourished until the end of the 16th century, when it was gradually superseded by the baroque style. In Italy there were three principal periods in the development of the Renaissance: (1) the early Renaissance, from the appearance of the new style early in the 15th century to the end of the century; (2) the High Renaissance, approximately the first quarter of the 16th century; and (3) mannerism. the remaining portion of the 16th century.

The Renaissance began in Italy, where there was always a residue of classic feeling in architecture. A Gothic building such as the Loggia dei Lanzi in Florence continued to use the large round arch instead of the usual Gothic pointed arch. and preserved the simplicity and monumentality of classic architecture. The Renaissance might have been expected to appear first in the city of Rome, where there was the greatest quantity of ancient Roman

ruins, but during the 14th and early 15th centuries, when the Italians were impelled to renew classicism, the political situation at Rome was very unfavourable for artistic endeavour. This was the time of a schism in the church, with the papacy located at Avignon in south France and no central power at Rome. Florence, however, under the leadership of the Medici family, was economically prosperous and politically stable.

A. Early Renaissance

In 1401 a competition was held between sculptors and goldsmiths to design a pair of doors for the old baptistery at Florence. The sculptor Ghiberti won, and a losing goldsmith, Filippo Brunelleschi, resolving to be the leader in one of the arts, then turned to the study of architecture. Brunelleschi spent the period between 1402 and 1418 alternately in Florence and Rome. During this time he studied mathematics intensively and formulated linear perspective, which was to become a basic element of Renaissance art. At the same time Brunelleschi investigated ancient Roman architecture and acquired the knowledge of classic architecture and ornament, which he used as a foundation for Renaissance architecture. His great opportunity came in 1418 with the competition for the completion of the duomo, or cathedral, of Florence. The medieval architects had intended a great dome over the crossing of the cathedral, but it had never been created, and no one knew how to accomplish it. Winning the competition, Brunelleschi began the great dome in 1420 (the finishing touches were applied in 1467, after Brunelleschi's death). The Florentine dome is really not in the Renaissance style since it was built with rib construction and a pointed arch form which were medieval. But the dome was raised on a drum, which the medieval architects had not intended; the idea of a dome being made more prominent by the added stature of a drum became characteristic of the Renaissance style. (See Dome.)

While he was erecting the dome, Brunelleschi produced in Florence other notable examples of the Renaissance style. The loggia of the Ospedale degli Innocenti (1419–51) was the first building in the Renaissance manner; a very graceful arcade was designed with Composite columns, and windows with classic triangular pediments were regularly spaced above each of the arches. This style was more fully exploited in the church of S. Lorenzo (1419 to c. 1470). Using the traditional basilica (*q.v.*) plan (*i.e.*, a long rectangle with the sanctuary at one end], the plan and elevations were organized on a system of proportions with the. height of the nave, or central aisle, equal to twice its width. All the ornament is classic with Corinthian columns, pilasters and classic moldings. Brunelleschi used almost exclusively the Corinthian order with the decorative elements cut in a very crisp manner. All the moldings, door and window frames, and orders are of a soft blue-gray stone (pietm serena) contrasted against a light stucco wall. The ornamental features have very little projection, being rather lines on a surface. Colour was used in Florentine architecture as a contrast to stress the linear relationships rather than for over-all patternistic use as in north Italian architecture.

The traditional plan for medieval churches was the Latin cross plan, as at S. Lorenzo, with one arm of the cross longer than the others so as to form the nave or main body of the church. During the middle ages this cross plan was considered a symbolic reference to the cross of Christ.

During the Renaissance the ideal church plan tended to be centralized, that is, it was symmetrical about a central point, as is a circle, a square or a Greek cross which has four equal arms. Many Renaissance architects came to believe that the circle was the most perfect geometrical form and, therefore, most appropriate in dedication to a perfect God. Brunelleschi also worked with the central plan. In the Pazzi chapel (1430–42), set down in the medieval cloister of Sta. Croce at Florence, the plan approaches the central type. On the interior it is actually a rectangle, slightly wider than it is deep; at its rear is a square bay for the sanctuary and at the front is a porch. There are three domes, a large one over the centre of the chapel, a small one over the sanctuary and a small one over the centre of the porch on the exterior. Its plan, but not its interior space, resembles a Greek cross. On the exterior the large dome is covered by a conical roof with a lantern at the top. The porch has a horizontal entablature supported by six Corinthian columns but broken in the centre by a semicircular arch which centralizes the composition, repeats the shape of the dome in the porch behind it and gives a lift to the horizontal façade. Above the columns and hiding the tunnel vault over the porch is a lovely paneled wall comparted by coupled Corinthian pilasters. The architecture is very ornate and decorative with medallions of cherub heads on the entablature and a wave pattern (the ancient strigil pattern) on the upper entablature.

Soon after the commencement of the Pazzi chapel, Brunelleschi began a true central plan church, that of Sta. Maria degli Angeli (begun 1434) at Florence, which was never completed. It was very important because it was the first central plan church of the Renaissance, the type of plan which dominates Renaissance thinking. The plan is an octagon on the interior and 16 sided on the exterior with a dome probably intended to cover the centre.

One of the outstanding examples of secular architecture was the Medici palace (1444–59) at Florence by Michelozzo Michelozzi, a follower of Brunelleschi. Created for Cosimo de' Medici, the great political leader and art patron of Florence. the palace had extensive additions in the 17th century. Arranged around a central court, the traditional Florentine palace plan, the Medici palace (now Medici-Riccardi palace) is a tremendous block on the exterior.

Medieval Florentine palaces were built of great rusticated blocks of stone, as if they had just been hacked out of the quarry, giving the impression of fortification, a desirable effect in that tumultuous time. With the Renaissance some fundamental changes appeared. Michelozzo crowned his palace with a massive horizontal cornice in the classic style and regularized the window and entrance openings. Even the rustication of the stonework was differentiated in each of the three stories. The ground floor has the usual heavy rustication; the second story is marked by drafted stonework with smooth blocks outlined by incised lines; and the third story has smooth ashlar stonework with no indications of the blocks. Unlike medieval patternistic rustication, the rustication of the Renaissance, while carefully distinguished between the stories, set up a logical relationship among them.

This Renaissance treatment of a palace façade was carried further in the Palazzo Rucellai (1447–51) at Florence following the design of the great humanist and architect Leon Battista Alberti. For the first time during the Renaissance Alberti applied classic orders to a palace elevation, using pilasters of the different orders superimposed on the three stories, so that there was another relationship established among the differentiated stories, from the short, strong Tuscan pilaster on the ground floor to the tall, decorative Corinthian at the top. About 1450 Alberti began a book on architecture, De re aedificatoria, printed in 1485, but with numerous later editions and translations. The Italian treatise was obviously modeled upon the ancient Roman one of Vitruvius, even to its organization into ten books. For Alberti the beauty of architecture consisted of a harmonious relationship among the parts, with ornament, including the classic orders, being auxiliary to the proportion.

The culmination of Alberti's style is seen in two churches at Mantua. The earlier, S. Sebastiano (begun 1460, never fully completed), was built on a Greek cross plan and was intended to have in its first design an ancient temple front of six pilasters and a dominating triangular pediment. Even more important was Alberti's other church at Mantua, S. Andrea (begun 1470, completed in the 18th century). Both in plan and interior elevation this church was very influential on later architecture. The plan is a Latin cross, with one long arm for the nave flanked by side chapels, but the crossing at the eastern end was treated almost as if it were of a central plan with the nave added to it. This plan became a favourite for churches of the late 16th and early 17th century. The façade is of square proportion, with a wide bay at the centre twice the width of each of the side bays. The interior elevation was organized on this same alternating system, the so-called "rhythmic bay" which was to be popularized in the early

16th century by the architect Bramante. As a result of this system there is a close correspondence between the interior and exterior composition of S. Andrea.

From Florence the early Renaissance style spread gradually over Italy, becoming prevalent in the second half of the 15th century. In the architecture of north Italy there was a greater interest in pattern and colour. Colour was emphasized by the use of variegated marble inlays, as in the facade of the Church of the Certosa at Pavia (begun 1491) or in most Venetian architecture. The favourite building material of north Italy was brick with terracotta trim and decoration with which a pattern of light and dark was created over the entire building. On occasions when stone was used, as at the Palazzo Bevilacqua in Bologna (1479–84), the blocks were cut with facets forming a diamond pattern on the facade. This was actually a decorative treatment of rustication. Even the classic orders were affected by this decorative approach. Classic pilasters often had panels of candelabra and arabesque decoration in delicate relief on the surfaces of their shafts; the lower third of a column was often carved with relief sculpture. Florentine artists such as Filarete with his project for the Ospedale Maggiore at Milan (begun 1457) brought to Lombardy in northern Italy classic decoration and a slight knowledge of Renaissance architecture.

From Lombardy the style was transferred to Venice by such Lombard architects as Pietro Lombardo and Mauro Coducci. The church of Sta. Maria dei Miracoli (1481–89) at Venice with its facade of coloured marble revetment is a typical example of Lombardo's work. The Venetian palace, such as the Palazzo Corner-Spinelli (late 15th century) and Palazzo Vendramin-Calergi (1501–09), both of which are by Coducci, with large and numerous windows, was more open than the palaces of central Italy.

At Rome in the second half of the 15th century there were several notable Renaissance palaces, principally derived from the style of Alberti, who spent extensive periods in Rome as a member of the papal court. The Palazzo Venezia (1455–91) has a rather medieval exterior, but set within the palace is a characteristically Renaissance court (1468–71), of which only two sides forming an angle were completed. It has been suggested without definite proof that Alberti may have furnished the design for this court; it at least reveals his influence in its full understanding of the classic style. The court consists of two stories of semicircular arches supported by piers on which are attached superimposed classic half columns, Tuscan below and Ionic above. The model for this arcade is the ancient Colosseum (*q.v.*) of Rome. The sense of mass created by the heavy piers contrasts with the lighter effect of the early Renaissance court typical of Florence, which has arches supported on columns. The Palazzo della Cancelleria (1485–1511) shows its dependence upon Alberti's style in its facade, which resembles in part his Palazzo Rucellai in Florence. The lower story simply has drafted stonework, but the two upper stories have rather flat Corinthian pilasters as well as the drafted stone. Unlike the Rucellai palace the bays composed by the pilasters alternate wide and narrow, but this alternation had been used by Alberti already in S. Andrea at Mantua. Alberti's influence is also visible in the facades of the churches of S. Agostino (1479–83) and Sta. Maria del Popolo (1472–77) at Rome.

These examples of the early Renaissance in Rome were rapidly approaching the simplicity, monumentality and massiveness of the High Renaissance of the early 16th century. The architect Donato Bramante, who was to create this new style, was active in Lombardy in north Italy, but his work in Milan, as at Sta. Maria presso S. Satiro (about 1480–86), was still completely in the Lombard early Renaissance manner. However, he was in contact at this time with the great Florentine artist Leonardo da Vinci, who was active at the Milanese court. Leonardo was then considering the concept of the central plan church and filling his notebooks with sketches of such plans, which Bramante must have studied. When Bramante moved to Rome at the very end of the 15th century, his study of ancient ruins combined with the ideas of Leonardo and the growing classicism of Roman early Renaissance architecture resulted in the flourishing of the High Renaissance.

B. High Renaissance

High Renaissance architecture first appeared at Rome in the work of Donato Bramante at the beginning of the 16th century. The period was a very brief one, centred almost exclusively in the city of Rome; it ended with the political and religious tensions that shook Europe during the third decade of the century, culminating in the disastrous sack of Rome in 1527 and the siege of Florence in 1529. The High Renaissance was a period of harmony and balance in all the arts, perhaps the most classic moment in this respect since the 5th century B.C. in Greece. It was an idealistic age in which individual characteristics or idiosyncrasies tended to be eliminated. As a result, although the architects are known as individuals, it is sometimes difficult to identify on a stylistic basis the particular architect of a High Renaissance building. The problem of attribution is further complicated by the fact that the style was confined to a small group of architects centring around Bramante in Rome.

Political and cultural leadership shifted from Florence to Rome, particularly because of a group of powerful popes who were interested in developing the papacy as a secular power. The greatest of all was Julius II (1503–13), who was likewise a fabulous patron of the arts. Almost all the leading Florentine and other Italian artists were attracted to Rome. With the exception of Giulio Romano none of the important artists active in Rome at this time were Roman by birth.

Donato Bramante, the leader of this new manner, had already acquired an architectural reputation at Milan. Almost immediately after his arrival in Rome in 1499, there was an amazing change in Bramante's work, as he became the exemplar of the High Renaissance style and lost his Lombard early Renaissance qualities. The Tempietto (1502), or small chapel, next to S. Pietro in Montorio typifies the new style. Erected on the supposed site of the martyrdom of St. Peter, the Tempietto is circular in plan with a colonnade of 16 columns surrounding a small cella. The chapel was meant to stand in the centre of a circular court which was likewise to be surrounded by a colonnade, so that the whole structure was to be self-contained and centralized. The enclosing circular court has never been erected. The ultimate inspiration of the Tempietto was a Roman circular temple, like the temples of Vesta at Rome or Tivoli, but so many notable changes were made that the Renaissance chapel was an original creation. On the exterior it was organized in two stories. the Doric colonnade forming the first story. Above is a semicircular dome raised high on a drum. The present large finial on the dome is of a later date and destroys some of the simplicity of the massing. Niches cut into the wall of the drum help to emphasize the solidity and strength of the whole, as does the heavy Doric order that Bramante was so fond of, in contrast to Brunelleschi who had a predilection for the ornate Corinthian. The monument is very simple, harmonious and comprehensible.

Several churches by other architects present the same qualities as the Tempietto on a larger physical scale. The church of Sta. Maria della Consolazione (1508–34) at Todi by a minor architect, Cola da Caprarola, is likewise centralized in plan, being square with a semicircular or polygonal apse opening off each side. The mass is built up of simple geometric forms, with a cube at the centre surrounded by half cylinders and capped above by the cylinder of a drum and a hemispherical dome. The Florentine architect. Antonio da Sangallo the elder, influenced by Bramante, created his church of S. Biagio at Montepulciano (1518–45) on a Greek cross plan. On the facade in the two recesses of the arms of the cross were to rise two towers, the right one never completed. Otherwise the massing is similar to that of Todi with dome and drum above. All the moldings and ornamental elements were carved with strong projection, so that on the interior heavy Roman arches, with deep coffers containing rosettes, define the tunnel vaults rising over the arms of the church. The sense of solid yet harmonious mass is enhanced by the travertine stone of which it is built.

Sangallo's church at Montepulciano reflects Bramante's greatest undertaking, the rebuilding of S. Pietro in Vaticano at Rome.

Early in 1505 Pope Julius II began to consider the question of a tomb for himself appropriate to his idea of the power and nobility of his position. The sculptor Michelangelo soon presented a great project for a freestanding tomb, but such a monument required a proper setting. The Renaissance biographer Vasari claimed that the question of an appropriate location for this projected tomb brought to the pope's mind the idea of rebuilding St. Peter's, which was in very poor condition. Bramante, therefore, prepared plans for a monumental church late in 1505, and in April 1j06 the foundation stone was laid. The projected church was a Greek cross in plan, with towers at the four corners and over the crossing a tremendous dome. inspired by that of the ancient Roman Pantheon but raised in this case on a drum. In elevation there was a very careful definition of all the parts of the church, so that one could visualize the plan from the composition of the elements of the elevation At his death in 1514 Bramante had completed only the four main piers which were to support the dome. but these piers determined the manner in which later architects attempted the completion of the church.

As important as the central plan churches of this period were several notable secular buildings. At the papal palace of the Vatican next to St. Peter's, Bramante added two important features. The great Belvedere court (begun 1503) was planned to bring together the two disparate elements of the older palace attached to the church and the Belvedere villa of Innocent VIII on the hill above the palace. The new court was terraced up the hillside on three levels joined by monumental stairs. It was enclosed on the two long sides by arcaded loggias with superimposed orders. This large court was completed in the latter 16th century with some minor changes. and in 1587 the whole concept was destroyed by the building of the present Vatican library across the centre of the court. Just before his death Bramante also began a series of superimposed loggias attached to the face of the old Vatican palace looking out over the city and river. Completed by Raphael, there are two superimposed arcades with Tuscan and Ionic orders and a colonnade with Composite columns.

The largest palace of the High Renaissance is the Farnese palace (1518–66) at Rome designed and commenced by a follower of Bramante, Antonio da Sangallo the younger, nephew of the older Sangallo. At Sangallo's death in 1546 Michelangelo carried the palace toward completion. making important changes in the third story. On the exterior Sangallo gave up the use of the classic orders as a means of comparting the facade into a number of equal bays; he used instead a facade more like the Florentine, but with quoins or rough cut blocks of stone at the edges of the elevation to confine the composition in a High Renaissance fashion. The façade is composed in proportions as a double square. On the interior the central square court is more classic using superimposed orders. Based on the ancient Roman Theatre of Marcellus or the Colosseum, the two first floors have an arcade supported by rectangular piers against which are set half columns. On the third story Michelangelo eliminated the arcade and used pilasters flanked by half pilasters which destroyed the High Renaissance idea of the careful separation and definition of parts.

One of the most charming buildings of the period is the Villa Farnesina (rjog–21) at Rome by Bramante's finest pupil. Baldassare Peruzzi. who came from Siena. Designed for the fabulously wealthy Sienese banker Agostino Chigi, the villa was the scene of numerous fantastic banquets. A suburban villa, the Farnesina was planned in relation to the gardens around it with two small wings projecting from the central block toward the gardens. Originally there were tno open loggias facing the gardens from two sides of the villa; one loggia is now completely walled in. The elevation appears as two stories comparted into equal bays by Tuscan pilasters. Other important buildings were designed by the painter Raphael, such as the Villa Madama (begun 1517) at Rome or the Palazzo Pandolfini (1j16–20) at Florence.

C. Mannerism

From the third decade of the 16th century political and religious tensions erupted violently in Italy, particularly in Rome, which was sacked in 1527 by imperial troops. The school of Bramante and Raphael, which had produced the High Renaissance style, was dispersed throughout Italy as the artists fled from devastated Rome. Two years later another imperial army, with the backing of the Medici, besieged the city of Florence, imposing upon Michelangelo the difficult choice of supporting his native city or the family which had protected and patronized him. The Medici were soon established in Florence not merely as a leading family but as the outright rulers. In such a period of insecurity, the harmonious and self-sufficient manner of the High Renaissance could not survive. It was gradually replaced by a complex style, sometimes called mannerism, which continued until the end of the 16th century when the baroque style developed. Mannerism was antithetical to most of the principles of the High Renaissance. In place of harmony, clarity and repose it was characterized by tension. complexity and novelty. Mannerist architects were no less interested in ancient classic architecture than their predecessors; in fact. they displayed an even greater knowledge of antiquity. However they found other qualities in Roman architecture to exploit.

The change in style can be seen in the work of an architect, Baldassare Peruzzi, who was active in both periods. Unlike his High Renaissance Villa Farnesina, Peruzzi's design for the Palazzo Massimo alle Colonne (about 1535) in Rome shows indications of mannerism. The facade of the palace was curved to fit the site on which it was erected; instead of remaining the passive form it had been in the earlier phases of Renaissance architecture, the wall surface was beginning to assert itself. The classic order is limited to the ground floor of the palace; the upper three stories have imitation drafted stonework made of brick covered with stucco. inscribed to feign stone coursing. Under these three stories in the centre of the facade is a loggia or colonnade, which seems of questionable adequacy as a support for the apparent load. The second story has classic rectangular windows crowned by Peruzzi's usual neat lintel supported on volutes, but the windows of the upper two stories are set horizontally with rather elaborate curvilinear moldings about them. There is, therefore, no longer a harmonious balance between the various stories. The architecture shows a greater emphasis on decorative qualities than on the expression of structural relationships.

In its earlier phase, until about 1550, mannerism presented a strong reaction against the High Renaissance. In the latter half of the century the free treatment of the classic vocabulary, which was typical of early mannerism became somewhat restrained. In central Italy, because of the impact of the sack of Rome, the quantity of early mannerist architecture was limited. A typical example is the project which Antonio da Sangallo the younger prepared for the completion of St. Peter's at Rome. A wooden model (begun 1539), still preserved in St. Peter';. reveals that Sangallo's plan is a combination of a central plan church with a large vestibule which makes the whole scheme approach a Latin cross. As a result, the exterior of the church resembles a Latin cross, but the interior space denies this by being centralized. In the same way the exterior elevation, unlike Bramante's project, does not express clearly the disposition of the interior of the church. The number of the architectural elements is increased so that the simplicity and clarity of the High Renaissance is lost. The dome of Sangallo's project has two superimposed arcades around its base and a double lantern above, so that the dome form is almost completely lost in a many-tiered, wedding-cake effect.

One of the great figures of the mannerist period was the Florentine artist Michelangelo. He executed some extreme examples of mannerist architecture at Florence. In his Laurentian library (1523–71) the vestibule fully illustrates his manner. Spatially it is a tall box set on end rising three stories. The large columns that line the wall of the main story are set into recesses so that a question arises as to whether the column or the wall is the supporting element. This treatment enlivens the expressive quality of the wall, for unlike its rather passive expression in the High Renaissance the wall now seems to be pressing forward between the columns. The small decorative pilasters were designed to taper toward the base in contrast to the usual classic and Renaissance pilaster. The small floor area of the vestibule is almost

completely filled with the staircase leading up to the reading room. The stairs are an extreme example of the freedom of mannerism; the function of the stairs is subordinate to their design. Commencing as three flights of stairs. the side flights at the top divert their traffic into the middle one, which was designed with curved steps so that the total effect resembles moving lava. The stairway dominates the vestibule instead of remaining a neutral. functional form. The whole atmosphere of the vestibule is that of an architectural space in tension, which contrasts with the quiet monotony of the long horizontal reading room above.

Michelangelo's later architecture in Rome was more restrained but still reveals some of the qualities of mannerism. At the death of Sangallo in 1546 Michelangelo was commissioned to complete the great church of St. Peter's at Rome. During the next 18 years he was able to complete most of his design for the church, except the faqade and great dome above. In plan he returned to a central plan church reminiscent of Bramante's idea but with fewer parts. His elevation, still visible at the rear or sides of the church, is composed of gigantic pilasters with a rather high attic story. Between the pilasters are several stories of windows or niches. Unlike the harmonious orders and openings of the High Renaissance, these are constricted by the pilasters so that a tension is created in the wall surface. Michelangelo planned a tremendous semicircular dome on a drum as the climax of the composition. Engravings of his original project suggest that this dome would have been overwhelming in relation to the rest of the design if the church had been completed in accordance with his concept. The great central dome was executed toward the end of the 16th century by Michelangelo's follower Giacomo della Porta who gave a more vertical expression to the dome by raising it about 25 ft higher than a semicircle. This resulted in a slightly pointed profile which became the prototype for the baroque dome, whereas the semicircular dome had been typical of the Renaissance. In the early 17th century Carlo Maderno added a large nave and faqade to the front of the church, converting it into a Latin cross plan and destroying the dominating quality of the dome, at least from the exterior front.

Early mannerism in north Italy developed out of the dissolution of the school of Bramante after the death of Raphael in 1520 and the sack of Rome in 1527. Giulio Romano, the chief assistant of Raphael, became court artist and architect in the city of Mantua, while Michele Sanmicheli, a pupil of Bramante and Antonio da Sangallo the younger, returned to practise in his native town of Verona and at nearby Venice. Romano's Palazzo del Te at Mantua has a formal exterior with imitation drafted stonework and Doric pilasters, but the pilasters were not spaced in the High Renaissance manner, with an absolute regularity or an alternate rhythm of wide and narrow bays. The pilaster bays instead have a much more complex rhythm of several different widths. Mannerist tension was expressed in the court by the designing of every third triglyph of the Doric frieze to drop slightly, deliberately giving a sense of insecurity that tended to deny the structural expression of the order.

The leading early mannerist architect in Venice was the Florentine sculptor Jacopo Sansovino. who fled to the north from Rome after the sack. Sansovino's architecture, as represented by the loggetta (1537–40) at the foot of St Mark's campanile or by the Library of St. Mark's (Libreria Vecchia; 1536–88), is an example of the very decorative side of mannerism. The library has t o stories of arcades; the upper story is much taller than the lower. It has no basement, merely three low steps, so as to match the Gothic Palazzo Ducale opposite it. The upper entablature is extremely heavy, equaling half the height of the Ionic columns on which it rests. The decorative nature of the building is indicated by the fact that relief sculpture has been applied universally to the entablature and spandrels of the arches, with no unadorned wall surfaces.

This period of free and decorative mannerism was folloaed by the more restrained, classic phase of late mannerism seen to perfection in the architecture of one of the greatest architects of the Renaissance, Andrea Palladio. His native city. Vicenza, on the mainland not far from Venice, was almost completely rebuilt with edifices after his design; the Venetian mainland around Vicenza was profuse with his villas. The Villa Capra or Rotonda (1550–53; with later changes) near Vicenza is magnificent in its simplicity and massing. In the centre of a cubelike block (a cube is typical of most Palladian villas) is a circular hall, and on all four sides are projecting classic temple fronts as porticoes. There is an absolute classic rigidity in the plan which, when applied to domestic architecture is even more abstract than High Renaissance architecture. In Venice Palladio built several churches, all with the Latin cross plan and rather similar faqades. S. Giorgio Maggiore (1565–1610) has a Roman temple front, on four giant half columns, applied to the centre of the faqade; abutting the sides are two half temple fronts with smaller coupled pilasters. The resulting composition suggests the interpenetration of two complete temple fronts in a mannerist way, since the elements of the composition are less independent than they would be in High Renaissance architecture, although the details are fully classic. Also typical of mannerism is the way in which the interior space, instead of being classically confined, is permitted to escape through a colonnaded screen behind the sanctuary into a large choir at the rear.

Palladio's greatest fame in the history of architecture rests on his treatise. I *Quattro libri dell'urchitettura* (1570). The book promulgates a very classic theory of architecture; in fact, one chapter (I. xx) on the abuses in architecture decries some of the characteristics of mannerism. In the 17th century Palladio's writings played an important role in the formulation of the French Academic theory of architecture.

In England there were at least two waves of Palladianism (*q.v.*), one centred around Inigo Jones in the early 17th century and another around Lord Burlington in the 18th century, which later spread to America.

Late mannerism at Rome and Florence was more varied. Pirro Ligorio's Casino of Pius IV (1558–63) at the Vatican is extremely decorative, with its faqade covered with rich stucco relief and pebble mosaic ornament. In Florence the Uffizi palace (1560–74) by Giorgio Vasari and others was built about a very long, narrow court that seems to have been created by the compression of the tall side walls. It has a more dynamic spatial expression than the harmonious passive courts of the High Renaissance, which are generally square or circular. The most important architect of this period is Giacomo da Vignola, who wrote a treatise, *Regole delle cinque ordini d'architettura* (1562), devoted solely to a consideration of the architectural orders and their proportions. Like Palladio's book, Vignola's *Rules* became a textbook for later classic architecture. Of his many buildings the project for the church of Gesù (1568–75) at Rome, the central church of the Jesuit order, was very influential on the later history of architecture. The plan is a Latin cross with side chapels flanking the nave, but the eastern end is a central plan, capped by a dome. The plan was derived from Alberti's early Renaissance plan of S. Andrea at Mantua. The Gesu plan was imitated throughout Europe, but especially in Italy, during the early baroque period of the 17th century. Vignola built the church except for its faqade, which was executed by Giacomo della Porta. Della Porta, inspired by Vignola's original design, created a faqade concentrated toward its centre. which, like the plan, was the prototype for most early baroque façades of the late 16th and early 17th century.

III. FRANCE

The Renaissance style of architecture appeared in France at the very end of the 15th century and flourished until the end of the 16th century. As in other north European countries and Spain the new Renaissance manner did not completely oust the older Gothic style, which survived in many parts of France throughout the 16th century. French Renaissance architecture is divided into two periods: (1) the early Renaissance, from the end of the 15th century until about 1530, and (2) mannerism, from about 1530 to the end of the 16th century.

A. Early Renaissance

The. many invasions of Italy from 1494 until 1525 by French armies acquainted the French kings and nobles with the charms of Renaissance art. During the reigns of Louis XII and Francis I the French possessed the city of Milan for the first 25 years of the 16th century. It was in Lombardy, therefore. that contact was made between French art and the Renaissance, and it was the Lombard Renaissance style that appeared in France during the early Renaissance.

The new style had a certain prestige since it was imported by the nobility and aristocracy, while the middle class burghers continued to support their native Gothic style. This social difference also applied to the artists themselves. The French aristocracy imported Italian architects and artists who had been influenced by the Italian Renaissance, in which artists were considered to have a higher social level than artisans. The French builders and craftsmen who executed the designs of the Italians still belonged to the social level of medieval artisans. This created a friction between the two groups, which was, of course, furthered by the French resentment toward imported foreign artists.

With the exception of a few brief outcroppings of classicism in such centres as Marseilles and Gaillon, French early Renaissance architecture was centred in the Loire valley, since the capital of France was at Tours during the reign of Louis XII and the early part of the reign of Francis I. Most of the new architecture was secular, such as the chbteau (*q.v.*), which was descended from the medieval feudal castle, combined with the idea of an Italian villa. A characteristic example is the chbteau at Blois, where two wings in the early Renaissance manner replaced parts of the 13th-century chbteau. The first wing, erected for Louis XII (1498–1503), is almost completely in the Flamboyant style (*q.v.*) and structure, with high roofs, an asymmetrical elevation, depressed arches and ogee arches. The only hint of the Renaissance is the occasional use of a bit of classic decoration, such as the egg and dart molding, mingled with the Gothic. The second wing, built by Francis I (1515–24), is more nearly in the Renaissance style. The structure remained Gothic with a high roof and dormers and the irregular spacing of the vertical windows, but all the ornament was in the classic mode, although its handling was often nonclassic. Classic pilasters were used to divide the elevation into bays, but there is no consistency in the proportions of the pilasters. The most notable feature of the interior elevation of the wing of Francis I is a great octagonal open staircase, five sides of which project into the court. Within is a spiral staircase set on a continuous tunnel vault that is supported by radiating piers. On the surface of the piers are panels in low relief of arabesque decoration, of a type which is found often in Lombard Renaissance architecture. The richness of the Lombard style blends very well with Flamboyant Gothic, which had always been characterized by intricate and rich decoration. The exterior elevation of the wing of Francis I consists of a series of open loggias, the two lower ones arched, the upper one with a straight entablature, reminiscent of the famous series of loggias that had just been completed by Bramante and Raphael at the Vatican palace in Rome. However, the Italian High Renaissance concept was expressed in France in early Renaissance terms with squat pilasters, irregularly spaced bays and somewhat depressed arches.

The finest example of the early Renaissance style is the château or hunting lodge erected for Francis I at Chambord (1519–47). The Italian architect Bernabei Dornenico da Cortona presumably made the basic model for the chbteau, but the designs of Italian architects were usually executed by French builders, in this case Pierre Nepveu, often with many changes. Chambord is a tremendous structure, about 500 ft. wide, with a plan showing the gradual breakdown of the old castle plan. There is a rectangular court surrounded by walls with round towers at the corners, but on three sides of the court there are only low curtain walls. The old donjon developed into the chbteau proper as a blocklike building aith round towers at each corner. The flat passageways over the curtain walls and on top of the central block were intended to form galleries from which the ladies of the court could observe the hunt. The plan of the main block of the chbteau reveals Italian influence in its symmetrical organization on cross-axes with a double spiral staircase at the centre. In the four corners left by the cross-axes are four identical apartments, each of which consists of three basic rooms (chamber. antechamber and cabinet); this form of apartment was from this time the favourite unit of French domestic planning. Typically for this period, the silhouette and structure remained Gothic in elevation, with strip windows, a multiplicity of elements and a general vertical expression. However all the ornament is in the classic vocabulary of pilasters, round arches, and at times a geometric decoration of slate panels set in the cream coloured stone.

B. Mannerism

Commencing about 1530 Francis I imported numerous Italian artists, such as Il Rosso, Primaticcio, Serlio, Vignola and Cellini. Most of these artists were mannerist in style. followers of Michelangelo or Raphael, so that the new period of French architecture partook of Italian mannerism. The relations between the French and Italian artists became more strained, in part as a result of factions in the royal patronage. Francis I and his Italian daughter-in-law Catherine de Médicis favoured the imported Italians, while the son and successor of Francis I, Henry II, and the latter's mistress Diane de Poitiers supported the French artists. The style that resulted from this tension lasted until about 1590 and is sometimes known as the style of Henry II, although it actually was produced under five different kings, beginning late in the reign of Francis I.

The full influence of the new Italian style can best be seen in the chbteau at Fontainebleau. In 1528 Francis I began to make revisions and additions to his medieval chateau, the exterior architecture being carried out by French builders under Gilles Le Breton, and. therefore, belonging to the French early Renaissance manner. The Italian mannerist painter, Il Rosso, after his arrival in 1530, was placed in charge of the interior decoration of the Gallery of Francis I (1535–37). The gallery is a long, narrow room covered by a wooden ceiling with rather intricate coffering. On each side of the room is a high dado of carved walnut with rich decoration above of stucco relief sculpture and painting. As Rosso was a mannerist painter it meant that France went directly from the early Renaissance style of the Loire chbteaux to mannerism. This was natural for the French since mannerism has affinities with the early Renaissance and late Gothic styles; it appealed to the French whose traditional native style was Gothic. Rosso, aho died in 1540, was succeeded by another Italian, Primaticcio, who decorated the ballroom or gallery of Henry II (1548–56) and added the wing called the Aile de la Belle Cheminée (1568) at Fontainebleau.

The most important Italian architect to build in France was Sebastiano Serlio, a pupil of Baldassare Peruzzi, who arrived in 1541 to take Rosso's place as court srchitect. Serlio prepared plans for the rebuilding of the royal palace of the Louvre at Paris, but his ideas seem to have been too grandiose for Francis I. He did manage to build two chateaux, the casino of the Cardinal of Ferrara at Fontainebleau (about 1546), now destroyed, and the château of Ancy-le-Franc (about 1545–55) in Burgundy. Encountering opposition to his architecture from the French builders, Serlio devoted most of his time to an architectural treatise which he had begun in Italy. Various books of the treatise were published during his lifetime from 1537 on, but the collected work was published after his death with the title *Tutte l'opere d'archi-*

tettura et prospetiva (1584). This treatise was quite influential in spreading the Renaissance style in France, England, and the Low Countries.

The influx of Italian artists soon compelled the French architects to adopt Renaissance principles of design as well as Renaissance ornamental details. No longer content to be builders following the guild tradition, many of the French architects began to study the theory of design and often went to Italy as the source of the Renaissance style. A typical example was Jacques Androuet du Cerceau the elder, who was in Rome probably in the 1540s and was more important for his writings on architecture than for executed building. In addition to several treatises on architecture, Androuet du Cerceau published *Les plus excellents bastiments de France* (1576–79), two volumes of engravings of the most notable buildings in France in the Renaissance manner. As many of the buildings have been destroyed or radically changed, his book is an indispensable source for a knowledge of the architecture.

After Serlio's failure with the palace of the Louvre in Paris, a French gentleman of the court, Pierre Lescot, was ordered to design and build a Renaissance palace to replace the medieval castle of the Louvre. During the latter part of his reign Francis I centred the capital of France at Paris rather than in the Loire valley. Lescot in collaboration with the famous sculptor Jean Goujon designed a palace in 1546 set around a square court about 175 ft. wide. Only two sides, the west and south, of Lescot's court were built (1546–51). The execution and amplification of this design extended to the middle of the 19th century. The small section carried out under Lescot, the gallery of Francis I, reveals a thorough understanding of the principles of Italian design, but is expressed in French terms. The classic elements are used as low-relief surface decoration with little emphasis on mass.

The two leading architects of the second half of the 16th century, Philibert Delorme and Jean Bullant, studied in Rome. Delorme was trained as a builder before going to Rome and, therefore, was always interested in the constructive side of architecture as well as in the theory of design. About 1546 Delorme was commissioned by Henry II's mistress, Diane de Poitiers, to design her chbteau at Anet. The original château (about 1546–52) formed three sides of a court closed at the front by a screen wall and entrance gateway. Much of the chdteau has been destroyed; only the left wing of the house, the screen wall and the chapel which formed part of the right wing survive. The entrance gateway, which originally contained Cellini's bronze relief of Diana (now in the Louvre), is very mannerist with a complicated superstructure, a semicircular arch with raised bands cutting across the moldings, and, at the top, a bronze group of a stag which strikes the hour with his hoof as the accompanying hounds bay mechanically. The chapel at Anet has a centralized Greek cross plan with a large circle capped by a dome at the crossing. The exterior of the chapel is mannerist with the windows cutting through the entablature and half pediments abutting the main block.

Delorme commenced in 1564 a large palace called the Tuileries, since it was situated on the site of tileworks in front of the Louvre. It was originally conceived as a very large building, but the architect was able to carry out only a very small section, which was destroyed in 1871.

Again elements of mannerism were visible. On the first story Delorme used his own so-called French order, consisting of Ionic half columns and pilasters with decorative bands across the shafts, but this order was actually an Italian mannerist treatment of the classic order. Delorme also wrote on architecture. His most important publication, the *Premier tome d'architecture* (1567), was based on Vitruvius and Alberti, but it is much more practical in its approach than Alberti's work, since it was largely drawn from Delorme's own practice.

Jean Bullant also wrote a book on architecture, *Règle générale d'architecture des cinq manières de colonnes* (1564), inspired by the Italian Vignola's treatise which was issued two years previously. In fact, Bullant's architecture was rather like that of Vignola in that it was very classic in details but often mannerist in relationships. His early and best preserved works were for Anne, duc de Montmorency and constable of France: part of the chbteau of Ecouen (about 1555) and the chatelet (about 1560) at the chbteau of Chantilly. The last shows many mannerist qualities. For example, the main block of the chatelet is two stories high, but it is comparted by a series of pilasters that are higher than one story, yet not as high as the two stories. This is typical of Bullant's work; it results in the upper windows cutting through the cornice and ending as dormers in the roof. He was also very fond of penetrating the lower part of his window pediments, either with the arch of the window or with a separate little window.

The architecture of the second half of the 16th century was typically mannerist; numerous architectural treatises appeared, as they had in mannerist Italy. The mannerist style died out in the early 17th century as slight hints of the baroque style blended with a renewed classicism to form gradually the Academic style prevalent in the 17th century.

IV. SPAIN

The unification of Spain in 1492, with the final expulsion of the Moors, was accompanied by the appearance of Italian Renaissance decorative elements in Spanish architecture. There were three phases of Spanish Renaissance architecture: (1) the early Renaissance or Plateresque, from the late 15th century until about 1560; (2) a brief classic period, coexistent with the Plateresque from about 152j to 1560; and (3) the Herreran style from 1560 until the end of the 16th century.

A. Plateresque

The earliest phase of Renaissance architecture in Spain is usually called the Plateresque (*q.v.*) (from *platero,* "silversmith") because its rich ornament resembles silversmith's work. There has always been a long tradition in Spain of elaborate decoration, explained in part as an influence from Moorish art. The Moors, of course, possessed almost all of Spain during the middle ages and left this decorative heritage to the Spaniards. During the early 16th century minor north Italian sculptors and artisans, particularly from Lombardy and Genoa, were imported into Spain to execute tombs and altars for the Spanish nobles and ecclesiastics. These artisans introduced the north Italian Renaissance vocabulary of classic decoration, such as the pilaster paneled with arabesque or rinceau strips or the candelabrum shaft. Spanish architects soon picked up these decorative elements and applied them to their buildings.

The Renaissance Plateresque style is purely one of architectural ornament. There was no change in structure; heavy malls mere used aith either Gothic ribbed vaults or intricately carved wooden ceilings, indicating Moorish influence. Many of the elements of decoration also preserved the influence of Gothic and Moorish art, such as the Flamboyant Gothic pinnacle and pierced balustrade, or coats of arms and bits of heraldry used as ornamental motifs. Richly coloured tiles created decorative patterns on the walls as in Moorish art. The richness of the classic decoration imported from north Italy blended effectively with the elements of the Moorish and Flamboyant Gothic styles to form the new Plateresque style. The luxuriance of its ornament was a fitting expression of the splendour-loving culture that Spain developed as the wealth of the Americas began to pour in during the early 16th century.

In most cases the new Plateresque decoration was confined to rich spots or panels of ornament around the portals and windows of the buildings. These ornamental areas were relieved by large expanses of bare wall, as in the façade of the Royal hospital at Santiago de Compostela (begun 1501) by Enrique de Egas, or his Hospital of Santa Cruz at Toledo (1504–14).

The greatest centre of the Plateresque style was the town of Salamanca, with buildings such as the university (about 1516–29) and the Monterey palace (1539). Perhaps the most outstanding

example of the style is the Ayuntamiento, or town hall, of Seville (1534–72) by Diego de Riaño, with Lombard paneled pilasters on the ground floor and half columns completely covered with relief sculpture on the second floor. Also in the Lombard manner are the numerous medallions spotted over the wall under the windows or between the pilasters.

B. Classic

Although the exuberant Plateresque style lingered in some regions until about 1560, it was soon superseded by a much more classic style, which appeared in 1526 in the palace of Charles V within the Alhambra (*q.v.*) at Granada. The palace of Charles V was the first Italian classical building in Spain, in contrast to Plateresque buildings whose classicism, was limited to a few elements of Italian Renaissance decoration. Charles V as king of Spain and the Holy Roman emperor was the most powerful political figure in Europe. It was his army that invaded Italy and sacked the city of Rome in 1527 as Pope Clement VII cowered in the Castel San Angelo. As a result of his political and military power. his wealth (which was enhanced by the gold of Mexico and Peru) and his adroit diplomacy, Charles V dominated Italy, as well as Spain, the Low Countries and Austria. His palace in the Alhambra reflected the increasing contact with Italy. Designed by the Spaniard Pedro de Machuca. who had studied in Italy, the work on the palace of Charles V continued through most of the 16th century. but it has never been completed.

The palace is square in plan with a huge central circular court (100 ft. in diameter), which was intended for bullfights and tournaments. The plan is, therefore, fully Renaissance, being centralized and symmetrical; it is organized on cross-axes formed by the four entrances. one in the centre of each side. The façade shows a full understanding of the principles of Italian Renaissance design in its superimposition of orders (*i.e.,* Ionic pilasters or half columns above Tuscan, and Corinthian above Ionic), and in the alternating rhythm of the triangular and segmental pediments above the windows of the second story. The interior court is surrounded by a colonnade with a similar superimposition of Doric and Ionic.

C. Herreran

The classicism of the palace of Charles V was succeeded by an extremely austere and cold style named after the greatest Spanish architect of the 16th century, Juan de Herrera. Perhaps more important than the architect was the social and cultural atmosphere in which the Herreran style developed, from about 1560 to the end of the 16th century. Charles V had been a true Renaissance prince; his only son Philip II. who came to the throne in 1556, was one of the most typical representatives of the age of Mannerism as it was manifested in Spain. Philip II was morbid and melancholic, a religious fanatic, against whose strict rule the Low Countries soon rose in revolt, beginning the difficulties that gradually dispelled Spanish political and cultural power in Europe.

The finest example of the Herreran style illustrates clearly the change in cultural atmosphere under Philip II. This is the palace-monastery of the Escorial (*q.v.*) (1563–84), which Philip II had built as a retreat on a rather dreary plain outside Madrid. It is a great contrast to the worldly palace of Charles V with its tournament court set in the luxurious, sensuous Alhambra. The Escorial was more than a royal palace, as it also contained provisions for a monastery and college within its great complex. A city in itself, the Escorial was planned as a tremendous rectangle (675 ft. by 525 ft.), with a large church at the centre dominating the whole. The orientation toward religion is indicative of the age of the growing Counter-Reformation, which was in part opposed to the secularism of the classic Italian Renaissance.

The Escorial was begun by the architect Juan Bautista de Toledo. who may be responsible for the planning, but the execution and architectural style was that of his assistant and successor, Herrera. Philip II himself reviewed the drawings for the palace, removing anything ornamental or ostentatious. On the exterior the architecture is very simple, a plain wall with a monotonous series of unadorned windows expressing the general monastic character of the whole. The only element of the classic Renaissance on the exterior is at the central portal with two stories of giant Doric half columns supporting a classic triangular pediment. The church, at the centre of the complex, has two bell towers and a great dome set on a drum, which surmount the whole. The austerity is enhanced by the cold, gray granite of which the Escorial was built. On the interior a similar severity of manner is indicated by the lack of decoration. Except for the classic Doric order, which is the least ornamental of the orders, there is no architectural decoration. Plain arches of stone were used under the vaults without any coffering. Occasional raised panels on the wall surface suggest where Plateresque ornament would be located normally, but instead of relief sculpture, there are only starkly smooth panels. Even the Doric order was handled severely; the pilasters on the interior show no entasis (*i.e.,* an upward taper of the width of the pilaster to give a sense of lightness and to relieve the strict verticals). The Escorial is impressive in its size and mass and in the consistency of its austerity, but it has a forbidding quality that no other building can match. Other examples of Herrera's design are the cathedral at Valladolid (begun 1585, completed in the 18th century) and the court of the Lonja, or Exchange, of Seville (1583–98).

V. GERMANY AND THE LOW COUNTRIES

A. Germany

The burgeoning of Italian Renaissance architectural forms in Germany was even slower than in other north European countries. Only by the middle of the 16th century was the Renaissance style manifestly important. generally in those regions in closest contact aith Italy such as southern Germany or the trade route along the Rhine river leading from the south to the Low Countries. The style lingered in Germany until about the middle of the 17th century. The few hints of classicism in Germany prior to the mid-16th century can be considered the early Renaissance phase. They were limited to minor architectural monuments, such as the Fugger chapel in St. Anna at Augsburg (1509–18), which was the first Renaissance building in Germany. or they consisted of bits of Renaissance decoration attached to Gothic structures. An example of the latter is the Schloss Hartenfels at Torgau (1532–44) by Konrad Krebs, which is completely medieval in structure but has occasional fragments of classic ornament, arabesque pilaster strips, candelabra and medallions applied to the surface. A great staircase in the court was somehow derived from that of the French chbteau at Blois, indicating that the Renaissance influence was fourth hand, passing from its source in central Italy through Lombardy, and then to France and eastern Germany.

After 1550 Renaissance style architecture in Germany often had mannerist details derived from Italian ornamental engravings. German architecture of this period was abundant with medallions, herms (*i.e.,* architectural elements topped by human busts) and caryatids and atlantes (*i.e.,* human figures used as columns or pilasters). The German treatise on the five orders by Wendel Dietterlin entitled *Architectura* (1593) is profuse with mannerist ornament. An architectural example is the Otto Heinrichsbau (1556–59) added to the Gothic castle at Heidelberg (burned by the French in 1689). The three tall stories presented the usual verticality of northern architecture, but there was an understanding of the classic superimposition of the orders with Corinthian above Ionic. However, there was a certain freedom in the treatment of the orders, for a Doric frieze was supported by the Ionic pilasters.

From Italian mannerism came the rustication of the lower order, the use of herms as window mullions and the caryatids flanking the portal. Other examples of the German Renaissance are the porch of the Rathaus, or town hall, at Cologne (1569–73) by the Dutchman Wilhelm Vernuiken and the Friedrichsbau (1601–04) added to the castle at Heidelberg by Johannes Schoch.

B. The Low Countries

Flanders in the Low Countries, because of trade and finance, was in close communication with Italy from the 15th century. As a result there are slight hints of the Renaissance style in the architecture of the early 16th century, as in the palace of Marguerite of Austria, now the Palais de Justice (1507–25), at Malines completed by Rombout Keldermans.

The most important building of the Flemish Renaissance style was the Stadhuis, or town hall, at Antwerp (1561–65), designed by Loys du Foys and Nicolo Scarini and executed by Cornelis de Vriendt (Floris). It was decided to replace Antwerp's small medieval town hall with a large structure, 300 ft. long, in the new style, as a reflection of its prosperity as the leading northern port of the 16th century. As with many northern buildings there is a lack of monumentality, for its physical hugeness is not expressed in the way that it would be in an Italian building. There is a low basement with a rusticated arcade, originally used by traders during fairs. Above are two principal stories with superimposition of Doric and Ionic pilasters, between which large windows almost completely open each bay.

The advent of the baroque style early in the 17th century replaced the Renaissance in Flanders much sooner than it did in Germany. There were a few examples of the 16th century Renaissance style in the northern Low Countries, such as the town hall at Leyden (1579) and the town hall of The Hague (1565). It was during the 17th century, when Holland was independent of Spain, that architecture flourished.

Stange, *L'Architecture des Pays-Bas méridionaux aux XVI^e, XVII^e et XVIII^e siècles* (1926); G. Horst, *Die Architektur der deutschen Renaissance* (1928).

VI. ENGLAND

The Renaissance style of architecture made a very timid appearance in England during the first half of the 16th century, and it was only from about 1550 that it became a positive style with local qualities. In fact, the Gothic style continued in many parts of England throughout most of the 16th century, and English Renaissance architecture was a very original fusion of the Tudor Gothic (see Tudor Period) and classic styles. This style flourished until the early 17th century when the architect Inigo Jones created a much more Italianate style that replaced the English Renaissance style.

During the reign of Henry VIII (1509–47) some elements of Italian Renaissance decoration were imported by England through a few minor Italian artists, such as Pietro Torrigiano who executed the tomb of Henry VII (1511–18) in Westminster abbey. At the great palace of Hampton Court, begun by Cardinal Wolsey in 1514 and continued by Henry VIII until 1540 a few bits of Italian Renaissance decoration have been added, although the structure is completely in the Tudor manner. On the gateways are several terra-cotta medallions by the Italian Giovanni da Maiano, and there is a symmetry and regularity in the plan of the palace that hints of the Renaissance. (*See* also Elizabethan Style.)

The Renaissance style really begins in England in the middle of the 16th century in architecture built for the circle of the Lord Protector Somerset, who served as regent after Henry VIII's death. During the 16th century the patron played a much greater role in the development of English Renaissance architecture than did the architect; there were almost no professional architects who were trained as the Italians were in the theory of design and building. Most of the building was executed by mason- or carpenter-designers. A typical example of the role of the patron in introducing the Renaissance style to England is to be found in the quadrangle which John Caius added to Gonville college, now Gonville and Caius, at Cambridge (*q.v.*). Caius had spent a long time in Italy as well as elsewhere in Europe. The architecture of the new court was basically Tudor Gothic, but Caius planned three gateways in connection with the court, two of which were in the Italian style. The three gates were to mark the progress of the student through the university. At the entrance was the Gate of Humility, an unadorned doorway, now destroyed. The Gate of Virtue. opening into the new quadrangle, is a fine classic portal with Ionic pilasters, but with a Tudor Gothic many centred arch for the opening. Finally the Gate of Honour is a separate tiny triumphal arch leading out toward the schools for the final disputation and degree. Caius probably designed these gates with the aid of the Flemish architect Theodore de Have.

There was no religious architecture created in England during the 16th century, in part because of the break of Henry VIII with Rome. It is in the great country houses of the nobility that the Renaissance style is visible. Sir John Thynne, steward to the Lord Protector Somerset, designed several notable examples. The finest of these was his own house Longleat (1568–about 1580), on which he had the assistance of the mason Robert Smythson, who was to be the leading architect of the late 16th century. Except for the symmetry of the plan, arranged around two courts, there was little new in planning at Longleat, for the Tudor house was usually organized about a court. The typical English great hall at Longleat, was an element derived from the hall (*q.v.*) of the medieval castle, and retained in English architecture through the 16th century. The main entrance of the house opens directly into one end of the great hall, but a low screen at the end of the hall, topped by a musicians' gallery, forms a passageway. In elevation Longleat is a long horizontal building with a wealth of windows; it is one of the most open secular buildings in Europe of the 16th century. There is a rectangular quality about the whole exterior, which is characteristic of English architecture; it is augmented by the repeated use of the bay-window unit. There are now three stories on the exterior, with the correct classic superimposition of the Doric order on the ground floor and Ionic and Corinthian orders above, but the third story was probably added after Thynne's death in 1580, replacing a pitched roof and dormers.

Robert Smythson, who aided Sir John Thynne at Longleat, went on to design and build several notable houses, the finest being Wollaton hall (1580–88) near Nottingham. On his tomb Smythson is called "architector and surveyor," not merely a mason. Wollaton has a magnificent site set up on a small hill overlooking a large park. The plan of the house is a square with four, square, corner towers, resembling a plan in the treatise on architecture by the Italian architect Serlio, whose book was influential in English Renaissance architecture. The great hall is in the centre of the square; it rises an extra story above the whole building. The house has a low basement story that contained the kitchens and service rooms; it is one of the first buildings to use this arrangement, which became common in the history of later English and American architecture. On the exterior the massing is that of rectangular blocks, whose rectilinear quality is further emphasized by the numerous many-mullioned rectangular windows. The decoration is completely classic with superimposed pilasters, round arched niches and classic balustrades, but it shows touches of Italian mannerism, which came into England primarily from Flanders. The pilasters and half columns have raised bands across their middles, and the gables crowning the corner towers are decorated with Flemish strapwork (*i.e.*, bands raised in relief assuming curvilinear forms suggestive of leather straps).

Other examples of this style are Hardwick hall (1590–97) in Derbyshire probably by Smythson, Kirby hall (about 1570–78) in Northamptonshire perhaps by the mason Thomas Thorpe, and Montacute house (1588–1601) in Somerset.

With the possible exception of Robert Smythson, there are no important professional architects in England during the latter half of the 16th century. Once the surveyor John Thorpe mas considered the most prominent architect of the period, Wollaton hall and Kirby hall being attributed to him as well as most of the other notable houses. This opinion was based on the discovery in the 18th century of his notebook of 280 drawings illustrating all these houses, but investigation of his life proved that he was too young to be concerned with most of the buildings and that his notebook was merely a collection of representations of all the famous buildings of the time. It is possible that Thorpe intended

to prepare a book with representative examples of English architecture very much in the manner of the book prepared in France by Androuet du Cerceau. There were, however, some designs by Thorpe himself. One for his own house, presumably never built, was based in plan on his own initials I and T, and has the playful, abstract, unreal quality of mannerism.

John Shute, a miniaturist. published the first English treatise on architecture during this period of the English Renaissance. Entitled *The First and Chief Groundes of Architecture* (1563), the book is primarily concerned with the five orders and was derived from Vitruvius and Serlio but had almost no influence on the architecture of the time.

RENAISSANCE ART. The period extending roughly from 1300 to 1600 was, with much fanfare, declared by Italian historians of the time to mark the Renaissance, or rebirth, of the humanistic spirit of classical antiquity. The "barbaric and benighted" centuries that intervened were then designated the middle ages. These three centuries did indeed witness a change in the intellectual and aesthetic climate of Europe, spanning as they did the time from Thomas Aquinas to Descartes, Dante to Tasso, Chaucer to Milton, Giotto to Michelangelo, Gothic to baroque. According to these humanistic writers the Renaissance originated in Italy and later spread throughout Europe whenever and wherever Italian influence was felt; the period marked a revival of classical learning in the Greco-Roman manner; and there was a sharp shift from otherworldly religiosity to worldly psychology.

To accept such assertions uncritically would be highly misleading. All of Europe was undergoing a conscious departure from the prevailing standards of the middle ages. In the north the transition was not so abrupt as in Italy, but it came about none the less decisively as the age of scientific discovery overcame the medieval heritage of mysticism and superstition and brought about a new attitude toward life. Through the works of such artists as Grunewald, Durer, Cranach and Holbein men saw their environment through different eyes. If the change occurred more suddenly and explosively in Italy than elsewhere, it was perhaps because that country was closest to the Roman tradition in letters, building and crafts, all of which had never really died out, and because the Gothic, a northern style, was never particularly compatible with the sunny south and the volatile temperament of its people. Virgil and other Roman authors had continued to be read during the middle ages, and scholarship and learning can hardly be said to have languished in medieval universities. Ionic and Corinthian capitals appear quite regularly in Romanesque and Gothic architecture. classical molding ornaments (egg-and-dart, leaf-and-tongue) are frequently found, and Gothic sculptural figures are clothed in graceful classical flowing drapery (*see* GOTHIC ART).

While an increasingly secular spirit was apparent in the Renaissance, the majority of important buildings were still churches; statuary, paintings and music continued to be mainly religious in orientation.

In longer perspective, then, the Renaissance appears to be more a fermentation of ideas and a reorientation of scholarly and aesthetic thought than a rediscovery of ancient values and viewpoints. The period expressed itself in new ways, created new forms, invented new modes of representation and eventually arrived at a new understanding of the world. For convenience these tendencies can be grouped in such categories as Renaissance humanism. individualism and scientific naturalism.

Humanism.— It is a truism that every era finds what it wants in the classics. In literature and philosophy western Europe during the Renaissance veered away from a largely Roman orientation toward an inclusion of Greek studies, particularly the works of Homer and Plato. In Latin, however, humanists sought inspiration and models in the classical style of Cicero, Lucretius, Virgil and Tacitus rather than in the writings of the medieval church fathers. More broadly the humanists placed increasing emphasis on man and his values especially the dignity of man as realized in the study of the humanities rather than scholastic theology.

In architecture. humanism resulted in the study of Vitruvius' ancient treatises and in the careful measurement and observation of the surviving ancient monuments. The consequences can be seen in Brunelleschi's Pazzi chapel in Florence, which is a model of spatial clarity, crisp contours and the elegant use of classical decorative detail. The new architecture, as exemplified in the works and writings of Alberti, Bramante and Palladio reveals the correct yet imaginative use of the classical orders and an eye for just proportions. In design, humanism resulted in the turning away from medieval variants of such classical motives as acanthus leaves, Ionic volutes, bead-and-reel patterns toward more authentic versions based on the study of ancient examples. In painting it resulted in the study of Euclid's geometry for the mathematical laws of linear perspective, as well as the exploration of themes drawn from classical literary and mythological sources.

In sculpture humanism resulted in calm classical stances, figures clothed in authentic Roman togas and the rediscovery of the expressive power of the nude as revealed in the works of Donatello and Michelangelo.

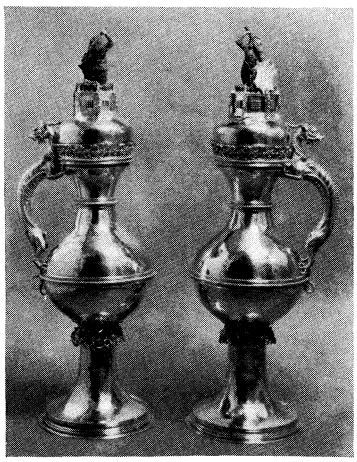
Individualism.— One manifestation of humanism was the establishment of man as the measure of all things. Such works as Pico della Mirandola's essay on the *Dignity of Man,* Machiavelli's *Prince* and Castiglione's *Courtier* emphasized the personal, political and social importance of man. Churches began to come under the direct patronage of individual families and to bear the names of their donors, as, for instance, the Scrovegni chapel in Padua, built and decorated by Giotto; the Brancacci chapel in Florence with murals by Masolino da Panicale and Masaccio; and the Church of S. Lorenzo in Florence with the Medici chapel by Michelangelo. Portraiture in painting assumed a position of major importance, and self-portraits by artists often were given considerable prominence in their religious and historical pictures. The social position of major individual artists was upgraded from that of an artisan to a place almost on a plane with that of their patrons.

Leonardo da Vinci insisted that painting, sculpture and architecture were truly liberal arts. and Michelangelo took pains to point out that he worked more with his brains than his hands. Individual artists became acutely conscious of their personal fame, and many achieved sufficient renown to become the subjects of biographies, such as those in Vasari's *Lives of the Most Eminent Painters, Sculptors and Architects* and the *Autobiography of Benvenuto Cellini.*

Scientific Naturalism.— In late Gothic sculpture, manuscript illuminations and tapestry designs there was a decreasing interest in allegory and moral preachments and an awakening to the beauties and delights of nature for their own sake. Artists began thinking more in terms of aesthetic problems than religious revelations. As with the nominalistic philosophy of William Ockham, personal observation was in ascendancy over the authoritarian view of scholasticism, interest in the natural world began to override that in the supernatural, and symbolism was superseded by accurate representation. A plant, in other words, was a plant, not a symbol of the a priori universal idea of plant as it existed in the mind of God, and the rendering of particular flora and fauna was based on nature. This visual revolution opened new vistas to Renaissance artists who proceeded to investigate optics, the mathematical bases of perspective drawing, the rational proportions of the human body, all with the idea of achieving a more natural way of representing the world of appearances. This phase of the Renaissance reached a climax in the scientific studies of Antonio Pollaiuolo and Verrocchio, who dissected cadavers in order to render more accurately the bone and muscle structure of the human body in action. It was this heritage they bequeathed to Leonardo da Vinci, whose *Notebooks* give evidence of his over-

RENAISSANCE ART

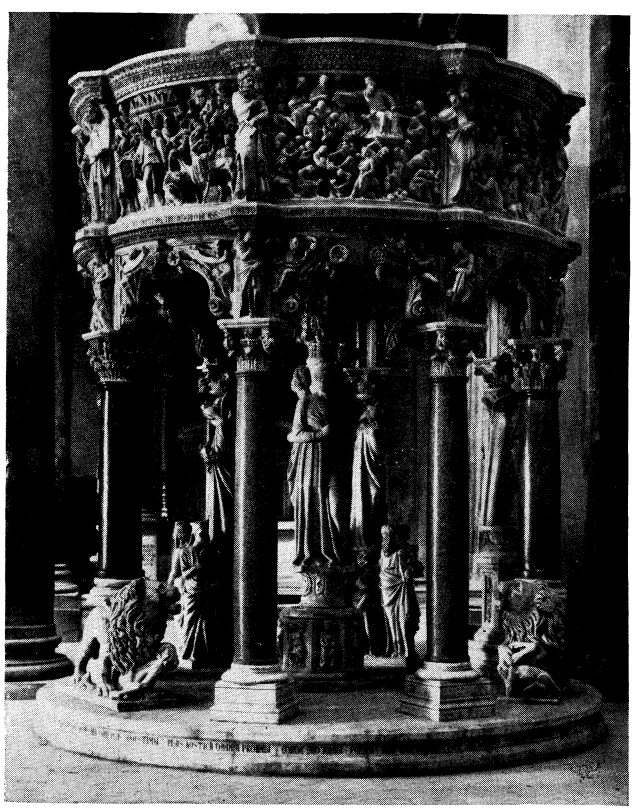
"Abraham Sacrificing Isaac," bronze relief by Filippo Brunelleschi (1377–1446); Italian. This bronze was entered in the competition for the design of the doors of the baptistery of San Giovanni, Florence (see picture at right). In the National museum, Florence



Silver gilt ewers with painted enamels; 25 in. high, 8¼ in. wide. German, 15th century. In the Metropolitan Museum of Art, New York

"Abraham Sacrificing Isaac," bronze relief by Lorenzo Ghiberti (1378–1455) which won for him the contract for the second bronze door of the baptistery of San Giovanni, Florence. In the National museum, Florence

Terra cotta bust of Lorenzo de' Medici by Andrea del Verrocchio (1435–1488); Italian. In the National Gallery of Art, Washington, D.C.



Marble pulpit in the baptistery, Pisa cathedral, completed in 1259, by Niccolò Pisano (*c.* 1220–c. 1283); Italian

Court of the Medici-Riccardi palace, Florence, by Bartolommeo di Michelozzo (1396–1472); Italian

whelming interest in science.

The disintegration of Renaissance art is first apparent in the work of the mannerists of the middle and late 16th century. The term Mannerism (*q.v.*) was coined to describe the work of certain artists who departed from accepted Renaissance ideals and emulated the manner rather than the spirit of the great masters — Leonardo, Michelangelo and Raphael. Mannerism had its origin in the psychological conflicts of the later works of the masters themselves, especially Michelangelo, who was torn between the pagan, Platonic ideal of classical beauty and the vigorous reaffirmation of traditional Christianity as exemplified in the Counter-Reformation movement.

Michelangelo's mannerism is expressed in the twisting. turning, writhing bodies of his slave figures for Julius II's tomb and in the implausible positions of the figures atop the Medici tombs, as well as in the brooding melancholy and resignation of the late "Pietà." In his architecture it is found in the Laurentian library where the eye is led simultaneously in divergent directions, where a juxtaposition of discordant elements prevails rather than a harmonious reconciliation of opposites and where there is a deliberate violation of the canons of proportion.

Later mannerist artists became the first to work largely within the shadow of the giants of the immediate past. Since they could not excel their predecessors either in technique or in grandeur of expression, they could only adopt some of their vocabulary and use it to startle the spectator and produce the unexpected. Tintoretto and Caravaggio performed daring feats of foreshortening, devised surprising multiple-perspective effects,and used chiaroscuro to create dramatic spotlighting. Parmigianino's "Madonna With the Long Neck," reveals human figures uith exaggerated oval faces, tapering fingers and willowy bodies. The sculptural equivalent is seen in the elegant elongation and winsome stance of Benvenuto Cellini's "Nymph of Fontainebleau," and in the airy grace and precarious balance of Giovanni da Bologna's bronze figure of "Mercury in Flight," whose winged foot is poised for a brief instant in his swift course. The stage was thus set for the emergence of a new style, the baroque. *See* BAROQUE ART.

RENAIX (Flem. *Ronse*), town, province of East Flanders, Belgium, 8 mi. S. of Oudenarde, at the foot of the hills of Flanders. It has yielded many pre-Roman and Roman finds. There are manufactories for woollen and linen goods. Pop. (1955) 25,442.

RENAN, ERNEST (1823–1892), French philosopher and orientalist, was born on Feb. 27, 1823, at Tréguier. His father's people were of the fisher-clan of Renans or Ronans. He was only 5 years old when his father died, and his sister Henriette, 12 years older than Ernest, a girl of remarkable character, was henceforth morally the head of the household. Ernest was educated in the ecclesiastical college at Tréguier. In the summer of 1838 he carried off all the prizes at the college. Through his sister, who was teaching in Paris, Felix Dupanloup heard of him. and sent for him at once, and placed him in the new ecclesiastical college of St. Nicolas du Chardonnet. He then proceeded to study for the priesthood at the Seminary of Issy, then at St. Sulpice, and finally he found his way to Stavistas, a lay college of the Oratorians. He soon found himself torn between his desire to lead the life of a Catholic priest and his intellectual inability to accept in its entirety the ordinary presentation of Catholic doctrine, or to submit to ecclesiastical authority. Even at Stavistas he found himself too much under the domination of the church, and, after a few weeks there, he reluctantly broke the last tie which bound him to the religious life, and entered M. Crouzet's school for boys as an usher. There he made the acquaintance, in 1846, of the chemist Marcellin Berthelot, then a boy of 18. To the day of Renan's death their friendship continued. Renan was occupied as usher only in the evenings. In the daytime he continued his researches in Semitic philology. In 1847 he obtained the Prix Volney for his *General History of Semitic Languages.*

The revolution of 1848 confronted him with the problems of democracy. The result was an immense volume, *The Future of Science,* which remained in manuscript until 1890. *L'Avenir de la science* is an attempt to conciliate the privileges of a necessary *élite* with the diffusion of the greatest good of the greatest number. In 1849 the French government sent him to Italy on a scientific mission. In Italy the artist in him awoke and triumphed over the savant and the reformer. On his return to Paris Renan lived with his sister Henriette. A small post at the National library, together with his sister's savings, furnished him with the means of livelihood. In the evenings he wrote for the *Revue des deux mondes* and the *De'bats* the exquisite essays which appeared in 1857 and 1859 under the titles *Études d'histoire religieuse* and *Essais de morale et de critique.* In 1852 his book on *Averroès* had brought him not only his doctor's degree, but his first reputation as a thinker. In his two volumes of essays Renan shows himself a liberal, but no longer a democrat. Nothing, according to his philosophy, is less important than prosperity. The greatest good of the greatest number is a theory as dangerous as it is illusory. Man is not born to be prosperous, but to realize, in a little vanguard of chosen spirits, an ideal superior to the ideal of yesterday. Only the few can attain a complete development. Yet there is a solidarity between the chosen few and the masses which produce them; each has a duty to the other. The acceptance of this duty is the only foundation for a moral and just society. The aristocratic idea has seldom been better stated.

Renan now began to frequent more than one Parisian salon, and especially the studio of Ary Scheffer, whose niece and adopted daughter, Cornélie, he proposed to marry in 1856. Henriette consented not only to the marriage, but to make her home with the young couple, whose housekeeping depended on the sum that she could contribute. The history has been told by Renan in the memorial essay, *Ma Soeur Henriette.* In 1859 appeared his translation of the *Book of Job* with an introductory essay, followed in 1859 by the *Song of Songs.*

Renan was now a candidate for the chair of Hebrew and Chaldaic languages at the Collège de France. The Catholic party upheld by the empress, would not appoint an unfrocked seminarist, a notorious heretic, to a chair of Biblical exegesis. Yet the emperor wished to conciliate Ernest Renan. He offered to send him on an archaeological mission to Phoenicia. Leaving his wife at home with their baby son, Renan left France, accompanied by his sister, in the summer of 1860. Madame Renan joined them in January 1861, returning to France in July. The mission proved fruitful in Phoenician inscriptions which Renan published in his *Mission de Phénicie.* They form the base of his *Corpus Inscriptionum Semiticarum.* At Amshit, near Byblos, Henriette Renan died of intermittent fever on Sept. 24, 1861. Her brother, himself at death's door, was carried unconscious on board a ship waiting in harbour and bound for France. On Jan. 11, 1862, the Minister of Public Instruction ratified Renan's election to the chair of Hebrew. But his opening lecture, in which, amid the applause of the students, Renan declared Jesus Christ "an incomparable Man," alarmed the Catholic party. Renan's lectures were pronounced a disturbance of the public peace, and he was suspended. He refused the librarian's post he was offered in exchange, and thenceforth lived by his pen.

Vie de Jésus.—Henriette had told him to write the life of Jesus. They had begun it together in Syria, she copying the pages as he wrote them, with a New Testament and a *Josephus* for all his library. The book is filled with the atmosphere of the East. It is the work of a man familiar with the Bible and theology, and no less acquainted with the inscriptions, monuments, types and landscapes of Syria But it is scarcely the work of a great scholar. Renan still used his literary gifts to pursue a scientific ideal. He produced the *Apostles* in 1866, and *St. Paul* in 1869, after having visited Asia Minor with his wife. His object was "to evoke from the past the origins of Christianity." In *St. Paul,* as in the *Apostles,* Renan shows his concern with the larger social life, his

sense of fraternity, and a revival of the democratic sentiment which had inspired *L'Avenir de la science.*

The Franco-German War was a turning-point in Renan's history. Germany had always been to him the asylum of thought and disinterested science. Now his heart turned to France. In *La Re'forme intellectuelle ef morale* (1871) he endeavoured at least to bind her wounds, to safeguard her future. At the same time the irony always perceptible in his work grows more bitter. His *Dialogues philosophiques,* written in 1871, his *Ecclesiastes* (1882) and his *Antichrist* (1876) (the fourth volume of the *Origins of Christianity,* dealing with the reign of Nero) show a disenchanted and sceptical temper. Gradually he aroused himself from his disillusioned mood, and observed with genuine interest the struggle for justice and liberty of a democratic society. The fifth and sixth volumes of the *Origins of Christianity* (the *Christian Church* and *Marcus Aurelius*) show him reconciled with democracy, confident in the gradual ascent of man.

Later Works and Death. — In 1883 he .published *Souvenirs d'enfance et de jeunesse,* which have the Celtic magic of ancient romance and the simplicity, naturalness and veracity prized in the 19th century. But his *Ecclesiastes,* published a few months earlier, his *Drames philosophiques,* collected in 1888, give a more adequate image of his fastidious, critical, disenchanted, yet not unhopeful spirit. They show the attitude towards uncultured Socialism of a philosopher liberal by conviction, by temperament an aristocrat. We learn in them how Caliban (democracy), the mindless brute, educated to his own responsibility, makes after all an adequate ruler; how Prospero (the aristocratic principle, or, if we will, the mind) accepts his dethronement for the sake of greater liberty in the intellectual world: since Caliban proves an effective policeman, and leaves his superiors a free hand in the laboratory; how Ariel (the religious principle) acquires a firmer hold on life, and no longer gives up the ghost at the faintest hint of change. Religion and knowledge are as imperishable as the world they dignify. Thus out of the depths rises unvanquished the essential idealism of Ernest Renan.

At sixty years of age, having finished the *Origins of Christianity,* Renan began his *History of Israel (3* vol., 1887–91) based on a lifelong study of the Old Testament and on the *Corpus Inscriptionum Semiticarum,* published by the Académie des Inscriptions under his direction from the year 1881 till the end of his life. He died on Oct. 12, 1892.

There is no collected edition of Renan's works. There is an English translation of the *Vie de Jésus* in Everyman's Library (1927). His *Correspondance* has been edited in 2 vol. (Paris, 1926–28). For Henriette Renan *see* Prof. Giraud, *Soeurs de grands hommes* (1926) and Renan's *Lettres Intimes* (1923).

RENARD, ALPHONSE FRANÇOIS, (1842–1903), Belgian geologist, was born at Renaix on Sept. 27, 1842. His first work (with Charles de la Vallée-Poussin, 1827–1904) was the *Mémoire sur les caractères mineralogiques et stratigraphiques des roches dites plutoniennes de la Belgique et de l'Ardenne française* (1876). In later essays and papers he dealt with the structure and mineral composition of many igneous and sedimentary rocks, and with the phenomena of metamorphism in Belgium and other countries.

Still more important were Renard's later researches connected with the "Challenger" expedition (*q.v.*). The various rock specimens and oceanic deposits were submitted to him for examination in association with Sir John Murray, and their detailed observations were embodied in the *Report on the Scientific Results* of *the Voyage of H.M.S. ('Challenger." Deep Sea Deposits* (1891). The more striking additions to our knowledge included "the detection and description of cosmic dust, which as fine rain slowly accumulates on the ocean floor; the development of zeolitic crystals on the sea bottom at temperatures of 32° and under; and the distribution and mode of occurrence of manganiferous concretions and of phosphatic and glauconite deposits on the bed of the ocean" (Geikie). Renard was professor at the Jesuit College of Louvain and then at the University of Ghent.

Renard died at Brussels on July 9, 1903.

RENARD THE FOX: *see* REYNARD THE FOX.

RENAUD DE MONTAUBAN (Rinaldo di Montalbano), one of the most famous figures of French and Italian romance. His story was attached to the *geste* of Doon of Mayence by the 13th-century *trouvère* who wrote the *chanson de geste* of *Renaus de Montauban,* better known perhaps as *Les quatre fils Aymon.* The four sons of Aymon give their name to inns and streets in nearly every town of France, and Renaud's sword Floberge, and his horse Bayard passed with him into popular legend. The poem opens with the dissensions between Charlemagne and the sons of Doon of Mayence, Beuves d'Aigremont, Doon de Nanteuil and Aymon de Dordone.

The rebellious vassals are defeated by the imperial army near Troyes, and, peace established, Aymon rises in favour at court, and supports the emperor, even in his persecution of his four sons, Renaud, Alard, Guichard and Richard. At the end of the usual series of violent adventures and catastrophes, Renaud gives himself up to religion, working as a mason on the church of St. Peter at Cologne. where he receives martyrdom at the hands of his jealous fellow labourers.

The connection of the four brothers with Moritessor, Dortmund, Mayence and Cologne, and the abundant local tradition, mark the heroes as originating from the region between the Rhine and the Meuse. Nevertheless, their adventures in Gascony, with the king of which they take service against the Saracens, are corroborated by historical evidence. and this section of the poem is the oldest. The enemy of Renaud was Charles Martel, not Charlemagne; King Ton was Odo of Gascony; the victory over the Saracens at Toulouse, in which the brothers are alleged to have taken part, was won by him in 721, and in 719 he sheltered refugees from the dominions of Charles Martel, Chilperic II, king of Neustria, and his mayor of the palace, Raginfred, whom he was compelled to abandon.

In a local chronicle of Cologne it is stated that St. Reinoldus died in 697, and in the Latin rhythmical *Vita* his martyrdom is said to have taken place under Bishop Agilolf (d. 717). Thus the romance was evidently composite before it took its place in the Carolingian cycle.

In Italy Renaud had his greatest vogue, and many episodes were added, as well as the personage of the hero's sister, Bradamante. Rinaldo di Montalbano had been the subject of many Italian poems before *Il Rinaldo* of Tasso.

BIBLIOGRAPHY.—The *chanson* of *Maugis d'Aigremont* and the prose romance of the *Conqueste de Trebizonde* belong to the same cycle. The prose *Ystoire de Regnault de Montauban* (Lyons, *c.* 1480) had a great vogue. It was generally printed as *Les quatre fils Aymon,* and was published in English, *The Foure Sonnes of Aymon,* by William Caxton, and subsequently by Wynkyn de Worde and William Copland. See *Hist. litt. de la France,* xxii., analysis by Paulin Paris; *Renaus de Montauban* (Stuttgart, 1862), ed. H. Michelant; *Storia di Rinaldino,* ed. C. Minutoli (Bologna, 1865); F. Wulff, *Recherches sur les sagas de Magus et de Geirard* (Lund, 1873); *Renout von Montalbaen,* ed. J. C. Matthis (Groningen, 1873); *Magus saga,* ed. *G.* Cederschiöld (Lund, 1876); A. Longnon, in *Revue des questions historiques* (1879); R. Zwick, *Uber die Sprache des Renaut von Montauban* (Halle, 1884); *The Four Sonnes of Aimon* (E. E. Text Soc., ed. Octavia Richardson, 1884); F. Pfaff, *Das deutsche Volksbuch von den Heymonskindern* (Freiburg im Breisgau, 1887), with a general introduction to the study of the saga; a special bibliography of the printed editions of the prose romance in L. Gautier's *Bibl. des chansons de geste* (1897); reinventions of the story by Karl Simrock (Frankfurt, 1845), and by Richard Steele (1897).

RENAUDOT, THÉOPHRASTE (1586?–1653), French physician, philanthropist, journalist, founder of the first French newspaper and friend of Richelieu, was born at Loudun (Poitou). He studied surgery in Paris and, when only 19, he received, by favour apparently, the degree of doctor at Montpellier.

In 1612 Renaudot was summoned to Paris by Richelieu and was appointed to organize a scheme of public assistance. Many difficulties were put in his way, however, and until 1625 he spent most of his time in Poitou. In 1630 Renaudot. as commissary general of the poor, opened in Paris a *bureau d'adresse,* a com-

bined labour bureau, intelligence department, exchange and charity organization, which directed indigent sick persons to doctors prepared to give them free treatment. Renaudot established (1635) a free dispensary, despite the opposition of the ultra-conservative medical faculty in Paris, which refused to accept the new medicaments he proposed and restricted themselves to the old prescriptions of bloodletting and purgation. Under the protection of Richelieu, Renaudot started the first French newspaper, the *Gazette* (1631; *see* NEWSPAPER). In 1637 he was authorized to add pawnbroking to the activities of the bureau, and the first pawn shops were opened.

The medical faculty campaign against Renaudot, headed by Guy Patin, was prosecuted with increased vigour after the deaths of Richelieu and Louis XIII, and eventually he was denied the right to practise medicine in Paris. The *Gazette* remained to him, however, and in 1646 he was appointed by Mazarin historiographer to the king.

Renaudot died on Oct. 25, 1653.

BIBLIOGRAPHY.—E. Hatin, *Théophraste Renaudot* (1883); G. Bonnefont, *Un Oublié, Théophraste Renaudot* (n. d.); A. Castiglioni, *History of Medicine*, trans. by E. B. Krumbhaar, p. 575 (1941).

RENAULT, BERNARD (1836–1904), French paleobotanist who made many fundamental contributions to knowledge of the structure of Carboniferous plants, was born on March 4, 1836, at Autun. After graduating from Autun college in 1855, he entered the Institut Brenot at Dijon, where he became professor of chemistry and physics. He received the degree of doctor of physical science at Paris in 1867. Meanwhile, Renault had begun as a hobby the study of plant fossils.

In 1872 Renault became *préparateur* in the Paris Natural History museum and, in 1876, assistant naturalist, a post he held until his death in Paris on Oct. 16, 1904.

One of his early papers described the remarkable anatomy of the stem of *Sphenophyllum* (wedge grass). He discovered the fern genus *Botryopteris* and established the family Botryopteridaceae. He discovered *Poroxylon* and, in 1879, published an account of cordaitean (ancient seed plant) structure in *Structure comparée de quelques tzges de la flore carbonifère*. Renault hypothesized that certain Paleozoic seed plants had motile sperm, structures thought at the time to be exclusively cryptogamic (nonseed-bearing). He also investigated fossil microorganisms. Renault's larger works include *Bassin houiller et permien d'Autun et d'Épinac: flore fossile* (1893–96), treating, especially, the internal structure of all groups of Paleozoic plants, and *Cours de botanique fossile fait au Muséum d'histoire naturelle* (1881–85), a series of lectures.

Accounts of Renault are given by D. H. Scott in *Jour. Roy. Micro. Soc.*, pp. 129–145 (1906), and in A. Roche, *Biographie de Bernard Renault* (1905), the latter listing Renault's more than 200 publications. (J. W. TT.)

RENAULT, LOUIS (1843–1918), French jurist who in 1907 was awarded a Nobel peace prize for his services to international law, was born on May 21, 1843, at Autun. From 1868 to 1873 he was professor of Roman and commercial law at the University of Dijon. From 1873 until his death he was professor in the faculty of law at the University of Paris, where in 1881 he became professor of international law. In 1890 he was appointed jurisconsult of the ministry of foreign affairs, a post specially created for him, and thereafter French foreign policy was scrutinized by him in the light of international law. He served at numerous conferences in this capacity, notably at the two Hague conferences in 1899 and 1907, and at the London naval conference of 1908–09.

Renault was prominent as an arbitrator, his more famous cases being the Japanese House Tax case of 1905, the Casa Blanca case of 1909, the Sawarkar of 1911, the Carthage of 1913 and the Manouba of the same year. Among his writings are numerous articles and monographs on the specialized topics of international law. Together with his friend and colleague, C. Lyon-Caen, he produced a compendium of commercial law in two volumes, a treatise in eight volumes, and a manual which ran to many editions.

In 1879 Renault published his *Introduction to the Study of International Law*, and in 1917 *The First Violations of International Law by Germany*, concerning the invasion of Belgium and Luxembourg in breach of Germany's treaty obligations. He died on Feb. 7, 1918, at Barbizon. (E. H. LD.)

RENDERING, ARCHITECTURAL: *see* ARCHITECTURAL RENDERING.

RENDSBURG, a town in *Land* of Schleswig-Holstein, Germany, on the Eider and on the Kaiser Wilhelm canal, 20 mi. W. of Kiel, on the Altona-Flensburg railway. Pop. (1950) 36,991. Rendsburg came into existence under the shelter of a castle founded by the Danes about the year 1100 and was an object of dispute between the Danish kings and the counts of Holstein. In 1252 it was adjudged to the latter and the town was surrounded with ramparts in 1539. The war of 1848–50 began with the capture of Rendsburg by the Holsteiners and it formed the centre of the German operations. In Nov. 1863 the town was occupied by the Saxon troops acting as the executive of the German Confederation, and it was the base of the operations of the Austrians and Prussians against Schleswig in the spring of the following year. Rendsburg was jointly occupied by Austrian and Prussian military until 1866, when it fell to Prussia. It consists of three parts—the crowded Altstadt, on an island in the Eider; and new towns on the north and south banks of the river. Its importance rests on the commercial facilities afforded by its connection with the North sea and the Baltic through the Kaiser Wilhelm canal, by which transit trade is carried on in grain, timber, Swedish iron and coals. The principal products are dyes, iron, artificial manures, machines and tobacco.

RENÉ I (1409–1480), duke of Anjou, of Lorraine and Bar, count of Provence and of Piedmont, king of Naples, Sicily and Jerusalem, was born at Angers on Jan. 16, 1409, the second son of Louis II, king of Sicily, duke of Anjou, count of Provence, and of Yolande of Aragon. By his marriage treaty (1419) with Isabella, elder daughter of Charles II, duke of Lorraine, the comte de Guise, as he then was, became heir to the duchy of Bar, which was claimed as the inheritance of his mother Yolande, and in right of his wife, heir to the duchy of Lorraine. René, then only ten, was to be brought up in Lorraine under the guardianship of Charles II and Louis, cardinal of Bar, both of whom were attached to the Burgundian party, but he retained the right to bear the arms of Anjou. When Louis of Bar died in 1430 René came into sole possession of his duchy; and in the next year, on Charles II's death, he succeeded to the duchy of Lorraine. But the inheritance was claimed by the heir-male Antoine de Vaudémont, who with Burgundian help defeated René at Bulgnéville in July 1431. The duchess Isabella effected a truce with Antoine de Vaudémont, but the duke remained a prisoner of the Burgundians until April 1432, when he recovered his liberty on parole on yielding up as hostages his two sons, John and Louis of Anjou. His title as duke of Lorraine was confirmed by his suzerain, the emperor Sigismund, at Basle in 1434. This proceeding roused the anger of the Burgundian duke Philip the Good, who required him early in the next year to return to his prison, from which he was released two years later on payment of a heavy ransom. He had succeeded to the kingdom of Naples through the deaths of his brother Louis III and of Joanna II (of Durazzo), queen of Naples, the last heir of the earlier dynasty. Louis had been adopted by her in 1431, and she now left her inheritance to René.

The marriage of Mary, daughter of Charles I of Bourbon and niece of Philip of Burgundy, with John, duke of Calabria, René's eldest son, cemented peace between the two princes. After appointing a regency in Bar and Lorraine, he visited his provinces of Anjou and Provence and in 1438 set sail for Naples, which had been held for him by the duchess Isabella. In 1441 Alphonso of Aragon laid siege to Naples, which he sacked after a six months' siége. René returned to France in the same year; and though he retained the title of king of Naples his effective rule was never recovered.

René took part in the negotiations with the English at Tours in 1444, and peace was consolidated by the marriage of his younger daughter, Margaret, with Henry VI at Nancy. René now made over the government of Lorraine to John, duke of Calabria, who

was, however, only formally installed as duke of Lorraine on the death of Queen Isabella in 1453. René had the confidence of Charles VII of France (who had married his sister, Mary of Anjou) and is said to have initiated the reduction of the men-at-arms set on foot by the king. with whose military operations against the English he was closely associated. He entered Rouen with him in Nov. 1449 and was also with him at Formigny and Caen.

After his second marriage (1454) with Jeanne de Laval. daughter of Guy XIV, count of Laval, and Isabella of Brittany, René took a less active part in public affairs and devoted himself more to artistic and literary pursuits. In 1453 he made an unsuccessful attempt on northern Italy. In 1467 his son John took Barcelona from John II of Aragon and held it till his death in 1470 *(see* ANJOU).

The king of Sicily's fame as an amateur of painting has led to the attribution to him of many old paintings in Anjou and Provence, in many cases simply because they bear his arms. These works are generally in the Flemish style and were probably executed under his patronage and direction, so that he may be said to have formed a school of fine arts in sculpture, painting, gold work and tapestry. Two of the most famous works once attributed to René are the triptych, the "Burning Bush," in the cathedral of Aix, showing portraits of René and his second wife, Jeanne de Laval, and an illuminated Book of Hours in the Bibliothèque Nationale, Paris. The "Burning Bush" was in fact the work of Nicolas Froment of Avignon. Among the men of letters attached to René's court was Antoine de la Sale, whom he made tutor to his son, the duke of Calabria. He encouraged the performance of mystery plays: On the performance of a mystery of the Passion at Saumur in 1462 he remitted four years of taxes to the town; and the representations of the Passion at Angers were carried out under his auspices. He exchanged verses with his kinsman Charles of Orléans. The best of his poems is the idyll of Regnault and Jeanneton, representing his courtship of Jeanne de Laval. Le *Livre des tournois,* a book of ceremonial, and the allegorical romance, *Conqueste qu'un chevalier nommé le Cuer d'amour espris feist d'une dame appelée Doulce Mercy,* with other works, were perhaps dictated to his secretaries or compiled under his direction. He died on July 10. 1480.

RENEE OF FRANCE (1510–1575), second daughter of Louis XII and Anne of Brittany. was born at Blois on Oct. 25, 1510. After being betrothed successively to Gaston de Foix, Charles of Austria (the future emperor Charles V), his brother Ferdinand, Henry VIII of England, and the elector Joachim II of Brandenburg, she married in 1528 Hercules II of Este, son of the duke of Ferrara, who succeeded his father six years later. Renée's court became a rendezvous of men of letters and a refuge for the persecuted French Calvinists. She received Clément Marot and Calvin at Ferrara, and finally embraced the reformed religion. Her husband, however. who viewed these proceedings with disfavour, banished her friends, took her children from her, threw her into prison. and eventually made her abandon at any rate the outward forms of Calvinism. After his death in 1559, Renée returned to France and turned her duchy of Montargis into a centre of Protestant propaganda. During the wars of religion she was several times molested by the Catholic troops, and in 1j6z her château was besieged by her son-in-law, Francis, duke of Guise. She died at Montargis.

RENFREW, a royal and small burgh and the county town of Renfrewshire, Scot., near the south bank of the Clyde, 5½ mi. W. by N. of Glasgow by road. A small part of the parish of Govan is included in the burgh boundaries. Pop. (1951) 17,091. Industries include large shipbuilding works, engineering and the manufacture of rubber and paint. The Clyde trust has constructed a large dock and there is a ferry to Yoker. South of the town is the municipal aerodrome and civil airport. Robert III gave a charter in 1396, but it was a burgh (Renifry) at least 250 years earlier. Close to the town, on the site of Elderslie house, Somerled. lord of the Isles, was defeated and slain in 1164 by the forces of Malcolm IV. against whom he had rebelled. Robert III bestowed upon his son James (afterward James I of Scotland) the title of baron of Renfrew, still borne by the eldest son of the sovereign.

RENFREWSHIRE, a southwestern county of Scotland, bounded north by the river and Firth of Clyde, east by Lanarkshire. south, southwest and west by Ayrshire and northwest by the Firth of Clyde. The county has an area of 224.7 sq mi. The surface is low and undulating, except toward the Ayrshire border on the west, where the principal height is the hill of Stake (1,711 ft.) and the confines of Lanarkshire on the southeast, where a few points attain a height of 1,100 ft. The southwestern hills are formed of volcanic rocks, basalts, porphyrites, tuffs and agglomerates of the age of the Calciferous Sandstone series. Practically all the area west of these rocks is occupied by the Carboniferous Limestone series. Boulder clays and glacial gravels and sands cover extensive areas. Much of the higher land in the centre is well wooded. In the northwest Loch Thom and Gryfe reservoir provide Greenock with water, and southeast of Barrhead Balgray reservoir and Glen reservoir reinforce the water supply of the Glasgow area. Castle Semple loch and other lakes are situated in the south and southeast. Strathgryfe is the only large vale in the shire; the scenery at its head is wild and bleak, but the lower reaches are pasture land. The wooded ravine of Glenkilloch, to the south of Paisley, is watered by Killoch burn, on which are three falls.

Greenock. Gourock, Wemyss bay and Inverkip are holiday resorts on the northwestern coast of the county.

History.—At the time of the Roman advance from the Solway the land was peopled by the British tribe of Damnonii. To hold the natives in check the conquerors built in 84 the fort of Vanduara on high ground now covered by houses and streets in Paisley; but after the Romans retired (410) the territory was overrun by Cumbrian Britons and formed part of the kingdom of Strathclyde, the capital of which was situated at Alclyde, the modern Dumbarton. In the 7th and 8th centuries the region practically passed under the supremacy of Northumbria, but in the reign of Malcolm Canmore became incorporated with the rest of Scotland. During the first half of the 12th century, Walter Fitzalan, high steward of Scotland, ancestor of the royal house of Stuart, settled in Renfrewshire on an estate granted to him by David I. Until their accession to the throne the Stuarts identified themselves with the district, which, however, was only disjoined from Lanarkshire in 1404. In that year Robert III erected the barony of Renfrew and the Stuart estates into a separate county, which, along with the earldom of Carrick and the barony of King's Kyle (both in Ayrshire), was bestowed upon his son, afteruard James I. From their grant are derived the titles of earl of Carrick and baron of Renfrew, borne by the eldest son of the sovereign. Apart from such isolated incidents as the defeat of Somerled near Renfrew in 1164, the battle of Langside in 1568 and the capture of the 9th earl of Argyll at Inchinnan in 1685, the history of the shire is scarcely separable from that of Paisley or the neighbouring county of Lanark.

Agriculture **and** Industries.— The hilly tract contains much peat moss and moorland, but over those areas which are not thus covered the soil. which is a light earth on a substratum of gravel, is deep enough to produce good pasture. In the undulating central region the soil is better. particularly in the basins of the streams, while on the flatlands adjoining the Clyde there is a rich alluvium which, intensively used for arable and horticultural cropping as well as dairying, yields heavy crops. Near the populous centres some orchards and market gardens are found, and an increasing acreage is under wood. Most of the cattle are maintained in connection with dairying. Sheep farming, though on the increase, is

not so important as in the other southern counties of Scotland and pig raising is on the decline.

In point of commercial and manufacturing importance Renfrewshire is second only to Lanark. Granite. limestone and sandstone are quarried. The thread industry at Paisley is very extensive. Cotton and flax spinning, printing, bleaching and dyeing are carried on at Paisley, Renfrew, Barrhead and elsenhere; noollens and worsteds are produced at Greenock and Renfrew. Engineering works and iron foundries are at Greenock, Port Glasgow, Paisley. Renfrew. Barrhead and Johnstone Sugar is a staple article of trade in Greenock and there are chemical works at Cathcart. Paisley, Hurlet and Nitshill. Tin boxes are manufactured and tin is printed at Greenock Jams and preserves are processed at Paisley. Shipbuilding is especially important at Greenock and Port Glasgoxv. Paper mills are established in Johnstone and Linwood There are tanning industries at Paisley, Bridge of Weir and Barrhead. Numerous miscellaneous industries — such as the making of starch, cornflour, earthenware and soap are important in Paisley and elsenhere.

Trade and fisheries are centred at Greenock. Barytes and fireclay are mined and there are limestone and sandstone quarries.

The trading estate at Hillington. 2½ mi. east of Paisley. nas the first to be established in Scotland as part of a plan to attract new industries to the area. The municipal aerodrome and civil airport, near Renfrew and about 7 mi. west of central Glasgow, serves all parts of the world.

Population and Administration. — The population in 1961 was 338.815 Thus. though the shire is only 27th in point of size of the 33 Scottish counties, it is fourth in population. The large burghs are Paisley (1961 pop 95,753), Greenock (74,578), Port Glasgow (22 551) (*qq.v.*). The small burghs are Johnstone (*q.v.;* 18 369). Barrhead (14,442), Gourock (*q.v.;* 9,609) and Renfrew (*q v ;* 1'7.946). which is the only royal burgh. There are five county districts.

The shire returns one member to parliament for the eastern, and another for the western division. Paisley and Greenock each return one member. Renfrewshire forms a sheriffdom with Argyll. and there is a resident sheriff-substitute at Paisley and one at Greenock.

RENI, GUIDO (1575–1642), painter and engraver of the Bolognese school, the great precursor of neoclassicism, was born on Nov. 4. 1575, at Bologna. At the age of ten he entered the studio of Denis Calvaert, a Flemish painter. At 20 he was attracted by the anti-Manneristic novelty of the Carracci family and joined their "Academy of the Natural." In his early years Guido was not precocious. He trained himself by copying from Annibale Carracci, from plaster reproductions of classical pieces and from the St. Cecilia of Raphael. In 1599 he was received into the guild of painters. Between 1600 and 1601 Guido mas in Rome, where a few years later he opened a studio of his own. The most important work to survive from this first period in Rome is the "Crucifixion of St. Peter" (Vatican). In 1604 Guido was in Bologna, collaborating in the painting of frescoes in the cloisters of S. Michele in Bosco In 1607 he was back in Rome, sent for by Pope Paul V to paint the Vatican frescoes of the "Nozze Aldobrandine" and "Le Dame" (1608). He entered the service of Scipione Cardinal Borghese and painted for him the fresco "St. Andrew's Progress to the Gallons" (1608) in the chapel of S. Gregorio Magno al Celio and "The Eternal Father and the Minstrel Angels" in the chapel of S. Silvia. Guido surrounded himself with helpers — Lanfranco. Albani. Gessi, Antonio Carracci, Cavedone. Sementi—who were fascinated by his noble if somenhat tyrannical personality. The frescoes illustrating the stories of the Virgin in the pontifical chapel in Montecavallo (Palazzo Quirinale) date from 1610 and. though not the best knonn, are perhaps the most poetic of his frescoes. Following some quarrels with the pope's treasurer. Guido returned to Bologna; but. recalled to Rome by the pope himself in 1612. he finished some frescoes in the pontifical chapel of Sta. Maria Maggiore. Between 1613 and 1614 followed the celebrated fresco "Phoebus and the Hours preceded by Aurora' in the Borghese garden house (now Palazzo Rospigliosi). In 1614 Guido was again in Bologna and painted the fresco "The Glory of St. Domenic" in the church of the same name. From 1617 to 1621 he worked at the Mantuan court of Duke Ferdinand Gonzaga (four paintings of the "Labours of Hercules," non at the Louvre, Paris). In' 1622 he went to Naples to paint the frescoes of the treasury of S. Gennaro, but. having quarreled with his patrons he returned to Rome almost at once, leaving behind his pupils Gessi and Sementi, whom he had employed the previous year for the painting of the frescoes in the Chapel of the Sacrament of Ravenna cathedral. The last documented visit to Rome is in 1627. He settled down in Bologna, mhere from around the year 1630 began a decade in which his art was shown to the greatest perfection, starting with the famous "Madonna With Rosary" (Bologna) He died on Aug. 18, 1642. in Bologna and is buried in S. Domenico.

Highly praised by his contemporaries and subsequently by all defenders of the Academy up to the neoclassicists, above all in France. Guido, like Raphael and the classicists, came under the condemnation of the romanticists and the epoch of Ruskin. By the middle of the 20th century art criticism had studied afresh Guido's personality, making a better appraisal of 17th-century "Academism." in a new historical perspective. In Rome, the main inspiration for Guido's art was the Raphael frescoes and the

CULVER SERVICE

archaeological marbles, the Niobe and the Laocoon, and he stands apart from the baroque art of his day. His striving is toward a harmony of statuary, classical and elusive at the same time, in which reality is presented in idealized proportions. But since Guido works toward classicism in a period from which classical traits are absent, he remains isolated, far removed from the realistic optimism in Rome from which were to spring the baroque forms of art.

For Guido, the classical ideal becomes a feeling for beauty as the very stuff of poetry. The greatness of Guido lies in the manner in which he evokes the musical harmony of this myth of beauty, filling it with the altogether modern sentiment of nostalgia. The creative process is calm and serene, just as are the studied softness of colour and form. Guido's feeling of melancholy was, however, soon to become debased into sentimentalism and mannerized religiosity.

Other major works by Guido Reni are to be found in the galleries and churches of Bologna, Rome, Naples, Siena and Crema in Italy, in the Louvre, Paris, in the National gallery, London, at Dulwich, London, and in the Kunsthistorisches museum, Vienna.

RENKUM, a municipality of the Netherlands, situated 2½ mi. W. of Arnhem (*q.v.*) on the Utrecht road and comprising the villages of Oosterbeek (the local government centre), Renkum, Doorwerth, Heelsum and Wolfheze. Pop. (1947) 11,458; (1957) 27,382 (mun.). Area 18½ sq.mi.

A tourist and international conference centre in beautiful surroundings, it was especially associated with the battle of Arnhem in World War II; on the Oosterbeek village green is the Airborne memorial put up by the Dutch in memory of the British airborne forces. The Arnhem-Oosterbeek war cemetery is outside the town and Castle Doonverth is now the Airborne museum. Renkum is linked by road and rail with main towns. Local industries include rubber, paper and brickmaking.

RENNELL, JAMES RENNELL RODD, 1ST BARON (1858–1941), British diplomatist, ambassador in Rome when Italy entered World War I, was born in London on Nov. 9, 1858. He was educated at Haileybury and Balliol college, Oxford, where he won the Newdigate prize (1880) for English verse. He entered the diplomatic service in 1884 and was sent to Berlin, where he wrote a biography of the German emperor Frederick III. The accuracy of this, when published in 1888, much annoyed the new emperor William II. In spite of this, Rodd's career was highly successful. After holding appointments in Rome, Paris and Zanzibar, he became in 1894 second-in-command to Lord Cromer in Cairo, Egy. For his work there, particularly during the Fashoda crisis, he was knighted in 1899. He was ambassador in Rome from 1908 to 1919, retiring from the diplomatic service in 1921. He was Conservative member of parliament for St. Marylebone, 1928–32, and was raised to the peerage in 1933. He died at Shamley Green, Surrey, July 26, 1941. He published works on classical Greece and Renaissance Italy, and *Social and Diplomatic Memories,* 3 vol. (1922–25). (R. N. W. B.)

RENNENKAMPF, PAUL (1854–1918), Russian general, was born on April 17, 1854. He entered the army in 1873 and in 1882 was appointed to the general staff. Promoted to the rank of general in 1900, he distinguished himself in the Russo-Japanese War (1904–05). In 1913 he was appointed to command of the troops in the Vilna military district. In Aug. 1914, he commanded the northern army which invaded East Prussia. His inaction during the battle of Tannenberg, where the southern army under Alexander Samsonov was destroyed on Aug. 26–29. was a bitter disappointment, and he was even suspected of treachery.

Personally brave, Rennenkampf, as an army commander, showed himself in the strategic sphere alternately rash and timid, because of his inability to grasp the situation as a whole. At the beginning of 1915 he was recalled, and later under pressure of public indignation was dismissed from the service. Rennenkampf was killed at Taganrog by the Bolsheviks in 1918.

RENNER, KARL (1870–1950), Austrian politician, was born on Dec. 14. 1870, the son of a peasant, at Dolni-Dunajovice (Unter-Tannowitz), Moravia.

Renner studied law at the University of Vienna and early attached himself to the Social Democratic party. He advocated the transformation of the Habsburg empire into a federal democratic commonwealth based on equal political and cultural rights for all nationalities. He was elected deputy to the Austrian *reichsrat* (parliament) in 1907 and, after the collapse of the empire, he became, on Nov. 12, 1918, the first chancellor of the Austrian republic. He then supported the idea of a union of Austria with a democratic federal Germany.

Renner was largely responsible for the decrees of the *nationalrat* (lower chamber) which called for the dethronement of the dynasty of Habsburg-Lorraine and the banishment of all members of this house if they did not submit entirely to the laws of the republic, and he was in charge of the negotiations which led to the former emperor Charles's leaving Austria in March 1919.

On May 12, 1919, Renner went to Paris as head of the Austrian delegation to receive the conditions of peace. As the foreign minister, Otto Bauer (*q.v.*), resigned rather than take the responsibility for certain provisions of the treaty, Renner took over the conduct of foreign affairs and on Sept. 10, 1919, signed the Treaty of St. Germain by which Austro-German union *(Anschluss)* was prohibited.

The first coalition ministry had been succeeded in Oct. 1919 by a second, in which Renner was again chancellor and secretary for foreign affairs. Relations between the Austrian government and Hungary, which since the regime of the revolution had been succeeded by a reaction, were very strained. Renner, who as a Social Democrat, was inimical to the nationalist Hungarian government, refused to grant demands put forward to extradite the Hungarian revolutionaries who had fled to Vienna. This brought him into conflict with the Christian Democrats and their representatives in the cabinet. The coalition dissolved in June; but Renner remained in charge of foreign affairs until Oct. 1920. When in 1930 the Social Democrats became the stronger party, Renner was elected president of the *nationalrat;* he resigned in 1933.

After the annexation of Austria to Germany in 1938, Renner remained unmolested. In a public statement a few days before the plebiscite of April 10, 1938, he had recalled that he had already supported the *Anschluss* idea in 1918.

After the occupation of Vienna by the Soviet army, Renner obtained approval from, the Russians for the formation of an Austrian democratic government and on April 29, 1945, became chancellor of the second Austrian republic. On Dec. 20, 1945, the newly elected *nationalrat* nominated him president of the republic. He died at Doebling, near Vienna, on Dec. 31, 1950.

His principal works are *Grundlagen und Entwicklungsziele der Österreichisch-ungarischen Monarchie* (1906); *Oesterreichs Erneuerung* (1919); *Die Wirtschaft als Gesamtprozess und die Sozialisierung* (1924). (A. F. P.; X.)

RENNES, a town in the *département* of Ille-et-Vilaine, western France, formerly the capital of Brittany, lies at the confluence of two rivers, the Ille and the Vilaine, in the centre of a basin that opens widely on the outer reaches of Normandy, Maine, Anjou and lower Brittany. Pop. (1954) 112,553.

The town is built on a regular plan, the main axis running east and west along the canalized Vilaine. The plan originated in the reconstruction after the great seven-day fire of 1720 which destroyed the best part of the old town, but spared the magnificent house of the parliament of Brittany, the work of Salomon de Brosse, finished in 1654. It was to the credit of Jacques III Gabriel, the king's architect (whose son designed the Place de la Concorde in Paris) sent down to supervise the plans, that he achieved the harmony of the centre with the house of parliament, with a remarkable austere coherence. Also by Gabriel is

the town hall, a very gracious edifice in the Louis XV style. The cathedral was partly rebuilt at the beginning of the 19th century, its most interesting element being a 15th-century gilt carved wood altarpiece of German work.

Other interesting architectural remains, all on the northern bank of the river, are the Mordelaise gate (15th century) and the cluster of 16th-century houses and 17th-century mansions in the narrow, crooked streets round the cathedral. No building of architectural value suffered from the extensive damage caused by World War II, except the interesting late Gothic church of Saint-Germain. The museum building, destroyed by enemy action in 1944, may now be considered one of the most modern provincial museums in France, the most interesting exhibit being a Nativity by Georges de La Tour (1593–1652). The recent extensions of the city, especially since 1945, have taken place mainly in the south, beyond the railway lines and yards.

Rennes, which is the seat of an archbishop, is also the seat of a prefect (an ***inspecteur*** *général* supervising the whole region of Brittany), the headquarters of the 3rd Army corps, and the centre of a university (founded in Nantes in 1461 and transferred to Rennes in 1735) with faculties of law, arts, sciences and medicine. It is also the seat of a court of appeal and a court of assize. The town, a centre of communications. is an important railway junction on the Paris-Brest line, with lines to Saint-Malo and Nantes. The French railways have extensive workshops east of the town. Rennes is a nexus of roads and road transport, where two main axes meet, Paris-Brest and St.-Malo-Bordeaux. The large airport of Rennes-St.-Jacques was still partly under military control in the early 1960s.

Rennes. originally an agricultural centre, was before World War II a food-producing town with a few light industries. Postwar developments have led important industrial firms to establish themselves in the town, the main example being the large Citroen automobile works. Other factories include furniture, agricultural implements, chemicals, fertilizers and printing presses.

In Celtic times, Rennes was the capital of the Redones. The Romans made it the centre of communications of the province of Armorica. It was only in the 10th century, when the count of Rennes subdued the province, that the town became pre-eminent as the seat of the dukes of Brittany, and the place of their coronation. In 1356 Bertrand du Guesclin saved the town from capture by the English under the duke of Lancaster. The parliament of Brittany, founded in 1551, held its sessions at Rennes from 1561, they having been previously shared with Nantes. Henry IV entered the city in state in May 1598. In 1675 an insurrection broke out against tobacco and stamp duties. In the repression that followed parliament was transferred to Vannes where it remained until 1689. During the French Revolutionary Wars, Rennes at first opposed the decrees of the constituent assembly: then, reconciled with the revolution, it became the headquarters of the Republican army against the Vendéens. (C. F. L.)

RENNET, a milk-clotting preparation from calf stomachs, used in making junket, cheese and casein (*q.v.*).

If the fourth stomach (abomasum) of a calf is cut up and covered for several days with 10% brine and a preservative (*e.g.*, thymol), the extract so prepared will contain the enzyme rennin and will curdle many times its own volume of warm milk. This is a result of the action of the rennin upon one of the several kinds of casein present in the milk. A large fragment of the molecule is split off. Rennin is secreted by the gastric mucosa of the calf in the form of an inactive substance prorennin, which is changed into rennin by contact with dilute acid. Rennin, like pepsin, digests proteins but it differs from pepsin in requiring only a mildly acid reaction and in breaking fewer bonds in the protein molecule.

The clotting of milk does not necessarily indicate the presence of rennin since most, if not all, proteolytic enzymes including those from plants can clot milk. When sufficiently purified, rennin crystallizes as microscopic cubes, capable when re-dissolved of coagulating about 10,000,000 times their own weight of milk. (N. J. BE.)

RENNIE, JOHN (1761–1821), Scottish civil engineer, who built or improved many canals, bridges, docks and harbours, was born at Phantassie, East Lothian, June 7, 1761. He worked under Andrew Meikle, millwright, and attended classes at Edinburgh university, though he did not graduate. His first major work was the Albion mills, Blackfriars, London (built 1784–88, destroyed by fire 1791). Rennie greatly extended the use of iron for gears and other parts of machinery. After John Smeaton (*q.v.*) retired, Rennie carried out work on the Kennet and Avon, Rochdale, Lancaster and other canals.

From about 1800 Rennie carried out extensive drainage improvements in the Lincolnshire fens. He constructed or improved many harbours including Wick, Grimsby, Holyhead and Hull and built the London and East India docks on the Thames, and many bridges including Waterloo, Southwark and London bridges. He carried out extensive improvements to naval dockyards at Plymouth, Portsmouth, Chatham and Sheerness; he also began to build the breakwater that shelters Plymouth sound. Rennie died in London on Oct. 4, 1821, and was buried in St. Paul's cathedral.

After his death his business was divided between his sons. George, the elder, ran the mechanical engineering side and John (later Sir John) the civil, including the completion of London bridge and Plymouth breakwater.

See S. Smiles, ***Lives of the Engineers*** (1904). (S. B. HN.)

RENO, a city of Nevada, U.S., the seat of Washoe county, is situated on the Truckee river, 14 mi. from the western boundary of the state. at an elevation of 4,500 ft. The city lies near the foot of the Sierra Nevada range amid magnificent and varied scenery. It has a moderate climate throughout the year.

Reno received its start in 1859 when a settler named M. C. Fuller built an inn on the south side of the Truckee river to accommodate travelers and freight teams from the Virginia City mines. When the Central Pacific railroad reached the spot in 1868, a land auction was held and homes were built almost overnight. The new town was named after Gen. Jesse Reno of Virginia, a federal officer in the American Civil War who was killed in the battle of South Mountain. Reno received a charter as an incorporated city in 1879.

Until 1900 Reno's business activity centred around its value as a distribution point. Then after several well-known people were granted divorces under the liberal state law, the town became famous as a divorce centre. (The state recognizes seven grounds for an absolute decree and requires only six weeks' residence before bringing suit.) Another attraction is the "no-waiting" period for marriages in Nevada. In an average year during the 1950s, for example, almost 20,000 marriages were performed in Washoe county compared with about 4.500 divorces granted.

Being close to the Sierra Nevada, Reno is a recreation centre during all seasons of the year. Good skiing, hunting and fishing areas are located nearby. With the full legalization of gambling in the state in 1931, the city began to attract tourists and weekend visitors to its many gambling casinos, most of which also furnish musical entertainment. The gambling combined with the fact that three federal highways run through the city account for the flourishing motel trade.

There are some small manufacturing plants in the area and Reno also continues to be an important warehousing and distribution centre because of Nevada's "Free Port" law under which merchandise originating in either the east or the west and moving in interstate commerce may be stored and assembled in transit free of taxation.

The University of Nevada is located on a beautiful 60-ac. campus overlooking the city from the north.

Immediately adjacent to Reno is the city of Sparks, founded in 1903 by the Southern Pacific Railroad company and named in honour of the state's incumbent governor at that time. For many years most of the town's residents were railroad employees. However, in the 1950s new housing developments constructed to meet the demands of people employed in Reno caused a sharp jump in population. The business district is centred along one main street which also serves as a federal highway. Gambling and the motel trade are also important businesses in Sparks.

The population of Reno in 1960 was 51,470. For comparative

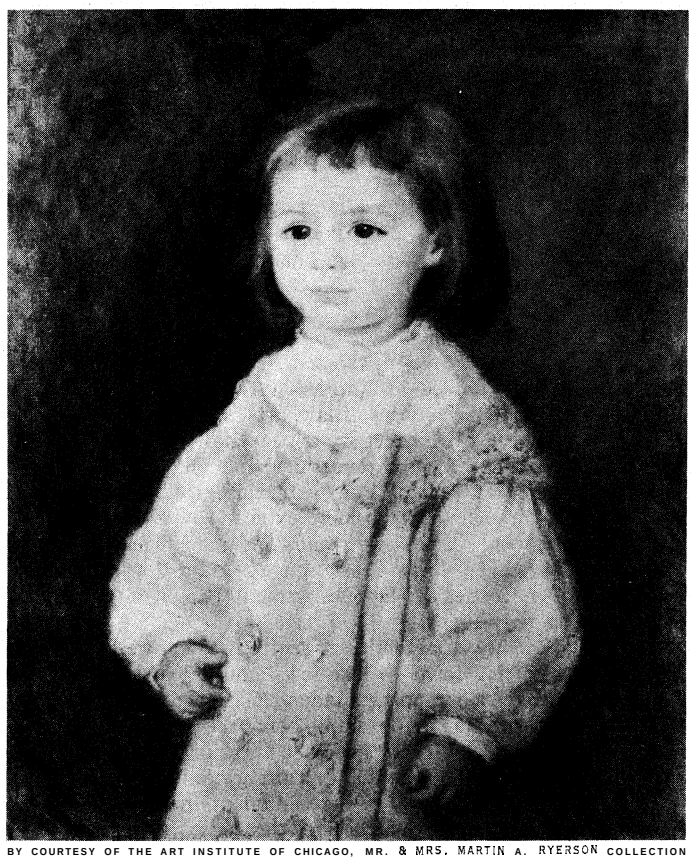
population figures for both Reno and Sparks see table in NEVADA: Population. (D. W. Ds.)

RENOIR, PIERRE AUGUSTE (1841–1919), French painter, one of the greatest of the Impressionists, was born at Limoges on Feb. 25, 1841, the son of a tailor who moved to Paris about 1845. After working as a painter of porcelain and as a painter of fans and banners, in 1862 Renoir entered the studio of C. G. Gleyre. where he made the acquaintance of Monet, Sisley and Bazille (with whom he frequently shared a studio until 1870). In 1864 and 1865 Renoir first exhibited at the Salon, but his entries were rejected in 1866 (despite the intervention of J. B. C. Corot and C. F. Daubigny) and again in 1867. With the closure of Gleyre's studio in 1864, Renoir spent some time of each year up to 1867 working in the region of Fontainebleau, frequently in the company of one or another of his friends. Although his studies in the Louvre had been devoted largely to the French painters of the 18th century, some landscapes of this period show the influence of the Barbizon school, while the influence of Courbet is more evident in the figure work (*e.g.*, "Diana," National gallery, Washington). In the years immediately following, Renoir worked in close contact with Monet both in Paris (1866–67) and at Bougival (1869), and the pictures executed (*e.g.*, "The Skaters," 1868; "La Grenouillère," 1869) represent one of the earliest stages of the concerns and techniques of Impressionism and were developed from the example set by Manet. The Salon of 1870 included however. the "Bather," which is still reminiscent of Courbet, and the "Woman of Algiers." which gives clear evidence of Renoir's enthusiasm for Delacroix.

During the Franco-German War of 1870–71 Renoir served with a regiment of cavalry, returning to Paris during the period of the Commune in 1871. In the years immediately following, he resumed the practice of working with Monet, particularly at Argenteuil, near Paris. In these years (c. 1872–76) there developed, mainly by these two artists working in close collaboration, the form of painting known as Impressionism, a term usually understood to refer to a system of painting in which there is a far greater concern with the representation of light and atmosphere than with the representation of the physical characteristics of things and people. Renoir became a member of the "Société anonyme des artistes peintres, sculpteurs et graveurs," founded in 1874, and exhibited at four of the eight so-called "Impressionist" exhibitions organized by that society between 1874 and 1886. Characteristic examples of his work during the 1870s are "La Loge" ("The Box at the Theatre") 1874; "Portrait of Monet," 1875; "Paris Boulevards." 1875; "Mme. Charpentier and Her Daughters," 1878; and "Boating Party at Chatou." 1879.

During the course of 1881–82, Renoir visited Algeria. Guernsey and Italy (where he admired the work of Raphael and the wall paintings of Pompeii), and worked with Cézanne at L'Estaque. It was about this time that Renoir, in common with the majority of the Impressionists, began to modify his style. "I had gone to the end of Impressionism," he said later. "and I was coming to the conclusion that I did not know either how to paint or draw." The characteristic work of this period is the large "Bathers" (1884–87, C. S. Tyson collection, Philadelphia), which illustrates the renewed importance given to the representation of volume and structure defined principally by line. with colour (which tends to be acid) and brush strokes playing a subordinate role. A key work for the comparison of the style of the "dry period" with that of the preceding Impressionist phase is "The Umbrellas" (National gallery, London), which seems to have been painted over a number of years from about 1881–82 to 1885–86.

The work of the late 1880s is varied in character, but by the early 1890s the characteristics of the late style had begun to appear. In the late works the subject matter and the compositional devices of Impressionism are frequently used (*e.g.*, "Lunch at Berneval"), but the range of colour (usually based upon warm, earthy reds and yellows) is arbitrary and personal and the paint is applied in a manner derived from the traditional system of glazing. The most frequent theme of the late years was that of the female nude characterized by a monumentality of proportions comparable to that found in Rubens, and by considerable stylization of features. Examples of this period are "Bather With a Hat" (c. 1904, Vienna); "Seated Bather" (1914, Chicago); "Woman Tying Her Shoe" (c. 1918, Courtauld Institute of Art, London) and "Rest After Bathing" (1919, Louvre, Paris).



BY COURTESY OF THE ART INSTITUTE OF CHICAGO, MR. & MRS. MARTIN A. RYERSON COLLECTION

"CHILD IN WHITE" BY AUGUSTE RENOIR. IN THE ART INSTITUTE OF CHICAGO

In his late years Renoir undertook sculpture, but since he was crippled with arthritis almost all the works were executed by assistants working under close supervision. Renoir died at Cagnes in Provence on Dec. 17, 1919.

(R. A. Dy.)

RENOUF, SIR PETER LE PAGE (1822–1897), British Egyptologist. was born in Guernsey on hug. 23, 1822. He was educated at Elizabeth college there, and proceeded to Oxford, uhich he left without taking a degree, upon his becoming a Roman Catholic under the influence of Newman He took an active part in church controversy and his treatise (1868) upon the condemnation of Pope Honorius for heresy by the council of Constantinople in A D 680 was placed upon the index of prohibited books. After holding various educational posts Renouf became in 1866 keeper of oriental antiquities in the British museum. succeeding Samuel Birch.

Renouf was also elected in 1887 president of the Society of Biblical Archaeology, to whose Proceedings he contributed. among other important papers, the translation of The Book of the Dead nith a commentary. He retired in 1891. and died in London on Oct 14, 1897.

RENOUVIER, CHARLES BERNARD (1815–1903), French philosopher. leading exponent of the neocritical modification of Kantianism, was born at Montpellier. Jan. 1, 1815. He went to Paris in 1831 and attached himself at first to the comte de Saint-Simon and his group. He studied mathematics at the École Polytechnique (1834–36) and then devoted himself to the study of social science and philosophy.

Renouvier's first works were handbooks of philosophy, ancient

(1842) and modern (1844); he contributed several articles to Pierre Leroux's *Encyclopédie* nouvelle. The revolution of Feb. 1848 led him to write his Manuel *républicain* de *l'homme* et du citoyen (1848) and his Gouvernement direct (1851), the latter in collaboration with a group of democratic socialists. After the coup d'e'tat of Dec. 1851, he confined himself to philosophical and religious speculation.

Renouvier became the declared enemy of any doctrine that explained man's moral life in terms of a necessary though passing manifestation of a universal law or reality. His philosophical theories were related to three parallel themes. The first, derived from his study of Augustin Cauchy's work on the infinitesimal calculus, is the law of numbers: any real group must be finite. The second theme is liberty: free will is the root not only of moral life but also of intellectual life and no certainty is ever attainable without it. The third theme is idealistic relativism, derived from Kant and from Auguste Comte: only phenomena have any real existence and each phenomenon is relative in that it can only be apprehended as a component or a compound in relation to another given phenomenon. Renouvier claimed that all known systems of philosophy could be classified in one of two categories: (1) those maintaining the infinite, necessity, substance, the "thing in itself," historical fatalism and pantheism; and (2) those maintaining the finite, liberty, phenomenalism and theism. A choice had to be made between the two, but could not be determined on purely intellectual grounds. Renouvier's own option was determined by his belief that man has a moral destiny: a philosopher, he claimed, does not believe in death. He shared Leibniz's belief in the indissolubility of the monad. Thus Renouvier's universe is built around the destiny, not of humanity itself as with Comte, but of the individual. God, for him, is not a substance or an absolute, but the moral order itself, infinite only as the infinity of moral perfection.

Renouvier refused to believe in the inevitability of progress. His Uchronie (1876, anonymous; 2nd ed., 1901) gives an outline of the development of European society such as it might have been if Christian preaching had failed and Europe thus had had no middle ages. Later, his concept of the evolution of the physical world echoed Herbert Spencer's evolutionist naturalism. Renouvier died at Prades on Sept. 1, 1903.

His works include Essais de critique *générale,* 4 vol. (1854–64); Science de la morale (1869); *Esquisse d'une* classification systkmatique des doctrines philosophiques, 2 vol. (1885–86); Philosophie analytique de l·histoire, 4 vol. (1896–97); La Nouvelle monadologie, with L. Prat (1899); Les *Dilemmes* de la *méta*physique pure (1900); Le *Personnalisme* (1903); and Critique de la doctrine de Kant, edited by L. Prat (1906).

RENT. Various species of rent appear in Roman law (*q.v.*). In English law rent is a certain and periodical payment or service made or rendered by the tenant of a corporeal hereditament and issuing out of (the property of) such hereditament. Its characteristics, therefore, are (1) certainty in amount; (2) periodicity in payment or rendering; (3) the fact that rent is yielded and is, therefore, said "to lie in render," as distinguished from profits *à* prendre in general, which are taken, and are, therefore, said to lie in prendre; (4) that it must issue out of (the profits of) a corporeal hereditament. A rent cannot be reserved out of incorporeal hereditaments. But rent may be reserved out of estates in reversion or remainder (see LAWS OF REAL PROPERTY AND CONVEYANCING) which are not purely incorporeal. It is not essential that rent should consist in a payment of money. Apart from the rendering of services, the delivery of hens, horses, wheat, etc., may constitute a rent. But at the present day, rent is generally a sum of money paid for the occupation of land. It is important to notice that this conception of rent was attained at a comparatively late period in the history of the law. The earliest rent seems to have been a form of personal service, and was fixed by custom. Rent service is the oldest kind of existing rent.

It is the only one to which the power of distress attaches at common law, giving the landlord a preferential right over other creditors exercisable without the intervention of judicial authority (see DISTRESS). The increasing importance of socage tenure, arising in part from the convenience of paying a certain amount, whether in money or kind, rather than comparatively uncertain services, led to the gradual evolution of the modern view of rent as a sum due by contract between two independent persons.

Classes of Rents.—Rents, as they now exist in England, are divided into two great classes—rent service and rent charge. A rent service is so called because by it a tenure by means of service is created between the landlord and the tenant. The service is now represented by fealty, and is nothing more than nominal. Rent service is said to be incident to the reversion—that is, a grant of the reversion carries the rent with it (see REMAINDER). A power of distress is incident at common law to this form of rent. A rent charge is a grant of an annual sum payable out of lands in which the grantor has an estate. It may be in fee, in tail, for life—the most common form--or for years. A rent charge may also be granted out of another rent charge (Law of Property Act, 1925, s. 7, 122 [1]). A rent charge must be created by deed or will, and might be either at common law or under the Statute of Uses (1536). As from Jan. 1, 1926, a rent charge may be created or reserved without the intervention of a use (Law of Property Act, 1925, ss. 65, 187). The grantor has no reversion, and the grantee had at common law no power of distress, though such power was given him by the instrument creating the rent charge. Annual sums charged on land by way of rent charge may be recovered (a) if unpaid for 21 days, by distress; (b) if unpaid for 40 days, by entry into possession of the land and a p propriation of income, and/or demise. by s. 45 of the Conveyancing Act, 1881, a power of redemption of certain perpetual rents in the nature of rent charges is given to the owner of the land out of which the rent issues. Rent charges granted since April 26, 1855, otherwise than by marriage settlement or will for a life or lives or for any estate determinable on a life or lives were required, in order to bind lands against purchasers, mortgagees or creditors, to have been registered in the Land Registry in Lincoln's Inn Fields (Judgments Act, 1855). After 1925, however, rent charges of this character became equitable interests only, and as such are overreached by conveyances to purchasers of a legal estate in lands (Law of Property Act, 1925, s. 2). There was no need, therefore, to provide for the registration of such rent charges, and the Land Charges Act, 1925, enacted that after Jan. 1, 1926, they should not be entered in the register of annuities (s. 4 [1]). Rent charges in possession charged on land perpetually or for a term of years absolute are "legal estates," registrable as such under the Land Registration Act, 1925 (ss. 2, 3, viii., xxv.); and certain classes of rent charge may be entered in the register of land charges under the Land Charges Act, 1925 (s. 10). Rent charges are barred by nonpayment or non-acknowledgment for 12 years (Limitation Act, 1874). The period of limitation for arrears of rent is six years. As to the colonies see Burge, Col. and For. Laws (by Bewes, iv., pt. 2, 460).

Forms of rent charge of special interest are tithe rent charge (see TITHES), and the rent charges formerly used for the purpose of creating "faggot votes." The device was adopted of creating parliamentary voters by splitting up freehold interests into a number of rent charges of the annual value of 40s., so as to satisfy the freeholders' franchise. But such rent charges were rendered ineffective by the Representation of the People Act, 1884, s. 4, which enacted (subject to a saving for existing rights and an exception in favour of owners of tithe rent charge) that a man should not be entitled to be registered as a voter in respect of the ownership of any rent charge.

A rent charge reserved without power of distress is termed a rent-seck (*reditus siccus*) or "dry rent," from the absence of the power of distress. But, as power of distress for *rents-seck* was given by the Landlord and Tenant Act, 1730, the legal effect of such rents has been since the act the same as that of a rent charge.

Other Varieties **of** Rent.—Rents of assize or quit rents are a

relic of the old customary rents. They are presumed to have been established by usage, and cannot be increased or diminished. Provision was made in 1922 for the extinction after 1925 of quit rents and other manorial incidents (Law of Property Act, 1922, ss. 138, 144).

Fee farm rents are rents reserved on grants in fee. They, like quit rents, now occur only in manors, unless they existed before the statute of Quia Emptores was enacted or created by the Crown. A rent which is equivalent or nearly equivalent in amount to the full annual value of the land is a rack rent. As to ground rent, see GROUND RENT. A dead rent is a fixed annual sum paid by a person working a mine or quarry, in addition to royalties varying according to the amount of minerals taken.

The object of a dead rent is twofold—first, to provide a specified income on which the lessor can rely; secondly (and this is the more important reason), as a security that the mine will be worked, and worked with reasonable rapidity. Rents in kind still exist to a limited extent. All peppercorn, or nominal, rents seem to fall under this head. The object of the peppercorn rent is to secure the acknowledgment by the tenant of the landlord's right. In modern building leases a peppercorn rent is sometimes reserved as the rent for the first few years.

Labour rents are represented by those cases. not unfrequent in agricultural leases, where the tenant is bound to render the landlord a certain amount of team work or other labour as a part of his rent.

Payment of Rent.—Rent is due in the morning of the day appointed for payment, but a tenant is not in arrears until after midnight on that day. Rent made payable in advance by agreement between a landlord and his tenant is called *forehand* rent. It is not uncommon in letting a furnished house, or as to the last quarter of the term of a lease of unfurnished premises, to stipulate that the rent shall be paid in advance. As soon as such rent is payable under the agreement the landlord has the same rights in regard to it as he has in the case of ordinary rent. Where a cheque in payment of rent is lost in the course of transmission through the post, the loss falls on the tenant, unless the landlord has expressly or impliedly authorized it to be forwarded in that way. and the landlord s consent to take the risk of such transmission will not be inferred from the fact that payments were ordinarily made in this manner in the dealings between the parties

A tenant may deduct from his rent (i.) the "landlord's property tax" (on the annual value of the premises for income tax purposes), which is paid by the tenant, if the statute imposing the tax authorizes the deduction (which should be made from the rent next due after the payment); (ii.) taxes or rates which the landlord had undertaken to pay but had not paid, payment having thereupon been made by the tenant; (iii.) payments made by the tenant which ought to have been made by the landlord, *e.g.*, rent due to a superior landlord; (iv.) compensation under the Agricultural Holdings Act, 1923 (s. 37), and Landlord and Tenant Act, 1927 (s. 11 [2]).

A landlord's main remedy for non-payment of rent is distress (*q.v.*). Besides distress the landlord has his ordinary remedy by action. In addition, special statutory remedies are given in the case of tenants holding over after the expiration of their tenancy (see EJECTMENT). Under the Rent Restriction Acts, 1920–25, landlords of dwelling houses to which these statutes apply were prevented during their continuance from effectually raising the rents above specified limits, and except in certain cases from recovering possession on the termination of the tenancy. The act of 1920 expired in England on Dec. 2j, 1927, and in Scotland on May 28, 1928. The provisions of Pt. II. of the act of 1923 continue in force for five years from the expiration of the act of 1920. (*See* further LANDLORD AND TENANT.)

Under the Landlord and Tenant Act, 1927, the landlord of trade premises may offer a renewal of the tenancy at such rent as, failing agreement, the statutory tribunal may consider reasonable, as an alternative to compensation for improvements (s. 2 [1] [d]) or goodwill (s. 4 [1]). The tenant of such premises may also apply for a new lease at a rent similarly approved (s. 5).

Scotland.—Rent is properly the payment made by the tenant to the landlord for the use of lands held under lease (see LANDLORD AND TENANT). In agricultural tenancies the legal terms for the payment of rent are at Whit Sunday after the crop has been sown, and at Martinmas after it has been reaped. But a landlord and tenant may substitute conventional terms of payment, either anticipating (fore or forehand rent) or postponing (back or backhand rent) the legal term. The rent paid by vassal to superior is called feu-duty (see FEU). Its nearest English equivalent is the fee farm rent. The remedy of distress does not exist in Scots law. Rents are recovered (i.) by summary diligence, proceeding on a clause, in the lease, of consent to registration for execution; (ii.) by an ordinary petitory action; (iii.) by an action of "maills and duties" (the rents of an estate in money or grain: "mails" was a coin at one time current in Scotland) in the Sheriff Court or the Court of Session; and (iv.) in non-agricultural tenancies by procedure under the right of hypothec, where that still exists; the right of hypothec over land exceeding two acres in extent let for agriculture or pasture was abolished as from Nov. 11, 1881; it was also excluded, by the House-letting and Rating (Scotland) Act, 1911 (s. 10), in lets to which that act applies, from all bedding material and all implements of trade used by the occupier and his family and from furniture selected by him up to £10 value (see DISTRESS; HYPOTHEC); (v.) by action of removing (see EJECTMENT). Arrears of rent prescribe after the expiration of a period of five years reckoned from the time of the tenant's removal from the land.

Labour or service rents were at one time very frequent in Scotland. The events of 1715 and 1745 showed the vast influence over the tenantry that the great proprietors acquired by such means. Accordingly acts of 1716 and 1746 provided for the commutation of services into money rents. Such services may still be created by agreement, subject to the summary power of commutation by the sheriff given by the Conveyancing Act, 1874 (ss. 20, 21). They will no longer be eligible from and after Jan. 1, 1935 (Conveyancing [Scotland] Act, 1924, s. 12 [7]). The Conveyancing (Scotland) Act, 1924, provides (s. 12) for the abolition or commutation of feu-duties payable in grain or other fungibles.

United States.—The law is in general accordance with that of England, apart from statute. The tendency of modern State legislation is unfavourable to the continuance of distress as a remedy. In the New England States, attachment on mesne process has, to a large extent, superseded it. Alabama, Colorado, Missouri, Montana, North Carolina and Oklahoma have refused to recognize the right of distress upon the ground that the landlord's rights have been secured by the substitution of other remedies. In the District of Columbia, Indiana, Minnesota, New York and Wisconsin it has been abolished by statute. "In those (states) in which it still exists, it has been modified by statutes, the general tendency of which is more or less to withdraw the control of the proceedings from the landlord and to rest it in public officials, thus assimilating it to the process of attachment." (2 Tiffany, Landlord and Tenant, section 325.)

Other Countries.—Under the French Code Civil (art. 2,102) the landlord is a privileged creditor for his rent. If the lease is by authentic act, or under private signature for a fixed term, he has a right over the year's harvest and produce, the furniture of the house and everything employed to keep it up, and (if a farm) to work it, in order to satisfy all rent due up to the end of the term. If the lease is not by authentic act nor for a specified term, the landlord's claim is limited to the current year and the year next following (see law of Feb. 12, 1872). The goods of a sub-lessee are protected: and goods bailed or deposited with the tenant are in general not liable to be seized. The French law is in force in Mauritius, and has been reproduced in substance in the Civil Codes of Quebec (arts. 2,005 seq.) and St. Lucia (arts. 1,888 seq.). There are analogous provisions in the Spanish Civil Code (art. 1,922). The subject of privileges and hypothecs is regulated in Belgium by a special law of Dec. 16, 1851; and in Germany by ss. 1,113 seq. of the Civil Code. The law of British India as to rent (Transfer and Property Act, 1882) and distress

(*cf., e.g.,* Act 15 of 1882) is similar to English law. The British dominions generally tend in the same direction. See, *e.g.,* New South Wales (the consolidating Landlord and Tenant Act, 1899, and Act 66 of 1915); Union of South Africa (Act 30 of 1921); Newfoundland (Act 4 of 1899); Ontario (Act 1 of 1902, s. 22, giving a tenant five days for tender of rent and expenses after distress); Jamaica (Law 17 of 1900, certification of landlord's bailiffs); Queensland (Act 1j of 1904). English rent restriction legislation was followed in British India (*e.g.,* Bombay, No. 3 of 1925; Burma, No. 1 of 1925) and in many of the colonies and dominions (*e.g.,* Hongkong, No. 8 of 1925; Malta, No. 1 of 1925; New Zealand, No. 3 of 1925).

RENT: IN ECONOMICS. In economics, rent is the name given to the income which the owner of a productive instrument gets by using it himself or by exacting a payment from another user. Much of the importance of the general theory of rent in economics comes from its application to the special case of income derived from land ownership. In the case of the incomes yielded by the ownership of reproducible instruments of production the principle of rent is subordinate, in the long run, to the principles which govern the rate of interest on capital, for the supply of such instruments will be maintained and increased if, but only if, the prospective return is sufficient to induce the investment of capital. At any given time, however, the income-yielding power of reproducible instruments of production is determined, not by what they cost, but by the value of their productive uses. That is, it is governed by the laws of rent. The specific hypothesis upon which the significance of the principle of rent depends is that the supply of the productive instruments which yield rent may be assumed to be given or fixed, so that the question remains only of how they may best be used.

Rent is generally held to have two distinguishing characteristics: first, it is a differential or graded return; second it is a surplus above costs. That it is a differential return depends upon the circumstance that productive instruments are described or measured in units (*e.g.,* acres) which are not themselves units of productive efficiency. It is obvious that if one acre of agricultural land is better (more fertile or nearer to the market) than another it will command a larger rent. It is also obvious that the rent which any given piece of land commands may be taken to be a measure of its differential superiority over land which just falls short of being good enough to be worth using. That rent may be regarded as a surplus over costs is a consequence of the circumstance that the supply of rent-yielding instruments is taken as given. Even if they were produced or improved (as land is improved) at a cost in the past, their past costs have no relevance to the practical question of how and for what purposes the instruments shall be used. The only costs which need to be taken into account are the costs of using them.

Rent's Relation to Product.— why, then, should rent be paid? The reason is that rent-yielding productive instruments, including rent-yielding land, exist in limited quantities, in the sense that if any one unit of them were withdrawn from use the aggregate product would be smaller. The rent of a given piece of land or of a given farm tends to be approximately equal to the value of the amount of product which is dependent upon using it. This amount can be determined by comparing the product which the given piece of land or farm will yield under proper cultivation with the product which could be got by employing the same amount of capital and labour on the best land which is not good enough to yield a rent (*i.e.,* at the "extensive margin of cultivation") or by employing it in cultivating rent-yielding lands more intensively (*i.e.,* at the "intensive margin of cultivation"). When the supply of a particular class of rent-yielding productive agents cannot be increased as rapidly as the demand for the products which they yield increases, they will command higher rents. Furthermore, unless there are compensating improvements in productive technique, production can be increased under such circumstances only by using instruments which had previously been below the level of profitable use or by making more intensive use of the latter instruments, *i.e.,* by increasing the labour and other types of instruments used in conjunction with them. Whichever method is followed, increasing costs are encountered. This circumstance is the basis of the doctrine that with a fixed supply of land an increased agricultural product can be had only at the expense of a more than proportionate outlay of labour and capital—a doctrine to which the name, "law of diminishing returns," has been given.

When economists refer to some other form of income or gain, not derived from the ownership of land or of other productive instruments, as rent, they generally mean either that it may be looked upon as a differential return or that it may be conceived to be a surplus above costs. Thus, "rent of ability" is a name sometimes given to the differential element in personal earnings. "Entrepreneur's rent" denotes the profits of an ably-managed and successful enterprise, conceived of as a differential above the return secured by a marginal undertaking which is barely able to meet its costs. "Consumer's rent" is the difference between the amount which the consumer pays and the value which he attaches to what he buys, as measured by the maximum amount which he would have been willing to pay if required. Similarly, "producer's rent" is the difference between what the state of the market enables the producer to get for his goods and the amount which would have sufficed to induce him to produce them. (See also ECONOMICS and LAND.) (A. Yo.)

RENTON, a manufacturing town in Cardross civil parish, Dunbartonshire. Scot. Pop. (1951) 5,170. It is on the Leven, about 2 mi. N.N.W. of Dumbarton. The leading industry is dyeing. with calico printing and bleaching.

A parish church stands on the site of Dalquhurn House, the birthplace of Tobias Smollett the novelist, to whose memory a Tuscan column was erected in 1774, the inscription for which was revised by Dr. Samuel Johnson when he visited Bonhill in that year with Boswell. The town was founded in 1782 by Jean Smollett (previously Telfer) of Bonhill (sister of Tobias Smollett), who resumed her maiden name when she succeeded to the Smollett estates.

Renton was named after Cecilia Renton, daughter of John Renton of Blackadder, who had married Mrs. Smollett's son Alexander Telfer.

RENTON, a city in King county, western Washington, U.S., on the south shore of Lake Washington, is located about 12 mi. S.E. of Seattle. It can be reached by deepwater vessels from Puget sound via the Ballard locks and Lake Washington.

A large airplane plant. devoted especially to the manufacture of jet transports, is located there. Lumber, shingles, steel and clay products, railroad freight and passenger cars, logging machinery and stokers are also produced. Coal mines, near Renton, exploited since the 1860s, played an important role in the history of the Pacific northwest. Truck and poultry farming are the chief agricultural activities of the area.

The city was named for William Renton, one of the founders of a coal-mining company, and was incorporated in 1901. For comparative population figures see table in WASHINGTON: Population. (R. E. Bu.)

RENTSCHLER, HARVEY CLAYTON (1881–1949), U.S. physicist, was born at Hamburg, Pa., on March 26, 1881. He was graduated from Princeton university, Princeton, N.J., in 1903 and took his master's degree there the following year. He received the Ph.D. degree from Johns Hopkins, Baltimore, Md., in 1908. Immediately afterwards, he became an instructor in physics at the University of Missouri, Columbia, Mo., and remained there until 1917, rising to the rank of associate professor.

He then accepted the position of director of research in the lamp division of the Westinghouse Electric and Manufacturing Co. at Bloomfield, N.J. There, out of experimental work in photochemistry on the case hardening of steel came his important contribution to medicine and food preservation, the sterilamp ("Bactericidal Effect of Ultraviolet radiation," *J.Bact.* 41:745–774, 1941). The lamp is a gaseous-conductor tube generating radiant energy, *i.e.*, ultra-violet rays with a wave length of 2,537 angstrom units. Such irradiation prevents spoilage through mould and yeast spores, and after tests proved satisfactory, lamps were installed in the processing and storage places of meat, bakery, dairy and brewing establishments. Although the work, which was done in association with Dr. Robert F. James, a biochemist at Westinghouse, was carried on with food preservation in mind, its medical application was also considered. In surgery, though the staff and materiel be germfree, the air contains bacteria which may infect the patient. Lamps were installed experimentally in the operating room of the Duke university hospital. Results proved postoperative infection and temperatures to be lower, and the lamps were subsequently installed at the Mayo Clinic, the N.Y. Medical Center and elsewhere. Dr. Rentschler also developed an ultra-violet light meter and conducted researches on the photoelectric emission from metals, the preparation and properties of ductile thorium and uranium, and the resonance and ionization of monatomic gases. He was made honorary D.Sc. by Princeton university in 1941, and the following year the honorary degree of doctor of laws was conferred on him at Ursinus college, Collegeville, Pa. His early researches with the refinement of uranium were credited with Westinghouse Electric's ability to provide the first batches of that element for atom bomb experiments in 1943. He died March 23, 1949, at East Orange, N.J.

RENWICK, EDWARD SABINE (1823–1912), U.S. inventor, was born in New York city on Jan. 3, 1823, the youngest son of James Renwick (*q.v.*) (1792–1863). He was graduated from Columbia college in 1839 and took his master's degree there in 1842. After several years of employment as an engineer, he went to Washington, D.C., where in 1849 he became associated with Peter H. Watson as patent expert in the U.S. circuit courts. Six years later he returned to New York where he worked independently in the same field. Renwick was also an inventor of some note. Among his accomplishments were a self-binder to improve the McCormick reaper (1851–53), an automatically heated and ventilated incubator for the raising of chicks and a chicken brooder (1877–86). He died at Short Hills, N.J., on March 19, 1912.

RENWICK, JAMES (1662–1688), Scottish covenanting leader, was born at Moniaive in Dumfriesshire, on Feb. 15, 1662, the son of a weaver, Andrew Renwick. Educated at Edinburgh university, he joined the section of the Covenanters known as the Cameronians about 1681 and soon became prominent among them. Afterwards he studied theology at the university of Groningen and was ordained a minister in 1683. Returning to Scotland "full of zeal and breathing forth threats of organized assassination," says Andrew Lang, he became one of the field-preachers and was declared a rebel by the privy council. He mas largely responsible for the "apologetical declaration" of 1684 by which he and his followers disowned the authority of Charles II; the privy council replied by ordering every one to abjure this declaration on pain of death. Unlike some of his associates, Renwick refused to join the rising under the earl of Argyll in 1685; and in 1687, when the declarations of indulgence allowed some liberty of worship to the Presbyterians, he and his followers, often called Renwickites, continued to hold meetings in the fields, which were still illegal. A reward was offered for his capture, and early in 1688 he was seized in Edinburgh. Tried and found guilty of disowning the royal authority and other offenses, he refused to apply for a pardon and was hanged on Feb. 17, 1688. Renwick was the last of the covenanting martyrs.

See R. Wodrow, *History of the Sufferings of the Church of Scotland,* vol. iv (Glasgow, 1838); and *A.* Smellie, *Men of the Covenant* (1904); also Renwick's life by Alexander Shields in the *Biographia Presbyteriana* (1827).

RENWICK, JAMES (1792–1863), educator and engineer, was born in Liverpool, England on May 30, 1792, of Scottish descent. He emigrated to the United States with his parents in 1794. Two of his sons, Henry Brevoort (1817–1895) and Edward Sabine (*q.v.*) were also engineers, and his second son, James (*q.v.*), a distinguished architect. Renwick was graduated from Columbia college in New York city in 1807 and then travelled through Europe with his good friend Washington Irving. Three years later he earned his master's degree from Columbia. In 1812 he taught natural philosophy there during the illness of Prof. John Kemp, serving without pay. He entered government service as topographical engineer with the rank of major and three years later was commissioned colonel of engineers in the state militia. In 1820 he was appointed to the chair of natural philosophy and experimental chemistry at Columbia, which position he held until his retirement in 1853 to become the first emeritus professor of that college. In addition to his regular courses at Columbia, he also lectured on geology, mineralogy, practical mechanics and astronomy. While teaching he was also active in many public engineering projects on which his expert advice was increasingly sought. President Van Buren appointed him in 1838 to the commission of three which tested inventions designed to safeguard steam engine boilers against explosions. Two years later he was a member of the commission appointed to survey the northeast boundary between the United States and New Brunswick; these findings were later incorporated in the Webster-Ashburton treaty. Prof. Renwick was a frequent contributor to the best current periodicals and wrote a number of books on scientific and mechanical problems including *Outlines of Natural Philosophy* (2 vols., 1822–23); *Treatise on the Steam-Engine* (1830); and biographies of David Rittenhouse (1839), Robert Fulton (1845), and Count Rumford (1848) for Sparks's *Library of American Biography.* He also translated from the French, Lallemand's *Treatise on Artillery* (2 vols. 1820) and edited American editions of books on chemistry and mechanics. He died on Jan. 12, 1863.

RENWICK, JAMES (1818–1895), U.S. architect, was born in the section of New York city then known as Bloomingdale, on Nov. 1, 1818, the second son of James Renwick (*q.v.*) (1792–1863). He was graduated from Columbia college in 1836 at the precocious age of 17, and became an engineer for the Erie railroad. Later, as assistant engineer on the Croton aqueduct, he supervised the construction of a distributing reservoir in what is now the midtown area of Manhattan. His career in architecture began in 1843 when his plans won in the competition for the design and erection of Grace church at Broadway and 10th street. By the time of its completion in 1846, Renwick, still a very young man, had established his reputation as an architect. His early commissions were mainly for churches, including Calvary, St. Stephen's, and St. Bartholomew's. In 1853 the plans he entered in the competition for the designing of the Roman Catholic St. Patrick's cathedral were chosen, and in 1858 the work of more than 20 years was begun. This example of Gothic revival in the heart of the city is now one of its landmarks and occupies the square block bounded by Fifth and Madison avenues, and 50th and 51st streets. In addition to his ecclesiastical designs, Renwick was also architect for many public and private structures, the most outstanding being the Smithsonian institution and Corcoran gallery in Washington, Vassar college at Poughkeepsie, and numerous hotels, theatres and fashionable residences in New York city and elsewhere. As architect for the Board of Governors of Charities and Correction of New York city, he also built a number of asylums and hospitals. Renwick's early work was mainly Gothic or Romanesque. Later his designs took on a more eclectic character with occasional bad results, but he had imagination and his planning was usually sound. He was a noted connoisseur and acquired a fine collection of paintings and *objets d'art.* He died in New York city on June 23, 1895.

REP, REPP or **REPS,** cloth made of silk, wool or cotton. The name is said to have been adopted from the French *reps,* a word of unknown origin; it has also been suggested that it is a corruption of "rib." It is woven in fine cords or ribs across the width of the piece. In various forms it is used for dresses, and to some extent for ecclesiastical vestments. In wool and cotton it is alsc used for upholstery purposes

REPARATIONS. In their customary meaning reparations are a levy on a defeated nation forcing it to pay some of the war costs of the winning countries. They were levied on the Central Powers after 1918 to compensate the Allies for some of their war costs, and reparations were meant to replace mar indemnities which had been levied earlier as a punitive measure as well as to compensate for economic losses. The United Nations (UN) levied reparations after World War II. principally on Germany, Italy, Japan and Finland. In the decade following the war, the meaning of the term became more inclusive; it was applied to the payments undertaken by the Federal Republic of (west) Germany to the state of Israel for crimes against the Jews in territory controlled by the Hitler regime and to individuals in Germany and outside it to indemnify them for their persecution. The term was also applied to the obligations of Israel to the Arab refugees who suffered property losses after Israel's victory over the Arab states in 1948.

There are two practicable ways in nhich a defeated country can make reparation. It can pay over in cash or kind a portion of the goods and services it is currently producing; *i.e.,* a part of its national income. Or it can pay over in cash or kind some of its capital in the form of machines, tools, rolling stock. merchant shipping and the like, which is a part of its national wealth. The payment of gold or other universal money is not a practicable method of paying reparations. The supposed consequence of reparations is a decrease in the income, and hence level of living, of the defeated nation, and an increase in the income of the victorious nation, the capitalized value of the increase being equal to its war costs. However. there is no warrant for these suppositions in either the economics of reparations or in historical experience with them. Experience suggests that the smaller the reparations levy the more likely it is to be paid, and conversely that large levies are unlikely to be collected. In both World Wars I and II the failure to obtain desired reparations was unmistakable. Indeed, some of the victorious nations eventually had to make payments to the defeated in the interests of restoring economic and political stability.

Magnitude of Reparations.—The size of the defeated nation's liability cannot be determined by the war costs for which it is directly or indirectly responsible. These costs are of two kinds, economic and social. The economic cost of war is the value of civilian goods and services which must be foregone in order that resources can be used for war production, plus the capital destruction resulting from war. The social cost is the burden created by loss of life and disorder in social institutions. The loss of life has economic implications, but its cost cannot be measured because the labour value of human life is not capitalized as, say, the income value of equipment can be. Estimates can be made of the economic costs of war, and they are usually much in excess of the capacity of the defeated nation to make reparation. For example, after World War II the principal belligerents submitted claims of $320,000,000,000 against Germany. This sum was more than ten times the preuar national income of Germany (at constant prices) and an even greater multiple of income after the war.

Since the magnitude of reparations cannot be determined by war costs. it must be determined by the defeated nation's ability to pay, and this is much less than its imputed liability. Its ability to pay is dependent on three factors: (1) its national wealth or alternatively its national income: (2) the ability of either the occupying powers or the government of the defeated nation to organize the economy for the payment of reparations; and (3) the capacity of the victors to organize their economies for the productive use of reparation receipts. The first of these is most important.

The political instability which usually follows a war makes it difficult to organize the defeated economy for the payment of reparations. Authority is diffuse and uncertain; there are conflicts among the victorious nations, and the populace of the defeated country is, to say the least, unco-operative, particularly in the matter of transferring its capital or income to recent enemies. Finally, the payment of reparations depends on the willingness and ability of the victorious countries to accept the new economic structure attendant upon transfers of income or capital. Here occurred the paradoxes of reparations history in the 20th century. Following World War I, some of the Allied Powers were able to conceive of no limit to a justifiable tribute from Germany, but when payments out of income began the Allies found the imports competing with domestically produced goods and services and thereupon took measures which prevented Germany from honouring its obligations. After World War II, the transfers of capital from Germany and Japan so threatened to dislocate the economic structure of Europe and Asia that measures were taken to reduce reparation liabilities.

METHODS OF PAYMENT

The payment of reparations in kind or cash out of income or capital constitutes an export surplus; *i.e.,* the paying nation sends out of the country more goods and services than it imports. Reparations are impossible without this surplus, and it is for practical purposes more dependent on increasing exports than on decreasing imports. The fact that reparations are possible only via an export surplus should not be obscured by the financial mechanics of reparations. The defeated nation usually compensates the private owners of capital for the export of the goods which constitute reparations, and to do this it taxes or borrows from its citizens. But reparations cannot be paid out of revenue raised internally; the revenue must be converted into income or capital for transfer to the victor nation or into the currency of that nation. After World War I, reparations were designed to be paid mainly in cash out of income. After World War II, they were meant to be paid in kind. mainly out of capital.

Payments in Kind.—If payments in kind are made out of capital, the defeated nation pays over to the victors specific assets within the defeated economy and titles to assets held abroad. After 1918, the Allies obtained the largest vessels in the German merchant marine and a small amount of additional capital. After 1945, the United Nations seized merchant vessels and industrial equipment in Germany and Japan, acquired German and Japanese owned assets within the victor countries and sought to obtain axis-owned assets within neutral countries. Most of the owners of this property were compensated by revenue raised within the defeated nations, the effect being to distribute the burden of the loss among enemy nationals whether property owners or not.

Reparations in the form of capital transfers in kind have certain, though limited, advantages. They avoid some of the more complex monetary problems of cash payments. They are adaptable to a general program of economic disarmament whereby victor nations dismantle and remove industrial equipment of actual or potential military value. Some of this equipment may be of immediate peacetime value to the victorious economies, relieving critical shortages and assisting in reconstruction. Against these advantages must be set the complex economic problems created by the transfers. It is difficult if not impossible to distinguish between industrial equipment of military value and that which can be used only to produce peacetime goods. The steel industry may be used for peaceful purposes or it may become the centre of the munitions industry. The war potential of an industry may be reduced by limiting its capacity but this also limits its peaceful uses. An even greater problem is the dislocation of economic structure which capital removals produce. Reducing plant capacity or eliminating it is a complex technical and economic undertaking. A slight error in removing too much of one kind of equipment can produce a great loss in another industry which in consequence must operate at undercapacity. Even with complete technical consistency in scaling down plant facilities there can be unnecessary losses when the reduced output is measured in monetary (*i.e.,* economic) units. The removal and transportation of capital is expensive, and if any of the labour is done by enemy nationals there is likelihood of additional expense through sabotage. Capital removals require a reallocation of resources in both the defeated and victorious countries. During the process there is a loss of income resulting from installation costs and partial unemployment. Meanwhile the defeated country may become a charge on its conquerors, requiring relief of various kinds until it

can become self-supporting. These problems are present in the most ideal circumstances which can be supposed.

In the conditions likely to be present, capital reparations mean a long-term reduction in income for the victorious nations as well as the defeated. This is probable because capital is removed from an economy where it has been used efficiently with trained labour to one where it must be used less efficiently for a considerable time. The net effect is then a lower income for all countries, victorious as well as defeated. This consequence is avoidable only by the creation of a perfect mechanism for the transfer of capital and by supposing that the recipient nations will be able to use it as efficiently as the paying nation. Such conditions are improbable. This being so, reparations are apt to produce quite the opposite of their intended effect. This was the experience after World War II.

Following World War I there was some payment of reparations in kind out of income. There mere other instances of this method. Out of its annual production, a paying country exports certain commodities to its creditors or performs certain services for them. It can, for example, ship specified quantities of raw material, fuel or manufactured goods, and it may perform transportation and labour services. It may send numbers of its workers to the victorious nation to restore areas damaged by the war and repatriate them when the work is completed. The difficulties encountered in a scheme of capital reparations are present here also but on a lesser scale. The excessive export of current output may force a reduction in plant operations uithin the defeated countries. The receipt of these goods and services by the victors disturbs their normal exchange pattern. After World War I, the immigration of German workers into France to restore the devastated areas caused French workers to protest that their wages were being reduced by the increased labour supply. After World War II, some British trade unions resisted the attempt of the Labour government to use German prisoners of war to relieve critical labour shortages. Similarly, some U.S. manufacturers complained that the import of Japanese goods on reparations account was driving down prices in the U.S.

Cash Payments. — Prior to World War II. reparations were more often made as cash payments than as transfers in kind. It was believed that such a method was easier to organize and more productive of a successful settlement (a viewpoint which was reversed after World War II). Cash payments can be made out of accumulated capital, in which case the paying country sells certain of its assets held either at home or abroad, converts the proceeds into the currency of the victorious nation and pays it over to the latter's government. The effect of capital transfers via cash payments need not be quite as disturbing as that of capital transfers in kind, though in practice both may produce much the same result. A conceivable advantage of the former is the greater opportunity given the paying nation to dispose of its capital at a minimum loss; it may sell it on the highest paying market and convert the receipts into the currency of the victor nation, uhile capital transfers in kind must be made directly to the victor nation and valued realistically at the worth to it.

After World War I, the bulk of reparations levied on Germany was to consist of cash payments out of income over a period of years. The successful execution of this plan called for an export surplus in the paying country and conversion of the surplus into the currency of the receiving nations. The effect was a reduction in the income of the paying nation and an increase in that of the recipients. Cash payments produce distinctive effects which are not present when reparation is made in kind; they arise because the debtor country must obtain the currency of the creditor nation. The nature and importance of the effects depend on the size of reparations in relation to the national income of the debtor and creditor countries, on the sensitivity of their price levels to expenditures and receipts from imports and exports, on the flexibility of their foreign exchange rates and on the money supply together with the rate at which it is spent. If any one result is more probable than others, it is a fall in the foreign value of the paying nation's currency and a concomitant rise in that of the receiving country. This in turn increases the real cost of reparations to the debtor and creates a corresponding gain to the creditor. Because its money buys less of the money of the creditor, the debtor must offer a greater quantity of exports in order to obtain a given quantity of the creditor's money. It is to be repeated that this is a probable, not an invariable, consequence.

There are two major conditions for the successful settlement of cash reparations. Payments must be within the defeated nation's ability to pay after full account is taken of their monetary effects. and payments must be acceptable to the receiving country. The latter must either increase its net imports from the paring nation or from a third nation which is in debt to the paying nation. The inherent complexities of a reparations program of any kind usually have been made more troublesome by the imposition of controls over the economies of the defeated and victorious nations. This was significant after World War II when the German and Japanese economies were closely regulated and when there was regulation in every important victorious nation excepting the U.S. Control over prices, the movement of goods and labour represent a comprehensible wish to soften the rigours of reconstruction and of readjustment from war. This, however, does not alter the fact that control removes from the economy the price mechanism whereby gains and losses from alternative lines of action can be compared. This was recognized after 1945 nhen an effort was made to remove Japanese industrial equipment to non-industrial nations of Asia and the Pacific. As the Japanese economy was controlled there was no realistic way of appraising the final results of the transfer, nor was there any method of measuring the usefulness of the equipment to the recipient nations because they too controlled their economies. Eventually it was concluded that the transfers had no economic justification.

REPARATIONS AND WORLD WAR I

Germany's Liability. — Without specifying the exact amount, the treaty of Versailles held Germany responsible for all damages to civilians and their dependents; for losses caused by the maltreatment of prisoners of war; for pensions to veterans and their dependents; and for the destruction of all nonmilitary property. Following a series of conferences in 1920, Germany's liability mas fixed tentatively at a minimum of 3,000,000,000 gold marks annually for 35 years with maximum payments not to exceed 269,000,000,000 marks. Germany immediately declared it was unable to pay even the minimum, and there followed successive reductions culminating in the decision of the London conference of 1921, which fixed the liability at 132,000,000,000 (all figures in gold marks) to be paid in annuities, or annual instalments, of 2,000,000,000 marks plus an amount equal to 26% of Germany's annual exports. Germany's default brought the occupation of the Ruhr in 1923 by French and Belgian troops in order to collect reparations by force. Dispossessed of this' important area, Germany was unable to make payments and each attempt to convert marks into foreign currency drove down their value. The result was the disastrous inflation of 1923 when the mark fell to a billionth of its par value.

In 1924 the Allies sponsored the Dawes plan which stabilized the nation's internal finances by a reorganization of the Reichsbank; a transfer committee was created to supervise reparations payments. The total liability was left to later determination, but standard annuities of 2,500,000,000 marks were set subject to increase. The plan was initiated by a loan of 800,000 marks to Germany. The Dawes plan worked so well that by 1929 it was believed that the stringent controls over Germany could be removed and total reparations fixed. This was done by the Young plan, which set reparations at 121,000,000,000 marks to be paid in 59 annuities. But hardly had the Young plan started operation than the world depression of the 1930s began and Germany's ability to pay dwindled to the vanishing point. In 1932 the Lausanne conference proposed to reduce reparations to the token sum of 3,000,000,000 marks, but the proposal was never ratified. Adolf Hitler came to power in 1933, and within a few years all important obligations under the treaty — political as well as economic — were repudiated.

Obstacles to Settlement. — Two circumstances were mainly responsible for the failure of reparations. One was the political

instability of Germany and its refusal to accept responsibility for the war. A more fundamental circumstance was the unwillingness of the creditor nations to accept reparation payments in the only practicable way they could be made—by the transfer of goods and services. The attitude of the creditors had its origin in the notion that a nation is injured by importing more than it exports. Through the 1920s the creditor nations tried to exclude Germany from world trade and simultaneously to increase their exports to Germany (on credit, of course).

Germany's Actual Payments.— The total of reparations paid is not exactly known because of uncertainty over payments between 1918 and 1924, their probable value being, however, 25,000,000,000 marks. From 1924 to 1931 Germany paid 11,100,000,000 marks. making total payments about 36,100,000,000 marks. During the postwar period. however. Germany borrowed 33,000,000,000 marks from abroad; it's net payments to the rest of the world were therefore 3,100,000,000 marks. The reparations program was most successful during the period of greatest borrowing, between 1924–31, when Germany paid 11,100,000,000 marks on reparations account and borrowed 18,000,000,000 marks, the net transfer being 6,900,000,000 marks to Germany. Although reparations often were called the cause of Germany's postwar difficulties, their direct effects were actually negligible. Reparations never were a sizable proportion of any important economic magnitude, being only a small fraction of government expenditures, exports, or national income.

In 1952. the Federal Republic accepted responsibility for the external debts of Germany (except those of the eastern zone), including the Dawes and Young plan loans which stabilized Germany in the 1920s in order to facilitate reparation payments. But the Federal Republic did not assume the reparations debt.

REPARATIONS AND WORLD WAR II

Reparations for the second war were viewed in two distinct ways. In one they were made incidental to a program of economic disarmament and were to be paid out of capital of: (1) actual or potential military value; and (2) that in excess of the amount permitted the defeated nations by the victorious powers. In the other view, reparations were regarded in the conventional way as payments in compensation for the costs of war and were to be made in kind out of capital and income.

The two conceptions are not wholly consistent, and the attempt to apply both of them created confusion and conflict. Removals of capital reduce the economic power of the defeated nation but they do not necessarily increase the power of the recipient nation correspondingly, so that the loss of income by the defeated nation may be (and usually is) greater than the gain to the victors. With each removal of capital, the ability to pay and receive reparations is lessened. If, on the other hand, maximum reparations are wanted by the victorious nations they cannot disarm the defeated nation of its economic power. These difficulties of the Allied reparations program were later complicated by two additional factors: the disagreement between the U.S.S.R. and U.S., which prevented the conclusion of peace treaties with the major defeated nations; and the establishment by the U.S. of the Economic Cooperation administration (ECA) for the purpose of capital reconstruction and development in Europe and Asia.

German Reparations.— The express policy was formulated at Potsdam in 1945. Uniform control was to be established over the entire German economy and administered jointly by four powers in their zones of occupation. The purpose was to dismantle German industry in order that the nation never again could engage in war. Dismantlement was to be limited by two considerations: the German level of living was not to be less than the average living level of other European countries excepting Britain and Russia; and Germany was to be left with sufficient capital in order to pay for its essential imports and so be self-supporting. Reparations were to be paid out of the difference between total German capital and the permissible amount. The distribution of reparations was to be made by the Inter-Allied Reparations agency established in 1945. A "level of industry" plan was formulated to specify the kind and amount of reparations available to claimant nations. It soon was recognized that the initial claims of $320,000,000,000 could not be satisfied, and the Allies announced their satisfaction with reparations which would "compensate in some measure for the loss and suffering caused by Germany."

Shortly after the end of the war, the political disagreement between eastern and western Allies made unified control impossible over the German economy. Its division into eastern and western areas curtailed the useful exchange of agricultural for industrial products and removed the possibility of Germany's supporting itself.

The division also increased the difficulties of capital removals since there was no way of appraising their effect on the total economy. The western powers sought to unify control over their zones in order to advance the reparations program. but here too there was disagreement over the amount of capital to be removed, France insisting on maximum removals in order to disarm Germany completely and Britain and the United States maintaining that Germany should be allowed enough industrial power to assist in the recovery of the entire economy of western Europe. In 1947 the U.S. offered large loans to European countries if they in turn would co-operate by increasing their output and by reducing trade barriers. The conditions were accepted and the ECA (originally called the Marshall plan) was begun. It was quickly discovered that European reconstruction would be assisted by allowing the Germans to retain the capital in their western areas (no assistance was given to the eastern area). There was then a conflict between the program for reparations and that for reconstruction. This was resolved by reducing reparations to a token amount, and by 1950 payments stopped. Moreover, west Germany had become so important by this time that the Allies made loans to it for reconstruction.

In 1953 the U.S.S.R. stopped collecting reparations from east Germany and stated it would return capital goods worth 3,000,000,000 ost marks.

After World War II, reparations from Germany probably were less than occupation costs and loans to it. The U.S.S.R. and Poland secured about a quarter of Germany's arable land and $500,000,000 in reparations out of income. Reparations in kind out of capital were extremely valuable to some of the receiving countries because of the world shortage of equipment after 1945.

Italy and Finland.— Italy's reparations debt was $100,000,000 to the U.S.S.R. to be paid in kind out of capital and income. Against this should be set relief payments by the western countries of a larger but unknown amount.

Finland's reparations payments were the most remarkable. By the armistice of 1944 with the U.S S.R., its liability was set at 300,000,000 gold dollars to be paid in kind out of income. the goods to be valued at 1938 prices. Valued at 1944 prices, the liability was $800,000,000, or 15% to 17% of Finland's national income, the heaviest burden on record. (Germany's World War I liability was never more than 3.5% of its national income.) One-third of the reparations was to be paid in wood products, a traditional export of Finland, and about two-thirds in metal and engineering products, most of which Finland had never made before. The penalty for late deliveries was equal to 80% of the value of the goods. The U.S.S.R. later reduced the bill one-fourth, but the reduction was in wood products. Finland completed its payments by 1952, on schedule, and thereafter sold many of the goods to the U.S.S.R. which it earlier had paid on reparations account.

Japanese Reparations.— The initial policy was identical with that for Germany and the consequences quite similar. Japan was to be disarmed of its economic power but left with enough capital to become self-supporting and to maintain a living level equal to that of other Asiatic countries. Reparations were to consist of capital in excess of the permissible amount. To this end an inventory of surplus capital was taken in 1945 and large-scale removals were planned. The Pauley report embodying the program was challenged and its conclusions were later modified, reducing Japan's liability. The major recipients were to be Asiatic countries which Japan had occupied during the war.

As in Germany, the collection of reparations was more expensive than expected and their value to the recipients less than expected. The claimant nations were unable to agree on their proper shares, which delayed execution of the program. Meanwhile, reparations capital in Japan was allowed to deteriorate, and Japan continued as a deficit economy supported mainly by the U.S. as the major occupying power. The continued deficit caused the U.S. to suspend all reparations deliveries in May 1949 To that date, total reparations paid out of assets held within Japan were 153,000,000 yen or $39,000,000 (at 1939 values). In addition. an unspecified sum was paid out of Japanese assets held in foreign countries. Offsetting total receipts from reparations u-as a considerably larger sum representing relief and occupation costs of the victor nations. As in Germany. occupation costs in Japan were not allocated as reparations receipts were. Some nations therefore obtained net reparations. Taken together, however, Allied reparations from Japan were also negative; net payments were made to Japan as well as to Germany. That these payments might have been still larger had no reparations whatever been collected is a moot question; it is to be noted that some of the payments were necessitated by the reparations program itself.

INDEMNITY PAYMENTS

At the close of its occupation, west Germany assumed liabilities of about $2,000,000,000 (8,000,000,000 DM) to make amends to the victims of nazi persecution. The internal restitution law of 1953, based on the restitution principles applied by the Americans in their zone, provided $952,000,000 to indemnify persons for bodily loss, loss of liberty and property, and injury to professional careers because of racial, religious and political persecution. It provided for paying persons who had been in concentration camps $3 5.70 for each month's imprisonment and for pensions to the survivors of victims. In 1953 also, west Germany agreed to pay the state of Israel $820,000,000 for the cost of resettling 500,000 Jews who to the end of 1951 had emigrated from countries formerly controlled by the Hitler government. The reparations did not cover restitution of Jewish property or claims against the government of east Germany.

After the war between Israel and the Arab states, the United Nations Conciliation Commission for Palestine estimated that $336,000,000 in land and movable property had been lost by the Arabs who became refugees from Palestine. The UN recommended Israel accept the liability and make reparation. Israel refused to accept responsibility on the ground that the losses were caused by the Arab states which started the war but agreed to make compensation through the UN if it received a loan or other assistance.

The agreement was a rare instance of a victorious country making compensation for war losses.

REPEAL, the abrogation, revocation or annulling of a law. The word is particularly used in the United States for the repeal of the 18th (prohibition) amendment of the constitution, and in English history for the movement led by Daniel O'Connell (*q.v.*) for the repeal of the Act of Union. *See* PROHIBITION; LIQUOR LAWS AND LIQUOR CONTROL.

REPHAIM (Heb. shades, ghosts), a race of reputed giants mentioned in the Bible as the prehistoric inhabitants of Canaan before the land was conquered by the Israelites. Rephaim are often held to be inclusive of the other Biblical giants, namely the Emim, Zuzim, Anakim and Horim. The giant legend, as well as that of longevity, is common in ethnic myths which tend to ascribe extraordinary powers and qualities to extinct forbears. The concept of larger than human proportions is also held to have arisen from the sight of ancient ruins and tombs. For example, the sarcophagus of Og, the king of "Bashan which was called the land of the giants" (Deut. 3:11) is described as being giant sized. In the later books of the Bible (Psalms 88:11; Job 26:j, etc.) Rephaim is the Hebrew word used to denote the shades of the dead which dwell in Sheol. similar to the ghosts (gigim, gidim) of Sumerian mythology. The valley of the Rephaim was a plain in Judah where David twice conquered the Philistines (II Sam. 5: 17–25).

REPIN, ILYA EFIMOVICH (1844–1930), Russian historical painter, was born in 1844 at Chuguyev in the department of Kharkov, the son of parents in straitened circumstances. He learned the rudiments of art under a painter of saints named Bunakov, for three years gaining his living at this humble craft. In 1863 he obtained a studentship at the Academy of Fine Arts of St. Petersburg, where he remained for six years, winning the gold medal and a traveling scholarship that enabled him to visit France and Italy. He returned to Russia after a short absence and devoted himself to episodes from Russian history. In 1894 he became professor of historical painting at the St. Petersburg academy. Repin's paintings are powerfully drawn. with not a little imagination and with strong dramatic force and characterization. He died at Kuokkala in Finland on Sept. 29, 1930.

His chief pictures are "Procession in the Government of Kiev," "The Arrest," "Ivan the Terrible's Murder of His Son" and, his best-known painting, "The Reply of the Cossacks to Sultan Mahmoud IV."

REPINGTON, CHARLES A'COURT (1858–1925), British military critic, was born on Jan. 29, 1858, and commissioned in the Rifle Brigade in 1878. After serving nith distinction in the Afghan War, the Sudan and South Africa, he was appointed military attach6 at Brussels and The Hague in 1900, being then a lieutenant colonel. Two years later his military career ended abruptly through domestic causes. and he took up journalism, becoming military correspondent of the *Times* in 1904. In 191j, after staying with the British commander in chief in France, he went home to call attention to the shell shortage. In Jan. 1918 a divergence of views caused him to leave the *Times* for the *Morning* Post, and after World War I he became military correspondent of the *Daily Telegraph,* a post which he held until his death at Hove, Sussex, on May 25, 1925.

His works include *Vestigia* (1919); *The First World War, 1914–18; Personal Experiences* (1920); *After the War; A Diary* (1922); *Policy and Arms* (1924).

REPINGTON (or REPYNGDON), **PHILIP** (d. 1424), English bishop and cardinal, u-as educated at Oxford and became an Augustinian canon at Leicester before 1382. A man of some learning, he came to the front as a defender of the doctrines taught by John Wycliffe; for this he was suspended and afterwards excommunicated, but in a short time he was pardoned and restored by Archbishop William Courtenay, and he appears to have completely abandoned his unorthodox opinions. In 1394 he was made abbot of St. Mary de Pré at Leicester, and after the accession of Henry IV to the throne in 1399 he became chaplain and confessor to this king, being described as "clericus specialissimus domini regis Henrici."

In 1404 Repington was chosen bishop of Lincoln, and in 1408 Pope Gregory XII made him a cardinal. He resigned his bishopric in 1419. Some of his sermons are in manuscript at Oxford and at Cambridge.

REPLEVIN, a term in English law signifying the recovery by a person of goods unlawfully taken out of his possession by means of a special form of legal process, this falls into two divisions — (I) the "replevy," the steps which the owner takes to secure the physical possession of the goods, by giving security for prosecuting the action and for the return of the goods if the case goes against him, and (2) the "action of replevin" itself. The jurisdiction in the first case is in the county court (*q.v.*); in the second case the supreme court has also jurisdiction in certain circumstances. At common law, the ordinary action for the recovery of goods wrongfully taken would be one of detinue; but no means of immediate recovery was possible till the action was tried, and until the Common Law Procedure Act 1854 the defendant

might exercise an option of paying damages instead of restoring the actual goods.

United States.—In the United States the action of replevin is almost entirely regulated by statute in each jurisdiction, and is materially different from the use and construction of the common law action of replevin in England. The action is laid upon a wrongful taking and a wrongful detaining or a wrongful detaining alone. It is a proceeding *in rem* to recover goods and chattels, *i.e.*, every kind of personal property to which the plaintiff has the right to present possession, and also, by statute, a proceeding in *personam*, to recover damages for either the detention or both the caption and detention, according to the wording of the statute. It is a possessory action, the gist of which is the right of possession in the plaintiff, but in nearly all cases the title is determined since the owner is entitled to possession, and possession by verdict where the title is in question awards title. It will not lie to recover real property or fixtures attached to the freehold, nor can it be maintained in any case in which the object sought is the determination of title to land. In some jurisdictions all damages growing out of the wrongful taking and detention may be assessed in the replevin action; in others, where the statute limits the recovery of damages to detention only, a separate subsequent action may be brought to recover compensatory and punitive damages sustained by a malicious wrongful taking (*Crockett* v. *Miller*, 112 Federal 729; *Petrie* v. *Wardman-Justice Motors*, Sup. Ct. *D. C.* No. 71,338). This is a rule peculiar to replevin, where so regulated by statute, and is at variance with the general rule of law requiring the adjudication in one cause of action of all claims and demands growing out of a single tort.

REPNIN, ANIKITA IVANOVICH, PRINCE (1668–1726), Russian general, and one of the collaborators of Peter the Great. He took part in all the principal engagements of the Great Northern War. Defeated by Charles XII. at Holowczyn, he was degraded to the ranks, but was pardoned as a reward for his valour at Lyesna and recovered all his lost dignities. At Poltava he commanded the centre. From the Ukraine he was transferred to the Baltic Provinces and was made the first governor-general of Riga after its capture in 1710. In 1724 he succeeded the temporarily disgraced favourite, Menshikov, as war minister. Catherine I. created him a field-marshal.

See A. Bauman, *Russian Statesmen* of *the Olden Time* (Rus.), vol. i. (St. Petersburg, 1877).

REPNIN, NIKOLAI VASILIEVICH, PRINCE (1734–1801), Russian statesman and general, grandson of the preceding, served during the Rhenish campaign of 1748 and subsequently studied in Germany. Peter III. sent him as ambassador in 1763 to Berlin. The same year Catherine transferred him to Warsaw, with instructions to form a Russian party in Poland from among the dissidents, who were to receive equal rights with the Catholics. Repnin convinced himself that the dissidents were too poor and insignificant to be of any real support to Russia, and that the whole agitation in their favour was factitious. At last, indeed, the dissidents themselves even petitioned the empress to leave them alone. The attempt had failed, and Repnin went to fight the Turks. At the head of an independent command in Moldavia and Walachia, he prevented a large Turkish army from crossing the Pruth (1770); distinguished himself at the actions of Larga and Kagula; and captured Izmail and Kilia. In 1771 he received the supreme command in Walachia and routed the Turks at Bucharest. A quarrel with the commander-in-chief, Rumyantsev, then induced him to send in his resignation, but in 1774 he participated in the capture of Silistria and in the negotiations which led to the peace of Kuchuk-Kainarji. In 1775–76 he was ambassador at the Porte. On the outbreak of the war of the Bavarian Succession he led 30,000 men to Breslau, and at the subsequent congress of Teschen, where he was Russian plenipotentiary, compelled Austria to make peace with Prussia. During the second Turkish war (1787–92) Repnin was, after Suvarov, the most successful of the Russian commanders He defeated the Turks at Salcha, captured the whole camp of the *seraskier*, Hassan Pasha, shut him up in Izmail, and was preparing to reduce the place when he was forbidden to do so by Potemkin (1789). On the retirement of Potemkin (*q.v.*) in 1791, Repnin succeeded him as commander-in-chief, and immediately routed the grand vizier at Machin, a victory which compelled the Turks to accept the truce of Galatz (July 31, 1791). In 1794 he was made governor-general of the newly acquired Lithuanian provinces. The emperor Paul raised him to the rank of field-marshal (1796), and, in 1798, sent him on a diplomatic mission to Berlin and Vienna in order to detach Prussia from France and unite both Austria and Prussia against the Jacobins. He was unsuccessful, and on his return was dismissed from the service.

See A. Kraushar, *Prince Repnin in Poland, 1764–8* (Pol.) (Warsaw, 1900); "Correspondence with Frederick the Great and others" (Rus. and Fr.), in *Russky Arkhiv* (1865, 1869, 1874, Petersburg); M. Longinov, *True Anecdotes of Prince Repnin* (Rus.) (St. Petersburg, 1865).

REPORTING, the business of reproducing, mainly for newspapers, but also for such publications as the *Parliamentary* or *Law Reports*, the words of speeches, or of describing the events in contemporary history by means of the notes made by persons known generally as reporters. There was no systematic reporting until the beginning of the 19th century, though there was parliamentary reporting of a kind almost from the time when parliaments began, just as law reporting in the middle ages began in the form of notes taken by lawyers of discussions in court. The first attempts at parliamentary reporting, in the sense of seeking to make known to the public what was done and said in parliament, were made by the *Gentleman's Magazine* in 1736. Access to the houses of parliament was obtained by Edward Cave (*q.v.*), the publisher of this magazine, and some of his friends, and they took surreptitiously what notes they could. These were subsequently put into shape for publication by another hand. Such reporting was a violation of the standing order of the house. passed in 1728, declaring the publication of any of its proceedings to be a breach of privilege, and on the attention of the house being called in 1738 to the reports in the *Gentleman's Magazine* it threatened to proceed with the utmost severity against the offenders. Thereupon Cave published his reports as "Debates in the Senate of Lilliput," and instead of giving the first and last letters of each speaker's name, employed such barbaric terms as "Wingul Pulnub" for William Pulteney. Dr. Johnson composed the speeches for the *Gentleman's Magazine* from 1740 to 1743, the names of the speakers being given in full. Though he said he took care not to let the "Whig dogs" get the best of it, he really dealt out argument and eloquence to both political parties.

In the latter half of the century the newspapers began to report parliamentary debates more fully, with the result that, in 1771 several printers, including those of the *Morning Chronicle* and the *London Evening Post*, were ordered into custody for publishing debates of the house of commons. A bitter struggle between the house and the public ensued. In 1772 the newspapers published the reports as usual, and their right to do so has never again been really questioned. Early in the 19th century, greater freedom of access to both houses was given to newspaper reporters. Special galleries for their accommodation mere provided in the legislative chambers of the new palace of Westminster erected in place of the old which was burned down in 1834. The press gallery of the house of lords was first used in 1847, and the press gallery of the house of commons in 1852. At this time the London newspapers had a virtual monopoly of parliamentary reporting, since only their representatives were admitted to the galleries.

The *Times* established a supremacy for the best parliamentary report, which has never been shaken. The other London papers, however, gave less and less attention to the debates while the leading provincial newspapers began to publish full reports of debates of local interest. They employed reporters in the service of the London journals but their reports mere printed a day late. Then telegraphic wires from London were placed at the disposal of provincial newspapers from six o'clock at night till three o'clock in the morning. The arrangement was first made by the *Scotsman* and by other newspapers in Scotland in the 1860s. When the telegraphs were taken over by the state in 1870 the facilities for reporting were increased in every direction. News agencies undertook to supply the provincial papers, but the reports which any agency

supplied were identical. In 1880 a select committee of the house of commons was appointed to consider whether the gallery should continue to be closed to all save the London papers and the news agencies. It reported in favour of the extension of the gallery and of the admission of provincial papers. The press gallery of the house of commons was accordingly enlarged and representatives of the leading provincial newspapers were admitted at the opening of the session of 1881. At this period the *Times* first established telephonic communication with the gallery. In 1951 that paper introduced a new tool of parliamentary reporting—the system of teletypesetting, by which a compositor in the palace of Westminster could set type by remote control of a linotype machine in the offices of the *Times*. This system had been used in the United States and by the *Scotsman* and the *Glasgow Herald* between London and their head offices.

What is commonly called "descriptive reporting" has in some cases nearly shouldered the reporting of speeches out of newspapers. The special correspondent or the war correspondent is a "descriptive reporter." The "interviewer" came into great prominence during the 188os and 189os. In 1900 in the English case of *Walter* v. *Lane* it was decided on the final appeal to the house of lords that the reporter of a speech, printed verbatim in a newspaper, was under the Copyright act of 1842 to be considered the "author." Absurd as it might seem to call the reporter the author of another man's speech, the decision gave effect to the fact that it is his labour and skill which bring into existence the "copy" to which alone can right of property attach. Strictly speaking, he is the author of the *report* of the speech; but for literary purposes the report *is* the speech. Any other persons present when the speech was made could equally have obtained copyright in *their* report of it; there may be more than one verbatim report. and therefore more than one "author." The effect of *Walter* v. *Lane* was not, it was considered, affected by subsequent legislation of the law of copyright.

Law reports have a special place in the English judicial system. When a new point of law is determined in a lawsuit, that case becomes in theory a precedent for future cases in which the same point arises. Whether a case in fact becomes a precedent depends mainly, however, on whether it is reported, and the reporting of cases has always been in private, or at least unofficial hands. Any law report made by a barrister may be cited in court—those, for instance, appearing in the *Times* are frequently so cited when no fuller report is available—but it is usual to cite reports specially prepared for the purpose. These should begin with a headnote stating succinctly the point determined, usually by reference to the facts found, followed by a full statement of the relevant facts, the arguments of counsel, and the judgment of the court on the law. Reports in this form date back to the time of Lord Mansfield, chief justice, in the late 18th century, and thereafter a strict doctrine of *stare decisis* evolved requiring the judges invariably to follow the decision of at least a higher court in future similar cases. In 1865 the Council of Law Reporting was set up, a non-profit-making body publishing the *Law Reports,* but a host of series of reports published commercially, mostly defunct by the mid-195os, competed with them, often printing more cases. Accordingly in 1953 the council instituted the *Weekly Law Reports,* at least as full as any private series, only select cases of which appear finally in the *Law Reports.* The *Law Reports* alone set out the arguments of counsel, which add considerable value to a report; for if a point was missed it may be raised again in a future case to show that the reasoning of the court was wrong—per *incuriam.* The odd fact remains that the great-majority of cases are never reported at all, and the selection of those so reported remains in unofficial hands. Comparison with other countries (such as the United States), where cases are generally reported, shows that the principle of *stare decisis* works better under the English system.

UNITED STATES

The first known reporting of news for current publication in America consisted of an account of a Guatemalan earthquake printed in a Mexican newssheet. The first known such publication in what is now the United States was in a broadside published in Boston in 1689 and entitled "The Present State of the New-English Affairs"; the reporter was Increase Mather, u-ho told of what was being done in England in regard to the Andros revolution.

Because colonial papers were made up chiefly of articles taken from other newspapers issued in England and other colonial towns, essays, political documents, etc., direct reporting by newsmen connected with their respective papers was limited to brief pieces about the most important local happenings written by the editor or a friendly contributor. It was not until the rise of the "penny press" in the 183os, with its emphasis on local news, that reporting came into its own as the most essential part of newspaper work. In 1851, Horace Greeley, one of the greatest U.S. editorial writers of the time, testifying before a British house of commons committee, insisted that U.S. readers gave far more attention to news than editorials. William Rockhill Nelson. founder (188o) of the *Kansas City Star,* declared, "The reporter is the essential man on the newspaper; he is the big frog in the puddle."

Types of News Reporting.—Most important of all are the local reporters, because (1) they outnumber those of any other category, and (2) local news is always regarded as of primary importance. A local reporter sometimes does little or no writing. A "leg man" telephones his news to a "rewrite man," and may visit the office of his paper only occasionally. A "cub" reporter is a beginner and usually has a routine "beat," while a "star" reporter receives from his editor the most important special assignments.

The capital, or state house, correspondent reports news of the state government. In states containing large cities, handling such news for metropolitan papers is a big task, especially during sessions of the legislature.

Washington correspondents cover the news of the national government. Their task is complicated, exacting, responsible. They cover the capitol, the White House, the various departments and bureaus, etc. There has been increasing insistence on "digging out" news of situations instead of waiting for its development in events, or merely collecting "handouts." There were about 1,400 reporters, including photographers, covering Washington in the 195os, three-fifths serving daily newspapers, one-fifth radio and television and one-fifth periodicals.

Foreign correspondence is the goal of many ambitious reporters, but in peacetime United States papers and news agencies keep only about 300 full-time U.S. reporters abroad. When they work in war areas, these men and women become war correspondents, accredited by military, naval, or air commands. During World War II, the U.S. war department accredited 1,186 U.S. correspondents and news officials. and the navy department 460 more—a total of 1,646 newsmen for all media.

Distribution by Media.—In modem communication! reporting is by no means limited to the men and women who gather and write the news. Gathering is essential to the process, but the reporter may write, picture, or speak the news for newspapers, magazines, books, radio, television, or motion pictures.

Newsphotography has been a means of reporting ever since the American Civil War pictures of Mathew B. Brady, and movie news shorts have been used ever since the Spanish War motion pictures of J. C. Hemment. With the development of the inexpensive halftone engraving process in the last two decades of the 19th century, pictures as news made an increasingly important contribution to reporting.

Beginning with an amateur broadcast of election returns in 1916, radio gradually came to play a large and essential part in the news distribution system, and all large broadcasting stations include on their staffs local newsmen who make direct reports. The networks have their own reporters at Washington and abroad, and radio reporters have seats in the senate and house press galleries.

Reportorial Ethics.—Strides toward professional standing have been made by reporting, through (1) better training in schools of journalism and liberal arts colleges, and growing acceptance of specialized training for journalism by employing editors; (2) increasing group solidarity through organization and the recognition of such codes as the Canons of Journalism of the American

Society of Newspaper Editors and Walter Williams' "Journalist's Creed"; and (3) a better wage scale, largely through the efforts of the American Newspaper Guild, organized in 1933. (F. L. MT.)

REPOUSSÉ (Fr. "driven back"), the art of raising designs upon metal by hammering from the back, while the "ground" is left relatively untouched. The term is often loosely used, being applied indifferently to "embossing." Embossing is also called *repoussé* sur *coquille* and *estempage*, but the latter consists of embossing by mechanical means and is therefore not to be considered as an art process. Moreover, it reverses the method of repoussit, the work being done from the front, and by driving down the ground leaving the design in relief.

Repoussé—a term of relatively recent adoption, employed to differentiate the process from embossing—has been known from remote antiquity. Nothing has ever excelled, and little has ever approached. the perfection of the bronzes of Siris (4th century B.C., in the British Museum), of which the armour-plate—especially the shoulder-pieces—presents heroic figure-groups beaten up from behind with punches from the flat plate until the heads and other portions are wholly detached—that is to say, in high relief from the ground of which they form a part. Yet the metal, almost as thin as paper, is practically of constant thickness, and nowhere is there any sign of puncture.

The art was not only Greek and Graeco-Roman in its early practice; it was pursued also by the Assyrians. the Phoenicians, and other oriental peoples, as well as in Cyprus and elsewhere, and was carried forward, almost without a break, although with much depreciation of style and execution, into mediaeval times. In the 11th century the emperor Henry II. presented as a thank-offering to the Basle cathedral the altar-piece, in the Byzantine style, decorated with fine repoussé panels of gold (representing Jesus Christ nith two angels and two saints), which is now in the Cluny Museum in Paris. Up to this time, also, repoussé instead of casting in metal was practised for large work, and Limoges became a centre for the manufacture and exportation of sepulchral figures in repoussé bronze. These were affixed to wooden cores. By the time of Benvenuto Cellini the art was confined almost entirely to goldsmiths and silversmiths (who, except Cellini himself, rarely cast their work); and to them the sculptors and artists of to-day are still content to relegate it.

The elementary principle of the method, after the due preparation and annealing of the plate, was to trace on the back of it the design to be beaten up, and to place it face down ards upon a stiff yet not entirely unresisting ground (in the primitive stage of development this was wood), and then with hammers and punches to beat up the design into relief. According to Cellini, his master Caradosso da Milano would beat up his plate on a metal casting obtained from a pattern he had previously modelled in wax; but he is not sufficiently explicit to enable us to judge whether this casting was a hollow mould, which would result in true repoussé, or in the round, which is tantamount to *repoussé sur coquille*, or embossing.

Nowadays the plate is laid upon and affixed to a "pitchblock," a resinous ground docile to heat, usually composed of pitch mixed with pounded fire-brick, or, for coarser work such as brass, with white sand, with a little tallow and resin. This compound, while being sufficiently hard, is elastic, solid, adhesive and easy to apply and remove. Gold and silver are not only the densest and most workable but the most ductile metals, admitting of great expansion without cracking if properly annealed. The tools include hammers, punches (in numerous shapes for tracing, raising, grounding, chasing and texturing the surfaces), together with a special anvil called in French a *recingle* or *ressing*, in English "snarl." The *recingle*, or small anvil with projecting upturned point, was known in the 16th century. This point is introduced into the hollow of the vase or other vessel such as punch and hammer cannot freely enter, which it is desired to ornament with reliefs. A blow of a hammer on that part of the anvil where the prolongation first projects from it, produces, by the return spring, a corresponding blow at the point which the operator desires to apply within the vase. The same effect is produced by the modern "snarl" or "snarling iron"—a bar of steel, with an inch or two of the smaller end upturned and ending in a knob—held firmly in a tightly screwed-up vice, whereby the blow is similarly repeated or echoed by vibration. The repoussé work, when complete, is afterwards finished at the front and chased up. *See* also METALWORK, DECORATIVE; SILVERSMITHS' AND GOLDSMITHS' WORK.

(M. H. S.)

REPRESENTATION, a term with the broad general connotation of making present something or somebody that is not present; but more especially the term is used in a political meaning and pertains t@modern government as a method of solving the problem of how to enable a very large number of people to participate in the shaping of legislation and governmental policy.

Representation in the broadest sense has roots which link it with the world of beliefs called magic, a world in which mysterious connections were regularly assumed to prevail between distinct persons and beings. both natural and supernatural. Without going into the historical evolution of the various meanings of "represent," "representation" and "representative." it is worth noting that the modern governmental meaning was not attached to these expressions until the 16th century, when parliamentary development began. Sir Thomas Smith, in his *De Republica Anglorum* (1583), uses the expression freely in describing parliamentary institutions.

It must be admitted, however. that a magical element remained in spite of the continuous effort to rationalize the relationship spoken of as representation. Some writers, such as Jean Jacques Rousseau, simply denied that representation of the will of the people is possible While few would be willing to follow Rousseau, it is generally agreed that representation of the electorate in modern representative assemblies poses very real problems, because the views both of the representative and of those represented are likely to undergo change as the situation changes.

Theoretical Problems of Representation.— In large modern countries the people cannot, of course, assemble in the market place as they did in democratic Athens or Rome. If, therefore, the people are to participate in government, they must select and elect a small number from among themselves to represent them and act for them. Through the course of a long historical evolution, the methods for such elections have been rationalized. The extended 19th-century struggle for electoral reform in England was fought over this issue; rotten boroughs, patrons and other features of aristocratic nepotism were eliminated. In these reforms. Jeremy Bentham's "rational" principle of utility prevailed against Edmund Burke's earlier defense of traditional practices. Direct general elections have since that time been accepted as the most "rational" method for choosing representatives, whether they be legislative or executive. For executives are also representatives of the people. The view that this is not so is a survival of attitudes developed during the monarchical age, when progressive forces fought the crown as unrepresentative. It is important that executives be included among the people's representatives because of the paramount role the executive establishment plays in modern government. Public policy in most modern democratic governments is shaped as much by the executive as by the legislative. Since parties are usually led by the chief executive, their role in determining the pattern of representation strengthens the executive's representative position.

Somewhat different are the role and position of the courts The thorough legal knowledge required of a good judge has stood in the way of choosing judges by election. Wherever judicial bodies have been elective. much dissatisfaction has developed. In most jurisdictions, judges are ordinarily selected on the basis of technical competence—a relatively objective standard. Elections have not seemed a "rational" method. The supreme court of the United States would certainly seem to most people less representative if it were elected by the people. The reason for this is that all representation involves ideas; for only through an idea can the making present of one thing or person by another be conceived. Another problem would arise as the result of the divisions of the electorate; minority interests might be neglected

The deepest and most obscure aspect of representation is its ideological foundation. There has always been controversy be-

tween those who would have the representatives of the people act as delegates carrying out instructions and those who would have them be free agents acting in accordance with their best ability and understanding. The latter alternative was stated by Edmund Burke in his celebrated speech (1780) to the electors at Bristol:

Parliament is not a *congress* of ambassadors from different and hostile interests, which interests each must maintain, as an agent and advocate, against other agents and advocates; but parliament is a *deliberative* assembly of *one* nation, with *one* interest, that of the whole; where not local purposes, not local prejudices ought to guide, but the general good. . . .

Certainly, gentlemen, it ought to be the happiness and glory of a representative to live in the strictest union, the closest correspondence, and the most unreserved communication with his constituents Their wishes ought to have great weight with him; their opinion high respect; their business unremitted attention. . . . But his unbiased opinion, his mature judgment, his enlightened conscience, he ought not to sacrifice to you, to any man, or to any set of men living. These he does not derive from your pleasure; no, nor from the law and the constitution. They are a trust from Providence, for the abuse of which he is deeply answerable.

Burke's idealistic conception accords neither with the reality of popular politics nor yet with the democratic ideal that the will of the people should prevail. The issue as to whose will is to prevail and is therefore to be taken as the will of the whole cannot be sidestepped by asserting, as Burke does, that parliament represents *one* nation, with *one* interest. While this is true in the abstract, the issue at hand is who is to say what that general interest is at a given time. For the conflict of various interests and their possible relation to a more comprehensive public interest is the real issue. Abstractly considered, a special mandate cannot be admitted, since it would make the members of representative assemblies into mandatories for special interests. But there is a great difference between a special mandate and a broad indication as to the general line of policy to be pursued.

The reason that the elected representatives of a party can be said to represent their electorate is basically that these representatives and those whom they represent are bound together by a world of ideas and beliefs that they share. Consequently, it can be assumed that any conclusion the representatives come to with regard to a new issue is likely to be the same as the conclusion the electorate would have come to had it been able to consider the new facts. But one gets lost in metaphysics of a rather shady sort when one claims that the majority represents the minority in any concrete sense. It is the majority and the minority together who represent the people as a whole and their general interest. But what about the single chief executive? All attempts to lift a chief executive above parties have proved abortive. A disastrous example is provided by the institution of the presidency under the German republican (Weimar) constitution. Such insistence upon the nonpartisan character of the chief executive is a result of the persistence of ideas prevalent during the monarchical age. when the king or the crown was supposed to be the preordained representative of all.

Dual Nature of Representation. — Historically speaking. representative assemblies developed in most European countries in the course of the later middle ages as an important part of the medieval constitutional order. Though great variations existed. the three estates were usually composed of nobility, clergy and the merchants of the cities (the burgesses). In the English parliament the higher nobility was joined with the higher clergy in "the lords spiritual and temporal," while the lower squirearchy and the burgesses together constituted the commons. This latter, the English system of two estates, proved more viable than the commoner continental system of three. The representatives of the loner estate mere originally called by the crown in order to secure additional financial support over and above the feudal dues. *(See* FEUDALISM; PARLIAMENT.) Quite naturally, these representatives when gathered together proceeded to present complaints and petitions in an effort to strike a bargain. Such bargains were in favour of their own class. They represented their class as agents of the local powers and acted under instructions or mandates. But when, after the deal was struck, the king and the two houses of parliament acted together as "the king in parliament," they were taken to represent the whole realm. This historical background shows clearly that it is not justifiable in drawing the sharp distinction Burke had in mind between agents with definite instructions and representatives speaking for one nation. An elected body is both: a deliberative assembly from *one* nation with *one* interest. that of the whole, *and* a congress of ambassadors from different and hostile interests. This dualism in political representation cannot be escaped. Many political philosophers have tried to do it, but with unsatisfactory results. The fascists and Communists have. by their insistence upon a monistic view. been forced into seeking some kind of religious or inspirational sanction, deifying the state, the proletariat or the folk and their respective leaders. The dualism of representing both the whole and one or another of its parts lies deeply embedded in representative schemes.

Representation Defined. — In the light of the foregoing, it is possible to suggest a definition of political representation: Representation is the process through which the attitudes, preferences, viewpoints and desires of the entire citizenry or a part of them are, with-their expressed approval, shaped into governmental action on their behalf by a smaller number among them, with binding effect upon those represented.

Some features of this difficult definition require further comment. It is necessary to speak advisedly of attitudes, preferences, viewpoints and desires, rather than of will, influence or control, because the large citizen bodies of modern times do not possess a clearly defined will in most matters of public policy, because of lack of knowledge. It is necessary to use the general expression "governmental action." rather than legislation or policy. because all kinds of governmental activity are expressive of popular reactions. Perhaps the most important part of this definition is the phrase "with their expressed approval." Since such approval can be secured only periodically, it must be in a form covering a specified period of time. Finally, it is essential for genuinely representative action that it be accepted by those represented as theirs and hence binding upon them in all its consequences — a result which flows from their expressed approval. But while periodic elections are the commonest method for demonstrating expressed approval, there are exceptions, such as in constitutionally established courts, where the expressed approval may be found in a constitution adopted by common consent; or as in a special interest represented in so-called economic councils.

SOME HISTORICAL AND CONSTITUTIONAL ASPECTS OF REPRESENTATION

Representative systems of the rationalized type are a modern growth. They certainly were not found, as Montesquieu implied, in the forests of ancient Germany. It has been shown that political representation arose as part of the medieval constitutional order. Like so many medieval institutions, this political representation drew its inspiration from the church, whose vast body of the faithful was presumably represented by the great councils in which all Christian people were believed to be present.

Reasons for the Late Appearance of Representation. — But why did representation appear so late in the history of mankind? Essentially, the answer must be that it was not needed before modern times. The great empires of Asia had been animated by religious beliefs in which the individual human being counted for little and his personal preferences for less. In classical antiquity, with its city-states, the small number of citizens made personal participation possible. Aristotle deemed this participation so vital that he opposed altogether a political framework larger than the average city-state. Such personal participation became impossible whenever such a city-state expanded beyond the local unit. Attempts to solve the problem through federal organization foundered because of the lack of an ideological base upon which a representative scheme might have been evolved. The Romans undertook to embody the citizenry of each city of their Latin federation in the Roman citizenry by using various fictions, but the system broke down when republican Rome expanded and the Romans adopted the Asiatic technique of deifying an emperor. Still, the Roman constitution unquestionably contained elements of genuine representation. These elements were crippled, however,

by the ascendancy of the unrepresentative senate. By contrast, the spirit of corporate solidarity in the medieval towns, shires, monasteries and cathedrals was sufficiently developed to make the group willing to participate in the larger community through group representatives. Unless such solidarity provides a common base of ideas, true representation cannot take place.

Representation and Constitutional Government. — Except in small communities, constitutional government is impossible without a system of representation. Constitutional government is government in which the use of power is restrained by a constitution which defines the functions of various power-holders. Restraint necessarily calls for dividing governmental power. Undivided power is unrestrained power.

From a historical standpoint, the need for securing responsibility in government is the central objective in all the various schemes of representation. This is true even of completely supernatural schemes, such as that by which a king is supposed to represent God on earth. For this notion may be the most powerful restraint upon the ruler and provide an impulse for him and his officials to act justly and avoid abuse of power. Examples abound not only in the experience of Europe but in such systems as the sultanate of Turkey or the empire of China. But this scheme works only as long as the faith lasts. If the ruler becomes an unbeliever, the most arbitrary tyranny easily develops.

The division of power may take many different forms. Perhaps the two most important modern forms are the so-called separation of powers, and federalism. For both, representation is of vital importance. Distinct federal divisions of the electorate, created and maintained under a constitution, require the selection of distinct groups of representatives among whom the several functions of government may be divided. (See FEDERAL GOVERNMENT.) The same is true under any kind of separation of powers; it presupposes a variety of representatives for different constituencies. Looked at from this angle. these schemes for dividing "power" really amount to dividing the people in a number of different ways and then giving these several subdivisions a voice in shaping governmental action through different representatives nho are kept from abusing their power by holding each other in check. Such a plan could, of course. have no practical effect unless the community were actually divided into a number of groups, parties and classes.

Not only does constitutional government depend upon representation, but representation in turn depends upon constitutionalism. For unless the community is ready to agree upon and live by a basic charter in accordance with which power is wielded, plans for representation are liable to break down, as they did in post-World War, I Italy and Germany. The representative quality rests upon a belief in common ground as far as doing things is concerned, and while there is no need for agreement on fundamentals other than the constitutional mores themselves, the latter, which have sometimes been called constitutional morality, are indeed of paramount importance. Representation, it might be said, is a game in which the rules are prescribed by the constitution as approved by the people. *(See* CONSTITUTION AND CONSTITUTIONAL LAW.)

Representation and Legislation. — Ever since the 16th century. legislation has been considered the most important phase of governmental action. Legislation involves the making of rules binding upon the whole community. Such general rules, it was felt, should bear the closest possible relation to the community's general beliefs. The higher law which Sir Edward Coke and others expounded as the yardstick for evaluating parliamentary statutes mas believed immutable, a precious heritage of principles upon which all legislation should be based. At this point, the Protestant idea that one cannot force men in matters of belief, now generally accepted by all Christians as well as by many other faiths, reinforced the growing idea of the necessity of consent in matters of general legislation. A specific act of government may be justified in terms of a specific emergency, but no general rule can be considered valid unless assented to by those to whom it is to apply. Since the citizenry is too large, representation becomes essential. "No taxation without representation" is a vivid expression of this general view.

There is another aspect which suggests the use of representative assemblies as the natural agents for the purpose of making laws. A general rule presupposes that there is a series of events which have certain aspects in common. There must be a normal situation. If an event is recurrent, time elapses. Time is available, therefore, for deliberation to determine what is right and proper. Deliberative processes in turn are well suited to the relatively slow procedure of representative bodies. Nevertheless, the procedure of a well-organized representative assembly is so arranged as to result in action; namely, the adoption of a general rule. The enactment of such a general rule requires careful adjustment of conflicting viewpoints; really workable compromises need to be reached. Through argument and discussion the area of agreement is determined in the representative legislature. It symbolizes the consent which legislation presupposes, if it is to be compatible with the dignity of man's autonomy in matters of basic conviction and belief.

ELECTORAL SYSTEMS AND REPRESENTATION

In our discussion so far the electing of representatives has been spoken of as if an election were as simple a thing as throwing a stone. Actually, some of the most difficult problems of representation arise in connection with elections. Should elections be secret or public? Should limiting qualifications be required of those participating in the elections? How should the country be divided so as to make it possible for people to vote? These and related issues have all been sharply debated at one time or another, with a view to their bearing upon the central issue of making the results representative.

To the ancients, democracy meant that the whole citizenry met in the market place and decided all matters of common concern. To the modern world, democracy means that the whole citizenry regularly elects representatives. after having read about their platforms in the newspapers or listened to them in a meeting or over the radio or television. But there is a great difference between those elections in which the citizen is confronted by a clear-cut alternative between electing either A or B, and thereby supporting either party X or party Y, and elections in which he must choose among A, B. C, D, E, F and so forth and thus align himself with one of at least half a dozen parties, none of which has any chance of securing a majority.

The English and U.S. System. — The so-called two-party system has long been traditional in the United States and Great Britain. British parliamentary government rested for a long time upon a strictly traditional system of elections. It abounded with abuses of all kinds, such as rotten boroughs — unpopulated or depopulated areas which retained the right of representation in parliament. Through a series of reforms Britain eventually arrived, in 1884–85, at the single-member constituency, though the constituencies continued to lack uniformity of size and structure. Elections thereafter were decided in England by relative majority or plurality. This means that the candidate who secures the largest number of votes wins the seat. The balloting is secret, though before 1885 it was public, with much brawling and rioting. The British electoral system is thus clearly directed toward the goal of dividing each constituency, and thereby all of the United Kingdom. into two parts: the majority which is to govern and the minority which is to criticize. This situation may mean permanent minority status for a man who belongs to the wrong party in a particular constituency. As the English writer Walter Bagehot wrote in *The English Constitution* (1873), "I have myself had a vote for an agricultural county twenty years, and I am a Liberal; but two Tories have always been returned, and all my life will be returned." A Democrat in Vermont or a Republican in Alabama is in the same situation.

The main criticism brought against this system of single-member constituencies is that the number of representatives elected is usually not proportional to the ratio of votes cast. Such is virtually certain to be the case, because in many constituencies one of the parties may predominate, as Democrats do in the southern states of the United States or Tories do in many rural constitu-

encies in England. It may result in apathy among the voters, or in a shift to primary contests as the key political decision. It may even happen that a minority of votes secures a majority of representatives.

Gerrymandering ("Electoral Geometry").—If the desirability of a majority (plurality) system of elections be conceded, the issue of how to divide the electorate appropriately is of great importance. As long as the population shifts, periodic readjustments of the boundaries of electoral districts are necessary, if gross injustices such as rotten boroughs are to be avoided. In the United States and elsewhere this issue is a familiar one; there is a recurrent political fight over reapportionment. Even with skillful and competent handling, there are bound to be lags. Under adverse conditions, reapportionment becomes a football of party politics. Since in order to gain a seat all a party needs is a small majority of votes, it is very tempting for the party in power to redraw the political map, that is, the boundaries of districts, wards and other subdivisions, so as to distribute its voting power most effectively. The resulting shapes of electoral subdivisions are often fantastic and not even always contiguous. Because a salamanderlike sprawling district was first constructed under a governor of Massachusetts, Elbridge Gerry, in 1812, this practice is known as gerrymandering. It is easy to construct cases which illustrate how the same electorate may give a majority to opposing parties as a result of adroit electoral geometry. (See APPORTIONMENT, LEGISLATIVE.)

The Issue of Proportional Representation. — The nonproportionality of single-member constituencies electing representatives by pluralities as well as gerrymandering has given rise to a series of proposals for proportional representation which seek to remedy these defects. The idea first appeared in the French national convention in 1793, without practical results. It was further elaborated by a number of writers (see Bibliography) who invented several systems.

It is clear that proportional representation responded to a widely felt need. The underlying idea of all the various proposals was to secure a representative assembly reflecting with more or less mathematical exactness the various divisions in the electorate. Why should such divisions be reflected? "The voice of minorities should be heard," is the answer.

The most penetrating philosophical argument in support of the general idea of proportional representation was set forth by John Stuart Mill. He called it "one of the very greatest improvements yet made in the theory and practice of government. . . . In the first place, it secures a representation, in proportion to numbers, of every division of the electoral body: not two great parties alone . . . but every minority in the nation. . . . Secondly, no elector would be nominally represented by someone whom he had not chosen. Every member of the House would be the representative of an unanimous constituency." Mill stressed the strong tie, the complete identification, the weakening of localism, the higher intellectual qualification of the representatives and the avoidance of collective mediocrity. Finally. Mill saw it as a check on "the ascendancy of the numerical majority" by offering "a social support for individual resistance. . . . a rallying point for opinions and interests which the ascendant public opinion views with disfavour." In his enthusiasm, Mill called proportional representation "personal representation" which offers a refuge to the "instructed elite." No objections of real weight could be seen by Mill, though in his usual deliberate manner he examined a few which he found wanting. Yet it is obvious that his whole argument rested upon certain unexplained major premises. His is an extreme individualist argument which he reinforces by the undemocratic preoccupation with the enlightened few who might be lost in the shuffle of the ignorant mass.

But the key assumption is that there can be no representation of the nhole without a representation of each of the whole's parts. What actually is the primary function of a representative assembly? Is it to represent or is it to do something else? To put the question is to answer it. The primary function is to participate in governing. In order to be able to do that, a representative assembly needs a measure of cohesion. It cannot be, as we have seen, solely a congress of ambassadors from different and hostile interests. It must be able to reach decisions.

The elusive quality of Mill's approach is made evident by the opposing view of Walter Bagehot, another eminent writer on government and a 19th-century liberal like Mill, albeit more to the right. Bagehot, in rejecting proportional representation, put the following question: What will proportional representation do to the functioning of a parliament as we know it? Bagehot was a practical man, a banker, and his great achievement in this debate was to spell out what everyone knew in practice, namely, that the function of a parliament was twofold: (1) for the majority to support the cabinet in its conduct of the government; and (2) for the minority to criticize the actions of the government. This combination of action and criticism enables a parliament to represent the people as a whole.

Bagehot considered the basic difference between election by majority and proportional representation the fact that proportional representation makes the constituency voluntary-each voter individually is able to choose his own constituency. He votes as a voluntary member of a group which has no other tie. A constituency being the group or segment of voters that is entitled to send a member to parliament or congress, this is indeed the basic point, although the language of advocates of proportional representation often obscures it. To put Bagehot's point another way. all proportional schemes suggest saying to the electorate: If a certain number among you, say 10,000, can agree upon a candidate, that candidate shall be elected. The majority system, by contrast, is based upon this approach: A certain number among you shall constitute an electoral district, and the one for whom the largest number among you vote shall be considered elected. "Under the compulsory form of constituency the votes of the minorities are thrown away. . . . Again this plan gets rid of all our difficulties as to the size of constituencies. . . . Again the admirers of a great man could make a worthy constituency for him." But central party organizations would acquire an overweening influence. "The crisis of politics would be not the election of members, but the making of the constituency. . . . The result of this would be the return of party men mainly. . . . Upon this plan, in theory voluntary, you would get together a set of members bound hard and fast with party bands and fetters infinitely tighter than any niembers now. . . ." These are brief bits from a memorable passage in Bagehot's The English *Constitution* which anticipated with remarkable clairvoyance some of the troubles that arose when proportional-representation schemes were actually tried. His arguments do not, of course, exhaust the problem. They are focused upon the issues which arise when the cabinet governs with the support of the majority of a parliament. They fail to take into account the problems which appear when the divisions or cleavages among the electorate have gone so far that failure to represent them adequately would undermine the belief of the people in the justice of the constitution.

Theory and practice suggest that the truth lies somewhere between the lines of argument taken by Bagehot and Mill. There are situations, such as in multinational Switzerland, where proportional representation is probably to be preferred, but then parliamentary government should be discarded or at any rate considered very difficult of operation. There are others, such as in Great Britain, where the later evolution of parliamentary government, with its increasing emphasis on executive leadership, would seem to make a majority system advisable.

The Problem of Justice. — A broader philosophical issue which deserves special consideration is the justice of a representative system. Mill, in his plea for proportional representation, laid considerable stress upon this aspect. "There is a part," he wrote in Considerations on Representative Government, "whose fair and equal share of influence in the representation is withheld from them; contrary to all just government. . . . The injustice and violation of principle are not less flagrant because those who suffer by them are a minority. . . ." Mill considers this matter of justice to the minority so obvious that he proclaims representation in proportion to numbers the first principle of democracy. What kind of justice and democracy is this? Let it be assumed for the

moment that representation should be that of individuals and that it is unjust to a minority not to be "represented," or "represented adequately." If there were only one such minority, perhaps it would not be too bad, although the number of representatives who would criticize rather than help to decide would be increased. It would mean less action, rather than different action. If there were many such minorities, so that no group any longer had a majority, it might mean complete inaction for long periods. This situation arose toward the end of the Weimar republic and spelled its doom. It arose in France in the 1930s with disastrous effects, and again in the early 1950s. What then about justice for the majority? Is it not a question of competing claims? Why should the question of what is just to the minorities be given precedence over what is just to the majority? Admittedly, the majority wants some action. If such action is, through proportional representation, delayed or altogether prevented, what is the justice of that? Problems of justice are problems of adjustment between conflicting claims.

The election of representatives, therefore, always involves the paring down of some claims; justice can be achieved only through a careful balancing of these. Presumably the majority's claims are weightier than those of any minority. Representation is a broad thing: The majority participates through acting, the minority through discussion and criticism. Proportionalists fail to consider the possibility that there might not be any majority at all, in spite of the fact that the need for action, and hence the existence of a majority, may be paramount. A just government is above all a government which governs, No government which fails to do that can possibly be just.

Experience **with** Proportional Representation.— AS contrasted with the time when Mill and Bagehot wrote, there is today a substantial body of experience with the workings of proportional representation. But the conclusions to be drawn from this experience divide the experts. On the one hand the enthusiasts for the proportional scheme contend that it is the only truly democratic method that at the same time solves the problem of gerrymandering and other forms of corruption.

On the other hand, there are scholars who have been inclined to blame proportional representation for the collapse of the Weimar republic. as well as the general tendency toward the anarchy of multiple parties and boss rule. A detailed analysis of the 20th-century experience of Belgium, the Netherlands, the Scandinavian kingdoms, Switzerland and Ireland, as well as local experience in the United States and in the British Commonwealth, makes it difficult for the detached observer to agree with either of these views. Leaving aside the rigid list system used in the German republic, and generally condemned. it would seem that all these countries achieved substantial stability and a great deal of social progress under proportional representation, whether combined with parliamentary government or not.

The systems differ from each other in many interesting details. In Belgium lists were used, but the voter could indicate personal preference for individual candidates; in the Netherlands the same was true, but there was also a national pool; in Norway and Sweden there were likewise lists in use, but the voter himself determined how the candidates on the lists were ranked. In Denmark a complicated plan of combining single-member constituencies with proportional representation by way of a transferable vote was employed. Switzerland made use of a list system which gave the voter extreme freedom in making up his list and an almost mathematical representation of views in the community was achieved; yet the resulting complex party structure in the representative assembly permitted effective action, because the Swiss did not use a parliamentary system of government. Finally. Ireland adopted the single transferable vote system long advocated by the British Proportional Representation society. with virtually every county an electoral district. A critical evaluation of the different systems may be looked for in the special works suggested in the bibliography below. Suffice it to say that these countries found proportional representation compatible with their governmental tasks and settled down to a general acceptance of it. The same might be said of quite a few U.S. municipalities.

The conclusion regarding proportional representation is not simple. It all depends upon the group and class structure of the community, the constitution and pattern of the government at large, the extent to which foreign policy is vital and imposes its requirements of integration and consistency. The fact that Switzerland did well under proportional representation does not prove that the United States might do well also.

Yet proportional representation does provide an opportunity for political self-expression to minorities which are already crystallized as politically self-conscious groups. If the representative assembly is capable of integrating these conflicting groups, either by foregoing the task of "supporting" the government, as in Switzerland, or by remaining content to co-operate with a monarchical head, as in the Scandinavian countries and the Netherlands, proportional representation may work better than a majority system. In many U.S. cities the city manager has provided a neutral balance wheel which enables a city council proportionally elected to function effectively. *(See* also PROPORTIONAL REPRESENTATION.)

In the last analysis, the problem of representation under modern conditions should be seen functionally in relation to the task assigned to the representatives. Legislation is one function, executive direction and leadership another, judicial and administrative determination something else again. Any system of representation, electoral or other, which works will be acceptable to the people at large and considered just; any system which fails to do so will be rejected or will become a fatal flaw which may bring on the collapse of the entire governmental system. For technical as the problems of representation may seem, they relate to the very core of modern popular government: Unless the people can be made present in their thought, their opinions and their will, democratic government becomes impossible.

BIBLIOGRAPHY.—Besides the broad philosophical discussions and some continental legal studies, there are only rather partisan analyses. The broad treatments of comparative government contain general analyses. Here might be mentioned Carl J. Friedrich, *Constitutional Government and Democracy,* ch. xiv, xv and xx (1950), and Herman Finer, *Theory and Practice of Modern Government* (1932). Special treatments are to be found in G. H. Hallett and C. G. Hoag, *Proportional Representation— the Key to Democracy* (1937), and F. A. Hermens, *Europe Between Democracy and Anarchy* (1951). An important source is still the *Report of the Royal Commission Appointed to Enquire into Electoral Systems,* Cd. 5163, and its *Minutes of Evidence,* Cd. 5162 (1910); May McKisack, *Parliamentary Representation of the English Boroughs in the Middle Ages* (1932); James Hogan, *Election and Representation* (1945); *W.* Konopczynski. *Liberum Veto* (1918). REPRESENTATIVE GOVERNMENT: *see* REPRESENTATION.

REPRISALS are measures of self-help in violation of normal international law to remedy past injuries or to stop continuing injuries in time either of peace or of war. They have been considered permissible only if in retaliation for an injury resulting from a violation of international law, if peaceful measures for obtaining redress have been exhausted without success and if the measures adopted are no more severe than the injuries complained of. (Naulilan Incident, Portugal and Germany. Arbitral Decision, July 31, 1928; H. W. Briggs, *The Law* of *Nations,* p. 951 [1952].)

Formerly a private person might be given "letters of marque and reprisal" by his government permitting him to seize ships of foreign flag at sea in order to gain compensation for a claim against a person of the nationality of the vessel's flag, in case the courts of that state had "denied justice." This practice was, however. ended by the Declaration of Paris (1856), which abolished privateering. Reprisals were, therefore, permitted only by the public forces of a state. *(See* PARIS, DECLARATION OF.)

Reprisals in time of war should be preceded by a public declaration calling upon the enemy to cease its illegal behaviour; should, so far as possible, be of a type not to injure innocent enemy or neutral persons; and should be stopped as soon as the enemy discontinues its illegal behaviour. The legitimacy of naval reprisals against the enemy, but injuring neutral commerce, was a matter of controversy between the United States and Great Britain before the War of 1812 and during the period of U.S. neutrality in World

War I. In spite of neutral protest, British prize courts sustained orders in council, injurious to neutral commerce. in their character of measures of reprisal. (*The Fox,* Edw. 311; *The Stigstad,* [1919] A.C. 279; *The* Leonora [1919] A.C. 974.)

Reprisals in time of peace have taken the form of territorial occupation, administration of customs, detention of vessels in port and "pacific blockade." The United States has contended that vessels of third states cannot be seized or otherwise interfered with for breach of "pacific blockade" although they can for breach of a "war blockade." In 1902 Germany, Great Britain and Italy changed their pacific blockade of Venezuelan ports to a war blockade in response to a protest based on this contention. In the 19th century pacific blockades in fact often extended to vessels of third states. and a League of Nations committee held that in accord with this practice economic sanctions against a covenant-breaking state might extend to vessels of nonmember states.

After the occupation of Corfu by Italy in 1923 as a measure of reprisal against Greece, a League of Nations committee of jurists implied that the obligation of members not to "resort to war" prohibited reprisals of warlike character. The more extensive obligations, of parties to the Kellogg-Briand Pact of 1929 and the Gnited Nations charter, to settle disputes only by peaceful means and to refrain from use of threat or force have been held to abolish peacetime reprisals in international law unless authorized by a competent international authority. Hostile acts in "individual or collective self-defence" against "armed attack" are, however, permitted by the charter (art. 51).

(Q. W.)

REPRODUCTION, the process by which a living thing, whether plant or animal, gives rise to another of its kind, is commonly cited as one of the outstanding characteristics of living matter. In so far as biologists have ever been able to discover, all life comes from pre-existing life. No living thing has ever been found to arise directly from nonliving matter. The only possible exception may be the filterable viruses, so-called because, being particles too minute to be visible under the highest powers of the microscope, they have their size estimated by the smallness of the pores through which they will filter. Such viruses apparently possess most of the characteristics of living matter including that of reproduction. The reproduction may be, however, merely the capacity for duplication from the products of their own chemical activities, or for reorganization of the several ingredients of the nutritive matrix in which they are located. In other words, they may be operating merely as centres of crystallization, as it were, of the various constituents of the surrounding medium into an organization similar to their own. This power is seemingly possessed by various nonliving fermentlike substances. How such synthetic duplication differs from ordinary protoplasmic reproduction—if it does—is by no means clear, since we still know so little about the chemical basis of the latter.

By Division and Growth.— At some point in their life cycle living things give rise to other living things like themselves or which will become like them through a process of development. In one-celled animals and in the simpler many-celled types, reproduction commonly consists in a division of a parent form into two or sometimes into several descendants. True protoplasmic growth is increase of living substance, and inasmuch as reproduction is a continuation of such substance in the form of new individuals, it may be looked upon as a process of overgrowth.

For purposes of emphasis and discussion it is common practice to, state the two great aims or ends of all living organisms as: (1) preservation of the individual, and (2) perpetuation of the race, but since these are both based fundamentally on nutrition they do not stand wholly apart. Growth is the outcome of nutrition, and reproduction may be regarded as a form of discontinuous growth. Constructive metabolism proceeds to a certain limit, and then the organism divides, or part of it is detached and continues life activities as a separate individual. Or to state it another way, reproduction is a means by which metabolic activities established in a given individual are passed on to be continued in the form of new individuals.

By Germ Cells.—In more complex creatures reproduction is manifested by the giving off of special cells termed germ cells, or gametes, which either alone, or more commonly after pairing, give rise to new individuals. Germ cells which pair (fig. 6) are usually differentiated into macrogametes and microgametes, and commonly, particularly in animals, come to be borne by different parents which are then designated as male and female.

The Multicellular Body.—In unicellular organisms the new individuals may continue to live apart as independent cells, but in the more complex plants and animals the division products remain associated, growing and functioning as components of a more highly specialized order (fig. 11). The advantage in this is evident, since each unit cell, although in a large measure retaining its identity, can, together with certain of its fellows, specialize in the perfection of some particular function, while depending on neighbouring groups of cells for the more effective carrying-out of other functions necessary to the organism as a whole. Just as in human society it is advantageous to have such specialists as carpenters, electricians, shoemakers, bakers, merchants, teachers, doctors and others, so in cell aggregates specialization in different directions, as for motion, digestion, sensation and the like, permits of the development of a more complex and efficient organism.

Although certain unicellular forms and certain nutritive cells, such as egg cells, may be visible to the unaided eye, cells for the most part are of microscopic dimensions. The clue to their small size, and possibly to the reproduction of organisms by division in the first place, lies apparently in the physical necessity of maintaining a certain ratio between surface and mass in a functioning body. It is a physical law that surface increases as the square, and mass as the cube. Or to put it more concretely, when a cell doubles in diameter the mass to be nourished increases eightfold but the surface through which nourishment is to be absorbed and wastes discharged increases only fourfold. It is evident, therefore, that with any considerable increase in size, the supply of foodstuffsand oxygen from without and the elimination of wastes from within must fall below the needs of the cell since the surface becomes insufficient to provide for the exchange. The cell solves this problem by dividing, thus reducing mass and increasing surface. This necessity of maintaining a certain balance between mass and surface, indeed, is probably back of the first protoplasmic reproduction. As already noted, it is essentially a matter of overgrowth and division, or, in other words, discontinuous growth.

The Rise of Sex.—Superimposed upon this original method of direct reproduction, however, we find, even in the firstlings of life, the foreshadowing of sex. Beginning with the simplest organisms, temporary or permanent pairing of two individuals may occur before initiation of reproduction. Out of this has grown sex, and as a result unquestionably much of the complexity and diversity of all higher organisms, whether plant or animal.

To understand the significance of reproduction and the intricacies imposed upon it through sex, it is well to begin with its initial expressions in the unicellular organisms, most of which are too small to be seen without the aid of a microscope. Probably the simplest living things are the blue-green algae. Examining the one-celled body of the most primitive of these, one sees a homogeneous granular-looking material which is really of jelly-like consistency. This is the essential living substance or protoplasm (*q.v.*). In these simple algae it is suffused by two pigments, a blue and a green, and is encased within a protecting and supportive wall—a lifeless product of the protoplasm itself termed cellulose. The green component, chlorophyll, is a pigment which is present in all green plants. Chlorophyll has the remarkable capacity of enabling plant protoplasm to utilize in the synthesis of food the energy supplied by sunlight. Out of the two simple raw materials, carbon dioxide (CO_2) and water (H_2O), which

when alone are devoid of available energy and possess no food value, chlorophyll enables the plant to build the simple sugar glucose, rich in usable energy. Part of the food thus manufactured is combined with nitrogenous ingredients of the cell to make new protoplasm, which serves for replacement and growth; some is stored as starch, or otherwise, and serves as food for future use.

Such cells as those of the blue-green algae are exceptionally simple in that apparently all parts of the protoplasm engage equally in the life activities; there are no specialized regions (fig. 1). Most cells, whether of single- or many-celled plants or animals, are differentiated into at least two distinct regions termed the nucleus and the cytoplasm or cell body. There is no clearly defined nucleus in the blue-green algae. In the nucleated cell the nucleus is usually discernible within the cytoplasm as a denser, more or less spherical body, sharply delimited by its own membrane. The cytoplasm, depending upon the kind of cell involved, may also contain other formed bodies, notably in all green plants beyond the blue-green algae, one or more bodies known as chloroplasts (fig. 2), within which the chlorophyll is confined and thus no longer diffused throughout the entire cell.

When the cell of a simple blue-green alga reaches a certain size, it solves the surface-mass relation by simply pinching in two in the middle to form two smaller cells. These in turn, wholly independently of each other, grow and repeat the process; and thus growth and reproduction are carried on indefinitely. This is perhaps the simplest conceivable type of reproduction. Commonly in various species of the blue-green algae the newly formed cells—two, four or more—may remain for a time side by side within a mucilaginous sheath (fig. 1). However, they continue to be mutually independent and eventually the "colony" breaks up and each individual goes its separate way.

There is also a group known as the green algae, so distinguished because they possess only the green pigment. Like the blue-green algae they may exist as one-celled individuals or in colonial form. A far greater complexity of structure is evident, however, in that the protoplasm is differentiated into three distinct parts or organelles: a central denser body or nucleus, which seems in the main to control the activities of the rest of the cell and bear the essential materials of heredity; an irregularly shaped body, the chloroplast, within which the chlorophyll is confined and which is therefore endowed with the power to manufacture food, and the surrounding matrix in which they lie, the cytoplasm (fig. 2). The cytoplasm serves primarily to use the food manufactured by the chloroplast in the maintenance and growth of the cell and to regulate the interchange of materials through the cell wall.

Mitosis and the Genes.—Although the size and shape of the cell varies greatly among the different species of the green algae, each species retains this characteristic protoplasmic differentiation. To maintain the life activities and permit of growth, these cells like all others must divide from time to time in order to preserve the essential ratios of surface and mass. When the cell reaches a certain size-limit division occurs, but the operation is of more intricate nature than that seen in the blue-green algae. The process, termed mitosis, characterizing the cell divisions of all higher organisms, involves a series of changes that bring about a precise division of the nuclear contents. How accurate this is can be appreciated only after a careful study of the operation in progress. In mitosis special bodies known as chromosomes appear as the result of a rearrangement of the nuclear contents (fig. 4). These are of characteristic number and appearance in each particular kind of plant or animal. In man the number is 46. Ordinarily, when cell division occurs, each individual chromosome divides and thereby passes samples of all its contents on to the new cells. Painstaking studies by means of the highest powers of the microscope have revealed that each chromosome carries, chainlike, a series of still smaller units, the chromomeres, representatives of each of which are contributed to the new generation of cells. Evidence from various sources establishes that the fundamental units of heredity, the genes, reside in these individual particles or chromomeres, and that thus with their division and regrowth each newly formed cell gets a full contribution of the inheritance mechanism. All characteristics of living organisms are primarily because of the influence of these genes, although in their expression, of course, environmental influences also play an important part. All hereditary differences involve differences in the genes of the individuals concerned.

Maintaining Numerical Constancy of Chromosomes.—Careful study has revealed that, in organisms characterized by biparental origin, the chromosomes are really in pairs, coming in single sets from each parent. In the cells of human tissues, therefore, there are 23 pairs, one of each kind from each parent. In mature germ cells this dual number is reduced to a single set in the finished germ--ovum or spermatozoon—and thus the numerical constancy is maintained. The separation is of such a nature that each definitive germ cell, while receiving only half of the original number of chromosomes, gets one of each pair (fig. 5); that is, one of each kind. If, for example, the original number of chromosomes is six—that is, three pairs—and we designate those which come from the father as ABC and those from the mother as abc, then the line-up for reduction-division may be any of those indicated in fig. 6. The individual chromosomes do not divide as in ordinary mitosis of body cells, but corresponding chromosomes merely lie side by side (paternal by maternal) and separate when the cell divides. Thus, whether a given chromosome of the reduced set is of maternal or of paternal origin is merely a matter of chance. The only necessity is that each final germ cell (gamete), whether of maternal or paternal origin, have one of each kind of chromosome, since each carries special hereditary determiners and has its own particular role to play in development of the new individual. That this is true is evident from the fact that the ova of certain animals can be stimulated by chemical or mechanical means to develop without being supplied'with the second set of chromosomes, yet the new individual is complete in all its parts, though typically possessing only a single set of chromosomes in each of its various cells. If, however, one of each kind of chromosome is not represented, the developing form shows characteristic deficiencies, depending on which one of the single (haploid) set is missing.

Advantages of Biparental Inheritance.—The obvious advantage in biparental inheritance lies in the fact that young produced by the mingling of hereditary materials from two lines of ancestry will be, to some extent, unlike either parent. They will represent various combinations of ancestral traits and will, therefore, show considerable variety. Of the many new combinations some will be better fitted to survive than others under the prevailing conditions of existence. As many different paths of life present themselves, depending upon the survival value of their commingled ancestral traits, the combinations in certain individuals prove to be better fitted now to this, now to that niche in surrounding nature than do those of others. The weak, the ill-adapted are weeded out generation after generation; those most in harmony with their environment survive. Inasmuch as environment is never constant, and in the course of years may change profoundly, a perpetual premium is placed upon capacity for modification and adjustment. Thus, apparently, primarily through sexual reproduction, much of the bewildering variety of structure and pattern in living things which confronts us has been built up.

Variants in Reproductive Devices—As one scans either the plant or the animal kingdom from the simplest to the most complex types, many variants in sexual reproductive devices may be observed. But all serve one final end; namely, the bringing together of two germ cells—commonly termed microgamete and macrogamete or, in animals, spermatozoon and ovum. These enter into a permanent union which constitutes the initial cell from which, through a succession of cell divisions, the new organism will arise. It is important to remember that no matter how discrepant these pairing gametes may be in size, they each carry the same number of chromosomes and therefore contribute the same number of genes.

In the simplest plants or animals the cells which unite may be of similar size; but, as forms rise higher in the scale of life, discrepancy in size becomes apparent until in the most complex organisms it may be extreme. The human ovum, for instance.

although itself only about $\frac{1}{125}$ of an inch in diameter, has a volume about 35,000 times that of the sperm (fig. 9), yet each contributes 23 chromosomes to the zygote.

Advantages of Dimorphic Gametes.—Apparently it has been found advantageous in organisms of biparental origin to have one of the gametes conserve stores of food for consumption of the newly developing form. But, since such increased bulk diminishes activity, a compensatory reduction in size commonly accompanied by motility develops in the opposite or male gamete. Moreover, inasmuch as the burden of effecting union has fallen largely to the microgametes, they have come to be produced in prodigious numbers, thus ensuring that one will reach and fertilize the more inactive macrogamete. In witness of this one has only to recall the countless millions of pollen grains, each bearing a microgamete, produced by a flowering plant, or the equally great numbers of spermatozoa carried in a single milligram of semen.

The occurrence of sex throughout the whole range of life, from all but the simplest organisms to man, is self-evident expression of its importance. It so pervades the make-up of the higher animals and plants that the significance of much of their structure and behaviour is interpretable only in terms of it. The reciprocal sexual structures and activities between the two forms we designate as male and female, whether in plants or animals, have come to their present state of mutual adaptation through millions of years of selection, and either set of such differences would be wholly meaningless without the other. Not only have special structures arisen which are connected with the reproductive system, but innumerable secondary characters such as devices to ensure pollination in plants, or ornaments which serve for allurement or sex-identification in animals, have appeared. There was much less intricacy in the make-up of living organisms during the millions of years of their existence before the coming of sex, but from that time on increasing complexities appeared in many groups and in many directions so that diversity of form and structure multiplied rapidly. It seems improbable, indeed, that living things could have become so remarkably complex without the establishment of sex.

Although the fundamental factors involved in reproduction, whether asexual or sexual, are readily discernible, the secondary differences in structures, activities and mutually adaptive relations which appear in both the plant and the animal kingdom become bewildering in their diversity. While most of these are interpretable in terms of special environing conditions, the paths of procedure are often very circuitous and the processes understandable only in terms of the distant ancestry from which modern forms have been derived.

In Unicellular Organisms.—Among one-celled organisms, whether plant (Protophyta) or animal (Protozoa), some form of division—equal fission as in the amoeba (fig. 3), budding or spore formation—is the dominant procedure even though it may be alternated, especially in the higher types, with occasional pairing analogous to the sexual unions of multicellular forms (Metazoa). In some members of the most primitive of the main groups of Protozoa (Rhizopoda, forms which can acquire large surface by the flowing out of pseudopodia) sex is possibly in a way foreshadowed in some in the coalescence of amoebulae into plasmodia as in the slime molds (Mycetozoa) from time to time. And the multiple conjugation seen in some Heliozoa and other protozoa, as well as in certain algae, may be a still further advance of the same nature. Such multicellular formations, through confluence of a number of individual cells, however, seem early to have given place to the union of only two cells, as seen in all higher organisms, and therewith the development of the bisexual form of reproduction characterized by the appearance of male and female types. In such protozoa as the colonial flagellate *Stephanosphaera,* the total fusion (conjugation) of two indistinguishable units (isogamy) occurs (fig. 8a); in others, such as *Vorticella,* the conjugating units differ in size (anisogamy, fig. 8b). In many different kinds of protozoa (for example, the radiolarians), special reproductive units (gametes) arise by division of the ordinary vegetative units. Such gametes are commonly dimorphic, and they unite in pairs to form a zygote, which may either grow into the original form or subdivide into many smaller individuals.

In any discussion of the evolution of sexual reproduction the situation seen in paramecium, a member of the most complex class of protozoa, the Infusoria, is interesting and instructive. Paramecium (fig. 7) possesses a large oval nucleus (macronucleus) and, in a small depression in its side, a tiny, spherical micronucleus. The macronucleus seems to be wholly nutritive; the micronucleus, reproductive in function. Commonly the elongate animal reproduces by a simple transverse fission into two. After a number of such divisions—usually several hundred—the process is interrupted ordinarily by a temporary union of two individuals during which, after disintegration of the macronucleus and elaborate preparations of the micronucleus, micronuclear material is exchanged. The animals then separate and resume reproduction by division. Regrowth is rapid and, under favourable conditions, 4 divisions in 24 hr. may occur. Calculations show that a single paramecium could thus produce 268,000,000 offspring in one month.

Investigations have shown that although the individuals of a particular species of paramecium may look alike, nevertheless they are divided into mating types. Individuals of the one type, commonly the progeny of a single individual (clone), ordinarily will not unite with each other but will conjugate actively with members of other strains. In some species such as Paramecium bursaria, as many as eight distinct mating types have been identified, members of any one of which, though not conjugating together, would conjugate readily with members of any of the other seven types. Variants are known, however, in which members of one mating type will conjugate with only one or a few of the other mating types.

In nonconjugating strains of paramecium, however, a process of internal nuclear reorganization, known as endomixis, occurs from time to time which apparently effects a physiological readjustment similar to that following conjugation. This suggests that some form of occasional constitutional reorganization is necessary. Although usually secured through nuclear exchange, under unusual conditions it may thus by endomixis be otherwise accomplished.

The exhaustive studies of Prof. H. S. Jennings and his associates, made to determine in what respect conjugating and nonconjugating members of the same stock differ, are enlightening. One of the fundamental experiments was to divide a given strain into two parts and keep them under identical conditions, except that conjugation was permitted in one line and prevented in the other. The nonconjugating strains maintained about the same even rate of division, with no evidence of decline. In the conjugating strains, however, marked differences in division rate appeared in different families. Thus, hereditarily diverse families arose even though the conjugating strains were all derived from the same parental stock. Evidently great variety resulted from the new combinations of hereditary characters incident to the interchange of nuclear materials between the two conjugants. Some of the new strains thus secured were vigorous, others weak. Obviously, such combinations as possessed survival value under the conditions prevailing would result in the perpetuation of the fortunate strains. It is significant, furthermore, that unfavourable changes of the conditions under which these infusoria live usually induce conjugation.

Such facts among the protozoa bear out the inference already reached regarding the relation between sex and heredity in the higher animals, namely, that there is enormous insurance value in the constitutional diversity brought about by biparental inheritance—insurance that, in a changing environment, at least some of the variants will probably prove fit.

Rejuvenescence.—It is believed by some biologists that sexual reproduction not only results in a diversified progeny but that the fusion of the two germ cells, or the exchange of reproductive nuclei in protozoa, also commonly induces an actual rejuvenescence—a restoration of youth, as it were—to the protoplasm of the newly formed zygote. Professor G. N. Calkins has shown, for example, that in the protozoan *Uroleptus* mobilis actual rejuvenescence follows conjugation. In this species, after about

200 or more divisions, in the absence of conjugation, the division rate slows down and the individuals pass into a decline followed by structural degeneration and death. Conjugation, however, renews the waning activities of the protozoon and initiates a new cycle of active growth and division.

Asexual Reproduction in Multicellular Organisms — In the lower levels of many-celled animals and extensively throughout the plant kingdom, it is common for more or less of the parent body to separate off as a new individual which may or may not become wholly free. In some instances, as in the sea anemone, the entire body may split longitudinally into two. The fresh-water Hydra buds off new individuals when food is abundant. On the other hand, a starving hydra may reabsorb its own buds. Certain species of starfish multiply by separating off their arms (see REGENERATION). And various wormlike forms, especially among the flatworms and the nemertine worms, may divide into several pieces, each of which develops into a completely functioning individual. In certain cases the asexual multiplication leads to the formation of colonies in which the individuals remain attached, as in the zoophytes and corals, the polyzoa and the compound tunicates.

Among plants an endless variety of asexual reproduction is evident, ranging from the innumerable forms of bulbs or bulblike structures to the new individuals produced through the sending out of runners, as in the strawberry, which root at intervals.

Hermaphroditism. — Many common animals, such as hydras, flatworms, earthworms, leeches and snails may have both ovary and testis present in the same individual (hermaphroditism), though not uncommonly the ova and the spermatozoa mature at different times, so that in spite of their double sex there is cross-fertilization, In such forms as the earthworm, for example, when two individuals enter into sexual union, they pair in such a way that the sperm receptacles of each conjugant are stocked with spermatozoa from the other, and when the eggs are shed they are thus fertilized by spermatozoa from the other individual. In various of the internal parasites, such as the liver flukes and tapeworms, there is self-fertilization (autogamy).

Alternation of Generations. — Although the asexual mode of reproduction is common in all except the highest metazoa and in the great majority of the metaphyta, these all, for the most part, also exhibit sexual reproduction. The latter becomes of increasing importance in the ascending scale of structural complexity. The highest animals which show asexual reproduction in the adult stage are the Tunicata. Here, in the salps, a solitary, so-called nurse buds off a chain of sexual individuals which eventually separate. The alternation of a nonsexual polyp form with a sexual medusa form, seen in the Coelenterata, is one of the most commonly cited examples of alternation of generations (metagenesis). Hydroid colonies are formed in such small branching colonial animals as Obelia, for example, by growth and budding from an original free-swimming planula larva which has become attached. To the human eye such colonies look like minute branching plants attached to submerged objects in the shallow water along the seashore. At the end of each branch is a nutritive polyp. From time to time cylindrical individuals (gonangia) arise which come to bear small lateral medusa buds. These eventually mature and are set free as minute medusae or jellyfish. The free-swimming medusae produce ova and sperm and thus reproduce sexually. Each fertilized ovum grows into a polyp, which again by budding produces the original nonsexual colonial type.

A classical example of metagenesis also frequently pictured in textbooks is that of a much larger kind of jellyfish known as Aurelia. A free-swimming. embryo becomes attached and develops into a polyp which, through a system of transverse budding (asexual reproduction), eventually becomes subdivided into a stack or column of saucer-shaped young medusae (ephyrae). These become free and swim away as individual jellyfish that produce ova and sperm and thus reproduce sexually. From the fertilized ova the new generation of polyps is produced. Not all coelenterates, however, exhibit such alternations of polyp and medusa generations. Many medusae are known in the life cycle of which there is no polyp form and the entire great group of anemones and corals, though for the most part reproducing by division as well as by eggs, have no medusa stage.

In the early developmental stages of even the highest vertebrates, however, twins or even quadruplets may arise by division of a single egg or embryo. Identical twins in man, for example, are believed by some embryologists to arise in this way. And in such simpler mammals as the armadillo the quadruplets which constitute the usual litter are definitely known to have been derived from a single ovum. The same is true of the multiple embryos which spring from a common source (polyembryony) in such parasitic insect forms as Encyrtus. In such vertebrates as the amphibia it is a relatively simple laboratory experiment to separate the first two cleavage cells of the dividing ovum and demonstrate that each will then develop into a complete and normal larva instead of the half of one it would have been without the operation.

In plants alternation of sexual with asexual generations is conspicuous in mosses and ferns. In such plants one phase in the life history (sporophyte) has to do with the production of spores —special reproductive cells which develop without fertilization. The second phase (gametophyte) is characterized by the production of macrogametes and microgametes, corresponding to the ova and spermatozoa of animals. Such gametophytes, therefore, constitute the sexual generation. In ferns, for example, spores are discharged from spore cases located on the fronds. Such as land on moist soil or sometimes on the fern frond itself, develop into small sexual plants termed prothallia (gametophytes). These eventually develop the usual two types of sex cells, the macrospores and the microspores (fig. 10). When the egg cell of such a prothallus is fertilized by a sperm cell (antherozoid) it grows into the familiar fern plant (sporophyte). In flowerless plants, and in the primitive flowering plants known as cycads and gingkos, the male cell (antherozoid) is locomotor as in most animals.

In flowering plants such alternate occurrence in one life history of two or more distinctive forms is not so obvious as in ferns and mosses, but close inspection shows that the male and female gametophytes exist in much reduced form as minute structures dependent on the sporophyte. The pollen grain, for example, is not itself a male germ cell but is really a minute gametophyte or bearer of the functional sperm cell. Likewise, the functional egg cell is borne by a female gametophyte or embryo sac which is a part of the flower itself (fig. 13). Looked at from the standpoint of alternation of generations the plant body which bears the flowers is the sporophyte, while special parts of the flower represent the gametophytes. Usually, an eight-celled structure, one cell of which is the egg cell, constitutes the female gametophyte (macrogametophyte); and (2) an even more reduced structure consisting of two sperm nuclei and a pollen tube nucleus constitutes the male gametophyte (microgametophyte).

The microspores form within the anthers (fig. 12) and upon nuclear division become pollen grains. The dehiscence of the pollen sacs frees the pollen. Shortly before or after being shed, a tube nucleus and two sperm nuclei arise from an earlier nucleus. One sperm nucleus eventually unites with the egg to form the fertilized egg or zygote; the other unites with the so-called fusion nucleus (see centre of embryo sac, fig. 13) to form a triple-fusion nucleus made up of three haploid sets of chromosomes. The zygote germinates to form the young sporophyte. The triple-fusion nucleus, in some seeds, gives rise to a nutritive endosperm around the embryo.

Where alternation of asexual with sexual generation occurs in either the plant or the animal world, it is usually associated with some advantageous hastening of productivity in favourable seasons of the year or under other special environing conditions. In the competitions of living things the struggle is severe, and great numbers must be produced in order that a select few, adapted to the prevailing conditions, may survive and maintain the race. Commonly, the quickest and easiest way to get numbers is through asexual reduplication, leaving it to the slower and more intricate methods of sexual reproduction to establish from time to time that variability which is necessary as the basis for adap-

tive selection.

Dual Hosts.—Some of the most complicated life cycles are found under specially hazardous conditions of existence, where the chances against successful propagation are meagre. Numerous examples occur among the internal animal parasites. If parasites increased in too great numbers within a given host, not only would the host be destroyed but with it often the parasites themselves. This is avoided commonly by the utilization of two hosts, part of the life cycle being passed in one, part in the other. Thus, in such human parasites as malaria, for example, female mosquitoes from any of the several species of Anopheles are the sources of infection in man. Spindle-shaped cells (sporozoites), which invade the human red blood corpuscles, are injected from the saliva of the mosquito when she bites. These multiply by division within the red blood cells. Liberated through destruction of the corpuscles they enter new red cells, and the process is repeated until a large number of red blood corpuscles have thus been destroyed and the number of parasites enormously increased. Such reproduction in the blood cells of man (primary host) are asexual. Eventually male and female gametocytes are formed, but these undergo their final transformations and conjugation only if withdrawn from the blood of man into the stomach of the anopheles mosquito (secondary host). The resulting zygotes penetrate to the outer wall of the mosquito's stomach where, in saclike pockets, they undergo repeated nuclear divisions with the eventual formation of numerous spindle-shaped sporozoites. With the rupture of the surrounding sac, the sporozoites make their way through the body spaces to the salivary glands of the mosquito whence they are injected with the saliva into the human host.

Many similar examples of alternate hosts might be cited among both vertebrates and invertebrates, and the various devices hit upon for securing transmission from one host to another afford some of the most complex and perplexing chapters in the study of animal relations. In the common pork tapeworm (*Taenia solium*), for example, man, the primary host, becomes parasitized by eating underdone pork (secondary host) which contains the encysted larvae. When taken into the human alimentary canal, the small head, bearing suckers and a circlet of hooks, attaches to the intestinal wall and the worm begins to grow rapidly in length by the formation of segments. These increase in size from the anterior toward the posterior end, new segments arising in the narrow neck region. The whole chain is regarded by zoologists as a colony of individuals. Without mouth or alimentary canal of its own, the parasite is wholly dependent upon the digested food in the intestine of its host. The terminal segments, filled with embryos, are shed from time to time and pass from the body of the host. When the embryos are swallowed by a pig, they become freed as six-hooked larvae which bore their way out of the intestinal tract and encyst as so-called "bladder-worms" in the muscles or other structures of the pig. They attain their adult form only when such infected flesh is eaten and they are released into the human intestinal tract. The chances against the perpetuation of such forms are obviously great, yet there is an abundance of both pork and beef tapeworms.

The Life Span.—In unicellular organisms there seems to be no death from old age. When an alga or an amoeba reaches a certain size and nutritional state, it simply divides and what was one living individual now is two (fig. 3). If death occurs, it is because of some harmful condition in the environment such as lack of food, existence of enemies or the like. The protozoon we view through our microscope has no dead ancestors; it is the direct descendant of the original of its kind. With the establishment of a body as distinct from the germ, natural death enters the scene. The cells which jointly constitute what we might call the vegetative individual eventually perish; only the reproductive individuals known as germ cells maintain continuity between successive generations.

Although, if we may judge from what we see in nature, the penalty paid for a body is death. the higher realizations of living matter could not have been attained without that combination of diversity and unity made possible through the association of specialized cells which make up the bodies of the more complex organisms. Under these circumstances, from the standpoint of survival value of the species, it is desirable for the individuals of today to give place eventually to those of tomorro , because environing conditions are never constant for extensive periods. and it is only by giving the reproductive variants a chance that new fitnesses may be established and prolonged survival be made possible. Insurance of the welfare of the species is the all-important accomplishment.

What determines the life span of any one particular species is not always evident, but it may be safely said that in general organisms live only long enough to ensure their continuance as a race or stock (see LONGEVITY). Duration of life is, within generous limits, automatically adjusted to survival of the species Where the hazards of existence are numerous or outstanding, the rate of reproduction is high and the number of offspring produced is great; uhere the risks are fewer and the individual is better prepared to cope nith them, the rate is low (fig. 14) In generai there is an automatic adjustment between length of life of the individual and the chances of the young for survival. Any extraordinary increase in numbers, as may happen with unusual abundance of food, favourable weather conditions or removal of natural checks, is eventually offset by such factors as competition within the group itself for food, disease incident to propinquity and by the multiplication of enemies which feed upon its members. Either sudden increase or decrease in numbers is likely to prove disastrous. Slight fluctuations which do not upset the so-called "balance of nature" are more likely to prove safe.

PHYSIOLOGY OF REPRODUCTION

It is common knowledge that the majority of animals and plants have more or less definite times at which they breed. though the ova (estimated at ***200.000*** in man) are possibly preformed at birth. These depend often upon seasonal or environmental conditions and it is well known that spring and summer are the times for reproductive activity among birds, insects and a host of other animals. Unusual warmth or cold may hasten or check the periodic development of sexual activity and the accompanying internal and external changes which take place in the body. The connection between breeding and food supply is also generally realized. Moreover. where climatic and nutritive conditions are approximately uniform throughout the year. periodicity in the breeding habits of animals is often obliterated. Thus. Semper states that sexual periodicity is absent among molluscs. insects and other land animals in the Philippine Islands. On the other hand, the regularity of the migratory movements, which directly relate to changes in the reproductive organs and the instincts for breeding, occurs to a great extent independently of temporary climatic conditions, though not wholly so. *(See* MIGRATION BIRD.) It is clear. however. that broadly speaking, the factors which control the periodic changes in the generative system in association with breeding are of two kinds, the external ones referred to above, and internal factors inherent in the animals themselves, and particularly in the essential reproductive organs Before attempting to describe these changes and the manner in which they occur it will he well, briefly, to describe the reproductive organs, referring more particularly to the higher animals.

The Generative System.—Among vertebrates the sexes are nearly always separate, although a few species are hermaphrodite The usual arrangement, however, is for each individual to have its own characteristic sexual organs, those of the other sex. if represented at all, failing to develop or undergoing early degenera tion. In the male or' all lower vertebrates (including birds) the

testes lie dorsally inside the body cavity and discharge their products, the spermatozoa, along with fluid secretions, into ducts communicating with the exterior by a passage (the cloaca) common to the urogenital and alimentary systems. In most mammals, on the other hand, the testes lie outside the main body cavity in a double sac (the scrotum) between the anus (or opening of the gut) and the penis. The testes are largely composed of tubules whose walls give rise to the spermatozoa and these latter are budded off into the interior as in other animals. Between the seminiferous tubules are interstitial cells. These give rise to chemical substances (hormones, *q.v.*) which pass internally into the blood. (See ENDOCRINOLOGY.) There is strong evidence that these internal secretions by their power of stimulation are responsible for the growth and development of the distinctively male characters and instincts. Thus, the presence of the testes is commonly regarded as the test for maleness.

In all mammals the spermatozoa pass out from the testis by a number of short ducts (the *efferent* ductules) into a coiled tube lying alongside it (the epididymis). This acts as a storehouse for the spermatozoa until they are ejaculated. Spermatozoa may remain alive within the epididymis and still be capable of fertilizing ova for 30 days (rabbit). The epididymis is a long coiled tube with muscular walls and the coils lie in juxtaposition so that the whole forms one discrete body closely applied to the testis. From each epididymis a duct (the *ductus* deferens) passes back through the inguinal canal (a passage connecting the scrotum with the body cavity). The two vasa deferentia open close together in the common channel with which the urinary bladder also communicates. This passage (the urethra) is continued within the erectile copulatory organ or penis, at the end of which it opens to the exterior. In addition to these organs there are several accessory glands communicating with the common urogenital passage. These are the seminal vesicles, the prostate gland and *Cowper's* glands, all of which contribute fluid substances to the semen in which the spermatozoa swim; the secretions are believed also to cleanse the urethra of urine prior to the ejaculation of semen. The above description applies more especially to man, but in the majority of the lower mammals the organs are similarly arranged.

The ovaries, the essential reproductive organs of the female, likewise serve a double function. They produce the ova and also elaborate internal secretions comparable to those of the testes; these secretions are responsible for initiating the development of the female characters, as well as being a necessary factor in the sexual and reproductive processes. In the lower vertebrates the ova are large because of the amount of food substances (yolk) contained in them (as with the egg of the fowl), but in mammals they are microscopic, each being about $\frac{1}{125}$ in. in diameter (this, however, is considerably bigger than a spermatozoon, which is about $\frac{1}{500}$ in. in length). The ova art? contained within little sacs (Graafian follicles). These begin by being very small, but as they approach maturity their cavities enlarge until they protrude from the surface of the ovary; eventually (unless, as often happens with many of them, they have degenerated) they discharge their ova to the exterior in ovulation.

The ovaries are attached, one on either side, to the dorsal wall of the abdominal cavity by the broad ligament. The tubes which convey the ova to the exterior are also suspended by this ligament, a double fold of tissue arising from the wall of the body cavity. In the lower vertebrates the oviducts are provided with glands secreting albumen or egg white which coats the ovum as it passes down the tube. The egg shell in those animals in which it is formed is also secreted by a gland; in birds this is at the posterior end of the oviduct just in front of where it opens into the common urogenital passage. At the anterior end each oviduct has a fimbriated trumpet-shaped aperture which expands at ovulation and receives the eggs as they pass into the body cavity. The interior of the expanded end is provided with cilia which direct the passage of the ova into and down the tubes. The oviducts are usually paired to correspond with the ovaries, but in birds only the left ovary and oviduct are present. In mammals and birds the ova are usually fertilized by the spermatozoa in the passage of the oviduct, but in the lower vertebrates (*e.g.*, most fish) this often occurs outside the body. In mammals, the oviducts (small, somewhat-coiled tubes) swell out posteriorly to form the *cornua* uteri, or womb. These may continue double throughout their entire length and open separately into the vagina (rabbit) or after continuing separate for a considerable distance may unite together to form the corpus uteri or body of the uterus (cow, sheep, mare, bitch, etc.) or they may extend for only a short distance before opening into the corpus uteri, which is a sac or bag (man). At the hind end the corpus uteri narrows down to form a neck (cervix) and this opens into the vagina by the os uteri. The uterus is the organ which contains the developing young during pregnancy. It has thick muscular walls on the outside and a mucous membrane with numerous glands lining the cavity inside. These secrete a fluid which helps to nourish the developing embryo during pregnancy and supplies a medium in which the spermatozoa swim after copulation. The vagina is the broad urogenital passage which extends backward through the pelvis and opens to the exterior at the vulva. The latter is constituted by all the female generative organs visible externally. The lateral boundaries are the labia, or lips. The clitoris is a small rod-like erectile structure and corresponds to the penis of the male but is solid.

The mammary glands, although not directly concerned with the reproductive processes, are dependent upon the ovaries for growth. They consist of milk-secreting tissue and are provided with ducts which convey the milk to the nipple, whence it can be drawn off.

The Reproductive Cycle.—At the approach of the breeding season in most animals the gonads (testes and ovaries) undergo marked growth. This is very pronounced in fishes and is hardly less marked in birds. Thus, in the sparrow in winter the testis is no larger than a grain of mustard seed but at the breeding season it reaches the size of a small cherry.

The male breeding season, when it occurs, is called the season of rut. The increase in the size of the testes which occurs prior to rut is accompanied by activity not only of the cells which give rise to the spermatozoa (the spermatogenetic tissue of the seminiferous tubules) but also of the interstitial cells. In some mammals the testes are not permanently retained in the scrotum but descend thither at the beginning of rut and are withdrawn into the abdomen again after the rutting season is over (*e.g.*, many rodents). In insectivores (*e.g.*, mole and hedgehog) the testes descend periodically into temporary receptacles. In the mole it is estimated that the testes increase in size 64 times, and the seminal vesicles, prostate and other accessory glands likewise show enormous growth. The time for sexual intercourse is continuous throughout rut, there being no short periods of quiescence within the breeding season as in the females of many species. Among domestic animals generally there is no special season of rut, the male being capable of service throughout the year, the semen evacuated normally containing an abundance of spermatozoa. In this respect these species differ from their wild ancestors, for in the undomesticated state the male usually experiences a rutting season at the same time as the breeding season in the female.

In the female mammal the times for sexual intercourse, instead of extending continuously over a season of considerable duration, as with the male, are restricted to periods of "heat" or oestrus. These may recur at rhythmical intervals within one breeding season (mare, cow, ewe, sow) or there may be only one oestrus to the season (bitch). The former condition has been described by Walter Heape as polyoestrous, the latter as monoestrous. The whole cycle of changes is known as the oestrous cycle. In the case of a typical monoestrous mammal, such as the dog, the oestrous cycle is divided as follows: anoestrum (period of rest); pro-oestrum (period of growth and preparation); oestrus (period of desire); pregnancy or (alternatively) pseudopregnancy.

During the anoestrum the reproductive system is, relatively speaking, quiescent. The Graafian follicles which contain the ova probably undergo slow growth and ripening, but they do not become conspicuous upon the ovarian surface until near the end of the anoestrum. The uterus is relatively anaemic and the

glands inactive. The mammary glands are also inactive unless lactation is in progress after recent pregnancy. The entire anoestrum in the bitch lasts about three months.

The pro-oestrum is marked by increased activity of the generative system generally. It is the time of coming on heat. The follicles come to protrude visibly from the surface of the ovaries. The uterus also undergoes growth, the blood vessels increase in size and number and the glands in the mucous membrane elaborate more secretion. At a slightly later stage a definite haemorrhage occurs in the uterus and blood is passed out to the exterior at the vulva. The mammary glands may also become slightly congested. The entire pro-oestrum lasts from one to two weeks and external bleeding may go on for ten days, but it is usually slight, consisting of no more than a sanguineo-mucous flow.

Oestrus or heat is the period at which (and, ordinarily, only at which) sexual intercourse takes place. It is marked internally by ovulation, that is, the rupture of the Graafian follicles and the discharge of the ova, which then become mature and ready for fertilization by spermatozoa. The wall of the uterus undergoes repair at this time but the glandular secretion is abundant and more liquid in character, to provide a suitable medium for the spermatozoa. In the bitch oestrus lasts about a week.

Oestrus is succeeded by either pregnancy or pseudopregnancy. Each of these periods in the bitch lasts about two months. At their termination the uterus and the generative organs pass back to a condition of rest, and so the oestrous cycle is repeated. The complete cycle takes about six months in the bitch, there being typically two cycles and two oestrous periods in the year but there is a good deal of individual and racial variation.

If pregnancy takes place as a result of fertilization of the ova, discharged during oestrus, these segment and become attached to the inside wall (mucous membrane) of the uterus, which grows around each of them. The structure formed in this way is highly vascular and serves as the organ of nourishment for the developing embryos to which the ova give rise. (See VERTEBRATE EMBRYOLOGY.) This organ is the placenta and is characteristic of nearly all mammals. The embryos are attached to the placenta of the mother by the outer of a number of membranes, and vascular processes (villi) grow out from this membrane (the *chorion*) into the hypertrophied uterine mucous membrane now forming the maternal placenta. Thus, a close connection is formed between the embryo and the mother and the placenta acts as an organ of respiration, supplying the developing young with oxygen brought thither in the maternal blood, and an organ of excretion, getting rid of carbon dioxide and the waste nitrogenous products, besides supplying the necessary nutriment, During pregnancy also the uterine muscles undergo a great hypertrophy, and are responsible for a great part of the increased weight which occurs in that organ. Thus, in the human subject, the virgin uterus weighs about 30 grams, whereas the same organ at the close of pregnancy, apart from the contained young, weighs 1,000 grams. It is through the rhythmical contraction of the uterine muscles that the young are expelled in parturition (the act of giving birth). The mammary glands undergo great development during pregnancy in preparation for the secretion of milk at its close.

If the ova discharged at ovulation are not fertilized during oestrus (as when coition does not occur) they die in the uterus and disintegrate. Nevertheless, in the bitch and many other mammals the uterus and mammary glands pass through growth-changes which, though not so pronounced, are similar in character to those during pregnancy. Thus, the mucous membrane becomes highly vascular and the glands greatly enlarge. The mammary glands also undergo marked development and toward the end of the period secrete milk. Even virgin bitches secrete milk freely about two months after the cessation of oestrus. At the end of this pseudopregnancy the generative system as a whole subsides into a condition of rest.

The ovarian changes (at any rate in the bitch) are also similar in both pregnancy and pseudopregnancy. The Graafian follicle, after parting with its ovum, becomes converted into the corpus luteum, or yellow body, so called because of a pigmented fat (lutein) formed inside it. The yellow body is formed by the rapid hypertrophy of the cells surrounding the cavity of the follicle; this is so great that the individual cells increase in size 16 or 20 times. This structure, which plays an important part during pregnancy, lasts throughout that period (and correspondingly during pseudopregnancy) and then undergoes degeneration.

In polyoestrous animals there is a succession of oestrous periods within a single breeding season, that is to say, that if coition does not take place at the first oestrus, or if for some other reason the ova discharged at ovulation are not fertilized, the animal, instead of experiencing a prolonged pseudopregnancy followed by an anoestrum (as with the bitch), undergoes a short period of apparent quiescence, called by Heape the dioestrum, and then comes on heat again. Thus, with the sheep, the ewe, if she fails to become pregnant at her first oestrus, comes back to the ram (as the shepherds say) after about 15 days, and if she again fails, may experience a third oestrus after another 15 days, and so on for a succession of cycles until the breeding season is over or the ewe succeeds in becoming in-lamb. This short (or dioestrous) cycle in the sheep is therefore 15 days. The number of dioestrous cycles which the animal is capable of experiencing depends partly on the breed and partly on the environment, whether favourable or otherwise. Among sheep of all breeds there is a complete gradation between the monoestrous condition of certain wild varieties and the extreme of polyoestrum exhibited by certain merinos, in which there may be no anoestrum (even in the nonoccurrence of pregnancy) but (in the absence of the ram) an unbroken succession of dioestrous cycles which last the whole year. Many wild animals (*e.g.*, rodents) are polyoestrous and the dioestrous cycle may last for only a few days.

In polyoestrous animals ovulation typically occurs during oestrus and is followed by the formation of the corpus luteum. The time of persistence of this structure varies according to whether or not pregnancy occurs. In the absence of pregnancy the corpus luteum persists for the duration of the dioestrum and then begins to degenerate as if to make way for the ripening of a fresh batch of follicles in the ovary and a new oestrous period. If, however, pregnancy takes place the corpus luteum continues in the ovary until parturition as in monoestrous animals. In reality, the dioestrum, instead of being a period of complete rest, is of the nature of a very abbreviated pseudopregnancy, and the uterus undergoes some growth changes in association with the presence of the corpus luteum in the ovary.

In man there is typically no anoestrum (except among the Eskimos in winter) and the menstrual cycles, each lasting about a month, correspond to the dioestrous cycles of the polyoestrous lower mammal. The actual menstrual phenomena probably represent the degenerative changes at the end of an abbreviated pseudopregnancy (or dioestrum) telescoped into the pro-oestrum of a new cycle. Ovulation takes place most commonly about the 14th day after the beginning of the menstrual flow but it may occur at other times, though rarely, in the week or ten days before the beginning of menstruation.

In some animals (rabbit, ferret) ovulation takes place only after coition. The actual process can be demonstrated in an anaesthetized rabbit whose ovaries have been exposed to view (J. Hammond). It is possible that in man also ovulation may sometimes require the additional stimulus set up by coition. In most domestic animals (bitch, sow, ewe, cow, mare) ovulation takes place spontaneously at or about the time of oestrus.

The Testis and Ovary as Organs of Internal Secretion.— It has been mentioned that the testis, besides producing the spermatozoa, is also an organ elaborating an internal secretion which is discharged into the blood. A similar statement may be made about the ovary. The evidence for these conclusions falls under three heads: (1) the effects of removing these organs (castration and spaying); (2) the effects of transplanting the testis or ovary into animals whose own gonads have previously been removed and (3) the result of injecting tissue extracts prepared from testes or ovaries.

The general effect of castration in all vertebrate animals is to prevent the development of the secondary characters of sex, that is, of those characters which, while correlated with the sex in

question, are not directly concerned with reproduction. This statement applies to ovariotomy or the extirpation of the ovaries in the female as well as to castration in the male. It is essential, however, that this operation should be performed early in life to have its full effect. It not only ensures permanent sterility (whenever it is done) but if performed on the young stops the development of superficial sexual characters as well as the accessory reproductive organs (prostate gland, etc.). Thus, in man, castration prevents the growth of hair on the face and various parts of the body and arrests the enlargement of the larynx and the consequent deepening of the voice normally characteristic of puberty in the male. In stags castration inhibits the growth of the antlers and in those breeds of sheep which are horned in the male and hornless in the female it prevents development of the horns; moreover, the horn growth is arrested at any stage of development at which castration is performed. With fowls, castration is followed by an arrest of the development of the erectile structures about the head (comb, wattles, etc.). Castration has been practised on the domestic animals from the earliest times, for it improves the quality of the flesh and favours fattening in meat-producing animals and is conducive to a greater tractability in working animals since the disturbing effects of sexual desire no longer occur.

If the testes are removed from the normal position and grafted to an abnormal one (or if the testes of another male are transplanted immediately after castration), the organs exert their usual influence on the secondary sexual characters and accessory sexual glands, although their normal nerve connections have been severed. Since, then, the influence of transplanted organs can not be through intermediation of the nervous system it would seem that it must operate through chemical substances passed into the blood and so into the general circulation. Thus, in experiments upon fowls the testes have been removed and broken up into pieces, which have attached themselves to different parts of the alimentary canal or the wall of the body cavity, and the birds have developed into typical cocks with comb, wattle, etc., male voice and sexual and combative instincts. Furthermore, the experiments of Eugen Steinach and others have shown that the grafting of testes into females whose ovaries had been removed may cause the development of secondary male characters and bring about a partial or complete reversal of sex. For the successful implantation of testis tissue, as with most other organs in higher vertebrates, the material to be transplanted must come from an animal of the same species; in salamanders and frogs sometimes grafts may become incorporated and persist in the host organism when the living transplant has come from a donor of different species. Mammalian testis grafts will secrete hormone when they are incorporated into any locality in the host organism, but the grafts will produce spermatozoa only when transplanted into the scrotum or in the anterior chamber of the eye. In these two localities the body temperature is sufficiently low to permit formation of completed spermatozoa. The scrotum functions as a heat regulator, effectively reducing the temperature below ordinary body temperatures. Testes of mammals that fail to descend into the scrotum, or are located as grafts in the abdomen, are unable to produce spermatozoa because of the higher temperature in this locality. Testes of birds, which have even higher body temperatures than do mammals, are more heat resistant; however, active division of the germinal cells of the testis apparently occurs almost exclusively at night during periods of sleep in which the body temperature falls by several degrees.

Ovariotomy leads to the suppression of the distinctly female characters. If done before puberty the uterus and mammary glands do not develop and the general bodily form tends toward a neutral condition not dissimilar to that of the castrated male. If performed after puberty ovariotomy is followed by cessation of the oestrous or menstrual cycles and the uterus undergoes atrophy in much the same way as occurs normally at the menopause (climacteric) or time of permanent cessation of reproductive activity (in women at from 45 to 50). If, however, the ovaries (or one of them) instead of being removed are grafted to an abnormal position such as the ventral wall of the body cavity or into a kidney the oestrous cycle is continued and the uterus remains normal. Since the ovary in such a position is without its normal nerve supply it is presumed that its influence on the organism is because of internal secretions passed into the circulation. The corpus luteum is also known to be an organ of internal secretion serving the special function of secreting into the blood substances essential for maintaining the raised nutrition of the uterus during pregnancy and for the development of the mammary glands, for if this structure be removed surgically pregnancy can not continue, the uterus lapses and the mammary glands fail to develop. The corpus luteum also plays some part in controlling the short or dioestrous cycle, for so long as it is present in its integrity heat can not occur; but if it is extirpated some days before a new oestrous period is normally due, the period occurs shortly after the operation of removal. Thus, Hammond, by squeezing out the corpus luteum of a cow, has induced oestrus after 9 days instead of the usual 19 to 21.

Internal Secretions and the Control of Reproductive Processes.—An understanding of the role exercised by internal secretions in the first establishment of a functional reproductive system at the age of puberty, and in the control of the rhythmical processes occurring during reproductive life, is largely a development of the 20th century. Internal secretions from the sex glands, while immediately responsible for the principal functional changes, are themselves regulated by the secretory activity of other endocrine glands, especially those from the pituitary gland.

Analyses of the oestrous cycles in the guinea pig, repeated approximately every 15th day, were made by C. R. Stockard and G. N. Papanicolaou in 1917, and five-day cycles in the rat were carefully described by J. A. Long and H. M. Evans in 1922. The inactive period of the cycle, or dioestrum, gradually changes to the pro-oestrum as renewed growth of follicles occurs in the ovary. The entire female reproductive tract—oviducts, uterus and vagina—become more vascular, increase in size and show active changes in their glands; the vaginal epithelium exhibits renewed cellular activity under the old epithelial wall, which is rather precipitously cast off into the cavity of the vagina. The period of oestrus, or acceptance of the male, in these small rodents is restricted to a few hours in comparison with several days for larger mammals; it occurs as follicular size approaches the maximum and as samples of the castoff vaginal cell wall show nucleated epithelial cells mixed with the old cornified cells of the vaginal epithelium. Ovulation occurs approximately 10 hr. after the first mating is permitted. The growth, or estrogenic, phase of the cycle is followed by the luteal or regressive phase and this involution period is indicated by the character of cells appearing in a smear taken from the vagina. The cornified cell stage of the smear is gradually superseded by one in which scattered leucocytes appear and the final quiescent stage of the dioestmm is characterized by a scanty smear composed of cells almost exclusively made up of leucocytes.

Thus, the state of the reproductive cycle can be diagnosed rapidly from the living female by means of examining a smear made from the open vagina. The known correlations between the character of the smear and the ovarial condition makes it possible to understand the condition of the ovary simply from microscopic observations of the vaginal smear. Since removal of the ovaries abolishes all cyclical phenomena as well as recurrent phases of activity on the part of the uterus and vagina, the vaginal smear technique provides a rapid test for the estrogenic hormones involved in these changes in the reproductive tract, and thereby has aided tremendously in efforts to identify the source and to follow the procedures of isolation of these hormones.

The fundamental activities of the sex glands (testes and ovaries) are not self-regulating phenomena, but were shown clearly to be dependent upon secretions from the anterior lobe of the pituitary gland by Philip E. Smith and Earl T. Engle in 1927. This sex-gland activity involves both the formation of mature germ cells and the hormone secretion by the respective sex gland. Removal of the pituitary gland (hypophysectomy) in the adult animal leads to immediate involution of the sex glands, with loss of capacity to mature sex cells and inability to secrete hormones. Conversely, the introduction under the skin of a normal animal

of finely ground fresh pituitary substance, or extracts made from fresh or dried pituitary tissue, rapidly stimulates excessive activity on the part of the gonads. Defective secretion of pituitary hormones introduces defective activity on the part of the testis or ovary.

Some notion of the delicacy of interaction between the gonads and pituitary body can be appreciated from a knowledge of the regularity in the short recurrent oestrous cycles, and such phenomena as menstruation in the human females, as well as from the regularity in the strictly annual breeding cycles. In many wild mammals the gonads are active for but a short span of the year. During the periods of low gonadal, or reproductive, activity the pituitary gland is far less potent in stimulating sex-gland activity when introduced into a test animal than it is at the approach of the breeding season. Also, since the sex glands of the sexually inactive seasonal breeding animal can be stimulated rapidly into intense activity it becomes evident that the problem oi the control of the seasonal sexual activity is essentially the problem of seasonal pituitary activity.

The external environment as well as internal conditions both play a role in these reproductive processes and in the secretory activity of the pituitary body. The relative lengths oi day and night have marked influences on the reproductive state of birds especially, as well as of some mammals, whereas other animals, particularly hibernating ones, appear to be less responsive to light changes. Jacques Benoit (1937) demonstrated clearly that the effect of added light was indirect in that it incited the pituitary gland of light-treated ducks to greatly increased secretory activity.

The secretion of substances (hormones) by the pituitary gland in the adult animal, that so markedly affect the reproductive system, is modified by factors other than light. The nutritive state of the animal is important. Simple inanition or starvation affects the secretory activity of the gland; lack of vitamin B_2 (lactoflavin or riboflavin) in the diet has a similar effect. The concentration of sex hormones in the circulation tends to inhibit secretion oi the substances acting upon the gonads, hence a reciprocal gonadal-hypophyseal interaction constitutes at least one contributory element to the intimate control of the reproductive cycles

The initiation of sexual activity, or the condition commonly known as puberty, depends upon the secretory activity of the pituitary gland. Prepuberal animals can be thrown into reproductive activity long before it normally occurs if pituitary secretions are merely introduced under the skin.

Other organs of internal secretion than the pituitary gland probably play a definite role in the control of breeding cycles. This appears to be true for the thyroid secretions in some animals and less definitely for other products of internal secretion.

Fertility **and** Sterility. — The number of spermatozoa discharged in a normal ejaculation of human semen is estimated at 226,000,000, whereas the number of ova ejected at one ovulation is usually only 1. For mammals generally the number of ova discharged is on an average only slightly more than the average number of young in a litter. It follows that the female rather than the male controls the size of the litter. (On the other hand, Sanders has shown for horses that a reduction in the number of spermatozoa may reduce the chances of the ovum being fertilized) The sheep discharges one or two (sometimes three and rarely more) ova at oestrus, but by flushing the ewes, that is supplying them with extra or stimulating food before and during breeding, the number may be increased and consequently a higher proportion of lambs obtained. This is an example of the influence of favourable nutrition upon fertility. Too high feeding (resulting in adiposity), however, promotes atrophy of the ova in the ovary and so is conducive to sterility. There is evidence also that sterility may be caused by the absence of certain essential accessory food substances or vitamins (*q.v.*) and that one such vitamin is present in green food (Herbert Evans). Degeneration of ova in the ovary may therefore be caused by faulty nutrition of various kinds, but some degeneration is normal

Sterility may result from coition at an inappropriate time, that is, at too long an interval before or after ovulation, for Hammond has shown in the rabbit that the ova are not capable of being fertilized for longer than four hours after their release from the ovary, and that the spermatozoa in the female passages do not retain their power of fertilization for more than two days (In the male passage, where they are quiescent, they retain this power for 30 days.) It is probable that in many other mammals the duration of viability of the spermatozoa and ova is not widely different. In animals such as the mare, which has a prolonged oestrus (a week or more), sterile unions may well be the result of this cause (Hammond).

Artificial insemination is sometimes successfully resorted to in cases where sterility has been because of an abnormal constriction of the *os uteri* or to the presence of an acid secretion in the vagina.

Fertility, like other characters, is capable of being transmitted from one generation to another Thus, rams which were twin lambs may hand on the tendency to produce twins to the next generation of ewes, and by breeding from rams which were twins the fertility of a flock may be increased.

REPRODUCTIVE SYSTEM. The reproductive system comprises the organs. glands, secretions and other elements by means of which animals are able to reproduce themselves. Since in some parts of its course the reproductive system shares certain structures with the urinary system, the two are commonly referred to in medical practice as the genitourinary or urogenital system. (See URINARY SYSTEM.)

This article has to do with the anatomy and functions of the reproductive system in human beings, and is divided into sections on the male and female systems; there is a third section on embryology.

MALE REPRODUCTIVE SYSTEM

The external genitalia of the male consist of the penis, the erectile copulatory organ; and the scrotum, a loose pouch of skin just beneath the base of the penis (see fig. 1). Within the scrotum

FIG. 1.—DIAGRAMMATIC SAGITTAL SECTION SHOWING THE RELATIONSHIP OF THE MALE REPRODUCTIVE ORGANS

are the gonads or testes, which produce the male germ cells, called spermatozoa. The spermatozoa accumulate in a convoluted tubular organ, the epididymis, which is closely applied to the surface of the testis. From the epididymis, the germ cells pass through a muscular duct, the ductus deferens, and into the urethral canal of the penis, through which they are discharged into the female reproductive tract. Opening into the male reproductive passages are accessory glands: the seminal vesicles, prostate gland and bulbo-urethral (Cowper's) glands. These contribute secretions that add to the bulk of the semen and create a fluid medium favourable for transport and sustenance of the spermatozoa.

EXTERNAL GENITALIA

Penis. — The penis is made up of three cylinders of erectile tissue covered by skin and subcutaneous tissue devoid of fat. Two of these cylinders, the corpora cavernosa, are side by side, while the third, the corpus spongiosum, is underneath. The posterior ends of the two corpora cavernosa diverge at the root of the penis, becoming more and more fibrous in structure, and are attached on each side to the inner border of the pubic arch. The corpus spongiosum ends posteriorly in a bulbous enlargement that is situated between the diverging columns of the corpora cavernosa. The head of the penis is formed by a large bell-shaped expansion of the corpus spongiosum, known as the glans. On its posterior surface are two concavities, which receive the rounded anterior ends of the corpora cavernosa. On the upper surface and sides of the penis the posterior rim of the glans projects as a well-marked ridge, the corona glandis, which is set off from the shaft by a constriction called the neck of the penis. The corpus spongiosum is traversed for its entire length by the urethra, a canal that begins

at the bladder, passes downward through the prostate and pierces the urogenital diaphragm to enter the bulb of the corpus spongiosum from above. Thence it runs forward through the shaft of the penis to terminate in the external meatus, a vertical slit at the end of the glans. The penile portion of the urethra serves for passage of both urine and seminal fluid and is therefore a portion of the reproductive system that is shared with the urinary system.

The skin of the penis is thin, distensible and loosely attached to underlying structures. Near the head it forms a fold, the foreskin or prepuce, that normally covers the greater part of the glans; when this is drawn back, two folds on the undersurface of the penis are seen to unite to form a median fold, the frenulum, which is attached to the glans just below the meatus. In the depression behind the corona, the skin is reflected from the inner aspect of the prepuce onto the glans where it forms a thin, closely adherent. transparent layer that is rich in sensory nerve endings. The prepuce is often removed in the practice of circumcision (*q.v.*).

The corpora cavernosa consist of a strong, fibroelastic, cylindrical sheath, from the inner surface of which incomplete walls of connective tissue extend into the interior. dividing the corpus into a labyrinthine system of spaces or compartments. These spaces in the erectile tissue are lined with endothelium and are interposed between the arteries and the deep veins of the penis. When the penis is flaccid, the spaces in the corpora cavernosa are largely collapsed, but upon psychical or mechanical stimulation, the blood vessels supplying the penis are dilated and the influx of blood into the erectile tissue is thereby enhanced. At the same time a layer of muscle investing the posterior part of the corpora cavernosa contracts and restricts the outflow. The impounding of blood within the vascular spaces of the corpora cavernosa causes them to elongate and to become distended and stiffened, resulting in erection of the penis. The internal structure of the corpus spongiosum and glans resembles that of the corpora cavernosa, but the connective tissue trabeculae are finer and the spaces they delimit are smaller. The engorgement of this finer-meshed erectile tissue causes the enlargement of the glans and the swelling of the wall of the urethra in erection.

Scrotum. — The scrotum is a pouch of skin that is divided into two compartments by a wall down the middle. Each compartment contains a testis, an epididymis and a portion of the spermatic cord. The left half of the scrotum reaches a somewhat lower level than the right half. The skin contains scattered coarse hairs and well-developed sebaceous and sweat glands. The deep layers of the scrotal skin contain smooth muscle fibres forming the dartos. Contraction of these fibres draws up the scrotum and produces a corrugated appearance of the skin.

During development of the fetus, the scrotum arises as a pair of outpouchings of the abdominal wall called the genital swellings. The testes develop in the abdominal cavity and later descend into the genital swellings. The vessels, nerves and ductus deferens that are drawn down with the testis constitute the spermatic cord. The passageway in the abdominal wall through which the testis and spermatic cords enter the scrotum is called the inguinal canal. It is at first widely open but eventually forms a flat-sided oblique passage in the abdominal wall about 3 cm. (1½ in.) in length. In the adult it remains a point of potential weakness in the body wall through which abdominal contents may be forced into the scrotum in the common pathological condition called inguinal hernia. In the descent of the male gonads the layers of the anterior abdominal wall are carried into the scrotum as coverings of the testes and spermatic cord. Thus the entrance to the inguinal canal, the abdominal inguinal ring, is formed by a funnel-shaped expansion of the transversalis fascia as it envelops the spermatic cord; the exit from the canal, the subcutaneous inguinal ring, is surrounded by the aponeurosis of the external oblique muscle.

In the scrotum, beneath the dartos, there is a thin layer of connective tissue, the external spermatic fascia, which is continuous at the subcutaneous inguinal ring with the aponeurosis of the external oblique muscle of the abdominal wall. The next deeper layer in the scrotum, the cremasteric fascia, contains bundles of muscle fibres derived from the abdominal internal oblique muscle. In fear, rage or exposure to cold, contraction of the cremasteric muscle tends to draw the testes upward toward the abdominal cavity. The next layer, the internal spermatic fascia, is relatively thin and is derived from the transversalis fascia of the abdomen. The innermost layer, the tunica vaginalis, is a double layer forming the serous investment of the testis; it is derived from the peritoneum lining the abdominal cavity. The outer, parietal layer is closely adherent to the internal spermatic fascia; the inner, visceral layer invests the testis and a portion of the epididymis. The scrotum has a lower temperature than the body cavity, and it is believed to have a heat-regulating function. Migration of the testes to a scrotal pouch occurs only in certain mammals, and for these species it has been shown that the germinal elements of the testis produce spermatozoa only at a temperature below that of the abdominal cavity.

Testes. — The testes or testicles are the essential male organs of reproduction. Each is oval, about 4–5 cm. (1½–2 in.) in length and 2.5–3 cm. (1 in.) in width. The testis has a dense fibrous capsule, the tunica albuginea, from which thin walls penetrate into the interior, dividing it into about 250 compartments or lobules. Within each lobule there are from one to three highly convoluted seminiferous tubules. These join straight tubules, tubuli recti, that open into a plexus of communicating tubes, the rete testis. The spermatozoa produced in the seminiferous tubules are carried via the tubuli recti to the rete testis, and from there they pass through 15 to 20 small ducts. the efferent ductules, into the epididymis.

Microscopically the seminiferous tubule has a small, irregular lumen surrounded by the germinal epithelium, which is enclosed by a basement membrane. The germinal epithelium is composed of the germ cells in different stages of maturation (called, according to their stage of development, spermatogonia, spermatocytes, spermatids and spermatozoa) and their supporting elements, the Sertoli cells. The mature spermatozoon is a highly specialized motile cell consisting of a head, a middle piece and a long tail or flagellum, which executes vigorous lashing movements that propel the cell forward. Spermatozoa are produced in astronomical numbers. It has been estimated that an average man discharges 400,000,000,000 sperm in his reproductive lifetime. A single ejaculate contains hundreds of millions, yet, if fertilization is achieved. only one of this enormous number enters the ovum. The condensed nucleus in the head of the fertilizing spermatozoon contains all the hereditary material contributed by the father. The endocrine function of the testes is believed to reside in the interstitial tissue, which is located between the seminiferous tubules. The cells of this tissue produce the male sex hormone responsible for maintenance of accessory reproductive organs and development of secondary sex characteristics such as deep voice, beard, muscular build, etc.

Epididymis.—The epididymis is a firm, elongated body closely adhering to the posterior surface of the testis. At the upper pole it is enlarged to form the head, and at the lower pole there is a lesser enlargement. the tail. The entire epididymis consists of an extremely tortuous tube that is 15 to 20 ft. long when extended. Because of its great length it can accommodate a large number of spermatozoa. The cells lining this convoluted tube are believed to produce a secretion that plays a role in the nutrition of the spermatozoa.

Internal Organs

Ductus Deferens. — The ductus deferens (or vas deferens) is the continuation of the tube of the epididymis. It extends from the tail of the epididymis to the posterior surface of the prostate, where it joins the duct of the seminal vesicle to form the ejaculatory duct (see fig. 1). The ductus deferens ascends from the epididymis to the subcutaneous inguinal ring, being joined in this part of its course by testicular arteries, veins, lymphatics and nerves to form the spermatic cord. These structures pass obliquely through the abdominal wall, via the inguinal canal. At the abdominal inguinal ring they separate, the ductus passing down the side of the pelvis and then turning inward along the back wall of the bladder to the prostate, where it meets its fellow of the opposite side.

The ductus deferens has a thick muscular wall with a uniform diameter of about three millimetres until it reaches the seminal vesicle; there it broadens out and forms the ampulla of the ductus deferens. the lumen of which has numerous outpocketings. Immediately before joining the excretory duct of the seminal vesicle, the ductus deferens again becomes round and slender.

Seminal Vesicles and Ejaculatory Ducts.—The seminal vesicles are two saclike appendages of the ductus deferens that are fixed to the rear surface of the bladder and lie lateral and parallel to the corresponding ductus deferens *(see* fig. 1). Each vesicle is composed of a thin-walled tubular structure, 10 to 12 cm. long, folded back and forth upon itself and enclosed in a fibromuscular capsule. Arising from the main tube are numerous pouches (sacculations or diverticulae). The excretory duct of the seminal vesicle on each side joins the ductus deferens to form an ejaculatory duct. The two ejaculatory ducts are narrow and thin walled and run side by side through the prostate gland to open into the urethra. The seminal vesicles were formerly regarded as seminal receptacles for the storage of semen, but according to the modern view their function is purely glandular and they do not store semen. The principal reserves of spermatozoa are contained within the epididymis, and those that are to be delivered in any one ejaculation accumulate in the ampulla of the ductus deferens just prior to ejaculation. Here, in the secretion of the ampulla, the spermatozoa first come into contact with fructose, the principal carbohydrate substrate for their metabolism: and it is probable that sperm motility is initiated at this time. The main source of fructose is in the secretion of the seminal vesicles which is discharged in the process of ejaculation into the prostatic urethra together with the secretion of the prostate and the spermatozoa contained in the ampulla. In man, the greater part of the volume of the ejaculate is derived from the secretion of the seminal vesicles.

Prostate.— The prostate is situated just below the bladder and is traversed by the urethra and the ejaculatory ducts. It is pyramidal in form. with the base upward in contact with the floor of the bladder. The vertical dimension is from 2.2 to 3 cm. (1 to $1\frac{3}{8}$ in.), the transverse diameter from 3.5 to 4 cm. ($1\frac{3}{8}$ to $1\frac{3}{4}$ in.) and the thickness from 2 to 2.j cm. ($\frac{4}{5}$ to 1 in.). The prostate is composed of glandular tissue enclosed in a dense fibrous capsule. Microscopically it consists of 30 to 50 branching tubuloalveolar glands embedded in a stroma rich in smooth muscle fibres, which aid in discharge of the prostatic fluid in ejaculation. The glands join 16 to 20 minute ducts that enter the prostatic urethra on either side of a longitudinal ridge in its rear wall, the colliculus seminalis. The secretion of the prostate is a thin, milky fluid that is weakly alkaline and has a characteristic odour. In old age the prostate commonly undergoes a generalized enlargement that may ultimately constrict the urethra and cause urinary obstruction.

Cowper's Glands.—Opening into the urethra where it passes into the bulb of the corpus spongiosum are the ducts of two small glands. the bulbo-urethral or Cowper's glands *(see* fig. 1). The glands themselves are about five millimetres in diameter and are situated on each side of the urethra within the urogenital diaphragm. They produce a mucoid secretion that probably functions as a lubricant.

FEMALE REPRODUCTIVE SYSTEM

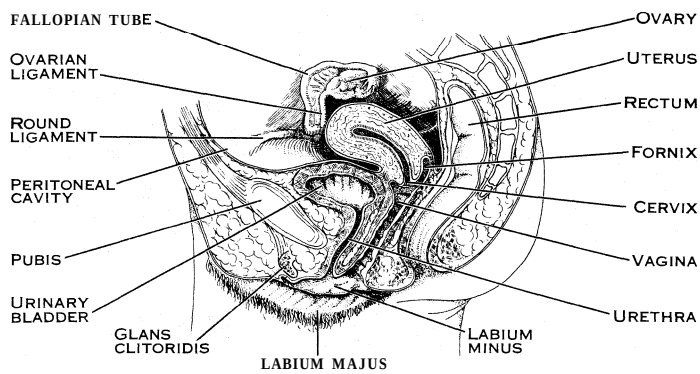
Genital Anatomy

External.— The external genitalia in the female collectively comprise the vulva. The vulvar orifice is bounded laterally by the labia majora, two prominent rounded folds of skin that correspond to the scrotum of the male. They have a sparse covering of hair and meet in the mid-line so that they largely conceal the other external genital structures. Between the labia majora are a pair of pendulous skin folds, the labia minora, that enclose a shallow elliptical depression called the vestibule. Toward the front the labia minora are continuous with one another, forming the prepuce, a thin fold of skin that covers the sensitive clitoris. The clitoris is a rudimentary erectile organ. the counterpart of the penis of the male. Opening into the vestibule below it are the urethra, the urinary passage from the bladder; and the vagina, the flattened fibromuscular tube that receives the penis during copulation. In virgins, the entrance of the vagina is narrowed by a circular fold of mucous membrane called the hymen.

Internal.— The internal reproductive organs consist of the female gonads or ovaries. located within the body cavity, and a system of tubular organs that communicate with the exterior at the vaginal orifice. Egg cells or ova are produced in the ovaries and are released singly at monthly intervals. Closely associated with the ovaries are the open ends of the right and left oviducts (Fallopian tubes). At the time of ovulation either of these may receive the ovum. If coitus occurs. the ovum may be fertilized by one of the spermatozoa reaching the upper part of the oviduct. The developing ovum then passes down through the oviduct to the cavity of the uterus or womb, where it becomes implanted and is nourished until birth. The lower end of the uterus projects into the upper end of the vagina (see fig. 2).

The dilated neck of the uterus and the vagina constitute the birth canal, through which the infant emerges at the termination of pregnancy.

Ovary.—The mature ovary is a firm organ about the size of a large almond shell, with a scarred or wrinkled exterior. Its surface is covered by a layer of low cuboidal cells forming the



FROM C. D. TURNER, "GENERAL ENDOCRINOLOGY"; REPRODUCED BY PERMISSION OF W. B. SAUNDERS COMPANY

FIG. 2.— DIAGRAMMATIC SAGITTAL SECTION SHOWING THE ARRANGEMENT AND RELATIONSHIP OF THE FEMALE REPRODUCTIVE ORGANS

germinal epithelium. Near the surface are many minute egg cells that have remained dormant since birth. Each is surrounded by a layer of flattened follicle cells. An ovum and its covering layer of cells form a primordial follicle. In a young adult woman each ovary may contain as many as 200,000 of these, but the number decreases progressively throughout the reproductive period of life. From time to time, certain of the primordial follicles begin to grow. The ovum within slowly enlarges and the follicle cells multiply rapidly, giving rise to a thick cellular wall. Fluid accumulates between the follicle cells and a central cavity gradually develops. The vesicular structure formed in this manner is called a Graafian follicle. Within it the eccentrically placed ovum and the cells immediately surrounding it form a domelike projection from the wall into the fluid-filled cavity. Several hundred partially developed follicles of this kind may be present in an adult ovary. In each ovulatory cycle one of these continues to grow to large size and finally releases a ripe ovum. The great majority of the follicles seen in the ovary develop only to a certain stage and then degenerate. Although their ova are thus wasted, these follicles nevertheless serve a useful purpose before their degeneration in that their cells are active in the production of female sex hormone. Of the thousands of primordial follicles present in the ovaries at birth, fewer than 400 are likely to produce mature ova during a woman's reproductive life.

Oviducts.—The oviducts (Fallopian tubes) are sinuous tubes of involuntary muscle, 4–5 in. long, running laterally from the uterus to the ovaries. They are lined by an extensively folded mucous membrane. Near the ovary the open end of the oviduct is expanded into a thin-walled, funnel-shaped structure, the infundibulum. Its edges are prolonged into a number of slender, tapering

processes called fimbria, some of which are attached to the ovary. By contraction of its muscular wall, the oviduct can change its shape and position. It is particularly active at the time of ovulation, when it becomes reddened from dilatation of all its blood vessels and moves so as to bring its open fimbriated end into close apposition with the surface of the ovary, thus facilitating the passage of the ovum directly into the infundibulum. The lumen of the oviduct narrows and becomes very small where it passes through the thick. muscular, uterine wall. Ciliated cells lining the oviduct maintain a constant slow movement of fluid from the body cavity toward the uterus.

Uterus.—The uterus, when not pregnant, resembles a flattened pear in size and shape. with the stem end directed downward toward the vagina (see fig. 2). The body of the uterus, the corpus uteri, is usually bent forward so that it lies upon the urinary bladder and is thus at an angle to the cylindrical neck. the cervix uteri. The thick wall of the uterus is composed largely of involuntary muscle. The uterine cavity is flattened from front to back and is roughly triangular in form, with the upper angles extending out toward the openings of the oviducts. and the lower angle directed downward toward the cervix (see fig. 3). The lining of the corpus uteri, the endometrium. is a mucous membrane specially adapted for the reception and sustenance of the fertilized ovum. It is covered by a single layer of ciliated and secretory cells that is continuous with the lining of many simple tubular glands that extend from the surface of the endometrium down to the muscle of the uterine wall. The glands are embedded in a loose connective tissue richly supplied with blood vessels. The cervix of the uterus has a slender cavity narrowed by projecting folds of mucous membrane. Opening into it are numerous branching, mucus-secreting glands, At its lower end the cervical canal communicates with the vagina through a narrow slit, the external os (see fig. 3).

Attachments.—The attachments of the ovaries! oviducts and uterus support them, while at the same time permitting their independent movement and allowing for enlargement of the uterus in pregnancy. The principal support for all three organs is provided by the two broad ligaments. Each of these consists of a double layer of peritoneum extending from the sides of the uterus to the lateral wall of the pelvis. The blood vessels, lymphatics and nerves reach the uterus by passing between the layers of the broad ligaments. Each ovary is suspended from the back of the broad ligament by a fold of peritoneum. the mesovarium. A small peritoneal fold also passes upward from the tubal end of the ovary to the pelvic wall. This is the infundibulopelvic ligament. Through it, blood vessels reach the ovary from above. The ovarian and uterine vessels communicate within the broad ligament. and blood can reach these organs via either route. The medial pole of the ovary is attached to the uterus by a stout band of connective tissue. the ovarian ligament. A fibrous cord, the round ligament. runs laterally from the uterus to the wall of the pelvis, from there anteriorly passing through the abdominal wall via the inguinal canal. to terminate in the skin and subcutaneous connective tissue of the labia majora. The round ligament in the female corresponds to the gubernaculum in the male, the fibrous band that attaches the lower pole of the testis to the skin of the scrotum. The cervix of the uterus is held back by the uterosacral ligaments, two folds of fascia and peritoneum that run from the back of the cervix around the rectum on either side to attach to the fascia over the anterior surface of the sacrum.

Reproductive Function in Woman

During childhood there are no signs of activity in the female genital organs, but at the beginning of adolescence (8 to 12 years) the ovaries are activated by the hormones of the pituitary gland (hypophysis) to begin the production of large follicles, which in turn secrete ovarian hormone. The latter is carried in the blood stream and stimulates development of all parts of the reproductive tract. In addition. the bony pelvis, breasts, hair and fat depots begin their progress toward maturity. There is a rhythmic alternation in the dominance of the hormones of the hypophysis and ovary.

Eventually the hormonal tides attain a height that results in bleeding from the endometrium and the first menstrual flow occurs (see MENSTRUATION).

Menstrual Cycles.—During the childbearing period of life the sequence of events in the cycle is usually as follows: at intervals of about a month. under stimulation from the hypophysis, one ovarian follicle outstrips its fellows in growth. In a few days it attains a diameter of about ½ in. and protrudes from the ovary like a clear blister. Usually only one follicle at a time enters upon this final growth period, but occasionally more may develop; if the ova produced are fertilized. multiple births may result. At ovulation the ripened egg cell loosens from the wall of the large follicle and soon the wall bulges, breaks and the viscid follicular fluid wells out, carrying the ovum along with it. At this time of the cycle. the level of ovarian hormone circulating in the blood stream reaches a peak, and the oviducts and uterus are stimulated to greater activity. It has been possible to peer into the body cavity through an endoscope at such a time and see the fimbriated end of the oviduct wrapped closely about the ovary while the organs move rhythmically. The close joining of the open end of the infundibulum to the ovary facilitates the entrance of the ovum into the oviduct. If spermatozoa are present, the egg may be fertilized almost as soon as it is liberated from the follicle. In any case it is swept into the oviduct by ciliary action and is slowly moved along by peristaltic contractions, reaching the uterus about the fourth day after ovulation.

In the interim, the uterine endometrium has grown thick through cell division and accumulation of interstitial fluid, and its glands have increased in length and complexity. This preliminary period of preparation of the uterus for reception of the ovum is called the follicular phase of the cycle becauseit is dominated by the hormone produced by the growing follicles. Ovulation is expected to occur on about the 14th day of a 28-day cycle, but it may occur as early as 7 days after the beginning of menstruation or may be delayed for 18 days or more. The period of the cycle subsequent to ovulation is called the luteal phase because it is dominated by the hormone produced by the corpus luteum, an organ of internal secretion that arises in the ovary from the wall of the ruptured follicle. Immediately after ovulation, while the egg is still in the oviduct. the thin wall of the collapsed follicle thickens rapidly and its cells undergo a marked.change in their appearance. A meshwork of thin-walled capillary vessels develops between them, and the entire structure is transformed into a conspicuous yellow body grossly visible in the ovary at the site formerly occupied by the follicle.

The hormone secreted by the cells of the corpus luteum produces further changes in the uterus that make it a most favourable site for implantation and nourishment of the embryo. Under its influence the contractions of the uterus are slowed down; the endo-

metrium thickens and its arteries lengthen and become more coiled; its glands grow more contorted and are distended with a secretion rich in nutrient substances. These changes take place whether the egg has been fertilized or not.

If conception does not occur, the corpus luteum remains active for only 10 to 14 days. With the decline in its hormone output, the blood flow to the uterus is reduced and the endometrium begins to shrink. Its superficial zone suffers particularly, for it is supplied by the coiled arteries. which, at this time, begin to constrict intermittently. The walls of the superficial vessels are damaged and ultimately break down, permitting blood to seep out into the surrounding tissue. The extravasated blood at first accumulates within the endometrium but finally drains into the cavity of the uterus. This marks the beginning of menstruation. The blood-soaked, degenerating tissue soon loosens and sloughs off, leaving a raw surface. The greater part of the thickness of the endometrium degenerates and is lost during menstruation, but the bases of the glands persist, and the multiplication and migration of their cells quickly restores the surface layer after menstruation is over.

A period of relative inactivity may ensue before another set of ovarian follicles enter upon their final growth and release the follicular hormone that stimulates anew the growth in thickness of the endometrium.

Menstrual cycles continue more or less regularly unless interrupted by pregnancy. They are accompanied by various general bodily changes. At the middle of the cycle a sudden slight fall, followed by a rise in the basal body temperature. may be detected. Rarely abdominal pain may be experienced at the time of ovulation. The relations between hypophysis and ovary may be affected by other hormones and by the nervous system as well. Changes in climate, living conditions, infections or psychic disturbances may consequently affect the reproductive cycle. When the responses of the ovaries begin to wane at the age of 45 to 50 years, the hormonal balance is upset and changes occur in the economy of the body as a whole. These give rise to the characteristic symptoms of the menopause (*q.v.*) or change of life.

(D. W. FT.)

EMBRYOLOGY

The development of the reproductive organs is closely interwoven with that of the urinary system (*q.v.*). It will here be convenient to take up the development at the stage in which the genital ridge is seen on each side of the attachment of the mesentery; external to this, and forming another slight ridge of its own, is the Wolffian duct. while, a little later, the Mullerian duct is formed and lies ventral to the Wolffian. Cntil the fifth or sixth week the development of the genital ridge is very much the same in the two sexes, and consists of cords of cells growing from the epithelium-covered surface into the mesenchyme, ahich forms the interior of the ridge. In these cords are some large germ cells which are distinguishable at a very early stage of development. It must, of course, be understood that the germinal epithelium covering the ridge. and the mesenchyme inside it, are both derived from the mesoderm or middle layer of the embryo. About the fifth week of human embryonic life the tunica albuginea appears in the male. from which septa grow to divide the testis into lobules, while the epithelial cords form the seminiferous tubes, though these do not gain a lumen until just before puberty. From the adjacent mesonephros. or perhaps coelomic epithelium, cords of cells grow into the attached part of the genital ridge, or testis, as it now is, and from these the rete testis is developed.

In the female the same growth of epithelial cords into the mesenchyme of the genital ridge takes place, but each one is distinguished by a bulging toward its middle. in which alone the large germ cells are found. Eventually this bulging part is broken up into a series of small portions, each of which contains one germ cell or ovum and gives rise to a Graafian follicle. Mesonephric cords appear as in the male; they do not enter the ovary, however, but form a transitory net ork (rete ovarii) in the mesovarium.

As each genital gland enlarges it remains attached to the rest of the intermediate cell mass by a constricted fold of the coelomic membrane, known as the mesorchium in the male and the mesovarium in the female. Lying dorsal to the genital ridge in the intermediate cell mass is the mesonephros, consisting of numerous tubules which open into the Wolffian duct. This at first is an important excretory organ, but during development becomes used for other purposes. In the male, as has been shown, it may form the rete testis, and certainly forms the vasa efferentia and globus major of the epididymis: in addition to these, some of its separate tubes probably account for the ductus aberrans and the organ of Giraldks (see fig. 4). In the female the tubules of the epoophoron represent the main part, while the paroophoron. like the organ of Giraldks in the male, is probably formed from some separate tubes (see fig. 4).

The Wolffian duct, which in the early embryo carries the excretion of the mesonephros to the cloaca, forms eventually the body and tail of the epididymis, the ductus deferens and ejaculatory

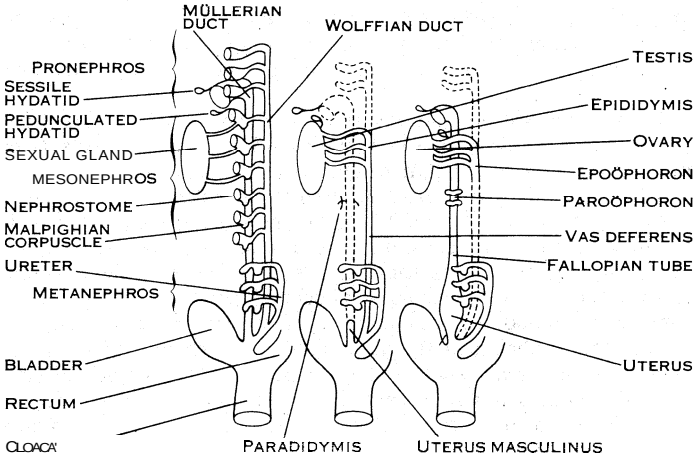

FIG. 4.— DIAGRAM OF THE FORMATION OF THE GENITO-URINARY APPARATUS (SUPPRESSED PARTS ARE DOTTED)

duct in the male, the seminal vesicle being developed as a pouch in its course. In the female this duct is largely done away with, but remains as the collecting tube of the epoophoron, and in some mammals as the duct of Gartner, which runs down the side of the vagina to open into the vestibule.

The Mullerian duct, as it approaches the cloaca, joins its fellow of the opposite side, so that there is only one opening into the ventral cloaca1 wall. In the male only the lower part of it remains as the uterus masculinus, but in the female the Fallopian tubes, uterus and probably the vagina are all formed from it (see fig 4). In both sexes a small hydatid or vesicle is liable to be formed at the beginning of both the Wolffian and Miillerian duct; in the male these are close together in front of the globus major of the epididymis and are known as the sessile and pedunculated hydatids of Morgagni. In the female there is a hydatid among the fimbriae of the Fallopian tube which of course is Miillerian and corresponds to the sessile hydatid in the male, while another is often found at the beginning of the collecting tube of the epoophoron and is probably formed by a blocked mesonephric tubule. This is the pedunculated hydatid of the male. The development of the vagina is peculiar. Instead of the two Miillerian ducts joining to form the lumen of its lower third, as they do in the case of the uterus and its upper two-thirds. they become obliterated, and their place is taken by two solid cords of cells, which later became canalized and the septum between them is obliterated.

The common chamber, or cloaca, into which the alimentary, urinary and reproductive tubes open in the fetus has the urinary bladder (the remains of the allantois) opening from its ventral wall (see PLACENTA ; URINARY SYSTEM).

During development the alimentary or anal part of the cloaca is separated from the urogenital. According to F. Wood Jones, the anal part is completely shut off from the urogenital and ends in a blind pouch which grows toward the surface and meets a new

ectodermal depression, the permanent anus, not being part of the original cloacal aperture but a new perforation. This description is in harmony with the malformations occurring in this region.

The external generative organs have at first the same appearance in the two sexes and consist of a swelling, the genital eminence, in the ventral wall of the cloaca. This in the male becomes the penis and in the female the clitoris. Throughout the generative system the male organs depart most from the undifferentiated type, and in the case of the genital eminence two folds grow together and enclose the urogenital passage, thus making the urethra perforate the penis, while in the female these two folds remain separate as the labia minora. Sometimes in the male the folds fail to unite completely and then there is an opening into the urethra on the undersurface of the penis—a condition known as hypospadias.

In the undifferentiated condition the integument surrounding the genital opening is raised into a horseshoelike swelling with its convexity over the pubic symphysis and its concavity toward the anus; the lateral parts of this remain separate in the female and form the labia majora, but in the male they unite to form the scrotum. The median part forms the mons Veneris or mons Jovis.

It has been shown that the testis is formed in the loin region of the embryo close to the kidney, and it is only in the later months of fetal life that it changes this position for that of the scrotum. In the lower part of the genital ridge a fibromuscular cord is formed which stretches from the lower part of the testis to the bottom of the scrotum; it is known as the gubernaculum testis, and by its means the testis is directed into the scrotum. Before the testis descends, a pouch of peritoneum called the processus vaginalis passes down in front of the gubernaculum through the opening in the abdominal wall, which afterward becomes the inguinal canal, into the scrotum, and behind this the testis descends, carrying with it the mesonephros and mesonephric duct. These, as has already been pointed out, form the epididymis and ductus deferens. At the sixth month the testis lies opposite the abdominal ring, and at the eighth reaches the bottom of the scrotum and invaginates the processus vaginalis from behind. Soon after birth the communication between that part of the processus vaginalis which now surrounds the testis and the general cavity of the peritoneum disappears, and the part which remains forms the tunica vaginalis. Sometimes the testis fails to pass beyond the inguinal canal, and the term "cryptorchism" is used for such cases.

In the female the ovary undergoes a descent like that of the testis, but it is less marked since the gubernaculum becomes attached to the Müllerian duct where that duct joins its fellow to form the uterus. Thus, the ovary does not descend lower than the level of the top of the uterus, and the part of the gubernaculum running between it and the uterus remains as the ligament of the ovary, while the part running from the uterus to the labium is the round ligament.

In rare cases the ovary may be drawn into the labium just as the testis is drawn into the scrotum.

REPTILES (Reptilia) is the name given to a class of vertebrates which hold a position in the animal kingdom intermediate between the amphibians and the birds, and the mammals. The group arose, perhaps in Lower Carboniferous times, from the Labyrinthodont Amphibia, and was already varied at the end of the Carboniferous. During Permian times the class branched out into many orders, one of which included the ancestors of the Mammalia, whilst from another the birds, crocodiles, Sphenodon, and perhaps the lizards and snakes arose. The tortoises are the descendants of another early group. In a recent survey by Nopcsa, it is pointed out that, of the 125 families into which he divides the reptiles, only 18 are represented by living forms, whilst of the 19 orders only four are extant. The modern forms fall into the orders Crocodilia, including the crocodiles and alligators; the Squamata, the lizards and snakes, the Rhynchocephalia, represented only by the Tuatera lizard of New Zealand, and the Chelonia, the tortoises and turtles. (For information on the natural history of these forms see CROCODILIAN; LIZARD; SNAKES; TURTLE.)

These living forms are characterized as follows:

(1.) The animal breathes air by lungs.

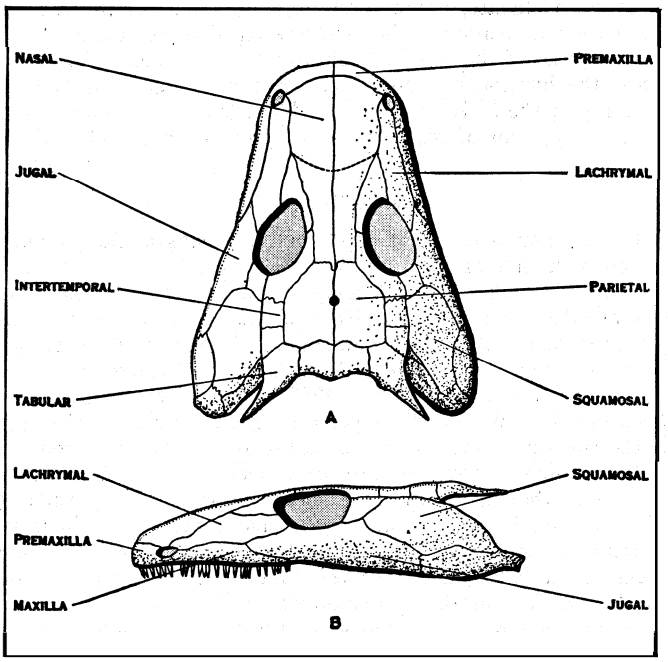
(2.) The body temperature is variable.

(3.) The skin is covered with horny scales formed by the epidermis.

(4.) Fertilization is internal, and an egg, consisting of a yolk surrounded by albumen and contained in a shell, is usually laid and hatched by the heat of the sun or of decaying vegetation. In some cases reptiles are viviparous.

(5.) In the brain the cerebral hemispheres are comparatively small. Their roof tends to become thinned and may be almost membranous. There is a well-developed hypopallium which becomes assimilated to the corpus striatum, losing the original stratification of the neurones. The mid-brain is relatively large and its roof forms a pair of large optic lobes.

(6.) The olfactory organ has its surface increased by a simple turbinal or concha, and there is a well-developed Jacobson's organ.



FROM PHILOSOPHICAL TRANSACTIONS OF THE ROYAL SOCIETY

FIG. 1.—SKULL OF THE **EMBOLOMEROUS** AMPHIBIAN PALAEOGYRINUS; (A) FROM ABOVE, (B) FROM THE LEFT SIDE

The posterior nares may be immediately below the external nostrils or may be carried back to the hinder end of the head.

The eyes are usually present, but may be hidden in burrowing forms. The retina normally contains both rods and cones, but may consist exclusively of either type. There is a pecten in the form of a folded sheet projecting into the vitreous humour.

The internal ear shows a more marked separation of *sacculus* and *utriculus* than obtains in Amphibia, a lagena always occurs and is associated with a perilymphatic duct, in some cases so as to form a rudimentary cochlea. The tympanic cavity lies high up and the tympanic membrane is either superficial or lies at the end of a short external auditory meatus. The membrane is con-

nected to that closing the *fenestra ovalis* by a straight rod, whose inner end, the columella, is bony, whilst the outer half, the extra-columella, is often four-rayed, a short dorsal process being connected to the end of the paroccipital process and a ventral process often continued into the hyoid.

(7.) There is a well-developed tongue capable of free movement. The mid-gut has the usual structure; there is a cloaca and an urinary bladder of allantoic origin. The lungs are more elaborate than those of Amphibia and less than those of mammals.

(8.) The heart is three- or four-chambered, there being two auricles and a ventricle more or less completely divided into two. There is no bulbus; three arteries arise from the ventricle; of these one is the right systemic, another the pulmonary, whilst the third is the left systemic and both carotids. The posterior cardinals have both almost disappeared as such, the post-caval vein returning most of the blood from the posterior part of the animal to the heart. There is a coronary circulation.

(9.) The functional kidney in the adult is a metanephros discharging by a ureter into the cloaca. The ovary is often single and the egg always large. The oviduct is provided with glands which secrete albumen and a shell. A copulatory organ is usually present in the male, but is variable in structure.

(10.) The pre-sacral part of the vertebral column is usually less clearly divided into regions than in mammals and birds. There are two sacral vertebrae and a longer or shorter series of caudals. The atlas consists of a pair of neural arches, a single inter centrum and a centrum which forms an odontoid, though it may not be fused to the axis. There is sometimes a pro-atlas. The vertebra of the rest of the column always consists of a neural arch and a centrum with inter-centra forming chevron bones in the tail. Small inter-centra may be present throughout the column. Ribs are usually present on all vertebrae except the posterior caudals; they may be single or double headed. A true sternum is usually present, connected to some of the dorsal ribs by sternal ribs.

The neural cranium is generally incompletely ossified, a good deal of the lateral walls anteriorly being membranous. It is often movably connected to the dermal bones of the skull roof and palate. There is a single occipital condyle, mainly basi-occipital but with contributions from the ex-occipital. A supra-occipital is present and articulates with the parietals. The inner ear lies within the opisthotic, usually fused with the ex-occipital, the pro-otic and the supra-occipital. An ossification in front of the pro-otic, in the side wall of the cranium, is absent in only two orders. There is an ossified basi-sphenoid, but the unossified pre-sphenoid is usually underlain by a para-sphenoid.

The dermal bones of the skull form a roof, which may be very incomplete or, indeed, absent, over the masticatory muscles, whilst the orbit is surrounded by a ring of bones which are continuous with the maxillae and nasals which enclose the anterior end of the head. In the palate the pterygoids are always large bones articulating with the basi-sphenoid and extending back to the quadrate. Pre-vomers and palatines are always present and ectopterygoids usually so. In many forms an epipterygoid is ossified. The lower jaw is complex, it articulates with the quadrate by an articular bone of endochondral origin, and at least five membrane bones contribute to its structure.

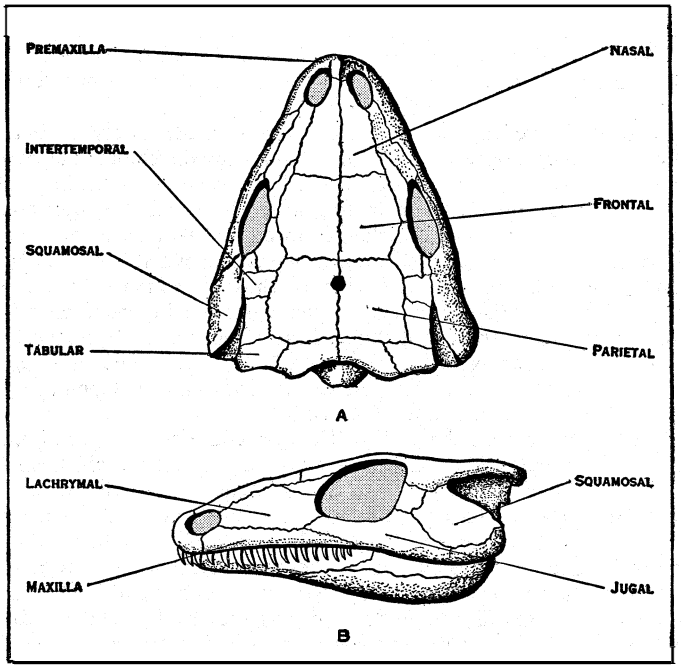
Fore and hind limbs are usually present, but either or both may be absent. The shoulder girdle consists of a pair of scapulae and "coracoids," both contributing to the glenoid cavity. There are generally clavicles and an inter-clavicle. The hand and foot are primitively pentadactyl, the fourth digit being the longest.

(11.) Segmentation of the egg is incomplete (meroblastic). No primitive streak is formed and a rudimentary archenteron with both roof and floor may be established. There is an amnion and an allantois, membranes developed for the protection, nutrition and respiration of the embryo.

Amphibian Ancestry.—The Amphibia, which were the ancestors of the reptiles, spent the greater part of their life in water, probably crawling on to land only to pass from one pool to another. They laid small eggs, which were fertilized after they had passed out from the body of the mother. These eggs developed into an aquatic larva which breathed by means of gills; subsequently, when this larva had reached a relatively large size, the gills were absorbed and the animal became dependent on the air for the main bulk of its oxygen. An aquatic animal may have, and in the case of the Amphibia did have, a soft skin which can only remain healthy if it be kept moist. Living Amphibia secure this condition by pouring out mucus and water from glands in their skin, which is therefore slimy. An animal which adopts this method has great difficulty in roaming far from water, the possibility of dying from desiccation being always present. Thus one of the first changes necessary to make an effectively terrestrial animal from an amphibian is to alter the character of its skin in such a way that it becomes water-tight, and has a dry outer surface. Such a change in a vertebrate is most readily achieved by thickening the epidermis and laying down keratin in its outer layers; continuation of this process leads to the formation of the horny scales of reptiles, which are made by localized patches of skin exceptionally active in the production of keratin. As such a skin does not require to be kept moist, glands are very poorly developed in the skin of reptiles.

During the transition from water to air the sense organs necessarily undergo great modifications. The olfactory organ, which had become adapted to the relatively large amounts of odorous substances which could come to it in solution in water, had to be made capable of recognizing the much smaller amounts brought to it as vapour through the air. In the intervening stage of the Amphibia the nose becomes double, one part of it, Jacobson's organ, functioning in water, the rest in air. When the reptiles became completely terrestrial, Jacobson's organ took on the new function of smelling the material lying in the mouth, and the rest of the organ became the normal organ of smell.

The eye, adapted for focussing objects under water, has to be so changed in its proportions as to see its surroundings through air.



FROM PHILOSOPHICAL TRANSACTIONS OF THE ROYAL SOCIETY

FIG. 2.—SKULL OF THE COTYLOSAUR SEYMOURIA; (A) FROM ABOVE. (B) LEFT SIDE

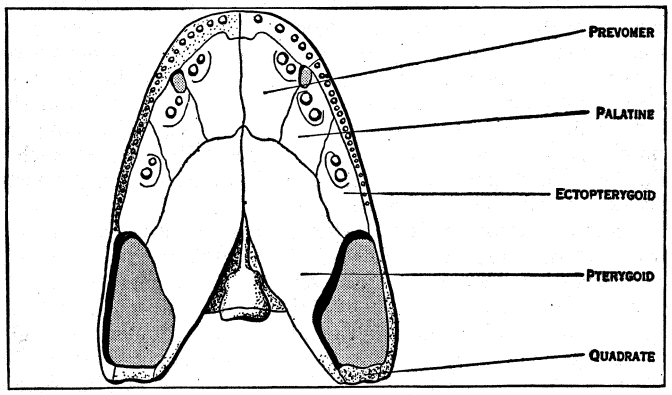
That part of the ear whose function is to determine the position of the animal with respect to gravity and to recognize changes in position. can remain unaltered, but the lagena, which, with its associated structures, the columella, middle ear and tympanic membrane, is concerned with hearing in the ordinary sense, necessarily undergoes changes on account of the very different specific gravity of the mediums, water or air, through which sound waves come to it.

Aquatic Amphibia have, in common with fish, a special sense,

whose organ is the lateral line, which is concerned with the recognition of movements in water; with the transition to land this sense is entirely lost.

Any animal living in water is so nearly floating that the proportion of its weight which has to be supported by the limbs is extremely small. As soon as it comes out of water practically the whole of its weight falls on the legs. Thus the skeleton and musculature necessarily become more powerful.

The most serious changes, however, are those in the mode of reproduction. An amphibian which lays its eggs in the water can fertilize them there, but a terrestrial animal can only lay an egg



FROM PHILOSOPHICAL TRANSACTIONS OF THE ROYAL SOCIETY

FIG. 3.— PALATE OF THE EMBOLOMEROUS AMPHIBIAN, BAPHETES

if it be included in a shell which will protect it from mechanical injury and, a matter of more importance, from drying up. Such a shell cannot be perforated by a spermatozoan, so that fertilization must take place within the body of the mother before the shell is formed. The uro-genital organs of both sexes have to be so modified as to allow this to take place, and the oviduct of the female must be provided with the glands that are necessary for the formation of the shell.

The amphibian egg may be comparatively small; it only needs to contain a food supply sufficient to maintain the developing embryo to a stage when it hatches as a small larva capable of feeding on the abundant food present in the water in which the egg was laid. The animal, which hatches from an egg laid on land, must make its appearance at a stage in development when it can maintain itself under conditions similar to those in which its parents live. The time taken in reaching such a stage of development is considerable, and the egg included in its shell has no opportunity of obtaining food or water from outside. Thus, when laid, the egg must contain everything necessary for the development of the embryo up to the time of hatching.

The reptile ovum, the yolk of the egg, contains the great bulk of the food materials, whilst the albumen, the white which surrounds it, is mainly a water store. The egg-shell is porous and transmits gases. The character of the development of the large egg is necessarily modified by its bulk, much of the yolk remaining undivided into cells until it is absorbed and converted into part of the animal's own tissues. Special embryonic membranes, the amnion and allantois, are produced during the development for the protection of the embryo and for its nutrition and respiration, the allantois serving also as a reservoir for the nitrogenous waste products produced by its metabolism.

The great majority of these changes, including all those which are of the greatest importance, cannot be determined from fossil material, and we are driven back for the discrimination between fossil reptiles and fossil amphibians to the use of technical points mainly of little functional importance to the animal. The break between the Amphibia and Reptilia was regarded by Huxley and other early workers as the most important in the vertebrate phylum; such contrasted terms as Ichthyopsida and Sauropsida, Anamniota and Amniota emphasize its importance. None the less we now know an animal, *Seymouria*, from the lowest Permian of Texas, which is regarded by one group of students as an amphibian and by another as a reptile. As the osteology of this animal is very completely known, the doubt which exists as to its systematic position illustrates vividly the completeness with which the gap between these two divisions has been bridged.

Seymouria is a small animal about 2 ft. in length, with a comparatively small head, no visible neck, a somewhat stumpy body, and a short tail. The limbs were very muscular, but short. The hands and feet were placed far away from the middle line, and the stride was exceedingly small. Each limb has five digits.

The skull of *Seymouria* consists of two parts, which could have easily been separated from one another. These are the brain case, made of bones which have replaced the cartilage which existed in the-embryonic skull, and a superficial coating covering the whole outer surface of the head (except for the nostrils, orbits and pineal foramen), and the roof of the mouth, made of bones which have developed in the lower layers of the skin. The pattern formed by these dermal bones is identical with that which is found in the more primitive Labyrinthodont Amphibia, and is important, because from it the structure of the corresponding parts of the skulls of all other reptiles can be derived, by a process of reduction. The palate of *Seymouria* is, in essence, identical with that of an Embolomerous Labyrinthodont. The brain case, however, differs somewhat from those of the Amphibia. For example, the single occipital condyle is convex instead of being concave, and there is a large fenestra ovalis leading into the ear which does not exist in the Embolomeri. There are also variations in other details of the structure of the otic region. In the lower jaw, *Seymouria* is identical with an amphibian, but the vertebral column is very different.

In the amphibian the first vertebra articulates with the condyle by a disc-shaped inter-centrum followed by a disc-shaped centrum, of the same character as those which succeed it. In *Seymouria* the rounded condyle articulates below with a concavity on an inter-centrum which represents only the lower half of that of the amphibian, and with facets carried on the lower ends of the two halves of the neural arch. The centrum of the atlas is a curious trefoil-shaped bone which fits in between the three elements which articulate with the condyle; this arrangement is completely reptilian. The structure of a vertebra from the middle of the back of *Seymouria* is quite peculiar. There is a small cylindrical centrum separated from the next by an intercentrum having the shape of half a disc. The neural arch is enormously heavy, it articulates with the centrum alone and the pre- and post-zygopotheses are produced laterally as masses of bone which overhang the much smaller centrum. The articulating faces are quite flat and placed horizontally, so that the back, although free to move from side to side, must have been extremely stiff dorso-ventrally.

Vertebrae of this type are known in no amphibian, but in a less exaggerated form occur in many of the more primitive reptiles. It is reasonable to believe that they were evolved as a clumsy method of giving that stiffness to the back which is necessary to an animal which, living in air, has to support the whole of its weight. The ribs of *Seymouria* do not differ essentially from those of some Labyrinthodonts. The limb girdles and limbs are of the amphibian pattern except in one or two details, e g, the occurrence of an ent-epi-condylar foramen piercing the humerus, and the number of the phalanges, which is two, three, four, five, three, the characteristic reptilian number.

Thus it is possible to be in doubt whether an extinct animal whose skeleton is completely known is an amphibian or a reptile, the break between the two being completely bridged so far as the skeleton is concerned. From a skeleton similar to that of *Seymouria* it is possible to derive those of all later reptiles, and in this way, by sorting out separate evolutionary lines to establish a classification which may express not only differences of structure existing between the animals contained in it, but something of their phylogenetic relationships.

Evolutionary Development.— The reptiles, as a whole, with a few doubtful exceptions, divide into two great branches, the mammal-like reptiles and the rest. The differences between the members of these two groups are to be found mainly in the structure of the brain case and the back of the skull. In all the

mammal-like reptiles the inner ear lies in the lower part of the side wall of the brain case, the brain extending far above it, while in all other reptiles the ear extends throughout the whole of the side wall of the cranium and is not exceeded in height by the brain. In *Seymouria* the tympanic membrane is stretched across a notch on the outer surface at the back of the skull; in the mammal-like reptiles this notch is destroyed, so that the occipital surface of the skull is flat and the tympanic membrane, if it exists at all, lies ventrally in the neighbourhood of the hinder end of the lower jaw, to one of whose elements it is attached. In the remaining reptiles the tympanic or otic notch is preserved, bounded above by a special process of the squamosal or tabular bone, and by the free distal extremity of the paroccipital. The tympanic membrane, when present, lies high up on the side of the head, far removed from the lower jaw. In the mammal-like reptiles the stapes is attached directly to the quadrate bone, while in the others it is continued by an extra columella which is inserted into the tympanic membrane.

It is customary to recognize a primitive group of reptiles, the Cotylosauria, which includes the most primitive members of each division of the reptiles. The animals included in it agree with *Seymouria* in that the dermal bones of the outer surface of the skull form a continuous sheet, perforated only by the nostrils, orbits and pineal foramen. This group is restricted to Permian and Triassic time, and its members thus possess very primitive limbs and limb-girdles. They are usually devoid of a neck, the shoulder-girdle lying immediately behind the head. The back is short and the vertebrae of which it is composed have very massive neural arches which articulate with one another by horizontal surfaces. The centra are perforated and transmit a continuous notochord. There is usually a series of intercentra throughout the column. The shoulder girdle has three bony elements, the scapula, procoracoid and coracoid in each side of the cartilage girdle; all of them contribute to the glenoid cavity. Cleithra are often present, and clavicles and large inter-clavicles are universal. The fore leg is short and massive, the humerus projecting out at right angles to the animal's body and lying in a plane parallel to the ground. It can only be moved backwards and forwards, and is incapable of rotation. The elbow joint is flexible, so that the fore arm has much freedom of movement. The hand has five fingers, the number of the phalanges being 2, 3, 4, 5, 3, in the digits from 1 to 5. The pelvis consists of an ilium, pubis and ischium on each side, these bones meeting one another in continuous sutures, so that the whole structure is "plate-like." The hind limb projects out laterally and the knee is relatively inflexible; it could be stretched out straight, but, in many cases, could not be closed even to a right angle. The foot has five toes with a digital formula 2, 3, 4, 5, 4.

This super-order can be divided into three sub-groups, as follows:—(A.) *Seymouria morpha,* primitive forms represented by three genera, *Solenodonsaurus,* from the Upper Carboniferous of Czechoslovakia; *Seymouria,* from the basal Permian of Texas, and *Kotlassia,* from the Upper Permian of Russia, which may not properly belong to the group.

These animals possess skulls which very greatly resemble those of the Embolomerous Amphibia. (*See* AMPHIBIA.) These skulls have a narrow otic notch differing from that of all other reptiles; the neural cranium is peculiar in that the powerful paroccipital processes which arise from the sides of the brain case extend outwards and upwards to support the tabular bones. The basioccipital, together with the exoccipitals, form a rounded condyle. There are well marked basisphenoidal tubera and the basipterygoid processes of the basisphenoid are short, and in *Seymouria* support the pterygoid, not directly, but through the intervention of the epipterygoid. The parasphenoid is short and narrow. The palate is almost completely roofed with bone, there being small palatal nostrils and sub-temporal fossae in addition to a very conspicuous inter-pterygoid vacuity. The palatine bears a large tusk, the marginal teeth in the upper jaw form a uniform unbroken series and exhibit an indefinite replacement. The lower jaw is built up from nine bones, dentary. splenial, post splenial, angular, sur-angular on the outer surface, the series of three coronoids between the prearticular and dentary, and an articular bone which, unlike that of all contemporary Amphibia, is not a mere part of the sur-angular. With this exception, the jaw is identical with that of a Labyrinthodont.

The vertebral column is massive, there is no distinction of neck, trunk, and lumbar region, all the vertebrae from the atlas back to the sacrum bearing two-headed ribs; there is one sacral vertebra. In the shoulder girdle a coracoid is absent, the lower part of the primary structure being ossified entirely as a pre-coracoid. The glenoid cavity has the characteristic screw-shaped form of the early Tetrapod. The humerus is an extraordinary bone, nearly as wide as it is long, while the fore arm is short. The hand is short and broad, the five fingers ending in small claws.

The pelvis is plate-like, the pubes and ischia being exceptionally large elements; the femur, short, broad and unusually massive, exactly resembles that of contemporary Amphibia. The fibula is widened distally, and the tarsus is remarkable among reptiles in possessing three bones in its proximal row, the intermedium being still separate from the tibiale. The foot is five toed, with the normal formula.

The mammal-like members of the Cotylosauria belong to the group (B.) Captorhinomorpha. This group includes a considerable number of reptiles, all of Lower Permian age, which vary a good deal in their general structure. The most typical are Captorhinus and its descendant, Labidosaurus. These animals are comparatively small, with no neck, rather long bodies and not excessively long tails. They had a straddling gait, the ventral surface touching the ground and the feet being placed well away from the side of the body. The head is pointed, the face in front of the eyes narrow, while the temporal region is wide. The skull is completely roofed and there is no trace of an otic notch, the head having a square cut appearance posteriorly. The brain case seems to be high, and is loosely connected with the rest of the skull by the summit of the supraoccipital and the ends of the paroccipital process. The stapes is very massive and extends from the fenestra ovalis, which is placed below the level of the brain, to the quadrate to which it is attached.

The lower jaw differs from that of *Seymouria* by a lateral compression of its hinder half, and by the reduction of the coronoids to one.

The vertebral column is characterized by the massiveness of the neural arches and the obsolescence of the neural spines. The centra are small and perforated, the intercentra much reduced. All the ribs are single-headed. The remainder of the skeleton does not differ materially from that of *Seymouria,* which has been described above.

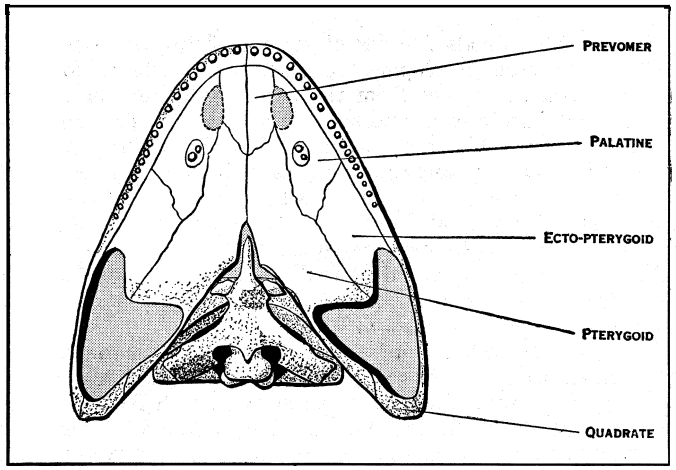


FIG. 4.—SKULL OF THE COTYLOSAUR SEYMOURIA (AFTER WATSON)

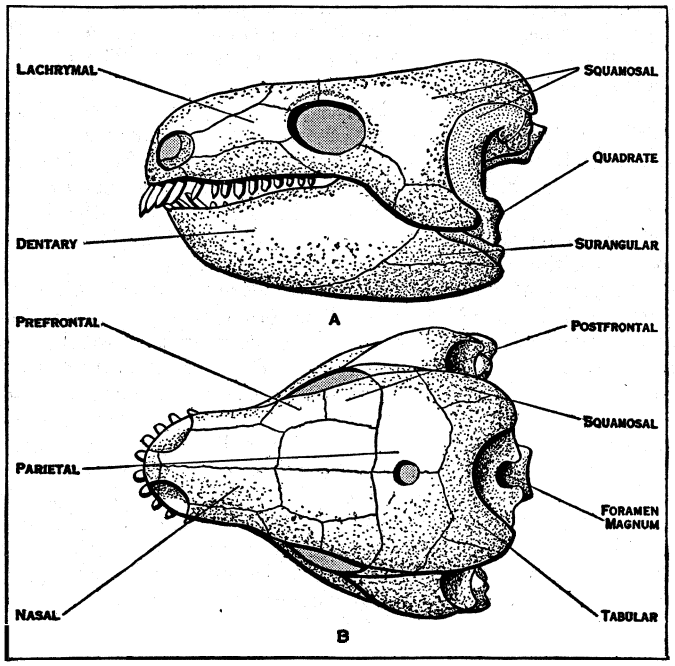
The earliest and most primitive members of the group of mammal-like reptiles belong to the order Pelycosauria. The most primitive members of this group, such as Varanosaurus and Mycterosaurus are small, rather slender animals, with elongated pointed heads. They had no visible neck, the shoulder girdle being placed behind the skull. The body was long and the

tail even longer. Their skulls differ from those of the Captorhinomorpha most obviously in that the dermal roof is no longer complete, but is perforated by a large lateral vacuity which is bounded by the jugal, postorbital and squamosal bones. This opening serves to give room for the thickening of the masticatory muscles, which necessarily occurs when they are shortened so as to close the mouth.

Another important difference is that the supraoccipital bone becomes so widened that, with the overlying interparietal and tabular, it forms a plate on the hinder surface of the skull, which reduces the post-temporal fossae to very small proportions.



FROM WILLISTON, "OSTEOLOGY OF REPTILES", (HARVARD UNIVERSITY PRESS)

FIG. 5.---SKULL OF THE CALYLOSAUR, DIADECTES; (A) LEFT SIDE WITH LOWER JAW, (B) FROM ABOVE

The only important changes in the post cranial skeleton are that the neural arches become light and narrow, the neural spines high, and the articulation faces of the zygapophyses are obliquely placed.

From such animals a series of short evolutionary lines arose, which led to the development of some extraordinary forms in which the neural spines from the head to the root of the tail become immensely elongated, and, in some cases, provided with lateral processes like the yard-arm of a ship. These animals, Dimetrodon and Naosaurus, must have been of grotesque appearance, one with a huge head with great piercing teeth, the other with a very small head with crushing dentition, each with a crest, as high as its own length from head to the root of the tail. Animals so specialized naturally had only a short range in time, they only occur in Lower Permian rocks, but the latter ranged from Czechoslovakia to Texas.

More conservative members of the group gave rise to a number of reptilian orders whose remains have been found in the Middle and Upper Permian rocks of Europe and South Africa, and in the Trias of South Africa, Asia and North America. The most important of these orders, the Theriodontia, included the ancestors of the mammals, and its members exhibit a series of stages which seem to bridge the structural gap between a Pelycosaur and a mammal very completely.

Some of these changes are illustrated by a comparison of the skulls of *Scymnognathus* and *Cynognathus*.

The skull of *Scymnognathus*, a Gorgonopsid, differs from that of a primitive Pelycosaur in that in it the whole head is flattened, the temporal vacuity, instead of facing laterally, is directed upward and is greatly increased in size; this change implies that the muscles which close the mouth had changed, an originally rather simple mass splitting up into pterygoidal, temporal and masseter muscles. In order to give room for this powerful development the side of the roof of the skull, formed by the jugal postorbital and squamosal, is bowed out, with the result that the quadrate and quadrato-jugal, being fixed in position by their articulation with the lower jaw, become detached from the side of the head and remain inserted in a depression on the front face of the squamosal, within the temporal vacuity. At the same time they are somewhat reduced in size.

The enlarged masticatory muscles require a more extensive area of attachment on the lower jaw, to provide which the upper and hinder end of the dentary becomes free and grows upward. At the same time, the hinder half of the jaw, composed of the surangular, angular, articular and prearticular bones, become converted into a thin sheet by a lateral compression, and the lower border of the angular is notched, a special lamina of the bone being reflected over the outer surface of its posterior part. To this reflected lamina the lower edge of the tympanic membrane seems to have been attached.

The palate, though it still has the posterior nares placed far forward, is advanced because it is very much vaulted, owing to the downgrowth of the maxillae on each side of it. Posteriorly, the pterygoids, with a parasphenoid held between them, form a narrow girder which connects the basisphenoid with the anterior part of the palate.

The stapes still articulates with the quadrate. The brain case is incompletely ossified in front of the point of exit of the fifth cranial nerve. The branches of that nerve pass on each side of the rod-like epipterygoid, and the cerebral hemispheres are enclosed in a single ossification homologous with the sphenethenoid of a frog.

Cynognathus has advanced beyond *Scymnognathus* in that the face has become deeper and more rounded, and the nostrils larger. The temporal vacuity has enlarged so that it is bounded above by the parietal, and this bone is drawn up into a deep sagittal crest which allows of longer temporal muscles. The quadrate and quadrato-jugal have become greatly reduced in size, but retain their position and function.

The coronoid process of the dentary has increased enormously, and now overlaps the rest of the lower jaw so greatly that it has nearly, but not quite, acquired an independent articulation on the squamosal.

The hinder part of the lower jaw, though still retaining all its constituent bones, has become so small that it seems inadequate to resist the very great stresses to which it might be subjected during feeding. The reflected lamina of the angular is still present in the form of a slender downturned process.

The palate has changed greatly, the original roof of the median area is still present in part, but it is concealed from view by a secondary palate exactly like that of a mammal, which is formed by ingrowths from the maxillae and palatines. By this change the posterior nares are driven so far backward that they open behnd the cheek teeth, and the animal became capable of breathing whilst the mouth was full of food undergoing mastication. The ectopterygoid is greatly reduced, and the posterior part of the pterygoid, the quadrate ramus, has vanished altogether, its place being taken by a process which grows backward from the root of the epipterygoid.

The side walls of the brain case have become bony by a widening of the upper end of the epipterygoid, now recognizable as the homologue of the mammalian alisphenoid. This arrangement involves the inclusion in the cranial cavity of a space, the cavum epiptericum, which in most other reptiles lies outside the cranium. By a continuation of changes in the same direction as those which converted a Gorgonopsid such as *Scymnognathus* into the Cynodent *Cynognathus*, a primitive mammalian structure is easily reached.

The face changes little, a disappearance of the internarial processes throws the bony nostrils into one, the prefrontal and postorbital disappear, and the orbit becomes confluent with the temporal fossa.

Further growth of the dentary leads to the development of a new temporo-mandibular joint between that bone and the squa-

mosal, and the quadrate and hinder part of the jaw, freed from any function in connection with the jaw, become available as auditory ossicles. The stapes persists, little changed, the quadrate, further reduced in size, becomes the incus. The articular is the malleus, and the prearticular its processus folianus. The angular, to which the tympanic membrane has been attached for a very long period, becomes the tympanic, and the surangular disappears.

This account of the origin of the mammalian auditory ossicles is confirmed by the mode in which those bones develop in every mammal; indeed, all marsupials are still born in a stage in which the lower jaw still moves on the old reptilian joint between the incus and malleus, and the musculus tensor tympani still functions as a jaw muscle.

The palate of *Cynognathus* requires very few modifications to become typically mammalian. The already minute ectopterygoid vanishes, the great flanges of the pterygoids, which exist to ensure the accurate closure of the mouth, become unnecessary when the new temporo-mandibular joint is established, and vanish, and the posterior ramus of the alisphenoid becomes the tympanic process.

The skull of *Scymnognathus* is connected to the complex atlas by a single condyle composed of the basi and exoccipitals, that of *Cynognathus* has a mammal-like pair of exoccipital condyles.

More serious modifications have to be made in the ear region and brain case. The opisthotic and pro-otic of *Cynognathus* house only part of the inner ear, the summit of that organ lying in the supraoccipital. In mammals, the whole lies in a single bone, the periotic. The mammalian periotic is a much smaller bone than the pro- and opisthotics of a cynodont, and, unlike them, it is comparatively unimportant as a buttress for the squamosal. None the less, it is not impossible to homologize the different regions of the two sets of structures.

The post-cranial skeleton of Cynodonts shows a similar resemblance to that of mammals, some of the more important features of the evolution being discussed in the section *Locomotion* of this article. Thus we know in considerable detail the evolutionary stages which lie between the structure of an embolomerous amphibian and that of a mammal. Unfortunately, we can trace no such ancestry for the birds. We are certain that they sprang from a group of reptiles very remote from the mammal stock, but we are still faced by a considerable gap.

Classification.—The classification of reptiles is necessarily based on skeletal characters, and is still in a state of flux. The existing divergences of view are not very important; they relate to the phylogenetic position of a few orders, and do not seriously affect the main outline.

Class **Reptilia.**—Tetrapodous vertebrates, which breathe air throughout their life. The body temperature is variable. The heart possesses a sinus venosus. two auricles and a ventricle incompletely or completely divided into two; there is no conus arteriosus. Both svstemic arches persist. The red blood corpuscles are nucleated, oval and biconvex. The kidney is a metanephros, and there is an allantoic bladder, in most forms. There is a cloaca, which in living reptiles is divided into a series of regions. The skin is either naked or covered with scales, never with feathers or hair. It includes very few glands, always placed in special situations, and not generally distributed. The skeleton is ossified. The skull comprises a cranium, of cartilage bones, and an extensive series of bones, which, dermal in origin, sink in and become membrane bones in the later forms. The occipital condyle is single or double. The lower jaw articulates with a quadrate bone and is built up of a number of bones. There is a rod-like columella auris. The vertebrae consist mainly of centra and neural arches, intercentra, when present, being small. Ribs occur on all precaudal vertebrae, those in the thoracic region joining to form a sternum in the mid-ventral line.

The pectoral girdle, when fully developed, includes at least a scapula and precoracoid, clavicles and an interclavicle. The pelvic girdle, except in one or two cases, articulates with two or more sacral ribs. The limbs are primitively pentadactyle and the phalangeal formula 2, 3, 4, 5, 3 or 4.

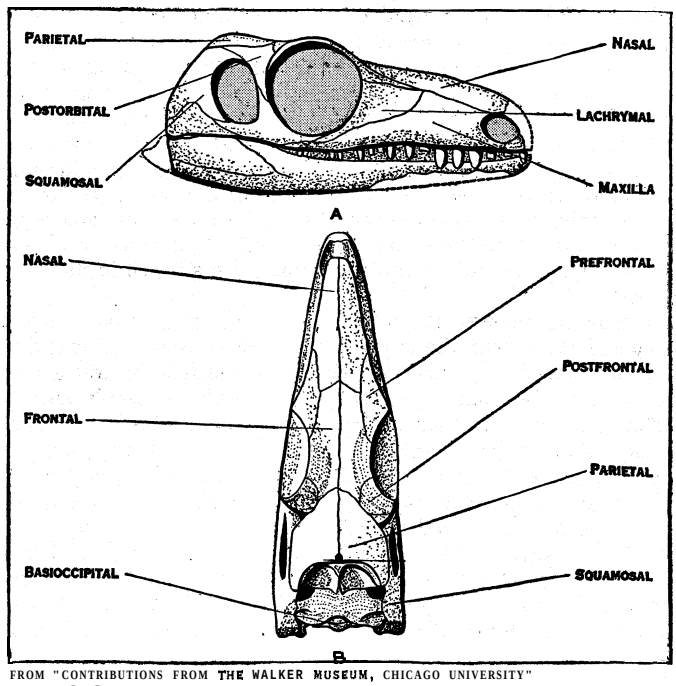
Fertilization is internal, the eggs are large and yolk laden, usually laid, when they are surrounded by a coat of albumen and a shell which is often calcified. Cleavage is meroblastic, a primitive streak is not formed, the embryo is surrounded by an amnion and an allantois is developed.

Super-order. Cotylosauria. Archaic reptiles in which the temporal region of the skull is completely covered by a continuous roof of dermal bones. Stapes either articulating with the quadrate or ending in a tympanic notch. Lower jaw usually with more than one coronoid. Presacral vertebrae (except in Pantylus) with very heavy neural arches with horizontal zygapophysial articular faces. Ribs one or two headed. No ossified sternum. Abdominal ribs sometimes present as fine bony rods. Shoulder girdle with scapula and precoracoid at least, a coracoid usually present in addition. Cleithra usually, clavicles and an interclavicle always present. Humerus with (usually) a screw-shaped head, short and with widely expanded extremities. Pelvis, plate-like, the suture between the pubis and ischium extending from the acetabulum to the middle line.

Order 1. Seymouriamorpha. Cotylosaurs in which the skull greatly resembles in all external features that of the Embolomerous Labyrinthodonts, the dermal bones are sculptured and the otic notch extends far forward below the tabular and supratemporal, so that the quadrate slopes backward. Stapes ending in the otic notch. Fenestra ovalis low down on the cranium, below the level of the base of the brain. Intercentra present and very large, ribs one or two headed. Only one sacral vertebra. Shoulder girdle without coracoid or cleithrum, limbs primitive.

Upper Carboniferous to Upper Permian. Families, *Seymouriidae, Kotlassiidae.*

Order 2. Captorhinomorpha. Cotylosaurs in which the otic notch has been obliterated by a movement backward of the upper end of the quadrate. Dermosupraoccipitals and tabulars, when present, restricted to the occipital surface. Stapes articulating



FROM "CONTRIBUTIONS FROM THE WALKER MUSEUM, CHICAGO UNIVERSITY"

FIG. 6.—SKULL OF PELYIOSAUR MYCTEROSAURUS; (A) RIGHT SIDE WITH LOWER JAW, (B) SKULL FROM ABOVE

distally with the quadrate. Brain case behind the incisura prooticum short and high, fenestra ovalis ventrally situated. Intercentra usually present. One or two sacral vertebrae. Shoulder girdle with both precoracoid and coracoid. Cleithrum present or absent. Limbs' primitive, though sometimes slender.

Lower Permian. Families *Captorhinidae, Pantylidae, Limnoscelidae.*

Order 3. Diadectomorpha. Cotylosaurs in which the otic notch is enlarged by a movement forward of the lower end of the quadrate, dermosupra occipitals and tabulars when present on the

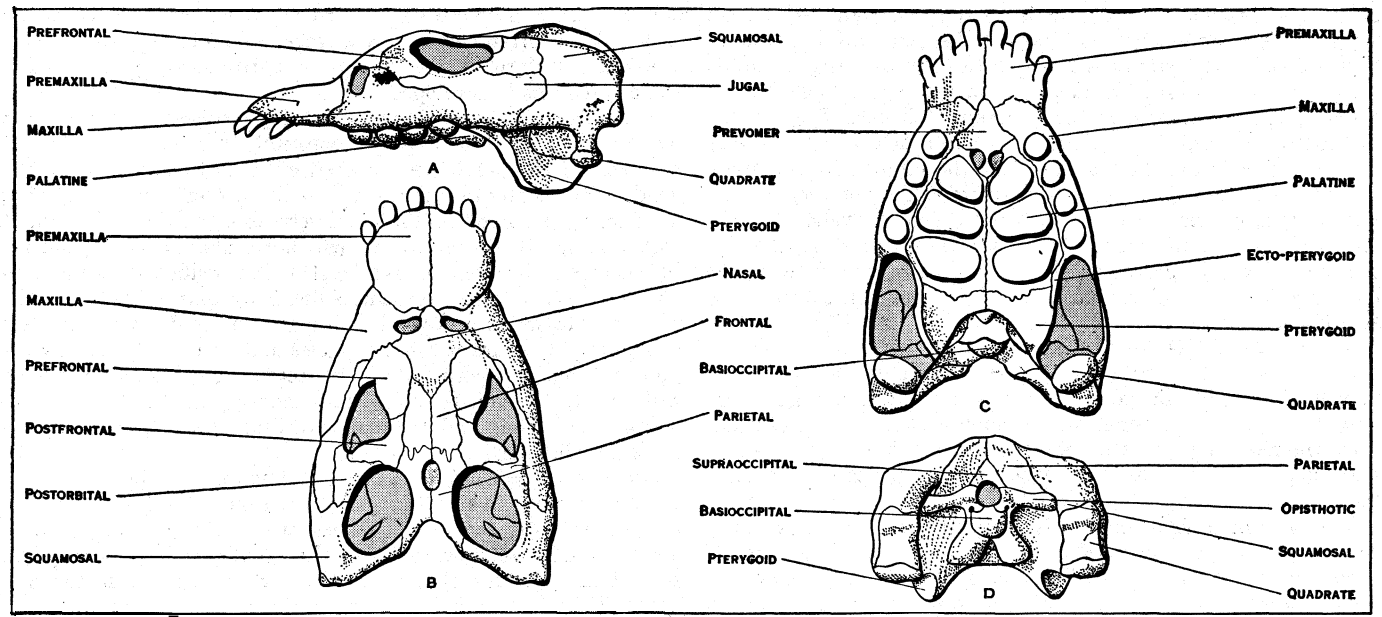


FIG. 7.— SKULL OF PLACODUS: (A) LEFT SIDE. (B) FROM ABOVE, (C) FROM BELOW, (D) OCCIPUT (AFTER BROLI)

upper surface of the skull, the latter overhanging the otic notch. Stapes terminating freely in the otic notch. Brain case long, fenestra ovalis placed at about the middle of its height. Intercentra usually present. Two to four sacral vertebrae. Shoulder girdle with a scapula alone or with three cartilage bones. Cleithrum usually present. Humerus always with expanded ends but often of advanced structure. Ilium sometimes backwardly directed.

Lower Permian to Middle Trias. Families: *Diadectidae, Pariasauridae, Procolophonidae*

Super-order Theromorpha (or *Anomodontia*). Mammal-like reptiles. Reptiles in which the temporal region of the skull is perforated by a single vacuity, bounded primitively by the postorbital and squamosal, but enlarging so that the parietal and jugal also enter its borders. Cranium short and high behind the incisura prooticum, fenestra ovalis below the level of the base of the brain. Stapes articulating with the quadrate. The lower jaw, and especially its hinder end, laterally compressed, the angular in all except, perhaps, the most primitive forms, with a notch in its lower border.

A pro-atlas present, the neural arch of the atlas usually a pair of bones, which, with the intercentrum, rest on the anterior end of a trefoil-shaped odontoid. Vertebrae with slender neural arches with oblique articular faces, centra notochordal or deeply amphicoelous. Intercentra usually present, at any rate in the cervical region, ribs always two-headed anteriorly, usually single-headed posteriorly. An ossified sternum sometimes present, abdominal ribs present as slender rods in primitive forms. Pectoral girdle with scapula, precoracoid and coracoid in all forms (except one, Varanops), clavicle with expanded lower end, and interclavicle a wide flat sheet. Cleithra usually present, but small. Pelvis very variable, plate-like in primitive forms, with an obturator foramen in later types. Ilium, directed forwards, vertically, or backward. Two to seven sacral vertebrae. Limbs exhibiting all stages of advance from primitive cotylosaur-like organs to a pro-mammalian condition. Digital formula primitively 2, 3, 4, 5, 3 or 4 reduced to 2, 3, 3, 3, 3 in later forms.

Order 1. Pelycosauria. Primitive Theromorpha in which the pterygoids articulate with the basipterygoid processes of the basisphenoid by a movable joint. The quadrate is relatively large and the quadrato-jugal forms part of the lateral surface of the skull. The shoulder girdle has a screw-shaped glenoid cavity shared by the scapula, coracoid and precoracoid, and the limbs are primitive. The pelvis is plate-like.

Upper Carboniferous and Lower Permian. Families: *Poliosauridae, Ophiacodontidae, Sphenacodontidae, Edaphosauridae, Caseidae, Bolosauridae, Palaeohatteriidae.*

Order 2. Deinocephalia. Theromorpha in which the pterygoids are attached to the basisphenoid by an immovable joint. The basioccipital and basisphenoid are produced downward below the occipital condyle as a thick sheet of bone. The quadrate is unreduced and the quadrato-jugal is on the lateral surface. The shoulder girdle in early forms has the glenoid cavity borne only to a very slight extent on the precoracoid, but it is screw-shaped; in later forms this structure disappears and the glenoid cavity is restricted to the scapula and toracoid. The limbs are of modernized type. The pelvis is plate-like, the ilium being attached to four sacral ribs.

Middle Permian. Families: *Tapinocephalidae, Titanosuchidae.*

Order 3. Dromosauria. Small Theromorpha in which the facial region of the skull is very short, the temporal fossa is bounded above by the postorbital and squamosal and the zygomatic arch is reduced to a narrow rod so that the quadrate and quadrato-jugal project below it. Shoulder girdle with the glenoid cavity on the scapula and coracoid, precoracoid large. No cleithra Pelvis plate-like. Limbs very long and slender, digital formula 2, 3, 3, 3, 3.

Upper Permian. One family only.

Order 4. Dicynodontia (or *Anomodontia).* Theromorpha in which the preorbital part of the skull is very short, whilst the temporal vacuity is greatly enlarged. The latter is bounded above by the postorbital and squamosal. The quadrate and quadrato-jugal are reduced, and rest in a recess in the front face of the lower end of the T-shaped squamosal, which is widely expanded laterally so as to form a sheet in the plane of the occipital surface. The pterygoids are rigidly fixed to the basisphenoid, and are not produced into transverse flanges. The premaxillae are fused and toothless, the maxillae may have a large canine or a series of small cheek teeth, or both, or be toothless. A horny beak like that of a tortoise was always present. The articular of the lower jaw always has the unique feature of a convex articular surface. Intercentra are absent except in the atlas and axis. The tail is short. The glenoid cavity is entirely, or almost entirely, restricted to the scapula and to the coracoid. There is an acromium on the scapula which also shows the beginnings of a mammal-like scapular spine.

There is an obturator foramen in the pelvis. The limbs are short and powerful, the track wide, and the digital formula 2, 3, 3, 3, 3.

Upper Permian to Middle Trias. Division into families not yet carried out.

Order 5. Theriodontia. Theromorpha in which there is a differentiation of the dentition into incisors, canine and cheek teeth. The face is usually long, the temporal fossa, short in primitive forms,

elongated in the more advanced types, the parietal entering into its border.

Quadrate and quadrato-jugal, fused, much reduced and carried in a recess on the front face of the squamosal.

Pterygoids forming great transverse flanges, behind which they suddenly contract to form a narrow girder extending back to the basisphenoid. Palate at first with the large posterior nares placed anteriorly, becoming vaulted, the air passage being finally cut off from that for the food by a secondary palate. The dentary, always extending above the surangular, in a free coronoid process. Limbs and their girdles variable.

Sub-order 1. Gorgonopsia. Primitive Theriodonts, with the postorbital and squamosal meeting above the temporal fossa. Single occipital condyle: No sub-orbital vacuities. No secondary palate. Scapula without acromion, plate-like pelvis, digital formula (of hand) 2, 3, 4, 5, 3.

Upper Permian.

Sub-order 2. Cynodontia. Advanced Theriodonts, with the parietai entering the temporal fossa. No sub-orbital vacuities. A secondary palate. Pair of exoccipital condyles. Scapula with acromion. Pelvis with an obturator foramen. Limbs modernized, digital formula 2, 3, 3, 3, 3.

Top of the Permian and Lower Trias.

Sub-order 3. Therocephalia. Primitive Theriodonts with large temporal vacuities into whose border the parietal always enters. Large sub-orbital vacuities. No secondary palate or vaulting of the mid line of the anterior part of the palate. Single occipital condyle.

Upper Permian.

Sub-order 4. Bauriamorpha. Advanced Theriodonts, with the parietal forming part of the temporal fossa. Large sub-orbital vacuities, a secondary palate. Single occipital condyle.

Lower to Upper Trias.

Order 6. Thalattosauria. A group of marine reptiles, still incompletely known, but perhaps allied to the Pelycosauria. If so interpreted they may be defined by the following characters:—Skull with a very elongated face formed by the maxillae and premaxillae, nostrils dorsal and immediately in front of the large orbit, nasais small. The large temporal fossa is entirely lateral and is bounded above by the postorbital and squamosal. Quadrate large. A supratemporal present. Parietals short and wide. Vertebrae with biconcave centra which are short cylinders, ribs single-headed. Scapula and coracoid incompletely ossified. Humerus with expanded ends and a twisted shaft. Radius and ulna short flattened bones.

Upper Trias.

Super-order Archosauria (Diaptosauria). Reptiles in which the temporal region of the skull is perforated by two vacuities, the upper of these, the supratemporal fossa is bounded by the parietal, supratemporal, squamosal and postorbital the lower, the infratemporal fossa lies between the postorbital squamosal, quadrato-jugal and jugal bones.

The brain, at any rate in the later forms, is completely enclosed by bone, a pair of latero-sphenoids surrounding the cerebral hemispheres and stretching back to have a suture with the pro-otic. The epipterygoid forms no part of the wall of the cranial cavity. The fenestra ovalis lies half way up the wall of the brain case. There is always a distinct neck, often of eight vertebrae.

The pectoral girdle contains a scapula and precoracoid on each side, the true coracoid never appearing. Cleithra are never present. The sternum usually ossifies from a pair of centres. The limbs are never of the primitive Cotylosaurin character, and are often very highly modified. The digital formula is 2, 3, 4, 5, 4 or 3.

Order 1. Thecodontia. Primitive Archosauria in which a supratemporal, tabular and interparietal may be present in the skull. A preorbital vacuity may be present or absent. The ribs may have one or two heads and a sternum if ossified is paired.

Clavicles and an interclavicle are always present, the pelvis is plate-like, and there are only two sacral vertebrae.

Upper Permian to Upper Trias. Families: *Eosuchidae, Phytosauridae, Pseudosuchidae, Erythrosuchidae, Erpetosuchidae* and others not yet defined.

This order is, in a sense, artificial, it includes the ancestors, for the greater part unknown, of the remainder of the orders of Archosauria, and in addition contains a number of animals which belong to short-lived unsuccessful side branches.

Order 2. Crocodilia. Archosaurs usually of medium or large size, and adapted more or less completely to an aquatic habit. The skull is characterized most clearly by the fact that the quadrate is very large, and lies at a very low angle with the horizontal. The wedge-shaped otic cavity so formed is closed behind by a downgrowth of the squamosal, which, with the overlapping "exoccipital" reaches the quadrate. The tympanic membrane lies some distance below the outer surface, and the external auditory meatus can be closed by a muscular flap. The elongated face is chiefly formed by the maxillae, the external nostrils, usually confluent in the bony skull lying quite anteriorly. There is always a secondary palate, the choanae lying posteriorly between the palatics or pterygoids. The vertebrae are amphiplatean or procoelous, the ribs double-headed throughout the presacral part of the column, the dorsal ribs articulating entirely with the neural arch. The coracoid is elongated, clavicles are absent; and the sternum is unossified. The ilium is a small bone supported by two sacral ribs, and the pubis is excluded from the acetabulum.

The hand is five-fingered, the foot has the fifth toe reduced to a stump of its metatarsal.

Lower Jurassic (Upper Trias) to Recent. Families: *Teleosauridae, Metriorhynchidae, Dyrosauridae, Goniopholidae, Libycosuchidae, Pholidosauridae, Stomatosuchidae, Gavialidae, Crocodilidae.*

It is not improbable that the Crocodilia sprang from the family *Erpetosuchidae* of the order Thecodontia.

Order 3. Saurischia (Deinosauria parts) Archosauria, with a well-developed preorbital vacuity. The neck is sharply marked off from the trunk. The presacral ribs are two-headed, and the dorsal ribs articulate only with the neural arch. Clavicle and interclavicle are lacking, the coracoid is short. There are three or more sacral vertebrae. The pubis and ischia form diverging rods, primitively the pelvis is plate-like, but the bones separate from one another in later forms. The acetabulum is perforate. The fore limb is shorter than the hind, and the femur moves in a plane parallel to the animal's length. The body is thus held well above the ground, and the animal is often bipedal.

Sub-order Theropoda. Carnivorous Saurischia, in which the dentition consists of a single series of the codont, laterally compressed teeth in the premaxillae and maxillae. The cervical vertebrae may be opisthocoelus. The fore limb is often very much smaller than the hind, and the animals are usually bipedal. The hand tends to be reduced to the first three fingers, which are provided with powerful claws, and the foot becomes functionally tridactyl and symmetrical about the third toe.

Middle Trias to Upper Cretaceous.

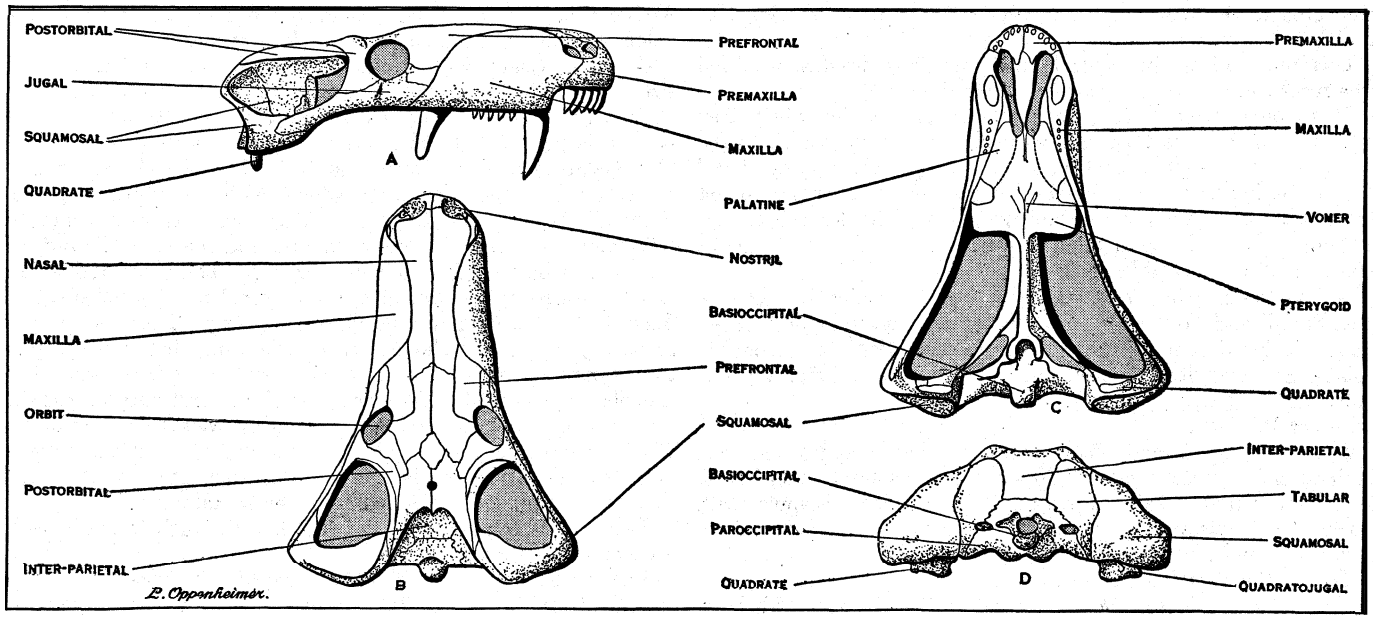
Families: *Hallopidae, Podokosauridae, Coeluridae, Compsognathidae, Ornithomimidae, Plateosauridae, Zanclodontidae, Anchisauridae, Megalosauridae, Spinosauridae.*

Sub-order Sauropoda. Herbivorous Saurischia, usually of gigantic size. The skull is extremely small, and the dentition feeble. The cervical and many or all the dorsal vertebrae opisthocoelic, Accessory articulating faces are developed in the neural arch of the dorsal vertebrae. The dorsal centra are excavated laterally, so that they may be reduced to mere shells of bones.

The animals are quadripedal, and walk on the ends of the metapodials, both feet are five toed, but some of the digits have a reduced number of phalanges and most lack claws.

Middle Jurassic to Upper Cretaceous. Families: *Cetrosauridae, Allantosauridae, Camarosauridae, Diplodocidae, Titanosuchidae.*

Order 4. Ornithischia (Deinosauria pars). Archosauria of herbivorous diet. The preorbital fossa is usually small or absent, the nostrils very large. The quadrate, unless secondarily fixed, is movable, a spherical head on its upper extremity resting in a cup in the squamosal. Premaxillae usually toothless, and covered with a horny beak, which opposes a similar structure carried by a special predentary bone in the lower jaw. Posterior end of the dentary raised into an upstanding coronoid process. The pubis bifid, a prepubic process stretching forward along the belly, and a posterior part passing downward and backward parallel to the



BY COURTESY OF THE ZOOLOGICAL SOCIETY OF LONDON

FIG. 8.—SKULL OF THE GORGONOPSID REPTILE, SCYMNOGNATHUS
A. Right side, B. from above, C. from below, D. occiput

ischium. Ilium elongated anteroposteriorly. Acetabulam perforate. Fore leg shorter than the hind, the animal being often bipedal. Hand usually pentadactyl, foot often tridactyl.

Rhaetic to Upper Cretaceous.

Super-family Ornithopodidae. Families: *Hypsilophodontidae, Camptosauridae, Ignanodontidae, Trachodontidae. Super-family Stegosauridae.* Families: *Scelidosauridae, Stegosauridae, Acanthopholidae, Polocanthidae. Super-family Ceratopsidae,* with one family.

Order 5, *Pterosauria.* Archosauria fully adapted for flight. The vertebrae and many long bones are hollow and, where occupied by air sacs, arising no doubt, like those of birds, by extension of the bronchi. Skull elongated, triangular in plan, and peculiar in that the quadrato-jugal excludes the jugal from the border of the infra temporal fossa. Teeth may extend throughout the jaws, be restricted to their anterior ends, or be absent altogether.

Cervical vertebrae large, procoelous, and very freely movable, head carried nearly at right angles to the neck. Dorsal vertebrae small, sometimes largely fused, sacrum of four to 10 vertebrae, tail either very short or greatly elongated and quite stiff.

Scapula and coracoids elongated slender rods, the latter articulating with a large shield-shaped sternum. Clavicular arch absent. Ilium long, pubis and ischium fused with it and with each other, not meeting in a median symphysis. Prepubic bones present. Fore limb supporting a wing, which is formed by a fold of skin arising from the side of the body and stretched between the upper arm, fore arm and greatly extended fourth finger, and the hind leg. Fingers one to three, present and clawed.

Sub-order Rhamphorhynchoidae. Pterosaurs, with a long tail, wing metacarpal short, fifth toe well developed.

Upper Trias? Lower Lias to Upper Jurassic.

Sub-order Pterodactyloidae. Pterosaurs, with a short tail, wing metacarpal long, and fifth toe reduced or absent.

Upper Jurassic to Upper Cretaceous. Families: *Pterodactylidae, Ornithocheiridae.*

The birds, class Aves, are certainly descendants of Archosaurian reptiles; had the group become extinct in Cretaceous time it would be regarded as an order equivalent to those listed above.

The remaining reptilian orders cannot usefully be grouped into super-orders.

Order Rhynchocephalia. Reptiles in which the temporal region is perforated by two fossae; the supratemporal fossa seems to differ from that of Archosauria in that the post frontal enters into its margin, whilst the infratemporal fossa differs by the exclusion of the quadratojugal.

The preorbital part of the skull is short, and there is no preorbital opening. The fenestra ovalis is placed high in the skull. The dentary bears a single series of acrodont teeth which bite into a groove between the similar teeth on the maxilla and palatine, so that with use they acquire a wedge-shaped section. The vertebrae have amphicoelous centra, and all the ribs are single-headed. An unossified sternum is present. The shoulder girdle includes scapulae, precoracoids, clavicles and an interclavicle.

The pelvis has an ilium attached to two sacral vertebrae and directed downward in front. The pubis and ischia are plate-like in primitive forms, but diverge widely in later times. The limbs are pentadactyl, and the fifth metatarsal has a hook-shaped upper extremity.

One group of Rhynchocephalia, the *Champsosauridae,* became highly adapted to an aquatic life in estuaries.

Middle Trias to Recent. Families: *Rhynchosauridae, Saurano-dontidae, Sphenodontidae, Champsosauridae.*

Order Squamata. (The following account does not include the characters of the reptile Pleurosaurus, which is, perhaps, a member of the order.)

Reptiles in which the dermal roof of the temporal region is so far reduced that only a single temporal arcade, or none at all, remains. The quadrate is thereby freed so that it can move, its rounded head articulating with one or two bones which are connected with the parietal. If two bones be present the inner is firmly applied to the front face of the posterior wing of the parietal, and rests against and may even be firmly fixed by suture to the front face of the end of the paroccipital process. This bone is either the supratemporal or squamosal, or, very improbably, tabular. The outer bone is fixed to the lateral surface of the inner, often overlapping it on to the parietal; it stretches forward as the hinder part of the temporal arcade, and meets the postorbital and sometimes the jugal. This bone is either the squamosal or quadrato-jugal. In the palate the pterygoid no longer reaches the prevomers, and the whole is often very lightly constructed.

The vertebrae are usually procoelous, but may be amphicoelous; there are two sacrals or none. Ribs are single-headed throughout. The shoulder girdle, if present and fully developed, consists of scapulae and precoracoids, often enlarged and notched or fenestrated, clavicles, an interclavicle and a sternum. The pelvis has a forwardly and downwardly directed ilium, the pubes and ischia are divergent rods. The limbs are pentadactyl primitively, but may be reduced or absent.

Sub-order Lacertilia (Lizards). Squamata in which a temporal arcade is usually present, and in which the two rami of the lower

jaw are connected suturally at the symphysis. An epipterygoid is present in the normal position and the anterior part of the brain case is very little ossified. The pterygoid articulates with the basipterygoid process of the basisphenoid.

Upper Jurassic to Recent.

Division Ascalabota.

Section Gekkota.

Families: *Ardeosauridae, Gekkonidae, Uroplatidae.*

Section Iguania. Families: *Iguanidae,* and *Agamidae.*

Section Rhiptoglossa. Family *Chamaeleontidae.*

Division Antarchoglossa. Section Scincomorpha. Families: *Xantusiidae, Scincidae, Anclytropiidae, Flyliniidae, Dibamidae, Gerrhosauridae, Lacertidae, Tejidae, Amphisbaenidae.* Section Anguimorpha. Families: *Euposauridae, Varaniidae, Dolichosauridae. Aigialosauridae, Mosasauridae, Pygopodidae, Glyptosauridae, Helodermatidae, Anguidae, Xenosauridae, Anniellidae, Zonuridae.*

Sub-order Ophidia (Snakes). Squamata in which the temporal arcade has completely vanished, and the quadrate is very freely movable. The pterygoids have lost all connection with the basisphenoid, and the palate has become mobile, connected to the cranium only by ligaments and by its connection with the maxillae and quadrate. Much of the palate and the maxillae may vanish in burrowing forms. The brain case is completely ossified, the epipterygoid being absorbed into it. The two halves of the lower jaw are loosely connected by an extensible ligament.

The vertebral column is extraordinarily long, in one case containing 565 vertebrae. Each vertebra has a procoelous centrum and a heavy neural arch, on which additional articulating faces, the zygosphenes, and zygantra, are developed. The single-headed ribs are long and are very freely movable antero-posteriorly; by such movements they cause the transversely widened ventral scales to catch the ground, and force the animal along.' There is never any trace of a fore limb or its girdle. All three elements of the pelvic girdle may be present in one family, the Glauconidae, but in most this limb is entirely absent. Upper Cretaceous to Recent.

Families: *Typhlopidae, Glauconiidae, Ilysiidae, Uropeltidae, Boidae* (boa constrictors), *Xenopeltidae, Colubridae.* As the last family contains nine-tenths of all known snakes it is subdivided into the series Aglypha (harmless snakes), Opisthoglypha (poisonous but little dangerous to man) and Proteroglypha (typical poisonous snakes).

Sub-order Pleurosauria. A small group of extinct reptiles including only one or two genera, which may be related to the Squamata; if so, these are not, as usually held, derived from the Archosauria. Aquatic reptiles with a very long body and lizard-like limbs partially adapted for swimming. Limb girdles of Lacertilian type. Skull elongated and depressed, quadrate short and immovable. There is a single temporal fossa, bounded below by a broad arcade composed of the squamosal, postorbital and jugal. There is no supratemporal, and the outer surface of the quadrate is covered by a quadrato-jugal. Upper Jurassic. One family.

Order Sauropterygia (Plesiosauria). Reptiles which show a progressive adaptation to a marine life.

Skull with a single temporal vacuity surrounded by the parietal, squamosal, postorbital and post-frontal, and therefore apparently homologous with the upper temporal vacuity of Rhynchocephalia, and not with the single fossa of Theromorpha and Squamata. The single temporal arcade is formed almost entirely by the squamosal and postorbital, the jugal being a small bone wedged in between the postorbital and the hinder end of the maxilla. A quadrato-jugal is absent. The fenestra ovalis lies high in the side wall of the brain case. The palate is primitive, the posterior nares being anterior, and the pterygoids reaching the prevomers.

Except in Placodonts, the neck is long, often exceedingly so (76 vertebrae in Elasmosaurus), the back is long and the tail short; there are usually three sacral vertebrae, but may be more. The cervical ribs, though double-headed in early forms, articulate only with the centra, the single-headed dorsal ribs being supported entirely by the long transverse process of the neural arch.

The pentadactyl limbs are large, and are more or less completely converted into paddles by a flattening and shortening of the radius and ulna and tibia and fibula, and an increase in the number of phalanges. The shoulder girdle consists of scapulae and coracoids, which meet one another in median suture. Clavicles are'probably always present, an interclavicle usually so. The ilium is small, the pubis and ischium, though separated by an obturator foramen, are expanded into flat sheets of bone. A strong plastron of abdominal ribs is always present.

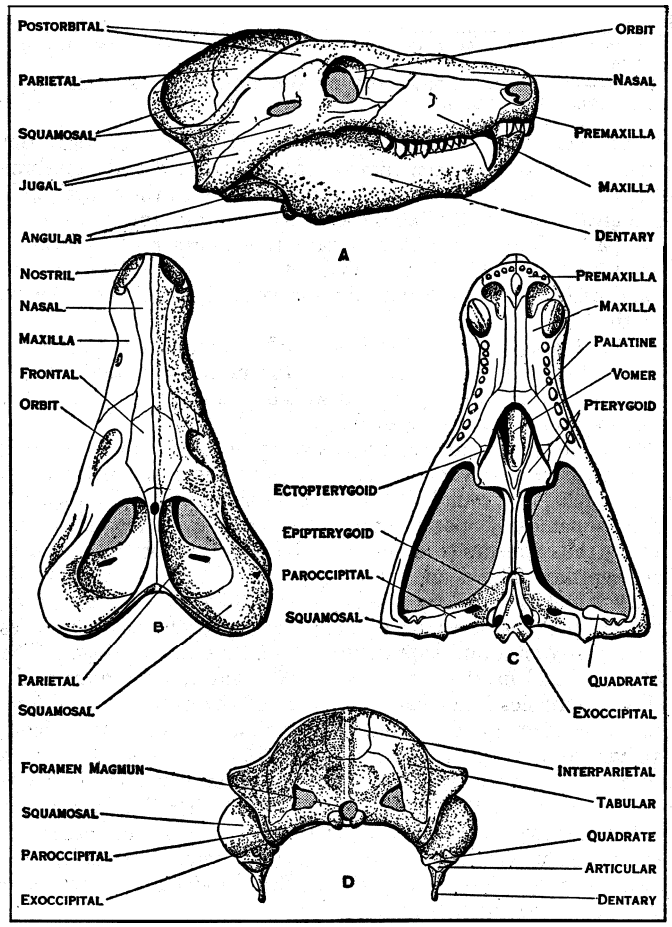
Sub-order 1. Trachelosauria. A single, small reptile, with a long neck consisting of 20 vertebrae whose centra support two-headed ribs. Dorsal ribs single-headed and articulating with the long transverse processes of the dorsal neural arches.

Ilium and femur like those of a land reptile.

Lower Trias.

Sub-order 2. Nothosauria. Sauropterygia in which the limbs are still incompletely converted into paddles, the elbow and knee joints still being flexible. Phalangean formula 2, 3, 4, 5, 3 or 4.

In the skull the opisthotic is enlarged distally, and articulates with the squamosal quadrate and pterygoid, so as to close the middle ear cavity behind. Clavicular arch powerful; coracoids



FROM ANNALS & MAGAZINE OF NATURAL HISTORY (TAYLOR AND FRANCIS)

FIG. 9. — SKULL OF THE CYNODONT. CYNOGNATHUS

A. From the right side, with lower jaw, B. from above, C. from below. D. occiput

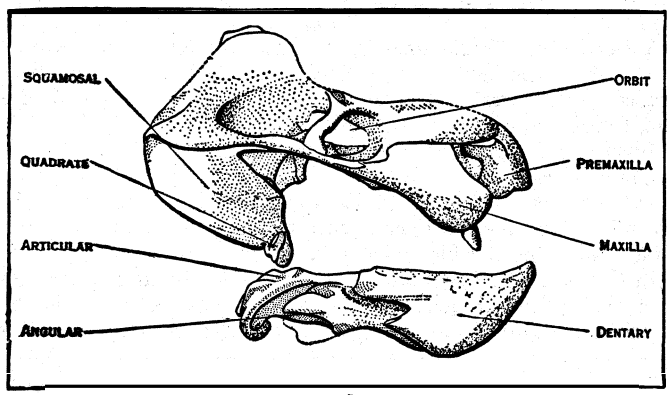
meeting in a short symphysis, which lies behind a line joining the glenoid cavities. Ilium articulating with both pubis and ischium.

Middle Trias, perhaps just appearing in the Lower Trias. Families not discriminated.

Sub-order 3. Plesiosauria. Sauropterygia in which the limbs are completely converted into paddles, with no freedom of movement at any joint; the number of phalanges in the five fingers and toes is increased, reaching 6, 13, 15, 13, 9 or more. The distal end of the opisthotic is slender, resting on the binder surface of

the squamosal. Clavicular arch, when present, reduced to flat sheets of bone, supported by the greatly enlarged acromia of the scapulae. Coracoids with a symphysis which extends forward between the glenoid cavities. Ilium articulating only with the ischium. Rhaetic to Upper Cretaceous. Families not yet discriminated.

Sub-order 4. Placodontia. Sauropterygia in which the skull has become modified to support great crushing teeth in the maxil-



FROM "PROCEEDINGS" BY COURTESY OF THE ZOOLOGICAL SOCIETY OF LONDON AND DR. PEARSON

FIG 10.—SKULL AND LOWER JAW OF THE DICYNODONT REPTILE KANNEMEYERIA. RIGHT SIDE

lae and palatines. Neck with eight vertebrae, the cervical ribs articulating with both centrum and neural arch; dorsal vertebrae with concave nrticulations, ribs attached solely to the neural arch. Limb girdles essentially like those of Nothosauria, fore limb somewhat paddle-like, but with the primitive number of phalanges, Femur like that of a land animal. A well-developed armour of dermal ossifications both dorsally and ventrally. Middle Trias to Rhaetic.

Order Ichthyosauria. Reptiles which are fully adapted for a marine life. The head is elongated, the neck short and the tail very long and powerful, provided with a terminal fin, which is the most important swimming organ.

The limbs are paddles, they are never large, and the hind limbs may become very small. The skull has a single temporal fossa which is surrounded by the parietal, supratemporal (often called squamosal) postfrontal, and sometimes frontal. This opening thus appears to differ in its boundaries from all found in other reptiles. The deep, but usually very short temporal arcade is very largely formed by a bone, often called the supratemporal, which is, perhaps, the true squamosal; it contains also processes of the postfrontal and supratemporal, and a quadrato-jugal. The postorbital and jugal are narrow bones round the enormous orbit.

The nostril lies immediately in front of the orbit, and the long rostrum is built up from the premaxillae and nasals. The biconcave vertebral centra are extremely short, and the neural arches feeble. The ribs are two-headed at least anteriorly, and articulate solely with the centra. There is no sacrum. The hinder part of the tail is downturned very slightly in Triassic forms, nearly at right angles in those from the Upper Jurassic, in order that it may support the lower lobe of a vertical caudal fin whose upper lobe has an unossified skeleton.

The shoulder girdle consists of scapulae and coracoids which meet in a powerful median symphysis between the glenoid cavities, and a rigid clavicular arch. The pelvis has a narrow ilium and pubis and ischia, separated by an obturator foramen, but expanded into great sheets in Triassic forms. In both fore and hind limbs the proximal bone is very short and widened distally, the remainder of the limb, in the later forms, being reduced to an interlocking mass of polygonal bones. The number of fingers is often increased to seven or more, and the phalanges increase to a very great number.

Middle Trias to Upper Cretaceous. Families: *Mixosauridae, Ichthyosauridae.*

Order Chelonia. Reptiles in which the trunk is enclosed in a shell built up from a series of dermal bones; with which the neural arches and ribs become continuous. The limb girdles are unique, in that they lie entirely within the ribs. Skull without any temporal vacuity, but the continuous sheet of bone which, in the primitive forms, overlies the temporal muscles may be emarginated either from the back or from below, or from both, so that in extreme cases the squamosal may be left without connection with any other bones of the skull roof. The powerful vertically-placed quadrate is then only supported by its abutment. in the pro-otic opisthotic and pterygoid.

Postfrontals and lachrimals are always, nasals usually absent, and the external nares are confluent. Except in Triassochelys, the jaws are toothless, and they always support a horny beak. There is often a small secondary palate, not homologous with that of mammals or crocodiles, formed by extensions of the palatines and prevomers. The eight cervical vertebrae are so formed that the neck is flexible, bending into a vertical loop in Cryptodeira, and into a horizontal S in Pleurodeira.

The dorsal vertebrae are ten in number, the first being free, or nearly so, from the shell, whilst the rest are fixed immovably by their attachment to the neural plates of the carapace; the two sacral vertebrae are similarly attached. The posterior dorsal vertebrae are pecuhar, in that each of their neural arches rests on two centra.

The shoulder girdle consists of a scapula, whose acromian process is produced into a long rod lying horizontally, and approaching its fellow in all forms except Triassochelys, and a coracoid which form a curious pedunculate glenoid camty. Cleithra are Present only in Triassochelys. Clavicles and an interclavicle are entirely detached from the shoulder girdle and form part of the plastron.

The ilium usually articulates, not with the sacral ribs, but with the carapace; the pubis and ischium are lacertilian-like. The limbs are much modified, in order to reach the girdles which lie within the shell, and to allow of their withdrawal in the more primitive forms. The fifth metatarsal is hook shaped. Both feet are pentadactyl, the phalangeal formula never exceeding 2, 3, 3, 3, 3, and being sometimes reduced to 2, 2, 2, 2, 0.

The shell, in its fullest development, consists of a dorsal carapace, built up from a median row of nuchal, preneural, eight neural and two suprapygal bones, and lateral rows, each of eight costals, articulating with the neurals, a variable development of supra marginals may occur secondarily; in their absence the costals articulate with a continuous chain of marginals which connect carapace and plastron.

The plastron consists of three plates anteriorly, the epiplastra which are clavicles, and an entoplastron, the interclavicle; a pair of hyoplastra, two pairs of mesoplastra, one pair of hypoplastra and one of xiphiplastra. The neural bones are co-ossified with the neural spines of the dorsal vertebrae, the costals with the ribs of the second to ninth dorsals.

Sub-order Amphichelydia. Chelonia with no power of completely withdrawing the head within the shell, mesoplastra present, pelvic girdle not fused with the plastron. Families not yet discriminated. Middle Tnas to Eocene.

Sub-order Pteurodezra. Chelonia which withdraw the head sideways. Mesoplastra usually present, pelvic girdle fused with the carapace, and usually with the plastron. Families: *Pelomedusidae, Chelyidae, Miolanidae, Plesiochelyidae.* Jurassic to Recent.

Sub-order Cryptodira. Chelonia which withdraw the head vertically. Mesoplastra absent, pelvic girdle never fused with the plastron. Families: *Thalassemydidae, Chelydridae, Testudinidae, Cinosteriidae, Platysternidae, Chelonidae, Protostegidw, Dermochelyidae, Dermatemydidae, Trionychiidae.* Jurassic to Recent.

There is a considerable number of small Palaeozoic reptiles which do not fall into any of the 19 orders defined above. Of these the more important are: Eosaurus from the Coal Measures of the United States, which may be Cotylosaurian; Eunotosaurus from the Upper Permian of South Africa, which may be an ancestor of the Chelonia; Broomia from the Upper Permian of South Africa, which may be an ancestral lizard; and Araeos-

celis, from the Lower Permian of Texas, which has also been regarded as a lizard ancestor.

Limbs and Locomotion. — The Lower Permian reptiles of all groups possess limbs which either belong to a definite characteristic type or are clearly simple derivatives of it.

In all of them a distinct neck is absent, the body is of circular section, although variable in length, and the tail is usually of considerable size.

The fore limbs were attached to the body immediately behind the head, the upper arm lies parallel to the ground, and was capable of being moved backward and forward only. The elbows were thus pointed directly outward. The forearm lay nearly parallel to the principal plane of the animal, and made a very small angle with the ground. The wrist was large in comparison with the forearm, and the hand possessed five somewhat spreading digits. The hind leg was attached to the body at a considerably higher level than the fore leg. The thigh projected freely from the body, almost at right angles, and the lower leg made a wide angle with it, indeed the stiff knee could not, in many cases, be bent to a right angle. The ankle joint was flexible, and the five toes greatly resemble the fingers of the same animal.

As the large head makes the load carried by the fore legs rather larger than that on the hind, the hand is generally larger than the foot.

These animals, like the lizards and salamanders of to-day, threw their backbones into lateral waves as they walked. Their procedure was as follows: — When the animal is standing with its right fore leg advanced to the greatest possible extent, and the right hand on the ground, the head is turned to the left, and the left hand lies near to it but is ready to be lifted. The trunk is thrown over to the right side and the base of the tail to the left. This body flexure implies that the right hind leg is turned somewhat backward and the left hind leg is directed forward. The left hand is then lifted from the ground by movement at the elbow, and carried forward not only by a movement of the upper arm on the shoulder girdle and a straightening of the elbow, but also by a bending of the backbone so that the head becomes directed to the right. This movement of the back involves a corresponding twist of the pelvis, which brings the left hind leg to its backward position, and makes it necessary to lift the right foot from the ground. The right hind leg is then swung forward by motion, mainly at the hip joint, and the foot placed down as far ahead as possible. During these movements the animal, as a whole, has travelled forward and the right hand is ready to be raised. Its movements agree exactly with those of the left, and it is followed in turn by the left hind foot.

Thus the animal progresses with a waddling gait, the head and body being constantly thrown from side to side of the line along which the animal is moving. The feet are moved one at a time, so that the animal is never standing on less than three of them, and are placed wide apart. This mode of walking must have been extremely slow and clumsy; measurements suggest that a reptile about a yard in length, without the tail, must have made a track 1 j in. in width, with a stride of some 6 or 8 inches.

Fossil materials enable us to trace the steps whereby the later reptiles gradually improved their modes of walking, until on one line, they became like the more primitive mammals, walking with their bodies raised high above the ground, the feet brought in towards the middle line and the stride long, whilst along a second course they became bipedal, striding along on their hind legs, with their heads raised high in the air.

The nature of the skeleton and musculature which is associated with the primitive type of locomotion is as follows: — The shoulder girdle consists of the pair of primary elements, each of which is in the most primitive forms, *Seymouria* and *Varanopus*, ossified as two bones, the dorsal scapula and ventral precoracoid. The glenoid cavity has a characteristic shape in that its articular surface is a rather narrow screw-shaped strip of a cylinder whose axis is nearly vertical. The glenoid cavity is shared nearly equally by the two bones. The two halves of the primary shoulder girdle do not touch one another in the mid line ventrally; but are held in position with respect to one another by the powerful clavicular arch. This consists of pairs of cleithras and clavicles and an interclavicle. Each cleithrum is firmly attached to the front edge, and sometimes to the upper end of the scapula. The clavicle is firmly attached to the front face of the lower end of the cleithrum and has no contact with the scapula; its lower end is turned inward so as to underlie the thorax, and is usually widened, its lower end underlying the lateral margin of the interclavicle. The interclavicle is usually a thin flat bone, with a widely expanded anterior end, and a narrower shaft projecting posteriorly under the sternum, which is unossified.

The whole girdle was held in position by muscles, the serrati passing from the ribs to the inner surface of the scapula and by others, sternomastoids and cleidomastoids passing from the head to the clavicular arch. Posteriorly, the coracoid is attached to the ventral surface of the abdomen.

The humerus of these reptiles has its extremities very much widened and placed nearly at right angles to one another. The articular surface of the head is screw-shaped, and fits the glenoid cavity so accurately that the bone cannot be rotated, and is restricted to a to-and-fro motion along a definite track. The widened proximal end allows the muscles which pass from the humerus to the ventral part of the animal, the pectoral and coraco-brachials, to have a mechanically favourable insertion. The widened lower end of the humerus similarly secures a favourable insertion for the flexor muscles which pass from it to the palmar surface of the hand and forearm, and take the whole weight of the anterior part of the body.

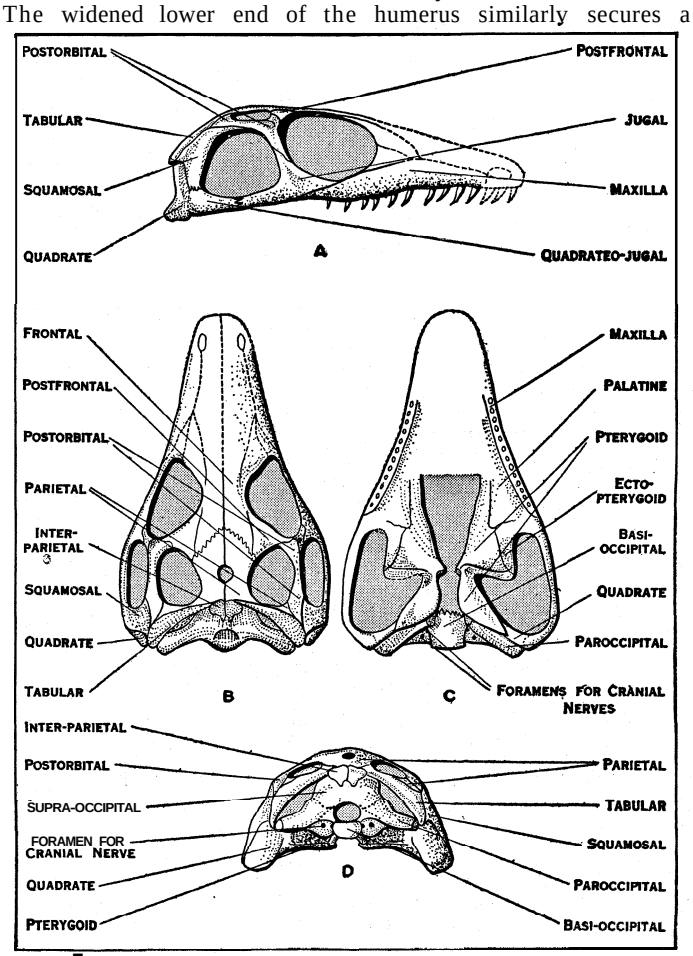


FIG. 11. — SKULL OF THE PRIMITIVE THECODONT, YOUNGURA
A. Right side, B. from above, C. from below, D. occiput

The lower end of the humerus bears a hemispherical boss on its front face, with which the head of the radius articulates, and a cylindroid articulation on its end which fits into the sigmoid notch of the ulna. The distal ends of the radius and ulna are widely separated; they articulate with the four bones: radiale, intermedium, ulnare and pisiform, of the proximal row of the carpus. The middle row of the wrist usually consists of only two

bones, the centralia, one of which forms part of the inner border, whilst the other separates the intermedium from the distal row. This consists of five bones, of which the fourth, which articulates with the ulnare, is the largest. The metacarpals articulate directly with the corresponding carpals and the number of phalanges is 2, 3, 4, 5, 3 respectively. This ensures that the ends of the fingers lie in a straight line at right angles to the animal, when the hand is placed on the ground.

The pelvis is attached to the vertebral column by the sacral ribs, which vary in number in Lower Permian reptiles from one

to four. It consists of three pairs of bones, the ilia, pubes and ischia. These meet in a triradiate suture, so that each supports about one-third of the acetabulum, with which the head of the femur articulates. The pubis and ischium of the same side are firmly united by a continuous suture and the two halves of the pelvis articulate continuously. so that the whole structure is usually described as plate-like. The femur is a straight bone, with the articular face of its head placed on the end of the shaft. The condyles at the distal end are only slightly curved, well separated and placed at such an angle as to suggest that the knee could neither be extended into a straight line nor flexed beyond a right angle.

The tibia is a bone with an expanded upper end, and is always shorter than the fibula, which is unusually massed. At their lower ends the two bones are widely separated. The tarsus, in one case (Seymouria) has a proximal row of three bones, the tibiale intermedium and fibulae, corresponding with those of the carpus, but in nearly all other reptiles and their descendants, the mammals and birds, the intermedium is no longer found as an independent bone, even during development, and has fused with the tibiale to form an astragalus. As a result of this fusion the tibia articulates only with the astragalus, whilst the fibula impinges on both astragalus and fibulare or calcaneum. The calcaneum is always in direct contact with the fourth and fifth (if present) distal tarsal, whilst the astragalus is separated from the first three distal tarsals by a row of two or more, usually one, centrale, the mammalian navicular. There are primitively five digits, the fourth being the longest. The phalangeal formula is 2, 3, 4, 5, 4.

The great majority of the changes which take place in the structures of these limbs during the evolution of the reptiles can be explained by a consideration of the mechanics of the structures under modified conditions of locomotion.

In the line of the mammal-like reptiles, and also in some of the other forms, the first change which takes place in the shoulder girdle is the addition of a bone, the coracoid, to the two existing in the primary shoulder girdle. These animals then acquire a pectoral girdle which resembles the pelvis in that the facet for articulating the proximal bone of the limb is carried almost equally on three bones. The glenoid cavity at first retains its screw shape, the humerus being restricted in its motion to an excursion along an arc lying nearly parallel to the ground. Gradually, as an integral part of the whole process whereby these animals acquired a more rapid and less clumsy gait, the plane of this glenoid cavity becomes twisted round, so that the humerus moves freely in a dorso-ventral direction and the elbow is no longer directed outward, but is drawn in toward the side of the body, nearly to the stage in which it exists in the more primitive mammals. This change results in the restriction of the glenoid cavity to the scapula and coracoid alone, the precoracoid no longer contributing to it.

Concurrently with this change, the humerus took up a more vertical position, so that the muscles connecting it with the coracoid could become smaller, in part because the forces they had to exert were actually reduced and, in part, because their insertion became more favourable. Thus the coracoid and precoracoid suffer steady reduction compared with the scapula. Finally, in order to secure a larger surface for its attachment, one muscle, which serves to support the animal's weight and to drive the humerus downwards, migrates on to the inner surface of the scapula, the tendon by which it is attached to the humerus passing over a notch in the front border of the scapula below the point at which the clavicle is attached to that bone. In this way a definite acromium becomes established, and the upper part of the anterior border of the scapula becomes recognizable as the homologue of the spine of a mammalian scapula.

The most important change in the clavicular arch is the gradual reduction and final complete disappearance of the cleithrum. The other bones sink in from their original position in the skin. so that they become surrounded by muscles on all sides, but otherwise they suffer comparatively little change during the evolution of the mammals.

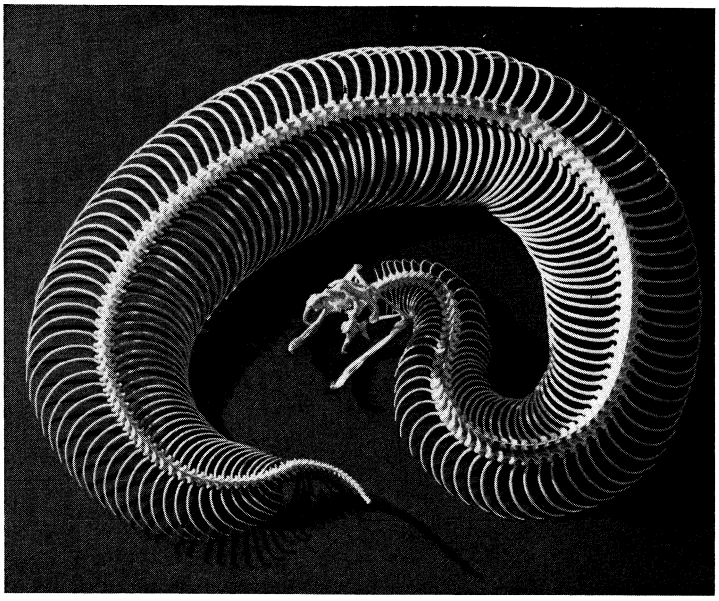
The great changes in the position of the fore limb during the development of the mammal-like reptiles necessitate corresponding modifications of the structure of the humerus and other limb bones. Of these, the most striking is the gradual narrowing of the two ends of the humerus and their rotation until they become nearly parallel.

In the hand, the number of phalanges in the third and fourth fingers is reduced to three, so that the formula becomes that characteristic of mammals, 2, 3, 3, 3, 3. It is evident that this change is associated with a new pose in which the third finger, which becomes the longest, lies parallel to the mid line of the animal and the others are symmetrically placed on each side of it.

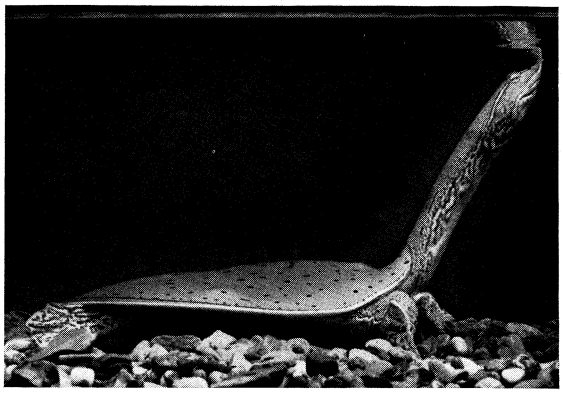
In the pelvis, the most important changes are a widening of the upper part of the ilium associated with an increase in the number of vertebrae in the sacrum, and the development of an obturator foramen, a gap lying in the suture between the pubis and ischium.

The femur so changes its shape that it can lie with the knee directed as much forward as outward, and the lower leg become capable of much freer movement. At the same time the astragalus and calcaneum shorten so that the tibia and fibula rest partly on their upper surface, thus forming an ankle joint which is on

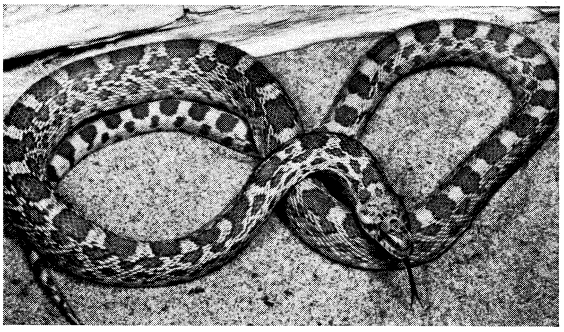
REPTILE



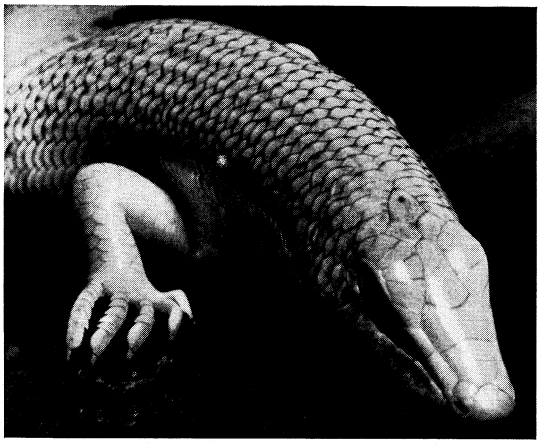
Skeleton of a gaboon viper (*Bitis* gabonica), showing arrangement of vertebrae and ribs. The sharp fangs of tnis snake — which is poisonous — may be seen in the upper jaw



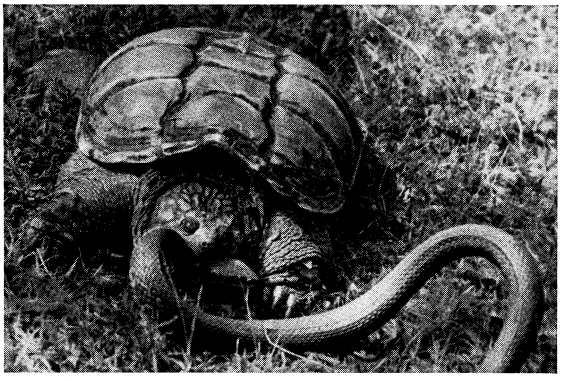
Spiny softshell turtle (*Trionyx* species) with its neck stretched out to bring its nostrils above the water. All reptiles are air breathing and have lungs



Bull snake (*Pituophis catenifer* subspecies) with its forked tongue extended. The flicking of the tongue is a response to odour or vibration. When retracted, the tongue touches Jacobson's organ, a chemical receptor in the roof of the mouth

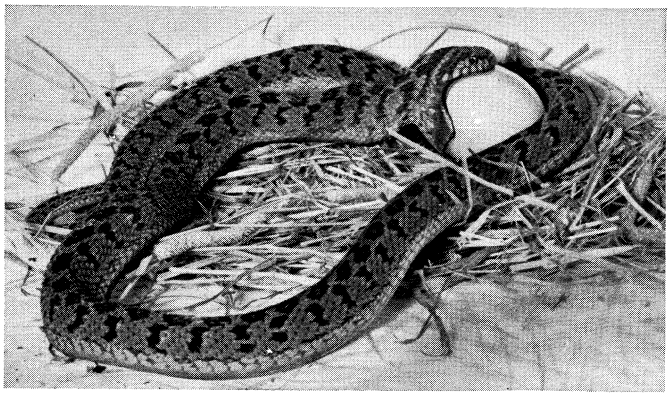


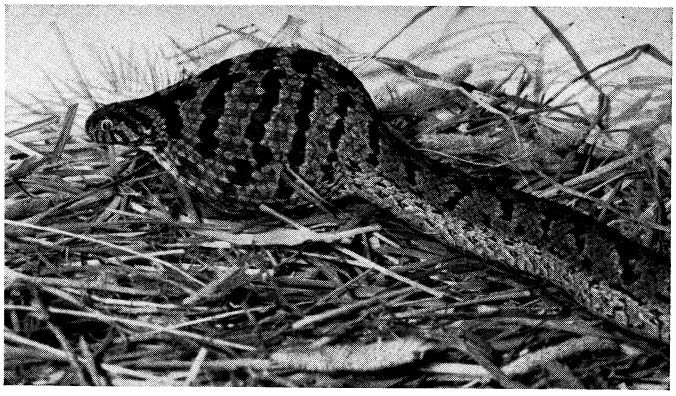
Close-up of the head of a sand skink (*Scincus philbyi*), showing the scaly epidermis characteristic of reptiles. The scales are composed of keratin, a hornlike tissue, which prevents drying of the skin, thus making it possible for reptiles to adapt themselves to nonaauatic life



Snapping turtle (*Chelydra serpentina*) eating a water snake (*Natrix* species). The great majority of reptiles are carnivorous, feeding on a variety of animal life

Two photos showing the egg-eating snake of Africa (*Dasypeltis* scaber) enjoying its favourite meal. The joints and hinging of the lower jaw in snakes make it possible for them to swallow objects much larger than themselves





BODY STRUCTURE AND DIET OF REPTILES

REPTILE

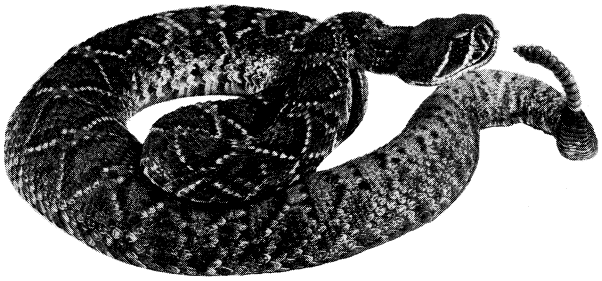
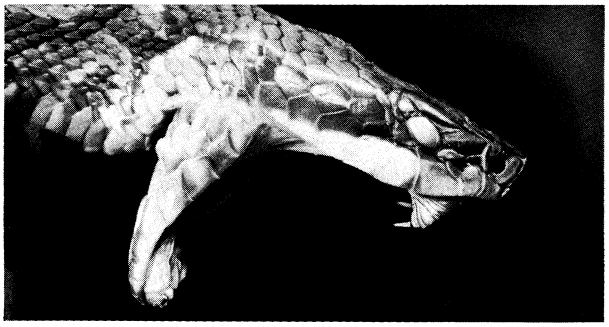
Asiatic toad-headed agamid (*Phrynocephalus mystaceus*) in defense posture. The large, brightly-coloured flaps are attached to the corners of the mouth. When extended, as shown, the mouth appears much larger and wider and is thus more formidable to enemies

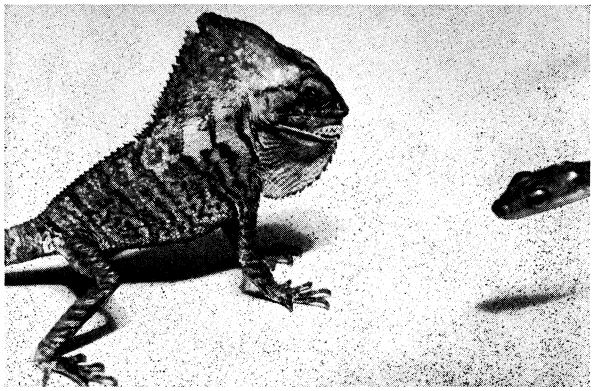
Australian lace monitor (*Varanus varius*), a large lizard (six feet long) with a heavy tail which can be an effective weapon when swung vigorously. The monitors also have strong jaws and large teeth



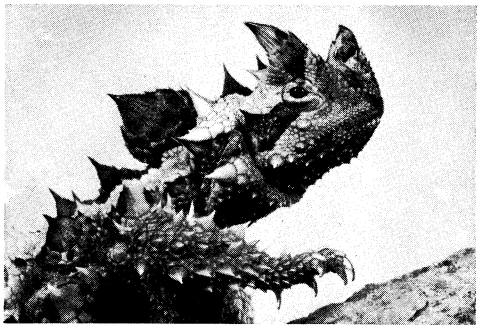
Diamondback rattlesnake (*Crotalus* species) showing the rattle which is used as a warning or threatening device. Other snakes employ noise, for example, hissing and spitting sounds, as a defense



Detail of the mouth and fangs of a water moccasin, or cottonmouth (*Agkistrodon* [*Ancistrodon*] *piscivorus*), a poisonous snake that injects its venom into its victims through a duct in the fangs



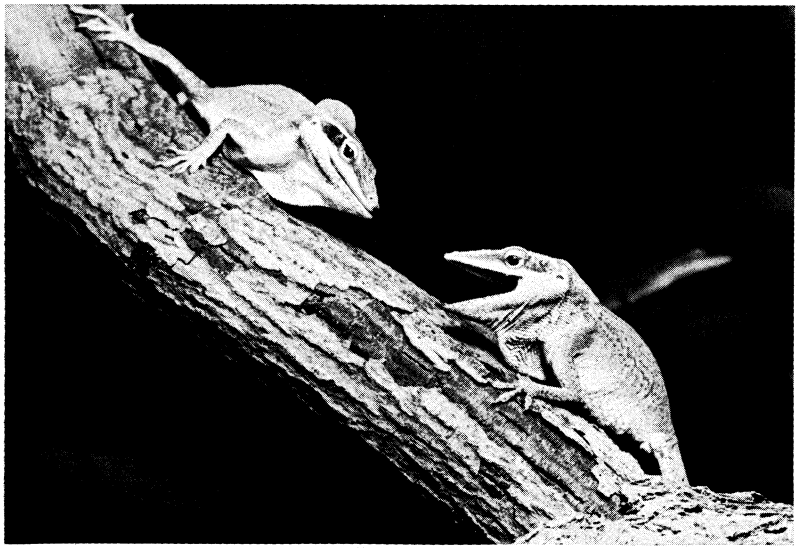
Reaction of a helmeted iguanid (*Corythophanes cristatus*) to a snake. The dewlap is extended and the body tensed to jump. This lizard will run on its hind legs when frightened



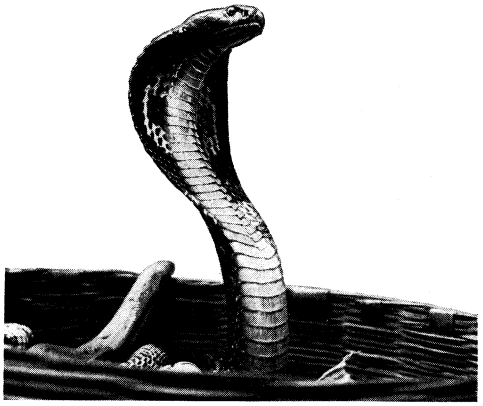
Head of an Australian thorny devil, or moloch (*Moloch horridus*), an example of passive defense through body form. Despite its appearance, the moloch is inoffensive

DEFENSE AND REACTION TO DANGER

Two male green anoles (*Anolis carolinensis*) preparing to fight. The one on the left is in a defensive position with the crest raised, dewlap extended, the dark spot behind the eye displayed and body widened and flattened



An Indian cobra (*Naja naja*) with its hood extended. Spreading or inflation of all or part of the body in defense is common among many types of reptiles



BY COURTESY OF (TOP RIGHT) AUSTRALIAN NEWS AND INFORMATION BUREAU, (SECOND LEFT) U S. FISH & WILDLIFE SERVICE PHOTOGRAPHS (TOP LEFT) R MERTENS (SECOND RIGHT) HUGH SPENCER, (THIRD LEFT) D. DWIGHT DAVIS, (THIRD RIGHT) JOHN WARHAM, (BOTTOM LEFT, BERNARD GREENBERG (BOTTOM RIGHT) YLLA—RAPHO GUILLUMETTE

the way to a mammalian structure and the phalangeal formula of the foot becomes reduced to 2, 3, 3, 3, 3.

The non-mammal-like reptiles exhibit so many different types of adaptation that a full analysis of the structures of their limbs is impossible; indeed, it has not yet been systematically attempted. Some of the main types of life are here discussed with reference to a particular case.

Nondescript. — The majority of lizards and Rhynchocephalia exhibit a simple modification of the mode of locomotion found in the most primitive reptiles. In them the body and tail are thrown into lateral waves, which pass steadily backward so that each point along the back swings from side to side across the animal's track as the creature moves forward. The hands and feet are widely separated, the body only just raised off the ground, and only one foot is moved at a time. In detail there is much variety; both fore and hind feet may be much everted, so that the first digits point forward and the toes increase in length from one to four, so that when in the natural position their claws end on a straight line at right angles to the body. In some cases, however, the fingers are directed forward and the hand is nearly symmetrical about the third finger, and even the foot is less asymmetrical than in the more primitive forms. Nevertheless, these animals always retain the original phalangeal formula.

These animals have a primary shoulder girdle consisting of a scapula and precoracoid, the glenoid cavity has lost all trace of the screw shape of primitive reptiles and permits considerable freedom of motion. In the larger and more advanced lizards the anterior part of the scapula and coracoid is much enlarged, and these bones are perforated by fenestrae.

The clavicles have an expanded, and sometimes fenestrated, lower end, and the interclavicle is usually cross-shaped. There is a large sternum, which is usually calcified although not ossified, with whose antero-lateral borders the precoracoids articulate.

The pelvis of these reptiles is of very characteristic pattern, the ilia are narrow rods with an expanded lower end which contributes to the acetabulum. It slopes downward and forward and is firmly held by its articulation with the two sacral ribs. The pubis and ischium are separated by a large obturator foramen which, in many cases in the bony skeleton, is confluent with that of the opposite side. The hind limb presents few features of interest, but it may be noted that a patella is sometimes present, and that most of the motion at the ankle-joint takes place between the two rows of tarsals and not, as in mammal-like reptiles, between the tarsus and lower leg.

One universal and unexplained feature of the hind foot of these reptiles is that the fifth distal tarsal is absent, and that the upper end of the fifth metatarsal has moved up into contact with the calcaneum, and has become much widened so that the whole bone is hook-shaped. As a result, the fifth toe tends to be widely separated from the other four.

This feature occurs in Rhynchocephalia, Thecodontia, Crocodilia, Dinosauria, Squamata, and Chelonia, and has been held to imply a close relationship between these orders.

Cursorial Progression. — The only group of non-mammal-like reptiles which became highly adapted for rapid progress on hard land was the Dinosauria. They arose from Thecodonts whose general body proportions and gait generally resembled those of certain lizards. These animals possessed slender scapulae and small precoracoids, clavicles and interclavicle were present, and there was, in some cases, a sternum with a single pair of ossifications. The fore limb was slender, the hand small and with five fingers. The pelvis had an ilium which was antero-posteriorly extended, but so low that the acetabulum lay on the level of the vertebrae. The pubis and ischium were plate-like, but much elongated and directed largely downward. The hind legs were much longer and more massive than the fore, a condition made possible to a quadripedal animal by the presence of a long tail, which acted as a counterpoise to the body. Although it is certain that these animals had a straddling gait, it is probable that the feet were placed unusually near to the middle line and the feet were not so asymmetrical as those of most lizards.

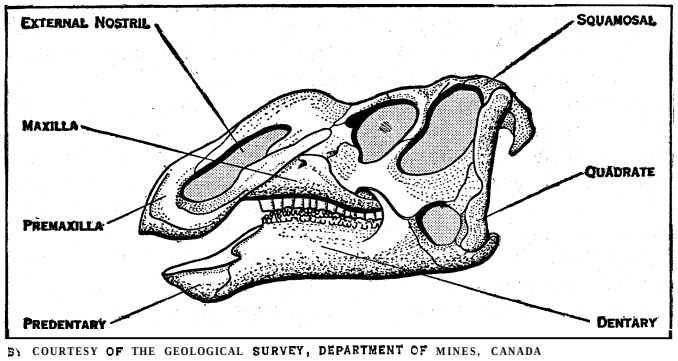
From such reptiles the Saurischia, the carnivorous dinosaurs arose by an increase in the length of the hind legs, and concurrent reduction of the arms. They became predominantly bipedal, a habit which necessitates the raising of the body so far above the ground that the whole animal balances about the pelvis. This pose can only be attained if the thighs are turned in until they lie parallel to the body of the animal, and the feet are placed on the line which marks the middle of the track. Such an arrangement ensures that the body need no longer be thrown from side to side, as it is in all more primitive reptiles.

A further result is that, as the powerful muscles which are used for propelling the animal forward no longer press the heads of the femora into the acetabula, this depression no longer needs a floor and becomes perforated. At the same time, in order to lengthen the muscles attached to them and thus enable the leg to swing through a larger arc, the pubis and ischium, both elongated, stretch downwards and away from one another, meeting only at the acetabulum. The reduction in size of the forelimb, which occurs because it is no longer required to carry the weight of the body, results in a reduction and final loss of the clavicular arch, and in a reduction in size of the precoracoid. Subsequently, certain carnivorous dinosaurs increased greatly in size and became quadripedal again, retaining in many parts of their skeleton features which arose during the bipedal stage in their ancestry.

The long limbs which are necessary for a bipedal cursorial life, involve elongated feet. These are secured by lifting the heel entirely off the ground, so that the animal walks on the ends of the metatarsals, the toes stretching out along the ground as they do in birds. As the foot is placed directly under the body it tends to become symmetrical about the middle third toe, and rapidly becomes either functionally or actually tridactyl. The hand, which serves as a grappling hook for catching the prey, is reduced to three fingers, all provided with claws, that on the thumb becoming very large indeed in the latest forms.

The other group of dinosaurs, the Ornithischia, pursue a somewhat similar course of modifications; they also become bipedal, some of them secondarily returning to a quadripedal life. But in them the extension of the pubis and ischium into long downwardly directed rods, which is necessary to afford suitable muscle attachments, takes place in such a way that the pubis acquires two branches, one directed downward and forward, the other directed backward so that it lies parallel to the ischium. The early stages of this arrangement are not known, but it persists throughout the whole group.

Flight.--One group of lizards, the genus Draco, has the habit of living in trees and of passing from tree to tree by making great



BY COURTESY OF THE GEOLOGICAL SURVEY, DEPARTMENT OF MINES, CANADA

FIG. 13.—SKULL AND LOWER JAW OF THE ORNITHOPODOUS DINOSAUR KRITOSAURUS

leaps, whose length is extended by the presence of a parachute, made by flaps of skin which project from the sides of the body and are supported by the much elongated ribs. Such gliding is scarcely flight in any true sense, it cannot be maintained by any action of the animal whilst in the air, and its extent is limited by the speed acquired at the original jump and by the height of the point of departure. A similar gliding habit, carried out without any elaborate mechanism by a mere concavity of the ventral surface, is exhibited by certain arboreal snakes from Borneo. The only reptiles which have acquired true flight were

the extinct Pterodactyls.

There are two series of the animals, in one of which the tail is extremely short and probably functionless, whilst in the other the tail is a very long stiff rod bearing a horizontal fin at its hinder end. The presence of this fin renders the maintenance of the body on an even keel much easier than it can have been in the tailless forms. The wing of every pterodactyl consists of a fold

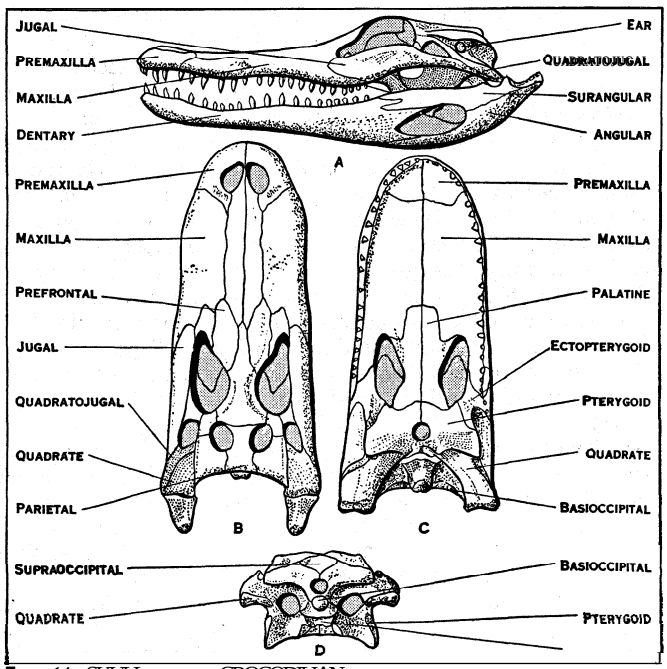


FIG. 14.—SKULL OF A CROCODILIAN, THE ALLIGATOR; (A) LEFT SIDE. WITH LOWER JAW. (B) FROM ABOVE, (C) FROM BELOW, (D) OCCIPUT (AFTER ANDREWS)

of skin which is supported by the greatly extended fourth finger and by the hind leg; it may or may not have connected the hind legs together, either directly or by passing on to the base of the tail. The structure of the fore limbs, which enabled these animals to perform automatically the many carefully-adjusted movements which are necessary for flight, is so strictly determined by mechanical considerations that it is practically uniform in all known species of the group.

In all of them, the scapula is an elongated narrow rod of bone which may articulate with the neural spine of the dorsal vertebrae. Its lower end forms the upper half of the glenoid cavity and is fused with the coracoid. This bone is elongated and straight, its distal end rests in a groove in the front of the large sternum, so that it is enabled to take directly the stresses resulting from the powerful wing muscles. The humerus is short, and the radius and ulna lie parallel to one another. The carpus consists of three bones, with the distal of which the wing metacarpal is articulated, so that it can revolve on its axis. The main joint at which the wing was folded lay between the metacarpal and first phalanx. The movements at the elbow and wrist are inseparably connected, and serve to alter the camber and angle of attack of the wing, thus enabling the animal to fly at varying speeds. It is interesting to note that a successful aeroplane, with an unusual range of flying speed, has been designed on lines suggested by the tailless pterodactyls.

Swimming.— Two extreme modes of swimming are open to a tetrapod. It may convert its limbs into paddles by whose actions it rows itself through the water, or it may use its tail as a propeller, either flattening it and causing waves to pass along its length or producing a fin at the extreme tip, which can be used like a screw propeller. Both types are found in reptiles.

The Chelonia include amongst the fresh water tortoises a number of animals which swim well with limbs which, except for the webbing of the toes, are much like those of a land animal. But in the marine turtles and in the fresh water Carettochelys from New Guinea, the limbs are transformed into paddles, mere bags of skin surrounding the whole of the elongated digits.

The Plesiosaurs carried this principle to its limit; in them each limb is a rigid oar, flattened and widened distally, circular in section where attached to the body. It was feathered when brought forward, then turned so that its broad plane was vertical for the swimming stroke.

The crocodiles, the semi-marine lizard Amblyrhynchus, and the sea snakes are the living exponents of the second mode of swimming. In them the powerful tail is laterally flattened, and is swung from side to side so that a series of waves passes along its length. The limbs are used for steering and for maintaining stability in the water. The only groups of reptiles which have formed a caudal fin are the Ichthyosaurs and the marine crocodiles of the family Metriorhynchidae. In each case the end of the vertebral column is suddenly turned down so that it passes into the lower lobe of a forked fin whose upper lobe is supported only by non-ossified structures. These animals show a reduction of the limbs, the pelvic limb of Ichthyosaurs and the pectoral limb of the crocodiles being reduced to a tiny paddle.

Limblessness.—Many lizards belonging to unrelated families, but chiefly of burrowing or sand living habits, exhibit a reduction of limbs associated with an elongation of the body. The process takes place gradually, all stages being known in one or other form between normally developed limbs and their complete absence. In snakes the reduction is always complete in the case of the fore limbs, whilst the hind limbs may be represented by a claw-like spur on each side of the vent. In some cases all three bones of the pelvis and the femur may be present. Normally, all trace of limbs, except for a rudimentary nerve plexus, is lost.

Skin.—The fact that the reptiles were originally distinguished from the amphibians by their more completely terrestrial habits, implies that in them the skin had become capable of withstanding desiccation, and the serious wear to which it became exposed.

The skin of amphibians is maintained in good condition by a coat of mucus, poured out from glands which lie all over it; that of reptiles is dry and covered by a watertight layer of horn, very well adapted for resisting abrasion. The horny layer, though continuous, is not of the same thickness throughout, but is divided into specially thickened areas, the scales which are connected by flexible regions. The scales may be flat, fitting together like a mosaic or separated widely, or they may be prolonged backwards so that they overlap and are overlapped by others, like slates on a roof. The scales often have a definite arrangement, which is used in the classification of Squamata.

The skin, as in other Amniotes, consists of a compound squamous epithelium which rests on a conum built of connective tissues. The actual scale consists of the keratinized outer layers of the epidermis, its thickness is increased by additions to its inner surface, and it grows in area either all round or at one end. The area of the scale is always raised by a special papilla of the corium, which may project so far that the scale overlaps that behind it. The scale is colourless, its transparency allowing the pigment in the cutis to show through.

The outer layer of the keratinized epithelium is worn away in crocodiles and Chelonia, but in the Rhynchocephalia and Squamata it comes away either in flakes or, in some lizards and snakes, in one piece. Such cast skins exhibit perfectly the continuity of the horny skin, which in them even covers the eyes. This process of shedding the skin is facilitated in some or all of these reptiles by a special mechanism which allows the head to be distended with blood. The papilla of the corium which fills the centre of each scale may, in crocodiles, some lizards and many fossil reptiles, be ossified as a bony scute.

The carapace and plastron of the Chelonia consist essentially of such scutes. Each ossifies in the corium, the bone finally occupying nearly the whole thickness of that layer, leaving only a thin sheet of connective tissue to support the peritoneum, and a similar sheet containing pigment cells below the epidermis in which the horny shields are developed. The originally dermal ossifications of the carapace extend so far down into the body of the animal that, in the end, they completely surround the middle parts of the ribs, which first calcify and are then ossified by ex-

tension of membrane bone from the scute.

Most of the glands found in the skin of reptiles are scent glands, which give to these animals their characteristic odour of musk, which has, no doubt, a sexual significance. All these glands are sac-shaped, multicellular structures opening by a pore on the surface, and their secretion is set free by disruption of cells.

The musk glands have the following distribution: — In crocodiles there is a pair which open by longitudinal slits on the inner sides of the lower jaws, and another pair lie within the lips of the cloaca; these are present in both sexes. Crocodiles possess also a row of small sac-like glands without external openings along each side of the back.

In Chelonia there is a pair of inguinal glands opening near the hypoplastra, and sometimes an anterior pair similarly related to the hyoplastra. Sphenodon has a pair of cloacal glands. Lizards have cloacal glands and, in addition, in certain forms there are the so-called femoral pores, which extend along the lower and hinder surface of the thigh to pass on to the belly in front of the cloaca. They are present in both sexes, but best developed in males. Each pore opens in the middle of a scale and leads into a canal which ends in a pocket with many shallow diverticula. The cells of the walls of these become detached, filling up the lumen of the gland and duct, and forming a rod which may project beyond the surface of the skin. It is possible that these structures are of assistance in copulation.

Muscular System. — No useful account of the muscles of reptiles can be given here, the functional effects of those used in locomotion are described in the section Locomotion.

Body Cavity. — The body cavity of reptiles is always more or less completely divided into sacs. A completely closed pericardium is always present. In lizards, a post-hepatic septum built up by special folds of the mesentery and suspensory ligament of the liver, may reach the ventral surface and bring about an almost complete division of the peritoneal cavity into two. In snakes, similar folds enclose the two lobes of the liver and the stomach in separate sacs. In Chelonia, the lungs lie above a fold of peritoneum which reaches the liver, excluding them from the general cavity. In crocodiles, there are two pleural cavities and a combinatidn of other folds connected with the liver forms a complete transverse partition separating the pericardium, lungs and liver from the rest of the peritoneal cavity. This sheet is muscular, and probably functions in respiration like the non-homologous mammalian diaphragm.

Digestive System: Teeth. — The teeth of reptiles may be found on the pre-maxillae, maxillae, on all the bones of the palate, and on the dentary and coronoid bones of the lower jaw. Individual teeth are generally simple cones with a conical pulp which produces dentine and an enamel cap. They may be set in sockets (thecodont) or fused to their supporting bone (acrodont or pleurodont). In the majority of reptiles they are shed periodically, and replaced as often as necessary. In reptiles, the marginal teeth of both jaws appear to belong to two series, whose members alternate with one another, and in primitive forms were functional alternately.

Thus, in these animals two teeth are usually separated by an empty emplacement in which a new tooth will arise, the original pair being shed together when it has grown to its full size. When the original teeth have been shed a new dental papilla passes outward from the lingual side to the empty socket and there produces a new tooth. In crocodiles this process has already happened before the tooth is shed, so that these new tooth crowns may often be found in the pulp cavity of the original tooth. Sphenodon, and some other recent reptiles with acrodont teeth, exhibit no replacement after maturity has been reached. The mammal-like reptiles in their various orders show all stages in the reduction of tooth change from the primitive unlimited replacement of all teeth to a mammalian condition in Cynodonts, where the incisors, canines and pre-molars are replaced once during the animal's life, and the molars, when once formed, are never shed.

The dentition of reptiles is usually homodont, that is, uniform or regularly varying from front to back of the jaw, but the Theriodont dentition is heterodont and mammal-like. The tooth crown may be elaborated into a crushing mechanism, in Placodonts, some Ichthyosaurs, and very effectively in the Trachodont dinosaurs, where several successive series of teeth are in use at one time, forming a splendid triturating surface, in Cotylosaurs, Theromorpha, and even, though imperfectly, in some lizards. The peculiarly specialized fangs of poisonous snakes are described in the article on these animals.

Tongue. — A tongue is present in all reptiles. In crocodiles and Chelonia, it is a short, broad, fleshy structure attached to the floor of the mouth over a large area. In crocodiles, a fold on the hinder margin of the tongue engages with a similar structure of the palate, so as completely to separate the air passage from that for food. In lizards the tongue may be flat, broad and not protrusible; it may be narrow, cylindrical and capable of being extended out of the mouth, or its cylindrical anterior half may telescope into the posterior portion, so that the whole can be projected far in front of the snout. This last type reaches its climax in the chameleon (*q.v.*).

Buccal Glands. — The only salivary gland of universal occurrence in reptiles is a sub-lingual. Upper and lower labial glands occur only in lizards and snakes, where they are arranged in rows between the lips and the teeth. The poison glands of the lizard Heloderma, and of the snakes, are special developments of such upper labial glands. They are described in the article SNAKE.

Gut. — In Chelonia, Sphenodon, lizards and snakes, the oesophagus passes gradually into the stomach, which is, in them, usually spindle-shaped, with its openings widely removed from one another. In crocodiles, the stomach is placed more transversely, the opening of the oesophagus and the pylorus being approximated. This stomach is an oval sac whose proximal portion is very muscular, recalling, in its arrangement, the gizzard of a bird; indeed, it customarily contains pebbles used for triturating food. The pyloric end of the stomach is distinct. The stomach always contains gastric glands.

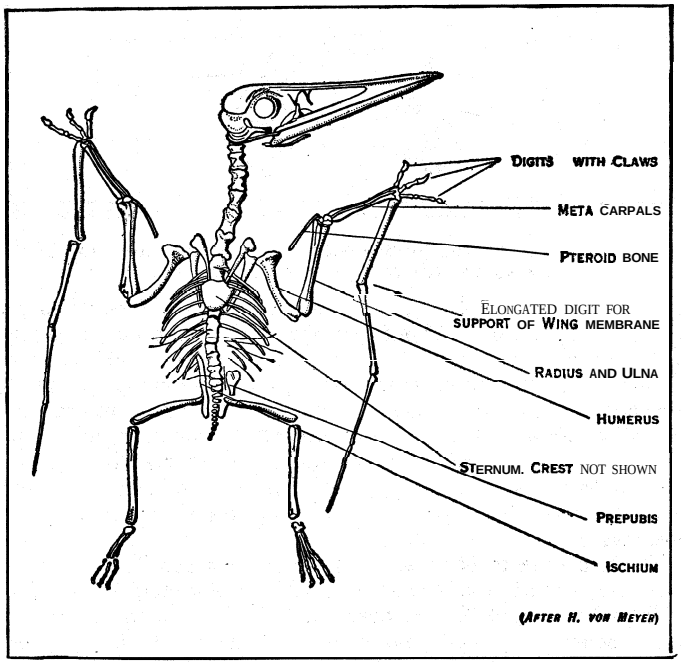

FIG. 15—PTERODACTYLUS SPECTABILIS FROM THE LITHOGRAPHIC STONE

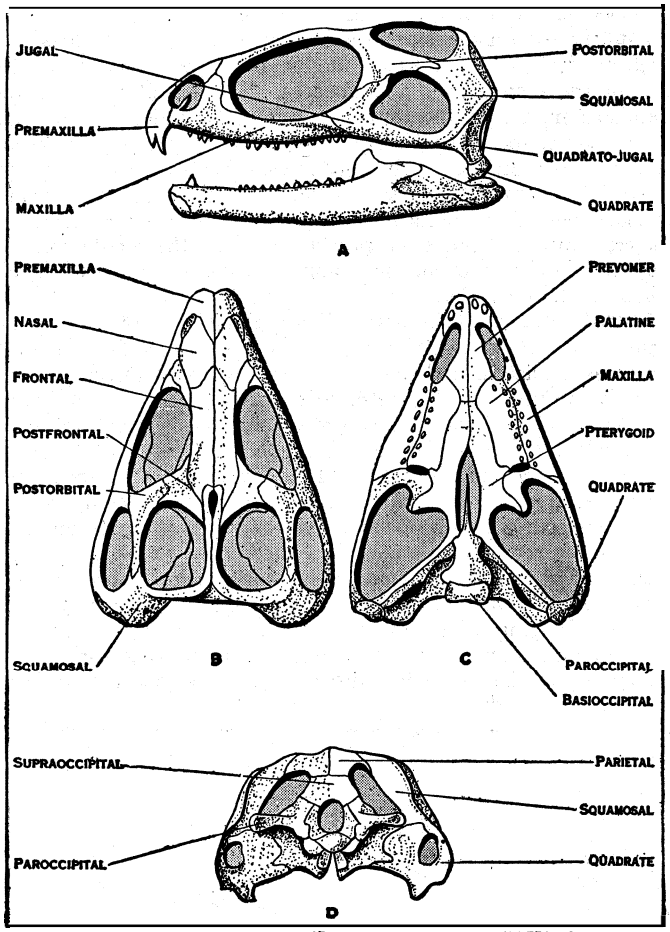
A pyloric valve usually exists, and the duodenum is not usually sharply marked off from the rest of the small intestine; only in crocodiles does it form a loop round the pancreas as it does in birds and mammals. The walls of the mid gut are usually thrown into folds or ridges, but seem to contain few or no glands. There is usually or always an ilio-colic valve separating the mid from the hind gut; immediately beyond this the latter gives rise to a caecum in some lizards and snakes. The rectum ends in a cloaca which is usually of elaborate structure.

Cloaca. — The cloacal opening ieads into a proctodeum, a cham-

ber whose walls give origin to the copulatory organ or organs in the male, and their representative in the female duct to the pair of anal glands; the peritoneal canals when present open into it.

Copulatory organs are absent in Sphenodon, in Squamata they are a pair of papillae capable of being protruded through the lateral ends of the transverse cloacal slit, and of being retracted; being turned inside out by the contraction of special muscles



FROM WILLISTON, "WATER REPTILES OF THE PAST AND PRESENT" (UNIVERSITY OF CHICAGO PRESS)

FIG. 16.—SKULL OF THE RHYNCHOCEPHALIAN. SPHENODON: (A) LEFT SIDE, (B) FROM ABOVE, (C) FROM BELOW. (D) OCCIPUT

derived from the tail musculature. Each has a groove on its lateral surface which extends on the wall of the cloaca nearly to the opening of the vas deferens. In crocodiles and Chelonia, a median unpaired penis arises from the ventral wall of the proctodeum; it can be erected through the activities of corpora cavernosa, and is then extruded through the anterior end of the longitudinal cloacal slit. The dorsal or posterior surface of the penis is furrowed by a deep groove, which is probably converted into a canal during erection The groove leads backward to the openings of the seminal ducts.

The proctodeum is separated by a ridge which is, in effect, a sphincter, from the urodaeum, into which the ureters, vasa deferentia, oviducts and bladder open. A bladder is found in Sphenodon, Chelonia and most lizards; it is absent in all other reptiles. The urodaeum is partially subdivided in many reptiles; in snakes a dorsal recess receives the ureters and gonoducts, in crocodiles they open into the dorsal side of the urodaeum, whilst in Chelonia they discharge directly into the neck of the bladder. In Sphenodon, lizards and snakes, the oviducts open rather dorsally, in crocodiles and Chelonia ventrally, the vasa deferentia having a similar opening in all forms.

The urodaeum is, in some aquatic Chelonia, produced into a pair of their walled sacs on the dorsal side, which are constantly filled and emptied of water, thus serving as accessory respiratory organs, In all reptiles except crocodiles and Chelonia there is an additional cloacal chamber, the coprodeum, which serves for the storage of faeces.

Urogenital System.—The kidney of an adult reptile is always a metanephros, discharging by a single ureter. The kidney may be elongated and its surface furrowed, or it may be a small compact organ. The urine of Chelonia and Crocodilia is fluid, that which is voided by snakes and lizards contains crystals of insoluble urates, an arrangement which prevents waste of water in these animals, which often live in very arid surroundings.

The ovaries are always paired, and large owing to the size of the yolky eggs. Interstitial tissue is small in amount. The oviducts have independent funnel-shaped ostia, and are usually provided with glandular walls which secrete the albumen and shell. In some viviparous forms they can combine with the faetal membranes to form a placenta. The elongated testes are connected with an epididymis of mesonephric origin.

Respiratory System.—All reptiles breathe by lungs. These are always produced by the elaboration of a median ventral outgrowth of the pharynx. The glottis lies immediately behind the tongue and is sometimes protected by a rudimentary upstanding epiglottis. There is a larynx, supported by arytenoid and cricoid cartilages, there being no thyroid cartilages; muscles passing from the laryngeal cartilages to the "hyoid" enable the glottis to be opened and closed. There are often vocal chords, which give to Sphenodon, crocodiles, some tortoises and lizards a voice, usually a grunt or squeak. The trachea is often long and its cavity is kept open by cartilaginous rings. The bronchi may be very short in Sphenodon or very long in tortoises. The lung is very variable in its structure; it may be almost as primitive as in Amphibia or become comparable to that of a bird.

In Sphenodon and snakes the cavity of the lung is single, but the walls are divided up into a series of cells by upstanding ridges or septa. In some lizards certain of these septa elongate so that the original single sac begins to be cut up into lobes, each with cellular walls. In crocodiles, this process has gone on so far that the lung is definitely divided into a number of chambers each of which receives a number of wide side canals, the parabronchi, in whose walls lie the alveoli. In Chelonia this process has gone so much further that the whole lung is spongy, the alveoli, through whose walls the whole of the respiratory exchange takes place, being connected with an irregularly branched series of bronchial tubes.

Not only is the actual structure of the lung altered in this way, but reptiles show an advance over the Amphibia in an increased size of the lung resulting from the development of a special anterior projection, the prebronchial part, which, very small in Sphenodon, becomes much more extensive in more advanced reptiles. In chameleons, long, hollow non-respiratory process of the lungs pass backward among the viscera; they are important as morphological forerunners of the air sacs of birds and Pterodactyls. In elongated legless reptiles one of the lungs is usually reduced, and may be absent.

The mode of respiration in Reptilia is not well known. In all except the Chelonia, movements of the ribs may be expected to draw air into the lungs, whilst the muscular post-hepatic diaphragm of crocodiles is, no doubt, used as is the comparable structure in mammals. In Chelonia, and probably also in other reptiles, air is actively forced down into the lungs by movements of the floor of the buccal cavity brought about by the hyoid and its musculature. In Chelonia, the protrusion and withdrawal from the shell of the neck and legs gives a pumping action which, by creating a virtual vacuum, draws air into the lungs.

Vascular System.—The heart of reptiles lies in the thoracic region, usually between the lungs. There is a sinus venosus, at least in most, which opens by a valve guarded slit into the right auricle. Right and left auricles are completely separated, and open independently into the ventricle or ventricles. The lower edge of the interauricular septum is expanded laterally into, usually, very large right and left membranous valves, which direct the arterial blood to the left, the venous to the right side of the ventricular cavity. The ventricle is incompletely, or, in Crocodilia, completely divided by an upstanding ridge into right and left

halves. Except for a possible relic in Sphenodon, there is no trace of a conus arteriosus nor of a truncus. Three arteries arise independently from the ventricle, and are then twisted round one another like a rope, so that they cross one another. That vessel whose origin is most to the right is the left systemic arch, the next is the pulmonary arch, and the third is the right systemico-carotid, from which arise both carotids. As a result of this arrangement, in Chelonia the pulmonary arch arises from a partially separated cavum pulmonale, and the two systemics from a cavum venosum, which has to be traversed during systole by the blood from the left auricle, which is originally discharged into the cavum arteriosum on the left side of the ventricle. In crocodiles, the right systemico-carotid alone leaves the left ventricle, whilst both pulmonary arch and left systemic come off from the venous right ventricle: but in them the left and right systemics are connected by a special opening, the foramen of Panizzi at the point where they cross. Although it has been shown by the electrocardiograph that the nature of the contraction of the heart in tortoises is much as in mammals, very little is known of its general physiology.

Arterial System.—The pulmonary arch soon divides into two branches, one to each lung; in Sphenodon and some lizards it gives off a paired laryngotracheal artery which is a relic of a

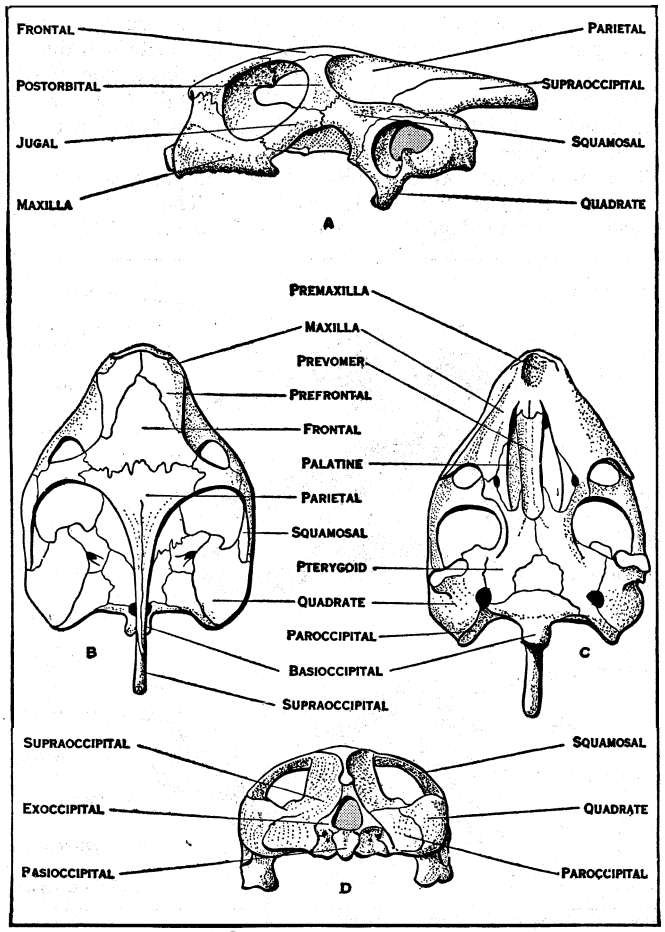


FIG. 17.—SKULL OF A TORTOISE, TESTUDO
A. Left side, B. from above, C. from below, D. occiput

Urodela structure. The systemic arches unite to form the dorsal aorta; from one or both of them arise coronary arteries to the heart. From the right come off both subclavians, and the left usually gives off a coelic branch. The carotids may arise independently from the right systemico-carotid, or may be formed by the branching of a single primary carotid. In snakes the right carotid is usually much reduced or absent.

Venous System.—The venous system is exceedingly complicated, differing in details in the four orders but with a common ground plan. The pulmonary veins pass straight from the lungs into the left auricle.

The venous blood is returned to the heart by the pair of precaval, and single postcaval veins which open into the sinus venosus. The branches of the precavals come from the head and fore limb, the subclavian often receiving an azygous vein from the anterior part of the body wall which represents part of the embryonic posterior cardinal. Nearly the whole of the blood which

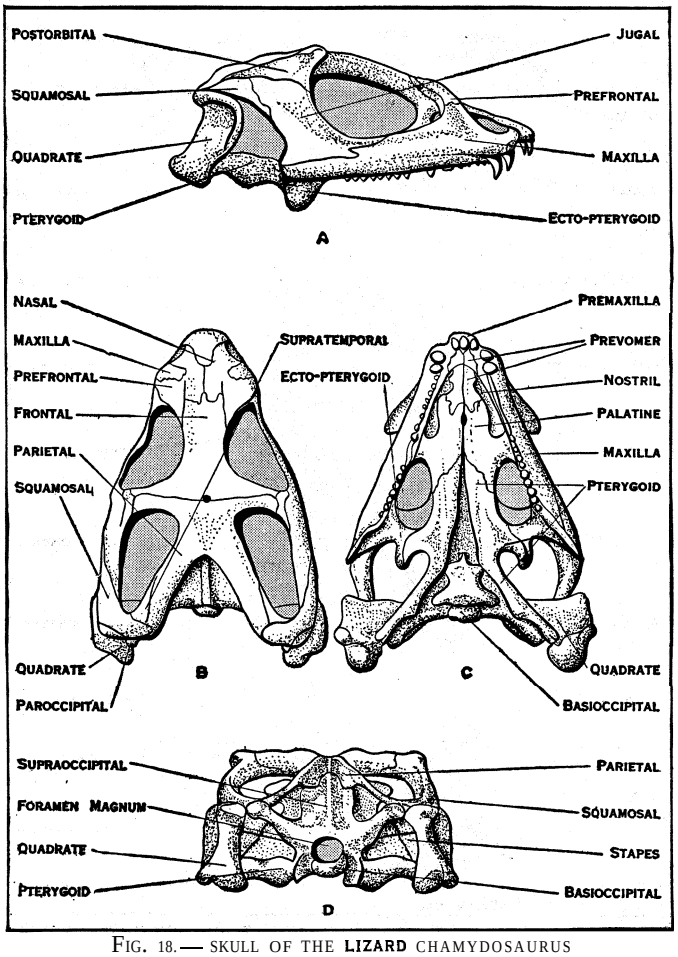

FIG. 18.—SKULL OF THE LIZARD CHAMYDOSAURUS
A. Right side, B. from above, C. from below, D. occiput

enters the heart through the postcaval has previously passed through one of the portal systems.

The renal portal system drains the tail, and part of the hind limbs, the afferent renals arising from the bifurcated anterior end of the caudal vein and the iliacs. The efferent renals open into the postcaval, whose hinder end is formed by them. The supra renal portal system consists of a series of afferent veins which come from the body wall; the efferents discharge with the gonadial veins into the postcaval.

The hepatic portal system includes the series of veins from the gut, which form the true hepatic portal vein and also the median anterior abdominal vein, which is originally formed by a fusion in the middle line of pelvic veins, themselves built up from the iliacs and a series of vessels from the hinder part of the body wall of the abdomen. The anterior abdominal passes along in a mesenteric sheet in the ventral part of the body cavity to enter the liver and there receive the hepatic portal or a branch from it. Finally, the whole of the blood in the liver passes by the hepatic veins into the posterior cardinal.

Lymphatic System.—Definite lymphatic canals are well developed in reptiles; those of the head unite into thoracic ducts which open into the innominate veins. There is a pair of posterior lymph hearts discharging into the iliacs.

Blood.—The red blood corpuscles are oval, biconvex and nucleated; they are larger than those of birds and mammals, smaller than those of Amphibia.

"Ductless Glands."—A spleen is constantly present in reptiles, placed near the stomach or within the loop of the duodenum behind the pancreas. The reptilian thyroid is a median structure placed somewhere on the ventral surface of the trachea.

There are two pairs of thymuses in Sphenodon and lizards, derived from the second and third pharyngeal pouches in the latter. In snakes there are usually two pairs derived from the

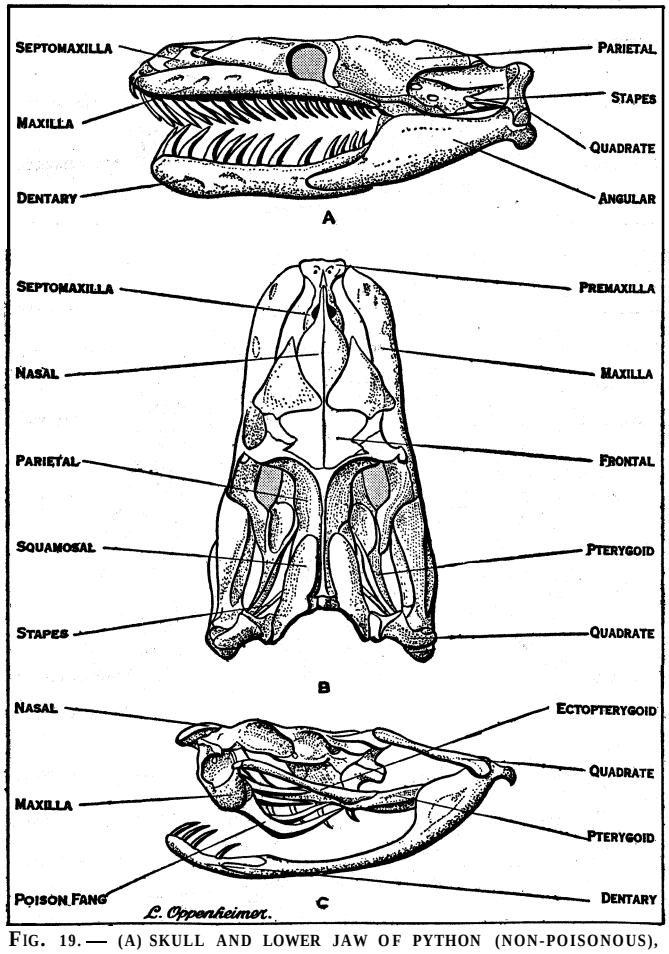

FIG. 19.— (A) SKULL AND LOWER JAW OF PYTHON (NON-POISONOUS), (B) SAME FROM ABOVE. (C) LEFT SIDE OF SKULL AND LOWER JAW OF RATTLESNAKE (POISONOUS)

dorsal extremities of the fourth and fifth pouches. A variable series of epithelial bodies, either dorsal or ventral, is present, and there is an ultimobranchial body of the left side, at any rate, in lizards.

Nervous System: Sense Organs.—Skin. Tactile corpuscles are found in the cutis of all reptiles. In crocodiles a group of them lies at the bottom of a pit, filled with non-conified cells near the anterior border of each of the large ventral scales. In Chelonia they lie in the thin layer of connective tissue between the epidermal scutes and the bony shell. In certain Agamids some of the scales of the dorsal surface bear long rod-like projections and are surrounded by nerve endings so that they may function as specialized tactile organs as do some mammalian hairs.

Taste.—It is clear that some sense of taste exists, the taste buds being probably on the tongue.

Smell.—The sense of smell is well developed in all recent reptiles. although it was much reduced or absent in the later Pterodactyls.

The external nostril, often provided with a valve, leads into a short vestibule, which opens out into the true olfactory chamber, whose wall is lined with the sensory epithelium which contain the olfactory cells. The area of the surface of this epithelium is increased by the presence of a ridge, the concha, which stretches into the cavity from the outer side. In crocodiles there is an additional concha, and there are reasons for believing that in Cynodonts, ethmo- and naso-turbinals were developed as in mammals. The nasal cavity finally opens to the palate by the internal nostril, which may be carried far back by the formation of a secondary palate.

Jacobsen's organ is, in Chelonia, a mere diverticulum of the ventral part of the nasal cavity. In Squamata it becomes an independent chamber, separated from the nasal cavity by the septomaxillary bone; it then has a special opening to the palate and may be very highly developed, receiving a large proportion of the olfactory nerve fibres. Its function is clearly to smell food after it has been taken into the mouth.

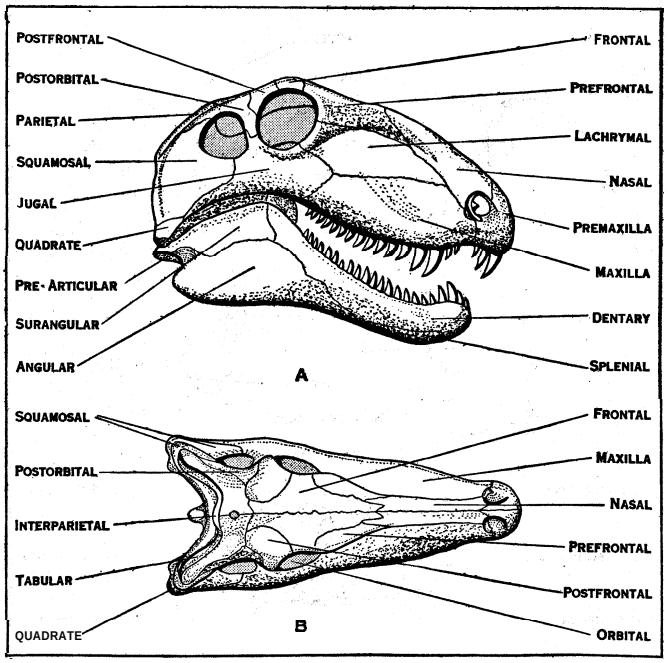
Jacobsen's organ soon vanishes in crocodiles. A special nasal gland is developed in the concha of reptiles, and the naso-lachrimal duct opens on the lateral wall of the nasal cavity.

Eye.—The eyes of reptiles are normally provided with movable upper and lower eyelids, and a nictitating membrane which is usually transparent and can be drawn across the cornea. The nictitating membrane may vanish in some lizards; in snakes it is permanently drawn across the eye, fuses with the remnant of the upper eyelid, and has a cornified scale on its outer surface, which is shed with the rest at ecdysis.

In some desert lizards the lower eyelid has a transparent window in the middle and is fused with the upper. In chameleons there is no nictitating membrane, and the upper and lower eyelids fuse, leaving only a small hole the size of the pupil. There are Harderian, conjunctival and lachrimal glands, whose secretion is discharged into the nose and palate by the naso-lachrimal duct.

The sclerotic coat of the eye ball often contains a ring of supporting ossicles, the cornea is convex. The crystalline lens is supported in a capsule by ciliary muscles, and accommodation can be carried out over a wide range.

The iris is usually brightly-coloured, and the pupil can contract either to a circular or a slit-like condition. The pupilary reflex to light is usually difficult to evoke. The retina is built up of



FROM "CONTRIBUTIONS FROM THE WALKER MUSEUM, CHICAGO UNIVERSITY"

FIG. PO.— SKULL OF THE PELYIOSAUR, SPHENACODON; (A) RIGHT SIDE. WITH LOWER JAW, (B) FROM ABOVE

small elements, both rods and cones being present in some forms, rods or cones alone in others. The retina, like that of birds, often contains pigmented oil granules, yellow, red, green, and, in Chelonia, blue and violet. Nutrition of the contents of the eye ball is secured, in many reptiles, by the presence of a pecten, a pigmented vascular projection, at first conical and when more highly developed fanshaped which arises from the fundus. A pecten is absent in Sphenodon and rudimentary in Chelonia. In snakes its place is taken functionally by a vascularization of the choroid. In chameleon there is a macula and fossa like that of

birds or primates. The eyes of reptiles are always laterally directed, but can be moved through a small arc of about 20°. They possess the normal series of six eye muscles and a retractor bulbi in addition. Reptiles appear to possess a colour sense, but accurate observations are lacking.

Pineal Eye.—In Sphenodon and lizards the epiphysis of the brain lies in a foramen between the parietal bones, and is covered by a transparent scale. It ends in a vesicle whose outer wall is lens-shaped, whilst the lower surface is a pigmented retina. It appears to exhibit no perception of light. The immense size of the pineal foramen in some fossil reptiles suggests that the pineal eye was functional in them.

Ear.—All reptiles have an inner and middle ear, an outer ear being present in crocodiles and the extinct Cynodonts. The inner ear is more advanced than that of Amphibia in that the utriculus is connected to the swollen sacculus by a duct from which the endolymphatic duct rises. There is a lagena which, in crocodiles, becomes much elongated and provided with a rudimentary organ of Corti seated on a basilar membrane.

The endolymphatic duct ends blindly, usually within the skull, but in Geckos is extended into a sac under the skin of the neck. There is a special perilymphatic duct which forms a closed tube definitely associated with the lagena. In crocodiles this begins to form definite scalae comparable to those of the mammalian cochlea.

The cavity of the middle ear is formed by an upgrowth from the first visceral pouch; in Sphenodon and lizards the cavity communicates with the pharynx by a wide opening, in Chelonia by a narrow Eustachian tube. In crocodiles the Eustachian tubes of the two ears meet and form a duct running in a special canal between the basisphenoid and basioccipital to open in the middle line just behind the choanae; lateral branches from the duct pass in canals between the basisphenoid and the pterygoids up into the supraoccipital and cranial roof, there enlarging into air spaces which again communicate with the tympanic cavities. Finally, a tube rising from each cavity leads air down into the quadrate and lower jaw. The history of this elaborate arrangement can be made out from fossil materials. In snakes, the tympanic cavity is totally obliterated. The outer wall of the tympanic cavity is the tympanic membrane, which, in crocodiles and most lizards, is a thin sheet sunk below the surface of the head at the lower end of an external auditory meatus. In Sphenodon and Chelonia it lies flush with the surface, and its outer surface is indistinguishable from that of the neck. In snakes and chameleons it is absent.

The tympanic membrane is connected with the fenestra ovalis by a rod, whose inner end is an ossified columella or stapes, whilst the unossified outer end is the extra columella. This is small and simple in Chelonia, absent in snakes, where the end of the stapes articulates with the quadrate, and in Amphisbaenans. In lizards, the extra columella has a dorsal process attached to the end of the paroccipital process, and often detached, a ventral process applied to the quadrate, and a plate for insertion in the tympanic membrane. The whole structure is of hyoidean origin, and the hyoid articulates with the end of the paroccipital process. In Sphenodon it fuses with the end of the extra columella, and in crocodiles it arises from its shaft to pass down the air canal to the lower jaw and become continuous with Meckel's cartilage.

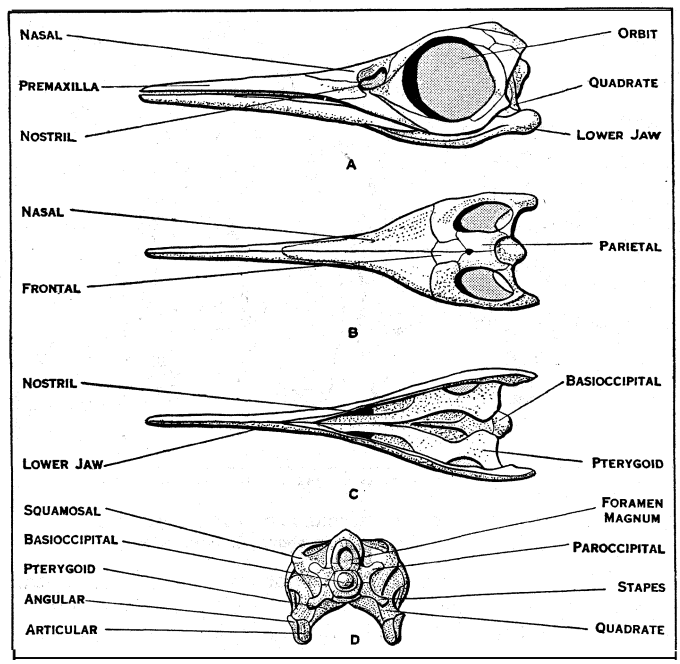
Most or all reptiles are capable of hearing, but we know nothing of their ability to discriminate musical notes.

Peripheral Nervous System.—The spinal nerves of reptiles agree in all important characters with those of other Tetrapods, the only interesting peculiarity being the presence in snakes of rudimentary pectoral and pelvic plexuses, relics of the limbs of their ancestors.

The sympathetic system presents an advance over that of most Amphibia in that many of the ganglia in the thoracic region are fused into a single large ganglion, and that the cervical sympathetic is separated into deep and superficial portions, each running continuously from the ganglion of the vagus to the thorax, the details varying in different orders. This arrangement is derived from that of Urodeles and leads directly to birds.

The cranial nerves of reptiles differ from those of living Amphibia in the absence of all trace of the lateral line system, except the auditory nerve, in the presence of a spinal accessory nerve XI. and in the fact that the hypoglossal nerve XII. passes out through the exoccipital bone.

Brain.—The reptilian brain is larger proportionately than that of an amphibian of the same size. The cerebral hemispheres



BY COURTESY OF THE CARNEGIE MUSEUM

FIG. PI.—SKULL AND LOWER JAW OF THE ICHTHYOSAUR OPHTHALMOSAURUS; (A) LEFT SIDE, (B) FROM ABOVE. (C) FROM BELOW

are pointed and usually pass gradually into the olfactory lobes. Their hinder ends are free and often project posteriorly so as to conceal the diencephalon.

In Sphenodon and in Chelonia the whole of the upper surface of the hemisphere, from the hippocampus on the inner surface to the lateral face, is covered by a pallium, devoted to the sense of smell. This layer of cells then turns inward from the surface, and lies on the top of the corpus striatum, forming a hypopallium. In lizards, and especially in crocodiles, the dorsal surface of the hemisphere becomes less and less nervous until, in birds, it is a mere membrane playing no part in the functioning of the brain. In these reptiles the hypopallium becomes broken up by a penetration of nerve fibres, loses its pallial appearance and becomes assimilated to the corpus striatum. Thus, presumably in these animals, and certainly in birds, behaviour is controlled and memory exercised by a part of the brain quite different from that which fulfils these functions in mammals. In some reptiles, at any rate, the first trace of the neopallium, which is the important and developing part of the brain in mammals, is represented by a small cortical area in which alone other senses than smell gain a direct representation.

The mid brain of reptiles has its roof thickened and raised into a pair of optic lobes, which not only receive the endings of the optic nerves from the retina but are the motor area, stimulation of which brings about movements of the body.

The cerebellum of reptiles is always larger and better developed than that of Amphibia, though in living forms it is not externally divided into regions, as is that of a bird or mammal.

The brain of the extinct pterodactyls is interesting because, in the reduction of the olfactory lobe, the large size of the cerebellum and the lateral position of the optic lobes, it exactly resembles that of a bird, is indeed more like that of recent birds than is the brain of Archaeopteryx, which is the most primitive member of that class.

Reproduction.—Fertilization of the reptilian egg always takes place internally, in contrast to the condition in many Amphibia.

FIG. 22.—SKULL OF THE PLESIOSAUR. MURAENOSAURUS
A. From the left side, B. from above, C. from below

The egg is always large and provided with so large a store of food materials in the form of yolk that the growing embryo, without any additional materials, can hatch in a form capable of fending for itself, and is usually a miniature copy of its parents.

This ovum is surrounded by a semi-fluid layer of albumen, and enclosed in a membranous shell which may be calcified as is that of a bird. Usually the egg is laid before development has gone far, but in some cases it is retained within the oviduct until the foetus is ready to he born. These animals, including many lizards and snakes, are thus viviparous. In their case the egg shell is thin, and food materials may pass through it; indeed, in some cases it is practically absent, and the little lizard secures nourishment from its mother through a special placenta.

Cleavage is meroblastic, resulting only in the formation of a primitive plate of cells. Gastrulation involves an actual invagination, resulting in the formation of an archenteron which has both floor and roof. The process is, indeed, similar in principle to that in the Gymnophionan Amphibia. No primitive streak is formed behind the blastopore in Chelonia, Sphenodon, lizards or snakes.

The later development much resembles that of birds or monotremes. A headfold is formed, followed by tail and lateral folds, which gradually raise the embryo from the yolk and extraembryonic structures. An amnion arises from the extraembryonic somatopleure, as in birds, and an allantois is formed later by a ventral outpushing of the hind gut.

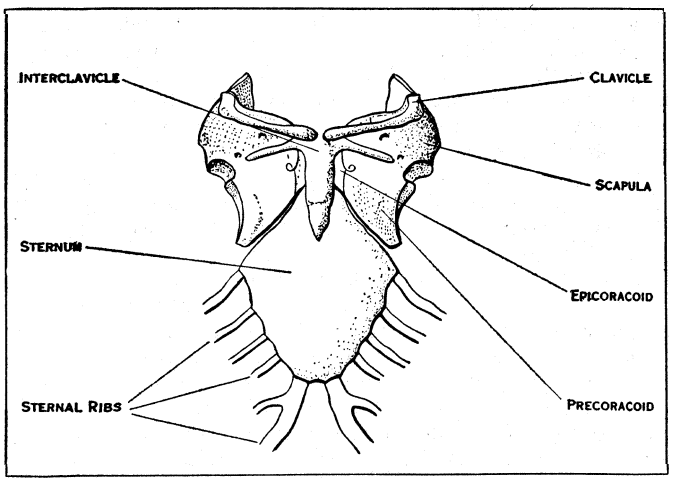

FIG. 23.—SHOULDER GIRDLE OF A LIZARD AMBLYRHYNCHUS FROM BELOW. SHOWING THE RELATIONS OF THE CLAVICLES, INTERCLAVICLE PRECORACOID AND STERNUM TO ONE ANOTHER

It serves not only as a reservoir for the excretory products of the embryo, but also as a respiratory organ. The embryo breaks its way out of the shell by the aid either of an egg-tooth, placed mesially on its nose or of a caruncula on its head. (*See* also VERTEBRATE EMBRYOLOGY.)

Mode of Life.—No general statements can be made about the habits of reptiles. Counting extinct forms, they have occupied all the habitats which are today filled with mammals, except that they are excluded from polar regions by the impossibility of hatching their eggs there, and in extreme cases of achieving a sufficiently high rate of metabolism. The temperature of the body of reptiles, like that of Amphihia, and unlike that of the birds and mammals, is determined by that of their surroundings, rising when the animal is in a warm place, and sometimes becoming very high in bright sunlight, and falling at night, perhaps to freezing point. The animal's muscular activity always keeps it a very few degrees above the air temperature.

Distribution.—Apart from the limitation imposed by temperature, no general statements can be made about reptilian geographical distribution; any useful account would occupy much space, and involve a discussion of the interrelationships of the families of lizards and snakes, a disputed field.

The oldest reptile bone is an isolated femur from the Lower Carboniferous of Scotland Eosauravus, from the Upper Carboniferous of Ohio, is probably a reptile, and Solenodonsaurus, from the top of the Upper Carboniferous of Czechoslovakia is certainly one. The evolution of the reptiles was rapid, nearly all orders being fully established by the end of Triassic times. Several important orders became extinct at the end of the Trias, but the reptiles were the dominant group of vertebrates to the end of the Mesozoic, when, within a short period though not simultaneously, many orders became extinct, leaving only the four which still survive.

Economic Importance.—Reptiles are of slight importance to man. Poisonous snakes are responsible for many deaths of man and domesticated animals in all tropical and some temperate regions. The marine turtle, *Chelone midas,* found in tropical ocean waters, provides the best of all soups; several fresh-water forms are often eaten, the most familiar of these being the terrapins, of the genus ***Chrysemys.*** The eggs of various species are also eaten. The skins of crocodilians, and of certain of the larger lizards and snakes, are tanned and used as leather. This consists only of the cutis, the horny epidermis being removed. This leather is extraordinarily tough, and the presence of the papillae which underlie the scales gives it an attractive surface The pigment, or at any rate such of it as is melanine, may remain in the leather and give it characteristic patterns Use of reptilian leathers for women's shoes and handbags led to the destruction of many of these animals Some alligators are bred for the purpose.

REPTON, a township in Derbyshire, Eng., about 8 mi. S.W. of Derby by road. Pop. (1951) 1,59j. Its famous boys' school was founded in 1557 by Sir John Port; the modern buildings incorporate considerable portions (restored) of an Augustinian priory established in 1172. There was a monastery in the 7th century, the first bishop of Mercia being established there. The parish church of St. Wystan has pre-Conquest work in the chancel, and beneath is a remarkable Saxon crypt. part of the wall of which may have been included in the original monastery chapel

REPUBLIC, a term denoting (1) a state not ruled by a monarch or emperor, generally a public interest and not a private or hereditary property; (2) a state where power is not directly in the hands of or subject to complete control by the people, in contrast with a democracy (*q.v.*); **(3)** more loosely, any regime where government depends actually or nominally on popular will. The latter meaning is implied more generally in the adjective, "republican," than it is in the noun.

"Republic" derives from the Latin words res *publica,* public affair or thing. That concept was in turn loosely equivalent to the classical Greek ta ***koinonia,*** common things or property, a term originally applied in the early city-state to the city's treasure, the public funds, and then by analogy coming to symbolize and denote the common interests. From these root origins derive in turn the concepts of commonwealth. which was the official title of Great Britain under Oliver Cromwell's rule, the first republic in the English-speaking world, and common weal or common welfare, at that same time a widely held designation of the proper end or purpose of government.

The term republic has generally been applied by historians first to the government of ancient Rome after the expulsion of the Etruscan kings, the Tarquins, and prior to the establishment of the empire by Augustus. During that period, indeed, political

institutions, constitutional arrangements and the locus of effective political power varied widely, though the regime might be generally described as one of aristocratic, or patrician, ascendancy moderated by popular. or plebeian, influence and assent. But the dual concepts which subsequently characterized the republican idea, absence of monarchy and a collective public interest and business, were present.

Some historians have also applied the term to the ancient Greek city-state. There, however, governments were normally classified by the numbers exercising power, such as monarchy, aristocracy and democracy. and their perversions. tyranny, oligarchy and ochlocracy (or, frequently, again democracy), where rule was arbitrary rather than directed by the principle of the good of the city. Nevertheless, one root idea of a republic. that of common interest and participation, was present in the contrast between Greek city-state and barbarian empires, with their irresponsible rulers and submissive mass of subjects.

In any event, republic, when applied to ancient governments, has implied some popular and collective power and the absence of hereditary or autocratic rule, as contrasted with government by kings or emperors.

The modern usage of "republic" derives from these dual ideas, absence of monarchy, and some degree of avowed concern for the common welfare of the state and for public control or participation. During the later middle ages there were established some brief-lived local republics, consequent on revolt. But it was in certain city-states of Italy during the Renaissance, of which the most celebrated are Venice and Florence (during a limited period after the expulsion and before the return of the Medici) that the republic re-emerged as a meaningful designation and form of government. Here again absence of monarchy, of an established lordly ruling family or of a self-imposed absolute ruler was the first test. In such republics a share in control of government was often confined to noble or wealthy privileged families. while the form of government tended to be by a small group, co-opted or elected on a narrow franchise, though sometimes with a titular head of state, such as the doge in Venice. On occasion, too, as a result of popular pressure or revolt, government might for a while come to rest on a broader base, and to include representatives of at least the lesser burghers and the artisans.

But republics which combined the ideas of absence of monarchy, a realm of public affairs and popular consent or participation first emerged, generally as temporary phenomena, in the 17th and 18th centuries. Cromwell's commonwealth, though it developed into rule by one man not unlike the more moderate modern dictatorships, had its genesis in antimonarchical doctrines and forces, expressed in the Great Rebellion against Charles I. During that conflict, too, the concept of the interest of the community at large in government became firmly associated with the republican idea. The Dutch republic, though it was headed by a stadholder. initially the equivalent of a modern strong president, combined opposition to monarchy (and to Catholicism) with a concept of independence not unlike the later idea of national self-determination, with implications of a common collective interest and a certain degree of public participation and control. Similar considerations also played a part in the early evolution of the Swiss republic. which after many vicissitudes became the modern federal republic of Switzerland. Here, however, the independent city-states of the Reformation, republican even when theocratic and in some cases free still earlier, provided a foundation.

The antimonarchical idea constituted a major element in both the American and the French Revolutions. The former created a lasting republic. the United States of America, while the second created a temporary republic in France but firmly established the republican idea and spread it throughout most of western Europe. In both revolutions the twin ideas of consent of the governed and the rights of man played a major part. A little later the separation of the Spanish-American colonies from Spain produced numerous republics which rested on similar ideas. During the 19th century, however. the moral significance of the republican idea declined in Europe, where monarchies continued and republics remained the exception. Constitutional government spread in the monarchies, and by the early 20th century the term "republic" no longer connoted the substance and content of political institutions and practice. "Democracy" tended to supplant "republic" in describing governments free from arbitrary and imposed authority. Democracy was widespread in Great Britain (also the British Commonwealth) and the Scandinavian countries—all monarchies. In Latin America, on the other hand, nominal republics were often dictatorships on behalf of oligarchies.

In these and other instances, the term "republic" had been stripped of its earlier appeal as the alternative to divine-right monarchy and autocracy.

After World War I, the emergence of dictatorships, which might function formally within a monarchical state (Fascism in Italy), might reject the idea of a republic without restoring monarchy (Francisco Franco's Spain), though restoring the title of empire (Hitler's third *Reich*), or might continue nominally as republics, rendered the classification of regimes into monarchies or republics practically meaningless. After World War II, moreover, the term had still less relevance. The United States of America, Franco's anti-Communist dictatorship in Spain and Joseph Stalin's Communist dictatorship in the U.S.S.R. were all nominally republics. In essence, the basic classification of governments was into constitutional governments and dictatorships, a division which corresponded in ethos to the former opposition of republic and monarchy. The term republic no longer had a manifest connection with struggles over liberty, authority and sovereignty.

The adjective "republican," however, was still sometimes used with connotations equivalent to its ancient meaning in political ethics.

In the United States the term "republic" has special connotations and is frequently used with supposed historical justification to contrast with democracy and as a ground for denial that the U.S. is technically a democracy. The bases for this contrast are (1) the ancient and purist use of the term "democracy" to denote small-scale direct democracy; (2) the classical fear, which continued at least to the end of the 18th century, of such democracy as unstable and fickle; (3) the Ciceronian interpretation, which widely influenced the U.S. founding fathers, of the Roman republic as a mixed and balanced government; and (4) the revival by Montesquieu in the 18th century of the idea of democracy as direct and small scale, and his insistence that democracy mas impossible in a larger state, which could be at best a representative republic. These ideas were studied and combined by a number of the founding fathers, and especially by James Madison. who used the term "republic" (1) as a technical designation for representative government as opposed to direct democracy and (2) to insist on the necessity for a system of checks and balances against the dangers of straight majoritarian decision in a legislature elected by majority on a single principle of representation. The insistence that republic is not synonymous with democracy either as direct democracy or as absolute majoritarian democracy, but rather is synonymous with constitutional democracy. is correct in the specific U.S. context, though that usage is a narrowing of the wider use of the term to denote any nonmonarchical regime. The guarantee to the states of the union of a republican form of government (in a nation whose given title deliberately excluded the designation republic) seemingly refers primarily to the more generic usage and it does not imply specific forms or checks.

REPUBLICAN PARTY (U.S.), was organized in 1854. Various small group meetings, the earliest in Ripon, Wis., mere held in a half dozen states. A mass meeting at Jackson. Mich., attended by former Whigs, Democrats and Free Soilers on July 6, 1854, adopted for themselves the name Republican. This was an appealing title not only for those who recalled Jeffersonian "republicanism," but for those who placed the national interest above all sectional interests and were opposed to states' rights. The

issue presented by slavery in Kansas had called this party into existence. It was from the beginning strongly nationalistic. The pronouncement that slavery was a moral, social and political evil was coupled with denunciation of the Kansas-Nebraska legislation and the Fugitive Slave law.

An informal gathering, national in scope, meeting in Pittsburgh, Pa., on Feb. 22, 1856, planned the first national convention, which assembled in Philadelphia, Pa., on June 17. Its platform denied to congress the right to recognize slavery in a territory, and held that congress had the right to abolish slavery in the territories and ought to do so. This view. no longer that of extremists, was representative of widespread sentiment in the north. John C. Frémont, widely known for his western exploration, who in 1849 had been elected to the senate from the state of California, was the nominee for the presidency. He won 114 electoral votes, but was defeated in a three-cornered contest against Millard Fillmore, candidate of the American ("Know-Nothing") and Whig parties, and the cautious and conservative Democrat, James Buchanan, who was elected.

Ensuing events rapidly consolidated and intensified the anti-slavery movement, and on May 16. 1860, a Republican national convention assembled in Chicago, Ill. This organization came to power in 1861 with Abraham Lincoln as president. In a four-party contest the Republican victory was that of a minority. Yet the new Republican party had rapidly displaced the Whig party in the north as the opponent of the Democratic party.

Lincoln's primary policy was the preservation of the union at any cost. The outbreak of rebellion in southern states and the secession of 11 states played havoc with existing party lines. For four years the armed conflict came to no positive conclusion. In the autumn of 1864 the president faced the necessity of going to the people at the stated election time, and did so with slight hope of a vote of endorsement. His supporters confessed their weakness. In calls for a convention and in the convention, they termed themselves the Union party. This party, with Lincoln as its nominee and a war Democrat, Andrew Johnson: as vice-presidential nominee, did defeat the Democrats who had in their national convention that year declared the war a failure. The war was continued to a successful conclusion, but the assassination of Lincoln, who died on April 15, 1865, brought a complete realignment of political forces.

Within a year of the end of hostilities, the Republican party had reappeared and was functioning as an organization bent upon retaining control of the government and taking a form that was to prove the most powerful yet seen in the history of parties in the United States. Throughout the following 30 years, the Republicans and the Democrats — who by the autumn of 1866 appeared as the one agency of strong opposition — fought for control of the national government, the Republicans usually winning.

The fight for improvement in the civil service, for genuine tariff revision, for a democratic land policy, for protection of the Indians — persisted within the parties. Within the Republican party, insistent insurgents and faultfinding groups protested in vain at the rigidity of party control. Two groups left the party, the Liberal Republicans in 1872, and the Progressives in 1912. Yet on each occasion many leaders and millions of voters remained.

In the years of chaotic reconstruction, the Republicans ruled harshly in the south and attempted to confer their political power upon the unprepared Negro. In these years the Republican party organization was revealed as of selfish design and cowardly practice, ruled by a small and usually self-perpetuating group of politicians who made party regularity a fetish. Their list of nominees for the presidency included Generals Ulysses S. Grant, Rutherford B. Hayes, James A. Garfield and Benjamin Harrison. and Maj. William McKinley. To the support of these tickets rallied voters from the villages and country districts of the old east and of the new west, mostly men of small means attached to the traditions of their pioneering forefathers. The Republican appeal was frankly to businessmen as the 19th century ended.

The tariff was included in the Republican platform as an issue in the campaign of 1896, but as this battle approached much greater prominence was given the question of the free and unlimited coinage of silver. William McKinley of Ohio was nominated by the Republicans on a gold standard platform and won the election.

Republicans in congress had in 1896 favoured recognition of the independence of the Cubans, who were in revolt against the government of Spain. In the Republican party platform that year was expressed the hope that not only would the Cubans win in their struggle for liberty, but that the government of the United States would actively use its influence to restore peace and give independence to the island. In his inaugural speech in March 1897, McKinley indicated his unwillingness to take steps that might appear to call for a war of conquest. But in April 1898, the president, responding to a strong popular demand, recommended the intervention of the United States. The congress then declared the war that for many months had seemed to members of both parties desirable and inevitable. The war nevertheless exposed issues in world relations that led to a sharp division between the two parties. A treaty of annexation of the Hawaiian Islands had been negotiated by Pres. Benjamin Harrison in 1893 and withdrawn by Pres. Grover Cleveland. The Republicans. who came to favour such annexation, argued military and commercial necessity. Despite strong Democratic opposition, in the summer of 1898 by joint resolution of congress the republic of Hawaii was annexed to the United States with territorial status,

The nation entered upon the congressional campaign of 1898 before the end of the war with Spain. The Republicans gained 8 seats in the senate, although the Democrats gained in the house by 29. The administration now called for the cession of the Philippines to the United States, and Spain was forced to yield.

A new era in Republican party domination was dawning. Theodore Roosevelt, who in 1898 had been elected governor of New York. was supported for the vice-presidency in the campaign of 1900 by Republican party boss T. C. Platt, who was anxious to get him out of New York politics. Roosevelt had a large and enthusiastic support among the delegates from western states, and was nominated against the wishes of both McKinley and Marcus Alonzo Hanna, who, however, bowed to the will of the convention. The problem of the party managers was one of first magnitude when, in the autumn of 1901, the assassination of President McKinley brought to the presidency the independent and imaginative Roosevelt. As the Republican party at this time was not possessed of a definite party program, as it had been in 1897, there was both opportunity and need for a leader who could reshape its appeal and its purpose. This President Roosevelt proceeded to do.

The business of the Republican organization had been primarily the task of running the government. Longer lease of power than usual had strengthened this tendency. The rising tide of social democracy made it certain, however, that no agency for the expression of the public will could long escape revaluation in the light of the demands of the common people for a larger share in self-government. In considering the course of action that should be his at this juncture, President Roosevelt chose to direct his attention to the trusts that had become powerful enough to disregard the government. The president's attack was directed not upon large business, as such, but upon powers that believed themselves superior to the government. The popularity of Roosevelt's position on the trusts and his aggressive action in the coal strike of 1902 brought to his support thousands who had for many years been interested in governmental control of corporations.

Roosevelt's acquisition of the widespread popular support that won him re-election in 1904 was made possible by the failure of the Democratic party to justify the expectations aroused in 1896. The party had seemed at that time to promise emancipation from the oppressions of organized wealth and a great minority of the voters had twice supported William Jennings Bryan for these reasons. When Roosevelt professed to desire these ends, many Democrats came to his support.

The overwhelming endorsement of Roosevelt in 1904 gave to his second administration a more personal character than had prevailed in the preceding three years. That Roosevelt subsequently brought about the nomination of William Howard Taft, who was elected in 1908, led to a widespread but erroneous belief that the Republican party organization was responsive to the Roosevelt

leadership. The overthrow of the Republican majority in the house of representatives in the congressional elections of 1910 ended the complete control of the national government which that party had held for 14 years. This election revealed the strength of insurgency in the west. A group of western Republicans henceforth opposed the national party upon all important measures.

In Feb. 1912. Roosevelt announced that if the Republican nomination were offered him by the national convention, he would accept. He was attempting to obtain what he had appeared to have in 1908, but which he had never won in open contest, either in 1901 or in 1904, that is, control of the party machinery. He was now prepared, on a platform advocating more direct government, to make the party organization responsive to the demands of the voters of the party. Presidential primaries in 12 states revealed that the majority of the voters participating were favourable to his candidacy. However, before the national convention assembled, it was known that there would be sufficient votes to nominate Taft. A third of the delegates, nevertheless refused to participate, foreshadowing defeat of the ticket. A mass meeting of citizens from 40 states met in Chicago in Aug. 1912 and organized what they termed the Progressive party (see PROGRESSIVE PARTY, THE). The platform called for a change in political machinery and for an aggressive program of social legislation. Roosevelt was nominated for the presidency and Gov. Hiram W. Johnson of California, was named for the vice-presidency. The contest that followed—with Taft the Republican nominee—assured election of the Democratic candidate, Woodrow Wilson.

Not until 1920 were the Republicans successful in placing another nominee in the presidency. Sen. Warren G. Harding of Ohio succeeded President Wilson for a period of 29 months. When Harding died suddenly, he was succeeded by Calvin Coolidge. By this time, the Republican party had become more than ever a coalition of sectional leaders and of divergent economic interests. The outstanding national figures were insurgents, riot regulars. Most conspicuous and powerful was Sen. Robert M. LaFollette of Wisconsin, who led an insurgent group out of the party in 1924. Coolidge was re-elected in the three-party contest on a wave of prosperity, which continued until after the election of Republican Herbert Hoover in 1928. Hoover represented, to a large following of independents and liberals, a new conception of government in the interests of the people in a new scientific age. As an engineer by profession, Hoover had established himself as a great humanitarian in the administration of relief abroad and later in the direction of the United States Food administration under President Wilson. World-wide depression that overtook the United States economy when it had not yet recovered from the business panic of 1929, and defections within the Republican party in congress led to Hoover's defeat in 1932, when Franklin D. Roosevelt became president. His repeated re-election, the succession of Harry S. Truman upon the death of Roosevelt on April 12, 1945, and the re-election of Truman—kept the Republicans in a minority position for 20 years.

In 1952, with the nomination of an outstanding military figure of World War II, Dwight D. Eisenhower, the Republicans again swept into power under the dominance of a group of liberals, as opposed to the conservatives led by Sen. Robert A. Taft. In both domestic and foreign affairs pursuing a moderate course, Eisenhower attracted much non-Republican support.

The Republicans meeting in mid-August of 1956, enthusiastically renominated President Eisenhower and accepted again, as his running mate, Richard M. Nixon of California. The president waged an aggressive campaign, and was drawn by the attacks of the opposing party to a spirited defense of foreign policy including the continuation of hydrogen bomb tests and maintenance of the draft for military service. President Eisenhower polled 35,582,236 votes to 26,028,887 for Adlai E. Stevenson, the Democratic nominee. The Republicans failed to win control of either the house or senate, however, and in 1958 the Democratic party increased its majorities in both houses.

In 1960 the Republicans nominated Nixon for president and Henry Cabot Lodge, U.S. ambassador to the United Nations, for vice-president. Both candidates vigorously defended the Republican administration's record and emphasized U.S. diplomatic gains and domestic advances. Foreign policy debate with Democrats, especially over points concerning action to meet Communist influence or military threat, led to strong charges and countercharges in campaign speeches and in Nixon's joint television appearances with Sen. John F. Kennedy, the Democratic candidate. At the polls on Nov. 8, despite the closest popular vote in the 20th century, Nixon and Lodge failed to carry most of the more heavily populated states with their large electoral vote and were defeated.

REPUBLICAN RIVER, a river of the central United States, rises in eastern Colorado in Kit Carson and Lincoln counties, flows east in southern Nebraska, bends southeast at Superior, Neb., and flows into the Kansas river at Junction City in northeastern Kansas, 445 mi. from its source. The entire course of the river is over flat, level land with light rainfall. The stream is dry much of the year, especially in the upper part. During the spring and early summer months and during flood periods runoff is heavy. A control dam at Trenton, Neb., completed in May 1953, has a total storage capacity of 254,000 ac.ft. Water is used for irrigation in the Frenchman-Cambridge irrigation project. Cattle, wheat and corn are the main products from the Republican drainage. McCook, Franklin and Red Cloud, Neb., and Belleville, Concordia and Clay Center, Kan., are important towns on the river.

(M. J. L.)

REQUEST, LETTERS OF. The legal terms "letters rogatory," or "of request" (commission rogatoire), express a request made by one judge for the assistance of another in serving a citation, taking the deposition of a witness, executing a judgment or the doing of any other judicial act. The only trace of such a practice to be found in England or the United States, independent of statutory enactment, is in the admiralty doctrine that the sentence of a foreign court of admiralty may be executed on letters of request from the foreign judge or on a libel by a party for its execution. The British and United States courts issue commissions to private persons, generally, however, to consular officers, but sometimes to foreign judges in their private capacities, for the purpose of taking the depositions of witnesses. Many countries object to this process and require letters of request, which have to be forwarded through diplomatic channels. In ecclesiastical law, letters of request are issued for the purpose of sending causes from one court to another. Letters of request are also issued for other purposes: to examine witnesses who are out of the jurisdiction; to enforce a monition; etc.

REQUESTS, COURT OF, originally a committee of the king's council in England. Petitions of poor persons were heard by the justices in eyre and on the fall of the eyre were referred by the council to the chancery. By an Order in Council of 1390 these petitions were transferred to a committee of the council and the lord privy seal became its president. At first the court followed the king, but about 1516 Wolsey assigned to it a permanent seat in Whitehall, when it became known as the court of Whitehall or the court of poor men's causes. Lastly, it obtained its official title of the court of requests. The judges were at first those privy councilors who happened to be present, together with judges and masters as assessors. Eventually four privy councilors, or masters of requests, were appointed at fixed salaries.

REREDOS, an ornamental screen of stone or wood built up or forming a facing to the wall behind an altar in a church. Reredoses are frequently decorated with representations of the Passion, niches containing statues of saints and the like. In small churches the reredos is usually replaced by a hanging behind the altar, known as a dorsal. (See also ALTAR.) The use of the word reredos for, the iron or brick back of an open fireplace is obsolescent.

RESACA DE LA PALMA, a battle between Mexico and the United States, fought near Brownsville, Tex., May 9, 1846. U.S. troops under Brig. Gen. Zachary Taylor, ready to renew the conflict after the indecisive battle of Palo Alto (May 8), pursued a column under the Mexican Gen. Mariano Arista, who had entered

a dense growth that continued interruptedly to the Rio Grande, 7 mi. to the south. About halfway through the thickets, Arista disposed his command behind an old river channel which crossed the road at right angles. The bed (Resaca de Guerrero) was full of ponds and mud, impassable in many places. The U.S. troops. about 1,700, came upon the Mexican guns planted in the road and hacked their may toward their enemy. There was little direction or plan to the encounter, but one of Arista's flanks was accidentally turned and his force was routed. (W. A. G.)

RESCHEN SCHEIDECK, Alpine pass leading from the lower Engadine to the upper valley of the Adige. Near the summit (4,947 ft.) is the hamlet of Reschen, while below is the former hospice of St. Valentin auf der Haid, mentioned as early as 1140. Starting from Landeck, the motor road runs up the Inn valley to Pfunds, where it mounts above the gorge of Finstermiinz to the village of Nauders (27¼ mi.) joining the road from the Swiss Engadine (53½ mi. from St. Moritz). There it mounts gently to the pass and then descends, with the Adige, to Mals (15½ mi.), where the pass is sometimes wrongly named Llalserheide. The road now descends the upper Adige valley, or Vintschgau. past Meran (37¼ mi.) to Botzen (20 mi. from Meran) where the Brenner route is joined.

RESEARCH, INDUSTRIAL. The use of tools and machines to wring a living out of nature and to gain a measure of comfort and security reaches back to the earliest times, but until the late 18th century the tools were simple and progress was slow.

The Beginnings of Organized Scientific Research.—A century and a half earlier Francis Bacon had turned men's minds from mediaeval theorizing to observation, experiment and measurement, and scientific research (as the term is understood today) began to establish itself as a new force enabling man to understand the nature of things and turn this knowledge, if he chose, to his material advantage. The pioneers of the Industrial Revolution did not wait for research to grow up, so that before long experiment began to overhaul empiricism and in due course the application of knowledge obtained from scientific research became a powerful factor in creating. step by step, our modern standard of living.

Relation Between Industrial and Fundamental Research.—It is usual to speak of the research which has been directly associated with producing these results as industrial research, but although the term is well justified and generally understood, there is in fact no hard and fast dividing line between the various categories of research. It is truer to say that scientific research is a spectrum shading from fundamental research at one end to technical advance at the other. But just as the difference between one part of the spectrum and another can be recognized, so can the difference between fundamental research, pursued without concern or regard for material advantage, and industrial research which is undertaken for the economic, social and other advantages to be obtained from it. Nevertheless, it is fundamental research that produces the great discoveries and ultimately revolutions. Michael Faraday's researches on electromagnetic induction opened up the road to modern power stations; and after J. J. Thomson had coaxed the secret of the electron out of matter, Ernest Rutherford could begin to pick the lock of the atomic nucleus. J. A. Fleming's discovery of the thermionic valve arose from sheer scientific curiosity about the blackening of the carbon filament lamp, but it led to the creation of new industries — radio, radar and television — based on electronics.

But if fundamental research is the goose that lays the golden eggs, the goose is quite incapable of hatching them out. This is the business of the industrial scientist and technologist who. between them, make it possible for the industrial machines to deliver their products in an ever-increasing stream of abundance. Industrial research is not, however, concerned only with exploiting fundamental discovery. It bases itself squarely on the accumulated store of natural knowledge, attends to the need of the particular industry-it serves and through its work in the laboratory and workshop brings new manufacture a stage nearer. This may be simply an improvement of an existing process, but it may be an entirely new one and the product may be new also.

Industrial research has extended its scope to include the systematic study of industrial operations, the handling of materials and the layout of plant. And since it is concerned broadly with the economic efficiency of industry. it works to raise the level of productivity through the better use of resources, human and material. Technological advance is apt to conflict with habits of work and current conceptions of management, and the industrial scientist finds himself involved increasingly in the deep and largely uncharted sea of human relations.

INDUSTRIAL RESEARCH IN GREAT BRITAIN, EUROPE AND THE COMMONWEALTH

Research in Industry.—By far the greater part of industrial research in Great Britain is undertaken by industry in its own laboratories. Accurate figures are not available but in a survey made by the Federation of British Industries in 1950–51 (see **Bibliography**) a questionnaire was sent to 1,400 firms and the 361 replies indicated that 301 firms spent £23,779,000 on research and development as compared with the following figures of earlier surveys. Thus, in 1930, £1,736,000 was spent on research and development; in 1935, £2,696 000; in 1938, £5,442 000; and in 1945–46, £21,815,000. In the 1945–46 survey it was concluded that the total amount spent by all firms could be estimated as of the order of £30,000,000. The figure in 1955 was certainly not less than 650,000,000.

There are no corresponding figures available for the European countries, but as in Great Britain, large industrial research staffs are maintained by the leading manufacturing firms and particularly those in the newer industries which have sprung from research or have been, from the beginning, dependent on the laboratory; e g., oil, chemical, electrical and synthetic fibres. The main emphasis is on applied research and development, but it is recognized that a certain proportion of fundamental research should be undertaken, both for its own sake and to attract and retain scientific staff of good quality. This is not only important in itself but exercises a beneficent influence throughout the company, extending to the development and production departments. Development is many times more costly than the research itself, but any comparison of costs must take into account the fact that all research does not end in development. Many research projects do not turn out as expected and in any event costs and the market have the final say in the choice of which projects should be developed.

There is no way of evaluating the results of research in terms of accountancy. Most good industrial research laboratories can point to some outstanding achievements over a period of years and claim rightly that if they had done nothing else they would have paid for themselves handsomely. But although this may inspire confidence it does not enable a board of a company to determine how much of its profits it should devote to research. Research expenditure in industry is frequently expressed as a proportion of annual turnover, and the proportions, as would be expected, vary greatly from industry to industry (3% is not uncommon in firms in the newer science-based industries). There is, however, no logical justification for comparing or estimating research expenditure on this basis; experience and judgment are the only guides and boards of companies who are alive to the needs of the times endeavour to maintain a level of research which will enable them to remain competitive in world markets

The Role of the Government in Industrial Research.— The government has a smaller but nevertheless distinctive place in industrial research because of its special and general responsibilities. In Great Britain, government departments are concerned. directly or indirectly. with maintaining health and safety; adequate housing; methods of growing, storing and distributing food; transport by road rail and air; the maintenance of communications; the provision of electricity and gas; the development of atomic energy; and the provision of fuel and its economical use to meet the requirements of the nation. The government has general responsibilities also for the maintenance of physical and engineering standards and for promoting a high level of industrial productivity.

The realization at the beginning of the 20th century of the loss caused by the profusion of standards used by engineers and the advantages to be gained by a system based on accurate measure-

ment and a careful investigation of the properties of materials led in 1901 to the setting up of the British Engineering Standards committee. In this work the National Physical laboratory, which was founded at about the same time, co-operated and continues to co-operate very fully. The scope of the committee's activities gradually widened, and in 1931 the British Standards institution came into being as the approved body for the preparation and promulgation of national standards.

George V, then prince of Wales, showed a keen perception of the needs of his time when he opened the National Physical laboratory in 1902 with these words: "The object of the scheme is, I understand. to bring scientific knowledge to bear practically upon our everyday industrial and commercial life, to break down the barrier between theory and practice, to effect a union between science and commerce. . . ." The aims of industrial research could not be more tersely expressed.

These aims were furthered in 1915 by the creation of a committee of the privy council, with the lord president of the council presiding, "to direct, subject to such conditions as the Treasury may from time to time prescribe, the application of any sums provided by Parliament for the organization and development of scientific and industrial research." Simultaneously, an advisory council was established to consider and report on proposals for instituting specific researches; for establishing or developing special institutions for the scientific study of problems affecting particular industries or trades; and for the establishment and award of research studentships and fellowships. To serve these bodies the department of scientific and industrial research was established in Dec. 1916 as a separate department of state with its own parliamentary vote, or grant. The new department assumed responsibility, jointly with the Royal society, for the National Physical laboratory, and later the geological survey of Great Britain became part of it. Separate establishments were formed to cover other main fields of applied research. In addition, a scheme was planned for co-operative research associations to be set up by various industries with financial assistance from the government; and a system of grants to young graduates to enable them to undergo training in research was instituted.

In 1955 the department of scientific and industrial research controlled 14 research establishments and financed in partnership with industry 42 co-operative research associations. Its grants to universities for special researches and its maintenance allowances to students for postgraduate training in research amounted to more than £700,000 annually. The gross expenditure of the department in 1953–54 was slightly less than £6,000,000.

The principle on which the department of scientific and industrial research is based has been followed in varying degrees and by various means both in European countries and the commonwealth. National research councils have been set up in some countries which not only act as policy-making co-ordinating bodies but in some cases undertake programs of research on their own account. A detailed analysis of the different types of organization was made by the United Nations Educational, Scientific and Cultural organization in 1952. (See *Bibliography.)*

National programs of industrial research undertaken under direct government control may vary according to local conditions but the general pattern conforms to what may be called the prototype organization, the U.K. department of scientific and industrial research. The principal national organizations are listed in the table; fuller details will be found in two surveys by O.E.E.C. and the British Commonwealth Scientific conference (see *Bibliography).* In some countries the government controls research directly, through these organizations; in others the organization does not itself undertake research, but sponsors it by means of grants.

In Great Britain and several other commonwealth countries steps were taken after World War II to develop research results of potential value arising in government laboratories or elsewhere as the national interest required. In Great Britain the National Research Development corporation was set up under the Development of Inventions act, 1948, as a national corporation with funds available for investing in any development work required "in the public interest." Its functions were slightly modified in 1954.

Chief Organizations for Industrial Research in Europe and the Commonwealth

Country	Organization and date of foundation*
Australia†	Commonwealth Scientific and Industrial Research Organization 1949 (1926)
Belgium‡	L'Institut pour L'Encouragement de la RCcherche Scientifique dans l'Industrie et l'Agriculture (*I.R.S.I.A.*), 1944
Canada†	National Research Council, 1916
Denmark‡	Der Teknisk-Videnskabelige Forskningstaad, 1946
France†	Centre National de la Récherche Scientifique (C.N.R.S.), 1939 (1901)
German Fed. Rep.‡	Deutsche Forschungsgemeinschaft, 1949 (1920)
Great Britain†	Department of Scientific and Industrial Research, 1916
India†	Council of Scientific and Industrial Research, 1942
Italy†	Consiglio Nazionale delle Ricerche (C.N.R.), 1923
Netherlands†	Nederlandse Centrale Organisatie voor Toegepast Natuurwetenschappelijk Onderzoek (T.N.O.), 1932
New Zealand†	Department of Scientific and Industrial Research, 1926
Norway†	Norges Teknisk-Naturvitenskapelige Forskningsrad (N.T.N.F.), 1946
Pakistan†	Council of Scientific and Industrial Research, 1953
South Africa†	Council for Scientific and Industrial Research, 1945
Spaint.	Consejo Superior de Investigaciones Cientificas, 1939
Sweden‡	Statens tekniska Forskningsrad, 1942
Switzerland‡	Fonds National Suisse de la Récherche Scientifique, 1952

*Date of foundation of earlier organization from which the present one developed is given in brackets. †Undertakes research directly. ‡Sponsors research by grants.

A further aspect of development is illustrated by projects undertaken jointly, to spread the cost of the work, by several European countries under the auspices of the Organization for European Economic Cooperation. International co-operation in research increased greatly during and after World War II.

Co-operative Research Associations. — In this field Great Britain was again a pioneer, as the department of scientific and industrial research from the time of its establishment in 1916 encouraged and supported research in individual industries through the setting up of co-operative research associations, financed partly by the industry concerned and partly by the government. The initial intention was that ultimately the associations should depend solely on industrial sources, but this principle was abandoned in 1945 when it was announced that government grants would form a permanent part of the normal income. The grants are reassessed at five-year intervals and the general tendency is to increase progressively the proportion of industrial income to government grant as the research association becomes established. On the industrial side, members' subscriptions are assessed by the association generally in relation to the size of each firm. After the passing of the Industrial Organization and Development act in 1947, some of the research associations derived their industrial income from a statutory levy, while other industries introduced a voluntary levy for the same purpose. Contributions from nationalized industries are regarded as industrial contributions. The nationalized industries largely assumed their predecessors' responsibilities and commitments to the research associations.

The co-operative research association type of organization has proved particularly suited to Great Britain. It has been successfully adopted in certain industries in several of the other Commonwealth countries, notably New Zealand, South Africa and India.

Co-operative research groups also exist in Belgium, Denmark, France, the German Federal Republic, the Netherlands, Norway and Sweden and other European countries. Methods of financing vary according to the country, but in most cases industrial income is supplemented by government grants. Details are given in the O.E.E.C. survey mentioned previously. Norway and Sweden have introduced a novel feature in that they provide in addition a central establishment where equipment and services are placed at the disposal of various industrial research groups for definite programs, generally for limited periods of a few years. Each group has its own staff and finances its own work. There is no rent, but a service charge is made covering 50% of the cost, the rest being met by state grants.

Independent Industrial Research Organizations. — In contrast with the growth of co-operative research organizations in Great Britain and Europe, centralized research services for industry in the United States have developed on different lines, the emphasis after 1945 being on the provision of facilities for confidential sponsored work. The rapid growth of nonprofit sponsored research

institutes in the United States, of which Mellon, Battelle and Armour were the first to be established, was not reflected to any considerable extent elsewhere, but some of the U.S. institutes began to open branches in Europe. Thus the Battelle Memorial institute established in 1952 a European counterpart known as Battelle International with branches in Switzerland and Germany.

In Great Britain after 1945, two sponsored research organizations, the Fulmer Research institute and the Sondes Place Research institute, were opened and were well established by 1955, but neither was operating on the scale of the larger American institutes.

Education for Research.—An adequate supply of scientists and technologists is one of the first requirements of any industrial community. Germany was one of the first countries to realize this and toward the end of the 19th century established a series of technical high schools which played an important part in its industrial development. Other European countries later established similar institutions, while in the United States colleges such as the Massachusetts Institute of Technology, Cambridge, filled a similar role.

In Great Britain there are many educational institutions which provide training in technologies as well as academic and commercial courses. Most of them have strong regional associations, and often specialize in education for practice in local industries. Some, however, are truly national institutions, and a few work in close association with universities. Most of the universities themselves cater for some branches of technology, but on the whole they give greater emphasis to training in basic science. After World War II increased attention was given by the ministry of education, the University Grants committee, the Advisory Council on Scientific Policy, the Federation of British Industries and others to the urgent necessity for increasing the supply of science teachers in the schools and of the scientists and technologists needed by industry where there is a considerable leeway to make up. The importance of higher technological education was repeatedly stressed and the need to extend facilities for the teaching and study of the applied sciences and technologies was accepted by the government. Policy became not to create completely new technological institutes of university status, but rather to expand and develop certain existing institutions of which the first would be the Imperial College of Science and Technology, London, where due emphasis would be placed on the development of postgraduate work. Other major expansions were planned at Manchester, Glasgow, Leeds and Birmingham.

GROWTH OF U.S. INDUSTRIAL RESEARCH

The object of industrial research is the discovery and invention of useful processes and products. Hence this discussion of industrial research should be read collaterally with the article INVENTIONS AND DISCOVERIES.

It is impossible to make an important scientific discovery or to invent a process or machine without engaging in experimentation. Even a discovery made by accident must usually be developed by experimentation before it can be adopted. The prehistoric savage who first made pottery or thought of fashioning a basket or learned how to use heat in a hundred different ways engaged in the kind of experimentation that is still the mark of the empirical investigator and inventor but nevertheless deserves to be classed as research. In this broad sense industrial research is as old as man.

Industrial research in the modern sense is organized, planned, skilfully directed, continuous and as self-perpetuating as industry itself. It has been a powerful factor in the astounding industrial growth of the United States since 1900. It gained momentum with the disappearance of the last frontiers and the depletion of natural resources once supposed to be inexhaustible. It accounts in part for the transformation of the United States from an agricultural into an industrial nation.

There is no question that the flowering of scientific discovery in the latter half of the 19th century had much to do with the rise of organized industrial research. Such successful inventions as the telegraph, the telephone, the electric incandescent lamp, the generation and distribution of electric energy had sprung from the discoveries of such men as Michael Faraday (1791–1867) and had been reduced to something approaching commercial practice by imaginative, dogged empiricists of the Edison type. Industry had little more to do than make the most of these discoveries and inventions. Its next obvious step was to make the discoveries themselves, and this it cautiously proceeded to do.

Industrial research was individualistic in Europe until about the middle of the 19th century and in the United States until about 1900. The individual investigators were independent inventors of the Morse-Bell-McCormick-Edison type or occasional chemists and mechanics in the employ of the few manufacturing companies that could not dispense with expert technical guidance. There is no industry in which a chemist cannot be advantageously employed, yet industry showed no great interest in chemistry. University chemists were long distrusted largely for the reason that they knew little about the industrial processes that they were to improve. It was not until 1902 that E. I. du Pont de Nemours instituted organized chemical research—the first in its field to do so. Because of this distrust of the chemist the United States lagged behind Europe in organized industrial chemistry. Not until 1889 did the U.S. petroleum industry employ its first professional chemist, William Burton, who devised a cracking process once important in oil refining.

Before the beginning of the 20th century it was still possible for a gifted mechanic to acquire the knowledge and skills that he needed to evolve important inventions in widely different fields. With the advance of science and technology the "universal genius" found himself unable to cope with problems that could be solved only by highly trained mathematicians, physicists, chemists and scientists drawn from a dozen different disciplines. Yet it is from a kind of "universal genius," the individualistic Thomas A. Edison (1847–1931), that American industry learned how industrial research could create inventions on which whole new enterprises could be built. His private laboratory with its machine shop, its facilities for making instruments and models and its large reference library was something new in the annals of professional, individualistic invention. The 70-odd men who were employed in this laboratory in the 19th century were not formally organized, yet they constituted an organization because they all worked under Edison's direction on different portions of a common problem. Edison therefore deserves the credit of having set an example. Despite his frank dislike of "theorists" and university professors and his reliance on the try-and-try-again method, which might compel him to suffer a thousand failures before he achieved success, he employed good physical chemists and mathematical physicists, among them Arthur E. Kennelly (1861–1939), who was an independent discoverer with Oliver Heaviside (1850–1925) of the ionosphere, a layer in the sky that reflects radio waves over oceans and continents to their destination.

The great industrial laboratories of today all have their theorists. The General Electric company sprang in 1892 out of Edison's work and the enterprises that he founded or with which he was associated. The company's laboratory was the first in American industry to cultivate fundamental research.

The growth of industrial research has been uneven. The older the industry the more backward is it likely to be scientifically and technologically and the newer, the more active. Such new industries as electrical communications, telephony, radio, petroleum refining and television have sedulously fostered research almost from their beginnings, and such old industries as coal mining have been laggard. Mass-production industries (again automobiles, petroleum, electrical communications, electrical machinery) spend the

most money on research and employ the greatest number of scientists, engineers and laboratory technicians. Research policies are determined partly by the spirit of an industrial organization, partly by the character of the industry and the pressure of competition.

Edison's example and success do not alone explain the rise of industrial research in the United States. A high-tariff policy was also a factor; for high tariffs assured large profits, so that there was no great incentive to improve industrial products and processes through research. The merits of a new invention or discovery had to be almost glaringly obvious before a businessman would buy it. Neither he nor his banker could turn to specialists who could appraise the potentialities of an innovation. Hence the individualistic inventor was of necessity a gambler. who usually spent his own money in carrying out his ideas and took the risk of recouping himself with what profits he could make. Organized and planned industrial research has not taken all the risk out of discovery and invention but it has reduced it, so that millions are poured into experimentation with the strong probability that the harvest will be reaped in 20 or 30 years. The problems to be studied and the ends sought are usually determined by managerial policy. Directors of research are frequently responsible executives and sit on boards of directors. Indeed so intimate is the relation of the laboratory to manufacturing and selling that investors of large sums are as much concerned with research policies of the companies in which they may take a financial interest as they are in balance sheets. Research is probably the most powerful factor in the growth of an industrial enterprise, and the possibility of growth always receives the shrewd investor's attention.

The growth of the trust also had much to do with the rise of industrial research in the United States. Federal courts had interpreted the patent laws with the utmost liberality so as to carry out the constitution's purpose of encouraging invention. These interpretations made it possible for a patentee to do what he pleased in fixing prices, limiting markets geographically, granting licences, stipulating what materials should be used by the licensee in carrying out the patented process or making the patented product. The federal courts have for years been curtailing the monopolistic privileges granted to patentees. Cnder the patent law, as it was generously interpreted, it was possible to do legally for 17 years (the life of a patent) what was illegal under the antitrust law. Hence the great corporations turned to the patent monopoly. Patents imply invention and discovery and hence research. This is one reason why after 1900 more and more industrial laboratories were established.

Another reason, perhaps the most important, was the influence of the state on industry in such emergencies as war. The continental blockade prompted Napoleon to encourage French production of materials that could no longer be imported. The effect of military pressure on industry was always apparent. In the United States, the National·Academy of Sciences was chartered in 1863 "to investigate, examine. experiment and report upon any subject of science or art desired by any department of Government." In World War I Pres. Woodrow Wilson implemented this purpose by establishing the National Research council (see *Co-operating Agencies* below), a body that has played a conspicuous part in the development of the United States as a military power, though its activities are by no means restricted to military matters. In World War II the amalgamation of government and industry was virtually complete. Every university, every research laboratory was under contract to the government to conduct research of both military and industrial importance. In total war it is impossible always to separate military from industrial purpose. The far-flung research activities of the federal government were largely under the direction and control of the Office of Scientific Research and Development. The invention of the atomic bomb by scores of organized physicists and chemists called for the creation of the industrial communities of Oak Ridge, Tenn., and Hanford, Wash., and the laboratories of Los Alamos, N.M. So huge was this undertaking that it had to be separately administered. In addition the army and navy maintained their own research establishments. In other words, science was completely mobilized, no matter where it was pursued or by which organization. This mobilization did not disintegrate with the end of World War II. The so-called "cold war" waged by the U S.S.R. in its successful aggressions and the fear of western democratic nations that they would have to fight for their freedoms and their manner of life made it necessary to preserve the system of government-controlled industrial and other research that had evolved in World Wars I and II.

Industrial research has long been a major industry in itself. By the 1950s more than $2,500,000,000 was being spent annually by American industrial laboratories, according to a survey made by the Research Development board of 2,000 companies which together spent about 85% of the funds available for research. These 2,000 companies employed about 100,000 engineers who were engaged in what may be truly called research. Two out of every three of the 100,000 were on the payrolls of companies with 5,000 or more employees.

The larger the company the more self-sufficient is it likely to be. In other words it makes in its own shops about everything that the research laboratory may need. with the exception of special instruments. The smaller the company the more likely it is to contract with outside organizations for the building of experimental machinery and apparatus. The research laboratories of these smaller companies specify clearly yet broadly what is wanted but leave the preparation of working drawings and the production of prototype equipment to the contractor. The number of workers required to support a research scientist or engineer was 1.5 on the average in the mid-1950s, but as low as 0.9 for companies with less than 500 employees and as high as 1.6 for companies with 5,000 or more employees.

The expansion of industrial research and development in the United States after World War I and again after World War II was without precedent. It is difficult to separate industrial research from applied research as a whole, in which term must be included research carried on for military, agricultural, medical and other purely utilitarian purposes, so that government cannot always be separated from industrial participation. In 1951, for example, the federal government paid for nearly half of the cost of industrial research and development. The total cost of research undertaken by industry, including $1,400,000,000 paid by the government, was $2,500,000,000 in 1952. The government's share of expenditures ranged from 85% in aircraft production to as little as 3% in petroleum refining.

Statistics show that fundamental or basic research, on which industry must depend for its own improvement, was still neglected in the 1950s; that military necessity had forced the federal government to direct the course of industrial research into certain channels; and that research paid for by industry was highly concentrated in a few industries and in the large corporations. Industrial research, whether carried on with government or with private support, is still enormously concerned with practical results and very little with fundamental science. Despite its remarkable technical progress the United States was utterly dependent on European discoveries in basic science in meeting the industrial demands of peace and war. When it was found that the European stock of knowledge had been virtually exhausted and that it could not be rapidly replenished because of the destruction wrought in World War II and the loss of many scientists, the United States at last created the National Science foundation and charged it, among other things, with the task of cultivating fundamental science. It is the only agency that can appraise the effect of all the specialized programs of the federal government and aid the president and congress in appraising the government's scientific policies.

There is no question that military necessity did much to stimulate organized industrial research in every advanced country. One powerful stimulus came from World War I in which new and importunate demands were made on American industry. So it happened that the number of industrial laboratories in the United States increased from about 300 to more than 2,200 between 1920 and 1940.

Individualistic and organized industrial research both call for the application of fundamental scientific knowledge or "theory" to the production of goods. The purpose of fundamental or theoreti-

cal research in any branch of science is to add to the sum total of human knowledge regardless of practical results or profits. In the early days of organized industrial research it was not considered the function of the laboratory to engage in fundamental or theoretical research. Most industrial organizations' research laboratories continue to adhere to this principle and insist on practical results and profits. A few of the very large corporations engage on a fairly large scale in what may be properly called fundamental or theoretical research. Thus the Eastman Kodak company devotes much attention to the theoretical problems of photochemistry, the Bell Telephone lahoratories study sound and speech, the General Electric company the chemical transformations that occur in exhausted lamp bulbs and vacuum tubes and the generation of light by means that have no immediate commercial chance of success. Technological progress is hardly possible unless theories are developed and new principles and laws discovered in the university, industrial. government or other laboratory. If a process breaks down in the effort to improve it, if a product is faulty for no apparent reason it is fair to assume that the basic theory applied must be discarded or corrected to reach the industrial goal in view. Thpugh it is concerned primarily with practical results, industrial research is too often belittled as a mere exploitation of the conclusions reached by idealistic theoretical scientists who are not concerned with profits. The distinction between fundamental and applied or industrial research is not sharp. At best it is merely a convenience too often overstressed. For example. before it mas possible to arrive at an experimental plane that could travel faster than sound (that is, at a speed higher than about 730 m.p.h. at sea level) an immense amount of fundamental research in aerodynamics had to be conducted: yet always a practical result was kept in view. Science is science whether it is pursued in the factory or the university laboratory. In fact, fundamental and applied science are interdependent. Advance in one affects the other. The interdependence is manifest in the increasingly important part played by universities in solving the scientific and technological problems of industry.

The results of practical research carried on by universities for industry or for the federal government have been impressive and have changed the pattern of technical education. That change is not approved by scholars who cling to tradition. University professors often patent their inventions and discoveries and assign the patents to their universities. The royalties collected are an aid in meeting educational obligations. The argument that these activities distract attention from fundamental research is hardly supported by the available evidence. In some of the schools the royalties are turned back into research or used to expand the technical teaching program. Nevertheless, educators are alarmed at a trend which reduced the funds available in colleges and universities by nearly $4,000,000 in 1951–52, whereas in the same period the funds available for applied research useful to industry increased by $50,000,000.

Most of the money given to the universities for applied research comes from the department of defense or its close affiliates. In fact the department is the principal support of applied scientific research in the United States.

More important is the virtual conscription of university professors of science and technology to carry on military or industrially useful research for the government on a contract basis. The amount of federal money thus expended runs into the millions, as the figures presented earlier. indicate. The chief objection to this method of subsidizing the universities. in the opinion of some observers, is a whittling away of academic freedom or, mole specifically. of the right of the university scientist to publish what he has discovered. The exigencies of military secrecy prevent publication. There is no doubt that science, particularly nuclear physics, has been held back by this contractual system. Not only must most of the advances made be kept secret but the professor who engages in research for the government is thoroughly examined to make certain that he is not what is called a "security risk." This invasion of academic freedom aroused resentment in many quarters and engendered fears for the future of university education.

Industrial Research by Companies.—One of the largest research establishments in the United States is the Bell Telephone Laboratories, Inc., which employs numerous physicists, chemists and engineers ior original investigation and development of new iorms and improvement of existing forms of apparatus and equipment ior electrical communication. In the laboratories oi E. I. du Pont de Nemours and' company, Wilmington, Del., chemists and engineers have studied problems of the heavy chemical, paint, lacquer, solvent, plastics, textile, dye, rubber and explosive industries. Other great laboratories were established by the Aluminum Company of America at New Kensington, Pa.; Dow Chemical company, Midland, Mich.; Eastman Kodak company, Rochester, N.Y.; General Electric company, Schenectady, N.T., Lynn and Pittsfield, Mass., and Cleveland, O.; General Motors corporation, Detroit, Mich.; Gulf Research and Development company, Harmarville, Pa.; Hercules Powder company, Wilmington, Del.; Monsanto Chemical company, St. Louis, Mo.; Radio Corporation of America Manuiacturing company, Harrison and Camden, N.J.; Standard Oil Development company, Linden, N.J.; and Westinghouse Electric corporation, East Pittsburgh, Pa., and Bloomfield, N.J.

Numerous conipanies have taken advantage of the industrial fellowship system of Mellon Institute of Industrial Research in Pittsburgh, Pa., as a means of solving problems in manufacturing practice. In 1954, for example, 80 fellowships were sustained by as many different companies, largely chemical manufacturers, and other iellowships were supported by trade associations.

A large number oi companies in the field of chemical industry make research grants to educational institutions, chief among them being E. I. du Pont de Nemours and company. Other firms making many grants to universities include E. R. Squibb and Sons; Merck and company; Standard Oil Company of California; Upjohn company; and Standard Brands, Inc.

Many college laboratories are used not only for purposes of instruction but also to a great extent for industrial research work and for commercial testing.

A considerable number of companies, mostly small concerns that have no laboratories of their own or larger companies that encounter few problems or are engaging in research for the first time, are regular or occasional clients of consulting laboratories. There are several hundred commercial laboratories in the country. and some of them are strongly staffed and excellently equipped for scientific investigation, particularly in specific industries. For example, a firm of consultants which has a main laboratory and also branches in other cities employs a large staff of scientists and their assistants for varied research. Most oi these commercial organizations do testing as well as research work.

Trade Association Research.—The U.S. department oi commerce has expressed the opinion that "among constructive activities of trade associations none is more fitting nor more profitable than scientific research." The study of production and distribution problems to evolve more efficient and more economical methods has in fact become a leading association activity. We shall describe here associative industrial or technological research, and not commercial or economic investigations which, while entirely different in nature, are oiten related to the former.

Five different procedures have been applied with success in conducting associative industrial research: (1) a number of associations co-operate with government departments and bureaus in accordance with the research associate plan; (2) other associations sustain scientific investigations in Mellon Institute of Industrial Research at Pittsburgh, Pa., in Battelle Memorial institute, Columbus, O., or in other research foundations; (3) some associations support fellowships or scholarships in educational institutions: (4) still others carry on research in commercial establishments, such as the laboratories of proiessional consultants; (5) a number of associations have founded their own lahoratories.

Federal Government Research.—For many years the scientific and technical research facilities of various government departments have been available, by legislative enactment! to duly qualified workers (Supp. Rev. Stat., 2, 71–2, 1532; Stat. L., 27, 1010; Bureau of Standards *Circular No. 296*). This plan has been developed especially. in the national bureau of standards, where various research associates are employed by associations or specific groups. Each associate is subject to the bureau's regulations and has most of the rights and privileges

of the members of the bureau staff. The investigational results are immediately accessible to the industry concerned and are published by the bureau. Specialists on the bureau's staff may be consulted by the association and its rescarch worker, and the latter is also permitted to use the scientific equipment, special laboratories and shops of the institution.

In general this flexible. closely co-operative plan was successfully applied. There are in fact nor a few notable instances of economic savings to technology from research in the bureau. It has been reported (Department of Commerce, "Trade Association Activities," *Domestic Commerce* Series *No. 20,* 1927) that great savings have come to industry and the public from the bureau's brakelining research, from its tire investigations and from its motor fuel studies. Research in the bureau eventuated in the iounding of a dextrose industry in the U.S. The following are among the outstanding investigations: constitution of petroleum, colour standardization, dental materials, silver, nonferrous alloys. soldered plumbing fittings, aviation lighting, railroatl signal glasses and portland cement.

Many agencies of the federal government do research and development. The agricultural research service and the Forest Products laboratory of the department of agriculture and the bureau of mines of the department of the interior have advanced technology by researches on behalf of various industries. The bureau of mines conducts various investigations in mining, metallurgy, health and safety, and on the economics oi the production, preparation and utilization of minerals. The laboratory of the National Advisory Committee for Aeronautics has maintained for years a central research plant serving the industries concerned and government alike. Certain researches of the public health service oi the department of health, education and welfare—investigations of dusty trades, sewage disposal, water purification, illumination of buildings and motor fuels—have also benefited industry.

The research and development work of the Atomic Energy commission is especially wide and important. Action toward national security accounted for 85% of the total government research and development budget in the mid-1950s. About 87% of this activity was in the realm of physical sciences. The National Science foundation, which conducted a wide survey of current industrial research, iosters much pure science investigation that promised to be basically useful to technology. Operations research with its multilateral scientific approach is supplementing physical science investigation in attacking comprehensive problems of industrial management.

Industrial Fellowship *System.*—Some of the research of Mellon institute is sustained by associations of manufacturers, according to the institution's industrial fellowship system. These association fellowships pertain to air pollution control, industrial hygiene, refractories and other fields. embracing water pollution abatement. The multiple fellowship of the Industrial Hygiene Foundation of America represented a collective. effort by 350 companies in behalf of employee health. Fundamental research in industrial health is nurtured and member companies are provided with practical plant applications to prevent industrial illness. The water pollution fellowship aimed to make both basic investigations and practical studies of any subjects promising to improve the water economy of the U.S. The American Refractories institute's multiple fellomship, established in 1917, was continued without interruption thereafter. Its incumbents enriched both refractories technology and metallurgy by their studies of the evaluation of refractories for specific purposes and by the improvements effected in manufacturing and testing methods.

An association fellowship of this type enables direct research service to a numher of industrial concerns instead of to an individual company. Its activities also give rise to stable relations of co-operation among the members of the association by the exchange of technical experience and research results. An association fellowship usually acts as a clearing house of information for the sustaining organization and gives technical assistance and scientific advice to the members. One of the prominent advantages of association research is that it enables a small manufacturer, who cannot afford to have a research laboratory of his own, to profit from the investigational work in the same way as a larger manuiacturer. Association rescarch reduces the cost factor to a minimum and thus promotes the welfare of manufacturers in the field concerned, without respect to size. Moreover, problems may be studied that require more time and expense than should be borne by a single manufacturer or company in view of the wider application of the results. The correlation of research effort, such as is done in the fellowships supported by associations, prevents unnecessary duplication in scientific inquiries.

Association Fellowships in Educational Institutions. — This class of research became important in many industrial fields. It serves to train technical specialists as well a; to aid in solving production problems. The Illinois Institute of Technology. Chicago, Purdue university, \Vest Lafayette, Ind., Ohio State university, Columbus, Columbia university, New York city. Iowa State college, Ames, and the universities of Illinois (Urbana), Michigan (Ann Arbor), Wisconsin (Madison), Minnesota (Minneapolis), Chicago, Cincinnati (O.) and Pittsburgh (Pa.) led in encouraging industrial research by associations and also by individual companies. Various trade associations sustained such investigational work, the American Petroleum institute being a leader in making educational grants.

Association-Owned Laboratories. — Industrial. research is not conducted in any set type of laboratory nor in accordance with any fixed plan. The nature of the problems, the financial support available and the uses to which the research findings are to be put determine the method. If problems are extensive and association members are so appreciative of the value oi research that they will contribute to the building and maintenance of a laboratory, it is often advisable for an association to do its own research.

Co-operating Agencies.—The National Research council serves as a general clearinghouse of information on research work undertaken throughout the country. Its division oi engineering and industrial research endeavours to co-ordinate the scientific resources of the nation as regards engineering and secures the co-operation of engineering agencies in which investigational facilities are available. It works in co-operation with the Engineering foundation and various national engineering and technical societies. Associations or companies undertaking research may ascertain irom the council what work has been done or is in progress along similar lines, thus avoiding duplication of effort.

The American Standards association, the American Society for Testing Materials and the American Engineering council are some of the organizations whose effectiveness depends in many cases on the collaboration that they receive from trade associations as well as individual concerns that carry on research.

RESEDACEAE, the mignonette family of dicotyledonous annual and perennial herbs and shrubs. There are six genera and about 70 species.

Reseda odorata is the fragrant mignonette (*q.v.*), a popular garden annual; R. *luteola* is dyer's rocket or weld (*q.v.*).

RESENDE, ANDRE DE (*c.* 1499–1573), the iather of archaeology in Portugal, became a Dominican friar but, about 1540, entered the ranks of the secular clergy and was made a canon of Bvora. He traveled in Spain, France and Belgium and corresponded with Erasmus and other leading humanists. He was also intimate with King John III of Portugal.

Resende died in Bvora, Sept. 9, 1573

Resende's main Portuguese works are *Histdria da antiguidade da cidade de Evora* (1553) and *Vzda do Infante D. Duarte* (1789). His chief Latin work is De *antiquitatibus Lusitaniae* (1593).

See Francisco Leitão Ferreira, *Notícias* da Vida de *André* de Resende, ed. by A. Braamcamp Freire (1916).

RESENDE, GARCIA DE (1470–1536), Portuguese poet and editor, was born at Évora, and began to serve John II as a page at the age of ten, becoming his private secretary in 1491. He was present at his death at Alvor on Oct. 25, 1495. He continued to enjoy the same favour with King Manoel, whom he accompanied to Castile in 1498 and from whom he obtained a knighthood of the Order of Christ. In 1514 Resende went to Rome with Tristão da Cunha, as secretary and treasurer of the famous embassy sent by the king to offer the tribute of the east at the feet of Pope Leo X.

In 1516 he was given the rank of a nobleman of the royal household and became *escrivão de fazenda* to Prince John, afterward King John III, irom whom he received further pensions in 1525. Resende built a chapel in the monastery of Espinheiro near Bvora, the pantheon of the Alemtejo nobility, where he was buried.

Resende collected the best court verse of the time in the *Cancionezro Geral,* probably begun in 1483 though not printed until 1j16.

The *Cancioneiro* is redeemed from complete insipidity by Resende, and his verses on the death of D. Ignez de Castro inspired the great episode in the *Lusíadas* of Luiz Vaz de Camões (*q.v.*). Resende is the compiler of a gossiping chronicle of his

patron John II., which, though plagiarized from the chronicle by Ruy de Pina, has a value of its own. Resende's Miscellanea, a rhymed commentary on the most notable events of his time, which is annexed to his Chronicle, is a document full of historical interest, and as a poem not without merit.

His *Cancioneiro* appeared in **1516,** and was reprinted by Kausler at Stuttgart (3 vols., 1846–52). A new edition was published by the Hispanic Society of America in 1904. The editions of his *Chronicle* are those of 1545, 1554, 1596, **1607, 1622,** 1752 and **1798.** For a critical study of his work, *see* Antonio de Castilho, *Excerptos, seguidos de uma noticia sobre sua vida e obras, um juizo critico, apreciação de bellezas e defeitos e estudo da lingua* (Paris, **1865).** Also Anselmo Braamcamp, *As sepulturas do Espinheiro* (1901) *passim,* especially pp. 67–80, where the salient dates in Resende's life are set out from documents recently discovered; and Dr. Sousa Viterbo, *Diccionario dos Architectos . . . Portuguezes,* ii. 361–74.

RESERVE: see ARMY and the sections *Defence* of FRANCE, GERMANY, UNITED STATES and other countries.

RESERVES: see BANKING AND CREDIT.

RESERVES, NATURAL: see NATURAL RESOURCES.

RESERVOIRS. These may be divided into two classes, "impounding reservoirs" and "service reservoirs," the latter being concerned with the distribution of water (see WATER SUPPLY).

Impounding Reservoirs.--Owing to the fact that the flow of streams and rivers varies greatly throughout the year, it is necessary to provide works to store water if any substantial use is to be made of the annual discharge. Such works are known as impounding reservoirs, their function being to store water when the stream flow is ample for the purpose of augmenting the natural flow in dry weather.

The urgency for the construction of such reservoirs must have become apparent in very early times in countries where the climatic conditions were such that the streams ran dry for a portion of the year, and records exist of one being made in Ceylon as early as 504 B.C. Anciently reservoirs were formed by an embankment across the valley through which a stream flowed, and were sometimes of vast extent, the Padavil-Colan Tank in Ceylon, for instance, having an embankment 11 mi. long and, in parts, 70 ft. high.

Storage — Having selected a catchment area capable of yielding sufficient water, the capacity of the reservoir has next to be determined. This will depend upon the incidence and intensity of the rainfall and the loss by evaporation and absorption, conditions which vary within wide limits. In countries subject to long periods of drought, the necessary capacity will be greater than in those enjoying a temperate climate, and in India, for instance, where the rain falls only during monsoon periods, two years' storage of the daily quantity may be necessary.

Few records exist of the flow of streams in the British Isles taken over a sufficiently lengthy period to be of service, and recourse has generally to be made to the annual rainfall records, from which the annual discharge of the stream is deduced. Long period rainfall gaugings show that the rainfall of the driest year is about two-thirds, the mean fall of the two driest years about three-quarters, and the rainfall of the three driest consecutive years about four-fifths, of the average annual rainfall. Notwithstanding the wide variation of climatic conditions, these proportions hold fairly well over a large portion of the land surface of the globe (see "The Variations of Rainfall," by A. R. Binnie, Proc. *Inst.* C.E., vol. 109).

As storage increases in relation to the average flow of a stream, the maintainable yield increases in a decreasing ratio until a maximum is reached where there would be little advantage in further increase, and in the British Isles the economic limit is generally taken as that capacity which would be sufficient to equalize the flow of the three driest consecutive years.

The average annual rainfall of the three driest consecutive years, being approximately four-fifths of the average annual rainfall; and the average annual loss by evaporation and absorption being about 14 inches; the average annual discharge of the stream during the three driest consecutive years would be that due to 4 average rainfall—14 inches running off the catchment area, which may be denoted by f. The formula known, from its author, as the Hawksley Formula gives the number of days storage which should be provided to maintain this flow= $\frac{1000}{\sqrt{f}}$

In many cases it is not necessary to provide so large a storage, as some quantity may be required which is less than the average flow of the stream during the three driest consecutive years.

Fig. 1 gives the relation between the maintainable yield and the capacity to be provided for catchment areas in the British

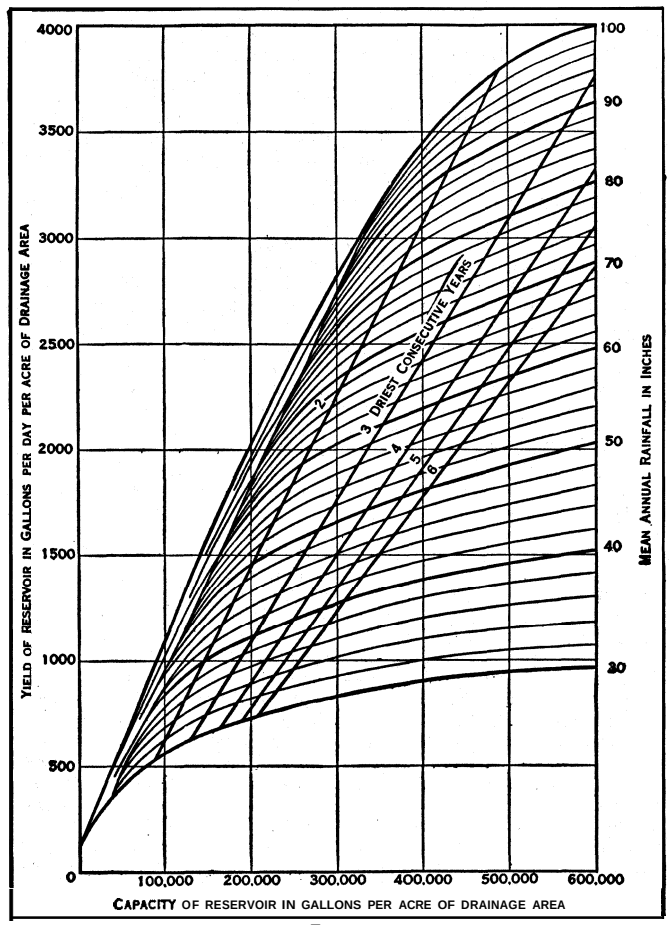

FIG. 1

Isles having a mean annual rainfall varying from 100 to 30 in., and is due to the investigations of Dr. G. F. Deacon. The capacity of the reservoir in gal. per ac. of catchment area is shown on the base line, and the yield of the reservoir in gal. per ac. per diem is given by the length of the vertical line between that capacity and the curve of average rainfall, the yield in gal. per ac. per diem being read from the vertical scale at the left-hand side. The storage required for any particular average rainfall to balance the average stream discharge during different series of consecutive dry years, is given by the diagonal lines which intersect the curve of rainfall on the diagram.

The diagram gives the capacity above the lowest draw-off level of the reservoir, and as it is undesirable to abstract muddy water for supply, this level should be well above the bottom of the reservoir. The loss by evaporation from a water surface is greater than the loss on the catchment area, and in the British Isles the depth of the reservoir should be about 6 in. more than would be required to give the gross storage, whereas in tropical countries the allowance may be as much as 6 ft.

TYPES OF DAMS

Dams may be divided into two classes, masonry or embankments; and the selection of the particular type will depend upon the nature of the materials on which they will rest, and which are available for construction.

Where good sound rock exists at no great depth from the surface, a masonry dam is to be preferred, but where the rock can

only be reached at a considerable depth, the cost is prohibitive.

Masonry Dams.—Masonry dams should be arched in plan concave to the water face where the length of the dam is not too great, as such a form adds to the stability, and the pressure of the water tends to clote temperature or contraction cracks at right angles to the axis of the dam. It is desirable to slope the foundations towards the water face, especially where the depth below the surface is moderate, as this reduces the tendency to slide on the foundations and the possibility of overturning due to the uplifting pressure of water penetrating between the masonry and the rock. The design should avoid the development of tension in the masonry, tending to rupture the dam on a horizontal plane; and the maximum pressure at any point in the masonry should be limited to 10–15 tons per sq.ft., depending on the materials used for construction and the nature of the underlying rock. Prof. Rankine pointed out the importance of avoiding tension, and evolved the theory on which most modern dams have been designed, viz.: that the resultant pressure due to the weight of the masonry and the water thrust must fall within the inner third of the dam if tension is to be avoided. Any fissure developing at the water face due to tension tends to increase owing to the water pressure, and may ultimately lead to the failure of the dam (see Prof. Unwin, *Proc. Inst.* C.E., vol. 126, and E. P. Hill, vol. 129).

The masonry of a dam is not isotropic as horizontal planes of weakness, where new work is superimposed upon that which has set, are difficult to avoid. It is advisable therefore to step the masonry at the water face so as to avoid the construction of a horizontal joint between old and new work.

The arched form of dam is economical when the radius of curvature is comparatively small, as the sectional area can be decreased by designing the dam as a horizontal arch transmitting the water thrust to its abutments. For reasons of economy modifications of the simple type of masonry dam have been introduced; these dams are of ferro-concrete construction, the pressure of the water being transmitted to buttresses by means of steel reinforced slabs or arches.

Earth Embankments.— The profile of the embankment requires careful study of the materials of which it will be composed, and slips have frequently occurred, leading to the complete or partial failure of banks, due to lack of local study and the adoption of a design which was unstable. Light sandy soils will stand at a high angle of repose, but clays or plastic materials require flatter slopes, the inclination decreasing as the base of the embank-

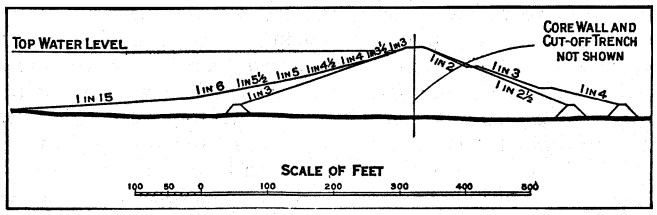

FIG. 2

ment is approached. On fig. 2 the inner line profile would apply to good banking material, and the outer line to clay or plastic material.

Care must be exercised to prevent the saturation of the outer slope of the bank, and when possible it should be composed of freely draining material. When such materials are not available, the outer portion should rest on a layer of stone terminating in a stone toe, vertical drains of dry stone being carried up through the bank at intervals.

Cut-off Trench.—In order to prevent percolation below the bottom of the embankment, a trench is first excavated across the valley bottom, carried down—if possible—to an impermeable substratum and continued into the hillsides, so as to cut off any percolation below top water level. This is filled with impermeable material, preferably concrete, so as to form a barrier to percolation below the bank; and an impermeable core wall is brought up in continuity with this barrier to prevent percolation through the bank.

Core *Walls.*—Puddle is the material generally used in, the British Isles to form the core wall, and reinforced concrete in America. Puddle is not an absolutely impermeable material, and the thickness of a puddle core wall must be much greater than that of a concrete core wall. The use of concrete core walls has been limited in the British Isles owing to the apprehension that such walls would crack under pressure due to unequal settlement of the embankment. That such fears are unfounded is proved by the numerous successful examples of such construction in America.

The very greatest care must be exercised in the construction of a puddle core wall to prevent the occurrence of any layer through which water could pass owing to the erosion which may take place, causing the formation of a cavity and the failure of the bank; whereas no erosion of the concrete would take place, and a crack would soon be sealed by earth carried in suspension by the water.

Tunnel Outlets.—It is necessary to divert the stream during construction, and for this purpose it is advisable to construct a tunnel round one end of the bank through which the stream may flow, and through which the supply pipe can ultimately be laid from the Valve Tower. A cheaper form of construction is to build a culvert under the bank, but many cases of whole or partial failure of such culverts have occurred due to the varying earth pressure. (*See* C. J. Wood, "Tunnel Outlets," *Proc. Inst.* C.E., vol. 59.)

Flood Works.—When a reservoir formed by a masonry dam overflows, water passes harmlessly over the top of the masonry into the stream below. It is obvious, however, that water cannot be allowed to overflow an earth embankment, as the material would rapidly erode, leading to the failure of the bank. It is therefore necessary to allow for the escape of flood water in such a way that the water level can never rise to a height that would endanger the bank.

The usual flood escape is provided by a weir of such a length and placed at such a level below the top of the bank as will ensure that the water in the reservoir can never rise above it, the weir discharging into a masonry channel placed in the hillside at one end of the bank. Another and more economical escape consists of a vertical shaft communicating below with the tunnel through which the stream was diverted during construction and terminating above in a bell-mouthed opening, the periphery of which forms the overflow weir.

Flood Intensity.— The maximum intensity of the flood discharge over the weir will depend on the extent of the catchment area, the maximum intensity of rainfall during a period bearing relationship to that area, and many other factors, such as the inclination of the valley, the steepness of the slopes, the permeability of the surface, and the presence of lakes or obstructions which would delay the discharge. It is impossible to determine the exact effect of many of these factors, and therefore recourse must be made to actual records of the maximum discharge from catchments of different areas.

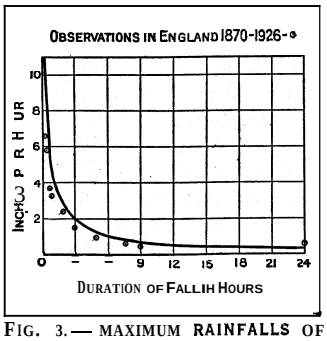

FIG. 3.— MAXIMUM RAINFALLS OF RARE INTENSITY

The main factor in determining the maximum intensity of a flood must obviously be the amount of rain which fell in a given period, a condition which varies so widely in different parts of the globe, that records of flood discharge in one country would not be applicable to another.

The curve on fig. 3 shows the relationship between rainfall and period, and is derived from the formula determined by Prof. Talbot as applicable to the Eastern United States for maximum rainfalls during different periods. The small circles show actual observations made in the British Isles, from which it appears that Talbot's curve fits British conditions fairly well. This fact is of importance as indicating that records of floods in the Eastern

States assist in arriving at the maximum intensity of discharge from different catchment areas in the British Isles. The larger the catchment, the smaller the flood discharge per unit of area. Most reservoirs are placed at comparatively high altitudes, where the catchment area is small, in order to impound water free from pollution and to furnish water to the district of supply by gravity. Failures of such reservoirs, due to insufficient provision for the discharge of flood water, are not infrequent and demand serious consideration. The formula $Q = 750/\sqrt[3]{M}$, where Q denotes maximum flood intensity in cu ft. per sec. per sq mi and M the drainage area in sq mi. agrees fairly well with records of maximum flood intensity in Great Britain. *See* also WATER SUPPLY AND PURIFICATION; DAM; WATERSHED. (W. J. E. B)

RESHAT NURI GUNTEKIN (1892–1956), Turkish novelist, short-story writer and playwright, first achieved fame with his *Chalikushu* (1922), the most popular Turkish novel of the day. Born in Istanbul, he was educated in Izmir and Istanbul and. after teaching in various schools, traveled widely in Anatolia as an inspector of education. He was elected to parliament (1939) and later became Turkish delegate to UNESCO. In *Chalikushu* (Eng. trans.. *The Autobiography* of *a Turkish Girl,* 1949) he combined a realistic description of the Anatolian scene with romance. Other novels and short stories in the same vein included *Aksham Guneshi* (1926; Eng. trans., *Afternoon Sun,* 1951). *Yeshil Gece* (1929), a penetrating study of the reactionary elements in Turkey. initiated the second phase of Guntekin's career. the writing of a series of novels dealing with the social problems brought about by radical changes in Turkish life. His style is easy and straightforward, though sometimes almost too sentimental He died in London. Dec. 6, 1956. (F. I.)

RESHT (RASHT), a former *ostan* (province) now Gilan, and its capital in Iran. The city is located on the left bank of the Siah Rud which is a branch of the Safid Rud and flows into the *murdab* or lagoon of Pahlavi (Enzeli). Population (1956) 109.493; *ostan* population 1,664,210 (1956). During the Bolshevik invasion in 1920 about 8,000 refugees left the town, but later returned; and a large part of the bazaar was burned. The town is situated in low malarious ground and was originally buried in jungle, but the Russians during their occupation of the place in 1723–24, cleared most of the jungle and it is now surrounded by rice fields. Resht is a centre of the rice trade and of the activities of the silk industry of Gilan. Resht suffered a good deal during World War I from the Russian army and, afterward in 1918, when the Dunsterville force had to fight its way to Pahlavi, strongly opposed by Kuchak Khan.

RESIDENCE, in general, a place of abode. In law, it usually means continuance in a place. *See* DOMICILE AND RESIDENCE.

RESIDENTIAL ARCHITECTURE. This article deals with the evolution of structures for human habitation. particularly single-family units, from earliest times to the present, in all parts of the world. (A discussion of the factors involved in the design and construction of contemporary dwellings will be found in HOUSE DESIGN. For discussions of multifamily structures, *see* APARTMENT HOUSE and HOTEL; for discussions of the social context of residential architecture, *see* HOUSING; CITY PLANNING; and ZONING. *See* also ARCHITECTURE.) The dwelling is the oldest branch of building, dating from man's first crude solutions for his most pressing problems: protection from the elements, wild beasts and human enemies. The architecture of shelters has developed extensively since the late 19th century.

Separate d ellings developed in three principal types: in hot climates the rooms usually were open or they surrounded an open-air courtyard; in colder regions the rooms generally were placed together in a compact block to facilitate heating. The third type was informal: the rooms were strung in rows at will. Bricks appeared with the beginning of civilization in Mesopotamia. Wood was the staple residential building material; brick and stone were employed in more luxurious houses. Two distinct methods of construction developed: one used the solid load-bearing wall, originally of rock or adobe, and later of masonry or reinforced concrete; the other method employed a framework of wood or, later, metal, with a covering of reeds, bark, wooden boards or, eventually, various composite materials. After the middle of the 19th century more glass and metal were introduced into the structure and, in an uneven progress, mechanical and electrical labour-saving devices were added to the ordinary house. Technical improvement in housing (*e.g.,* safety, comfort, sanitation) was complicated, however, by social pressures and by various intellectual and artistic trends.

Public buildings and palaces, monuments on which a higher art of building design was concentrated, were emulated in private dwellings. Residential design followed the main stream of public architecture through historic periods and styles, but was always a little more inclined to place convenience before effect. In western society, from the time of the Renaissance, the house came to be thought of as a vehicle of self-expression, and attracted the attention of architects. During the 20th century, residential architecture often led other forms of design.

The evidence of housing in prehistoric and preclassical eras is scant, and to some extent historians' accounts are in conflict. Nevertheless the houses of each important era may be visualized from archaeological fragments and knowledge of the materials that were available to the builders.

Primitive. — Masonry construction may have begun when the cave dweller sought to elaborate his cave by partially closing the mouth with a wall of piled rocks, or by adding external baffle walls, as in prepueblo dwellings on river banks in parts of the U.S. southwest. Frame construction may have begun when sticks were planted in a circle, their tops bound together and the conical frame covered with thatch or leaves. Either of the two structural systems mere used by prehistoric builders, according to the availability of materials. Defense was an important consideration to early village settlers. Little round cabins of stone, clay or wood were gathered within wooden palisades, rectangular huts were raised on piles above the water of lakes or sheltered bays. Roofs were pitched high on wooden frames, and thatched. Walls of thick wooden slabs were smeared over with clay to fill the crevices.

In the typical African compound each hut was made of a low circular wall of closely spaced and plastered sticks, roofed by a tall, conically framed cap of grass thatch. Huts were linked by fences. In the long houses of Borneo, which were elevated beside a river, series of one-family rooms were strung in long lines behind common verandas. The yurt of the wild nomadic Mongolian tribes was a circular house up to 20 ft. in diameter, made of felt fastened over a diagonally framed wall, its curved rafters rising to a wide smoke hole above the central fire. An exceptional example of primitive masonry and indigenous design is the Eskimo's igloo, a temporary winter home of compacted snow cut into beveled blocks and built into a dome. American natives produced several other ingenious house types. The wigwam of the Penobscot Indians of the north was a primitive cone, about ten feet wide and ten feet high, but the construction was slightly advanced. Bark paneling was held between t o separate frames of wooden poles lashed together at the ends. The construction of the tipi of the nomadic Indians on the semiarid plains was similar, but decorated hides or canvas (in the 20th century) formed a paneling more flexible than bark, and made the whole structure more easily portable.

The long house of the Iroquois tribes in the northeast was a windowless, rectangular building occupied by several families, each with an open alcove of its own. It was made, as the wigwam, of big bark panels held in a double framing. The pueblo of the U.S. southwest was a multistory agglomeration of family cells in adobe or stone. The ends of the closely spaced logs that supported the adobe slab roofs projected through the walls. Each floor receded from the one below, forming irregular roof terraces, from which ladders led up and down to other cells. (*See* also INDIAN, NORTH AMERICAN.)

Between the 17th and 19th centuries European colonists often revived the crudest types of mud and stick construction. Primitive dwellings are still being built in many parts of the world. In north Australia nomadic aborigines sleep in caves or behind low bark breakwinds erected for the night. Neolithic types of lake villages are still occupied in Cambodia and New Guinea. Various

rude forms of wood hut and mud cabin persist in Africa and parts of Asia. (See DWELLINGS, PRIMITIVE.)

Egyptian. — The great advances of Egyptian civilization did not extend to the poorer family house. It was still no more than a sleeping room and a storehouse, a low single cell open on one side. It was made of mud brick or of reeds plastered with mud and was roofed with palm leaves. However, the government did provide protection, eliminating the necessity of stockades, and the equable weather encouraged an outdoor life. Wealthier citizens built rooms behind or on either side of the central cell. The flat roof was strengthened with poles or with barrel vaults of brick and was used for eating and sleeping. Houses of leading citizens were either the block or the courtyard type. detached and sizable. A courtyard house was about 40 to 50 ft. square within a high surrounding fence. Rooms might occupy two sides of the square; the remainder was a semiroofed garden court serving as the main living area. In populous areas houses were pressed together on opposite sides of narrow streets. Often an outside staircase led to the flat roof. To the Egyptian the real home was the tomb (*q.v.*); it was the eternal habitation and the house was merely a temporary shelter. Nonetheless, the homes of the rulers were comfortable. An aristocrat's country house had a number of rooms grouped around a private courtyard. The house was set within a luxuriant formal garden enclosed by stables, storerooms and linking walls. Palaces were big, and the Pharaoh's central apartments were colourfully decorated and lavishly furnished for comfort and elegance. (*See* EGYPTIAN ARCHITECTURE.)

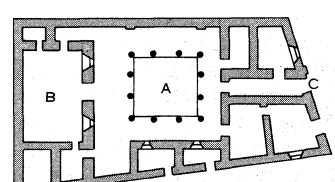
Western Asiatic. — The pattern of housing changed little in the Mesopotamian and Aegean cultures. The poor-man's house was generally a single-cell hovel. The middle classes had multiroom blocks of various sizes. The upper classes enjoyed elaborate buildings, reasonably comfortable and sanitary, with courts, gardens, loggias and colonnades developed into spatial compositions. Architecture was called upon to provide a rich visual background for the indulgent life. In Babylonia, although a somen-hat more even distribution of wealth improved the standard of housing, the techniques of building did not advance beyond those of the Egyptians. For about 2000 years these techniques remained fairly constant. The poor man's cell was of mud brick, laid in the form of a tall pointed dome. Plain-faced stucco houses lined the winding, crowded, muddy city streets.

The middle-class house was built of sun-baked bricks; it was a compact block with a flat roof, which, when shaded by a light awning, was the principal living space. A rich merchant's house typically consisted of two stories, with thick brick walls, a central court ringed by dark, narrow rectangular rooms, and a veranda with bright awnings in front. Most of the rooms were storerooms, but some were used for refuge when both roof and court became too hot. Then the walls were watered and their fine white plaster surfaces were cooled by evaporation. (*See* PRE-HELLENIC ARCHITECTURE.)



MARQUAND, "GREEK ARCHITECTURE," (MACMILLAN)

FIG. 2.—PLAN OF GREEK HOUSE, DELOS

(A) Court, (B) chief room or thalamus, (C) main entrance

Greek.—In the golden age of classic Greece the houses of ordinary peasants were still crude cabins. A colder climate than that experienced by previous civilizations necessitated some heating. Through the brief cold winter, farm beasts shared single unpartitioned brick rooms with their owners. Smoke from a central hearth on the earth floor rose to a hole in the reed roof. Although the refinement of the monumental architecture was unsurpassed, the houses of even the illustrious Greeks were modest. Temples, theatres and public meeting places were the centres of living for men. Wives were restricted. and generally segregated in rooms behind or above the men's quarters. Family life hardly existed. The thalamus, or inner chamber, was the official centre of house life. For the middle classes, three- or four-story rental tenements crowded the tortuous, earthy streets of the cities.

After the Macedonian conquest, the houses of the wealthy began to reflect some of the architectural qualities of the public monuments. The remains of a big house of Hellenistic date at Palatitza in Macedonia indicate multiple courts, long wings and ranges of rooms linked by colonnades. House exteriors became almost as formal as those of temples, and interiors were splendid with murals, statues, pottery and textiles. (See GREEK ARCHITECTURE.)

Roman. — The Roman house of every size and degree of wealth was centred around the atrium (*q.v.*). The atrium derived from the single cell of the primitive hut, with its smoke hole in the centre. As the room enlarged, so did the smoke hole, and columns were erected to support its edge. By the time of the empire the atrium had become a semiopen court ventilating and lighting surrounding rooms. The richer houses developed a peristyle, or court with a garden, at the back; a second story was added and the atrium was made resplendent with ornament and statues. The appearance of the reception rooms always took precedence over comfort in the family areas.

The middle-class house had a smaller atrium, sometimes roofed over, with kitchen and dining room behind and bedrooms above. The farmhouse combined barns, oil and wine Dresses, storerooms and the dwelling in bne building around a courtyard. Poorer free men in Rome and its more crowded colonies lived in bare rooms in tall, dark insulae, or apartment blocks, some seven stories high. Augustus limited their height, in one of the world's first building regulations, to 70 ft. There are indications that they too were planned to surround a court in which the staircase rose past balconies giving access to the upper floors. On the street front the ground floor was occupied by shops. The façade above mas usually of brick, pierced by rows of simple windows, a style of apartment housing that persisted into modern Italy. Sometimes the upper stories projected dangerously.

FIG. 3.— PLANOF SMALL POMPEIIAN HOUSE

(A) Vestibulum (outer entrance court), (B) atrium (inner entrance court), (C) impluvium (skylight), (D) ala (side hall), (E) tablinum (library), (F) andron (passage), (G) peristylum (court), (H) exedra (hall)

The Roman tradition lingered for many centuries. Provincial villas of the Roman style, built in the 7th century, are found in the south of France and Syria. In Britain the atrium was unsuited to the climate. It appeared only rarely, as in Bath, and in the Britons' hands the style degenerated. (See ROMAN ARCHITECTURE; VILLA.)

Medieval. — Until the 13th century the serfs of Europe lived in unrelieved squalor; sod huts partially dug out of the earth, or hovels made of low stone walls surmounted by roughly thatched roofs were typical dwellings. The early Norman castles of England were heavily fortified, dark and dirty and not intrinsically more livable than the poor man's abode. In the 13th century the manor house (*q.v.*) developed a little rugged comfort. It was centred on the hall (*q.v.*), a survival from Saxon times, to which were added buttery, pantry, larder and subsidiary compartments at one end and the solar at the other. The hall was sometimes 60 ft. by 20 ft., stone paved, with a central fireplace, small high windows, and a low dais at one end on which the family and guests

took their meals. The solar was the withdrawing room and bedroom, the private family room. Walls were thick, of brick or stone and an increasing amount of half-timber work (*q.v.*). Window glass was a luxury; openings had shutters, pointed to match the Gothic arches.

The new bourgeois or middle class of the middle ages lived in houses of two or three stories packed into the narrow streets of expanding towns. Typical three-story houses of the 12th century are found at Cluny, France. In such a house a central light court cuts the narrow plan in two, with only a gallery connecting the front to the rear rooms. The front room on the ground floor is a shop, the rear a kitchen. The floor above has living rooms in the front, sleeping rooms in the rear. An attic fills the high roof space. The "Musician's house" at Rheims (*c.* 1240) has a facade typical of the simple charm of the time, made notable by statues of musicians set in niches. The "Jew's house" at Lincoln is an early English town house with richly carved window arches in the Norman Romanesque manner. With their sensible plans and rudimentary plumbing these medieval town houses of northern Europe were potentially comfortable, and they changed little in 500 years. In the north of Italy town life matured earlier. Tall, sophisticated city palaces enclosed arcaded courts. The security of Venice permitted a more extroverted plan, with wider openings to the canal at the front and to the garden at the back. Walls were ornate in coloured marble and were animated by balconies, loggias and long ranges of windows, embroidered with Gothic tracery.

FIG. 4.—PLAN OF ROMAN FARMHOUSE. VILLA RUSTICA, BOSCOREALE, IT.

(A) Store for oil jars, (B) oil press, (C) wine press, (D) stable, (E) court, (F) bath, (G) kitchen

In rural areas the peasant's lot gradually improved and the farm-building complex developed, with barns, sheds and dwelling contained within a fence. Stone was usual in southern Europe, and wood in the north.

House planning, in the modem sense, began with a concern for the privacy of certain members of the household and for the accommodation of certain functions of living in English manors and the European burghers' houses. Between the 14th and 17th centuries rooms were increased in number and were more clearly differentiated. In England the great hall grew asymmetrical wings as required by function. Until the 16th century, however, circulation was tortuous, through rooms and up and down many stairs. The French chbteau (*q.v.*) at this period was a century ahead of the English manor. With its romantic, pointed roofs and round corner turrets, its symmetry and elegance reflected in a wide decorative moat, it made a graceful transition from the grimly fortified Gothic castle to the open, formal Renaissance mansion. The English manor's wings, growing from each end of the great hall, eventually linked to enclose a courtyard (*e.g.*, Compton Wynyates, Warwickshire, 1520). Late in the 16th century the wings opened into a U-shape, releasing the confined courtyard. At the same time the moat was abandoned (*e.g.*, Hatfield bouse, Hertfordshire, 1607–11). The great hall decreased in size and importance; the main passage, expanded to a wide glazed gallery, became the biggest and most pretentious room. It was graced with wood paneling, coloured window glass, black and white checker marble floor, restrained plaster ceiling and elaborate chimney pieces. The exterior, while often retaining the pointed arch and a free disposition of windows, was more composed and symmetrically balanced, gradually adopting the formalism of the Renaissance. (See ROMANESQUE ARCHITECTURE; GOTHIC ARCHITECTURE; CASTLE.)

Renaissance.—In Italy the architectural formality that persisted even through the middle ages grew easily into a full-blown classic revival. The master of residential architecture was Andrea Palladio (1518–80). In buildings such as the Villa Rotunda near Vicenza he adapted the temple form to domestic use without sacrificing classic symmetry, proportion, scale or ornament. The use of giant porticos resulted in precise geometric plans based on the circle and the square, which were developed into three dimensions in accordance with mathematical doctrines. The Renaissance was received enthusiastically by the French court and yielded houses of elegant conception and charming detail. The style came late to England, delayed by Henry VIII's break with Rome and the consequent anti-Italian prejudice. During the 16th century a classic quality entered via northern Europe, and the first English professional architect (John Shute) and the first architectural historian (Henry Wotton) appeared. But the English Renaissance proper began with Inigo Jones (1573–1652), self-trained artist and scholar and generally considered to be the first major English architect. He introduced the Palladian (from Andrea Palladio) style of pure form and the revived classic order (*q.v.*). The plan concept ruled the elevation and all was "masculine and unaffected," as Jones noted during his Italian travels. His monumental houses for the nobility usually consisted of a simple cubical block dominated by the pavilion, or classic loggia, with its single order of tall columns. (See RENAISSANCE ARCHITECTURE; TUDOR PERIOD; ELIZABETHAN STYLE; JACOBEAN STYLE.)

Baroque and Neoclassical.—England's most famous architect, Sir Christopher Wren, was mainly occupied with monumental work, but during his time the "Wrenish" style, a reserved baroque, eclipsed Palladianism. For two prosperous generations of country-house building the classic orders gave way to some originality. Still the house had a rectangular plan, rigid symmetry, a hipped roof and eave cornices broken by central pediments. Early in the 18th century the Palladian style returned, to be replaced about the middle of the century by the characteristically English neo-classical manner known as Georgian. This was an elegant, simplified, lightly ornamented style looking to Rome and Greece for inspiration, and relying for effect on harmonious proportions in the severe rectangles of the façades and the fine, regular glazing bars of the windows.

Robert Adam perfected a graceful personal style drawn from Greek and Roman precedents, plain in form but delicate in ornament, which was accused by its more robust opponents of being effeminate and paper-thin. A rich London house by Adam at 20 St. James street, a typically medium-sized house of its day and class, had seven main living and entertaining rooms on its tall ground floor, and bedrooms above. Within the narrow rectangular confines of the structure Adam shaped the music room as an oval and the dressing room as a circle. At the rear was a garden court enclosed by the stables and coach house. Smaller town houses, foregoing individuality, combined to form long façades, as in the magnificent curve of Royal Crescent at Bath. The typical house was plain red brick with simple windows, a thin cornice

and a neat stringcourse above the arched, fan-lighted doorway.

Early in the 19th century the firm Georgian style divided into the Romantic movement with its exotic Gothic and eastern conceits, and the Regency style, with its plain stucco walls, curved bays and spidery shadows of delicate iron balconies.

Colonial. — Through the 17th and 18th centuries European colonists carried their local house styles to the Americas, Asia and the antipodes, changing them no more than was necessary to adapt them to new materials and changed climatic conditions. After a temporary phase of primitive shelter Early American house types appeared. In the densely forested lands of the north, clearing was an essential first task and wood the obvious choice for building. The lapped horizontal weatherboard or clapboard, hardly known in England, was used generally. The rectangular, frame house with two low stories and a high gable roof was centred on a brick chimney stack. Later a lean-to addition at the rear produced a "salt box" profile. The Cape Cad style grew from an ingenuous functional plan of four rooms on each floor clustering around fireplaces in the stack; a small stairway rose between the stack and the central front door. In Virginia, which was warmer and richer, the plan was longer and thinner and there was a chimney at each end. Brick was more common. The stair hall cut through the centre of the house and opened to front and back.

FIG. 7.—PLAN OF OXBURGH HALL, NORFOLK, ENG., 1482

(A) Drawing room, (B) dining room, (C) great hall, (D) napery, (E) buttery, (F) kitchen, (G) bakery, (H) servants' hall, (I) breakfast room, (J) library, (K) laundry, (L) courtyard, (M) moat

As early as 1667 Palladian books and plan publications carried more sophisticated architectural ideas across the Atlantic. Architects arrived early in the 18th century; a John James was practising in Boston in the 1730s. Soon the American Georgian style appeared, closely following the English model. In the north the style was adapted to wood construction with slender columns or flat pilasters. The rooms were tall, the plan compact. Fine moldings dressed the eaves cornice, fanlights. stairaays and shuttered window trim. In the colonies at New Tork and Pennsylvania, German and Dutch influences were strong; in Virginia and Maryland great plantation homesteads settled in spacious lawns on river estates. These 'big houses were generously conceived and graciously furnished. They were characterized by the hospitable, heroic scale of a two-story portico in a single classic order. As far south as Charleston the Virginian influence was felt, but there the houses turned crabwise for protection: a formal Georgian end faced the street and tiers of veranda faced the private side garden.

In Mexico the Spanish colonial houses had plastered and pastel-washed rubble walls under sun-baked tile roofs. Rooms were arranged around terraces, arcaded courts, and fountains playing in private patios. *(See* IBERO-AMERICAN ARCHITECTURE.)

The Georgian and Regency styles were adapted in various ways to Australia. New Zealand and the islands of British colonization in the late 18th and early 19th centuries. The typical Australian country house was single-storied with a low, hipped shingle roof. It was surrounded by a wide, slim-posted veranda onto which the tall windows of the main rooms opened. *(See* COLONIAL ARCHITECTURE.)

Victorian. — During the second half of the 18th century, the most cultivated phase of European residential architecture, a profound change occurred in the poor-man's house. In the middle of the century the artisan. weaver, miller or farmer lived in essentially the same conditions as the freeman worker of earliest civilization. His house was also his workshop. and his children's place of work. By the end of the century the Industrial Revolution had interrupted the slow evolution of this house, not by transforming its building techniques but by upsetting the function of the home and the nature of family life. Most members of poor families spent days in the factory and nights in mass housing not unlike that of imperial Rome. Four- or five-story walk-up tenements gathered around the factories. They were ill-lit, poorly ventilated and the only outdoor living area they provided was on the pavement of a narrow street. The construction was brick, unencumbered with ornament or plumbing. By the middle of the 19th century, slum areas were extensive in most big cities. Room areas diminished and ingenious plans were devised to save space (*e.g.*, the New York "railroad" aaartments with rooms packed four deep, only the end ones seeing daylight). Meanwhile the citv was dissolving at the edges. Rail transport permitted middle-class workers to live away from their places of employment. Suburbs usually developed around the rail centres and radiated like spokes from the city. The typical Victorian suburban mansion was as elaborate as the palaces of earlier eras. but reduced in scale for a single family with servants and guests. The newly prosperous, hospitable manufacturers and merchants had no patience with cultivated tradition. Georgian and Regency taste was called mawkish and simplicity was seen as a poverty of dress unbecoming in the home of a man of substance. Ambition and acquisitiveness complicated the desire for comfort, sometimes resulting in a clutter of ornamentation unique in the world's history. The multiplying members of the lower middle class moved to the suburbs to nominally detached houses on narrow strips of land. The less successful man was able to emulate the mansion's ostentation effectively, thanks to the machinery of mass-produced moldings. pressings, printings and castings; any desired decorative effect could be reproduced cheaply. The ordinary man began to reap some of the benefits of industry. Built-in equipment and mechanical appliance, including the fitted English bathroom, were novelties in expensive homes early in the century and gradually became commonplace toward the end of the Victorian era. The great increase in personal possessions produced a storage problem that was solved by the built-in cupboard, closet and pantry. Cellar central heating was introduced in the U.S. in the 1830s and was fairly general in mid-century American homes. as were centrally supplied water and gas. Waterborne sewerage began in Hamburg in 1843 but was not adopted by many cities until late in the century. Electricity had

been proved an effective source of power by 1900. Industrial techniques did not, however, extend to the construction of the house. The promise, popularly recognized in the Crystal Palace in 1851, of a new world of mass-produced metal and glass homes, did not materialize as expected. (It had not yet arrived, but was still imminently expected, a century later.) No part of a wall or ceiling was left undecorated. During construction, handicraft ornament supplemented machine-made ornament. Graining, imitating expensive wood or marble, was often painted on plaster or plain boards, a practice about which John Ruskin (1819–1900) commented: "There is no meaner occupation for the human mind." Ruskin and William Morris (1834–1896) were among the few Englishmen who protested against commercialised design and the decline of taste. They sought a return to simple, natural ornament and an appreciation of genuine handcraft. In the U.S. the sculptor Horatio Greenough (1805–1852) called for the elimination of all ornament. These pleas had little effect. Ruskin helped to inspire the Gothic Revival, and Morris' medieval decorations helped it grow. In residential architecture the Gothic Revival usually manifested itself in tall gables with intricate fretwork ornament and pointed-arch windows, later enriched by polychromatic brickwork and ornate lead lights. It was the principal rival to a coarsened neoclassical style in the "battle of the styles," but there were many other revivals. Eclectic architects and builders raked history for embellishments and added to their houses distorted fragments of Norman castles, French châteaux, Swiss chalets. etc. The nadir of taste was reached in England about mid-century, in the U.S. after the Civil War.

Two major, separate revolts began toward the end of the 19th century. One was the art nouveau (q v.) movement initiated in Brussels, an attempt at a new nonhistorical style in which form and ornament were to be based on nature's shapes. This produced only a popular passing fashion of superficial sinuous lines on the trimmings of a house. The other revolt slowly developed toward a rational, styleless architecture shaped to the function of the shelter by the nature of the construction, devoid of ornament. These concepts were the basis of nearly all of international modern architecture as it gradually evolved during the next half-century in the work of temperamentally diverse architects in widely separated localities. (See also MODERN ARCHITECTURE; ARTS AND CRAFTS MOVEMENT, THE.)

20th Century. — The roots of 20th-century residential architecture may be traced in Morris' aim to elevate domestic taste, in the quasi-rational theories of the Frenchman E. Viollet-le-Duc (1814–1879), and in C. F. A. Voysey's big English country houses of the '90s, with their boldly composed roofs and plain white walls. Some of the most important formative steps were taken by nondomestic architects: Louis Sullivan in Chicago, Otto Wagner in Austria, Peter Behrens and Walter Gropius in Germany. Auguste Perret in France, and others. But the crystallization of the movement and a great number of the most auspicious early designs were in the residential field. Many of the best-known architects of the century, including Frank Lloyd Wright, Mies van der Rohe and Le Corbusier, first established their personal styles in houses.

A house on the Geneva water front in 1904 by Adolf Loos, exemplifying his passionate distaste for ornament, introduced the functionalist house. California houses in the early 1900s by Bernard Maybeck and Greene & Greene developed a carpenter-rationale unknown in Europe. However, the U.S. prairie houses by Wright (1869–1959) were published in Germany and injected a new enthusiasm into the European movement.

Although Holland was slow at first to accept the new movement, the vociferous de Stijl group appeared there in 1917. It formalized the theories of functionalism; it probably was largely responsible for the development in Europe through the 1920s and '30s of the naked white-plastered modern house in easily comprehensible cubist shapes. Plain blocks were fashionable for the first and only time; after half a century of ornamental excesses they seemed artistically satisfying, even when not accompanied by any creative idea.

In a postwar atmosphere the Bauhaus (*q.v.*) school was founded in Germany in 1919 by Walter Gropius. With its all-embracing concept of the creative simultaneity of technology and all the arts of living, it had untold influence on the development of house design throughout the world.

In France the Swiss-born architect Le Corbusier (1887–) contributed influential writings to the journal *L'Esprit* Nouveau. In 1930 he built his most famous house, the Villa Savoye, at Poissy; a wide white box, whose hollowness was emphasized by its open decks and by its being elevated on poles. It was one of the most vigorous expressions at that time of the new interest in negative form; *i.e.*, the composition of spaces rather than the proportioning of masses.

In Russia shortly after the revolution constructivism was a style recommended for the huge housing blocks. It was an experimental branch of modern architecture following structural methods. It soon met official reaction, and after 1930 the Soviet government adopted severe neo-Renaissance façades for its bulky apartment buildings.

The Stockholm exhibition of 1930 introduced modern architecture to Scandinavia. Sweden accepted the principles more thoroughly and naturally than any other country, and for many years the simplicity, without self-consciousness, of its houses and household wares received world-wide attention. Central urban-planning control, exceptionally high and level living standards, and a tradition of first-rate craftsmanship aided the development. Generally, 12-story elevator apartments were built near the cities, and 3-story walk-up flats and single-family houses formed satellite groups. All units were well planned and equipped to give comfort, if not privacy, and care was given to the external architectural relationships and the preservation of the best qualities of the landscape. Notwithstanding a certain monotony which developed later, Sweden thus produced the most cultivated and fully pervasive national pattern of housing in history.

Germany under Hitler called for a nationalistic style and outlawed the new architecture. Many of its leading designers left for England and later the U.S., where eventually they were responsible, with American confreres, for a revolution of taste against historic revivals. After World War II Germany returned to its earlier rational architectural principles for the design of many enormous apartment blocks. Its comparatively few single-family houses, however, tended to be designed in the traditional pattern of German country houses.

While the European functionalist phase developed through the early part of the century, most English-speaking countries persevered with architectural eclecticism. It was more restrained than in the 19th century and extremes, such as the Gothic Revival, were rare. But exotic effects continued to dress the faces of houses, such as, Italianate villa, Spanish mission and English style (outside England). At the same time more and more people wanted private, detached houses. In the 1930s some were "modernistic"; *i.e.*, ornamented with parallel grooves or streamlined curves or skyscraper profiles on the chimney tops.

During this time Frank Lloyd Wright built numerous houses of remarkable individuality, his artistic range including the wide, reposeful roofs of the Robie house, Chicago (1909), as well as the striking suspension of "Fallingwater" (1936–38) over a mountain stream in Pennsylvania. His favourite materials were wood and stone, his line horizontal, his spaces wide and subtly interrelated. He made each house an artistic idealization of free family life. In his retention of ornament and his increasing romanticism he steadily drew away from the Europeans. Not until after World War II was his art popularly recognized in the U.S.; then it had at least superficial influence on many houses.

During this period it was often possible for the poor to possess the ancient symbol of independence, the private house. The cities' suburbs, which had been growing slowly for a century, escaped urban control. Young married people sought immediately to own a home, and the home was the centre of nearly all social contacts and entertainment. A new nomadic segment of the U.S. population rebelled and took to living in car trailers which compressed all the mechanical aids of the 20th century into the area of an Inca hut. Town housing remained comparatively stable in the U.S. The more prosperous cities proceeded slowly with slum-clearance

schemes for their crowded tenement areas, usually rehousing the same number of people in taller blocks set apart on lawns. In many European and Latin-American countries, on the contrary, big new apartment blocks continued to increase the density of urban populations.

Most suburban houses were built without architects' guidance. Standard designs were repeated tirelessly with minor fashion changes and some colouring by local idioms. Mechanical equipment constantly increased and improved. Buckminster Fuller in 1927 designed a fully industrialized house hung on a central mechanized mast, and later many other proposals nere made in the same vein. But society resisted radical change from the traditions of wood and brick.

Architectural character continued to be dominated by a few creative men whose well-publicized ideas carried to suburbs everywhere. Some were bent on perfecting anonymous, universal shelters in which each owner could create an environment to his taste. Most residential architects, however, still aimed to compose in spaces and textures a delightful background for the kind of life the occupants liked to lead.

Asiatic. — Before contact with the west and modern technology, antique rules of building in Asia descended unchanged from one generation of builders to another.

Indian. — Building rules were recorded in Sanskrit about A.D. 500 in a code determining sizes, proportions, structure and details of design down to the doors, windows and drains. The poor peasant of the plains had a single hut. The villager had a house of four huts — one each for the men, women and cattle, and one for cooking and storage — on four sides of a courtyard. The Hindu multifamily group repeated the court and its rooms for each brother. A rich-man's house extended the system again with extra stories. In the thickly populated areas around great rivers the floors and walls were made of clay, the roofs thatched. In the arid northwest the walls were brick or stone, the flat roofs were of an indigenous cement. In the western Himalayas the court was

omitted, the stone walls rose two floors under a slate roof. In some parts intricate carvings adorned the balconies and surrounded the door and window openings.

The English in India developed a single-story house with a shaded veranda and well-ventilated rooms. It was known in the vernacular as a bungalow, a name which later came to mean in other countries a single-story house of any design. (See also INDIAN ARCHITECTURE.)

Chinese. — The traditional Chinese house was a single-story row of rooms linked by a narrow veranda and surrounded by a high wall. A screen directly inside the entrance gate balked devils, who cannot negotiate corners. Brick was common, and adobe faced with brick made the thicker walls. The top halves of some interior partitions were open latticework with paper panels. Windows usually had decorated paper panes. The roofs had a characteristic drooping gable, suggestive of tent origins. Houses of the rich had black ebony carvings against their brick walls and beneath their green glazed tile roofs. The plain interiors were often

well decorated with fine sandlewood or teak furniture and elaborate embroideries and porcelain. (See CHINESE ARCHITECTURE.)

Japanese. — In Japan the traditional vernacular house was based on an order of design that western civilization first approached in the 20th century. The house was light, adjustable, unpretentious, virtually unadorned and planned on a precise mathematical concept. The standard grass floor mat, about 6 ft. by 3 ft., was the module for all planning. Whether square or oblong each room was a multiple of the mat size (*e.g.*, a four-mat room). Posts on the perimeter of the veranda and at the corners of rooms supported the hipped or gabled roof frame. The roof was tiled or thatched on top and lined on its flat underside with boards or panels of wood. Some external walls. such as those for the kitchen and privies. were permanent in bamboo, boards or plaster. But the unique feature in the traditional Japanese house is that most exterior walls and nearly all interior partitions were movable screens sliding in grooves which ran in the floor and the ceiling between structural posts. These screens permitted the rooms to open to the veranda and to each other as required, and allowed for supervision of family activities by the patriarch.

The modern Japanese adoption of U.S. fashions threatened to end the tradition, but some Japanese architects have succeeded in advancing the structural principles of the unpainted wood and paper idiom without destroying its order, flexibility or unaffected artistry. See JAPANESE ARCHITECTURE.

RESINS are among the most versatile of all chemical compounds, and their industrial applications are still expanding. Natural resins range from pitch and asafetida to frankincense, myrrh and the fossilized form of resin known as amber. Synthetic resins are the bases of products as varied as nylon, billiard balls and equipment for softening or desalting water.

Prior to the introduction of synthetic resins, the term resin was applied exclusively to certain sticky substances which exude in the form of yellow or brown deposits from certain trees, particularly from the pine and the fir. As knowledge gradually accumulated concerning the nature of such natural resinous products as well as the means by which similar compositions could be made by known chemical reactions, a large and ever-increasing number of products have been included in the category of resins. At first these products of the laboratory were hesitatingly referred to as resinlike products, then as artificial resins and as resin substitutes and finally as synthetic resins. In almost every respect, the natural resin can be replaced by one of the synthetic varieties in many of the industrial applications, especially in the molding and the coating industries. Through the study of chemical reactions which lead to resinification! a better insight mas gained concerning the chemical transformation which takes place in the natural product with the result that, in certain instances, it became possible to combine chemically the natural and the synthetic product leading to the formation of a new material possessing unique properties.

At one time resins were recognized by certain well-known attri-

butes, that is, by their transparency and amorphousness and by their brittleness and conchoidal fracture. Synthetic resins of all types are known, and certain of them fail to exhibit any of these characteristics. Some of the latter preparations are tough and colourless, whereas others are opaque and crystalline. There appears to be only one property which is common to both natural and synthetic resinous products—in one stage of their existence both products are plastic.

The distinction between resins and plastics is at best arbitrary since many of the later synthetic materials can be called both resins and plastics. Historically, it appears that the term resin was applied to those products which were primarily used as substitutes for the natural product entering into coating compositions, whereas the term plastic was used to designate those compositions which involved a molding operation in their fabrication. It is generally recognized that resins, plastics, rubbers and fibres are part of one large group of chemical compounds, and by suitable transformations it is possible to change any one member of this group into another.

NATURAL RESINS

The resin formation in a tree occurs as a result of injury to the bark inflicted by wind, fire, lightning or other means. Initially this secretion is fluid in nature and appears in the form of an oleoresin or as a balsam. In contact with air certain of the more volatile components evaporate, and the residue oxidizes, polymerizes and gradually converts to a soft, resinous product which is readily soluble in appropriate media. As the natural resin gets older, it becomes more insoluble. When the resin flow from the tree is copious, some of the secretion passes into the ground, with the result that many of the fossil resins are found as buried deposits. Even in the case of the recent fossil resins, the chemical reaction leading to resinification may have proceeded for thousands of years. For example, the kauri pines are known to attain an average age of 1,000 years; and since resin can now be found in areas where the original forest has wholly disappeared, it is obvious that the resin must be extremely old. This resin is still soluble. The fossil resin, amber, is of a less soluble type. The very existence of this resin indicates that the process and time of polymerization from the oleoresin to resin, to recent fossil resin, to fossil resins must, in the case of amber, be reckoned in geological periods.

Resinous deposits are found in many parts of the world, and many varieties derive their names from the locality where they are collected. Not only are these products derived from many lands, but they have been known and used technically for long periods of time. Certain tree emanations were utilized by the Chinese and the Japanese in their preparation of oriental lacquers. There is reason to believe that the Incas and the Egyptians used varnishlike materials. The Carthaginians, Phoenicians and Greeks were acquainted with resinous products, and the association between resins and varnishes can be seen in the derivation of the word varnish. This term appears to originate from Berenice, queen of Cyrene, the name the Greeks applied to amber. The term Berenice became corrupted gradually to Pheronice and then Verenice and Vernis.

Amber is not used in the preparation of varnishes but is mainly employed in the fabrication of beads and in decorative wear. In certain respects amber can be handled in very much the same manner as that employed in the fabrication of cast plastics.
