SARSAPARILLA *TO* SORCERY

SARSAPARILLA, a drug prepared from the roots of several species of the genus *Smilax* (lily family). The origin of the name is Spanish. *zarza* meaning "bramble" and *parilla,* "little vine." The plants are indigenous to Central America from the southern and western coasts of Mexico to Peru. Only three species have been identified with certainty: *Smilax aristolochiifolia, S. regeli* and *S. febrifuga,* known in commerce, respectively, as Mexican, Honduras and Ecuadorian sarsaparillas. Other varieties, known commercially as Ecuadorian (or Guayaquil) and Central American (Jamaica or Guatemala), are derived from unidentified species of *Smilax.* The plants are large perennial climbing or trailing vines, growing from short, thick. underground stems from which rise numerous semiwoody flexuous angular stems, bearing large alternate-stalked leaves. The tendrils that provide support for the plants spring from the bases of the leaves. The roots are dried in the sun, then gathered loosely into bundles or bound tightly into cylinders, depending on the place of origin, and exported. Several sterols and a crystalline glycoside, sarsaponin, which yields sarsapogenin on hydrolysis, have been isolated from the root. Sarsapogenin is related to steroids such as progesterone and is used in their synthesis. Sarsaparilla is regarded popularly as a tonic, but in fact is inert and useless. A liquid extract in which it is combined with other flavouring agents is an ingredient of such carbonated drinks as the American root beer. (V. E.)

SARSFIELD, PATRICK (?–1693), titular earl of Lucan, Irish Jacobite and soldier. belonged to an Anglo-Norman family long settled in Ireland. He was born at Lucan, but the date is unknown. Patrick, nho was a younger son, entered Dongan's regiment of foot on Feb. 9. 1678. During the last years of Charles II he served in the English regiments which were attached to the army of Louis XIV of France. The accession of King James II led to his return home.

He took part in the suppression of the Western rebellion at the battle of Sedgemoor on July 6, 1685. In the following year he was promoted to a colonelcy. King James had adopted the dangerous policy of remodelling the Irish army so as to turn it from a Protestant to a Roman Catholic force, and Sarsfield whose family adhered to the church of Rome, was selected to assist in this reorganization. When the king brought over a few Irish soldiers to coerce the English, Sarsfield went in command of them. Sarsfield had a brush with some of the Scottish soldiers in the service of the prince of Orange at Wincanton. When King James fled to France, Sarsfield accompanied him.

In 1689 he returned to Ireland with the king. During the earlier part of the war he did good service by securing Connaught, and was promoted to brigadier, and then major general After the battle of the Boyne (July 1, 1690), and during the siege of Limerick, Sarsfield came prominently forward. His capture of a convoy of military stores at one of the two places called Ballyneety, between Limerick and Tipperary, delayed the siege of the town till the winter rains forced the English to retire. This achievement made him the popular hero of the war with the Irish. When the cause of King James was ruined in Ireland, Sarsfield arranged the capitulation of Limerick and sailed to France on Dec. 22, 1691. He received a commission as lieutenant general (maréchal de camp) from King Louis XIV and fought with distinction in Flanders till he was mortally wounded at the battle of Landen (Aug. 19, 1693). He died at Huy two or three days after the battle. In 1691 he had been created earl of Lucan by King James. He married Lady Honora de Burgh, by whom he had one son, James. nho died childless in 1718.

See J. Todhunter, *Life* of **Patrick** *Sarsfield* **(1895).**

SARTHE, a *dkpartement* of France, formed in 1790 out of the eastern part of Maine, and portions of Anjou and of Perche. Pop (1954) 420,393. Area 2,411 sq.mi. It is bounded north by the *département* of Orne. northeast by Eure-et-Loir, east by Loir-et-Cher, south by Indre-et-Loire and Maine-et-Loire and west by Mayenne. The *dkpartement* includes the greater part of the basin of the Sarthe, which drains the large bay in the southern flank of the hills of Normandy, and the city of Le Mans is at the focus of this bay, nhere the Sarthe from the northwest joins the Huisne from the northeast. It is floored largely by Jurassic and Cretaceous rocks succeeding one another eastuard, with the Armorican Palaeozoics on its western border. Southeast of the Huisne the Eocene deposits stand out, forming a relatively poor territory. The Loir flows through the southern edge of the department to join the Sarthe in Maine-et-Loire; along its chalky banks caves have been hollowed out which, like those along the Cher and the Loire, serve as dwelling houses and stores. The mean annual temperature is 51° to 52° F. The rainfall is between 25 and 26 in.

The *de'partement* is mainly agricultural. There are three distinct districts: — the corn lands to the north of the Sarthe and the Huisne; the region of barren land and moor: partly planted with pine, between those two streams and the Loir; and the wine-growing country to the south of the Loir. Sarthe produces much barley and hemp. The raising of cattle and of horses, notably those of the Perche breed, prospers, and fowls and geese are fattened in large numbers for the Paris market. Apples are largely grown for cider. The chief forests are those of Bercé in the south and Perseigne in the north; the fields in the department are divided by hedges planted with trees. Coal, marble and freestone are among the mineral products. The staple industry is the weaving of hemp and flax, and cotton and wool-weaving are also carried on. Paper is made in several localities. Iron-foundries, copper and bell foundries: factories for provision-preserving, marbleworks at Sablé, potteries, tileworks, glass-works and stained-glass manufactories, curriеries, machine factories, wire-gauze factories: flourmills are also important. The *département* is served by the Ouest-État, the Orléans and the State railways, and the Sarthe and Loir provide about 100 mi. of waterway, though the latter river carries little traffic.

The *de'partement* forms the diocese of Le Mans and part of the ecclesiastical province of Tours, has its court of appeal at Angers, and its académie (educational division) at Caen, and forms part of the territory of the IV army corps, with its headquarters at Le Mans. The *arrondissements* are named from Le Mans; the chief town, La Flèche and Mamers. There are *33* cantons and *386* communes. The chief towns are Le Xlans, La Fleche, La Ferté-Bernard, Solesmes (*qq.v.*) and Sablé.

SARTI, GIUSEPPE (1729–1802), Italian composer, was born in Faenza, Dec. *1, 1729*. He studied under the direction of Padre Martini at Bologna, and was organist at the cathedral in Faenza 1748–50. At the age of *22* he completed his first opera, *Pompeo in Armenia.* successfully produced in Faenza (*1752*). This success was followed by *Il Rè pastore,* in Venice (1753), which with others established his fame abroad.-

He mas called by Frederick V of Denmark to Copenhagen, where for several years he directed Italian opera and was made court conductor. He was then commissioned by the Danish king to engage singers in Italy for a new company. During his absence in Italy King Frederick died, and Sarti remained in Italy for three years. On his return to Copenhagen in 1768, he conducted the court opera until 1775, when he was dismissed for political reasons. During his stay in Denmark, he composed 20 Italian operas and many Danish Singspiele.

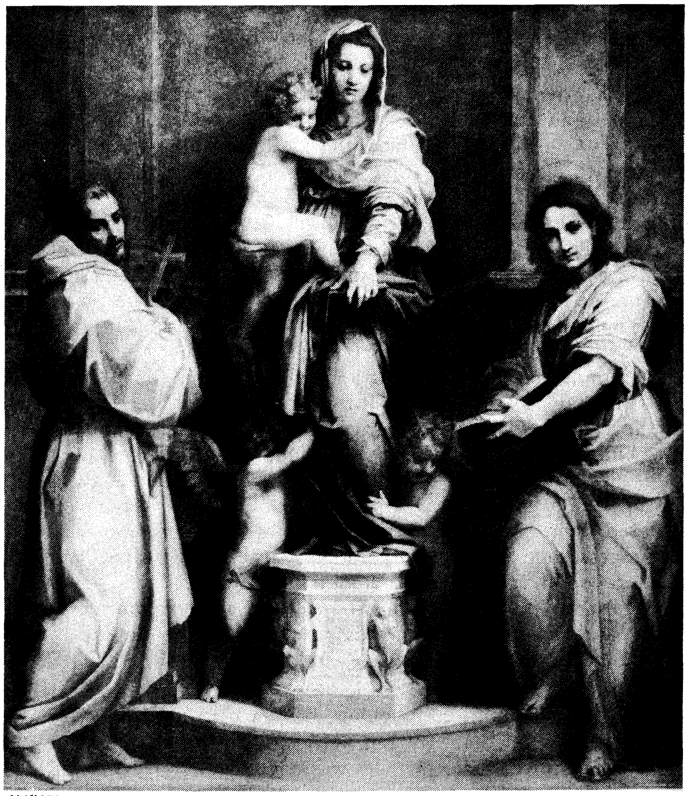
From Copenhagen he uent directly to Venice. where he was made director of the Ospedaletto conservatory. In 1779 he won the directorship of the cathedral in Milan, in competition with the leading musicians in Naples. This gave him the opportunity to write several masses, a Miserere *a 4,* and motets. It was during this period that he achieved his greatest dramatic success by writing some *1j* operas, among them *Giulio Sabino* (Venice, 1781) and *Fra i due litiganti il terzo gode (Le Nozze di Dorina)* (Milan, *1782*). This great success established his reputation and brought him many students of note, among them Cherubini, who became his assistant.

Sarti left Italy again upon invitation from Catherine II of Russia (1784) to go to St. Petersburg. On his way he stopped in Vienna, where he was received in court by the emperor, and met Mozart, who was then in his prime. In St. Petersburg, Sarti was welcomed with even greater favour in the court of Catherine II. Under his directorship, the Italian opera attained unparalleled success and perfection. The empress. uho showed great interest in his achievements, wrote the libretto for his opera *Olega.* Beside being a composer, Sarti was a skilled mathematician and physicist. He invented a device for counting tone vibrations for which he was made honorary member of the St. Petersburg Academy of Science. Among the works he composed for the Russian court is a Te Deum composed on the taking of Ochakov by Potemkin. In this composition Sarti used fireworks and cannon for accent and martial effect. He lost favour with the empress for a short time, and Prince Potemkin came to his aid by establishing a school in a village in Ukraine! and making Sarti director. The empress restored him to favour again, however, and made him head of a new conservatory planned after those of Italy.

Sarti was a prolific composer, and wrote 54 operas. They possess great character and charm, and Mozart wrote variations on an air from one of them. Among other compositions are a requiem, two Te Deums, two concertos, six sonatas for the harpsichord and many masses. Several of the masses are frequently performed. Very few of his compositions have been engraved. Most of his works were placed in the library of the conservatory in Paris, and that of Naples.

After the death of the empress of Russia, Sarti made plans to revisit Italy, and stopped on his way in Berlin, where he fell seriously ill and died July 28, *1802.*

SARTO, ANDREA DEL (1486–1530), one of the most popular Florentine painters of the early 16th century, was born in Florence on July *14, 1486.* His father. Xgnolo di Francesco, was a tailor *(sarto),* and from this fact the painter derived his name. In *1*508 Andrea was enrolled in the guild of the Medici e Speziali. According to G. Vasari, he was trained initially by a goldsmith, was later apprenticed for three years to a painter Gian Barile, and subsequently worked with Piero di Cosimo, traces of whose influence are found in his earliest authenticated works—five frescoes of scenes from the life of St. Philip Benizzi, executed in the entrance court of the Annunziata in Florence in *1 jog–10.* A sixth of the "Adoration of the Magi" dates from *1*511 and a



ALINARI

"MADONNA OF THE HARPIES" BY ANDREA DEL SARTO. IN THE UFFIZI GALLERY. FLORENCE

seventh of the "Birth of the Virgin" from 1514. Whereas the earlier of these frescoes are dry and somewhat academic in style, in the latest the scale of the figures is increased and the execution reveals the boldness and beauty of colouring of Andrea's mature work. At this time Andrea was closely associated with the painter Franciabigio, as well as with the sculptor Jacopo Sansovino. who exercised a deep influence on his figurative style. His relation to both artists can be traced in a celebrated cycle of grisaille frescoes of scenes from the life of St. John the Baptist in the Chiostro dello Scalzo. Florence. The Scalzo frescoes were interrupted in 1518 by a visit to France. where Andrea entered the employment of Francis I. The single relic of his activity in France is a painting of "Charity" dated 1518 in the Louvre. Paris. Returning to Florence in 1519 he resumed work in the Scalzo between 1522 and 1526. To this period belong his most ambitious frescoes, the "Tribute to Caesar" at Poggia a Cajano (1521), the great "Last Supper" at S. Salvi (about 1526) and the "Madonna del Sacco" in the cloister of the Annunziata (dated 1525). This last fresco, with its bold pyramidal design and delicate handling, is perhaps Andrea's finest work.

With a few exceptions. Andrea's most notable panel paintings are in the Uffizi and Pitti galleries in Florence. They include his best-known work, the "Madonna of the Harpies" (1517), the "Dispute about the Trinity" (1517–18), a magnificent "Lamentation over the Dead Christ" (1524) and three large altarpieces of the Assumption. In these he combines the compositional procedure of the Tuscan High Renaissance with a splendour of colour reminiscent of Venetian painting.

Andrea was also a distinguished portrait painter. His best work in this genre is the introspective "Portrait of a Sculptor" in the National gallery, London. A self-portrait is in the Uffizi gallery. As a draftsman, Andrea favoured the medium of red chalk, which he employed with exceptional directness and accomplishment. A large collection of his drawings is in the Uffizi gallery. Endowed with a less original talent than his great contemporaries Raphael and Leonardo da Vinci, and a more equable temperament than his disciples Rosso and Jacopo da Pontormo, Andrea del Sarto remains a central figure in Florentine High Renaissance art, whose work is marked by monumentality, sincerity and sensibility and by its disregard of external effect. The romantic story of his marriage to Lucrezia del Fede (probably 1517) is recounted by Vasari. Andrea del Sarto died of the plague at Florence on Sept. 29, 1530.

See I. Fraenckel, *Andrea del Sarto* (1935); B. Berenson, *The Drawings* of *the Florentine Painters,* 3 vol. (1938). (J. W. P.-H.)

SARTS. The Sarts are an Iranian Turkish tribe, numbering about 2,000,000, who live in Ferghana and Syr Daria territories. They are highly organized, living in permanent villages, with a developed Sufi system of education. They practise a system of agriculture, using irrigation canals, and growing fruit and cotton. They are also accomplished traders. In religion they are Sunnites, many of them belonging to the Sufi order. They have mixed considerably with the Tadjiks, the remnant of the old non-Turkic population, and physically are largely of the Alpine type. In culture they differ widely from most of the tribes speaking cognate languages. (L. H. D. B.)

SARZANA, a town and episcopal see of Liguria, Italy, in the province of La Spezia, 9 mi. E. of Spezia. Pop. (1957 est.) 16,846 (commune). The cathedral of white marble in the Gothic style, dating from 1204, was completed in 1471. The old citadel, built by the Pisans in 1263, was re-erected in 1388. Glass bottles and bricks are made there. Sarzana's position at the entrance to the valley of the Magra (anc. Macra), the boundary between Etruria and Liguria in Roman times. gave it military importance in the middle ages. The first mention of it is found in 983.

SASARAM, a town in Shahabad district. Bihar. India. on the Eastern railway, 90 mi. W.S.W. of Patna. Pop. (1951) 29.265. It is famous as containing the tomb of the emperor Sher Shah (1540–45). The tomb, the finest example of Pathan architecture in India. with a dome 101 ft. high, stands on an island in the middle of. an artificial lake. The town also contains the tomb of Sher Shah's father, another fine specimen of Pathan art; a building called the Kila, or fort. said to have been his palace; and the grave and unfinished tomb of Sher Shah's son. the emperor Salim Shah. Outside is the ruined tomb of Alawal Khan, the reputed architect of Sher Shah's and his father's tomb. A rock edict of Xsoka is inscribed on the Chandan Pir Shahid hill, close to the town.

SASEBO, a port town in Nagasaki prefecture. Kyushu, Jap. Pop. (1960) 262,484. Provided with a good natural harbour near the mouth of Ōmura bay, Sasebo was a naval base from 1896 until the end of World War II. It was a small village until the restoration (1868), but expanded rapidly after the wars with China and Russia. The town was partially destroyed in World War II, but because of facilities which years of experience had perfected, Sasebo revived as a commercial and fishing port. The harbour facilities are also used by the U.S. armed forces stationed in Japan. (R. B. H.)

SASKATCHEWAN, a prairie province of Canada lying between Manitoba to the east and Alberta to the west and containing part of one of the great grain-producing regions of the world. It has an area of 251,700 sq.mi., of which 31,518 sq.mi., mainly in the north. are covered by water.

Physical Geography. — Geology and *Physiography.*—Saskatchewan has purely artificial boundaries cutting across the major geologic and geographic zones of west central Canada (see CANADA: *Physical Geography;* Geographical Regions). The northern one-third is a part of the Canadian shield. Pre-Cambrian rock is exposed at the surface or underlies shallow glacial drift and sedimentary sands in a terrain which is rugged but not mountainous. Muskeg (swamps), many lakes and small streams are indicative of two immature drainage systems which carry the brackish water to Hudson bay via the Churchill or to the Arctic ocean via the Xthabasca and Mackenzie. The southern two-thirds of the province forms part of the great interior continental plains. In Saskatchewan these comprise two distinct levels or prairie steppes. The westernmost, at about 2,500 ft. above sea level. extends to the Missouri *coteau* (cuesta or scarp), a dominant feature which approximately defines the eastern edge of the remnant Tertiary formations. The Cypress hills and Wood mountains rise to 1.000 ft. above this level and comprise the youngest Tertiary beds. The second prairie steppe, at about 1,500 ft., terminates in the Manitoba escarpment, the eastern edge of Cretaceous formations on the prairies. Various series of hills between the two escarpments, including the Moose and Duck mountains and the Porcupine and Pasqua hills, are outriders of the older Tertiary beds. The province was almost entirely glaciated in Pleistocene times and the present surface soils of the plains originated from glacial depositions.

The Saskatchewan river (*q.v.*) drains a large part of the southern plains. Its two branches. entering the province from Alberta nearly 200 mi. apart. meet east of Prince Albert and flow toward Lake Winnipeg in Manitoba. A southwestern area drains southward to the Missouri river, and the southeastern corner of the province is drained by the Souris and Qu'Appelle rivers to Lake Winnipeg via the Assiniboine and Red rivers of Manitoba. Most southern Saskatchewan rivers flow through deep. U-shaped valleys which were eroded by glacial melt water in unconsolidated sedimentary beds as the last continental ice sheet retreated.

Climate, Soils and *Vegetation.*—Saskatchewan has a continental climate with relatively little marine influence, prevailing westerly winds and wide seasonal and daily ranges of temperature. Average monthly temperatures decrease northward. particularly in winter. The average January temperature in the south is 0° F. while in the extreme northeast it is −20° F. The isotherm of 65° F. in July runs along the southern border and that of 60° F. through the middle of the province. The low annual precipitation is concentrated fortunately in the growing season. Average precipitation varies from 11 in. in the southwest to 18 in. in the northeast part of the agricultural region, with wide local and seasonal fluctuations. Repeated low annual averages of precipitation led to the disastrous prairie drought of the 1930s which was accompanied by dust storms and insect infestations.

As a result of their glacial origin the clay and loam soils of the great plains in Saskatchewan are rich in mineral content. Modification in well-defined zones of vegetative cover, each in turn a characteristic of a particular set of climatic factors; has produced brown soils in the arid southwest, black soils in the prairies (grasslands) proper. degraded black soils in the parklands and gray wooded soils in the northern extremes of the plains area. The grasslands are primary producers of wheat, but the higher levels. particularly the Cypress hills, are wooded and break the monotony of the landscape. Scattered clumps of trembling aspen in the wide belt of parklands eventually thicken and merge into the mixed wood forest at a northwest-southeast line across the province between Prince Albert and Saskatoon. Northward a further transition takes place to dominantly coniferous species. It is the northern part of this mixed wood belt which contains the best of the province's merchantable timber. Still farther northward a wide expanse of potential pulpwood (chiefly black spruce and jack pine) deteriorates into a zone of little commercial value. There poor soil and low temperatures reduce the quality of the tree cover.

Wildlife.—Saskatchewan is rich in wildlife resources. The vast prairies, once the home of great buffalo herds, are still sparsely populated and continue to provide an almost unlimited habitat for deer and antelope, upland birds such as grouse. partridge and pheasant, and waterfowl—ducks, geese. cranes and swans. Deer, elk, moose and bear inhabit the parklands and forests, with caribou in the far north. Of the fur bearers. muskrat, beaver, mink. squirrel, otter and fisher are common, Nearly all Saskatchewan lakes and streams contain fish: many in sufficient abundance to be fished commercially.

History. — Saskatchewan takes its name from the Indian name for the great river of the plains, which is in full Sis-Sis-Katchewan-Sepie. the "Big Angry Water" or "Rapid river." The territory, then unexplored. was granted by Charles II in 1670 to the Hudson's Bay company for the exploitation of its fur. The first knowledge of this part of the territory came from an expedition of Henry Kelsey of the company (1690–92). Subsequent exploration was accomplished by the La Yerendrye brothers about 1750. and thereafter by Anthony Henday and Samuel Hearne. In 1774 I-Iearne established the first white habitation to remain a permanent community, at Cumherland House on the lower Saskatchewan river.

Until their merger in 1821 the Hudson's Bay company and the North-West company were rivals in the fur trade, particularly in the forested regions of the territory. They set up numerous temporary forts and trading posts. often in direct competition at one location. The consolidated Hudson's Bay company established additional permanent posts, such as Carlton House and Ft. Pitt, by the 1840s. All other settlement was confined to the vicinity of these posts.

The transfer of the territory to Canada in 1869 and railway connection from Winnipeg to St. Paul. Minn., in 1878 prompted immigration and homestead settlement. The dispossession of the resident half-breed population without proper recognition of their rights led to two uprisings. in the Red river valley in Manitoba (1869–70) and in Saskatchewan (1885). The North West Mounted Police were established in 1873. Organized government of the Northwest Territories south of latitude 60° came in 1875, with Ft. Livingstone the first government seat and Ft. Battleford taking over in 1877. In 1882 Regina was made the territorial seat of government. Completion of the Canadian Pacific railway in 1885 aided farm settlement and a surge of immigrants after 1901 led to the creation of the province of Saskatchewan in 1905, with Regina (*q.v.*) selected to be the capital city.

Rapid growth continued until World War I, the population increasing from 91.279 in 1901 to 492.432 in 1911, and municipalities, towns and cities were established. The University of Saskatchewan at Saskatoon was founded in 1907. There was wide diversity among settlers in nationality. culture and religion. Immigration slackened and practically stopped between World Wars I and TI. and the desperate depression years of the 1930s saw some emigration from Saskatchewan and some relocation within the province. Settlers from the "dust bowl" moved northward into the forested regions to resume agricultural and other activities there. The return of wetter seasons and improved crops in the 1940s encouraged reconsolidation and diversification of the provincial economy. In 1955, the jubilee year for Saskatchewan, a recognition program was undertaken to mark many historic sites throughout the province.

Population. — Saskatchewan's population, 925,181 in 1961, is concentrated in the southern half of the province. Less than 27, live north of the agricultural region. Settlement took place fairly rapidly in the grasslands and parklands, more slowly in the forest fringe. The main rail line of the Canadian National railway passing through Saskatoon and the park belt, where the risk of drought is less than on the prairies proper, enabled this zone to reach and retain the greatest nonurban density of population in the province. A gradual shift of urban-rural ratios continued after World War II, from 67, urban in 1901 to 21% in 1931 to 37% in 1956, in centres of 1.000 population and over. About 42% of Saskatchewan people were of British origin, 67, French, 16% German, 8% Scandinavian. and 9% Ukrainian, with a scattering of over 16 other national groups. About 23,300 Indians lived in Saskatchewan under federal care. The largest religious groups were United Church of Canada (30%) and Roman Catholic (24%), followed by Anglicans (11%) and Lutherans (11%). Over 24 other creeds were represented.

Government and Public Finance. — The lieutenant governor, appointed by the federal government, is the titular head in the province; he acts on the advice of the executive council. headed by the premier and comprised of selected members of the provincial legislature. The statutory number of members of the legislature is 55: they are elected for five years unless the assembly is dissolved sooner. There is a nonpolitical civil service. The province is represented at Ottawa by six senators (after 1915) and by members of the house of commons according to population; the 1952 Representation act gave Saskatchewan 17 members.

Through Saskatchewan's first 25 years as a province, the Liberal party remained in control, to be replaced for one five-year term through the worst of the drought and depression years by a Conservative administration. The Liberal party then returned, but the growing unrest and organization of farmer groups and their dissatisfaction with the control over the prairie economy exerted by eastern interests contributed to the election in 1944 of a social democratic party entitled the Co-operative Commonwealth federation (C.C.F.), headed provincially by the premier. T. C. Douglas. By 1960 there was elective municipal government in 11 cities. 106 towns, 372 incorporated villages and 296 rural municipalities. There are no counties.

Public revenue in Saskatchewan as in other provinces is drawn from retail sales and income taxes. licences, royalties and crown corporation profits; under a dominion-provincial tax rental agreement the dominion compensates Saskatchewan for income and corporation taxes. formerly levied by the province. Provincial revenue increased from under $12,000,000 in 1921 to over $132,-000.000 in the second half of the 20th century. After the economic crisis of the 1930s, stringent provincial controls were imposed on municipal borrowing.

Education. — Throughout Canada the control of education is vested in the provinces. Elementary education in Saskatchewan is public, undenominational. compulsory and free of charge. Private denominational schools are permitted if they conform to the general standard. Both classes of schools are supported hy public funds. Enrollment in public day schools totals about 200.000. in private schools about 3,000. Other provincial institutions include a correspondence school. a school for the deaf, two teacher training colleges and a technical institute. Provincial loans and scholarships are available to university. teachers college or nursing school students. The University of Saskatchewan at Saskatoon. with an affiliated college in Regina. offers a wide variety of advanced academic training and extension services, particularly in agriculture.

Production. — Until well after World War II, Saskatchewan's economy was primarily agricultural. During the war years the output of nonfarm industry represented just 20% of the value of total commodity production. The growth of the petroleum, mining. manufacturing and construction industries was rapid in the postwar years and by 1958 nonagricultural industries accounted for 65% of gross commodity production, or $927,000,000 of $1.327.000.000. The estimated gross retail trade in 1958 was valued at $902,000,000.

Agriculture.—Still the basic industry in Saskatchewan. agriculture accounted for 66% of the net value of all production over the ten-year period to 1958. Grain crops lead production; the average wheat crop for this period was 2i7.000.000 bu. or 57% of Canada's total. Long-term average yields for wheat, oats and barley are 15, 29 and 22 bu. per acre, respectively. Other major

field crops are flax, rye and forage. Livestock production expanded during the 1950s to add stability to the agricultural economy. The value of all livestock on Saskatchewan farms was estimated at $300,000,000. Gross farm income from this source was about 30% of total farm income.

The climate limits production of many orchard and specialty crops. but research. experimentation and assistance programs of provincial and federal departments of agriculture and the provincial university have assisted greatly in improving this and the entire agricultural situation. In the 1950s the average size of Saskatchewan's 103.000 farms was 607 ac. and the average total investment per farm was $20,615. Investment in farm mechanization is exceptionally high.

Minimum economic farm-unit size varies from several sections per family (a section being 640 ac.) in the arid southwest to between one-half and one section in regions with good soil and moisture conditions. Nearly 38% of Saskatchewan's iarrns are fully owned by operators. Over 40,000,000 ac. are under cultivation and very little suitable arable land remains uncultivated. Irrigation projects, such as that on the South Saskatchewan river: are planned to provide water for land already in agricultural use. The last free homestead land was taken up in 1930.

Forestry.—The accessible commercial forest zone in Saskatchewan covers 38.000 sq.mi. Despite heavy exploitation early in the 20th century and during World Wars I and II, inventories carried out in the 1950s indicated a very large increment in both saw timber and pulpwood species, totaling 232.000.000 cu.ft. per year. with large volumes readv for cutting. The remote location in relation to major markets retarded postnar development of forest industries. particularly pulp and paper. and the annual market value of production through the 1950s averaged less than $10,000,-000. with white spruce the most used species, followed by jack wine and black swruce. After World War II the provincial government implemented conservation and development policies in forest management. organized a parachute forest-fire suppression service and launched an extensive program of forest access road construction.

Fish *and Fur.*—The most important commercially fished lakes are in the north. They include Athabasca. Reindeer. Wollaston, La Ronge and six others which all support fish-processing and freezing plants serving many lesser lakes as well. These allow better utilization, particularly in summer operations, and a more stable industry. Air transport of produce is necessary in some instances. Major commercial fish species are whitefish, lake trout and pickerel. The provincial catch averaged over 10.000.000 lb. annually from 1950 to 1957, with an average market value of $1,600,000. The expanding northern mink-rearing industry consumed a further 5.600.000 lb. in 1958.

The wild fur industry remained important to a small section of the province's people as a supplementary source of income through the 1950s. with an annual market value of more than $2,000,000. A provincial government marketing service established after World War II did much to stabilize the industry. About 55.000 reared-mink pelts were produced in 1958.

Minerals.—The metals and petroleum industries made great progress after World War II. The value of output grew from only $2.000.000 in 1931 to $36,000,000 in 1949 and to more than $204.000.000 by 1958. Base-metal operations started early in the 1930s at Flin Flon on the province's eastern boundary and contributed over $30,000,000 of the total mineral output. From a slow start based on the heavy crude oils of the Lloydminster area, the petroleum industry expanded rapidly through the 1950s to produce 45.000.000 bbl. valued at $97,000,000. Similarly, the uranium industry started production in 1954 and reached a milling capacity of 3.500 tons of ore daily. with seven mines operating. all in the Uranium-Beaverlodge area. The 1958 value of production was $58.000.000. Industrial minerals. a small but steady source of income for many years, contributed $12.000.000. Fuel production—coal and natural gas—was valued at $6.000.000. Late in 1958 Canada's first potash mine started production near Saskatoon at a rated annual capacity of 600.000 tons.

Exploration in the south for petroleum was still very active. Vast areas of the Pre-Cambrian north had not been intensively explored in spite of an apparent high potential. A northern-development road-construction program was undertaken to facilitate prospecting and exploration. Reserves in the south of industrial minerals. potash and lignite coal appear to be relatively unlimited.

Power.—The major developed source of electric power in Saskatchewan in the early 1960s was the surface lignite coal deposits of the Souris valley. which provide relatively cheap fuel for thermal generation. Most of Saskatchewan (urban and rural) receives electricity services under a provincial government plan implemented by the Saskatchewan Power corporation. This agency. which controls the province's hydroelectric potentials. undertook studies in 1958 and 1959 looking toward utilization of two sites on the Saskatchewan river system with an estimated combined potential of 500.000 h.p. One of these was the South Saskatche~vanriver dam project near Outlook. The further undeveloped potential of this river system was estimated to be 400.000 h.p.

The hydroelectric potentials of the northern rivers, chiefly the Churchill and the Fond du Lac, had not been completely determined. One Churchill river site of 100.000 h.p. was developed in the early 1930s to serve the Flin Flon mining operations. The total electric energy generated in Saskatchewan in 1958 was 1,440,-000.000 kw.hr.

Manufacturing.—Resources development in Saskatchewan stimulated a growth of secondary industries, and manufacturing made steady advances after World War II. Manufacturing production climbed from $215,000,000 in 1949 to $326,000,000 in 1958. The province then had about 1,200 manufacturing operations employing an estimated 14.000 persons.

Postwar development brought the province new industries producing cement, wire and cable, paper products, steel pipe, clay products, building board, transiormers. mobile trailer homes and a variety of operations which serve the oil and gas industries. Total capacity of the nine oil refineries in the province was 71.000 bbl. per day. with the two largest in Regina. Construction on a steel rolling mill near Regina started in 1958.

Recreation.— Prior to World War II little attention was paid to the province's recreation resources. After the war, however, major development took place, prompted by local and tourist demands resulting from easier transportation and greater leisure and prosperity. Resident and nonresident angling and hunting licence sales increased from 61.000 to 215,000 in a ten-year period. Many new businesses were established, particularly in the north, to serve the sportsmen's needs. Provincial resources authorities intensified research and improved management techniques in an effort to ensure sustained yields.

The lake and forest scenery of the northern Pre-Cambrian landscape and the many lakes still inaccessible to sportsmen other than by float aircraft in the late 1950s appeared to ensure broad expansion in the province's tourist industry as northern access improved. Cse of the northerly Prince Albert National park increased greatly for summer family recreation through the 1950s. A comparable increase was evident in the use of the developed provincial parks in the Cypress hills, at Moose mountain in the southwest and Duck mountain near Kamsack. A broad provincial program of park establishment and development throughout the southern part of the province was under way in the late 1950s.

Communications.— The southern populated area is well netted with railways. Main trans-Canada lines serve Regina and Saskatoon east and west, as well as Moose Jaw, Swift Current, North Battleford and Yorkton, with good connections to Minneapolis and Chicago. Although northern Saskatchewan is trackless, the province had over 8,700 of Canada's 44,000 mi. of track in the 1950s. In 1960 improved municipal road mileage totaled 95.000, provincial highway mileage about 6,500 with graveled surface and about 1,500 with hard-top surface. Construction mas well under way on three all-weather development roads penetrating the north. The Trans-Canada highway passing through Regina, Moose Jaw and Swift Current was completed in Saskatchewan in 1957. Trans-Canada Air Lines services Regina and Saskatoon regularly east and west. Regular north-south and intercity aircraft routes cover most of the province, including the extreme north. Saskatchewan Government Telephones corporation services all cities and towns and much of rural Saskatche an. Government-operated two-way radio services all northern points from Prince Albert.

Saskatchewan has no seaports and the rivers are generally not navigable. Lake Athabasca, however, allows lake transport from the railhead in northern Alberta to penetrate to the centre line of northern Saskatchewan.

SASKATCHEWAN RIVER (RAPID RIVER), a river system of Alberta and Saskatchewan provinces, Can. Two large streams, the North and South Saskatchewan, which have their headwaters in the Rocky mountains in Alberta, cross the Saskatchewan boundary 200 mi. apart. unite east of Prince Albert and continue flowing eastward to empty into Lake Winnipeg. Through much of their courses both streams are well contained in deep immature valleys gouged out by escaping glacial melt water. Major tributaries are the Battle, joining the north branch, the Bow, Belly and Red Deer, joining the south branch, and the Carrot and Sturgeon Weir joining the main Saskatchewan. The length of the united Saskatchewan is 369 mi. and the total length to the head of the Bow is 1,205 mi. The Saskatchewan is believed to have been first explored by Henry Kelsey in 1690.

In the fur-trade days the river system served as an important transportation route and numerous forts and trading posts. such as Cumberland House. Carlton House. Ft. Pitt and Ft. Battleford, were located along its banks during the 18th and 19th centuries. It was later plied by steam-driven river boats in the early days of settlement, and in the forested area in Saskatchewan it served for log and lumber transport. It is now navigated only in its lower reaches.

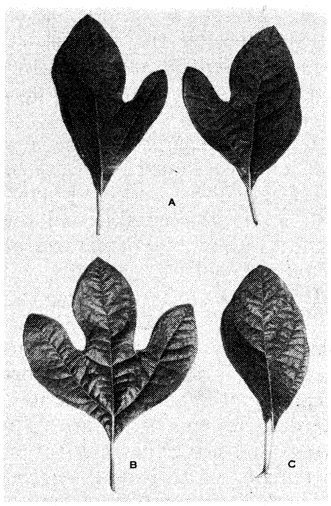
Hydroelectric development on the river began in the late 1950s; *see* SASKATCHEWAN: *Power*. (C. S. BR.)

SASKATOON, a city in the province of Saskatchewan, Can., was founded in 1883 as the proposed capital of a temperance colony and named after a local edible berry (Cree *Missaskatoomina*). Pop. (1956) 72,858; (1961) 95.526. It is situated on the banks of the South Saskatchewan river 150 mi. N.W. of Regina. almost at the centre of the settled area of the province. Both major Canadian railway systems serve the city and major provincial highways converge on it. It is served by Trans-Canada Air Lines and has regular air service with other Saskatchewan cities and the far north. It has daily and periodical newspaper services and television and radio stations; one radio station is French speaking to serve French communities to the north.

Its central position gives Saskatoon wide freight-control and distribution advantages in the province's famous wheat lands. It enjoyed rapid physical expansion and economic development after World War II. It is a major centre for grain storage and flour milling and also for livestock marketing and meat packing. It contains an oil refinery and iron foundries and serves a major potash-mining and refining industry in its vicinity.

It is the seat of the University of Saskatchewan and several affiliated colleges. a university hospital, a school of medicine, a teacher's college and school for the deaf, a National Research council laboratory and the Saskatchewan Research council headquarters. The university school of agriculture and experimental farm have made varied and major contributions to agriculture and rural life throughout the province. (C. S. BR.)

SASSAFRAS (*Sassafràs albidum*), a North American tree of the laurel family (Lauraceae). called also ague tree, with aromatic bark and foliage. It is native to sandy soils from Maine to Ontario and Iowa and south to Florida and Texas. While usually a small tree. it sometimes attains a height of 80 ft or more It has furrowed bark, bright green twigs and entire, mitten-shaped or three-lobed leaves, the three forms often on the same tnig. The yellow flowers. borne in small clusters, are followed by dark blue berries.



JOHN H. GERARD

SASSAFRAS (S. ALBIDUM) LEAVES. THE THREE FORMS. (A) MITTEN-SHAPED. (B) THREE-LOBED AND (C) ENTIRE, ARE OFTEN ON THE SAME TWIG

The root, especially its bark, is used in household medicine and in root beer; it yields oil of sassafras. used in perfumery. *See* OREGON MYRTLE: SPICEBUSH.

SASSANID or SASSANIAN DYNASTY (or SASANIAN), the ruling dynasty of the neo-Persian empire founded by Ardashir I in A.D. 226 and destroyed by the Arabs in 637. The dynasty is named after Sāsān, an ancestor of Ardashir I. (*See* PERSIA.)

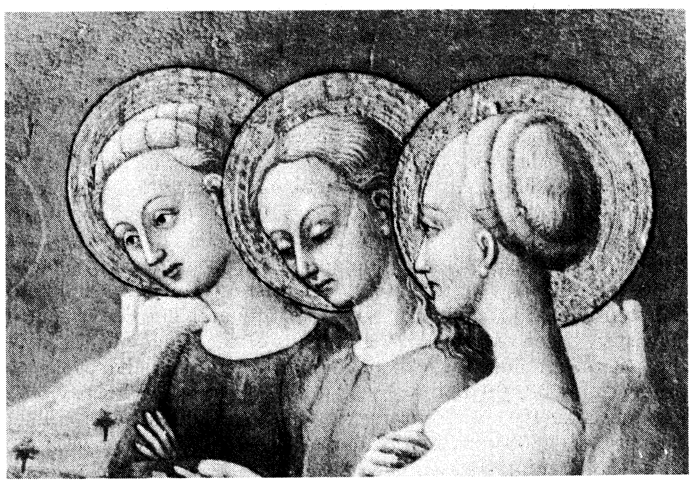
SASSARI, a town and archiepiscopal see of Sardinia. It., capital of the province of Sassari, in the northwest corner of the island. 12½ mi. by rail S.E. of Porto Torres on the north coast, 762 ft. above sea level. Pop. (1957 est.) 81.325 (commune). The town is modern. with spacious streets and squares. S. Maria di Betlemme has a good façade and Romanesque portal of the end of the 13th century. The museum in the university has an interesting collection of antiquities from all parts of the island, belonging to the prehistoric. Phoenician and Roman periods. Eleven miles to the east is the Trinità di Saccargia (12th century) with a lofty campanile, one of the finest Pisan churches in the island.

The name, in the form Thatari, first occurs in the 12th century A.D. when a church of S. Nicola is mentioned.

The town was in existence in 1217, when a body of Corsicans, driven from their island by the cruelties of a visconti of Pisa, took refuge there and gave their name to a part of it. In 1388, four years after the defeat of Meloria, Pisa ceded Sassari to Genoa; but Sassari enjoyed internal autonomy. and in 1316 published its statutes (still extant), which are perhaps in part the reproduction of earlier ones.

In 1323, however, Sassari submitted to the Aragonese king. It was sacked by the French in 1527. During World War II it was bombed by the Allies.

SASSETTA (STEFANO DI GIOVANNI) (1392?–1450), was the greatest Sienese painter of the middle 15th century. The date and place of his birth are not known. but it is believed that he was born in Cortona and that his parents moved to Siena. During the time he was an apprentice, great norks of art were being executed in Siena by famous artists whose influence is traced in some of



ALINARI

DETAIL FROM THE ".MARRIAGE OF ST. FRANCIS AND POVERTY" BY SASSETTA. IN THE MUSÉE CONDE. CHANTILLY. FRANCE

Sassetta's works.

His earliest dated work is an altarpiece designed for a chapel maintained by the Arte della Lana in Siena. Before this was completed he was engaged in the Opera del Duomo, and this connection brought him many important commissions.

Sassetta's paintings represent the religious trend of the time. He possessed a unique faculty of developing legend. His paintings show vitality, a facile quality of design and delicate pure colour. Some of his many works survive as fragments, as the chapels in which they had been painted were destroyed by earthquake. One of his best-known works is the "Journey of the Magi," in the Metropolitan Museum of Art, New York city. "The Meeting of St. Anthony and St. Paul," in the National Gallery of Art, Washington. D.C., "The Marriage of St. Francis and Poverty." in the Musée Condé. at Chantilly, and "St. Francis and the Wolf of Gubbio," in the National gallery, London, are among his other well-known paintings.

Sassetta's last work, left unfinished, mas to have been a fresco of the coronation of the Virgin, painted over the Porta Romana. He died in Siena in 1450.

SASTRI, V. S. SRINIVASA (1869–1946), Indian statesman, was horn of poor Brahmin parents at Valangiman, near Kumbakonam, Madras. on Sept. 22. 1869. He started life as a schoolmaster, but, deeply impressed by the rules of the Servants of India society, he was admitted to membership early in 1907 and succeeded to the presidency in 1915. Elected to the viceregal legislative council in 1916. he soon came to the front as the greatest Indian orator of his day. He gave discriminating support to the Montagu-Chelmsford reforms and was elected a member of the new council of state when the reforms took effect. In 1921 he served on the Indian Railway committee; represented India at the Imperial conference in London, at the League of Nations assembly at Geneva, and at the Washington conference on the reduction of naval armaments. The same year he was called to the privy council, being the third Indian to receive this distinction, and was made a freeman of the City of London. In 1922 he was deputed to Australia. New Zealand and Canada to confer with the respective governments as to the best methods of practical interpretation of the resolution of the 1921 Imperial conference on the rights of citizenship of lawfully domiciled Indians, and he achieved definite results.

In 1927 Sastri accepted appointment as first agent-general to the government of India in South Africa. with the hearty approval of Gandhi. During the first session of the round-table conference in London (Nov. 12, 1930–Jan. 19. 1931) he was an active member. In 1937 he was appointed by the government of India to inquire on Indian labour conditions in Malay. Sastri died on April 17, 1946, in the Madras presidency.

(F. H. Br.; X.)

SATAN is the English transliteration of a Hebrew word for "adversary" in the Old Testament. With the definite article the Hebrew word denotes "the adversary" par excellence, mainly in the Book of Job where the adversary comes to the heavenly court with the "sons of God" (Job i, 6). His task is to roam (the Hebrew word here has a play on sounds with the word "satan") through the earth (like a contemporaneous Persian official) seeking out acts or persons to be reported adversely (to the king); his function thus is the opposite of that of the "eyes of the Lord." which roam through the earth strengthening all that is good (II Chron. xvi, 9). Satan is cynical about disinterested human goodness and is permitted to test it under God's authority and control and within the limits God sets. (As G. Papini points out, the relations in Job between God and Satan are far closer than is usually imagined; Satan, too, belongs to the spiritual and supernatural world.) (See Job.)

In the New Testament the Greek transliteration Satanas is used and this usually appears as "Satan" in English translations. He is spoken of as the prince of evil spirits, the inveterate enemy of God and of Christ, with his throne among men (Rev. ii, 13) and takes the guise of an angel of light (II Cor. xi, 14). He can enter a man and act through him (John xiii, 27), almost as the Spirit of God in Old Testament thought could clothe itself in Gideon and rush on Samson; hence a man can be called Satan because of his acts or attitude (Matt. xvi, 23). By his subordinate demons Satan can take possession of men's bodies, afflicting them (II Cor xii, 7) or making them diseased (Matt. xii, 26; Luke xi, 18). To him sinners are delivered for the destruction of the flesh that the spirit may be saved (I Cor. v, 5). After the preaching of the 70 disciples. during which devils were subjected to them, Jesus saw Satan fall like lightning from heaven (Luke x, 18). According to the visions in the Book of Revelation. when the risen Christ returns from heaven to reign on earth, Satan will be bound with a great chain for a thousand years, then be released, but almost immediately face final defeat and be cast into eternal punishment (Rev. xx, 2. 7–10). He is identified with the ancient serpent (Rev xii, 9. xx. 2; cf Gen iii) His name, Beelzebul. used in the Gospels mainly in reference to demoniac possession, comes from the name of the god of Ekron, Baalzebub (II Kings i). (See Beelzebul.) He is also identified with the devil (diabolos), and this term occurs more frequently in the New Testament than "Satan." In the Koran the proper name "Satan" is used.

In Hebrew thought in the Old Testament there is no suggestion of any dualism, whether temporal. spatial or ethical. God himself forms light and creates darkness. makes weal and creates woe (Isa. xlv. 7). The evil spirit that terrifies men and leads them to murderous action is from the Lord (I Sam. xvi, 14). Hostile heathen powers could be spoken of as fighting against God and his people Israel, but they were the "rod of his anger" (Isa. x. 5), although there is an interesting interchange of God and Satan between two Old Testament writers (II Sam. xxiv, 1; I Chron. xxi, 1). There was thought to be a constant fight between light and darkness, chaos and law, life and death. Myths of which fragments survive in the Old Testament spoke of God's fight against the dragon of chaos, called Rahab or Leviathan (*e.g.,* Job ix, 13; Isa. xxvii, 1) and this fight. which took place at creation, continues constantly. Any philosophy of evil culled from the Bible must find room for evil within the concept of God and within his purpose his sun and rain, poured out on the good and the evil, make both weeds and nheat grow.

In later Judaism, under Persian influence, a form of duaiism developed. finding expression in cosmic speculation and in the idea of successive millenniums; traces can be seen in the Book of Daniel and in Revelation. Two ages or aeons of world history were spoken of as "this age" and "the age to come." In the former, the cosmic power of evil prevails, known variously in apocalyptic writings as Satan, Beliar. Mastema or Azazel, and identified with death and the evil impulse in man; this evil power will be overthrown by the messianic kingdom foretold in the Old Testament, and God will reign on a re-created earth, in paradise or in heaven. The devil and all his hosts were thought of as fallen angels who, like the heathen powers hostile to God, had lapsed through pride and envy into sin and abused their power as God's deputies. But Jewish thought did not depict the fallen angels as the strong energetic element in life, in contrast to the anemic. reasonable forces of good, as Blake accuses Milton of doing.

Persian dualism conceived of the conflict of good and evil as existent from the beginning, outside man, who could take sides and assist one or the other (see Dualism). Later Jewish dualism thought man himself and all nature and creation were affected by sin and the fall of man, and needed a new creation to remove the taint of evil. This was to be achieved not, as in the Old Testament, by a new heart and spirit in man (Jer. xxxi. 33 ff.; Ezek. xviii. 31) but by a dramatic divine intervention to overthrow Satan, whether in human form as the Anti-Christ (*q.v.*) or the beast or false prophet, or as a supernatural being.

Biblical ideas, mediated through the speculation of postbiblical Judaism, were transmitted to the theology of early Christian writers, in which the figure of Satan played a large part in the discussion of the nature of evil, the meaning of salvation and the purpose and efficacy of the atoning work of Christ. Early and medieval church writers discussed at length problems raised by belief in the existence of a spiritual being such as Satan in a universe created and sustained by an all-powerful, all-wise and all-loving God. Under the influence of the 18th-century revolt against belief in the supernatural. liberal Christian theology tends to treat the biblical language about Satan as "picture thinking" not. to be taken literally — as a mythological attempt to express the reality and extent of evil in the universe, existing outside and apart from man but profoundly influencing the human sphere. *See* also DEVIL.

SATARA, the headquarters city of Satara North district, Bombay state, India, and of the former British-Indian district of Satara. The town, 10 mi. from Satara Road station on the Southern railway, is named after the "seventeen" walls, towers and gates which the fort was supposed to have had. It is 2,320 ft. above sea level, near the confluence of the rivers Kistna and Vena, 56 mi. S. of Poona. Pop. (1951) 38.521.

On the overthrow of the Yadava dynasty in 1312 Satara passed to the Mohammedan power, which was consolidated in the reign of the Bahmani kings. On their decline toward the end of the 15th century the Bijapur kings asserted themselves, and under them the Marathas rose and laid the foundation of an independent kingdom with Satara as its capital. The Maratha peshwas, who removed the capital to Poona won the ascendancy in the 18th century, but after the war of 1817 the British restored the rajah, and assigned to him the principality of Satara, with an area much larger than the subsequent district. His successor dying without male heirs in 1848, the state was resumed by the British. The district thus formed was divided after India became independent in 1947. The Satara Jagirs were a group of five states — Akalkot Bhor. Jath. Aundh, Phaltan — tributary to Satara; the last two were controlled by the Bombay governor till 1933 through the Satara Agency.

SATARA NORTH DISTRICT comprises the old Satara district, less three subdivisions, with the addition (March 8. 1948) of Phaltan state and parts of five other states. Area 4.041 sq.mi.; pop. (1961) 1,427,020. Headquarters: Satara. The Sahyadri, or main range of the Western Ghats, runs down the west side. The north is drained by the Bhima river system. The hill forests provide much timber and firewood. In some parts the average annual rainfall is over zoo in. The black loamy clay soil grows millet, pulses, oil seeds and sugar cane. Cotton cloth, blankets and brassware are manufactured.

SATARA SOUTH DISTRICT comprises four subdivisions of the old Satara district. with parts of six former principalities, added on Rlarch 8. 1948. Area 3.297 sq.mi.; pop. (1961) 1.229.640. Headquarters: Sangli ([1951] 50.287). the seat of two colleges of Poona university. The other main town is Rliraj ([1951] 40.224). Soil, forest and crops are similar to those of Satara North. but rainfall is scanty and irrigation is from the Kistna river system. The Mahadeo range runs down the eastern border.

SATELLITE, in astronomy. a small opaque body revolving around a planet. as the moon around the earth (see PLANET and the articles on individual planets).

In the theory of cubic curves, Arthur Cayley defined the satellite of a given line to be the line joining the three points in which tangents at the intersections of the given (primary) line and curve again meet the curve.

SATIE, ERIK LESLIE (1866–1925), French composer, was born at Honfleur on May 17, 1866 (his mother being an Englishwoman), and studied at the Paris conservatoire. His early works proclaimed a persistent determination to be original. and were followed by a series of equally eccentric pianoforte pieces. He exercised influence, nonetheless, upon many of his younger French contemporaries of the "advanced" school: who hailed him as a prophet. But the public at large saw in him something of the *farceur,* and his interesting attempts to be daring did not seem to be accompanied by any commensurate genuine talent.

SATIN, a term strictly denoting a true silk texture developed with a perfectly even, smooth and glossy or lustrous surface on which either warp or weft threads preponderate and thus entirely obscure the other series of threads. The principle of fabric structure observed in the construction of satin fabrics is that known as the "satin" weave. which constitutes one of the simplest elementary weaves in which the intersections of the warp and weft threads are so evenly and perfectly distributed that there are no pronounced textural features discernible in the fabric. as the threads, either of warp or of weft only, are displayed on the surface with the least possible amount of deflection by their interlacement with the threads of the other system.

A true silk satin fabric may be produced either with a warp surface or a weft surface of pure silk, with the reverse side of cotton or other textile material. In either case, the silk must be of the best quality and perfectly even.

The term "satin," however, is now applied as a general description for many fabrics constructed on the principle of the satin weaves. For example, cotton fabrics constructed on the satin-weave basis are described as "satin" or "sateen" according to whether they are developed with a warp surface or a weft surface. It is also applied indiscriminately to many other fabrics having a smooth and lustrous finish. (H. N.)

SATIN SPAR, a name given to certain fibrous minerals which exhibit, especially when cut and polished, a soft satiny or silky lustre, and are therefore sometimes used as gem or ornamental stones.

Such fibrous minerals occur usually in the form of veins or bands, having the fibres disposed transversely. The most common kind of satin spar is a white finely fibrous gypsum, used for beads, etc.

Other kinds of satin spar consist of calcium carbonate, in the form of either aragonite or calcite (*qq.v.*).

See also GYPSUM.

SATINWOOD, a beautiful light-coloured hard wood, having a rich, silky lustre, sometimes finely mottled or grained, the produce of a moderate-sized tree. *Chloroxylon swietenia* (family Meliaceae), native to the subcontinent of India and to Ceylon. A similar wood, known under the same name, is obtained in the West Indies. the tree being probably a species of *Xanthoxylum* (family Rutaceae).

Satinwood was in demand for rich furniture about the end of the 18th century, the fashion then being to ornament panels of it with painted medallions and floral scrolls and borders. It is used for inlaying and small veneers.

SATIRE, in its literary aspect, may be defined as the expression in adequate terms of the sense of amusement or disgust excited by the ridiculous or unseemly, provided that humour is a distinctly recognizable element, and that the utterance is invested with literary form. Without humour, satire is invective; without literary form, it is mere clownish jeering. The first exercise of satire no doubt consisted in gibing at personal defects. To dignify satire by rendering it the instrument of morality or the associate of poetry was a development implying considerable advance in the literary art. In the accounts that have come down to us of the writings of Archilochus, the first great master of satire, we seem to trace the elevation of the instrument of private animosity to an element in public life. Simonides of Amorgus and Hipponax were distinguished like Archilochus for the bitterness of their attacks on individuals, with which the former combined a strong ethical feeling and the latter a bright active fancy. The loss of their writings, which would have thrown great light on the politics as well as the manners of Greece, is to be lamented. With Hipponax the direct line of Greek satire is interrupted; but two new forms of literary composition, capable of being the vehicles of satire, almost simultaneously appear. Although the original intention of fable does not seem to have been satirical its adaptability to satiric purposes was soon discovered. A far more important step was the elevation of the rude fun of rustic merry-makings to a literary status by the evolution of the drama from the Bacchic festival. The means had now been found of allying the satiric spirit with exalted poetry, and their union was consummated in the comedies of Aristophanes.

A rude form of satire had existed in Italy from an early date in the shape of the Fescennine verses, the rough and licentious pleasantry of the vintage and harvest. As in Greece, these eventually were developed into a rude drama. Verse, "like to the Fescennine verses in point of style and manner," was added to accompany the mimetic action, and these probably improvised compositions were entitled *Saturae,* a term denoting *miscellany,* and derived from the *satura lanx,* "a charger filled with the first-fruits of the year's produce."

The Roman people thus had originated the name of satire, and, in so far as the Fescennine drama consisted of raillery and ridicule, possessed the thing also; but it had not yet assumed a literary form among them. The real inventor of Roman satire is Gaius Lucilius (148–103 B.C.). The fragments of Lucilius preserved are scanty, but the verdict of Horace, Cicero and Quintilian demonstrates that he was a considerable poet. It is needless to dwell on compositions so universally known as the *Satires* of Lucilius's successor Horace, in whose hands this class of composition received a new development, becoming genial, playful and persuasive. The didactic element preponderates still more in the philosophical satires of Persius. Yet another form of satire, the rhetorical, was carried to the utmost limits of excellence by Juvenal, the first example of a great tragic satirist. Nearly at the same time Martial, improving on earlier Roman models now lost, gave that satirical turn to the epigram which it only exceptionally possessed in Greece, but has ever since retained. About the same time another variety of satire came into vogue, destined to become the most important of any. The Milesian tale, a form of entertainment probably of Eastern origin, grew in the hands of Petronius and Apuleius into the satirical romance, immensely widening the satirist's field and exempting him from the restraints of metre. Petronius's "Supper of Trimalchio" is the revelation of a new vein, never fully worked till our days. As the novel arose upon the ruins of the epic, so dialogue sprang up upon the wreck of comedy. In Lucian comedy appears adapted to suit the exigencies of an age in which a living drama had become impossible. With him antique satire expires as a distinct branch of literature.

In the Byzantine empire, indeed, the link of continuity is unbroken, and such raillery of abuses as is possible under a despotism finds vent in pale copies of Lucian. The first really important satire, however, of the middle ages, is a product of western Europe, recurring to the primitive form of fable, upon which, nevertheless, it constitutes a decided advance. *Reynard the Fox* (*see* FABLE), a genuine expression of the shrewd and homely Teutonic mind, is a landmark in literature. It gave the beast-epic a development of which the ancients had not dreamed. About the same time, probably, the popular instinct, perhaps deriving a hint from Rabbinical literature, fashioned Morolf, the prototype of Sancho Panza, the incarnation of sublunar mother-wit contrasted with the starry wisdom of Solomon; and the *Till Eulenspiegel* is a kindred Teutonic creation, but later and less significant. *Piers Ploughman,* the next great work of the class, adapts the apocalyptic machinery of monastic and anchoritic vision to the purposes of satire. The clergy were scourged with their own rod by a poet and a Puritan too earnest to be urbane. The Renaissance, restoring the knowledge of classic models, enlarged the armoury of the satirist. Partly, perhaps, because Erasmus was no poet, the Lucianic dialogue was the form in the ascendant of his age. Erasmus not merely employed it against superstition and ignorance with infinite and irresistible pleasantry, but fired by his example a bolder writer, untrammelled by the dignity of an arbiter in the republic of letters. The ridicule of Ulric von Hutten's *Epistolae obscurorum virorum* is annihilating, and the art of putting the ridicule into the mouth of the victim, is perhaps the most deadly shaft in the quiver of sarcasm. It was afterwards used with even more pointed wit though with less exuberance of humour by Pascal. Sir Thomas More cannot be accounted a satirist, but his idea of an imaginary commonwealth embodied the germ of much subsequent satire.

In the succeeding period politics take the place of literature and religion, producing in France the *Satyre Ménippée,* elsewhere the satirical romance as represented by the *Argenis* of Barclay, which may be defined as the adaptation of the style of Petronius to State affairs. In Spain, where no freedom of criticism existed, the satiric spirit took refuge in the *novela picaresca,* the prototype of Le Sage and the ancestor of Fielding; Quevedo revived the mediaeval device of the vision as the vehicle of reproof; and Cervantes's immortal work might be classed as a satire were it not so much more. About the same time we notice the appearance of direct imitation of the Roman satirists in English literature in the writings of Donne, Hall and Marston. The prodigious development of the drama at this time absorbed much talent that would otherwise have been devoted to satire proper. Most of the great dramatists of the 17th century were more or less satirists, Molière perhaps the most consummate that ever existed; but, with an occasional exception like *Les Précieuses ridicules,* the range of their works is too wide to admit of their being regarded as satires. The next great example of unadulterated satire is Butler's *Hudibras.* Dignified political satire, bordering on invective, was carried to perfection in Dryden's *Absalom and Achitophel.* In France Boileau was long held to have attained the *ne plus ultra* of the Horatian style in satire and of the mock-heroic, but Pope was soon to show that further progress was possible in both. The polish, point and concentration of Pope remain unsurpassed, as do the amenity of Addison and the daring yet severely logical imagination of Swift; while the *History of John Bull* places their friend Arbuthnot in the first rank of political satirists.

The 18th century was, indeed, the age of satire. Serious poetry had for the time worn itself out; the most original geniuses of the age are decidedly prosaic, and Pope, though a true poet, is less of a poet than Dryden. In process of time imaginative power revives, but meanwhile Fielding and Smollett have fitted the novel to be the vehicle of satire and much beside, and the literary stage has for a time been almost wholly engrossed by a colossal satirist, a man who has dared the universal application of Shaftesbury's maxim that ridicule is the test of truth. The world had never before seen a satirist on the scale of Voltaire, nor had satire ever played such a part as a factor in impending change. As a master of sarcastic mockery he is unsurpassed; his manner is entirely his own; and he is one of the most intensely national of writers, notwithstanding his vast obligations to English humorists, statesmen and philosophers. English humour also played an important part in the literary regeneration of Germany, where Lessing, imbued with Pope but not mastered by him, showed how powerful an auxiliary satire can be to criticism. Another great German writer, Wieland, owes little to the English, but adapts Lucian and Petronius to the 18th century with playful if somewhat mannered grace. Goethe and Schiller, Scott and Wordsworth, are now at hand, and as imagination gains ground satire declines. Byron, who in the 18th century would have been the greatest of satirists, is hurried by the spirit of his age into passion and description, bequeathing, however, a splendid proof of the possibility of allying satire with sublimity in his *Vision of Judgment.* Two great satiric figures remain—one representative of his nation, the other most difficult to class. In all the characteristics of his genius Thackeray is thoroughly English; his satire is a thoroughly British article, a little solid, a little wanting in finish, but honest, weighty and durable. But Heine hardly belongs to any nation or country, time or place. In him the satiric spirit, long confined to established literary forms, seems to obtain unrestrained freedom.

In no age was the spirit of satire so generally diffused as in the 19th century, but many of its eminent writers, while bordering on the domains of satire, escape the definition of satirist. The term cannot be properly applied to Dickens, the keen observer of the oddities of human life; or to George Eliot, the critic of its emptiness when not inspired by a worthy purpose; or to Balzac, the painter of French society; or to Trollope, the mirror of the middle classes of England. If *Sartor Resartus* could be regarded as a satire, Carlyle would rank among the first of satirists; but the satire, though very obvious, rather accompanies than inspires the composition. The number of minor satirists of merit, on the other hand, is legion. James Russell Lowell's *Biglow Papers* represent perhaps the highest moral level yet attained by satire. Mallock, in his *New Republic,* made the most of personal mimicry, the lowest form of satire; Samuel Butler (*Erewhon*) holds an inverting mirror to the world's face with imperturbable gravity; the humour of Bernard Shaw has always an essential character of satire—the sharpest social lash. One remarkable feature of the modern age is the union of caricature (*q.v.*) with literature.

(R. G.; X.)

SATPURA, a line of hills between the Narbada and Tapti rivers in central India. It is the western element of an upland series known collectively as the Satpura Line and including the Mahadeo hills, Maikal range and Chota Nagpur plateau. Stretching westward from about 85° 5' E. almost to the shores of the Gulf of Cambay this line is usually regarded as the northern limit of the Deccan plateau.

Historically it was important as a barrier to the southern advance of the Aryan invaders and it forms the frontier between Aryan and Dravidian India. The Satpura range proper is approximately 600 mi. long and reaches heights of more than 4,000 ft. It is mainly composed of Deccan lavas and is forested. It is plateaulike in build and bordered by steep scarps both to north and south. The main railway route from Bombay to the middle and lower Ganges crosses its lower section into the Narbada valley and proceeds by way of Jubbulpore to Allahabad. (T. Her.)

SATRAP, in ancient history, the name given by the Persians to the governors of the provinces. Cyrus the Great divided his empire into provinces; a definitive organization was given by Darius, who established twenty great satrapies and fixed their tribute. The satrap was the head of the administration of his province: he collected the taxes, controlled the local officials and the subject tribes and cities, and was the supreme judge of the province to whose "chair" every civil and criminal case could be brought. He was responsible for the safety of the roads and had to put down brigands and rebels. He was assisted by a council of Persians. to which also provincials were admitted; and was controlled by a royal secretary and by emissaries of the king. The regular army of his province and the fortresses were independent of him and commanded by royal officers; but he was allowed to have troops in his own service. The great provinces were divided into many smaller districts, the governors of which are also called satraps and hyparchs. The distribution of the great satrapies was changed occasionally, and often two of them were given to the same man. When the empire decayed, the satraps often enjoyed practical independence, especially as it became customary to appoint them also as generals-in-chief of their army district, contrary to the original rule. Hence rebellions of satraps became frequent from the middle of the 5th century; under Artaxerxes II occasionally the greater part of Asia Minor and Syria were in open rebellion. The last great rebellions were put down by Artaxerxes III. The satrapic administration was retained by Alexander and his successors, especially in the Seleucid empire, where the satrap generally is designated as *strategus;* but their provinces were smaller than under the Persians. (Ed. M.)

SATSUMA REBELLION, an attempt to overthrow the newly established government of Japan led by Saigō Takamori (*q.v.*) in 1877. The rebellion led by Saigō in Satsuma province was the last of a series of warrior revolts against the government of the emperor Meiji.

These revolts were inspired by the dissatisfaction of elements of the warrior class with the reforms of the new government, which in modernizing Japanese society aimed at doing away with feudal privileges. Such reforms put the warrior class. so privileged under the old regime, on the same legal footing as the rest of the population: they abolished the warrior's right to wear swords, his exclusive privilege of bearing arms and his special rights pertaining to dress, food and living quarters. Most serious, perhaps, was the abolishment of the exclusive right to bear arms, and formation of a citizen army.

The Satsuma rebellion was the most determined and serious of the warrior revolts against liquidation as a privileged class. There was bitter and bloody fighting during the campaign, but in the end the better equipped and disciplined forces of the government's people's army prevailed. The warriors' bitterness thereafter took political rather than military forms; and embittered warriors became one of the main elements in the opposition political parties that now sprang up. See also Japan: History. (T. C. Sh.)

SATUN (Setui), a small Siamese (Thai) *changrad* or district bordering Malaya. Area 1.031 sq.mi. Pop. (1956 est.) 60,004. It produces rice and rubber.

SATURN (Saturnus), a Roman god whose cult was so overlaid with Greek features as to obscure his original native character. His name is commonly connected with Latin *satus,* and thus he is a god of son-ing or seed. The ancients themselves regarded him as an importation and equated him with the Greek Cronus (*q.v.*), which may well be correct; there is some linguistic evidence (disregarding the connection with *satus*) that he came to Rome through Etruria. Further. he was worshiped in the Greek manner (*i.e.,* with head uncovered and not wrapped in the toga as was the Roman custom).

The remains of his temple at Rome. eight columns of the pronaos, still dominate the west end of the Forum at the foot of the *clivus Capitolinus.* The present remains are of a later rebuilding, but it was the oldest temple whose building is recorded. going back to the beginning of the republic. It served as the treasury (*aerarium Saturni*) of the Roman state. Saturn's cult partner is the obscure goddess Lua, whose name is connected with *lues* (plague or destruction) and to whom captive arms mere sometimes burned. But he was also associated with Ops, the cult partner of Consus, through her identification with Rhea. wife of Cronus.

His great festival. the *Saturnalia,* became the most popular of Roman festivals, and its influence is still felt throughout the western world. Originally on Dec. 17, it mas extended first to three and eventually to seven days. The date has been connected with the minter sowing season, which in modern Italy varies from October to January. Remarkably like the Greek *Kronia* (see Cronus), it was the gayest festival of the year. All work and business were suspended. Slaves were given temporary freedom to say and do what they liked. and certain moral restrictions were eased. The streets were infected with a Mardi gras madness: a mock king was chosen (*Saturnalicius princeps*); the seasonal greeting *io Saturnalia* was heard everywhere; presents were freely exchanged. principally wax candles and little clay dolls (*sigillaria*). The cult statue of Saturn himself, traditionally bound at the feet with woolen bands. was untied. presumably to come out and join the fun. The influence of the *Saturnalia* upon the celebrations of Christmas and the New Year has been direct. Concerning the gift candles. the ancients had a quaint story that an old prophecy bade the earliest inhabitants of Latium send heads to Hades and *phota* to Saturn; that they interpreted this as meaning human sacrifices, but that Hercules advised them to use lights (the word *phos* means "light" or "man" according to accentuation) and not human "heads."

Another tradition regarding Saturn, fostered chiefly by the poets, made him an early Italian king. or perhaps Cronus in flight from Zeus. who established in Italy a new height of civilization (*Saturnia regna*) and a Golden Age (*aurea saecula;* cf. Virgil, *Aeneid,* viii, 319 ff.).

Saturday of course was named for Saturn and first appears (*Saturni dies*) in Tibullus I, iii, 18.

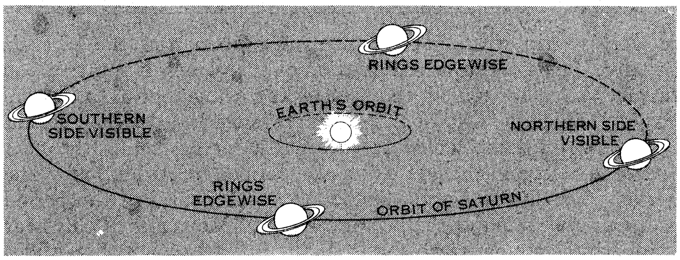
(R. B. Ld.)

SATURN, the sixth major planet in order of distance from the sun, and the most remote planet that was known before the discovery of Uranus in 1781. Its mean distance from the sun is about 885,900.000 mi. and its periodic time (time required to make a complete revolution about the sun) about $29\frac{1}{2}$ years. Its synodic period, or the interval between oppositions. is 378 days. To the naked eye Saturn, when in opposition. always appears as a star brighter than the first magnitude, but in consequence of the changing phases of its rings it varies greatly in brightness, its light being approximately trebled when the rings are open to their greatest extent. As regards colour. the planet shines with a warm, yellowish light like that of Arcturus.

Globe.—In telescopic appearance the globe of Saturn exhibits strong resemblances to Jupiter. It is even more flattened at the poles. its polar and equatorial diameters being respectively about 67,000 and 75,000 mi.; it is less bright near the margin than at the centre of the disk: and its surface is marked by dusky belts with light intermediate zones; but whereas these cloudlike hands are very conspicuous on Jupiter, they are usually feeble and ill-defined in the case of Saturn.

The volume of Saturn is about 750 times that of the earth. but the periodic times of its satellites show that it exceeds the earth only about 95 times in mass. Its mean density, therefore. is but 0.13 of that of the earth, or about 0.7 times that of water.

Rotation. — Because of the difficulty in detecting individual features of a sufficiently definite nature, the rotation of the planet



FROM "ASTRONOMY, BY R. H. BAKER (D VAN NOSTRAND COMPANY, INC.)

PHASES OF SATURN'S RINGS

has been observed only on comparatively rare occasions. The first determination was made in 1794 'by the elder Herschel, who derived a rotation period of 10 hr. 16 min. In Dec. 1876 a bright spot appeared near the equator which was observed by Asaph Hall, at Washington, for more than a month, and which showed a rotation in 10 hr. 14 min. 24 sec. A. S. Williams during 1891–94 deduced from observations of dark spots in the northern hemisphere mean rotation periods of 10 hr. 14 min. 45 sec. and 10 hr. 15 min. 10 sec. respectively, and in the same two years periods of 10 hr. 12 min. 52 sec. and 10 hr. 12 min. 36 sec. from a number of white equatorial spots.

In 1933 a very conspicuous bright spot was discovered near the equator of Saturn by W. T. Hay. Observations by William H. Wright at the Lick observatory showed that the period of rotation of the equatorial region of Saturn as determined from this spot agreed very closely with the value obtained much earlier by Hall. Spectrographic observations by Joseph H. Moore of the Lick observatory in 1936–37 confirmed the earlier discovery that the rotation period of Saturn becomes longer with increasing distance from its equator; in this respect Saturn resembles Jupiter. This results in a continual lagging behind of regions in high latitudes compared with those near the equator.

Physical Condition. — It is now clear that what is seen of Saturn is not a solid surface, but a layer of cloudlike or vaporous matter; the mean density of the globe is, indeed, less than that of any other major planet. It is further to be noted that considerations based on the large ellipticity of the disk, which is greater than would be assumed by such a globe of anything like uniform density rotating with the angular velocity of Saturn, indicate that the larger part of the planet's mass must be strongly concentrated toward the centre.

Radiometric observations made by William W. Coblentz and Carl O. Lampland indicate that the temperature of the surface is very low, of the order of $-150°$ C. A second major discovery has been the identification oi the red and infrared bands in the spectra of the outer planets with the compounds ammonia and methane. The identification was suggested by Rupert Wildt in 1932 and was definitely established a short time later by Theodore Dunham at Mount Wilson. The atmosphere of Saturn thus seems to consist, according to these investigators, of clouds of ammonia gas and crystals, methane and hydrogen. Underneath there may be a layer of ice, while the dense core itself probably consists of rocky metallic material.

Rings. — Saturn's most remarkable feature and that which renders it unique, so far as our knowledge goes, is the magnificent system of rings by which it is surrounded. That Saturn differs in appearance from other bodies was seen at once by Galileo when he turned his little telescope toward it in 1610. but his instrument was not sufficiently powerful to reveal the nature of what he saw. He noticed that the planet had a small attendant on each side, and accordingly represented it as a triple body. But during the next few years the appendages dwindled and finally disappeared, greatly to his perplexity and chagrin. as he feared he must have been misled by some kind of illusion. When they subsequently reappeared they continued to present a difficult problem to the telescopic observers of the day — sometimes seeming like arms stretching out on each side of the central body and sometimes like curved handles — and a number of curious drawings have come down to us which show how puzzled the observers were, but how near some of them came to the solution of the mystery.

The true explanation was ultimately arrived at by Christian Huygens in 1655. but. wishing for further time to make sure of his solution and yet secure himself against the possible loss of priority in the discovery, he published the following series of letters: aaaaaaa ccccc d eeeee g h iiiiiii llll mm nnnnnnnnn oooo pp q rr s ttttt uuuuu; which, when properly arranged, form the sentence *"Annulo cingitur, tenui, plano, nusquam cohaerente, ad eclipticam inclinato"* ("It is girdled by a thin flat ring, nowhere touching, inclined to the ecliptic"). These last few words explain the various appearances which so sorely puzzled the earlier observers with their imperfect instruments. The plane of the ring is inclined about 27° to the planet's orbit, and about 28° to the ecliptic, and keeps parallel to itself throughout the planet's revolution.

There are accordingly two opposite portions of the orbit, viz., near longitudes 172" and 352°, where Saturn is in Leo and Aquarius respectively, at which the ring can be presented edgewise to the earth and when this event happens (as it does either once or three times during each passage of the ring plane across the earth's orbit) the ring — because of its thinness — disappears from view even in powerful instruments. At intermediate positions, viz., when the planet is in Taurus and Gemini and in Sagittarius, it appears opened out at an angle of 27°, and is then seen to project slightly beyond the polar diameter of the planet's globe. The next important telescopic discovery as regards Saturn was the detection by G. D. Cassini, in 1675, of a black line or gap dividing the ring into two concentric rings. This is generally known as Cassini's division. The ring exterior to this division is narrower and less bright than the inner ring, while the outer portion of the latter is the most brilliant part of the whole system.

Within the second ring is yet another feature of great interest, a third ring, commonly known as the Crape ring, of which the brightness is so feeble that it long escaped detection. It was first recorded by Johann G. Galle, at Berlin, in 1838, but its existence was strangely forgotten until it was independently rediscovered in 1850 by G. P. Bond at Harvard and W. R. Dawes in England. It can be readily traced with a comparatively small telescope as a dusky band where it crosses the planet's globe, but is not so easily seen in the portions projected against the dark sky. The three rings are often denoted by the letters A, B and C. From time to time other divisions besides that of Cassini have been reported, but they seem to have been merely partial and temporary, except that known as Encke's division. in ring A, which is, perhaps, permanent, though probably not really a complete division. It usually appears as a pencillike shading rather than a sharp black line and sometimes merely as the boundary of the darker outer portion of the ring. The figures given by different authorities for the dimensions of the ring system differ somewhat, but those in Table I are approximately correct.

TABLE I.—Dimensions of Saturn's Ring System

The breadth of the Cassini division is probably rather more than 2.000 mi. The thickness of the rings is of the order of 10 mi. or less. It is noteworthy that all three are at least partly transparent; Saturn itself can be distinctly seen through the Crape ring and on some recent photographs it also shows through the

TABLE 11.—Saturn's Satellites

Name	Distance in equatorial radii of Saturn (1=37.500 mi.)	Period of revolution		Inclination of orbit to Saturn's orbit		Eccentricity	Stellar mag. at mean opposition	Discoverer	Date of discovery
		d	h	o					
Mimas	3.1	0	22.6	26	44.7	0.0190	12.1	Herschel	Sept. 17,1789
Enceladus	3.9	1	8.9	26	44.7	0.0001	11.6	Herschel	Aug. *28, 1789*
Tethys	4.9	1	21.3	26	44.7	0.0000	10.5	G. Cassini	March *1684*
Dione	6.3	2	17.7	26	44.7	0.0020	10.7	G. Cassini	March *1684*
Rhea	8.7	4	12.4	26	41.9	0.0009	10.0	G. Cassini	Dec 1672
Titan	20.2	15	22.7	26	7.1	0.0289	8.3	Huygens	March *1655*
Hyperion	24.5	21	6.6	26	0.0	0.1043	13.0	Bond	Sept. *16, 1848*
Iapetus	58.9	79	7.9	16	18.1	0.0284	10.1 to 11.9	G. Cassini	Oct. 1671
Phoebe.	214.2	550	10.6	174°.7		0.1659	14.5	Pickerinr	Aus. *1898*

outer ring. Moreover, on Feb. 9, 1917, M. A. Ainslie, at Blackheath, and J. Knight, at Rye, observed that a seventh magnitude star remained visible during its occultation by the outer ring, though Ainslie considered that it lost something like three-fourths of its light; it appeared to travel some distance along the Cassini division but did not pass behind ring B. On March 14, 1920, during the occultation of another seventh magnitude star, the star remained conspicuously visible in a 6-in. refractor at W. Reid's observatory (Rondebosch, S.Af.), even when behind the brightest part of ring B and despite the fact that, in consequence of the obliqueness of the line of sight. its light had to traverse a distance through the ring equal to eight times its real thickness.

The translucency of the ring system is also shown by the fact that it can be faintly seen against the sky as a narrow line of light on the occasions—sometimes extending over several weeks near the time of disappearance—when the plane of the rings passes between the sun and the earth. On this line of light two condensations are seen on each side of the planet, corresponding in position with the Cassini division and the Crape ring. They are apparently caused by the larger amount of sunlight transmitted at those places where the ring material is absent or relatively thin. The ring, as a whole, however, is sufficiently dense to cast a strong shadow, which is seen at such times as a narrow black band across the planet's equatorial regions.

The physical constitution of the rings is unlike that of any other object in the solar system. They are not formed of a continuous mass of solid or liquid matter, but of discrete particles of unknown minuteness, probably widely separated in proportion to their individual volumes, yet so close as to appear continuous when viewed from the earth. This constitution was first divined by J. Cassini early in the 18th century. But, although the impossibility that a continuous ring could surround a planet without falling upon it was shown by Pierre S. de Laplace and must have been evident to all investigators in celestial mechanics, Cassini's explanation was forgotten until 1857. In that year James Clerk Maxwell, in an essay which was the first to gain the newly-founded Adams prize of the University of Cambridge, made an exhaustive mathematical investigation of the satellite constitution, showing that it alone could fulfill the conditions of stability. In the light of this demonstration, it was of great interest when J. E. Keeler, at the Allegheny observatory, proved this constitution by spectroscopic observation in 1895. He found, by measuring the velocity of different parts of the ring to or from the earth, that, as we pass from its outer to its inner regions, the velocity of revolution around the planet increases, each concentric portion having the speed belonging to a satellite revolving in a circular orbit at the same distance from the planet. The relative velocities of different parts of the system are beautifully shown by the slope of the lines in a spectrogram of Saturn made by V. M. Slipher of the Lowell observatory.

Satellites.— Saturn is attended, so far as is at present known, by nine satellites. A tenth (Themis) was announced by W. H. Pickering in 1905, but its actual existence has not been satisfactorily confirmed. Details of the satellites are given in Table II.

The diameters assigned by observers to the smaller and fainter satellites are necessarily very uncertain, but that of Titan is probably not far from 3,000 mi. The diameter of Phoebe is, perhaps, only about 150 mi.

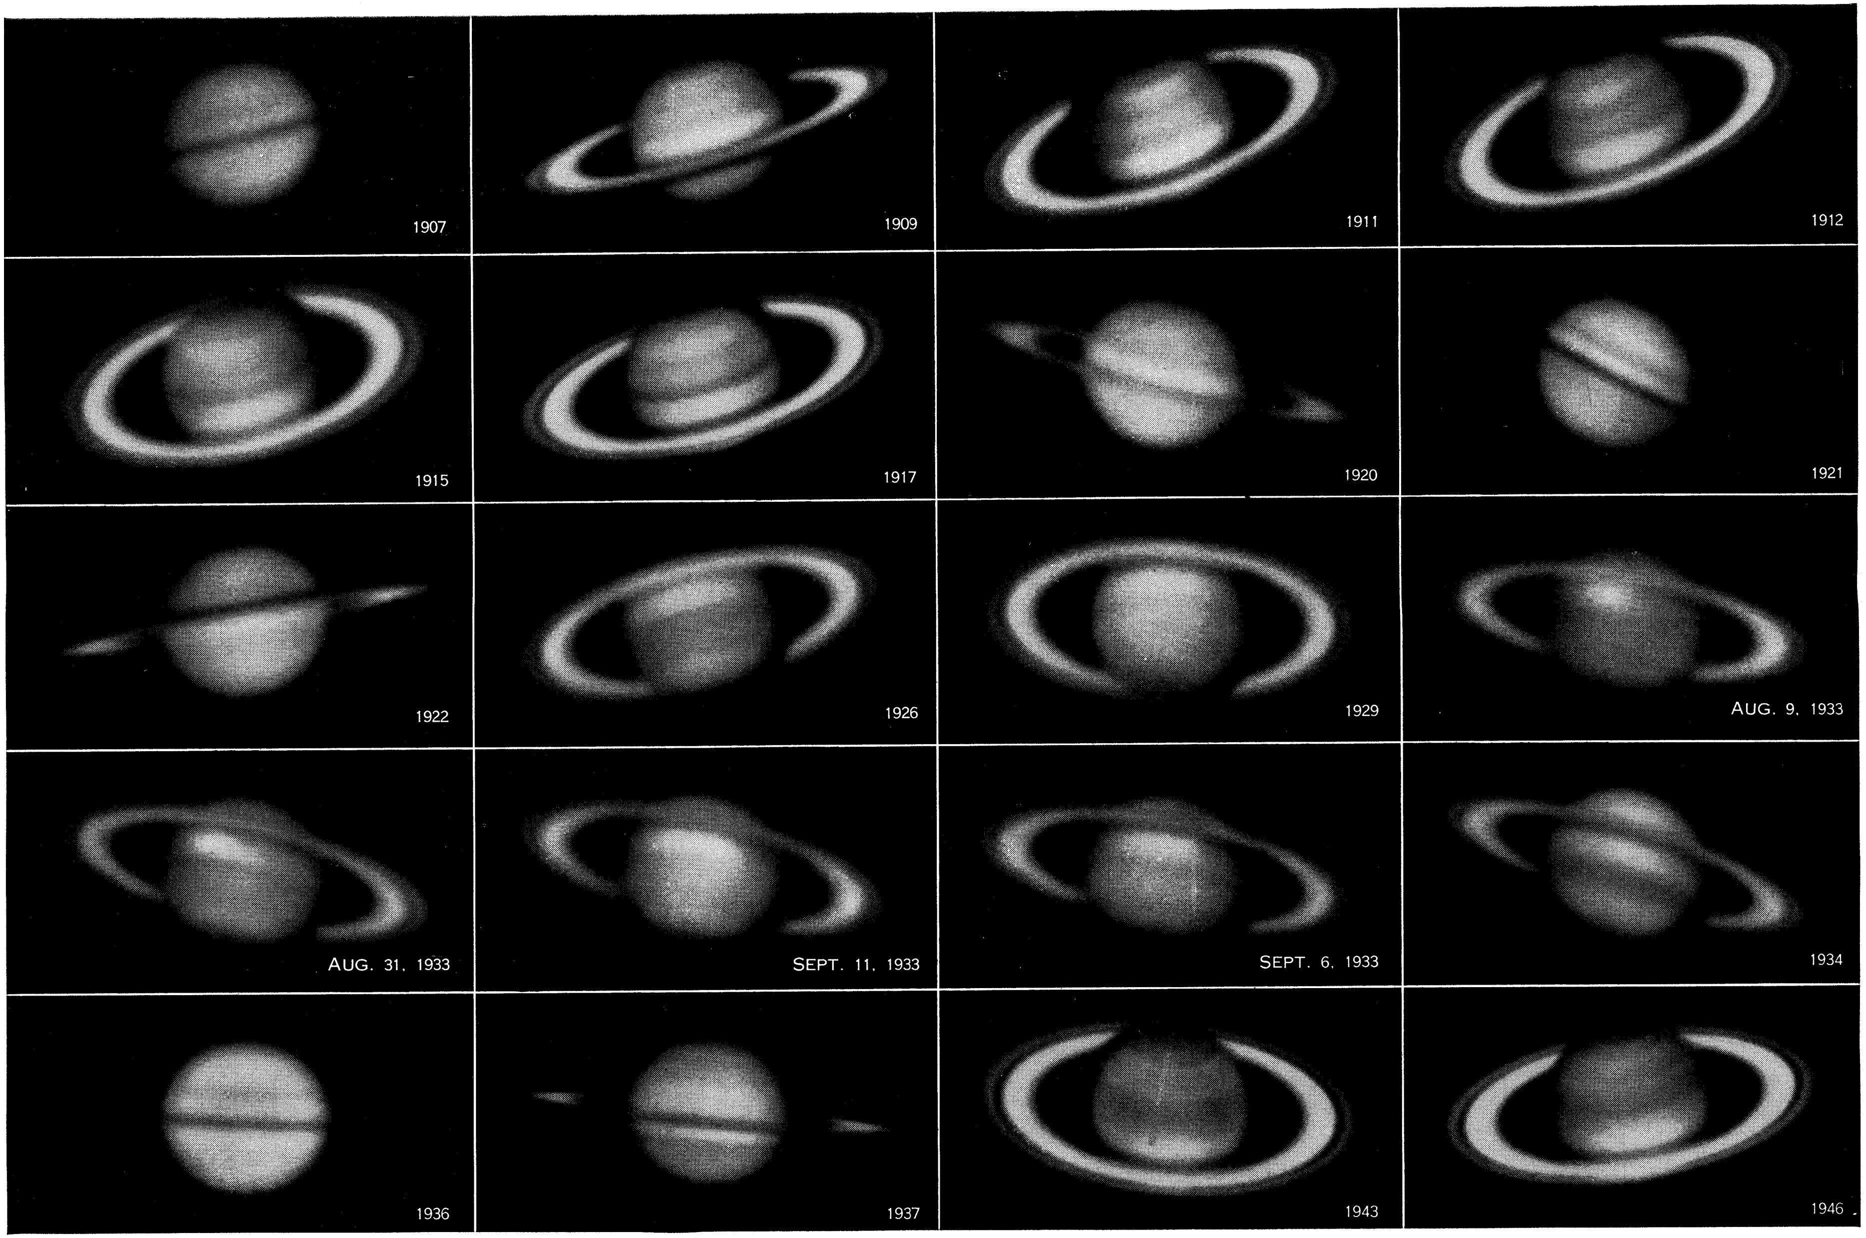
The five inner satellites seem to form a class by themselves. Their orbits are nearly circular and their planes coincide exactly or very nearly with that of the ring system and the planet's equator. Thus, so far as the position of the planes of rotation and revolution are concerned. the system keeps together as if it were rigid. This results from the mutual attraction of the various bodies. A remarkable feature of this inner system is the near approach to commensurability in the periods of revolution. The period of Tethys is nearly double that of Mimas and the period of Dione about double that of Enceladus. The result of this near approach to commensurability is a wide libration in the longitudes of the satellites, having periods very long compared with the times of revolution.

Each of the four outer satellites has some special feature of interest. Titan is much the brightest of all and is unique among all the satellites in the solar system in possessing an atmosphere. In 1944 conclusive evidence was found by Gerard P. Kuiper at the McDonald observatory that an atmosphere containing methane and possibly ammonia surrounds the satellite. Hyperion is so small as to be visible only in a powerful telescope, and has a quite eccentric orbit; its time of revolution is almost commensurable uith that of Titan the ratio of the periods being three to four, with the result that the major axis of the orbit of Hyperion has a retrograde motion of 18° 40' annually, of such a character that the conjunction of the two satellites always occurs near the apocentre of the orbit, when the distance of the orbit from that of Titan is the greatest. This is among the most interesting phenomena of celestial mechanics. Iapetus has the peculiarity of always appearing brighter when seen to the west than to the east of the planet; this is explained by the supposition that, like earth's moon, this satellite always presents the same face to the central body.

Phoebe, the outermost satellite, is more than three and one-half times as remote from Saturn as Iapetus, and the circumstances of its discovery are interesting. In studying photographs of the neighbourhood of Saturn taken at Arequipa observatory, Peru, Pickering found on each of three plates a very faint star which was missing on the other two. He concluded that these were the images of a satellite moving around the planet, which was then entering the Milky Way, where minute stars were so numerous that it was not easy to confirm the discovery. When Saturn began to emerge from the Milky Way no difficulty was found in relocating the object and proving that it was a ninth satellite. Its motion, however, was found to be retrograde or in a contrary direction to that of the other satellites. This difference of motion in a single system was, according to the knowledge of that time. a unique phenomenon, for although the satellite of Neptune and those of Uranus were known to have retrograde motions, they are the only satellites of those planets hitherto discovered. But more recently the 8th, 9th and 11th satellites of Jupiter have been found and the motion of these, like that of Phoebe, is retrograde.

See PLANET and also Index references under "Saturn" in the Index volume. (T. E. R. P.; W. W. M.)

SATURNIAN METRE (Lat. *Saturnius*), a native Italian metre, used in some of the oldest known Latin compositions. It was in later times wholly displaced by Greek metres and but few specimens survive. These are (1) inscriptions, notably some of the epitaphs of the Scigios; (2) fragments of Livius Andronicus's translation of the *Odyssey* and of Naevius's *Bellum Punicum,* with a very few remnants of other authors. The following are specimens of this verse:



BY COURTESY OF DR. E. C. SLIPHER

SATURN

Various aspects of the planet and its ring system (1907–46). In 1907, 1921 and 1936 the rings were edgewise and thus too faint to show in normal exposures; in 1915, 1929 and 1943 the rings were wide open. The great white spot of 1933 is shown on Aug. 9 and Aug. 31 almost unchanged, but on Sept. 11 it had rapidly expanded until it extended about 3/5 the way across the ball. The photograph of Sept. 6, 1933, shows the outburst of still another large white spot more than 100" in longitude following the first

Dabunt malum Metelli/ Naevio poetae
Quamde mare saevom/ vis et quoi sunt magnae.

The scansion is very doubtful; on the whole it is more likely that it is accentual than that it is quantitative. (On the accentual theory, in its most probable form, the line has 3 + 2 accents, and usually consists of 7 + 6 syllables, as *quóius fórma virtútei parísuma fúit.*) Some account of it will be found in Lindsay, *Early Latin Verse,* p. 9.

Nothing resembling the Saturnian exists in English; the example given by Macaulay ("The queen was in the parlour eating bread and honey") is not in the least like it.

SATURNIID MOTH, any of about 800 species of chiefly large, broad-winged moths of the family Saturniidae, commonly called giant silkworm moths. Although they are almost worldwide in distribution, most of the species are found in the tropics, especially in South America and tropical Africa. These night flyers are frequently vividly coloured and often remarkably patterned. Certain Asian kinds, called wild silkworms, spin a commercially valuable silk—a product not so fine, however, as that spun by the common Chinese silkworm (*Bombyx mori*) of another family (*see* SILK AND SERICULTURE).

The Saturniidae includes some of the largest insects; a few tropical specimens have a wing-span of about 9 in., whereas those in North America are smaller, having wing-spans up to 6 in. The larvae are large, usually green, caterpillars, most of which have colourful knobs or spines and, in many American sorts, irritant barbs. They are voracious leaf-eaters as caterpillars, but, unlike many other moths, the Saturniidae never feed after they have obtained wings.

Some species have been used for commercial silk from time immemorial and the silkworm which Aristotle cited (his *nekydalos*) as a familiar example of metamorphosis was almost certainly *Saturnia pyri.* Saturniids are used in the modern silk industry only in southeast Asia, and only the tusseh silkworm (*Antheraea pernyi*) and the eria, ailanthus or cynthia moth (*Samia cynthia*) have been used long enough to break into cultivated varieties. The North American polyphemus moth (*Antheraea polyphemus*) would be as useful in the silk industry as is the tusseh, except for the cost of labour.

Being large, handsome and often easy to rear, saturniids are favourites with amateur lepidopterists. They have also served as subjects in studies on hybridization and variation; more recently, the giant cecropia moth (*Platysamia cecropia*) has been used extensively in studies on endocrine control of transformation and hibernation.

Other members of the family include the emperor moth (*Saturnia pavonia*) of temperate Europe and Asia; the yellow (male) or reddish (female) io moth (*Automeris io*), the bright grass-green luna moth (*Actias luna*) and the maroon (female) to blackish (male) promethea moth (*Callosamia promethea*), all found in North America. The genera *Rothschildia* and *Copiopteryx,* common to South America, are among the most beautiful of the saturniids.

SATURNINUS, LUCIUS APPULEIUS, Roman politician. Quaestor in 104 B.C., he superintended the importation of corn at Ostia, but was removed by the Senate, apparently without any charge against him being made and so went over to the popular party. Tribune in 103, Saturninus made an arrangement with Marius for the allotment of 100 *iugera* of land to each of Marius' veterans.

It was probably at this time that he introduced his law on *maiestas* (treason), which seems to have been designed to increase the power of the tribunes. In 101 he was tried for violating the law of nations in connection with the embassy of Mithridates. The envoys had arrived with large sums of money to bribe the Senate and Saturninus exposed the affair and insulted the ambassadors. He escaped by appealing to the people. He further cultivated popularity by supporting the claims to citizenship of a freedman, Equitius, who posed as a son of Tiberius Gracchus (*q.v.*). Saturninus allied himself with C. Servilius Glaucia, and the two of them acted as Marius' political agents after his return from the war with the Cimbri. By bribery and murder Marius was elected consul for the sixth time in 100, Glaucia praetor and Saturninus tribune again. Saturninus then brought forward an extension of the African agrarian scheme, which included the distribution of the land north of the Po, taken from the Cimbri, among Marius' veterans, and the foundation of a number of new citizen colonies, to which Italians were to be admitted, a feature which caused a good deal of opposition. A further clause provided that every Senator should swear to observe it within five days of its becoming law. Metellus Numidicus, Saturninus' chief enemy, alone refused, and went into exile. The law was passed eventually after considerable disorder. At last Saturninus and Glaucia found themselves in danger of being disowned by Marius, and their only hope of safety lay in retaining office. In the elections at the end of 100 Saturninus was again elected tribune, and Glaucia stood for the consulship. During the voting their partisans beat C. Memmius, the senatorial candidate, to death. The Senate declared them public enemies, and called on Marius to take up arms against them. Saturninus was defeated in a battle in the forum, and took refuge in the Capitol (Dec. 10). Forced to surrender, he and Glaucia and their followers were imprisoned in the *Curia Hostilia,* and some of the opposite party tore off the roof and stoned them to death. (*See* also ROME: *Ancient History.*)

SATYRS, in Greek mythology, spirits half-man, half-beast. They are not mentioned in Homer; in a fragment of Hesiod they are called brothers of the mountain nymphs and Curetes, an idle and worthless race. They were a roguish but faint-hearted folk, lovers of music, wine and women, dancing with the nymphs or pursuing them, and striking terror into men. They had a special form of dance called *Sikinnis.* In early Attic art they were represented as grotesque men with horses' tails; later they approached the type of Pan (*q.v.*). A statue, supposed to be a copy of a work of Praxiteles, represents a graceful satyr leaning against a tree with a flute in his hand. In Attica there was a species of drama known as the satyric; it treated its themes in a half-comic manner and the chorus was composed of satyrs. Sophocles' *Ichneutai* and Euripides' *Cyclops* are the only extant examples. In Italy, the satyrs are often identified with the fauni (*see* FAUNUS).

In the Authorized Version of Isa. xiii, 21; xxxiv, 14 the word "satyr" is used to render the Hebrew *sĕʿīrīm,* "hairy ones." A kind of demon or supernatural being known to Hebrew folklore as inhabiting waste places is meant; a practice of sacrificing to the *sĕʿīrīm* is alluded to in Lev. xvii, 7, where the English version has "devils." They correspond to the "shaggy demon of the mountain-pass" (*azabb al-ʿakaba*) of old Arab superstition.

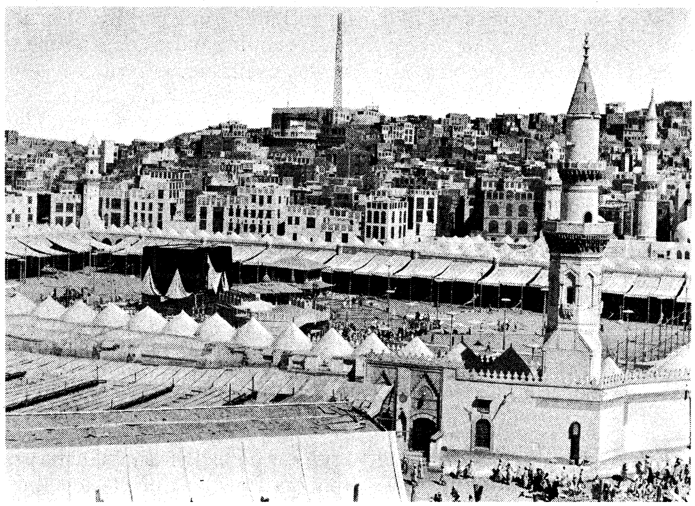
SAʿUD, ʿABD UL-ʿAZIZ IBN ʿABD UR-RAHMAN IBN FAISAL, IBN: *see* IBN SAʿUD, ʿABD UL-ʿAZĪZ IBN ʿABD UR-RAHMĀN IBN FAISAL.

SAUDI ARABIA (AL MAMLAKAH AL'ARABĪYAH AS SU'ŪDĪYAH), a kingdom of southwest Asia, ruled by the house of Saʿud in the 18th century, and founded in the 20th century as a modern kingdom by Abdul-ʿAziz II ibn Saʿud, occupies most of the Arabian peninsula. The kingdom is bounded north by Jordan, Iraq and Kuwait with two areas of neutral territory west and south of Kuwait; west by the Gulf of Aqaba and the Red sea; south by Yemen, Aden protectorate and Dhofar (Dhufar); east by Muscat and Oman, Trucial Oman, Qatar and the Persian gulf. Its boundaries with Jordan and Yemen in part and with its southern and eastern neighbours have never been fixed. The total area is 872,722 sq.mi.

PHYSICAL GEOGRAPHY

The ancient Arabian shield of igneous and metamorphic rocks protrudes eastward from the Hejaz (Al Hijaz) into Najd (Nejd) as a bulge curving round from the Gulf of Aqaba to a point less than 125 mi. W. of Riyadh and then receding toward the southern Red sea. The shield contains many extinct volcanoes surrounded by lava beds. Sloping eastward are the newer sedimentary areas in which rich oil fields are found. The shield gives symmetry to Saudi Arabia's geography, as many escarpments and sand deserts follow its contour.

Saudi Arabia's coastline on the Gulf of Aqaba and the Red sea is more than 1.100 mi long; its Persian gulf coastline, though of undetermined length, is somewhat shorter. Neither side has deep natural harbours. Islands and coral reefs in the Red sea are numerous, particularly in the Farasan bank, which runs along



PAN ASIA PHOTO NEWS FROM BLACK STAR

HOLY CITY OF MECCA WITH THE SACRED SHRINE OF THE KA'BA IN THE CENTRE OF THE COURTYARD

Saudi Arabia's coast for over 300 mi. In the Persian gulf the ownership of various islands is in dispute between Saudi Arabia on one hand and Kuwait. Iran, or Abu Dhabi (one of the Trucial states) on the other. A treaty signed in 1958 established a water boundary between Saudi Arabia and Bahrain.

Saudi Arabia's highest mountains are in Asir (*q.v.*) where peaks rise to over 9.000 ft. The mountains of Al Tubayq dominate the undefined border between Jordan and Saudi Arabia east of Aqaba. Southeast of Jabal Shammar escarpments parallel the bulge of the shield, the most prominent being Jabal Tuwayq, 800 mi. long from north to south. The Red sea coast plains are narrow, whereas plains in the central and eastern regions sometimes stretch over great distances. In the north the Syrian desert reaches down into Saudi Arabia. The largest sand deserts lie east of the shield; the Great Nafud in the north and the Rub' al Khali (the Empty Quarter) in the south, connected by the Ad Dahna sand belt.

The Asir mountains constitute the only area in the kingdom receiving adequate rainfall. Virtually all the rest of the country is desert, apart from scattered oases fed by underground water sources or flash floods. Winters are cool, and spring and fall days are often agreeable. but spells of good weather are interspersed with gusts or storms of swirling dust and sand. The fierce summer heat, tempered by aridity in the higher regions of the interior. is aggravated along the coasts by high humidity. (See also ARABIA: *Regional* Geography.) (G. S. RE.)

HISTORY

For archaeology, exploration and earlier history see ARABIA. The history of Saudi Arabia begins properly from Sept. 18, 1932, when by royal decree of King Abdul-'Aziz II ibn Sa'ud the dual kingdom of Hejaz (*q.v.*) and Najd with its dependencies, administered since 1927 as two separate units under slightly different systems, was unified under the style of "The Kingdom of Sa'udi Arabia." The change was far from being purely nominal, though no attempt was made to "liberalize" the supreme authority of the king as the absolute monarch of the new regime. It did however, represent a substantial change of direction. or attitude, in the domestic and foreign policies of the realm. Until 1926, when Ibn Sa'ud had finally extended his power over the whole of inner Arabia. the country had remained in almost total isolation from the rest of the world because of its poverty, its desert character and its fanatical religious xenophobia. The only foreign countries with which Ibn Sa'ud was acquainted were Turkey and Great Britain; but the conquest of the Hejaz had brought him into contact with other powers. and the new circumstances compelled him to take stock of his position. It was indeed the U.S.S.R. which took the lead. both in recognizing his new status and in raising its consul general to ministerial rank. Britain and France did the same soon afterward at discreet intervals.

Preliminary Period, 1926–32.—Ibn Sa'ud, enriched since 1926 by the substantial revenues of the Meccan pilgrimage, had realized from the beginning that the progress and stability of his regime would depend largely on co-operation with the west, particularly in the technical and economic spheres. He had not hesitated to temper the puritan breezes of his native Najd to the latitudinarian exigencies of his new province and the mildness of his attitude to the non-Muslim strangers within his gate had surprised those who had confidently predicted a sharp turn of the puritan screw on the Hejaz. long accustomed to Turkish apparatus and European contacts. At the same time it had caused some searching of heart among the divines and fanatics of his desert realm. where the Wahhabi brotherhood (known as *al-Ikhwan*), already acclimatized to the use of western instruments of war. tended to challenge the legality of infidel contributions to peaceful progress, such as the automobile, the airplane, the telephone and radiotelegraphy. Ibn Sa'ud had gradually disarmed the opposition to his projects by tactful persuasion; but there still remained a hard core of irreconcilable elements, the very elements which he himself had created and trained to carry the victorious banners of God through the length and breadth of the land he now ruled. In 1920 Faisal al-Dawish. Sultan ibn Bijad and other leaders of the *Ikhwan*, accusing him of betraying the cause for which they had fought so stoutly, took the law into their own hands, and staged an attack on Iraq and its British protectors.

This rebellion was crushed and Ibn Sa'ud had exorcised, though not without reluctance, the Frankenstein of his own creation. For the third time the Wahhabi movement had received its quietus: this time at the hands of its friends and probably for ever. Ibn Sa'ud was at last free to give his undivided attention to the development of his country, and to the problems of foreign policy which beset him on all sides. Above all he was concerned to assert and maintain the complete independence of his country and the exclusive supremacy of Islam therein. And, subject to their respect for these fundamental objectives, he was not only ready to co-operate with all nations but prepared to regard with sympathy some of the practices which had taken root in the Hejaz and other areas as the result of foreign contacts. The Wahhabi anathema on tobacco was not pressed in the Hejaz. and gradually became a dead letter elsewhere. The ban on music was progressively stifled by the radio. The amenities of air travel dispelled the myth of divine displeasure at indulgence therein. And so on until the latitudinarian spirit, slowly at first but with ever increasing momentum. dispersed the inhibitions of the puritan regime. On the other hand Ibn Sa'ud had rigorously set his face against any foreign interference whatever in the internal politics of the realm. An Indian Muslim delegation had received no encouragement in its idea that the Hejaz would be better governed as a pan-Islamic republic than by Ibn Sa'ud. The Egyptians had been sharply reminded that the protection of their annual pilgrimage was the exclusive concern of the Saudi government, and had ceased to send their traditional military escorts and bands. Britain and other European states had been politely warned against interference in the processes of Islamic law relating to crime. slavery, etc. Requests for permission to construct churches and other public places of worship for non-Islamic communities were courteously rejected.

The Reigns of Ibn **Sa'ud and Sa'ud IV.**—All these problems had been disposed of in the course of the seven years, as it were. of gestation. preceding the proclamation of the birth of Saudi Arabia. From the beginning it enjoyed full international recognition of its complete independence, though it was not until after the death of King Fuad I of Egypt in 1936 that diplomatic relations with that country, disturbed by a pilgrimage incident in 1926, were restored. After this, however, the relations of the two countries were a model of international co-operation scarcely ruffled by the Egyptian revolution of 1952, or by an unfortunate accusation by President Gamal Abdal Kasser in 1958 that King Sa'ud was plotting his assassination.

The political events of the years 1932–60 can be disposed of very briefly. In 1934 Ibn Sa'ud was involved in war with the Yemen over a boundary dispute; but a brief campaign. which carried the Saudi army as far south as Hudaida (al Hudaydah) in six weeks, ended in the treaty of Ta'if. The frontier was duly agreed and demarcated after which the relations of the two countries became uniformly cordial. During World War II Ibn Sa'ud declared his neutrality, though his personal bias in favour of the western allies was never in doubt. In 1945 he somewhat reluctantly agreed to declare war on Germany, and was thus able to take his country into the Cnited Kations organization as a founder member. He also joined the Arab league (*q.v.*), of which he and his successor always remained the most cordial of supporters. In 1946 Ibn Sa'ud paid a state visit to Egypt as the guest of King Faruk. It was on this occasion that he conceived the idea of a railway link between Riyadh and the Persian gulf; and five years later he had the satisfaction of inaugurating the new line on the arrival of the first train from the modernized port of Ad Dammam. In 1952 he celebrated the golden jubilee of his accession to the throne and on Nov. 9, 1953, he died at At Ta'if, at the age of 73, after a reign as long and distinguished as any in Arabian history. He had prepared the ground on which his successors would build a new regime, and he had provided the resources with which they could do so with every hope of success (see also IBN SA'UD).

It was his eldest surviving son Sa'ud ibn Abd Abdul-'Aziz who ascended the throne (as Sa'ud IV), while his second brother Faisal was proclaimed heir apparent. The opening years of the reign were mainly concerned with domestic policy and economic development, in which respects great progress was undoubtedly made. There was an enormous increase in the populations of Riyadh and Jidda. International airports at Dhahran and Jidda, and a large one at Riyadh emphasized the significance of Arabia in the nevi world. Roads, schools, hospitals, mosques, palaces and blocks of flats sprang up like mushrooms. Financial difficulties, at one time threatening disaster, were largely overcome. Commerce thrived as never before; revenue was buoyant, and ever increasing; government servants of all grades were lavishly paid, contented and ambitious. The very character of the principal urban societies was transformed out of all recognition by a heavy influx of *bourgeoisie* from the neighbouring lands. with its westernized outlook and apparel, though the court and all persons of Najdi origin still preserved their traditional garb, apart from the adoption of European footwear. The foreign ways of immigrant wives were tolerated, though without approval and with occasional attempts at restriction; and there was no sign of official recognition of the inevitability of female emancipation in modern Arabia.

In the international sphere the Americans dominated the scene without interference in administrative matters, while the Saudi government, perhaps wisely: showed no inclination to assert itself in the field of purely Arab politics, being content to work for Arab unity through the Arab league and to recognize the dominance of Egypt and Iraq in Arab counsels. Such Communist elements as intruded into the country at times were sternly discouraged; and the Saudi monarchy was firmly established.

Foreign and Domestic Problems.—In 1932, Ibn Sa'ud had found himself confronted by two important issues: the finalization of his relations with Britain and the various Arab states and principalities under British control or protection, and the fixation of his frontiers therewith; and the reinforcement of his depleted financial resources, severely strained by the cost of his operations against the *Ikhwan* rebels.

Negotiations with Britain during the 1930s failed to settle disputed boundaries in the south and east. Among these were the undefined landward boundaries of the Sultanate of Muscat and Oman which was in close treaty relationship with Britain and of the British-protected Trucial sheikhdoms. The area was considered important as a potential source of oil but no action was taken to disturb the established regimes until in 1952 tribal forces under Saudi Arabian control occupied the Buraimi oasis which Britain regarded as belonging partly to the Sultanate of Muscat and partly to the sheikhdom of Abu Dhabi. To counterbalance the Saudi Arabian influence a force of Oman levies was sent to the Abu Dhabi portions of the oasis. In Jan. 1953 the two forces came into collision. In July 1954 the British and Saudi governments agreed to submit the dispute to an arbitration tribunal. but when the tribunal met in Geneva in Sept 1955 the British representative. Sir Reader Bullard. withdrew accusing the Saudi authorities of extensive bribery to induce local sheikhs to transfer their allegiance. The negotiations broke down and levies from Muscat under British command reoccupied the oasis. During the Suez crisis in 1956 Saudi Arabia broke off diplomatic relations with Britain.

If oil was thus the basic cause of Anglo-Arabian estrangement, it was also to calm the troubled seas of Saudi finance beyond the wildest expectations of all concerned. The history and statistics of oil extraction in Saudi Arabia are set out in The *Economy* below. In terms of finance the result was that compared with the position after the conquest of the Hejaz in 1926 the country's annual revenue had by the early 1960s increased thirtyfold.

This sudden access of wealth was not an unmixed blessing. Inexperience. extravagance, and even corruption, to say nothing of the advent of fortune hunters from other Arab countries. raised their hydra heads in an orgy of ill-considered spending. The American way of life imposed itself easily on a hitherto xenophobe population. only to increase its xenophobia. The impoverished became rich overnight; yet the economy wilted. In March 1958 King Sa'ud issued a decree transferring full executive powers to Faisal but retained his right of veto. Faisal introduced a regime of austerity. The currency position, threatened with disaster, was restored to equilibrium and efforts were made to eliminate the worst features of the extravagance and corruption which wealth had encouraged. Attention was focused on useful projects such as the building of schools. hospitals and roads, and a modest beginning had already been made in higher education with the establishment of a university at Riyadh. The economy campaign proved unpopular with members of the royal family, whose subsidies and salaries were cut, and King Sa'ud forced the resignation of Faisal in Dec. 1960. The king then assumed the office of prime minister and appointed a new cabinet.

In July 1961, following the Iraqi sovereignty claim over Kuwait, Saudi Arabia sent troops in response to the Kuwait ruler's request for British and Saudi military assistance. The five-year pact which permitted the U.S. air force to lease Dhahran base on the Persian gulf was terminated in 1962. (H. ST. J. B. P.; X.)

POPULATION

In 1956, the population of Saudi Arabia was estimated at 6,036,000. There are no verified figures of the exact population as no accurate census has yet been taken. It is estimated that 78% of the population is nomadic and it is probable that both the town estimates and the estimated proportion of nomads are higher than a census would prove. Estimates of the principal cities are: Mecca 1250,000); Riyadh (150.000); Al Hufuf (Hofuf) (82,600); Jidda (200,000); Medina 160,000). Other towns are Abha (25.000); 'Cnayzah (Anaiza) (25,000); Buraydah (Buraida) (30.000); Ad Dammam (Damman) (30 600); Dhahran (12,000); Ha'il (30,000); Al Rhubar (20.000); Al Qunfudah and Najran (10.000 each); Al Qatif (30.000); Ras Tanura (15.000); Ta'if (50.000).

Arabs. like the people of Europe and America, are of the Caucasian family but there are some of Negroid ancestry because of past importations of Africans. The Saudi Arabs recognize no colour line and mixed racial strains abound in Saudi Arabia, especially in the Red sea coastal plain called the Tihama. But on the interior plateau of Najd, the hue of the Najdis and Bedouins in general is largely the brown Mediterranean type. The colouring of the people in towns varies from white to light brown. The Arab population are predominantly Sunni Muslims who mostly adhere to the Wahhabism (puritanical) interpretation. There are no native Christians or Jews but several thousand Christians (U.S., European and Arab) are employed in the oil industry. Jews have been barred from Saudi Arabia since 1948 and non-Muslims are forbidden to enter the sacred cities of Mecca and Medina.

The creation of industries in addition to the enormous developments of the Arabian American Oil company (Aramco) have been responsible for the growth of population (since 1945) in the cities of Jidda. Riyadh, Dhahran, Ad Dammam (*qq.v.*), Al Khubar and Al Qatif, where the increase has been two- to tenfold. For anthropology. see ARABIA: The People; ARAB; BEDOUIN.. For language see ARABIC LANGUAGE. (K. S. Tw.)

ADMINISTRATION AND SOCIAL CONDITIONS

Government. — The government of Saudi Arabia is patriarchal rather than constitutional. The nearly absolute rule of the king is bound by the laws of the *Shari'ah* (Islamic law, *q.v.*) which became clear when he was declared king of the Hejaz in 1926. The king (*malik*) rules the state with the help of the royal court. his cabinet or diwan (instituted in 1958), which includes a council of ministers (set up by decree in 1953), drawn largely from the royal family. The government is assisted by a consultative council and by the *'Ulama,* a council comprised of learned religious men.

The laws of Islam provide the country with civil and penal codes and also regulate religious problems. But the king has the power to issue a decree where the religious law is not applicable. The king is accessible to his subjects and hears complaints from all classes. At an appointed hour. all may appear and ask for justice. There can be no appeal against the king's decision. In 1932 it was proposed to provide the whole country with a single constitution but pending the implementation of this. the state has maintained its dual character with its two capitals: Riyadh as the seat of the government and Mecca as the spiritual capital (see also HEJAZ and NAJD).

The organized judiciary is an independent agency in the state and the public law is claimed to be derived from the Koran. The Cadis usually judge according to the predominant Hanbalite version of the *Shari'ah* law. Punishment is similar to that in the Mosaic code. the penalty for murder is decapitation by the sword; for theft (with violence) the left hand is amputated; for adultery the woman may be stoned to death. Justice. when not theoretically in conflict with religious law, can also be governed by tribal and customary law (*'urf*).

Administratively, the kingdom of Saudi Arabia is divided into provincial areas: Hejaz, Najd, the Al Hasa (Eastern Province). the Northern Frontiers district and Asir. There are municipal councils in most of the towns and villages. More than half the population are governed locally by tribal councils, the central government maintaining control through territorial amirs or sheikhs.

Living Conditions, Health and Welfare. — It is sometimes thought that Arabs live only in tents. This is true of the estimated 78% of the population who are Bedouins. But there are thousands of farmers and landholders who live in two- to five-storied buildings of mud-brick and stone, similar to the dwellings in the towns. After World War II many apartments, government offices and fine houses of reinforced concrete were constructed.

With the oil economy came the concept of hired labour and people are now also employed in government services, in various private enterprises, in construction and in mining. The greatest single industry is the oil operation of Aramco and this employed more than 16.000 persons in the early 1960s, most of whom were Saudi Arabs. In 1935, wages paid in this industry were $\frac{1}{2}$ rial and food per day (1 rial = $.27). Wages have now reached a minimum of 8 rials.

The traditional welfare system based on kinship continues to function throughout Saudi Arabia. The government has no extensive welfare programs although considerable sums have been earmarked for various development projects. Aramco has instituted a modern welfare plan which includes provision for pension plans, accident compensation and medical and educational services. Almsgiving, being one of the traditional good works of Islam, is common.

The scarcity of water contributes to unsanitary living conditions in many parts of the country. Malnutrition. a major health problem, gives rise to rickets, scurvy, anemia and trachoma. There is a high incidence of malaria, tuberculosis, venereal and parasitic infections. The annual influx of pilgrims aggravates public health problems, although the Saudi government has assumed the responsibility of caring for the sick and has established quarantine stations. notably at Jidda. Progress was made after the formation of a ministry of health in 1951 and hospitals, some with mobile units. were established in the major population centres.

Slavery still exists in Saudi Arabia. A royal decree of Oct. 1936 made the importation of slaves illegal unless the importers could prove that the slaves were recognized as such in the country of their origin. The conditions and rights of the existing slaves were also regulated by this decree.

Education. — Elementary education is free to all Saudi Arabs. The modern school system includes elementary, secondary, commercial and industrial schools, training institutes for teachers, and night schools. By the early 1960s there were about 600 government educational institutions staffed by about 4,500 instructors (many from neighbouring Arab countries) and attended by 75,000 students. There are many anti-illiteracy centres throughout the kingdom and in 1959 a royal decree authorized the establishment of government schools for girls. The King Sa'ud university at Riyadh (established in 1957) has colleges of arts and sciences, to which colleges of commerce and pharmacy were added in 1959–60.

Defense. — The Wahhabis have always been the backbone of the traditional militia. No accurate figures are known for the regular army but 500,000 is a probable maximum. A military academy at Riyadh provides for the training of about 600 officers a year. Since 1947 the U.S. government has conducted training of Saudi Arabs at Dhahran air base and U.S. aid has been expanded to provide for the establishment of a U.S. military training mission with army, navy and air force branches. In 1958 the ministry of defense announced a five-year plan calling for 58,000 men to be recruited annually. (K. S. Tw.; X.)

THE ECONOMY

The kingdom of Saudi Arabia inherited the primitive, tribal economy of Arabia. Many of the people are nomads, engaged in raising camels, sheep and goats. Agricultural production is localized and poor. Locust invasions are periodic. The scarcity of rain and water is a perpetual problem; the oases provide a few staple crops; dams have been built to trap the seasonal valley floods, and some irrigation is practised. But it was always difficult for the country to be self-sustaining even in essential foodstuffs, and the ordinary necessities of life (such as rice, flour, sugar. tea and piece goods) must be imported. Commodities which were produced and could be exported to pay for these imports included skins, hides and wool (all imperfectly prepared for foreign markets); dates from the Medina region (now suitably packaged); horses (but the importance of the Arabian horse as an export item has declined) and camels; coffee from Asir, and pearls from the Persian gulf. Asir has rock salt, and salt deposits especially in the Red sea could be further exploited: little attention has been given to fishing in either Red sea or Persian gulf. A notable experiment is the royal farm at Al Kharj, but this covers only about 3.000 ac. south of Riyadh. (See also ARABIA: Vegetation, *Animal Life* and *Natural* Resources.)

The New Oil Economy. — The discovery of oil changed the entire economic situation of Saudi Arabia. As early as 1923 Abdul-'Aziz II granted an oil prospecting concession to a British company, but this concession was never exploited.

In 1933 a large oil concession, to terminate in 1999, was secured by Standard Oil of California, which eventually shared ownership of the operating concern, the Arabian American Oil company (Aramco), with Texaco, Standard Oil (New Jersey), and Socony Mobil Oil on a 30-30-30-10 basis. Although oil was discovered in 1938, World War II curtailed activities until near its end. Rapid expansion began with the completion in 1945 of the Ras Tanura refinery, the rated capacity of which was later increased to 189,000 bbl. a day. Abqaiq (Buqayq) and Ghawar took their place among the world's largest producing fields, and in the early 1960s production of crude oil reached a daily average in excess of 1,500,000 bbl. In 1950 Aramco's owners put into operation the Trans-Arabian Pipe Line (Tapline), which runs 752.8 mi. from Al Qaysumah (300 mi. N.W. of Dhahran) in Saudi Arabia across Jordan and Syria to its Mediterranean terminal at Sidon, Lebanon. The capacity of the line was later increased to 470,000 bbl. a day. Crude oil not refined at Ras Tanura or pumped through Tapline is shipped from Ras Tanura port or piped to Bahrain for refining.

In 1951 Aramco discovered the first offshore field in the near east at Saffaniyah just south of the Saudi Arabia–Kuwait neutral zone. Intensive exploration of the Rub' al Khali began in 1950. Operations in this forbidding desert have led to the development of new techniques, particularly in the field of transportation. Water has been found in a number of deep wells drilled in the heart of the sands.

In 1950 Saudi Arabia and Aramco made a new agreement for sharing profits on the basis of the so-called 50/50 principle, this being the first application of this principle in the near east, where it was later widely adopted. This agreement gave Saudi Arabia a substantially larger return from the venture.

In 1949 Saudi Arabia granted a concession to the Pacific Western Oil corporation (later the Getty Oil company) for its interest in the Saudi Arabia–Kuwait neutral zone. Oil was discovered in the zone in 1953, and Saudi Arabia's share of the production reached about 55,000 bbl. a day. Another concession was secured in 1958 by the Arabian Oil Company Ltd. of Tokyo for Saudi Arabia's interest in the neutral zone offshore, with the provision that Saudi Arabia should receive 56% of this company's profits. The first well drilled in the neutral zone offshore in 1960 proved a successful strike.

Since 1955 Saudi Arabia has been surpassed in crude oil production only by Kuwait in the near east and by the United States, Venezuela and the Soviet Union. Saudi Arabia's proven reserves were estimated at 50,000,000,000 bbl., approximately 15% of the world total.

The oil fields also contain enormous quantities of natural gas: proven reserves in Saudi Arabia were estimated at more than 20,000,000,000,000 cu.ft. Aramco has developed the capacity to reinject about 400,000,000 cu.ft. a day to conserve gas for future use and to reinforce the underground pressure needed for oil production. Some gas is liquefied for use locally and for sale abroad.

Mining.—In 1934 the Saudi Arabian Mining syndicate obtained a concession. After examination of 55 ancient mining sites, work began at one, Mahd adh Dhahab in the Hejaz mountains. Gold and silver worth over $30,000,000 were extracted before the concession was relinquished in 1954 as no longer profitable. In 1954 the Saudi Arabian government, the United States Geological survey and Aramco undertook jointly an elaborate mapping program employing aerial photography to provide the basis for a more systematic survey of mineral resources. Large deposits of iron ore occur in northern Hejaz. Salt and gypsum are exploited commercially and cement is manufactured.

Trade and Finance.—Under the oil economy, trade in the few wares which the country had to offer, other than oil and gas, declined. In 1958 the government formed an Economic Development committee and trade agreements were negotiated with various countries. Many imports, such as machinery, motor vehicles and grain, became increasingly important as the economy grew more complex. The United States, Federal Republic of Germany and Japan are now the main suppliers, with the United Arab Republic ahead of other Arab states. In 1958 a severe check was placed on the import of luxuries in order to strengthen the national currency. In Jan. 1961 a Supreme Planning board (replacing the Economic Development committee) was formed to supervise the country's economic development.

The discovery of oil caused a drastic change in Saudi Arabia's finances. Freed from the old dependence on the pilgrim traffic to Mecca and Medina (the traditional source of national income), customs duties, and taxes on crops and livestock, which together provided a maximum of about 60,000,000 Saudi rials annually, the government's income by the early 1960s had risen to more than 2,100,000,000 rials, most of which came directly or indirectly from the oil industry. Oil revenues permitted a favourable balance of trade. In 1958 the government introduced its first realistic budget, and as a result of the improvement in the financial situation the rial was stabilized in 1960 at 4.5 rials to the U.S. dollar and established as the only legal tender. New rial notes were issued to replace the "pilgrim receipts" then in circulation; the Saudi gold sovereign was withdrawn and exchanged at a fixed rate of rials.

Transport and Communications.—Difficulties of terrain kept the various regions largely isolated, with the camel as the chief means of transportation, until mechanical transport was introduced in the 20th century. The Hejaz railway, completed from Syria to Medina in 1908, was damaged during World War I and its Hejaz stretch abandoned in 1924. After the unification of the kingdom, all areas were linked together by radio communications. Penetration of the interior by airplane became common after World War II; the principal cities were equipped with airports, and airlines brought the country closer to the rest of the world. In 1951 a railroad, 350 mi. long, was completed to the capital Riyadh from the new port of Ad Dammam on the Persian gulf just south of the oil-shipping port of Ras Tanura. The government also built a modern port on the Red sea at Jidda, the gateway to Mecca. Asphalt roads now speed pilgrims from Jidda to Mecca (45 mi.) and Medina (280 mi.), and other roads have been finished in the plan for a network of first-class arteries, which includes a transpeninsular highway. Even where asphalt is not laid, passable motor roads traverse the desert wherever necessary. A road paralleling Tapline leads to the neighbouring northern states of Jordan and Syria.

SAUERKRAUT is a food product of characteristic flavour, obtained by full fermentation, chiefly lactic, of properly prepared and shredded cabbage in the presence of not less than 2% nor more than 3% salt. It contains, upon the completion of fermentation, not less than 1.5% and usually not more than 2% lactic acid. The characteristic flavour and the lactic acid are produced by a sequence of bacteria which find ideal conditions for growth in the presence of the added salt and the nutrients which it withdraws from the shredded cabbage. Many refer to sauerkraut simply as "kraut." The word "sauerkraut" comes from the German *sauer,* "acid" and *kraut,* "cabbage." Sauerkraut is used as a delicious relish when served raw and as a vegetable when cooked. It is rich in vitamin C (ascorbic acid) and is excellent to add bulk without corresponding fattening properties. The juice is canned and used, as an appetizer. (F. W. FN.)

SAUGUS, a town (township) of Essex county, Mass., U.S., is located on the Saugus river 10 mi. N. of Boston. Settlement dates from 1629; the town was incorporated 1815. The Hammersmith ironworks, built on the river through the efforts of John Winthrop the Younger. operated from 1646 to 1676, producing up to eight tons of pig iron per week; the blast furnace. forges and slitting mill were restored in 1954 as an industrial shrine. The town was a manufacturing centre for shoes and woolen goods in the 19th century but is now chiefly residential. It has a council-manager form of government in effect since 1948. For comparative population figures see table in MASSACHUSETTS: *Population.* (HO. ST.)

SAUK or SAC. an Algonkian-speaking Indian tribe closely related to the Fox (*q.v.*) and Kickapoo. and once forming with these and the Shawnee a single tribe prohahly living in the Ohio valley. When first encountered by the French in 1667 they had been driven westward by the Iroquois to the region of Green Bay, Wis. Later they settled along the Mississippi river between Rock Island. Ill., and St. Louis, Mo., and formed a close alliance with the Fox. In 1804 the U.S. commander at St. Louis persuaded some of their minor chiefs to cede most of the tribal lands to the United States and although the Sauk protested that this treaty was illegal they were unable to prevent its enforcement. When a group led by Black Hawk (*q.v.*) refused to leave Illinois it was attacked by the state militia. overtaken while trying to escape across the Mississippi, and massacred. After the Black Hawk War the Sauk were forced to relinquish more territory; later they were moved to Kansas and eventually were settled in Oklahoma.

Sauk culture was of the prairie type. In summer the tribe lived in bark-house villages along bluffs near river bottoms where women raised corn and other crops. After the harvest the village broke up into family groups, which erected minter houses of poles covered with reed mats; in spring the tribe gathered on the Iowa prairies to hunt buffalo. Matrilocal residence was the rule in summer, when kinswomen co-operated in tending crops, but winter and spring brought a shift to patrilocal residence. The kinship system was of Omaha type, and the social organization included patrilineal clans that were crosscut by a nonhereditary dual division with important military and ritual functions. Regulating the inheritance of personal names. the clans also controlled religious ceremonies through ownership of sacred packs on which ritual was based. Some ceremonies, however, were held by secret societies. The Sauk were governed by a tribal council and hereditary chiefs; when war broke out these were temporarily replaced by war chiefs selected for their military ability. Early estimates of their population ranged from 1,500 to 3,000. In 1960 there were about 1,000 Sauk.

See Alanson Skinner. "Observations on the Ethnography of the Sauk Indians," *Bulletin* of the Public Museum of the City of Milwaukee, v (1923–25); Charles Callender, *Central Algonkian Social Organization,* Anthropological Publications of the Public Museum of the City oi Milwaukee (1961). (CH. C.)

SAUL, son of Kish, a Benjamite, was the first king of Israel. He began to reign *c.* 1025 B.C. The traditions as to his history are closely interwoven with those concerning Samuel and David. Various views may be taken of these records, among the most dramatic in sacred literature, but it is generally recognized by scholars that the stories of 1 Samuel preserve two different traditions about the rise of the monarchy in Israel. In each there is an account of Saul's election; each relates that he mas anointed by Samuel and records his rejection. It is probable that two distinct continuous histories have been combined in the existing text of Samuel. According to the later of the two traditions the elders of Israel, seeing that the sons of Samuel, who are destined to succeed him, are corrupt, demand that he shall make them a king "to judge them like all the nations." Samuel is displeased, but Yahweh reluctantly—for such a request was a grave affront to the deity, the true king of Israel—bids him concede the demand. The seer points out to the people that a king will oppress them, but fails to dissuade them (1 Sam. viii). He summons a solemn assembly at Mizpah, and. once more reminding them of their folly, chooses Saul, by lot under Yahweh's direction (x, 17–24). In an elaborate sermon (xii), he succeeds in convincing the people that their action has been sinful. And hardly has Saul seated himself upon the throne when Yahweh rejects him, and bids Samuel anoint David to succeed him in due time (xvi, 1–13). *See* SAMUEL.

The earlier tradition, which is distinctly more primitive in its religious ideas, contributes other sidelights on the matter. Samuel, to whom Saul comes seeking the seer's help in the finding of some lost asses, is previously warned by Yahweh that the suppliant is the divinely chosen saviour who is to deliver Israel from Philistine oppression. With wholehearted enthusiasm Samuel anoints Saul to be "prince over Yahweh's inheritance" (ix–x. 1). Saul and his son Jonathan achieve notable victories over the Philistines (xiii). According to this tradition Saul is a God-given saviour, like the heroes in Judges, who rescues his people from the grievous domination of the Philistines. An appropriate introduction to this narrative is missing from 1 Samuel. but the introduction to the story of Jephthah (Judg. x, 6–16)—to which what follows is certainly not the obvious sequel—would very well fit it. The suggestion has therefore been made that possibly according to an old tradition Saul was the immediate successor of Jephthah (*cf.* *Cambridge Ancient History,* vol. ii, p. 371ff.).

Though the reign of Saul was marked by considerable successes he was hampered by friction n·ithin as well as by foes without. Comparatively early his relations with Samuel seem to have become strained, and his declining years were embittered by the growing importance of his rival, David. Finally he fell a victim to his ancient enemies, the Philistines, who inflicted a heavy defeat on Israel in the battle of Mount Gilboa, where his sons were slain, and he himself perished. Here, again, there are two distinct accounts. According to one. being "greatly distressed by reason of the archers," he implored his armour bearer to kill him, that he might not be slain by uncircumcised Philistines, and when his armour bearer refused fell upon his own sword (1 Sam. xxxi, 1–7). The other story (2 Sam. i, 1–10) represents him as making a similar request to an Amalekite camp follower, who, unlike the armour bearer, complies. It is possible that this is a fiction on the part of the Amalekite, though the context hardly suggests such a view.

According to one estimate of the documents, the character of Saul was depreciated by Judean historians anxious to exalt David and by antimonarchists whose ideal was Samuel. Others have found in the narrative an ethical significance of perpetual value. However, Saul played a considerable part in the freeing of Israel from the Philistine yoke. Though his reign ended in the gloom of tragedy he achieved notable successes on the battlefield, and was a greater king than the existing narratives would lead us to suppose. This is borne out by the ascription to him of important victories (cf. 1 Sam, xiv, 42–51) and even more by the ancient lament irom the "book of Jashar" (2 Sam. i, 19–27), which paints the fallen king as "mighty," a warrior whose "sword returned not empty," "swifter than an eagle," "stronger than a lion," who brought good spoil to his people and whose death was to the Philistines a source oi exultation. That he maintained his position despite the popularity of David, and that his kingdom endured for a time after his death even with a weakling like his son Ishbosheth as its nominal head, point in the same direction. In short, we may discern in the scriptural narratives the figure of a brave, impulsive, superstitious man, whose contribution toward the building up oi the kingdom has been underestimated. (W. L. W.)

SAULT SAINTE MARIE, a city in Ontario! Can., and a port of entry, is on the north bank of St. Mary's river, the outlet from Lake Superior into Lake Huron, opposite the U.S. city of the same name. Pop. (1961) 43.038. Known to the French explorers from the time of Étienne Brulé, it was named Sault de Gaston early in the 17th century. The name was changed to Sault Ste. Marie ("Rapids of Saint Mary") in 1669 when a permanent mission was established by the French. The North West company established a trading post in 1783 and built a small lock to handle canoes and small boats for trading purposes, this being completed in 1797–98. The lock was destroyed by U.S. troops in the War of 1812 and rebuilt as a historical site late in the 19th century.

The growth of Sault Ste. Marie has been intimately associated with the rapids and the locks and canal around them. The present Canadian lock was built for military purposes in the late 19th century after use of U.S. locks was denied to Canadian troops sent to suppress the Riel rebellion of 1870. It was later widened to its present size: 16.8 ft. deep, 59 ft. wide and 900 ft. long. The canal itself is 1.38 mi. long.

In the middle part of the 20th century the locks and canal handled about 3,000,000 tons of shipping annually, considerably less than the U.S. system paralleling it. Cheap transportation led to the development of heavy industry. In the 1960s the Algoma steel plant, for example, had an annual capacity of more than 1,000,000 tons. Of the gainfully employed inhabitants of the city. more than half were engaged in manufacturing, and of those four-fifths were in iron and steel.

In addition, the "Soo" is a retail and wholesale centre and a notable tourist headquarters. (F. A. CK.)

SAULT SAINTE MARIE, a city of Michigan, U.S., the seat of Chippewa county and a port of entry, is located at the northeast end of the upper peninsula of Michigan on the south shore of the St. Mary's river, the connecting waterway between Lake Superior and the lower Great Lakes. A canal and four parallel locks provide a navigable channel for shipping past the rapids which mark a 20-ft. drop in elevation. Ferry service and a railroad bridge connect it with city of the same name in Ontario. It is a dairy, hay and small grain area and is the oldest settlement in Michigan. From 1917 it has had a commission-manager form of government. Its strategic location. both economically and geographically, makes the Sault a centre of government activity: the St. Rlary's Falls canal (popularly called Soo locks) is operated and maintained by the U.S. army corps of engineers; the U.S. air force maintains the Kincheloe air force base 18 mi. S. of the Sault and a radar base at the city limits; customs and immigration offices are at Sault Ste. Marie; and the U.S. coast guard has a base from which it maintains and controls navigation in the area. From 1948 the Sault branch of Michigan College of Mining and Technology has occupied buildings formerly used by historic Fort Brady, built in 1822 shortly after the United States took possession of the area. It is the centre of a summer and winter resort area with fine fishing, hunting and skiing. The manufacture of carbide and wood products provide the main industry.

The flags of three nations have flown at Sault Ste. Marie since the first white man, explorer Étienne Brulé, visited the area some time between 1615 and 1622. Jesuit missionaries are credited with naming the rapids and river Ste. Marie and are said to have introduced Christianity there. The site was a favoured residence and stopping place for Ojibwa Indians because of the great catches of whitefish that could be taken from the rapids. In 1668 Father Jacques Marquette founded a mission at Sault Ste. Marie and thereby established the first permanent white settlement in Michigan. The French took official possession of the interior of North America in a ceremony at the Sault in 1671. British occupation began in 1762. By the treaty of Paris (1783) Great Britain ceded land east of the Mississippi to the United States; however, it was not until 1820 that the C.S. flag nas raised at the Sault by Lewis Cass, governor of Michigan territory. Writings by Henry Rowe Schoolcraft (*q.v.*), first Indian agent in Sault Ste. Marie, provided source material for Longfellow's poem *Song* of *Hiawatha.*

Sault Ste Marie was incorporated as a village in 1879 and as a city in 1887. The original canal and state lock was opened in 1855.

The navigation season is limited to eight months because of severe winter conditions. Handling this lake traffic are the Poe, Davis, Sabin and MacArthur locks on the Michigan side of the St. Mary's river, and one lock on the Canadian shore. Construction of a new lock, 1,000 ft. long, on the site of the Poe lock was begun in 1961 as a part of the St. Lawrence seaway program of development on the Great Lakes. For comparative population figures *see* table in MICHIGAN: *Population* (G. A. Os.)

SAUMAREZ, JAMES SAUMAREZ (or SAUSMAREZ), BARON DE (1757–1836), English admiral, was born at St. Peter Port. Guernsey, on March 11, 1757. He entered the navy as midshipman at the age of 13. For his bravery at the attack of Charleston in 1776, on board the "Bristol," he was raised to the rank of lieutenant, and he was promoted commander for his gallant services off the Dogger Bank, hug. 5, 1781, when he was wounded. In command of the "Russell" (70 guns), he contributed to Rodney's victory over De Grasse (April 12, 1782). For the capture of "La Réunion," a French frigate, in 1793, he was knighted. He took part in the defeat of the French fleet off Lorient (June 1795), distinguished himself in the battle of Cape St. Vincent (Feb. 1797) and was present at the blockade of Cadiz (Feb. 1797–April 1798) and at the battle of the Nile, where he was wounded. On his return from Egypt he received the command of the "Caesar" (84), with orders to watch the French fleet off Brest during the winters of 1799 and 1800. Between July 6 and 12, 1801, he routed a superior combined force of French and Spanish ships at Algeciras. On the outbreak of the war with Russia in 1809 he was given command of the Baltic fleet. He held it during the wars preceding the fall of Napoleon, and his tact was conspicuously shown toward the government of Sweden at the crisis of the invasion of Russia. At the peace of 1814 he attained the rank of admiral; Charles XIII (Bernadotte) bestowed on him the grand cross of the military Order of the Sword. Saumarez was raised to the peerage in 1831, and died at Guernsey on Oct. 9, 1836.

SAUMUR, a town of western France. capital of an *arrondissement* in the *département* of Maine-et-Loire, 28 mi. S.E. of Angers on the railway to Tours. Pop. (1954) 15,528. The Saumur caves along the Loire and on both sides of the valley of the Thouet must have been occupied at a very remote period. The Tour du Tronc (9th century), the old stronghold of Saumur, served as a place of refuge for the inhabitants of the surrounding district during foreign invasions (whence perhaps the name Saumur, from *Salons Murus*) and became the nucleus of a monastery built by monks from St. Florent Le Vieil. On the same site rose the castle of Saumur 200 years later. The town fell into the hands of Foulques Nerra, duke of Anjou, in 1025, and passed in the 13th century into the possession of the kings of France. After the Reformation the town became the metropolis of Protestantism in France and the seat of a theological seminary which, as opposed to that of Sedan, represented the more liberal side of French Protestantism (Cameron, Amyraut. etc.). In 1623 the fortifications mere dismantled; and the revocation of the edict of Nantes reduced the population by more than one half. In June 1793, the town was occupied by the Vendéens, against whom it soon afterwards became a base for the republican army.

Saumur stands on the left bank of the Loire and on an island in the river. Two stone bridges unite the town on the island with the two banks of the river. The church of St. Pierre, of the 12th century, has a 17th-century façade and a Renaissance nave; and Notre-Dame of Nantilly has a remarkable façade, a doorway and choir of the 12th century, and a nave of the 11th. St. Jean is a 12th-century building in the purest Gothic style of Anjou. St. Nicolas-du-Chardonnet, 12th century Gothic, has a fine modern spire. The *hôtel* de *ville* is a 16th century building and the town has many houses of the 15th, 16th and 17th centuries, notably that known as the Maison de la Reine Cécile (15th century), built by René, duke of Xnjou. The castle was built between the 11th century and the 13th. and remodelled in the 16th. There is also an interesting almshouse, with its chambers in part dug out in the rock. The famous cavalry school of Saumur was founded in 1768. Saumur carries on a large trade in the sparkling white nines made in the neighbourhood, as well as in brandy, and it manufactures enamels and rosaries.

SAUSAGE is one of the older forms of processed food. The word is derived from the Latin *salsus,* meaning salted (and thereby preserved) meat. but mixtures of meat. blood. offal and other ingredients, encased in animal gut or other suitable materials and generally referred to as sausages, were known considerably prior to Roman times. The first authenticated reference appears in Homer's *Odyssey,* probably written about the 9th century B.C., and later Greek literature frequently mentions sausage, using the general term *oryae* or referring to specific types such as salami. Athenaeus, in the *Deipnosophistai* (*c.* A.D. 228), says: "Epicharmus mentions sausages. calling them oryae. a name by which he even entitles one of his plays. the *Orya;* this was about 500 B.C." Again: "Aristophanes says in the *Clouds* (423 B.C.): 'Let them make sausages of me and serve me up to the students.' " Salami, according to the *Deipnosophistai,* was mentioned by Eubulus in the *Lakones* and by Mnesimachus in his play the *Hippotrophos.* Since the time of Christ: sausage has been mentioned frequently in the literature of most peoples, and similar products were known to tribes such as the American Indians While the term *salsus* was used by the Romans to denote meat preserved through the use of salt. various kinds of sausage were generally popular with Romans and Greeks of all classes at the time of the Caesars. The ancient Romans were extremely fond of a sausage made of fresh pork and white pine nuts chopped fine with cumin seed: bay leaves and black pepper. So popular was this sausage that it became ritualistically identified with the Lupercalian and Floralian festivals and was condemned by the early Christian church because of this association. As a result. Constantine the Great. when he became emperor of Rome and embraced Christianity. prohibited sausage eating. This prohibition remained in effect throughout the reigns of several Christian emperors but was finally repealed because of popular protest and because of bootlegging.

Sausage making became a culinary art in the middle ages, and certain of the modern popular sausages derived their names from the cities in which they originated; *e.g.*, frankfurters (Frankfurt-on-Main, Ger.), bologna (Bologna, It.), romano (Rome), genoa salami (Genoa, It.), berliner (Berlin), gothaer (Gotha, Ger.), goteborg (Goteborg, Swed.), lyons (Lyons. Fr.), arles (Arles, Fr.). While there is no documentary proof, it has been deduced that salami may have been named for the ancient Grecian city Salamis, on the east coast of Cyprus.

Basically, all sausage is comminuted meat. although similar preparations have been made from fish and even from vegetables, and described as fish sausage, pea sausage, etc. The various types of meat sausage. of which about 200 are known to exist, differ primarily in the types of meat they contain, in their spicing and in their preparation. In general. preparation consists of the mincing. hashing or comminuting of lean meat, fat and in certain cases offal. the admixture of spices, curing salts or other ingredients, and the filling of the mixture into some form of casing. Commonly used natural casings are ox, pig or sheep gut. the diameter of which determines the size of the sausage. In some districts sausages are also filled into cloth bags which are treated with paraffin wax to prevent loss of moisture. In the U.S. the use of synthetic casings far exceeds that of natural materials. After filling, sausages may be smoked, cooked or air-dried, or treated with a combination of these processes. It is generally agreed that the main types of sausage comprise fresh, cooked, smoked; smoked and cooked, semi-dry and dry.

Fresh sausages are made from fresh meats, mainly beef and pork. sometimes with the admixture of veal or mutton. Fresh pork sausages, Bratwurst and fresh thuringer are examples of this type.

Cooked sausages are also made largely from fresh. uncured meats, although cured meats are sometimes incorporated. They are cooked after filling and smoked (if at all) after cooking. Examples include liver sausage and blood sausage.

Smoked sausages are made from cured meats and are subjected after filling to the heat and flavouring effect of wood smoke. They may subsequently be marketed uncooked (*e.g.,* smoked pork sausage. *mettwurst*), but most of these sausages are subjected to at least some degree of cooking. Sausages of this type include frankfurters. bologna, berliner and German *mortadella.*

Dry sausages may also be subdivided into various groups. depending on whether or not they are smoked before drying and on the degree to which they are dried. Essentially they are all made by comminuting the fresh meat'and other ingredients along with saltpetre, after which they are cured for two or three days. The mixture is then encased and the sausage is either cooked in a smokehouse at a high temperature prior to drying in air (cooked salami, thuringer *cervelat,* kosher salami) or is dried without smoking. Unsmoked dried sausages include Italian, Hungarian and German salamis and a wide variety of lesser-known sausages of European origin.

In Great Britain, and to a lesser extent in other countries of Europe. the pattern of sausage production follows that of the United States, more and more being produced by large factories distributing their branded goods on a nation-wide scale and less by small butchers catering for a local trade. In consequence, a considerable measure of standardization is occurring and many regional varieties of sausage are tending to disappear. Although liver sausages, black puddings (a type of blood sausage) and several types of continental sausage are produced, by far the greater bulk of sausages eaten in Great Britain are fresh pork or beef sausages.

The sale of sausages in cans is also increasing. probably stimulated by government orders for canned sausages for the feeding of the armed forces. In Great Britain, many of these canned sausages are produced by domestic firms, but there is a growing import trade.

Perhaps the most significant modern development, however, at least in the United States and Great Britain. was the development of "skinless" sausages. which met with such success that in the U.S. their consumption soon exceeded that of the traditional cased forms. In their preparation the ingredients are first filled into cellulose casings, which are tied off automatically into links. This casing is then immersed in hot and then in iced water, so that a small amount of protein from the meat is denatured and separated into a thin film immediately below the cellulose case. When this case is removed. the layer around the individual sausage links within the case prevents them from collapsing or sticking together during subsequent handling. They are sold wrapped in transparent film in packs of standard weight.

The development of skinless sausages greatly increased the demand for cellulose casings, but other synthetic casings are also growing in popularity. These artificial casings are in the main inedible. but edible casings are being prepared synthetically from derivatives of alginic acid.

Recipes for sausages are legion and are in some cases regulated to a certain extent by government legislation. Thus it is prohibited in Germany to use any binding material of a cereal or other nature. In the United States, on the other hand, the addition of up to 3.5% of cereal, starch or dried milk is permissible if declared. The British authorities allow sausages to contain considerable amounts of cereal filler. During World War II, statutory regulations were passed calling for the presence of not less than 65% meat in fresh pork sausages and not less than 50% meat in fresh beef sausages. These regulations mere rescinded in 1953, but courts tend to uphold prosecutions for adulteration on the basis of these figures.

Other additives to sausages may give rise to confusion where trade is carried out between one country and another. Thus, regulations differ concerning the use of various artificial colours and added preservatives, and of chemical emulsifying agents, such as various phosphate derivatives. which are used widely in some countries. In Great Britain, certain selected colours from a permitted list may be employed. and sulfur dioxide may be added as a preservative to the extent of 450 parts per 1,000,000. The use of phosphates is not controlled.

Of the continental European countries, Italy is generally considered to produce the greatest bulk of sausages. although Germany produces the greatest variety. Demand is especially high in Tuscany and many varieties are produced in and around Florence. but the largest producing area is centred around Bologna. Production is widespread through Germany — Frankfurt and Hamburg are particularly noted for high-class sausages. Hungary and Poland are also large sausage producing and eating countries; Switzerland and the Scandinavian countries provide their own types. Sausage production in Spain is greatest in Catalonia, the old town of Vich being noted for its sausages, which are prepared exclusively from lean pork and a small quantity of bacon, without the admixture of other meat.

Fresh pork and beef sausages, most popular in Great Britain. are prepared by chopping together selected proportions of lean meat with fat, cereal filler such as rusk; water, spices and salt, usually in a revolving bowl chopper. The mixture is then filled into hog or sheep casings or into cellulose casings for the production of skinless sausages. The sausages are linked, so many to the pound. and are usually marketed in cellulose-wrapped packages of standard weight.

In the United States, the main demand is for frankfurters, wieners and Vienna-type sausages, which are used in enormous quantities for the production of hot dogs. These are made to an almost identical formula. consisting of about 60% cured beef and 40% cured pork spiced nith nhite pepper, sugar. cloves coriander and nutmeg. The chopped mixture is filled into natural casings and is then smoked in hardwood smoke and cooked in steam or water. Frankfurters and Vienna sausages of varying composition are also made in several European countries. Bologna is made in the United States with a similar meat content, spiced with black pepper, cloves, coriander and ginger. It is filled into large beef or artificial casings and smoked and cooked before sale. Similar products are made in various European countries. Polony is a corruption of bologna, which it resembles.

Salamis consist mainly of cured lean pork, coarsely chopped. and some cured lean beef, finely chopped. The meats are moistened with red wine, flavoured with various spices and stuffed into large casings before being air dried. for from two to three weeks. Some types are also smoked for long periods. Savaloys are short thick sausages originally compounded of pigs' brains, the word being a corruption of the French *cervelet.* The name is applied to a type of highly seasoned and dried pork sausage. sufficiently cooked for it to keep a considerable time. *Cervelats,* a name presumably derived from the same source, are produced in several countries, including Switzerland and Sweden. They are generally compounded from about equal mixtures of cured pork and beef and are usually less highly spiced than salamis.

Liver sausages are made in virtually all countries, from finely ground fat pork and liver, along with spices and onions or other flavourings. Haggis (*q.v.*), the national dish of Scotland, is in essence a sausage (rarely looked upon as such). (J. I. A.)

SAUSSURE, FERDINAND DE (1857–1913), Swiss linguist, one of the most influential linguists of modern times, was born on Nov. 26, 1857, at Geneva. the scion of a family of scientists and writers. He studied at the universities of Geneva. Leipzig and Berlin, and obtained a doctorate at Leipzig in 1880. From 1881 to 1891 he was instructor at the *Ecole des Hautes Études* in Paris; from 1901 to 1913 he was professor of Indo-European linguistics and Sanskrit, from 1907 to 1913 also professor of general linguistics at the University of Geneva. Saussure attained his eminent position not through published works but through the school of linguistics he founded and the excellence of his disciples. The only book from his own pen was written when he was 21 years old: *Mémoire sur le système primitif des voyelles dans les langues indo-européennes* (Paris: 1878). But the most important work under his name. *Cours de linguistique générale* (2nd ed., 1922), is a collection of lectures published posthumously by his students. Saussure's principal tenet was that language is, and must be dealt with as, a social phenomenon. a structured system of signs that can be viewed descriptively (synchronically'i and historically (diachronically). The systematic structure *(langue)* is realized and becomes manifest in actual speech events *(parole)*— *a* dichotomy that has proved extremely useful and fruitful. His own Geneva school, the French and the Prague schools of linguistics, and particularly the structuralists everywhere, owe much to Saussure. He died on Feb. 22, 1913, at Geneva. (E. PM.)

SAUSSURE, HORACE BÉNÉDICT DE (1740–1799), Swiss physicist, known principally for his studies of the Alps, was born at Geneva on Feb. 17, 1740. From 1762 to 1786 he taught at the academy of Geneva. His early devotion to botanical studies led him to undertake numerous journeys in the Alps, and from 1773 onward he devoted much of his time to the study of that area. His interests included geology, physics and chemistry also.

In meteorology. the field of study in which he made the greatest contribution, he carefully investigated atmospheric humidity and developed the hair hygrometer. an instrument for measuring humidity. Descriptions of seven of his Alpine journeys were published in *Voyages dans les Alpes* (1779–96). De Saussure was elected a fellow of the Royal society and in 1772 founded at Geneva the Society for the Advancement of the Arts. He died in Geneva on Jan. 22. 1799.

SAUVEUR, ALBERT (1863–1939), U.S. metallurgist and teacher. who prior to 1900 developed methods of improving the quality of steel through studies of the crystal structure of metals. He pioneered the technique of photomicrographs in the late 1800s to further his studies of metal microstructures. Sauveur's work in the heat treatment of metal is still a scientific landmark. Born in Louvain. Belg., June 21, 1863. of French parentage, Sauveur received his early education in Europe and graduated from the Massachusetts Institute of Technology, Cambridge, in 1889. After a period of work as a chemist and metallurgist, he left industry in 1899 for Harvard university as an instructor. In 1905 he became a professor of metallurgy and in 1924 he was appointed the Gordon McKay professor of mining and metallurgy at the university. From 1898 to 1903 Sauveur was editor of *Metallographist,* and in the period 1903–06 he served as editor of *Iron and Steel Age.* He received many medals and honorary degrees from U.S. and European societies and universities. The Legion of Honour of France and the French Academy both elected him an officer. A national award established in 1934 by the American Society for Metals bears his name. Sauveur served the French and U.S. governments in World War I as a metals consultant, and in 1925 he was a U S. delegate to the Pan-American Scientific congress in Lima, Peru. He died in Boston, Mass., Jan. 26. 1939. (R. T. B.)

SAVAGE, RICHARD (d. 1743), English poet, was born about 1697. probably of humble parentage. A romantic account of his origin and early life, for which he supplied the material, appeared in Curll's *Poetical Register* in 1719. On this and other information provided by Savage, Samuel Johnson founded his *Life of Savage,* one of the most elaborate of the *Lives.* It was printed anonymously in 1744, and made the poet the object of an interest which would be hardly justified by his writings. In 1698 Charles Gerrard. 2nd earl of Macclesfield, obtained a divorce from his wife, Anna. daughter of Sir Richard Mason, who shortly afterward married Col. Henry Brett. Lady Macclesfield had two children by Richard Savage. 4th earl Rivers, the second of whom was born at Fox Court, Holborn, on Jan. 16, 1697, and christened two days later at St. Andrews, Holborn, as Richard Smith. Six months later the child was placed with Anne Portlock in Covent Garden; nothing more is positively knonn of him. In 1718 Savage claimed to be this child. His statements were suspicious, and Mrs. Brett maintained that he was an impostor. The matter was thoroughly investigated for the first time by W. Moy Thomas, who published the results of his researches in *Notes and Queries* (second series, vol. vi. 1858). Savage, impostor or not. blackmailed Mrs. Brett and her family with some success, for after the publication of *The Bastard* (1728), her nephew John Brownlow, Viscount Tyrconnel, purchased his silence by taking him into his house and allowing him a pension of £200 a year. Savage wrote tno successful plays: *Love in a Veil* (1718), adapted from the Spanish, and *Sir Thomas Overbury* (1724). *Miscellaneous Poems* was published by subscription in 1726. In 1727 he was arrested for the murder of James Sinclair, and only escaped the death penalty by the intercession of Frances, countess of Hertford (d. 1754).

Savage was at his best as a satirist, and in *The Author to be Let* he published a quantity of scandal about his fellow scribblers. Proud as he was, he was servile enough to supply Pope with petty gossip about the authors attacked in the *Dunciad.* His most considerable poem. *The Wanderer* (1729), shows the influence of Thomson's *Seasons,* part of which had already appeared. Savage tried without success to obtain patronage from Walpole, and hoped in vain to be made poet laureate. In 1732 Queen Caroline settled on him a pension of £50 a year. Meanwhile he had quarreled with Lord Tyrconnel, and at the queen's death was reduced to absolute poverty. Pope had been the most faithful of his friends, and had made him a small regular allowance. With others he now raised money to send him out of reach of his creditors. Savage went to Swansea, but he resented bitterly the conditions imposed by his patrons, and removed to Bristol, where he was imprisoned for debt. All his friends had ceased to help him except Pope, and in 1743 he, too, wrote to break off the connection. Savage died in prison Aug. 1, 1743.

See Johnson's *Life of Savage,* and *Notes and Queries* as already quoted He is the subject of a novel, *Rtchard Savage* (1842), *by* Charles Whitehead, illustrated by John Leech. *Richard Savage,* a play in four acts by J. M. Rarrie and H. B. Marriott-Watson, was presented at the Criterion theatre, London, in 1891. The dramatists took considerable liberties with the facts of Savage's career. *See* also S. V. Makower, *Richard Savage, a Mystery in Biography (1909).*

SAVANNA or **SAVANNAH,** originally a meadowland or large, grassy, treeless tract, but now also including level areas with tall grasses and isolated clumps of trees. as in Nigeria, where the more appropriate name would be park savanna. It has also been commonly applied to the grassy plains south of the centre of North America, and is there the equivalent of prairie (*q.v.*).

SAVANNAH, the leading seaport in Georgia, U.S.. is situated at the mouth of the Savannah river on an elevation of 42 ft., 18 mi. W. of the Atlantic coast; it is 260 mi. S.E. of Atlanta and 140 mi. S. of Columbia, S.C. The city was laid out by James Oglethorpe according to plans drawn in England, with rectilinear streets crossing at right angles, the plat being symmetrical with numerous squares reserved for public parks. These parks, studded with semitropical trees and flowers and surrounded with Georgian colonial and Greek revival buildings, give the city an atmosphere of tranquility and grace. It exceeds all Georgia cities in historical interest and it is a leading tourist and recreation centre. It is also a city of commercial and industrial importance. Pop. (1960) city 149,245; standard metropolitan statistical area (Chatham county) 188,299. (For comparative population figures for the city see table in GEORGIA: *Population.*)

History.— The original Georgia settlement in 1733. Savannah was the seat of colonial government and remained the capital of the commonwealth until 1786, although sharing this distinction with Augusta after 1778 (see also GEORGIA: History). Among the early residents were the brothers John and Charles Wesley, who came in 1736, John as a representative of the Society for the Propagation of the Gospel, Charles as secretary to Oglethorpe. Charles Wesley stayed only a few months; John Wesley remained until 1738. The evangelist George Whitefield visited the settlement for the first time in 1738 and several times thereafter; he founded in Savannah the Bethesda orphanage (later burned).

As early as 1744 there was established at Savannah an exporting and importing firm engaging in coastwise traffic and by 1750 the port was clearing vessels directly to Europe. Lumber products, sago powder, rice, indigo, beef, pork, animal skins, tar and turpentine were its early exports. In 1769 Savannah merchants condemned the British acts of trade and adopted nonimportation agreements but its revolutionary sentiment was comparatively moderate. During the American Revolution the town remained only briefly in rebel hands, being occupied by loyalist forces from 1778 to near the end of the conflict. After the war Gen. Nathanael Greene, who is buried in the city, settled on an estate, 14 mi. N. of Savannah, granted him by the state of Georgia. It was while visiting the Greene family there in 1793 that Eli Whitney invented the cotton gin. There was a devastating fire in the city in 1796, and in 1820 another fire coupled with a yellow-fever epidemic destroyed considerable life and property. Cholera swept the city in 1834 and hit the slave population severely.

In the meantime the importance of the port was increasing, partly as a result of improved transportation in the hinterland. The town's early means of contact with other communities was provided by rivers and coastal waters, but by the end of the 18th century a network of roads connected it with points in the back country. The "Savannah," the first steamboat to cross the Atlantic, sailed from Savannah for Liverpool in 1819. Commercial rivalry with Charleston and Augusta caused Savannah citizens to promote a railroad, known as the Central of Georgia, which was completed to Macon in 1843. By 1860 the Atlantic and Gulf railroad connected Savannah with points in southern Georgia. The city's commerce suffered during the Civil War as a result of the Union blockade but the city was not captured until late in 1864, when it became the objective of Gen. W. T. Sherman's march to the sea. The city was occupied by Federal troops on Dec. 21, 1864.

After the Civil War Savannah recovered fairly rapidly in spite of a yellow-fever epidemic in 1876. It remained the largest urban centre in Georgia until it was surpassed by Atlanta in 1880. Savannah's history in the 20th century is largely its increasing industrialization and its increasing importance as a maritime centre. It has a council-manager form of government, in effect since 1954.

Population Characteristics.— Both the city of Savannah and its metropolitan area increased in population during the middle part of the 20th century. the rate of increase between 1950 and 1960 being 23.2% in the city and 22.9% in the metropolitan area. The population of the city in 1960 was 35.7% native-born white, 1.4% foreign-born white and 62.9% nonwhite. Although the percentage of foreign-born residents is low, in the past it has been the highest in Georgia. In 1870, for example, the foreign-born comprised 24.2% of the white population. Among the foreign-born the Irish have predominated.

Commerce, Industry and Transportation.— In the latter part of the 20th century manufacturing was the leading occupation but wholesale and retail trade ranked a close second, with public utilities, including transportation and communication, being third. Professional and related services ranked next. Less than 1% of the people of the county were engaged in farming.

The city is served by railroads and state and federal highway systems, with bridges spanning the Savannah river and other water barriers in the vicinity. It has two airports and about 1,500 vessels enter the port of Savannah annually. Piers, docks, wharves and storage warehouses are located along the west side of the Savannah river. Savannah is the leading manufacturing port city between Baltimore and New Orleans. its industry including over 300 processing firms: the principal operations being pulp and paper, sugar refining, packaging. shipbuilding and repair. building materials (including felt, asphalt and roofing). fertilizers, castings and chemicals. The Hunter air force base. a permanent installation of the strategic air command, is located near the city, and within 40 mi. are two other military installations, the marine corps recruit depot at Parris Island. S.C.. and Ft. Stewart, a C.S. army antiaircraft and tank training centre.

Education and Cultural Activities.— Savannah was the earliest centre of artistic and cultural interest in Georgia. In 1801 a library society was established there. followed shortly by a theatre which brought to the community the outstanding productions of the times. The Telfair Academy of Arts and Sciences, a museum of permanent collections of all phases of art, was founded in the city in 1875. The community has several public libraries, a symphony orchestra, a little theatre, an annual camellia show and other similar attractions. Located in the heart of the city are Armstrong Junior college and the Savannah State college, both units of the university system of Georgia (see GEORGIA: *Education*). A Savannah woman, Juliette Gordon Low (1860–1927). is considered the founder of the Girl Scout movement in the U.S.; a number of places of interest in this connection are marked in the city. (Js. C. B.)

SAVANNAH RIVER, rising in northwest South Carolina, U.S., is formed 8 mi. N.W. of Hartwell, Ga.. by the confluence of the Tugaloo and Seneca rivers and serves as a natural boundary between Georgia and South Carolina. Its course is southeastward past Augusta and Savannah, Ga., to the Atlantic, a distance of 314 mi. North of Augusta the Savannah is fed by the Broad and Little rivers and south of Augusta by Brier creek. It is navigable for barge traffic from its mouth on the Atlantic to Augusta. 212 mi. upstream. The river is used extensively for hydroelectric power. The Hartwell dam near Augusta, scheduled for completion in 1963. was planned to provide the major upstream impoundment of the Savannah for hydroelectric, flood control and navigation purposes. There are three other dams near Augusta; the largest of these, Clark Hill dam, is 230 ft. high and 5,660 ft. long. The U.S. Atomic Energy commission's Savannah River plant is in Aiken and Barnwell counties in South Carolina, across the river from Augusta. Clark Hill provides power for the Atomic Energy plant and the river serves as a coolant for plant processes. Savannah. 17 mi. upstream from the mouth of the river, was the centre for James Edward Oglethorpe's initial Georgia colony. Deep-draft navigation by ocean vessels extends 5 mi. upstream beyond the city. At Savannah are one of the world's largest naval stores markets, large state-owned docks operated by the Georgia ports authority and a large refinery for processing sugar imported from the Caribbean. Union Bag–Camp Paper company's plant, near Savannah, is a large integrated pulp-paper plant, its capacity in the early 1960s being 1,900 tons of paper products daily. Many of the former rice and cotton plantations along the lower Savannah river are large producers of pulp wood. (M. C. P.)

SAVARY, ANNE JEAN MARIE RENÉ, Duke of Rovigo (1774–1833), French general and diplomatist, was born at Marcq in the Ardennes on April 26, 1774. He was educated at the college of St. Louis at Metz and entered the royal army in 1790.

After Marengo Napoleon Bonaparte gave him command of the gendarmes charged with the duty of guarding the first consul. In the discovery of the various ramifications of the Cadoudal-Pichegru conspiracy, Savary showed great skill and activity. He was in command of the troops at Vincennes when the duc d'Enghien (*q.v.*) was executed. In Feb. 1805 he became general of division. Shortly before the battle of Austerlitz (Dec. 2, 1805) he was sent by Napoleon with a message to the emperor Alexander I with a request for an armistice, a device which precipitated the attack which brought disaster to the Russians. After the battle Savary again took a message to Alexander, which induced him to treat for an armistice.

In the campaign of 1806 Savary showed signal daring in the pursuit of the Prussians after the battle of Jena. Early in the next year he received command of a corps, and gained a success at Ostrolenka (Feb. 16, 1807).

After the treaty of Tilsit (July 7, 1807) Savary proceeded to St. Petersburg as ambassador, but was soon replaced. Napoleon needed him in Madrid. With the title of duke of Rovigo, Savary set out for Spain. With Joachim Murat Savary made skilful use of the schisms in the Spanish royal family, and persuaded Charles IV, who had recently abdicated under duress, and his son Ferdinand VII, to refer their claims to Napoleon. Savary induced Ferdinand to cross the Pyrenees and proceed to Bayonne—a step which cost him his crown and his liberty until 1814. In Sept. 1808 Savary accompanied the emperor to the interview at Erfurt with the emperor Alexander. On the disgrace of Joseph Fouché (*q.v.*) in the spring of 1810, Savary received his appointment, the ministry of police. This office now became a veritable inquisition. Savary was among the last to desert the emperor at the time of his abdication (April 11, 1814) and among the first to welcome his return in 1815, when he became inspector general of gendarmerie and a peer of France.

After Waterloo Savary accompanied the emperor to Rochefort and sailed with him to Plymouth. He was not allowed to accompany him to St. Helena, but underwent several months' "internment" at Malta. Finally he was allowed to return to France and regained civic rights. The July revolution (1830) brought him into favour, and in 1831 he received the command of the French army in Algeria. He died at Paris in June 1833.

SAVE or Sava, a river of Yugoslavia and an affluent of the Danube. The Save rises in the Triglav group in Carniola from the Sava Bohinjka and the Sava Dolinka, which join at Radovljica. It then flows through Carniola and Croatia-Slavonia and joins the Danube at Belgrade. The Save has a length of 584 mi., the area of its basin being 36.957 sq.mi. It is navigable for river steamers from Sisak to its mouth. (*See* Danube.)

SAVERNAKE FOREST is a great beech wood covering 5,000 ac. on the chalk downs just south of the market town of Marlborough in Wiltshire, Eng.

From the Norman conquest until 1550 Savernake was a crown forest and a royal hunting ground extending over 20 sq.mi.; later it passed into private ownership. The ancient hereditary office of warden was held from 1083 to 1427 by the Esturmys, and later by the earl of Cardigan, their lineal descendant.

The finest scenic feature is the Grand avenue of lofty beeches which runs for 3 mi. from the main London-Bath road to Tottenham house. The forestry commission assumed responsibility for administering the woodlands. (H. L. En.; X.)

SAVIGNY, FRIEDRICH KARL VON (1779–1861), German legal scholar, one of the originators of the influential historical school of jurisprudence, was born in Frankfurt am Main Feb. 21, 1779. In Savigny's classic words, law "is first developed by custom and popular faith. next by judicial decisions—everywhere. therefore. by internal silently operating powers: not by the arbitrary will of a law-giver." Savigny became a doctor of law at the University of Marburg in 1800 and was one of the first members of the German nobility to teach in a university. He subsequently taught criminal law, Roman law and its history and property and contract law at Marburg and Landshut but spent most of his academic career (1810–42) at the University of Berlin. In 1803 his book on possession, *Das Recht des Besitzes*, was published. Soon thereafter he turned to the historical and jurisprudential interests that dominated the remainder of his career.

The immediate occasion that led him in that direction was the publication of a book, *Civilistiche Abhandlungen*, in 1814, by Anton Thibaut, a professor at Heidelberg, who demanded immediate codification of German law. Thibaut's book reflected the rise of German nationalism after the Napoleonic wars and a reaction against Roman and other foreign law. Savigny vigorously opposed codification in a monograph, *Vom Beruf unserer Zeit fur Gesetzgebung und Rechtswissenschaft* (1814), which gave much impetus to the emerging historical theory of law. Historical jurisprudence viewed law as a slow, almost imperceptible growth. like language.

This jurisprudential perspective was a phase of the romantic movement, which had begun in the latter part of the 18th century, and it took the form in Germany of a movement back to the simplest tribal origins of the German people, to their folk songs and tales and to their distinctive ethos, their *Volksgeist* ("national spirit"). The movement found expression in the philosophy of Johann Gottfried von Herder, the fairy tales of the Grimm brothers and Barthold Niebuhr's Roman history. The national spirit was the ultimate datum to be explored in its various manifestations. From this point of view law is not something that can be made but originates in the unique spirit of the people and is expressed spontaneously in custom and, much later, in the formal decisions of the judges. Accordingly, legislation and codes can, at most, give only verbal expression to existing law the actuality and meaning of which can be discovered by careful historical investigations. Thus, historical jurisprudence opposed not only codification but also natural-law philosophy as illusory and fictitious. Instead of assuming that familiar law was "universal," as Savigny charged was done in natural-law philosophy, historical jurisprudence insisted on thorough research into legal origins and transformations.

While the philosophy of historical jurisprudence was in the 20th century perverted by the Nazis in their glorification of the German *Volk*, it is certain that Savigny would have thoroughly disapproved of racist interpretations. He was a pioneering legal scientist who made lasting contributions to jurisprudence, especially in revealing the continuity of present legal institutions with past ones; in laying the foundations of legal sociology; and in articulating the methods of historical research. These contributions greatly influenced all the social disciplines. (*See* also Jurisprudence, Comparative.)

In 1815, shortly after the appearance of his epochal book, Savigny, Karl Friedrich Eichhorn and Johann Friedrich Ludwig Goschen founded the *Zeitschrift fur geschicktliche Rechtswissenschaft* as the organ of the new historical school. In 1815 also, the first volume of his six-volume treatise on medieval Roman law, *Geschichte des romischen Rechts im Mittelalter*, appeared, the last of which was published in 18.31.

Savigny then devoted himself to an elaborate treatise on modem Roman lam, *System des heutigen romischen Rechts* (8 vol., 1840–49), which contains his theory of private international law and his further study on possession and error. In March 1842 he was appointed high chancellor of Prussia by Frederick William IV and, after carrying out several important reforms especially in regard to bills of exchange and divorce, he resigned in 1848. In 1850 appeared his collected minor works, *Vermischte Schriften*, in 5 volumes, and in 1851–53 he published a book in 2 volumes on contracts *(Das Obligationenrecht)*, a supplement to his work on modern Roman law.

Savigny died in Berlin on Oct. 25, 1861.

SAVILE, SIR HENRY (1549–1622), warden of Merton college. Oxford, and provost of Eton, was the son of Henry Savile of Bradley, near Halifax, in Yorkshire. He was educated at Brasenose college, Oxford, where he matriculated in 1561 He became a fellow of Merton in 1565, proceeded B.A. in 1566 and M.A. in 1570. He established a reputation as a Greek scholar and mathematician by voluntary lectures on the *Almagest* and in 1575 became junior proctor. In 1578 he traveled on the continent of Europe, where he collected manuscripts. On his return he was named Greek tutor to the queen and in 1535 was established as warden of Merton. He proved a successful and autocratic head under whom the college flourished. A translation of four Books of the Histories of Tacitus, with a learned *Commentary* on *Roman Warfare* in 1591, enhanced his reputation. On May 26. 1596, he obtained the provostship of Eton, the reward of persistent begging. In Feb. 1601 he was put under arrest on suspicion of having been concerned in the rebellion of the earl of Essex. He was soon released and his friendship with the faction of Essex brought him the favour of James 1.

In 1604 Savile was knighted and in that year he was named one of the body of scholars appointed to prepare the authorized version of the Bible He was entrusted with parts of the Gospels, the Acts of the Apostles and the Book of Revelation. His edition of Chrysostom (8 vol., fol. 1610–13) was printed by the king's printer, William Norton, in a private press erected at the expense of Sir Henry, who imported the type. At the same press he published an edition of the *Cyropaediu* in 1618. In 1619 he founded and endowed the Savilian professorships of geometry and astronomy at Oxford. He died at Eton on Feb 19, 1622.

SAVINGS, NATIONAL. Saving means the setting aside for future use of part of current income—the excess over the amount currently consumed or paid in taxes. Saving may thus be performed by anybody having an income—by an individual, a family or by a business firm.

Because of disagreement as to the sense in which a government body has an income, there is some difference of opinion among economists as to whether or not it is appropriate to say that governments (as distinct from the citizens and businesses under their jurisdiction) carry on saving. Rut whether or not the government is said to save, the nation may he said to save the sum of the amounts saved by the individuals and business firms (plus government bodies if they are considered to have savings) which it includes. Since there are always some individuals and businesses whose current expenses and taxes outrun their incomes. and whose savings are therefore negative, national savings must be thought of as a net total with negative savings subtracted.

Forms Taken by Savings.—Saving is often spoken of loosely as if it mere synonymous with the piling up of savings deposits. or of idle cash. This interpretation is misleading. While it is true by definition that savings are not spent on the consumption of the saver, it does not follow that they are not spent at all; what is saved often is spent. It may be spent directly by the saver or indirectly by business firms he helps to finance, on the purchase of new items being added to the community's stock of wealth, such as new houses or machinery. It may be spent indirectly on the consumption of some other person who borrows or sells property to finance his negative savings. It may help to finance a government deficit, thus supporting whatever spending the government is carrying on, whether for battleships. highways, food to feed the hungry or for routine government expenses.

Part of current savings—sometimes a small part, sometimes a large part—appears in the form of increase in savings deposits and other cash assets held by the individuals or business firms doing the saving. The remainder is represented in their accounts by additions to their holdings of physical property, acquisition of government or private securities, reduction of their debts owed to others, etc.

Savings and Investment.—Under the generally accepted use of terms. it will always be found at the end of any accounting period thst if the revenues and expenditures of government are equal (the budget balanced) and if all government expenditures are on current account, national savings for the period amount to just as much as investment in new buildings, equipment, etc. This is a matter of definition. Saving means the excess of national income over consumption and taxes. Investment is taken to mean the excess of net national product (which is the same thing as national income) over the parts of the product made up of consumption goods and services and items bought by government expenditures.

Since economic progress depends largely on the increase of wealth through investment, it follows also that economic progress is linked with the achievement of national savings. Some increase in production might be possible without any net national savings. through increasing the labour force, finding new ways to use existing equipment and labour. and replscing old equipment and buildings as they wear out *(see* DEPRECIATION) with more modern types.

But to make full use both of the growing labour force and of new methods of production requires a net increase of plant. equipment, etc.; besides this there is always a backlog of opportunities to increase production. with pre-existing methods and labour force, for which more equipment would have been required.

The need of investment and savings to increase production is of course most acute in countries where modern technology has not yet been put into operation and in devastated areas where houses, workshops, transportation equipment, etc., have been destroyed.

This is the meaning of the much-misunderstood doctrine of "abstinence": if there is to be an increase of productive wealth, somewhere in the economic system somebody must abstain from consuming his entire income. It does not necessarily follow that those who abstain from consuming are suffering. On the contrary, insofar as saving is left to individuals. it is performed chiefly by persons with high incomes who both save heavily and consume considerably more than the average.

But for the community as a whole it is impossible both to consume the whole of current income and to build up productive wealth.

It should be observed that these propositions do not prove that economic progress either will or will not be served by an increased inclination to thrift on the part of individuals and business firms. Progress depends on the achievement of substantial investment and therefore of substantial savings. But as John Maynard Keynes pointed out, decisions to save and decisions to invest are taken by different persons operating under different incentives. A decision by one individual to save more, unaccompanied by a decision by him or anybody else to invest more. cannot be guaranteed to increase the volume of saving and investment actually realized; in fact, many economists argue that the effect would be to decrease that volume. This point will be examined further below.

Effect of Government on Savings-Investment Relation.—If the government's revenues and expenditures are unequal, the relation of savings to investment just described is modified. In a period of depression, for example. the tax base shrinks and reduces revenue. while the addition of relief, etc.. to government responsibility increases expenditure. Government is therefore obliged to finance its expenditures in part either by borrowing, by paying out cash on hand or by issuing money. Some savers, consequently. either use their savings to buy government securities. or hold more cash, or have larger balances with banks and other credit institutions while the latter have more cash and government securities. The same is true when a government deficit is incurred for war purposes.

In these circumstances it is no longer true that the net total of savings made by individuals and businesses is equal to the net total invested by individuals and businesses in new productive wealth. Private savings exceed private investment by the amount of the deficit Whether national savings are said to exceed national investment is a matter of language. Some part of government expenditure (used to pay for productive wealth such as hydroelectric dams, roads, needed buildings, recreation facilities) can reasonably be described as investment. Any excess of the deficit over such government investment can be described as negative saving by government, reducing the net total of national savings. This way of using language has the advantage of stressing the fact that when government savings are positive (*i.e.*, when government has an excess of revenue over current expenses, the excess serving to reduce government's net debt and to finance government investment) there can be an increase of the nation's productive wealth in the absence of private saving. It has the drawback, however, of inviting dispute as to the scope and measurement of government activity to be classified as investment (particularly in time of war) and leaving statistical measurements of national savings with a much wider range of possible error than measurements of private savings. See also INVESTMENT, ECONOMIC ASPECTS OF; INVESTMENTS: INDIVIDUAL.

Ways of Estimating Savings.—For an individual there are two ways to measure his savings for a given accounting period. One is to estimate his income and subtract his current expenditure: the difference being his savings. The alternative is to examine his balance sheet (his property and his debtsj at the beginning and end of the period and measure the increase in net worth which reflects his saving. While the figures taken out of the individual's accounts under these two procedures are different, the two are logically equivalent. In either case it is necessary to make sure that we do not include in income (or in the increase of net worth) any items which reflect merely changes in price levels at which pieces of property are valued, or items reflecting events not regarded as linked with income—broadly speaking.. to exclude capital gains and losses (whether realized or "paper") from income. For example, losses due to property destruction by enemy action in wartime, or gains due to a rise of prices on the stock market, would be excluded in income determination. If income is measured by the rules generally adopted by national income statisticians, the result is to exclude not merely the effects of price changes but some actual physical changes—chiefly losses —in wealth. The net total of savings estimated in this way tends to exceed the value of additions to the nation's stock of wealth to the extent that war damage, uninsured fire losses and similar events fail to appear in the income account. On the other hand, it tends to fall short to the extent that new wealth is found (for example through mineral discoveries) or that wealth becomes more useful through new techniques (for example, through the development of dry farming techniques which made previously worthless land take on value).

For national totals, estimates based on changes in national wealth would be too unreliable for use because of the inaccuracy of the reports on which wealth statistics are based. the extraordinary difficulty of allowances for price changes, and other drawbacks. But the general principles just described suggest three other ways of estimating national savings: (1) by estimating investment, with adjustments for government; (2) by estimating income of individuals, personal taxes paid, and consumption expenditures to give savings of individuals by subtraction, with separate estimates for savings of business corporations and of government bodies; and (3) by estimating changes in the various asset and liability accounts of individuals which reflect current savings. with separate estimates for the savings of business corporations and of government bodies. All these methods are in practical use.

War Savings.—Savings under war conditions follow different patterns than in peace. Individuals and businesses set aside a larger proportion of their incomes: so that net private savings grow enormously. On the other hand, private investment is restricted because war needs divert labour and materials from making buildings and equipment for private use. Public construction and acquisition of equipment by government expands, but most of the resulting facilities are either used up in the war or are inconvertible to civilian uses thereafter. The consequence is a great growth in the paper wealth of individuals and business firms (corresponding to the growth of the government's debt) with little or no growth in actual productive wealth.

Not much precise information is available about savings during World War I. Interwar studies reveal that individuals and business firms saved in 1919 a much larger proportion of income than in any year in the 1920s. and that savings in 1920, though declining, were still high. For World War II, comparatively reliable studies made at the time show that the proportion of income saved rose well above peacetime levels during 1941 and continued to rise thereafter. At the peak of war activity, individuals were saving nearly one-third of their disposable incomes (*i.e.*, income payments less personal taxes), and corporations well over one-half of theirs.

The total wartime accumulation by individuals amounted to far more than the income of any single year of the interwar period, and the great bulk took the form of additional currency, bank deposits, government securities and claims upon life insurance companies.

It is probable that the savings of the richer groups of the population made up a much smaller proportion of the war savings than of peacetime savings, bdt the difference must not be exaggerated. About half of the wartime accumulation of individuals and corporations was accounted for by the growth in their holdings of government bonds—more than two-thirds in denominations of $500 and upward—which were not to any great extent small savings. The proportion of the growth in ,bank deposits, currency and insurance claims representing large savers was probably still higher.

Motives for Saving.—Saving is a very complex phenomenon. Different savers save for different reasons, and a given saver for a mixture of reasons. At any given moment: furthermore, many individuals find themselves spending less or more than their incomes simply because their incomes are more or less than was expected when commitments to spend were made. This is true especially for farmers and self-employed business and professional men whose incomes are subject to unexpected fluctuations.

Insofar as saving goes back to decisions to save, the main motives seem to be the following: (1) provision for a future period when income is expected to be less or the need for expenditure greater than at present—for example, provision for retirement, education or vacations; (2) provision against unpredictable decline in income or growth in need—for example, against sickness in the family or loss of earning power by the breadwinner; (3) acquisition of higher income, either by improving the equipment, etc., of a business, or by being housed better or at less expense, or by obtaining interest, dividends, rent or other property income; (4) gain in social status through acquiring property; or (5) direct subjective satisfaction from accumulation ("miser's" instinct). Pulling against these motives, of course, is the desirability of current consumption, and the desirability of having more leisure at the expense of potential income.

This hypothesis about the motives for saving explains the record fairly well. High-income individuals have greater incentives to save than ion-income individuals, for example, because the former are: (1) a group many of whose members are enjoying temporary increase of income and must expect a drop later on; (2) have better opportunities to place savings where they will yield income; (3) are more able to gain power and social approbation by saving and (4) are less hard-pressed to maintain what they regard as necessary standards of consumption and of leisure. Rural people are more inclined to save than urban people of like income because: (1) their incomes are more uncertain; (2) their opportunities to gain income from saving are better and the fruits of their savings, in buildings, livestock, equipment, etc., are. more visible and thus more conducive to improved social standing and direct enjoyment and (3) their standards of consumption and of leisure are less exacting. War savings are higher than peacetime savings because: (1) incomes are regarded as abnormaiiy high and are above immediately previous levels; (2) ordinary outlets for negative savings (retirement of elderly people, education, prolonged vacations and medical treatments) are reduced; (3) incomes are less secure; (4) social pressures to save are intensified and (5) normal standards of consumption and leisure are suspended. The fact that the rising trend of real per capita income did not bring a rising trend in the proportion saved in the prewar and interwar period is explained by: (1) progressive urbanization; (2) rising standards of consumption and leisure; (3) the trend away from private houses and away from direct ownership by individuals of tangible business property (which reduces both opportunities to gain income and opportunities to gain social status and direct satisfaction by increase of property); (4) the downward drift in interest rates and (5) increased importance of some sources of negative savings (in particular the increased stress upon higher education and the increased proportion in the population of elderly people who tend to live on past savings).

SAVINGS AND LOAN ASSOCIATION, a co-operative savings institution of the type originally established to make loans to members for the purchase of homes. Such associations are also known in the United States as building and loan associations, co-operative banks, homestead societies, building societies and savings associations. The identifying labels nhich promise to become most common are savings and loan associations in the United States and building societies in Great Britain.

UNITED STATES

The modern savings and loan association in the United States resembles a bank, but is differently constituted. The savers purchase shares of stock and are thus owners of the association! not depositors. They receive dividends on their shares in proportion to the profits of the organization. The association is pledged to repurchase the shares bought by savers, after reasonable notice, but invests most of its funds in long-term mortgages. These features have characterized U.S. associations since their origin and have made them highly successful in home mortgage financing. By the early 1960s savings and loan associations held about 38% of the mortgage debt on nonfarm homes in the United States.

Origins and Development. — Savings and credit institutions for noncommercial groups developed in the United States in the first half of the 19th century. The savings and loan associations were, at first, informally organized groups of neighbours or of men in the same industry who pooled their savings to purchase homes. Though there were many plans for saving and borrowing, a common pattern was followed. Each member was committed to make regular payments to a fund. A member could borrow from the fund to purchase a home. His share and his home were the collateral for the loan. The borrowing member would continue his regular payments to the fund and also make interest payments. Both savers and borrowers were penalized by fines and forfeitures if they did not maintain regular payments. The association was not a permanent institution but was created for the period necessary to enable each of the members in turn to purchase homes. By the end of the 19th century these small neighbourly associations were replaced by permanent institutions which had members who were not saving to purchase homes and borrowers who were not members of the association before making their loans.

Savers and Owners. — Associations in the United States may be chartered by the federal or state governments. All federally chartered associations are mutually owned; every saving member is an owner and can vote for the selection of the management. State chartered associations may be mutual or stock associations. If they are stock associations, the savers receive investment certificates which do not carry the right to vote or to claim the residual profits of the association. In all cases the savers are not depositors; as noted above, they do not stand in the same relation to the association as does a saver in a bank. The depositor in the bank is a creditor of the bank; the saver in an association has an ownership right or investment. In practice, since the associations must compete for savings with other institutions, withdrawal requests are usually honoured promptly.

The formal difference of ownership shares as against deposits is of importance. The associations can be less liquid than banks; *i.e.*, more of the assets of the associations can go into long term investments since they are not required to meet every unexpected demand by depositors for their funds. Therefore associations allocate a larger percentage of their assets to mortgages. Compared to other institutions the associations write mortgages for longer periods and their loans are for a larger percentage of the appraised value of the property. Since mortgages of this type are more risky the associations' interest rate is usually higher.

There are many patterns of savings in use. Originally the associations were characterized by forced savings schemes. Individuals were expected to make regular payments to accumulate sufficient funds for the ownership of a stated number of shares. Since there nere many possible plans to accumulate an ownership share, there were several types of shares offered. If individuals did not maintain the payments for the shares the savers might be forced to pay a fine, lose part of their dividends or lose a bonus dividend. Forced savings are no longer popular and the usual form of savings is as flexible as that offered by a savings bank.

Amortized Loans. — The loan repayment provisions of the early associations were the prototype of the amortization plans used in repayment of mortgages in the 20th century. It was the pioneering work of the savings and loan associations that provided the experience for the federal government's policies in the 1930s for the reform of mortgage financing. The association plan, referred to as the direct reduction loan plan, involved a constant payment each month which in successive months would devote a larger percentage of the payment to principal than interest.

The associations generally prefer conventional mortgages to those insured by the Federal Housing administration (FHA) or guaranteed by the Veterans administration (VA) because these mortgages earn a higher interest rate. A higher interest rate gives the associations a higher profit and enables them to pay a higher dividend rate to savers. A higher interest rate is necessary in order to compensate savers for the slightly greater risk of investment in an association.

Local Nature. — The early associations in the United States aere small and local, and this feature of the associations is still important. The federally chartered associations must make most of their loans on property within a 50-mi. radius of the home office. More frequently the associations restrict themselves to a city or a neighbourhood within a city, though they may solicit savings from investors in a much wider area. Area restrictions serve to limit the size of the associations but their growth in the 1950s was nevertheless rapid. The more than 6,200 associations in existence in 1960 represented only a 17% increase over the total number in existence in the year 1900, but during this 60-year period the assets of the associations had increased 100-fold. The assets of the average association increased from approximately $100,000 in 1900 to more than $10,000,000 in 1960. Some associations in the early 1960s had assets exceeding $100,000,000. These associations were no longer small groups of neighbours or fellow workers joined together to provide homes for themselves but had become big business enterprises that extended credit to nonmembers and sought funds from investors over a wide area. Their size and diffusion of ownership meant that government controls were necessary to avoid abuses.

Public Policies.--;\lost state regulations are based on a detailed regulatory code adopted by the legislature which severely restrains the associations' freedom of action. In addition all associations which are members of the Federal Home Loan Bank system are subject to examination according to the detailed regulatory code adopted by the Federal Home Loan Bank board. The major purposes of the regulations are to make certain that an association is complying with its governing charter and that its investments are sound. By 1960 the great majority of all associations were members of the Federal Home Loan Bank system.

Members of the system may receive loans from the Federal Home Loan Bank board.

The Federal Savings and Loan Insurance corporation was established in 1934 to insure savings up to $5.000. In 1952 the ceiling was extended to $10,000. (See also HOUSING: II. Housing in the United States.) (J. Ms.)

GREAT BRITAIN

Building societies in Great Britain perform essentially the same functions as savings and loan associations in the United States. They accept money from the public, pay interest on it. allow it to be withdrawn and, in brief, provide a convenient investment service. They also lend money on the security of a mortgage of freehold or leasehold property. Although the earliest building societies undertook the construction of houses, this function was abandoned about the middle of the 19th century and consequently the name building society has become a misnomer. The term is. however, compulsory by law and although various alternatives have been suggested, none has met with universal acceptance.

History and Development. — In the latter half of the 18th century in Great Britain the artisans of the new machine age were emerging as a social group and, in order to give themselves some measure of self-protection against the misfortunes of life, many of them made regular contributions to sick and burial clubs and friendly societies. It was a similar motive — security — which led to the formation of building societies, and according to S. J. Price, who undertook extensive research on this subject, the earliest society of which any record has been found was established in Birmingham in or before 1775.

The early societies were all "terminating"; that is to say, they were intended to have a limited life. Each member agreed to pay a fixed sum at regular intervals from the establishment of the society until it mas disbanded. From this steady income the society bought a piece of land and built houses one after another until each of the subscribers had been housed. When the cost of the land and all the houses had been met, the society was dissolved.

As time went on societies began to borrow money from people who did not themselves want to buy a house and this accretion of funds enabled the borrowing members to purchase a house with less delay. As a result of this development there was no longer any need to bring each society to an end when all its original members had received an advance, so that gradually the "terminating" societies were replaced by "permanent" societies.

Building societies were first certified under the Friendly Societies acts of 1829 and 1834. Their rapid rise led, in 1836, to a special act which extended the friendly society regulations to them in so far as they were applicable, binding all members of a society by the rules. which were certified by specially appointed officers who gave security. Provision was made for control by a committee of management. The society's property mas vested in trustees empowered to bring and defend actions and to settle disputes by arbitration. Exemptions were given from stamp duty and the usury laws. By 1850 over 2,000 societies were registered in the United Kingdom.

In 1870 a royal commission was appointed to inquire into the working of friendly societies and building societies. As a result, an act was passed in 1874 and this remained the basis of later practice. Under this act the societies became corporate bodies possessing full legal powers corresponding to those of a limited company. The liability of an investing member was limited to the amount actually paid or in arrears on his shares and that of a borrowing member to the amount still payable under the terms of his mortgage.

The assets of the movement in 1890 have been estimated at £51,000,000 and from then until 1918 there was a steady but unspectacular growth to £68,000,000. Between 1919 and 1939 and again after 1945 there was an immense expansion of activity so that by the end of 1961 the total assets were more than £3,400,000.000.

Organization and Control. — Apart from statutory control, building societies are governed by their own rules. Management is vested in a small body, usually consisting of between 5 and 12 persons and termed the board of directors The directors are elected by the members in general meeting. The chief official is usually called either the general manager or the secretary.

The rules deal with such matters as the rights of members, the duties and powers of directors and officers, the holding of meetings of members and the method of voting. They also regulate the society's borrowing powers, the way in which shares are to be issued. how withdrawals are to be paid and upon what conditions advances may be granted and repaid.

Building societies are under the supervision of the chief registrar of friendly societies, who is, by virtue of office, also registrar of building societies. This official has a number of powers and duties derived from the Building Societies acts. He registers new societies, approves their names. examines their rules and receives from each society an annual report which is open for inspection by the public. The report consists of a list of names of the directors and officers. together with the society's accounts in great detail. A new society may not advertise for funds until the registrar gives it permission to do so. If the registrar considers it expedient he may, with the consent of the treasury, control and prohibit advertising and even prevent a society from accepting new investments from the public. Each year the registrar prepares a report on building societies which is submitted to parliament. The movement is nationally represented by the Building Societies association (founded in 1869).

Investment. — Building societies issue shares although they do not have a fixed share capital and do not offer shares for sale or purchase on the stock exchange. In a leading building society case, Lord Dunedin referred to the "so-called shares" of a building society and added that, though the word was the same, there was nothing more than a faint analogy between them and the shares of a joint-stock company. Building society shares are commonly called "paid-up shares" and the denominations vary from one society to another.

Some societies operate savings accounts under which the saver undertakes to pay a meekly or monthly amount over a period of time until he has accumulated the amount of a fully paid share. and societies often offer a higher rate of interest to encourage this type of regular saving.

There is no legal limit to the total amount of shares that a society may issue or to the number of shares that can be held by one person. In practice, however, nearly all societies impose a limit of £5,000 on the holding of any one member — husband and wife being regarded as one for this purpose. This limitation is due to sperial income tax arrangements with the board of inland revenue by which the income tax due on interest received from a building society is paid by the society. The arrangements do not cover surtax, which is paid by the investor on the gross equivalent (at the standard rate) and not on the amount of interest actually received. The tax paid by a society on behalf of investors who are individuals is computed at a special "composite" rate, This rate is fixed by reference to the proportionate amounts invested in building societies by (1) persons liable to tax at the standard rate; (2) persons liable at a reduced rate; and (3) persons not liable to pay any income tax. In genera!, interest on shares held by a limited company or other corporate body is liable to tax at the standard rate, as is interest on a holding of more than £5.000 by a private person.

Interest on shares is paid every half year or year either by warrant or by addition to the shareholder's account with the society. Some societies calculate interest by the day and some by the month. The length of notice required and the conditions on which withdrawals are to be paid are governed by the rules of the society. In practice most societies pay withdrawals at a month's notice. waiving even that period where the amount is small or the money is urgently required.

The Building Societies acts enable a society to include in its rules the power to borrow money either from an individual or from a corporate body. Such loans are known as deposits. The depositor is a creditor of the society and therefore entitled to priority of repayment over all the shareholders and his rate of interest is normally lower. The income tax arrangements for deposits are the same as for shares. A depositor is not a member and therefore has no voting rights. The act of 1874 limits the amount a society may take on deposit to two-thirds of the amount due on mortgages. By law, deposits cannot be accepted on terms of less than one month's notice for withdrawal, although in practice if the depositor requires his money urgently such notice is often waived by the society. In general, the larger the amount of the deposit, the longer is the notice required.

Mortgages. — Building societies can lend money only on the security of a first mortgage of freehold or leasehold property. In consideration of the advance which the society makes. the borrower charges his property to the society as security until the loan has been repaid. This is effected by means of a mortgage deed, on which stamp duty is payable according to the amount of the loan. The borrower becomes a member of the society and subject to its rules.

As a general rule societies lend their funds mainly on the security of private dwelling houses purchased for owner occupation. Some societies occasionally make loans on blocks of flats. commercial or industrial premises and farms, but the total value of such loans in any year is strictly regulated by the Building Societies act, 1960.. Many societies make loans on shops which have living accommodation.

Within the framework of the society's general lending policy the amount of the loan will be related to the value of the property, its suitability as security, the standing and reliability of the borrower and the value of any authorized additional security. The deeds of the property are retained by the society until the mortgage has been repaid.

The rate of interest charged on a mortgage loan is determined by various factors, which include the general level of interest rates. the rates paid by the society to investors. the composite rate of income tax and the level of management expenses. Interest is paid to the society without the deduction of tax, but a borrower obtains an allowance against his liability to income tax in respect of the interest paid.

The bulk of repayments are monthly, by a fixed sum from which the interest for the month is appropriated and the balance applied in reduction of the outstanding principal. Most societies calculate interest on an annual basis.

If a borrower should default in his repayments, the society can sue him on his personal covenant either for the principal debt outstanding or for the amount of subscriptions in arrears. Alternatively, the society can proceed against the property by taking possession, by appointing a receiver of the rents or by selling it.

When the mortgage debt has been fully repaid, the society will endorse the mortgage deed with a statutory vacating receipt. This receipt. which is sealed by the society, acknowledges payment of all money due under the deed. The mortgage deed together with the title deeds are then returned to the mortgagor.

Under the House Purchase and Housing act, 1959, the registrar of building societies was empowered to "designate" certain societies which means that investments with them are trustee investments.

Economic and Social Aspects. — The building society movement in the range of its membership and the magnitude of its financial resources touches the life of the country at many points.

From 1919 onward building societies in Great Britain attracted large sums. mainly from the smaller investors, because they offered security, a reasonable rate of interest, prompt withdrawal facilities and freedom from income tax deduction. Despite the unemployment of the interwar years, wage earners in general nere better off than in 1914. Many workers had a margin of income which gave them an opportunity to save and the "small savings" institutions, including building societies, benefited. During the years of full employment and comprehensive social insurance which succeeded World War II. the margin for saving increased even further and the share of that saving which went to building societies is shown by the fact that in 1946 total investments stood at £809,828,000, while by the end of 1961 they had exceeded £3,100,000,000.

The complementary function of building societies is the promotion of home ownership. After World War I the nation became aware of an acute housing shortage and the government gave direct encouragement to building. Between 1919 and March 1940 some 4,000,000 houses were built in England and Wales and of these about 2,500,000 were built by private enterprise without subsidy of any kind. The existence of the building societies' mortgage service made this private enterprise building possible.

Home ownership also expanded after World War II, although under the Labour government, which came into power in 1945, greater encouragement was given to building by local authorities of houses to rent than to private enterprise building. It was not until 1951 nhen the Conservatives took office that legislation was introduced to increase the proportion of private building allowed and to permit council houses to be sold. This gave a great impetus to building societies, and borrowers increased from 1,579,000 in 1951 to nearly 2,425,000 ten years later.

The steady growth in the number of investors and borrowers was accompanied by a gradual reduction in the number of societies, due mainly to the difficulty of the smaller societies in attracting sufficient funds from the public and in maintaining the necessary administrative machinery.

Development Abroad. — The building society idea has spread far and wide. There are societies in many countries of the commonwealth, most of them closely following British practice. In 1831 the building society idea was carried by three Englishmen to the United States, where societies flourish under the name of savings and loan associations. Similar bodies have been established in most countries of Europe and also in parts of Central and South America.

SAVINGS BANKS. A savings bank is one of the many institutional arrangements that society makes in order to bring together lenders and borrowers of funds. Although it is customarily looked upon as an agency utilized by individuals who wish to accumulate funds for future spending, the savings bank is also a lending institution and could not exist in its present form were it not. It performs an important economic function in its dual capacity of borrowing from individuals who wish to consume less than their income and of lending to others who wish to spend more. It is one of a number of institutions that serve to direct the flow of money income in such a way that a portion of the economic resources of a society are turned from the production of goods for current consumption to the creation of an addition to its total stock of capital. or its wealth.

As an agency of savings the bank facilitates the process by which an individual voluntarily abstains from spending the total of his current income in order to accumulate claims against future income. As a lending agency the savings bank assists individuals or groups who wish to spend more than their current income by promising to spend less than their future income. It is, then, an institution which brings together those who have more than enough for their current needs and those who have less than enough. It performs its economic function by exchanging future and present claims. An individual who makes a savings deposit sells his present claim against income currently produced for a claim which is redeemable at some future date; that is, he exchanges a portion of his current money receipts, which are redeemable in goods and services, for a savings deposit which will be withdrawn and redeemed at some future date. The evidence of the savings depositor's claim is his passbook. An individual or a group that wishes to borrow sells claims against future income —the evidence for which is some kind of a promise to pay—for claims against present income. The consequence of such transactions is the promotion of "real" saving, which is an increase in capital, as distinguished from "money" saving, which can be merely the act of not spending, or of hoarding.

There are other institutions than savings banks which perform a similar economic function in their dual capacity of receiving deposits (*i.e.*, of borrowing) and making loans. The most important of these are the savings departments of commercial banks; building and loan, or savings and loan, associations; insurance companies; investment trusts; and a number of minor (in terms of magnitude of deposits) of savings institutions, such as credit unions and similar co-operative credit organizations, industrial savings plans, and school savings programs. The act of bringing together saver and spender. or lender and borrower, need not be the work of an intermediary agency but the product of a direct relationship—a consideration that is of ever greater concern to savings banks. Individuals aho wish to save may purchase claims against future income directly from those who wish to borrow and will guarantee the redemption of the claims, the evidence of the transactions being a share, bond or other security. It is shown below (Table II) that the proportion of individual saving that is done by the direct purchase of securities is increasing.

History.—Savings banking is the product of two historical forces, one of which operated uniquely to create it alone and the other to create all savings institutions. The development of a liberal economic order, based upon specialization and exchange, presupposed an effective supply of money, in the creation of which all credit institutions participated. Such an order (dating from about 1550) carried with it certain ethical presuppositions concerning the nature of man, among which was the notion that he was capable of looking after himself amid the uncertainties of a market system. Savings banking, then, in addition to being one of the many credit institutions which an exchange economy finds indispensable is also a product of the effort to secure the individual against the caprices of capitalism. Not long in coming was recognition of the fact that if individuals were to be considered self-responsible they must have institutions enabling them to provide for such uncertainties as they might encounter. The original plans for savings banks were more than tinged uith a spirit of benevolence and paternalism emanating from the more fortunate members of the community who wished to help the poor and at the same time relieve themselves of the burden of charity.

In 1610, the Frenchman, Hugues de Lestre, published a treatise in which he urged the establishment of savings institutions for the poor in order that their lot might be bettered and that the rich might avoid the necessity of alms-giving. Seventy-seven years after, the irrepressible Daniel Defoe, finding himself in a debtor's prison, wrote a tract on the wonders that could be wrought by the practice of thrift. To this end, he proposed that the government establish a pension office. If each person in the realm—rich and poor. of all ages—were to pay each year four shillings into a common fund husbanded by the state, they could "forever banish beggary and poverty out of the kingdom." Such a happy state could be purchased for the price of "two pots of beer a month." While the French and English continued to write about savings hanks, elsewhere in Europe they were developing out of the municipal pawnshops, the most famous of which was the Monte de Pieth that for centuries operated in the Italian city states as a savings and loan agency. The eventual product of this development was the municipal savings bank. Almost concurrent was the development of private savings banks in Germany, the first of which began in Hamburg in 1778.

The first savings bank in Britain was founded in 1810 by the Rev. Henry Duncan, pastor of an impoverished flock in Dumfrieshire, Scotland. Duncan, who had been a student of the classical economist, Dugald Stewart, established the "Savings and Friendly Society," the members of which were divided into three classes: ordinary, who made regular deposits; extraordinary. who contributed to a surplus fund out of which premiums were paid to encourage frequent deposits; and honorary members. The bank was not operated for profit, and its officers devoted their time to its governance as a philanthropic service. Penalties were imposed upon those who did not deposit regularly, and ordinary members who wished to withdraw their savings had first to obtain the permission of the "Court of Directors" of the society. Duncan's bank was the origin of the trustee savings banks in the United Kingdom and of the mutual savings banks in America. Its success was soon indisputable, and by 1827 the plan had spread over Scotland, England and Ireland where £15,000,000 had been deposited. Most of these banks were motivated by a mixture of benevolence and economic insight. They soon became subject to governmental regulation, and in 1863 the Trustee Savings Bank act was passed. In 1861 the post office savings bank system was inaugurated, under the auspices of Gladstone, and the trustee banks declined in relative importance.

The origin of savings banking in the United States was quite similar to that in Britain, for the first banks were non-profit institutions founded for charitable purposes. The original bank was the Provident Institution for Savings, of Boston, which received its charter in December 1816. One month earlier, the Philadelphia Saving Fund society began business but was not incorporated until 1819. The Bank for Savings of New York, was incorporated in 1819 by the Society for the Prevention of Pauperism. The founders' roll of American savings banks includes a number of men of some historical importance, such as Condy Raguet, Thomas Eddy, James Savage, and Clement and Alexander Biddle. Out of these early organizations developed the mutual savings banks of America which are still largely confined to their place of origin in the north Atlantic states. Their growth was unexceptional until the decade preceding the Civil War when the number of banks increased from 108 to 300, the number of depositors from 250,000 to 700,000, and total balances from $50,000,000 to $150,000,000. By 1875 this latter figure had risen to $900,000,000 and by 1913 to almost $5,000,000,000—even though the period betneen the close of the Civil War and the turn of the century was one of falling prices.

The success of mutual banks resulted in the creation of additional savings institutions, but the mutual structure was not copied by the new banks, which began in the middle and far western states. These were organizations operated for profit and managed in the interest of the shareholders. Stock savings banks were established, and commercial banks began to accept savings deposits toward the end of the 19th century. Prior to 1913, however, the national banks (see BANKING) did not distinguish between savings, or time, deposits and demand deposits, because there was no legal basis for such a distinction in the National Bank act under which they operated Their acceptance of savings deposits brought them into competition with the mutual, stock and state banks.

When the federal reserve system was established in 1913, a distinction was made between kinds of deposits, and a lower reserve requirement was fixed for time deposits—those which could be withdrawn only after prior notice has been given.

The proliferation of savings plans late in the century brought a demand from many quarters for the institution of a savings system under the control and operation of the post office, and in 1910 the postal savings system was started.

In the entire history of savings banks, the inter-war period was the most eventful. Like other banks they reeled under two, near-fatal, blows. The first of these was the monetary disorder that fell upon almost every nation, in the reckless depreciation of currency and its irresponsible aftermath. The effect was to shake the confidence of the people in the value of money and to evoke a flight from currency to the hoarding of goods. In such circumstances. it is suicidal for an individual to abstain from current consumption in order to accumulate claims against future income, for the claims nhich the bank hands over to him may be worthless. That this nas well realized in Germany—where inflation drove the mark down to one one-billionth of its original value—is evident in the decline of savings bank deposits from 19,700,000,000 gold marks in 1913 to 4,600,000,000 gold marks in 1927. Inflation or the fear of inflation—which ever verges upon the probable in a world of budgetary disorder—will produce a flight from the currency and the disorganization of banking.

The second catastrophe nas the great depression of 1929. Depression, or deflation. produces a movement away from the holding of stocks of goods to the hoarding of money, and as the movement gains momentum these hoards are withdrawn from the banks and held privately. Concurrent with the heavy withdrawal of deposits after 1929 was a substantial decline in the value of bank assets, making it impossible for many banks to meet their obligations to depositors. The failure of thousands of banks created suspicions about the soundness of others until they, too, failed. The crisis reached its climax in the United States when all banks were closed by presidential decree in the spring of 1933 and later re-opened under new conditions. The effect of the depression, particularly in the United States, was to disturb profoundly the confidence of the people in the banking system and to disclose the inadequacy of conventional standards of bank management. It demonstrated that even the most scrupulous practices in maintaining required reserves and holding only prescribed investments did not render a bank capable of meeting all of its obligations when all depositors demanded payment and when earning assets were shrinking in value.

In the course of some 130 years both the purpose and practice of savings banking have changed drastically, and in these changes are reflected the changing character of individual saving habits. The banks are no longer benevolent institutions created by the wealthier members of the community for the succor of their less fortunate fellow citizens. They are avowed profit-making enterprises. as in the case of commercial banks engaging in the savings deposit business, or co-operative agencies, or public institutions operated by local or national governments. In the eastern United States uhere mutual savings banks still flourish, their early overtones of philanthropy and paternalism have passed away. Savings bank practices have also changed. Originally the monies received from depositors were invested in government securities, which were long in maturing, comparatively safe and bore a low rate of interest. Today savings deposits are invested as well in the securities of private enterprises, and, in the case of commercial banks in the federal reserve system and of most state banks, they may be loaned out for short periods to businessmen. That banking law now permits deposits to be invested in more venturesome enterprises, which while more profitable are more risky, is more important than that most banks now hold a large proportion of their earning assets in the form of government securities.

A stable postwar world, with a great demand for capital, can repeat the experience of the period following World War I when banks eagerly sought after deposits and offered numerous inducements to save. Not only was the rate of interest on savings deposits then incredibly high (when compared to what the founders of savings banking thought desirable) but the banks sought out custom by establishing financial services for their depositors. Since the beginning of the 20th century savings banks have encountered mounting competition from other outlets for individual savings, such as insurance companies, postal savings banks, investment trusts, co-operative agencies, and, greatest of all. from governments seeking to borrow from individuals. Finally, it should be noted that changes in the savings habits of individuals have lessened the permanence of their deposits. Studies made of the decade from 1930 to 1940 disclose that in the United States the majority of deposits were made, not as security against misfortune and old age, but for future spending anticipated with a considerable degree of certainty. with the consequence that the rate of turnover of deposits is antithetical to what were once conceived to be proper savings practices. In one important American bank—believed to be representative of many others—three-fourths of all savings deposits were withdrawn before they were five years old. It has also been discovered that in this decade the amount by which savings deposits increased was only a little greater than the amount of interest earned on the principal, which indicates, in effect, that individual savings deposits contributed in this period virtually none of the funds used in the formation of capital in the United States

All of these changes are symptomatic of the changing character of individual savings. The causes which once compelled an individual to lay aside funds for a rainy day have either disappeared or have found a different expression. The uncertainty that once haunted members of western, industrial society has become less terrible as governments have assumed the responsibility of looking after the jobless, the aged and the infirm—a development that is signalized by social security legislation and the socializing of charity. Moreover, those individuals who are able to invest against misfortune have alternative methods of doing it, such as purchasing insurance policies or, simply. securities of enterprises or governments. Savings deposits are still useful for accumulating funds for large expenditures—as for education and travel—but even for this purpose they are not as essential as they once were. The development of mass credit institutions—installment selling, small loan agencies, and the like—has diminished the necessity of saving to spend. Finally, the very notion of thrift has lost much of its enticement, because the contemporary man discounts the future at an inordinately high rate. He is a victim of what Adam Smith called "the passion for present enjoyment," and is refractory to the very instinct which Smith believed would redeem him—the desire to save which "comes with us from the womb, and never leaves us till we go into the grave." Not only does thrift no longer keep its high place among the cardinal virtues but is often looked upon as a pernicious practice by many of those very people who were once among its arch-advocates: the economists.

SAVINGS BANKS IN THE UNITED STATES

Savings banks in the United States are of three principal kinds: commercial banks in their savings deposit departments; mutual savings banks; and the postal savings system. In addition. although not banks, savings and loan associations and credit unions receive the savings of the public in savings accounts.

Savings Accounts Trends.—During the 1920s, total savings accounts rose from $17,300,000,000 to $34,600,000,000, an increase of over $1,700,000,000 per year. About two-thirds of this increase was in time deposits at commercial banks and savings deposits in mutual savings banks. During the 1930s, because of sharp declines during the depression years, total accumulations in savings accounts fell off $2,700,000,000. The sharpest drop relatively was in savings capital of savings and loan associations. followed by the decline in time deposits at commercial banks. Time deposits in mutual savings banks showed a steady rise during these years except in 1932 and 1933, and postal savings rose sharply during the depression years. During the 1940s, total holdings of savings accounts much more than doubled, reaching $73,100,000,000 in 1950. Particularly large savings were accumulated during the World War II period and the first three postwar years. The average annual increase in total savings accounts in this decade was $4,100,000,000 per year. In the five year. 1951 through 19jj there was a further marked increase in total holdings of savings accounts to an aggregate at the end of 1955 of $110,800,000,000. The average accumulation of funds in savings accounts during these five years was $7,500,000,000 per year.

At the end of 1955, time deposits in commercial banks constituted the largest aggregate of savings accounts or accumulated "over-the-counter" savings of any set of financial institutions in the United States. As indicated in Table I. savings accounts in commercial banks then totalled $46,000,000,000. Total savings capital in all savings and loan associations amounted to $32,300,000,000. Total time deposits in all mutual savings banks aggregated $28,200,000,000.

Total holdings of savings accounts. chiefly by individuals, are shown in Table I for selected years from 1920 through 1955.

In the early 1950s, time deposits in commercial hanks and time deposits in mutual savings banks lagged behind savings accounts in savings and loan associations in terms of rate of increase. In dollars, the increase in savings capital at all savings and loan associations from 1950 to 195j almost equalled the increase in savings accounts at the other four sets of institutions. In percentage terms. time deposits in commercial banks rose almost 33%, and time deposits at all mutual savings banks rose over 40%. During the same span of time total savings accounts at all savings and loan associations rose about 130%. Thus. during this period savings balances in savings and loan associations showed phenomenal

TABLE I.—*Holdings of Savings Accounts in Banks and Savings Institutions, December 31, 1920–1955*
(In billions of dollars)

Years	Commercial banks	Mutual savings banks	Postal savings	Savings and loan associations	Credit unions	Total savings accounts
1920	$10.5	$4.8	$0.2	$1.7	*	$17.3
1930	18.6	9.4	0.3	6.3	*	34.6
1940	15.4	10.6	1.3	4.3	$0.2	31.9
1950	35.2	20.0	3.0	14.0	0.9	73.1
1955	46.0	28.2	2.0	32.3	2.4	110.8

*Less than $50,000,000

Data shown are time deposits of individuals, partnerships and corporations for commercial banks and mutual savings banks; total savings capital, including savings accounts, deposits, and investment securities, for savings and loan associations; total amounts due depositors for postal savings; and share capital and members' deposits for credit unions.

gains, while the increases in savings deposits in commercial banks and mutual savings banks were more moderate. Postal savings deposits declined from a peak in 1947. Credit unions showed a large percentage increase.

Commercial Banks.—Time deposits in commercial banks, most of which are savings deposits, comprise a significant portion of total deposits of these institutions. On Dec. 31, 1955, time deposits, other than interbank, in all commercial banks aggregated $48,500,000,000, about 25.7% of their total deposits, which amounted to $188,300,000,000. Over the years, as shown in Table II, time deposits in commercial banks have increased substantially in amount.

During World War II, time deposits declined relatively from about one-fourth of total deposits in all commercial banks to about one-fifth. In the postwar period, however, time deposits have risen faster than other deposits. In the early 1950s time deposits other than interbank in all commercial banks rose 32.8%, whereas demand deposits and interbank deposits went up 17.7%. As a result, time deposits have again risen to their pre-World War II relationship to total deposits in commercial banks.

Wide differences exist among individual commercial banks in the importance of time and savings deposits in their deposit structure. In 1954, out of the total of 6,609 member banks of the federal reserve system, 1,311 had a ratio of time deposits to total deposits of 50% and over. Member banks numbering 2,696 had a ratio between 25% and 50%, and 2,602 member banks had a ratio under 25%, including 263 member banks with no time deposits. There were significant differences among these groups of banks, of course, in the role of interest on time deposits in disposition of total earnings, varying from 21.3% to 14.0% to 4.5%, respectively. Some large, medium-sized and small institutions fell into each of the three classes.

By reserve classification, the New York central reserve city member banks had in 1954 a ratio of time deposits to total deposits of 12.7%, and the Chicago (Ill.) central reserve city member banks a ratio of 17.1%. Corresponding ratios were 26.0% for reserve city member banks, 32.6% for country member banks, and 35.4% for insured commercial banks not members of the federal reserve system. Among federal reserve districts, the ratio of time deposits to total deposits was highest in the Philadelphia and New York districts and lowest in the Dallas and Kansas City districts.

A national bank is permitted to make mortgage loans equal in the aggregate to its unimpaired capital and surplus or to 60% of its time and savings deposits, whichever is the greater. These limitations as to aggregate mortgage loans, however, do not apply to Veterans Administration (VA)-guaranteed loans. State banks are generally subject to much the same general type of limitations that govern national banks, with variations according to the laws of each individual state. Total mortgage loans held by all commercial banks on Dec. 31, 1955 amounted to $21,100,000,000, about 43% of their total time deposits. This ratio rose after 1940, there being 28% in 1940, 16% in 1945 and 38% in 1950, reflecting strong commercial bank participation in mortgage lending.

No member bank of the federal reserve system or insured nonmember bank may pay any interest on any deposit which is payable on demand. Furthermore, the legal minimum and maximum reserve requirements for member banks against time deposits are between 3% and 6%, much less than the ranges of reserve requirements for member banks against demand deposits. Accordingly, in regulations of the board of governors of the federal reserve system, the terms "time deposits" and "savings deposits" are strictly defined. Savings deposits are evidenced by a passbook, and may be accepted only from individuals or nonprofit organizations, with the legal possibility of requiring notice of withdrawal. Furthermore, the board of governors of the federal reserve system, under provisions of the Federal Reserve act, establishes maximum rates that may be paid by member banks on time deposits—$2\frac{1}{2}\%$ after January 1, 1936 on savings deposits. The rate payable by a member bank may not in any event exceed the maximum rate payable by state banks and trust companies on like deposits under the laws of the states in which the member bank is located. The same maximum rates of payment were established for insured nonmember banks by the Federal Deposit Insurance corporation (FDIC), effective Feb. 1, 1936.

Mutual Savings Banks.—Mutual savings banks concentrate on savings deposits and generally accept no commercial or checking accounts. Such banks have no capital stock and are purely mutual organizations. With no shareholders, the mutual savings banks are governed by boards of trustees, most of them self-perpetuating bodies, made up of outstanding business and professional men. Mutual savings banks operate exclusively under state law and state charter and are supervised and examined by the state banking departments in their respective states. Most mutual savings banks are quite old institutions, and many have celebrated their 100th anniversaries.

All the net income of these financial institutions after operating expenses is paid to the depositors as dividends or is allocated to reserves for future losses. In the aggregate, total reserves and surplus of all mutual savings banks was 10.1% of total deposits at the close of 1955. Mutual savings banks pay "dividends" or "interest-dividends" to their depositors, but these have come to be viewed as interest.

At the close of 1955, the mutual savings banks had more than 16,000,000 regular accounts, with an average deposit of $1,742. Such regular accounts comprised $27,900,000,000 of total mutual savings bank deposits of almost $28,200,000,000. There were also about 5,000,000 additional accounts in school savings, club, payroll and other accounts: making a total number of accounts of just over 21,000,000.

Several states place a limit on the maximum amount which any one person or organization may have on deposit in any one savings bank. The laws pertaining to mutual savings banks provide that depositors may be required to give notice (typically 60 or 90 days) as stated in the savings account passbook before withdrawals are paid. In fact, however, savings banks ordinarily meet withdrawals without requiring notice. The ratio of turnover of mutual savings banks has increased over the last several years, as has the ratio of withdrawals to gross inflow of savings, indicating a greater use of mutual savings deposits for short-term purposes.

Fewer than half of the mutual savings banks are insured by the Federal Deposit Insurance corporation, but the insured institutions hold a large proportion of total deposits in mutual savings banks. On June 30, 1955, the 218 mutual savings banks which were members of the FDIC held total deposits of $20,600,000,000, while the 310 such banks which were not members had total deposits of $6,700,000,000. In Massachusetts and Connecticut the mutuals are insured under state insurance funds.

The mutual savings banks have a long history of conservative operation, with emphasis placed on safety and availability of savings entrusted to them, rather than on earning a high rate of dividend. In particular, the savings banks went into the great depression with substantial reserves and strong liquidity positions. "Runs" on mutual savings banks by their depositors were not as drastic as those in commercial banks. As a result, in spite of losses on some investments and mortgages, the savings banks went through the depression without a single failure or liquidation. No mutual savings bank had to go "on notice" or delay the meeting of withdrawal requests, except when all banks were closed during the bank holiday.

As in many types of financial institutions, the deposits or assets of the larger mutual savings banks comprise a large proportion of the total aggregates for all mutual savings banks. On Dec. 31, 1955 there were 100 mutual savings banks with deposits of $65,000,000 or more. Total deposits of these 100 largest mutual savings banks constituted $20,700,000,000 or about 75%, of the total deposits of $28,200,000,000 in all of the 527 mutual savings banks in the United States. The largest bank had deposits just over $1,250,000,000, while five others were over $500,000,000 and 11 others had deposits over $300,000,000. Fifteen mutual savings banks had total deposits from $200,000,000 to $300,000,000 and 3j banks had total deposits from $100,000,000 to $200,000,000. Of the 25 largest mutual savings banks, 18 were in New York city.

Mutual savings banks are in operation in 17 states, but are concentrated in the New England and Middle Atlantic seaboard states. On Dec. 31, 195j. New York mutual savings banks had total deposits of $16,500,000,000. Massachusetts mutual savings banks had total deposits of $4,500,000,000; Connecticut, $1,800,000,000; Pennsylvania, $1,500,000,000; and New Jersey. $1,000,000,000. Other states with mutual savings banks included Maine, New Hampshire. Vermont and Rhode Island in New England, and Delaware and Maryland in the Middle-Atlantic area. Mutual savings banks were also in operation in Ohio, Indiana, Wisconsin and Minnesota in the midwest, and in Washington and Oregon on the Pacific coast.

The investment powers of mutual savings banks are closely prescribed by state laws and by rules and regulations of state supervisory authorities. Investments in securities, for instance, are usually confined to a "legal list" of authorized securities from which the savings banks determine their bond portfolio. Some states limit real estate mortgage investments to 60% to 75% of savings bank deposits.

After World War II the legal investment provisions of various states were changed to enable the mutual savings banks to broaden their investments and so to increase earnings. Particularly important in this respect was the enactment of legislation which permitted mutual savings banks to purchase Federal Housing authority (FHA)-insured and VA-guaranteed mortgages without reference to the location of the residential property against which such loans had been made. New York passed such legislation for FHA-insured mortgages in 1948 and for VA-guaranteed mortgages in 1951. These laws provided substantially enlarged outlets for investment in mortgages, particularly by the large metropolitan savings banks, and gave rise to much greater marketability of FHA-insured and VA-guaranteed mortgage loans over the nation. In 1953 a New York law also permitted a savings bank to borrow funds for purposes other than paying depositors up to 5% of its assets. This measure was adopted to help savings banks meet varying mortgage commitments without having to sell securities. During the postwar period, the majority of mutual savings banks states legalized the purchase of some type of equity securities having an adequate earnings and dividend record and within certain restrictions in relation to surplus and assets. In certain states mutual savings banks were permitted to invest in large-scale housing developments.

Over the years the distribution of the earning asset portfolios of mutual savings banks among various classes of loans and investments shifted greatly. depending on rates of return available on the different types of legal investments, changes in risk characteristics and relative supplies available of the various classes of investments. In 1929 real estate mortgages comprised about 60%, and railroad. public utility and state and municipal bonds about 30% of total assets of all mutual savings banks. During the depression and the late 1930s, mortgage and corporate and municipal bondholdings declined both absolutely and relatively. and savings hanks substantially expanded their holdings of C.S. government bonds. On Dec. 31, 1940, as Table II indicates, mortgage loans comprised 42%, United States government obligations. 26%, and other securities 16% of total assets. During World War II and the first two years in the postwar period. the proceeds of the net increase in mutual savings bank deposits and some further reduction in holdings of mortgage loans and other securities were invested in U.S. government securities. At the peak in 1947, holdings of U.S. government obligations exceeded $12,000,000,000 and comprised over 60% of total assets of all mutual savings banks. Since then major emphasis has been placed upon real estate mortgages through investment of the proceeds both of net increases in savings deposits and of reduced holdings of United States government obligations.

On Dec. 31, 1955, total assets of all mutual savings banks stood at $31,300,000,000; total deposits at $28,100,000,000; and total reserves and surplus at $2,800,000,000. Mortgage loans held totalled $17,500,000,000; U.S. government obligations. $8,500,000,000; and other securities. $4,000,000,000. Included in this latter category were investments in corporate stocks, primarily bank stocks and preferred stocks. amounting to about $650,000,000. Mortgage loans exceeded 55% of total assets, the highest proportion since the late 1920s, and U.S. government obligations comprised only 27%, the lowest since 1940. Of the mortgage loans, $15,600,000,000 was residential. with $5,800,000,000 in VA-guaranteed mortgages, $4,200,000,000 in FHA-insured mortgages, and $5,600,000,000 in conventional mortgage loans. Nonfarm nonresidential mortgages totalled $1,800,000,000.

A special service offered by several mutual savings banks in Massachusetts. New York and Connecticut is savings bank life insurance, sold over-the-counter to reduce sales costs, in limited amounts which average less than $2,000. At the start of 1956, $856,000,000 of such life insurance was in force: and almost 700,000 policies had been issued.

Postal Savings System.— The postal savings system was authorized by congress in 1910. It was established partly as an aftermath to the panic of 1907 and partly to attract deposits from those who lacked confidence in usual banking institutions and from the many immigrants in those times who frequently sent their savings to institutions in Europe. Over the years, both before and after its founding, the postal savings system met vigorous opposition from banking circles as an unwarranted duplication of private facilities.

The U.S. government is solemnly pledged to the payment of postal savings deposits. Accounts may be opened and deposits made by any competent individual person over 10 years of age. Deposits with the postal savings system are evidenced by certificates issued in denominations from $1 through $500. No depositor may have to his credit more than $2,500, exclusive of accumulated interest. The depositor may at any time withdraw all or any part of his deposits, with any interest payable thereon, from the post office where the deposits were made.

Postal savings deposits earn interest at the rate of 2% a year. except in Mississippi, where the rate in 1954 was 1½%. The general rate of 2% has been in effect ever since the establishment of the postal savings system. Until recent years, only simple interest was paid. Interest has been compounded annually, however, on deposits represented by postal savings certificates issued on or after Sept. 1. 1954. The assets of the postal savings system are invested mainly in U.S. government obligations. although funds may also be redeposited in local banks at a required rate of 2½%.

Until 1930, growth of the postal savings system was limited, partly because the banks paid much higher rates than 2%, and total postal savings due depositors amounted to only $169,000,000 at the end of 1929. With the bank failures during the early 1930s, however, people withdrew savings from commercial banks and put them in postal savings deposits. By the end of 1933 the postal savings system had grown to $1,229,000,000, eight times its size before the great depression.

Then followed several years of little change in postal savings. and amounts due depositors totalled $1,315,000,000 at the end of 1939. During World War II. as a part of the general upsurge in savings at that time, and continuing in the early postwar period. the postal savings system experienced another period of rapid growth. reaching a high point of $3,523,000,000 late in 1947. Postal savings then declined. in part under the impact of vigorous competition from savings and loan associations and banks. The total amount due depositors by the postal savings system was just under $2,000,000,000 in Dec. 1955.

Savings and Loan Associations. — The most striking development in "over-the-counter" savings in the United States after World War II was the phenomenal growth of savings and loan associations. Total savings capital at these institutions rose from $7,400,000,000 at the end of 1945 to $14,000,000,000 in 1950 to $32,300,000,000 at the end of 1955. The increase during 1955 was just under $5,000,000,000 as compared with corresponding increases in time deposits at all mutual savings banks of $1,900,000,000 and at all commercial banks of $1,300,000,000.

Savings accounts in savings and loan associations are most commonly evidenced by a passbook. Ordinarily they are payable on demand but written notice of withdrawal may be required. They are not deposits, in a legal sense, and the return on them is called dividends, not interest. In 1955 at all savings and loan associations, withdrawals totalled $8,700,000,000 and gross inflow of new savings capital was $13,700,000,000 making the net inflow of savings just under $5,000,000,000.

Source: Board of Governors of the Federal Reserve System, National Association of Mutual. Savings Banks and Federal Home Loan Bank Board.

Early in 19jj there were about 6,000 savings and loan associations. of which 4,400 were chartered by states and 1.600 had a federal charter. The state or federal chartering authorities also supervise and examine the associations in the public interest. The Federal Savings and Loan Insurance corporation insures savings accounts up to $10,000 in insured savings associations. including all those with federal charters and about 1,800 state-chartered associations. Total assets of insured institutions comprise about 90% of the combined assets of the entire savings and loan business. The Federal Home Loan Bank system makes advances to member savings and loan institutions to maintain liquidity or to provide funds for mortgage lending. Funds for these purposes are derived in part from deposits received from and capital stock sold to member institutions and in part irom notes sold in the capital markets.

At the end of 1955, as shown in Table II. mortgage loans held by all savings and loan associations totalled $31,600,000,000, about 83% of their total assets. Holdings of cash and U.S. government obligations were $4.500,000,000, about 12% of total assets. Total reserves and undivided profits were $2,600,000,000, about 8% of total savings capital.

More than three-fourths of the mortgage loans held by savings and loan associations are conventional loans, the remainder being VA-guaranteed or FHA-insured. In the early 1950s savings and loan associations undertook about $37\frac{1}{2}$% of total home financing.

Economic Significance. — The gathering together of savings of the public and the investment of these funds by the savings banks and savings institutions is a service to the U.S. economy of the greatest importance. In the capital markets the annual increase in savings accounts is the largest single component of the supply of funds. Likewise, home mortgages, in which much of "over-the-counter" savings are invested. comprise the largest single component, by far. of the demand for funds. Such savings and investment are vital to the progress and growth of the nation.

Accordingly, in the early 1950s there was renewed attention to the economic importance of savings, and particularly to savings deposits and savings accounts. There was also intensified competition among financial institutions for the favour of the public and the opportunity to be entrusted with savings. Nowhere was competition stiffer than among commercial banks. mutual savings banks and savings and loan associations. Competition took several forms. Fundamental. of course, is the seeking of what is deemed fair treatment of net earnings under the federal income tax law. Rivalry was keen in new and attractive office quarters. in range of services offered and in advertising and public relations. Competition was sharp in rate of interest or dividend. At the same time, "over-the-counter" savings were under pressure from alternative forms of saving. such as social security and pension funds and the attractiveness of common stocks. Attitudes toward savings were challenged by inflation, by less cyclical instability in the economy after World War II, and by government welfare programs.

BRITISH AND EUROPEAN SAVINGS BANKING

The United Kingdom. — The first savings bank was established at Ruthwell. Dumfriesshire, Scot., in 1810. by the parish minister. the Rev. Henry Duncan. From then onward the movement spread through Scotland and England. with the result that in 1817 the first savings bank bill governing these institutions was passed, constituting the first act of its type ever to be adopted by any country (its main regulations are still in force). The principal act is the one of 1954, under which all trustee savings banks are certified.

The popularity of the trustee savings banks quickly spread: by 1859 there were 63j savings banks holding deposits amounting to £39,000,000; by 195j there were 84 separate trustee savings banks with more than 1,320 offices and funds amounting to more than £1,198,000,000.

The trustee savings banks are not conducted for private profit, their sole concern being to offer the most convenient and remunerative method of saving compatible with sound administration and security. They combine the security offered by close connection with the state with the freedom that comes from independent management. The banks are under the direction of bodies of trustees and managers who may not receive any payment for their services. The banks are subject to government supervision and are also inspected on behalf of the Trustee Savings Banks Inspection committee. The funds of the ordinary departments of the banks are invested with the commissioners for the reduction of the national debt. while the funds of the special investment department (where a slightly higher rate of interest is paid) are! with the commissioners' approval, invested in government securities and with municipal authorities.

The British Post Office Savings bank. founded by W. E. Gladstone in 1861as a department of the general post office. has been a model for similar banks in other countries; it works under government guarantee. (*See* POST AND POSTAL SERVICES: *The British Post Office us Banker.*) The amount standing to the credit of the depositors on Dec. 31.1955, was £1,698,652,000. The rate of interest in the post office savings bank is similar to that paid in the ordinary departments of the trustee savings banks, namely $2\frac{1}{2}\%$ per annum; and in both institutions the annual limit of deposit is £500, with a present total limit of £3.000.

The post office and the trustee savings banks, together with the National Savings committee (formed in 1916 to help to finance World War I by the sale of savings certificates) and their counterparts in Scotland and Northern Ireland. form the National Savings movement. which promotes the sale of national savings certificates and encourages deposits in savings banks.

The progress of savings from 1913 to 1955 is indicated in Table III.

TABLE III.—*Savings in the United Kingdom, 1913–1955*

Year	Millions of £ sterling				£ per head	
	In trustee savings banks (Nov. 20)	In post office savings banks (Dec. 31)	Savings certificates* (Dec. 31)	Total	Money value	Real value†

*Including accrued interest. †In terms of the prices of 1938

In addition to the sale of national savings certificates, the savings banks purchase government stocks and bonds, and government life annuities for their depositors. The total amount of stock held on their registers amounted to £124,500,000 in 19jj.

In Scotland there are. moreover, a few savings banks entirely independent of government supervision; and in England there is also the Birmingham Municipal bank, which is somewhat similar to the special investment department of the trustee savings banks but has in addition a house-purchase department. The joint-stock banks also accept savings deposits. while other large savings institutions are the building and co-operative societies.

The chancellor of the exchequer in his 1956 budget speech intimated that interest up to £1j on deposits in the post office savings banks and in the ordinary department of trustee savings banks would be free of income tax for each individual. It was also decided that the total limit of deposit in the special investment department of trustee savings banks would be increased from £1,000 to £2.000. In order further to stimulate savings through the national savings movement the chancellor of the exchequer announced the introduction of new issues of national savings certificates and defense bonds which would carry increased rates of interest. These concessions to depositors and investors through the national savings movement were made for the purpose of increasing savings in order to assist the nation in its fight against inflation.

France.— The first French savings bank was that of Paris, the Caisse d'Épargne de Paris. instituted in 1818. Soon thereafter other savings banks were established at Bordeaux. Rouen, Metz. Marseilles and Nantes, and by the end of 1955 there were 585 savings banks (including those in the countries of the French Union) with 3.785 offices. 12,750,000 depositors and funds amounting to 842,285,000,000 metropolitan francs.

The French savings hanks, like the British trustee savings banks, are controlled by a board of management. the members of which are chosen irom among well-known citizens of the locality. Government permission is required for the establishment of a new savings bank or a new branch office. and the banks are not permitted to encroach upon each other's territories by establishing branch offices in other localities than their own.

The maximum deposit for individual saving is 500.000 metropolitan francs. The funds of the banks are deposited with the Caisse des Dépôts et Consignations, a government institution, which invests them in government securities or in securities guaranteed by the government; in debentures issued by chambers of commerce; with the Crédit Foncier de France; or in French and foreign securities authorized by the minister of finance.

In 1950 an act was passed permitting the savings banks to use part of their deposits to grant credits in accordance with their own judgment to public bodies and institutions, for the purpose, primarily, of stimulating the national economy and the building of low-rent houses.

In addition to the savings banks there is the Caisse Xationale d'Épargne Postale, which is well-established throughout France and is the equivalent of the post office savings bank in the U.K., with deposits at Dec. 31, 19j5, of j59.933.560,000 fr.

German Federal Republic.— The German savings banks (*Sparkassen*) are mostly municipal savings banks. They are common welfare institutions juridically independent. incorporated under the provisions of public law and enjoying the guarantee of the municipalities. These are called "official savings banks"; but there are also a few private savings banks which do not enjoy a municipal guarantee. The legal regulations concerning savings banks are voted separately by each province. Until 194j there were five such juridical zones in Western Germany; viz., I'russia. Bavaria, Württemberg. Baden and Hesse. Through the dissolution of the Prussian state three new provinces, Schleswig-Holstein, Lower Saxony and Xorth Rhine-Westphalia. were created. each having its own savings bank laws. One of the characteristics of the German savings banks is that normal savings activities. the short-term current account and transier deposits *(Giro)* are handled simultaneously.

In 193; after World War II. the German savings banks founded the General League of the Savings Banks and Clearing House association. which has the legal character of a nonincorporated association. to promote the interests of its members. of member regional associations and of clearing houses through advice, assistance, the exchange of' experience. etc.

At Dec. 31.195j, there were 880 separate savings banks in the Federal Republic. with nearly 7,000 branches and agencies and a total of 13,248,000,000 DM. of savings deposited.

The **U.S.S.R.**—The new savings banks in the U.S.S.R. began early in 1923. The principal aim of these hanks. which are state organizations, is to collect the people's available resources by means of deposits or of subscriptions to state loans and to direct these resources to funds necessary lor national economy. The general management of the savings banks and of state credit. which is a section of the ministry of finance. invests the funds of the savings banks. controls their functioning and issues instructions relating to the technique of their operations. The funds of the savings banks are paid into the state savings bank. which invests them in government bonds.

The foundation capital of the savings banks. supplied by the government. was 10,000,000 roubles. The reserve funds are made up irom sums deducted from profits; another part of the net profit goes to the treasury, the remainder to the fund for the improvement of the material condition of the personnel.

At the end of 1950 the total deposits in these savings banks amounted to 17.000,000,000 roubles; the interest paid on deposits amounted to 5% on six months' notice and 6% for other deposits.

Other avenues through which Soviet families may invest their money include state loans: collective deposits with the co-operative banks *(Vsekobunk)*. municipal banks (*Tsekombank*) and rural banks (*Selkhozbank*); and payments to mutual-help associations and to social insurance. (R. T. H. S.)

SAVINKOV, BORIS (pen-name, Ropshin) (1879–1925), Russian revolutionary, joined the socialist-revolutionary party at the beginning of the 20th century and reached a high position in the councils of the party, becoming one of the five members of its "Militant Organization" and thus jointly responsible with the other members of that committee for the planning and execution of numerous terrorist assassinations. During the years immediately preceding 1914 he withdrew from active membership of the party, and in his novel *The White Horse* revealed a deeply pessimistic view of the position of the "intelligentsia" in pre-war Russia. From 1914 onwards he took a strongly pro-war attitude, and after the February 1917 revolution he became Kerensky's able assistant, holding the position of vice-minister for war in the 2nd coalition government of August. He played an equivocal part in the Kornilov affair, and after the Bolshevik revolution devoted himself to anti-Soviet activities. He was caught by the G.P.U. secretly entering Soviet Russia for purposes never clearly elucidated, was brought to trial in Moscow for his anti-Soviet activities, and was sentenced to ten years' imprisonment. He died in prison in 1925.

SAVOFF, MICHAEL (1857–1928), Bulgarian general and statesman, after three years in the Russian Staff academy in St. Petersburg, became a captain in the Bulgarian army when, on the outbreak of war with Serbia, he commanded one wing of the Bulgarian army at their brilliant victory of Slivnitza. In 1887 he was appointed assistant to the minister of war, and in 1891 minister. He resigned in 1897, but after a further period in the army, and as commandant of the military academy at Sofia, he again held the same office in 1902 in Petroff's cabinet. The military law of 1904 was largely due to him. He retired into private life in 1908, but was appointed commander-in-chief of the Bulgarian army during the 1st and 2nd Balkan wars (1912–13). Savoff signed the orders of June 29, 1913, commanding the Bulgarian Fourth army to attack the Greek and Serbian force, thus opening the second Balkan War. For this he was recalled and an enquiry opened which was, however, never concluded; Savoff declared that the order had been given him by King Ferdinand. Although holding no command in R'orld War I, owing to ill health, he strongly urged that Bulgaria join the Central Powers in order to recover Macedonia from Serbia. In Sept. 1918 he returned to Bulgaria from abroad in an attempt to overthrow the Malinoff cabinet, and keep Bulgaria in the war, but found that King Ferdinand had already abdicated. On Oct. 22, 1922, he mas appointed Bulgarian minister in Paris, but retired after the anti-Agrarian *coup d'état* of June 9, 1923. He died on July 22, 1928, at Vallier-de-Thiey, Alpes-Maritimes.

SAVOIE, a *département* of France, formed in 1860 of the old provinces of Haute Savoie, Savoie, the Tarentaise and the Maurienne, which constituted the southern portion of the duchy of Savoy. It is bounded north by the *département* of Haute-Savoie, east and southeast by Italy, southwest by the *département* of Hautes Alpes, and west by those of the Isère and the Ain. Pop. (1954) 252,192; area 2,389 sq.mi. It is mainly made up of the basin of the Isère. Probably the Isère formerly communicated with the Rhône past Chambéry and the Lac du Bourget. The sources of the Isère and of the Arc are separated by the ridge of the Col du l'Iseran (9,173 ft.). The loftiest points are the Grande Casse (12,667 ft.), the culminating summit of the Vanoise group, the Mont Pourri (12,428 ft.), the Pointe de Charbonel (12.306 ft.), the Aiguille de la Grande Sassière (12.323 ft.), the Dent Parrachée (12,083 ft.), the Levanna (11,942 ft.) and the Aiguilles d'Arves (11.529 ft.). A small portion of the department (including both shores of the Lac du Bourget) is in the part of the duchy of Savoy neutralized in 1815. The chief products are cattle and dairy products and wine. There are general inanufactures and tobacco is grown. It is divided into 3 *arrondissements* (Chambéry, the chief town, Albertville and St.-Jean-de-bfaurienne), 29 cantons and 330 communes. It forms the dioceses of Chambdry (an archbishopric), Moutiers-Tarentaise, St.-Jean-de-hlaurienne and Anneçy, it is in the XIVth military region (Lyons), and is in the *académie* (educational division) of Chambéry, where is its court of appeal. There are mineral springs at Aix-les-Bains (*q.v.*), while other sulfur springs rise at Marlioz and at Challes, those of Salins being saline, and those of Brides (the best known after Aix) alkaline. For the history of the district *see* SAVOY, HOUSE OF.

See J. J. Vernier, *Dict. top. du dép. de la* **Savoie** (1897).

SAVONA, a seaport and episcopal see of Liguria, Italy, the capital of the province of Savona, 27 mi. W.S.W. of Genoa by rail, 33 ft. above sea level, and after Genoa and Nice the most important city of the Riviera. Pop. (1957 est.) 69,817, commune. The greater part of the town is now modern with fine streets with porticoes. It is surrounded with green-clad hills and luxuriant orange groves. Near the shore stands the castle built by the Genoese in 1542, on the area of the old cathedral, and now occupied by large ironworks. The cathedral (1589–1604) is a late Renaissance building with a 12th century font, fine choir-stalls and pulpit (1500). In the Cappella Sistina, to the north. stands the finely carved tomb erected by Sixtus IV to his parents. Facing the cathedral is the Della Rovere palace erected by Cardinal Giulio della Rovere (Julius II) from the plans of Giuliano da Sangallo, now occupied by various public buildings, the prefecture. the post-office and law-courts.

The municipal picture gallery is interesting. and there are some fine old buildings in the town. Good majolica was made in the 16th. 17th and 18th centuries. The Teatro Chiabrera was erected in 1853 in honour of the lyric poet Chisbrera (1552–1637). The harbour, dating from 1815, has since 1880 been provided with a dock excavated in the rock, 986 ft. long, 460 ft. wide and 23 ft. deep. Savona is one of the chief seats of the Italian iron industry, having ironworks and foundries, shipbuilding, railway workshops, a railway signal factory. engineering shops, brass foundry, tinplate works, sulphur mills and glassworks. In 1934–36 an average of 4.014 vessels of 4,279,943 tons entered and cleared the port yearly. Most of the goods were imports, almost entirely foreign coal and petrol. The coal imported at Savona is dealt with by an extensive telpherage system. There is a railway through the mountains from Savona to Turin (91 mi. N.N.W.). The city was bombed by the Allies during World War II.

Savona is the ancient *Savo,* a town of the Ingauni, but less important than Vada Sabatia (Vado), 4 mi. to the W., up to which the coast road from Rome was reconstructed in 109 B.C., from which a road diverged across the Apennines to Placentia. In 1191 Savona bought up the territorial claims of the marquesses Del Carretto. Its whole history is that of a long struggle against the preponderance of Genoa. As early as the 12th century the Savonese built themselves a sufficient harbour; but in the 16th century the Genoese, fearing that Francis I of France intended to make it a great seat of Mediterranean trade, rendered it useless by sinking at its mouth vessels filled with large stones.

SAVONAROLA, GIROLAMO (1452–1498), Italian monk and reformer, born at Ferrara on Sept. 21, 1452, was the third child of Michele Savonarola and his wife Elena Bonaccossi of Mantua. Elena was tenderly loved by her famous son, and his letters Prove that she retained his fullest confidence through all the vicissitudes of his career. Girolamo was intended for the medical profession, but even as a boy he had intense pleasure in reading St. Thomas Aquinas and the Arab commentators of Aristotle. was skilled in the subtleties of the schools, wrote verses and studied music and design. To the mystic young student all festivities were repulsive, and although reared in a courtier-household he early asserted his individuality by his contempt for court life. At the age of 19 he was passionately in love with the daughter of a neighbour, a Strozzi exiled from Florence, but his suit was repulsed with disdain and this probably decided his career. He was full of doubt and self-distrust, but in 1474 his doubts were dispelled by a sermon heard at Faenza and he entered the monastery of St. Domenico at Bologna, where his novitiate was marked by a fervour of humility. He passed six quiet years in the convent: but his poems written during that period are expressive of burning indignation against the corruptions of the church.

In 1482 he reluctantly accepted a mission to Ferrara, and later he was sent to the convent of St. Mark in Florence. In 1483 he was Lenten preacher in the church of St. Lorenzo, but his plain, earnest exhortations attracted few hearers. His first success as a preacher was gained at San Gimignano (1484-85), but it was only at Brescia in the following year that his power as an orator was fully revealed. In a sermon on the Apocalypse he shook men's souls by his terrible threats of the wrath to come, and drew tears from their eyes by the tender pathos of his assurances of divine mercy. Soon, at a Dominican council at Reggio, Savonarola had occasion to display his theological learning and subtlety. The famous Pico della Mirandola was particularly impressed by the friar's attainments, and is said to have urged Lorenzo de' Medici to recall him from Lombardy. When Savonarola returned to Florence in 1490, his fame as an orator had gone there before him, and on Aug. 1, 1490, he first preached in the church of St. Mark.

Prior of St. Mark's.—In 1491 he was invited to preach in the cathedral, and his rule over Florence may be said to begin from that date. Lorenzo sent leading citizens to him to urge him to show more respect to the head of the state. Savonarola rejected their advice and foretold the impending deaths of Lorenzo, of the pope and of the king of Naples. In the July of the same year he was elected prior of St. Mark's. As the convent had been rebuilt by Cosimo, and enriched by the bounty of the Medici, it was considered the duty of the new superior to present his homage to Lorenzo. Savonarola, however, refused to conform to the usage. His election was due to God, not Lorenzo. In April 1492, Lorenzo de' Medici was on his death-bed at Careggi. Oppressed by the weight of his sins, he summoned the unyielding prior to shrive his soul. Savonarola reluctantly came and offered absolution upon three conditions. Lorenzo asked in what they consisted. First, "You must repent and feel true faith in God's mercy." Lorenzo assented. Secondly, "You must give up your ill-gotten wealth." This, too, Lorenzo promised, after some hesitation; but upon hearing the third clause, "You must restore the liberties of Florence," Lorenzo turned his face to the wall and made no reply. Savonarola waited a few moments and then went away. And shortly after Lorenzo died unabsolved.

Savonarola's influence now rapidly increased. The same year Innocent VIII. died (July 1492) and men's minds were full of anxiety, an anxiety increased by the scandalous election of Cardinal Borgia to the papal chair. During the delivery of one of his Advent sermons, Savonarola beheld the vision, recorded in contemporary medals and engravings, that is almost a symbol of his doctrine. A hand appeared to him bearing a flaming sword inscribed with the words: "Gladius Domini supra terram cito et velociter." He heard supernatural voices proclaiming mercy to the faithful, vengeance on the guilty, and mighty cries that the wrath of God was at hand. Then the sword bent towards the earth, the sky darkened, thunder pealed, lightning flashed, and the whole world was wasted by famine, bloodshed and pestilence. He was presently addressing enthusiastic congregations at Prato and Bologna whence he returned to Florence. He was rapturously welcomed by the community of St. Mark's, and at once proceeded to re-establish the discipline of the order. For this purpose he obtained, after much difficulty, a papal brief emancipating the Dominicans of St. Mark from the rule of the Lombard vicars of that order. He thus became an independent authority, no longer at the command of distant superiors. He relegated many of the brethren to a quieter retreat outside the city, only retaining in Florence those best fitted to aid in intellectual labour. Meanwhile he thundered forth predictions of heavenly wrath. In 1494 the duke of Milan demanded the aid of France, and King Charles VIII. brought an army across the Alps. The incompetent policy of Piero de' Medici, Lorenzo's successor, towards Charles drove Florence to revolt. But even at this crisis Savonarola's influence was all-powerful, and a bloodless revolution was effected. The resuscitated republic sent a fresh embassy to the French king, to arrange the terms of his reception in Florence. Savonarola was one of the envoys, Charles being known to entertain the greatest veneration for the friar who had so long predicted his coming and declared it to be divinely ordained. Charles entered Florence on Nov. 17, 1494, but the exorbitance of his demands soon showed that he came as a foe. The signory resolved to be rid of their dangerous guest; and, when Charles threatened to sound his trumpets unless the sums exacted were paid, Capponi tore up the treaty in his face and made the memorable reply: "Then we will ring our bells." The monarch, alarmed at the dangerous possibilities of fighting in the narrow streets of the city, accepted moderate terms, and, yielding to Savonarola's remonstrances, left Florence on Nov. 24.

The citizens turned to the patriot monk whose words had freed them of King Charles, and Savonarola became the law-giver of Florence. The first thing done at his instance was to relieve the starving populace within and without the walls; shops were opened to give work to the unemployed; all taxes, especially those weighing on the lower classes, were reduced; the strictest administration of justice was enforced, and all men were exhorted to place their trust in the Lord. And, after much debate as to the constitution of the new republic, Savonarola's influence carried the day in favour of Soderini's proposal of a universal or general government, with a great council on the Venetian plan. Savonarola's programme of the new government was comprised in the following formula: (1) fear of God and purification of manners; (2) promotion of the public welfare in preference to private interests; (3) a general amnesty to political offenders; (4) a council on the Venetian model, but with no doge. At first the new machinery acted well; the public mind was tranquil.

Dictator of Florence.—Without holding any official post in the commonwealth he had created, the prior of St. Mark's was the dictator of Florence, and guarded the public weal with extraordinary political wisdom. At his instance the tyrannical system of arbitrary imposts and so-called voluntary loans was abolished, and replaced by a tax of 10% (la decima) on all real property. His counsels were always given as addenda to the religious exhortations in which he denounced the sins of his country and the pollution of the church, and urged Florence to cast off iniquity and become a truly Christian city, a pattern not only to Rome but to the world at large. His eloquence was now at the flood. Pleasure-loving Florence was completely changed. Abjuring pomps and vanities, its citizens observed the ascetic régime of the cloister. Hymns and psalms rang in the streets that had so recently echoed with Lorenzo's dissolute songs. Both sexes dressed with Puritan plainness; husbands and wives quitted their homes for convents and persons of all ranks—nobles, scholars and artists—renounced the world to assume the Dominican robe. Still more wonderful was Savonarola's influence over children, and their response to his appeals is a proof of the magnetic power of his goodness and purity. He organized the boys of Florence in a species of sacred militia and it was with the aid of these youthful enthusiasts that Savonarola arranged the religious carnival of 1496, when the citizens gave their costliest possessions in alms to the poor, and tonsured monks, crowned with flowers, sang hymns and performed wild dances for the glory of God. In the same spirit, and to point the doctrine of renunciation of worldly enjoyments, he celebrated the carnival of 1497 by the famous "burning of the vanities" (*i.e.* masks and other objects pertaining to the carnival festivities, indecent books and pictures, etc.) in the Piazza della Signoria. Nevertheless the artistic value of the objects consumed has been greatly exaggerated by some writers. Savonarola was foe neither to art nor to learning. On the contrary, so great was his respect for both that, when there was a question of selling the Medici library to pay that family's debts he saved the collection at the expense of the convent purse.

Conflict with the Pope.—Meanwhile his uncompromising spirit roused the hatred of political adversaries as well as of the degraded court of Rome. Even now, when his authority was at its highest, when his fame filled the land, and the vast cathedral and its precincts lacked space for the crowds flocking to hear him, his enemies were secretly preparing his downfall. Events were taking a turn hostile to the prior and Alexander VI., having seen a transcript of one of Savonarola's denunciations of his crimes, resolved to silence this daring preacher.

Bribery was the first weapon employed, and a cardinal's hat was held out as a bait. But Savonarola indignantly spurned the offer. So long as King Charles remained in Italy Alexander's concern for his own safety prevented vigorous measures against the friar, but no Borgia ever forgave an enemy. He bided his time and in July 1495, a papal brief courteously summoned Savonarola to Rome. In terms of equal courtesy the prior declined the invitation, nor did he obey a second less softly worded, in September. Then came a third, threatening Florence with an interdict in case of renewed refusal. 'Savonarola disregarded the command, but went to preach for a while in other Tuscan cities. But in Lent his celebrated sermons upon Amos were delivered in the Duomo, and again he urged the necessity of reforming the church, striving by ingenious arguments to reconcile rebellion against Alexander with unalterable fidelity to the Holy See. Alexander now issued a brief, uniting St. Mark's to a new Tuscan branch of the Dominicans, thus depriving Savonarola of his independent power, while Piero de' Medici's followers continued their intrigues, and party spirit increased in virulence. The citizens were growing weary of the monastic austerities imposed on them, and Alexander foresaw that his revenge was at hand.

A signory openly hostile to Savonarola took office in May, and, in feigned anxiety for the public peace, besought him to suspend his discourses. Shortly afterwards the threatened bull of excommunication was launched against him, and Fra Mariano was in Rome stimulating the pope's wrath. Savonarola remained undaunted. The sentence was null and void, he said. His mission was divinely inspired; and Alexander, elected simoniacally and laden with crimes, was no true pope. Nevertheless the reading of the bull in the Duomo with the appropriate, terrifying ceremonial, made a deep impression on the Florentines. But in July Savonarola's friends were again in power and did their best to have his excommunication removed. During this time Rome was horror-struck by the mysterious murder of the young duke of Gandia, and the bereaved pope mourned his son with the wildest grief. Savonarola wrote him a letter of condolence, boldly urging him to bow to the will of Heaven and repent while there was yet time.

Florence then was plunged in new troubles through Medicean intrigues, and a conspiracy for the restoration of Piero was discovered and resulted in the execution of five leading citizens including Bernardo del Nero, a very aged man of lofty talents and position. It is said that at least Bernardo del Nero would have been spared had Savonarola raised his voice, but the prior would not ask mercy for them. This silence proved fatal to his popularity with moderate men. He was now interdicted from preaching even in his own convent and again summoned to Rome. As before, the mandate was disobeyed. He refrained from public preaching, but held conferences in St. Mark's with large gatherings of his disciples, and defied the interdict on Christmas Day by publicly celebrating mass and heading a procession through the cloisters. In 1498 the Piagnoni, as Savonarola's followers were called, were again at the head of the state, and at their request the prior resumed his sermons in the Duomo, while his dearest disciple, Fra Domenico Buonvicini, filled the pulpit of St. Lorenzo. For the last time the carnival was again kept with strange religious festivities, and some valuable books and works of art were sacrificed in a second bonfire of "vanities." But menacing briefs poured in from Rome, the city itself was threatened with interdict, and the Florentine ambassador could barely obtain a short delay. Now, too, the Piagnoni quitted office; the new signory was less friendly, and the prior was persuaded by his adherents to retire to St. Mark's. Alexander now demanded that the Florentines should silence the man themselves or send him to be judged by a Roman tribunal. Savonarola now despatched letters to the rulers of Europe adjuring them to assemble a council to condemn this antipope. But the papal threats were now urgent, and the signory entreated Savonarola to cease preaching. He obeyed, and concluded his last discourse with the most touching farewell.

The government hoped that Alexander would be appeased and Florence allowed to breathe freely. But although silenced, the prophet was doomed. A creature of the Arrabbiati, a Franciscan friar named Francesco di Puglia, challenged Savonarola to prove the truth of his doctrines by the ordeal of fire. At first the prior treated the provocation with merited contempt, but his too zealous disciple Fra Domenico accepted the challenge and, when the Franciscan declared that he would enter the fire with Savonarola alone, Fra Domenico protested his willingness to enter it with any one in defence of his master's cause. As Savonarola resolutely declined the trial, the Franciscan deputed a convert, one Giuliano dei Rondinelli, to go through the ordeal with Fra Domenico. Savonarola, perceiving that a trap was being laid for him, discountenanced the "experiment" until his calmer judgment was at last overborne by the fanaticism of his followers. On April 7, 1498, an immense throng gathered in the Piazza della Signoria to enjoy the barbarous sight. The Dominicans, led by Savonarola, and the Franciscans came forward, but neither Rondinelli nor Fra Francesco appeared and there were angry disputes between the two groups of friars. It was now late in the day, and a storm shower gave the authorities a pretext for declaring that heaven was against the ordeal. The Franciscans slipped away unobserved, but Savonarola raising the host attempted to lead his monks across the piazza in solemn order as before. On this the popular fury burst forth. Defrauded of their cruel diversion, the people were wild with rage. Fra Girolamo's power was suddenly at an end. Against the real culprits, the Franciscans, no anger was felt; the zealous prior, the prophet and lawgiver of Florence, was made the popular scapegoat. Notwithstanding the anguish that must have filled his heart, the fallen man preserved his dignity and calm. Mounting his own pulpit in St. Mark's he quietly related the events of the day to the faithful assembled in the church, and then withdrew to his cell, while the mob outside clamoured for his blood.

Arrest and Trial.—The next morning the government decided on his arrest, and no sooner was this made public than the populace rushed to the attack of the convent. The monks and their few remaining friends made a most desperate defence. In vain Savonarola besought them to lay down their arms. When the church was finally stormed Savonarola was seen praying at the altar, with Fra Domenico, armed with an enormous candlestick, guarding him from the blows of the mob. A few disciples dragged their beloved master to the inner library and urged him to escape, when a cowardly monk, one Malatesta Sacramoro, cried out that the shepherd should lay down his life for his flock. Thereupon Savonarola turned, bade farewell to the brethren, and, accompanied by the faithful Domenico, quietly surrendered to his enemies. The prisoners were conveyed to the Palazzo Vecchio.

Now came an exultant brief from the pope. His well-beloved Florentines were true sons of the church, but must crown their good deeds by despatching the criminals to Rome. The signory refused to send their prisoners to Rome but they did Rome's behests. Day after day Savonarola was tortured, and in his agony, with a frame weakened by constant austerity and the mental strain of the past months, he made every admission demanded by his tormentors. But directly he was released from the rack he always withdrew the confessions uttered in the delirium of pain. These being too incoherent to serve for a legal report, a false account of the friar's avowals was drawn up and published. Alexander was frantically eager to see his enemy die in Rome. But the signory insisted that the false prophet should suffer death before the Florentines whom he had so long led astray. The matter was finally compromised. A second mock trial was held by two apostolic commissioners specially appointed by the pope. Meanwhile the trial of Brothers Domenico and Silvestro was still in progress. The former remained faithful to his master and himself. No extremity of torture could make him recant or extract a syllable to Savonarola's hurt; he steadfastly repeated his belief in the divinity of the prior's mission. Fra Silvestro on the contrary gave way at mere sight of the rack, and owned himself and his master guilty of every crime laid to their charge.

The two commissioners soon ended their task. They had the pope's orders that Savonarola was to die "even were he a second John the Baptist." On three successive days they "examined" the prior with worse tortures than before. On May 22 sentence of death was pronounced on him and his two disciples. Savonarola listened unmoved to the awful words and then quietly resumed his interrupted devotions. Fra Domenico exulted in the thought of dying by his master's side; Fra Silvestro, on the contrary, raved with despair. The only favour Savonarola craved before death was a short interview with his fellow victims, This the signory unwillingly granted. The memorable meeting took place in the hall of the Cinquecento. During their 40 days of confinement and torture each one had been told that the other had recanted, and the false report of Savonarola's confession had been shown to the two monks. The three were now face to face for the first time. Fra Domenico's loyalty had never wavered, and the weak Silvestro's enthusiasm rekindled at sight of his chief. Savonarola prayed with the two men, gave them his blessing, and exhorted them by the memory of their Saviour's crucifixion to submit meekly to their fate. The following morning he prophesied that dire calamities would befall Florence during the reign of a pope named Clement. The carefully recorded prediction was verified by the siege of 1529.

The execution took place the same morning. First came the ceremonial of degradation. Sacerdotal robes were thrown over the victims, and then roughly stripped off by two Dominicans, the bishop of Vasona and the prior of Sta. Maria Novella. To the bishop's formula, "I separate thee from the church militant and from the church triumphant," Savonarola replied: "That is beyond thy powers." His disciples' bodies already dangled from the arms of the cross before he was hung on the centre beam. Then the pile was fired. At dusk the martyrs' remains were thrown into the Arno.

Every year on the anniversary of Savonarola's martyrdom flowers are strewn on the spot where it took place.

Savonarola's writings may be classed in three categories: — (I) numerous sermons, collected mainly by Lorenzo Violi, one of his most enthusiastic hearers; (2) an immense number of devotional and moral essays and some theological works, of which *Il Trionfo della Croce* is the chief; (3) a few short poems and a political treatise on the government of Florence. Although his faith in the dogmas of the Roman Catholic Church never swerved, his strenuous protests against papal corruptions, his reliance on the Bible as his surest guide, and his intense moral earnestness undoubtedly connect Savonarola with the movement that heralded the Reformation.

(P. V.; L. V.)

SAVOY, HOUSE OF, a dynasty which ruled the territory of Savoy and Piedmont for nine centuries, and from 1860 to 1946 over the kingdom of Italy. The name of Savoy (Sabaudia) was known to the Romans during the decline of the empire. In the 5th century the territory was conquered by the Burgundians, and formed part of their kingdom; nearly a hundred years later it was occupied by the Franks. It was included in Charlemagne's empire and was divided by him into counties, which evolved there, as elsewhere, into hereditary fiefs; but after the break-up of Charlemagne's empire, the Burgundian kingdom revived and Savoy was again absorbed in it. After the collapse of that monarchy its territories passed to the German kings, and Savoy was divided between the counts of Provence, of Albon, of Gex, of Bresse, of the Genevois. of hlaurienne, the lords of Habsburg, of Zähringen, etc., and several prelates.

Early Counts. — The founder of the house of Savoy was Umberto Biancamano (Humbert the White-handed), a feudal lord, who in 1003 was count of Salmourenc in the Viennois, in 1017 of Nyon on the Lake of Geneva, and in 1024 of the Val d'Aosta on the eastern slope of the Western Alps. In 1034 he obtained part of Maurienne as a reward for helping King Conrad the Salic to make good his claims on Burgundy. He also obtained the counties of Savoy, Belley, part of the Tarantaise, and the Chablais. With these territories Umberto commanded three of the great Alpine passes, *viz.*, the Mont Cenis and the two St. Bernards. His son Oddone married Adelaide, eldest daughter and heiress of Odelrico Manfredi, marquess of Susa, a descendant of Arduino of Ivrea, king of Italy, who ruled over the counties of Turin, Auriate, Asti, Bredulo, Vercelli, etc., corresponding roughly to modern Piedmont and part of Liguria (1045). Umberto died c. 1048? and was succeeded by his son, Amadeus I., at whose death the country passed to Oddone. Oddone ruled over territories on both sides of the Alps. He died in 1060, and was succeeded by his widow, Adelaide; but before her death in 1091 his son, Peter I., became count, and subsequently the latter's brother, Amadeus II.

Under Humbert II. (1080) occurred the first clash with the Piedmontese communes. but he and his successors, Amadeus III. (who died on his way home from the crusades) and Thomas I. (1189), adopted a policy of conciliation towards them.

Thomas, who reigned until 1233. acquired extensions of territory in the Bugey, Vaud and Romont to the west of the Alps, and Carignano, Pinerolo, Moncalieri and Vigone to the east; he also exercised sway over Geneva, Albenga, Savona and Saluzzo. At his death these territories were divided among his sons, Thomas II. obtaining Piedmont, Aimone the Chablais, Peter and Philip other fiefs, and Amadeus IV., the eldest, Savoy and a general overlordship over his brothers' estates. Thomas II., during the wars in Piedmont, was made prisoner by the citizens of Turin, but was afterwards liberated.

Amadeus V. (1285–1323), son of Thomas II., reunited the county of Savoy (his own territory), the principality of Piedmont, ruled by his nephew Philip, prince of Achaea (a title acquired through his wife, Isabella of Villehardouin, heiress of Achaea and the Morea), and Vaud, ruled by his brother Louis. But although this division was formally recognized in 1295. Amadeus succeeded in enforcing his own supremacy over the whole country and in regaining by war, purchase or treaty, the fiefs lost by his predecessors. He fought against the dauphins of Viennois, the counts of Genevois, the people of Sion and Geneva, the marquesses of Saluzzo and Montferrat, and the barons of Faucigny, acted as peacemaker between France and England, accompanied the Emperor Henry VII. of Luxemburg on his expedition to Italy, reorganized the finances of the realm and reinforced the Salic law of succession. He was succeeded by his sons, Edward (1323–1329), known as "the Liberal," on account of his extravagance, and Aimone, the Peaceful (1329–1343), who strove to repair the harm done to the state's exchequer by his predecessor and proved one of the best princes of his line.

Amadeus VI. (1343–1383), son of Aimone, the Peaceful, and known as the *Conte Verde* or Green Count because of the costume he habitually wore at tourneys, succeeded at the age of nine. He won a reputation as a bold knight in the fields of chivalry and inaugurated a new policy by devoting more attention to his Italian possessions than to those on the French side of the Alps and in Switzerland. In 1366 he led an expedition to the East against the Turks; and he arbitrated between Milan and the house of Montferrat (1379), between the Scaligeri and the Visconti, and between Venice and Genoa after the "War of Chioggia" (1381). Amadeus was the first sovereign to introduce a system of gratuitous legal assistance for the poor. He espoused the cause of Louis, duke of Anjou, and while aiding that prince in his attempt to recover the kingdom of Naples he died of the plague, leaving his realm to his son, Amadeus VII., the *Conte Rosso* or "Red Count" (1383–1391); the latter added Nice (1388) and other territories to his domains.

Amadeus VIII. (1391–1451), count, extended his territories both in Savoy itself and in Italy, and in 1416 was created duke by the emperor Sigismund. In 1430 he promulgated a general

GENEALOGICAL TABLE OF THE HOUSE OF SAVOY.

Humbert the Whitehanded (Umberto Biancamano) (d. c. 1048?).

Amadeus . (d. c. 1056). — Oddone or Otto = Adelaide, heiress of Turin (d. 1091)

Peter I. (d. 1078). — Amadeus I . (d. 1080). — Bertha = Emperor Henry IV.

Humbert II. the Fat (d. 1103).

Amadeus III. (d. 1148 or 1149). — Alice or Adelaide = Louis VI. of France.

Humbert III. the Saint (d. 1189).

Thomas I. (d 1233)

Amadeus IV. (d. 1253). — Pete! II., earl of Richmond (d. 1268). — Philip I. (d. 1285). — Thomas II., count of Piedmont (d. 1259). — Boniface, archbishop of Canterbury (d. 1270).

Boniface (d. 1263).

Louis I. of Vaud (d. 1302.) — Amadeus V. the Great (d. 1323). — Thomas III. (d. 1282).

Edward t e Liberal (d. 1329). — Aimone the Peaceful (d. 1343). — Anne = the eastern emperor, Andronicus III. — Philip, prince of Achaea (d. 1334).

Amadeus VI. (d. 1383). — James (d. 1367).

Amadeus VII. (d. 1391). — Amadeus (d. 1402). — Louis (d. 1418).

Amadeus VIII., first duke of Savoy, afterwards Pope Felix V. (d. 1451).

Louis (d. 1465). — Philip, count of Geneva (d. 1444).

Amadeus Ik. (d. 1472). — Philip II. (d. 1497). — Louis, king of Cyprus (d. 1482).

Philibert I. (d. 1482). — Charles I. (d. 1490). — Philibert II. (d. 1504). — Charles III. (d 1553). — Philip, founder of the house of Nemours (d. 1533). — Louise = Charles, count of Angoulême

Charles II. (d. 1496). — Emmanuel Philibert (d. 1580). — Francis I. of France.

Charles Emmanuel I. (d. 1630).

Victor Amadeus I. = Christina, daughter of Henry N. of France (d. 1637). — Thomas Francis, prince of Carignano (d. 1656).

Francis yacinth (d. 1638). — Charles Emmanuel II. (d. 1675). — Emmanuel Philibert (d. 1709). — Eugene Maurice count of Soissons (d. 1673).

Victor Amadeus II. (d. 1732). King of Sardinia, 1720; abdicated 1730 = Anne of Orleans, granddaughter of Charles I. of England. — Victor Amadeus (d. 1741). — Eugene. the famous general (d. 1736).

Charles Emmanuel III. (d. 1773). — Louis Victor (d. 1778).

Victor Amadeus III. (d. 1796). — Victor Amadeus (d. 1780).

Charles Emmanuel (d. 1800).

Charles Emmanuel IV. (d. 1819); abdicated 1802. — Victor Emmanuel I. (d. 1824); abdicated 1821. — Charles Felix (d. 1831). — Charles Albert (d. 1849). King of Sardinia; abdicated 1849.

Victor Emmanuel II. (d. 1878). King of Italy, 1861. — Ferdinand, uke of Genoa (d. 1855).

Humbert (d. 1900), king of Italy = Margherita of Savoy-Genoa. — Amadeus (d. 1890), duke of Aosta. King of Spain, 1870–73. — Clothilde = Prince Napoleon (d. 1891). — Maria Pia (d. 1911) = Louis, king of Portugal. — Margherita = Humbert, (d. 1926) king of Italy. — Thomas, duke of Genoa (d. 1931).

Victor Emmanuel III., king of Italy (d. 1947) = Elena Petrovich-Niegbsh (1873-1952); abdicated 1946. — Emmanuel Philibert, duke of Aosta (d. 1931). — Victor Emmanuel, count of Turin (d. 1946). — Louis Amadeus, duke of the Abruzzi (d. 1933). — Humbert, count of Salemi (d. 1918).

Yolanda Margherita (b. 1901). — Mafalda (b. 1902). — Humbert II (b. 1904) king of Italy = Marie José of Belgium; monarchy terminated 1946. — Giovanna (b. 1907). — Maria (b. 1914). — Amadeus, duke of Aoata (d. 1942). — Aimone, duke of Aosta (d. 1948). — Ferdinand, duke of Genoa (b. 1884). — Philibert, duke of Pistoia (b. 1895). — Maria! Rona Margherita (b. 1896). — Adalbert, duke of Bergamo (b. 1898). — Eugene (b. 1906).

statute of laws for the whole duchy, in spite of the opposition of the nobles and cities whose privileges were thereby curtailed. In 1434 he retired to the hermitage of Ripaille on the Lake of Geneva, but continued to conduct the chief affairs of the State and to mediate between foreign Powers, leaving matters of less importance to his son Louis. Five years later the council of Basel elected Amadeus pope, in spite of his not being a priest, and deposed Eugenius IV. Amadeus accepted the dignity, assuming the style of Felix V. In 1449 Amadeus abdicated and returned to his hermitage at Ripaille, where he died two years later.

15th Century.— Under Louis, Savoy began to decline, for he was indolent, incapable, and ruled by his wife, Anne of Lusignan, daughter of the king of Cyprus, who induced him to fit out an expedition to Cyprus, which brought him no advantage save the barren title of king of Cyprus, Jerusalem and Armenia. He went to France to seek aid of King Louis XI. against his nobles, and died there in 1465. In spite of his incapacity he acquired the city of Freiburg and the homage of the lords of Monaco. He was succeeded by his son, Amadeus IX. (1455–1472), who on account of ill-health left the duchy in the hands of his wife, Yolande, sister of Louis XI. During the minority of his son Philibert I. (1472–1482) Savoy lost Freiburg and many other territories. Philibert was succeeded by his brother Charles I. (1482–1490), who, freed by Louis XI. from the dangerous protection of Philip of Bresse and by death from that of the French king, crushed the rebellious nobles and seized Saluzzo (1487). He did much to raise the fortunes of his house, but died at the age of 31. Under his successors the duchy lost ground until the accession of Emmanuel Philibert in 1553.

Emmanuel Philibert.—At the time of his accession, Emmanuel Philibert was serving in the Spanish armies. Emmanuel could not take possession of the duchy at once, but continued to serve the emperor as governor-general of the Low Countries. By his victory at St. Quentin over the French in 1557 he proved himself one of the first generals of the day, and by the terms of the subsequent treaty of Cateau Cambrésis he was reinstated in most of his hereditary possessions (1559). Under Emmanuel Philibert Savoy lost all traces of constitutional government and became an absolute despotism of the type then predominating throughout the greater part of Europe. At the same time he raised his country from ruin and degradation into a prosperous and powerful monarchy.

Charles **Emmanuel** I.—His son and successor, Charles Emmanuel I. (*q.v.*), surnamed the Great, strengthened the tendency of Savoy to become less of a French and more of an Italian Power. In 1588 he wrested Saluzzo from the French, but his expeditions to Provence and Switzerland were unsuccessful. In the war between France and Spain after the accession of Henry IV., he took the Spanish side, and at the peace of Lyons (1601), although he gave up all his territories beyond the Rhone, his possession of Saluzzo was confirmed. His attempt to capture Geneva by treachery (1602) failed, and although on the death of Francesco Gonzaga, duke of Mantua and Montferrat, he seized the latter city (1612) he was forced by Spain and her allies to relinquish it. The Spaniards invaded the duchy, but after several years of hard fighting the peace of 1618 left his territory almost intact. In 1628 he sided with Spain against France; the armies of the latter overran the duchy. and Charles Emmanuel died in 1630. (See CHARLES EMMANUEL I.) His son, Victor Amadeus I. (1630–1637), succeeded to little more than a title, but by his alliance with France—his wife, Christina, being a daughter of Henry IV.—he managed to regain moat of his territories. He proved a wise and popular ruler, and his early death was much deplored. He was succeeded by his second son, Charles Emmanuel II., who, being a minor, remained under the regency of his mother. That princess, in spite of her French origin, resisted the attempts of France, then dominated by Cardinal Richelieu, to govern Savoy, but her quarrels with her brothers-in-law led to civil war, in which the latter obtained the help of Spain, and Christina that of France. In the end the duchess succeeded in patching up these feuds and saving the dynasty, and in 1648 Charles Emmanuel II. assumed the government. The war between France and Spain continued, and Savoy, on whose territory much of the fighting took place, suffered severely in consequence. By the treaty of the Pyrenees *(1669)* Savoy regained most of the towns occupied by France.

Victor Amadeus 11.—Charles died in *1675* and was succeeded by his only son, Victor Amadeus II. (*q.v.*). The French king's arrogant treatment of Victor Amadeus spurred the latter to join the league of Austria, Spain and Venice against him in *1690.* The campaign was carried on with varying success, but usually to the advantage of Louis, and the French victory at Marsiglia and the conduct of the allies induced Victor to come to terms with France *(1696).* By the treaty of Ryswick a general peace was concluded. In the War of the Spanish Succession *(1700)* Victor fought on the French side, until, dissatisfied with the continued insolence of Louis XIV. and of Philip of Spain, he went to the Austrians in *1704.* The French invaded Piedmont, but were totally defeated at the siege of Turin by Victor Amadeus and Prince Eugene of Savoy (1706), and eventually driven from the country. By the treaty of Utrecht *(1713)* Victor received the long-coveted Montferrat and was made king of Sicily; but in *1718* the powers obliged him to exchange that kingdom for Sardinia, which conferred on the rulers of Savoy and Piedmont the title subsequently borne by them until they assumed that of kings of Italy. In *1730* he abdicated in favour of his son, Charles Emmanuel.

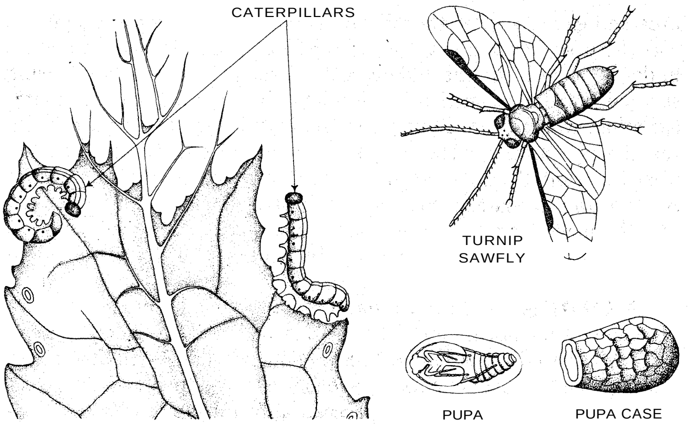
Charles **Emmanuel** 111.—Charles Emmanuel III. (1730–1773), a born soldier, took part in the War of the Polish Succession on the side of France against Austria, and for his victory at Guastalla *(1734)* was awarded the duchy of Milan, which, however, he was forced to relinquish at the peace of Vienna (1736), retaining only Novara and Tortona. In the War of the Austrian Succession, which broke out on the death of the Emperor Charles VI., he took the side of Maria Theresa *(1742).* By the peace of Aix-la-Chapelle in *1748,* following on the defeat of the French, Savoy gained some further accessions of territory in Piedmont. The reign of Charles's son, Victor Amadeus III. (1773–1796), was a period of decadence; the king was incapable and extravagant, and he chose equally incapable ministers. On the outbreak of the French Revolution he sided with the royalists and was eventually brought into conflict with the French republic. The army being demoralized and the treasury empty, the kingdom fell an easy prey to the republican forces. Savoy became a French province, and, although the Piedmontese troops resisted bravely for four years in the face of continual defeats, Victor at last gave up the struggle and signed the armistice of Cherasco. On his death in *1796,* he was succeeded in turn by his three sons, Charles Emmanuel IV., Victor Emmanuel I. and Charles Felix.

Charles **Emmanuel IV.**—Charles Emmanuel (1796–1802), believing in Bonaparte's promises, was induced to enter into a confederation with France and give up the citadel of Turin to the French, which meant the end of his country's independence. Realizing his folly he abdicated on Dec. *6, 1798,* and retired to Sardinia, while the French occupied the whole of Piedmont. After the defeat of the French by the Austro-Russian armies during Bonaparte's absence in Egypt, Charles Emmanuel landed at Leghorn, hoping to regain his kingdom; but Napoleon returned, and by his brilliant victory at Marengo he reaffirmed his position in Italy. The king retired to Naples, abdicated once more (1802), and entered the Society of Jesus; he died in Rome in *1819.* Victor Emmanuel I. *(1802–1820)* remained in Sardinia until by the Final Act of the Congress of Vienna (June *9, 1815)* his dominions were restored to him, with the addition of Genoa.

Italian Allegiance.— From this time the fortunes of the house of Savoy are bound up with those of Italy. *(See* ITALY: ***History.)*** Victor Emmanuel I. abdicated in *1821* in favour of his brother Charles Felix *(1821–1831).* The latter being without a son, the succession devolved upon Charles Albert, of the cadet line of the princes of Carignano, who were descended from Thomas, youngest son of Charles Emmanuel I. Charles Albert abdicated, on the evening of his defeat at Novara (April *20,* 1849), in favour of his son Victor Emmanuel II. (1849–1878), who on Feb. *18, 1861,* was proclaimed king of Italy. Victor Emmanuel had married in *1842* Maria Adelaide, daughter of the archduke Rainer, who bore him several children, viz., Princess Clothilde (1843–1891), who married Prince Napoleon; Humbert (*q.v.*), who succeeded him; Amadeus, duke of Aosta *(1845–1890)*; Oddone, duke of Montferrat *(1846–1866)*; and Princess Maria Pia *(1847–1911).* Humbert was succeeded by his only son, Victor Emmanuel III (*q.v.*), who on May *9, 1946,* abdicated in favour of his only son, Humbert II. On June *2, 1946,* however, the Italian people voted to end the monarchy.

The second son of Victor Emmanuel II, Amadeus, duke of Aosta, was offered the crown of Spain by the Cortes in *1870,* which he accepted, hut, finding that his rule was not popular, he abdicated in *1873* rather than cause civil war. In *1867* he married Princess Maria Vittoria dal Pozzo della Cisterna, who bore him three sons, viz., Emmanuel Philibert, duke of Aosta (1869–1931), Victor Emmanuel, count of Turin, and Louis Amadeus, duke of the Abruzzi *(1873–1933).* The first wife of Amadeus, duke of Aosta, having died in *1876,* he married Princess Maria Letizia Bonaparte in *1888,* who bore him a son, Humbert, count of Salemi *(1889–1918).* (L. V.)

SAWFLY, name given to members of the division Chalasto-



LIFE CYCLE OF **TURNIP** SAWFLY (ATHALIA SPINARUM)

gastra of the order Hymenoptera (*q.v.*), characterized by the broad base to the abdomen, where it joins the thorax and by the wing veins being less reduced than in other members of the order. Their name is derived from the fact that the lower or anterior blades of the ovipositor are toothed and sawlike. Their larvae are usually caterpillars and in most cases may be distinguished from those of moths and butterflies by having six or more pairs of abdominal feet and only a single pair of simple eyes or ocelli. When disturbed they roll themselves in a spiral fashion and some species discharge a thin fluid from glands above the spiracles. The females lay their eggs in incisions in plants, cut by the sawlike blades of the ovipositor, and the larvae are vegetable feeders. Species of several genera, notably *Pontania,* form galls on willows. The cause of the gall is stated to be a secretion injected along with the egg, and it has been suggested that it contains an enzyme which acts upon the plant so as to induce gall formation.

Reproduction in sawflies is of considerable interest: in many species males are unknown and parthenogenesis (*q.v.*) is the rule. In the gooseberry sawfly the unfertilized eggs give rise only to males, where the fertilized eggs produce individuals of both sexes, females predominating.

The true sawflies belong to the large family Tenthredinidae. and the larvae of many of these are injurious to plants. Thus, the gooseberry sawfly, *Nematus ribesii,* is very destructive to that plant and to currants, while the pear slug, *Caliroa limacina,* attacks pears. These two species and also the larch saafly, *Lygaeonetnatus erichsonii,* were accidentally imported from Europe into North America, where they likewise became destructive. Other harmful species in Europe are *Athalia spinarum,* the turnip sawfly, and *Lophyrus pini,* which attacks plantations of Scotch firs. The best remedy is to shake off and destroy the young larvae from bushes, where practicable, or to spray with an arsenical wash.

The small families Cephidae and Siricidae have larvae that are borers. The Cephidae make burrows, usually in stems; the best-known species is *Cephus pygmaeus,* which attacks wheat. It is destructive in North America, where *Janus integer,* the stem girdler of the currant is also troublesome; the latter seldom causes appreciable injury in Great Britain. The Siricidae bore into solid timber and are known as wood wasps or horntails. *Sirex gigas* is the most familiar European wood wasp and is not uncommon in Great Britain. (A. D. I.)

SAWMILL, a mill in which logs are cut into rough-squared sections or into planks and boards for sale or further treatment. The word is often applied to a mill equipped with planing, molding, tenoning and other machines for finishing processes. The biggest mills are usually situated where timber can be brought by river or rail, and the design of the mill is in some degree affected by the mode of transportation. More space is necessary for storage in the rail-borne system. Water-borne logs float into the mill and are dragged out in turn by a winch. An overhead crane serves the stock yard in the rail system, and carries the logs to the machines.

The cutting is performed on various kinds of big machines, a preliminary operation often being that of crosscutting to obtain convenient lengths. Cutting up into the various thicknesses is done by either reciprocating saws or band saws. (known also as circular saws), the log being held on a table which feeds it past the saw. The log frame is a machine with a set of vertically reciprocating blades, suitably spaced apart: it divides a log into boards at one pass of the table. The number of blades may be few, not exceeding four in some cases for cutting thick pieces, or as many as fifty for thin boards Resawing machines are those for further dealing with material partly broken up. such as flitches and deals. The great quantity of sawdust and chips from the machines is neatly disposed of by pneumatic ducts ending in the boiler house. *See* also LUMBERING: *U.S. Methods of Manufacture;* WOODWORKING MACHINERY.

SAW (or SCRUB) **PALMETTO** (*Serenoa repens*), a single species of small palms found in sandy soil from South Carolina to Florida and Texas. It generally has creeping stems, prickly leaf-stalks, fan-shaped leaves 2–23 ft. across, divided to or below the middle into 20 or more parts, and fragrant floners followed by almost round, black, one-seeded fruits. The leaves, both fresh and dried, are sent north in large quantities for Christmas decorations. (J. M. BL.)

SAWS AND SAWING MACHINES: *see* MACHINE TOOLS; WOODWORKING MACHINERY.

SAX, ANTOINE JOSEPH, known as ADOLPHE (1814–1894), maker of musical instruments, nas born at Dinant in Belgium on Nov. 6, 1814, and died in Paris in 1894. In 1835 he perfected a bass clarinet superior to any that had preceded it. He went to Paris in 1842, and set up a workshop in the Rue St. Georges. Sax discovered that it is the proportions given to a column of air vibrating in a sonorous tube, and these alone, that determine the character of the timbre produced. In 1835 he patented his saxhorn and a family of cylinder instruments called saxotrombas On June 22, 1836 he registered the saxophone. He also effected various improvements in piston instruments, of which the most important nas the substitution of a single ascending piston for a number of descending ones.

SAXE, MAURICE, COMTE DE (1696–1750), marshal of France, was the natural son of Augustus II of Saxony and the countess Aurora Konigsmark. He served under Prince Eugene in the Netherlands, and under Peter the Great against the Swedes. After receiving in 1711 formal recognition from his father, with the rank of count, he accompanied him to Pomerania. and in 1712 he took part in the siege of Stralsund. After serving in a campaign against the Turks in 1717, he had in 1720 obtained a commission as *maréchal de camp.* In 1725 negotiations were entered into for his election as duke of Courland. He was chosen duke in 1726, but found it impossible to resist opposition to his claims, although he maintained his authority till 1727, when he withdrew and took up his residence in Paris. On the outbreak of the war in 1734 he served under Marshal Berwick. On the opening of the Austrian Succession War in 1741, he took command of a division of the army sent to invade Austria, and on Nov. 19 surprised Prague during the night, and took it by assault. After capturing the fortress of Eger on April 19, 1742, he received leave of absence, and went to Russia to push his claims on the duchy of Courland, but obtaining no success he returned to his command. On March 26, 1743, he was promoted to be marshal of France.

Marshal Saxe was now one of the first generals of the age. In 1744 he was chosen to command the expedition to England on behalf of the Pretender, which assembled at Dunkirk but did not proceed farther. After its abortive issue he received an independent command in the Netherlands, and by dexterous maneuvering succeeded in continually harassing the superior forces of the enemy without risking a decisive battle. In the following year he besieged Tournai and inflicted a severe defeat on the relieving army of the duke of Cumberland at Fontenoy (*q.v.*). Thenceforward to the end of the war he commanded in the Netherlands with success. On Nov. 30, 1750, he died at Chambord.

Saxe was the author of a remarkable work on the art of war, *Mes Réveries.* It was published posthumously in 1757 (ed.

Paris. 1877). Saxe's Lettres et mémoires choisis appeared in 1794.

BIBLIOGRAPHY.—H Pichat, *La Campagne du Maréchal de Saxe dans les Flanders . . . Suivie d'une correspondence inédite de Maurice de Saxe pendant cette campagne* (1909), which contains a full bibliography; E. B. F D'Auvergne, *The Prodigious Marshal* (1931); T. R. Phillips, *Roots of Strategy* (1943).

SAXE-ALTENBURG. The district, later the duchy of Saxe-Altenburg, came into the possession of the margrave of Meissen about 1329, and later with Meissen formed part of the electorate of Saxony. In 1603 Saxe-Altenburg was made a separate duchy, lasting until 1672. In 1825 it again became a separate duchy under Frederick, previously duke of Saxe-Hildburghausen. His family's reign was ended by the German revolution of 1918.

SAXE-COBURG-GOTHA, formerly a sovereign duchy of Germany and a constituent member of the German empire, and after 1919 incorporated into Thuringia (*q.v.*).

History.— The district of Coburg came into the possession of the family of Wettin in the 14th century, and after the Wettins had become electors of Saxony this part of their lands fell at the partition of 1485 to the Ernestine branch of the house. From that time onward Coburg, Gotha and Saalfeld were frequently partitioned and repartitioned until 1826, when Ernest, duke of Saxe-Coburg-Saalfeld, exchanged Saalfeld for Gotha, took the title of duke of Saxe-Coburg-Gotha and became the founder of the house which ruled until the revolution of 1918.

SAXE-MEININGEN, GEORGE II, DUKE OF (1826–1914), famous for the company of actors he developed at his court theatre, was born at Meiningen on April 2, 1826, and succeeded his father, Bernhard. as duke in 1866. His company toured through Europe from 1874 to 1890, under the direction of Ludwig Chronegk, presenting 2,591 performances, largely of Shakespeare and Schiller, in 36 cities in nine countries. Antoine and Stanislavsky were among those impressed by the Meininger s ensemble acting, realistic crowd scenes and detailed historical accuracy in settings and costumes. Lee Simonson, on dubious grounds, credited the duke with many innovations and with extensive and enduring influence on theatre art (*The Stage Is Set*, New York, 1932). However, Duke George probably was the first *régisseur;* a talented designer, he imposed his interpretation on the whole production. He died on June 25, 1914.

See Max Grube, *Geschichte der Meininger* (1926); Argus Tresidder, "The Meininger and Their Influence," *Quarterly Journal of Speech*, 79:467–475 (Nov. 1935). (B. HT.)

SAXE-MEININGEN, a former duchy of Germany, and after 1919 a part of Thuringia (*q.v.*).

History.— The Duchy of Saxe-Meiningen, or more correctly Saxe-Meiningen-Hildburghausen, was founded in 1681 by Bernard, the third son of Ernest the Pious, duke of Saxe-Gotha, and consisted originally of the district around Meiningen. By the rearrangement of the Saxon duchies in 1826, the area of Saxe-Meiningen more than doubled by the addition of the duchies of Saxe-Hildburghausen and Saxe-Saalfeld, and the districts of Themar, Kranichfeld and Kamburg. Saxe-Meiningen became a member of the new German empire in 1871. In 1918 the ruling family lost power in the general revolution.

SAXE-WEIMAR-EISENACH, formerly a grand duchy of Germany and a sovereign and constituent state of the German empire, and after 1919 part of Thuringia (*q.v.*).

History.— In early times Weimar and district belonged to the counts of Orlamünde, and from the end of the 10th century until 1067 it was the seat of the counts of Weimar. In the 14th century it passed to the elector of Saxony, falling at the partition of 1485 to the Ernestine branch of the Wettin family. In 1641, having inherited Coburg and Eisenach, the three brothers, William, Albert and Ernest, founded the three principalities of Saxe-Weimar, Saxe-Eisenach. and Saxe-Gotha. Eisenach fell to Saxe-Weimar in 1644, and although the enlarged principality of Saxe-Weimar-Eisenach was temporarily split up into the lines Saxe-Weimar, Saxe-Eisenach and Saxe-Jena, it was united under Ernest Augustus, who began to reign in 1728. Charles Augustus, who assumed the government in 1775, attracted to his court scholars such as Goethe, Schiller and Herder.

The Congress of Vienna in 1815 added about 660 sq.mi. to its area and gave its ruler the title of grand duke. Charles Augustus was the first German sovereign to give a constitution to his state under article xiii of the federal act. Freedom of the press being secured under its constitution, Weimar became a focus of liberal agitation, which drew down upon the grand duke the wrath of the reactionary powers. He was thus forced to curtail some of the liberties granted. In 1866 the grand duchy joined Prussia against Austria and afterward entered the North German confederation and the new German empire (see GERMANY: *History*). In 1919 it was absorbed in the former republican state of Thuringia, with the capital at Weimar.

SAXHORN, the generic name of a family of brass wind instruments (not horns but valve bugles) with cup-shaped mouthpieces, invented by Adolphe Sax and in use chiefly in European military bands, instruments of a brighter tone quality being preferred in the United States for the same purposes. (See BOMBARDON; BUGLE; HORN; TUBA; VALVES [PISTONS].)

SAXIFRAGACEAE, the Saxifrage family of the order Rosales. embraces about 80 genera and 1,200 species of dicotyledonous plants of cosmopolitan distribution with concentration in the north temperate zone and subarctic regions. There are more than 40 genera in the western hemisphere, found from Alaska to Cape Horn. The plants are annual or perennial herbs, shrubs or small trees. The leaves are simple or compound, alternate or opposite, without stipules, often in basal rosettes. Floners are arranged in cymose clusters, bisexual, rarely unisexual, polygamous or neutral, with regular or bilateral symmetry, and with conical or cuplike floral axis free from the ovary, or the ovary imbedded in the floral axis and fused with it. The calyx is made up of four to five sepals, usually united and prolonged to a floral tube with a glandular disc; corolla, of four to five separate petals, is common; there may be five to ten or many stamens, and one pistil, mostly two carpellate, with parietal or axile placentation; styles and stigmas are mostly separate; fruit is a many-seeded capsule or a juicy berry.

Saxifraga, or rock-breaker (garden saxifrage) is the largest genus, comprising 325 species, of which 15 are British. They are crevice-loving herbs, of arctic and alpine habitats, usually with tufted leaves from crowns of rhizomes anchored by roots in mossy fissures or wet meadows. Many are prized ornamentals in rock gardens, including *S. umbrosa* (London pride), with crimson-dotted petals, and *S. rosacea* (rose saxifrage), with scarlet petals. *S. sarmentosa* (strawberry geranium) is a popular house plant, with attractive panicles of irregular flowers, propagating by a profusion of runners with terminal rosettes of leaves. (See also SAXIFRAGE.)

Chrysoplenium (golden saxifrage), including 50 species of delicate creeping herbs found in springheads and creek beds, has fourparted flowers, the eight golden anthers compensating for the lack of petals.

Parnassia (grass-of-Pamassus, *q.v.*) includes 40–45 species with circumpolar distribution; *P. palustris,* of shores and wet meadows, has showy white flowers.

Heuchera (alum root), with 30 species, is exclusively a North American genus. The plants are characterized by a naked flowering stem with rosette leaves from thick rhizomes which contain astringent principle. *H. sanguinea* (coral bells) is a rock garden favourite because of its graceful panicle of showy flowers. Any species, indeed, is suitable for rock gardens.

Astilbe (without lustre), a genus of about 20 Asian and 2 American species, are ornamental herbs with twice or thrice compound leaves, small numerous flowers in terminal clusters and fruits often follicular from distinct carpels. *A. japonica* is preferred in gardens.

The genus *Ribes* (currant and gooseberry, *qq.v.*) includes 140 species of smooth or prickly shrubs, widely distributed. *R. sativum* (garden currant) and *R. grossularia* (or *Grossularia reclinata;* the English gooseberry) bear edible berries. Among ornamentals are *R. odoratum* (golden currant) and *R. sanguineum* (cherry currant). All species of *Ribes* are valuable shrubs in providing shelter and food for wild life. but they also are the alternate host for the fungus that causes blister rust in white pine.

Philadelphus (*q.v.*), or mock orange, is a genus consisting of about 70 species, several Asian, 1 European and the remainder American. *P. coronarius* and its many forms are widely cultivated for their attractive clusters of showy-white fragrant flowers.

Deutzia, a genus of 70 species of Asian and 2 Mexican shrubs, has profusely flowering ornamentals. Among choice species for borders is *D. gracilis*, with slender arching branches.

BIBLIOGRAPHY.—L. H. Bailey, *Manual of Cultivated Plants* (1949); J. K. Small, *North American Flora*, vol. xxii (2) (1905); A. Engler, *Die Natürlichen Pflanzenfamilien*, 2nd ed. (1930). (O. LA.)

SAXIFRAGE (*Saxifraga*). a genus of plants which gives its name to the family Saxifragaceae of which it is a member. There are about 325 species distributed in the temperate and arctic parts of the northern hemisphere, frequently at considerable heights on the mountains. and also found on the Andes. They are mostly herbs, native to mountains and rocky places, with perennial rootstocks and leaves in tufts or scattered on the flower-stalks. The arrangement of the flowers is various, as also are the size and colour of the flowers themselves.

Some 8j species occur in North America, most numerously in the Rocky mountain region. Well-known species are the early saxifrage (*S. virginiensis)* and the swamp saxifrage (S. *pennsylvanica),* of the eastern United States and Canada, and the tufted saxifrage *(S. caespitosa),* found on rocks in mountains across the continent. Many species are in cultivation, including the numerous alpine species, such as *S. cotyledon*, with tall panicles studded with white flowers, and others, many adapted for rockwork. The strawberry geranium *(S. sarmentosa)* is a common conservatory and window plant. Fifteen species are found in Britain, some alpine plants of great beauty (S. *oppositifolia, S. nivalis, S. aizoides,* etc.) and others! like *S. granulata,* frequenting meadows and low ground, while *S. tridactylites* may be found on almost any dry wall. *S. umbrosa* is London pride or St. Patrick's cabbage, a common garden plant, a native of the Spanish peninsula and also of the mountains of west and southwest Ireland.

The saxifrages are among the most interesting alpine plants for culture in the rock garden. Some grow best in clefts in the rocks, others in gritty detritus characteristic of moraines. Nearly 200 species are cultivated by fanciers. Most of them prefer gritty soils: perfect drainage and freedom from acid conditions. Many are from alpine fell fields and will not stand too much midday heat. Among the best for rock gardens in the U.S. are *S. aizoon* (with several varieties); *S. apiculata,* a cushion plant; S. *cochlearis,* best grown in crushed limestone; *S. decipiens* (with hybrids of several colours); *S. hosti,* a cushion plant with white flowers; *S. moschata,* a dwarf, mosslike species; and *S. oppositifolia,* which makes prostrate mats and has many varieties. (N. TR.; X.)

SAXO GRAMMATICUS (mid-12th century–early 13th century), Danish historian whose *Gesta Danorum* is the first important work on the history of Denmark and the first Danish contribution to world literature. Little is known except that he was a Sealander belonging to a family of warriors, and that he was probably a clerk in the service of Absalon (archbishop of Lund from 1178–1201). Saxo is first mentioned in Svend Aggesen's *Historia Regum Danicæ compendiosa* (1185) as writing the history of Svend Estridsen (d. 1076).

The *Gesta Danorum* was written at the suggestion of Archbishop Absalon: its 16 volumes begin with the legendary King Dan and end with the conquest of Pomerania by Canute VI in 118j. The original manuscript is lost except for four leaves which were found in a French book in 1863. The preface, dedicated to Absalon's successor, Anders Sunesen, and King Valdemar II, must have been written before 1222. Like the rest of the work, it is written in a brilliant, ornate Latin, clearly influenced by the style of Valerius Maximus, Curtius and Justin. It was his Latin eloquence which in the early 14th century caused Saxo to be called "Grammaticus."

The first nine books of the *Gesta Danorum* give an account of some 60 legendary Danish kings. For this part Saxo depended on ancient lays, romantic sagas and the accounts of Icelanders. Most famous are his tales about Uffe (Anglo-Saxon, Offa), hmleth (Hamlet [*q.v.*]), Hading, Rolf Krake, the giant Starkad, Harald Hildetand and Ragnar Lodbrok. Saxo incorporated also myths of national gods such as Balder and Hother whom tradition claimed as Danish kings, and myths of foreign heroes, including the Gothic Jarmunrik (A. S. Eormenric) and the Germans Hedin and Hild. Three heroic poems are especially noteworthy, translated by Saxo into Latin hexameters, a medium which must have been incongruously alien to the concentrated, pithy style of the originals. the oldest known Danish poetry. They are *Bjarkemaalet*, a battle hymn designed to arouse warlike feelings; *Ingjaldskvadet*, a poem stressing the corruptive danger of luxury upon the old Viking spirit; and *Hagbard and Signe*, a tragedy of love and family feuds.

The last seven books comprise Saxo's account of the historical period. but he only achieves independent authority when writing of events close to his own time (from book 14 onward). Archbishop Absalon and his family, and oral accounts by Danish warriors, seem to have been Saxo's main sources for this period. His work is noteworthy for its sense of patriotic purpose based on a belief in the unifying influence of the monarchy. By presenting a 2,000-year long panorama of Danish history, he aimed to show his country's antiquity and traditions. Saxo's work became a source of inspiration to many of the 19th-century romantic poets in Denmark.

BIBLIOGRAPHY.—Saxo's *Gesta Danorum* was first published by Christiern Pedersen (Paris, 1514), modern ed by J. Olrik and H. Ræder (1931). Since 1575 it has been translated into Danish five times; Eng. trans. by Oliver Elton, *The First Nine Books of the Danish History of Saxo Grammaticus* (1894). *See* also A. Olrik, *Kilderne til Saxos oldhistorie*, i–ii (1892–4) and *Danske oldkvad i Saxos historie* (1898); C. Weibull, *Saxo* (1915); K. Malone, *The Literary History of Hamlet* (1923); S. Larsen, *Saxo Grammaticus, hans Værk og Person* (1925); Ellen Jørgensen, *Historieforskning og Historieskrivning i Danmark indtil Aar 1800* (1933). (E L BF)

SAXONS, a Teutonic people mentioned for the first time by Ptolemy about the middle of the 2nd century. At that time they are said to have inhabited the neck of the Cimbric peninsula, by which we have probably to understand the modern province of Schleswig, together with three islands lying off its western coast. We next hear of them in connection with piratical expeditions in the North sea about the year 286. These raids became more frequent during the 4th century, and at the beginning of the jth century the northern coast of Gaul and the south-east coast of Britain were known at *litora Saxonica*. During the same period the Saxons appear to have conquered a considerable portion of north-west Germany. According to their own traditions they landed at Hadeln in the neighbourhood of Cuxhaven and seized the surrounding districts from the Thuringians. By the middle of the 4th century they had advanced westwards into the basin of the Ysel, and in the following centuries we find them in possession of the whole of the basin of the Ems, except the coast district, while that of the Weser with all its tributaries belonged to them as far south as the Diemel, where they bordered on the Hessian Franks, the ancient Chatti. The conquest of the Boructuari who dwelt between the Lippe and the Ruhr marks the extent of their progress towards the south-west. This took place shortly before the end of the 7th century. They frequently came into conflict with the Franks and on several occasions had to submit to their supremacy. No thorough conquest was, however, carried until the time of Charlemagne, who, between the years 772 and 785, annexed the whole region as far as the Elbe, destroying in 772 the Irminsul, their great sanctuary, near Marsberg on the Diemel. Up to this time they had remained entirely heathen. At the beginning of the following century Charlemagne also conquered the Saxons known as Nordalbingi in western Holstein, a district which had perhaps been occupied by a southward movement from the original home of the tribe.

It is doubtful how far the Saxons who invaded Britain were really distinct from the Angli, for all their affinities both in language and custom are with the latter and not with the Saxons (Old Saxons) of the Continent. During the 5th century we hear also of Saxon settlements on the coasts of Gaul. The most important were those at the mouth of the Loire founded in the time of Childeric, Clovis's father, and at Bayeux, in a district which remained in their possession until towards the close of the 6th century. From the 6th century onwards, however, we hear practically nothing of the Saxons as a seafaring people. Almost all the southern coast of the North sea had now come into the possession of the Frisians, and one can hardly help concluding that most of the maritime Saxons had either voluntarily or by conquest become incorporated in that kingdom.

SAXONY, one of the German *Länder,* ranking among the constituent states of the German reich fifth in area and third in population, bounded in 1938 S. by Czechoslovakia, on the west by Bavaria and Thuringia and on the west, north and east by Prussia. Its frontiers have a circuit of 760 mi. and, with the exception of some small exclaves and enclaves, it forms a compact whole of a triangular shape, its base extending from northeast to southwest, and its apex pointing northwest. Its greatest length is 130 mi.; greatest breadth 93 mi., and total area 5,789 sq.mi.

Physical Features.—Saxony belongs almost entirely to the central mountain region of Germany, only the districts along the north border and around Leipzig descending into the great north-European plain. The chief mountain range is the Erzgebirge, stretching for 90 mi. along the south border, and reaching in the Fichtelberg (3,979 ft. and 3,953 ft.) the highest elevation in the country. The west and southwest are occupied by ramifications and subsidiary groups of this range, such as the Central Saxon chain, and the Oschatz group. The southeast angle of Saxony is occupied by the mountains of Upper Lusatia (highest summit 2.600 ft.). Northwest from this group. and along both banks of the Elbe, which divides it from the Erzgebirge, extends the picturesque Saxon Switzerland. The action of water and ice upon the soft sandstone of which the hills here are chiefly composed has produced deep gorges and isolated fantastic peaks, but the highest summit attains a height of only 1,830 ft.; the more interesting peaks, as the Lilienstein, Konigstein and the Bastei, are lower. Saxony lies almost wholly in the basin of the Elbe, which has a navigable course of 72 mi. from southeast to northwest. The Mulde, formed of two branches, is the second river of Saxony; others are the Black Elster, the White Elster, the Pleisse and the Spree, all part of the Elbe system. There are no lakes of any size. The best known of many mineral springs is at Bad Elster in the Vogtland.

Climate.—The climate is mildest in the valleys of the Elbe, Mulde and Pleisse and severest in the Erzgebirge. The average temperature varies from 48° to 50° The Erzgebirge is the rainiest district, 27½ to 33½ in. falling yearly; the amount decreases as one proceeds northward, and Leipzig, with an average annual rainfall of 17 in., enjoys the driest climate.

Population.—In 1939 the population of Saxony was 5,206,822, or 899.4 per square mile. Except the free towns, Saxony is the most densely peopled member of the German reich. The growth of the population after 1815, when Saxony received its present limits, has been as follows: (1815) 1,178,802; (1830) 1,402,066; (1840) 1,706,275; (1864) 2,344,094; (1875) 2,760,586; (1895) 3,787,688; (1905) 4,508,601. The preponderating industrial activity fosters the tendency of the population to concentrate in towns, and no German area, with the exception of the Hanseatic towns, has so large a proportion of urban population. The people of Saxony are chiefly of pure Teutonic stock; a proportion are Germanized Slavs, and to the south of Bautzen there is a large settlement of Wends, who retain their language.

The chief towns are Leipzig (pop. 1939, 701,606), Dresden (625,174), Chemnitz (334,563), Plauen (110,342), Zwickau (85,-484), Meissen (47,833), Bautzen (41,793), Zittau (38,271), Freiberg (35,847), Freital (36,6523, Pirna (36,130), Reichenbach (31,266), Glauchau (33,586), and Krimmitschau (26,942). Other important towns are Meerane and Werdau.

Communications.—The roads in Saxony are numerous and good, and there are over 1,268 mi. of railway. The only navigable river is the Elbe.

Agriculture.—Saxony is one of the most fertile parts of Germany, and is highly developed agriculturally. Fertility diminishes as we ascend towards the south, until on the bleak crest of the Erzgebirge cultivation ceases. In 1834 a law mas passed providing for the union of the scattered lands belonging to each proprietor, and that may be considered the dawn of modern Saxon agriculture. The richest grain districts are near Meissen, Grimma, Bautzen, Dobeln and Pirna. The chief crop is rye, but oats are hardly second to it. Wheat and barley are grown in considerably less quantity. Very large quantities of potatoes are grown, especially in the Vogtland. Beet is also grown extensively. Flax is grown in the Erzgebirge and Lusatian mountains, where the manufacture of linen was at one time a flourishing domestic industry. Enormous quantities of cherries, plums and apples are annually borne by the trees round Leipzig, Dresden and Colditz. The Saxon vineyards, chiefly on the banks of the Elbe near Meissen and Dresden, have passed through difficult times of late years, owing to the ravages of the phylloxera.

Livestock.—Cattle rearing, which has been an industry since the advent of the Wends in the 6th century, is important on the extensive pastures of the Erzgebirge and in the Vogtland. In 1765 the regent Prince Xaver imported 300 merino sheep from Spain, and so improved the native breed by this new strain that Saxon sheep mere eagerly imported by foreign nations to improve their flocks, and "Saxon electoral wool" became one of the best brands in the market. Sheep farming, however, has considerably declined within the last few decades. Swine furnish a very large proportion of the flesh diet of the people. Geese abound particularly round Leipzig and in Upper Lusatia, poultry about Bautzen.

Forests.—The forests of Saxony are extensive and have long been well cared for both by government and by private proprietors. The famous school of forestry at Tharandt was founded in 1811. The Vogtland is the most densely wooded portion of Saxony, and next comes the Erzgebirge.

Mining.—Silver was raised in the 12th century, and argentiferous lead is still the most valuable ore mined; tin, iron and cobalt rank next, and coal is one of the chief exports. Copper, zinc and bismuth are also worked. The country is divided into four mining districts: Freiberg, where silver and lead are the chief products; Altenberg, where tin is mainly raised; Schneeberg, yielding cobalt, nickel and ironstone; and Johanngeorgenstadt, with ironstone and silver mines. The coal is found principally in two fields—one near Zwickau, and the other in the governmental district of Dresden. Brown coal or lignite is found chiefly in the north and northwest. Peat is especially abundant on the Erzgebirge. Immense quantities of bricks are made ail over the country. Excellent sandstone for building is found on the hills of the Elbe. Fine porcelain clay occurs near Meissen, and coarser varieties elsewhere.

Industries.—The central-European position of Saxony has fostered its commerce; and its manufactures have been encouraged by the abundant water power throughout the country. Nearly one-half of the motive power used in Saxon factories is supplied by the streams, of which the Blulde, in this respect, is the chief. The early foundation of the Leipzig fairs, and the enlightened policy of the rulers of the country, have also done much to develop its commercial and industrial resources. The manufacture of textiles is carried on at Zwickau, Chemnitz, Glauchau, Meerane, Hohenstein, Kamenz, Pulsnitz and Bischofsmerda. The centre of the cotton manufacture (especially of cotton hosiery) is Chemnitz; cotton muslins are made throughout the Vogtland, ribbons at Pulsnitz and its neighbourhood. Woollen cloth and buckskin are woven at Kamenz, Bischofswerda and Grossenhain, all in the northeast, woollen and half-woollen underclothing at Chemnitz, Glauchau, Meerane and Reichenbach; while Bautzen and Limbach produce woollen stockings. Linen is manufactured chiefly in the mountains of Lusatia, where the looms are still to some extent found in the homes of the weavers. Damask is produced at Gross-Schonau and other places. Lacemaking, discovered or introduced by Barbara Uttmann in the latter half of the 16th century, and now fostered by government schools, was long an important domestic industry among the villages of the Erzgebirge, and has attained to a great industry in Plauen. Straw plaiting is carried on by the inhabitants of the mountain slopes between Gottleuba and Lockwitz. Waxcloth is manufactured at Leipzig and artificial flowers at Leipzig and Dresden. Stoneware and earthenware are made at Chemnitz, Zwickau, Rautzen and Meissen, porcelain (Dresden china) at Meissen, chemicals in and near Leipzig. Dobeln. Werdau and Lossnitz are the chief seats of the Saxon leather trade; cigars are very extensively made in the town and district of Leipzig, and hats and pianofortes at Leipzig, Dresden and Chemnitz. Paper is made chiefly in the west of Saxony. Machinery of all kinds is produced, from the sewing machines of Dresden to the steam locomotives and marine engines of Chemnitz. The last-named place. though the centre of the iron manufacture of Saxony, has to import every pound of iron by railway. The leading branch is the machinery used in the industries of the country—mining. paper making and weaving. The very large printing trade of Leipzig encourages the manufacture of printing presses in that city. There are a number of active breweries in Saxony. The smelting and refining of the metal ores is also an important industry.

The principal exports are wool, woollen, cotton, linen goods, machinery, china. pianofortes, cigarettes, flannels, stockings, curtains and lace. cloth from Reichenbach and Zittau, watches of superlative value from Glashutte and tops from the Vogtland.

Government. — The republican constitution of 1920 provided for a Lnndfng of 96 members. After 1933 this was superseded by the administration of a National Socialist district leader (*Gauleiter*) and federal governor (*Reichsstatthalter*), Martin Mutschmann. appointed by Hitler.

The Saxon *Oberlandesgericht* has its seat at Dresden, and the *Reichsgericht*—the supreme court of law for the whole German reich—at Leipzig.

Church. — The great majority of the inhabitants of Saxony are Protestants. The government of the Evangelical-Lutheran Church was vested in the Evangelical consistory at Dresden. Its representative assembly consisting of clergymen and lay members was called a synod (*Synode*). The Moravian Brethren established their chief seat at Herrnhut.

Education. — Of the four universities founded by the Saxon electors at Leipzig, Jena. Wittenberg, later transferred to Halle, and Erfurt. now extinct, only the first is included in Saxony. There are famous endowed schools (*Fürstenschulen*) at Meissen and Grimma. Saxony is particularly well equipped with technical schools. the textile industries being especially fostered by numerous schools of weaving, embroidery and lacemaking; but the mining academy at Freiberg and the school of forestry at Tharandt are probably the most widely known. The conservatory of music at Leipzig and the art collections at Dresden have a world-wide reputation.

HISTORY

The name "Saxony" has been borne by two distinct blocks of territory. The first was the district in the northwest of Germany, inhabited originally by the Saxons, which became a duchy and attained its greatest size and prosperity under Henry the Lion in the 12th century. In 1180 it was broken up, and the name of Saxony disappeared from the greater part of it, remaining only with the districts around Lauenburg and Wittenberg. Five centuries later Lauenburg was incorporated with Hanover, and Wittenberg is the nucleus of modern Saxony. the name being thus transferred from the west to the east of Germany. In 1423 Meissen and Thuringia were united with Saxe-Kittenberg under Frederick of bleissen. and gradually the name "Saxony" spread over all the lands ruled by this prince and his descendants.

The earlier Saxony was the district lying between the Elbe and the Saale on the east. the Eider on the north and the Rhine on the west, with a fluctuating boundary on the south. This territory was a stronghold of Germanic heathenism and included at Eresburg, the modern hlarsberp, one of the chief Germanic sanctuaries. marked by the *Irminsul*, a wooden pillar which was the centre of Saxon worship. The prolonged resistance which the Saxons offered to Christianity was chiefly a result of their hostility to the Franks, who threatened their independence. The reduction of the Saxons was attempted by Charles Martel and Pippin the Short and was finally carried through in a series of campaigns by Charles the Great (Charlemagne, *q.v.*). Before his death Saxony passed under Frankish supremacy, and within a century it had come to form an outpost of German and Christian influence against the Slavs of the provinces south of the Baltic.

The conversion of the Saxons to Christianity, which during this time had been steadily progressing. was continued in the reign of the emperor Louis I. Bishoprics were established at Bremen Munster, Verden, Minden, Paderborn, Osnabriick. Hildesheim, Hamburg and Halberstadt. The abbey of Corvey soon became a centre of learning for the country, and the Saxons undertook with the eagerness of converts the conversion of their heathen neighbours. Toward the middle of the century there were signs of a reaction against Frankish rule and toward heathenism among the Saxon free peasantry, but it had no permanent result, and the connection with the empire mas unbroken. By the treaty of Verdun in 843 Saxony fell to Louis the German, but he paid little attention to the northern part of his kingdom, which was harassed by the Normans and the Slavs. About 850. however, he appointed a Saxon noble named Liudolf as margrave to defend the *Limes Saxoniae*, a narrow strip of land on the eastern frontier. Liudolf, who is sometimes called "duke of the East Saxons," carried on a vigorous warfare against the Slavs and extended his influence over other parts of Saxony. He died in 866 and was succeeded by his son Bruno, who was killed fighting the Normans in 880. Liudolf's second son. Otto the Illustrious, was recognized as duke of Saxony by King Conrad I. and on the death of Burkhard, margrave of Thuringia in 908, obtained authority over that country also. He made himself practically independent in Saxony and played an important part in the affairs of the empire. He died in 912 and his son Henry I, the Fowler, not only retained his hold over Saxony and Thuringia but in 919 was elected German king. He extended the Saxon frontier almost to the Oder. improved the Saxon forces by training and equipment, established new marks and erected forts on the frontiers for which he provided regular garrisons. Towns were walled, where it was decreed markets and assemblies should be held, churches and monasteries were founded, civilization was extended and learning encouraged. Henry's son, Otto the Great, was crowned emperor in 962, and his descendants held this dignity until the death of the emperor Otto III in 1002. Under this able dynasty the Slavs .were driven back, the domestic policy of Henry the Fowler was continued, the Saxon court became a centre of learning visited by Italian scholars, and in 968 an archbishopric was founded at Magdeburg for the lands east of the Elbe. The extent of Otto the Great's dominions compelled him to delegate much of his authority in Saxony. and in 960 he gave to a trusted relative. Hermann Billung, certain duties and privileges on the eastern frontier and from time to time appointed him as his representative in Saxony. Hermann gradually extended his authority, and when he died in 973 was followed by his son Bernard I. who was undoubtedly duke of Saxony in 986. When Henry II was chosen German king in 1002 he met the Saxons at Merseburg, and on promising to observe their laws Bernard gave him the sacred lance. thus entrusting Saxony to his care. Bernard was succeeded by his son Bernard II, who took up a hostile attitude toward the German kings, Conrad II and Henry III. His son and successor Ordulf, who became duke in 1059, carried on a long and obstinate struggle with Adalbert, archbishop of Bremen, who was compelled to cede one-third of his possessions to Ordulf's son Magnus in 1066. The emperor Henry III sought to win the allegiance of the Saxons by residing among them. He built a castle at Goslar and the Harzburg; and his successor, Henry IV, also spent much time in Saxony.

In 1070 Otto of Nordheim, duke of Bavaria, who held large estates in that country, was accused of a plot to murder Henry, and his lands were confiscated. Otto; in alliance with Magnus, won considerable support in Saxony, but after some fighting both submitted and were imprisoned: and Magnus was still in confinement when on his father's death in 1072 he became titular duke oi Saxony. As he refused to give up his duchy he was kept in prison, while Henry confiscated the estates of powerful nobles, demanded the restoration of ducal lands by the bishops, and garrisoned newly-erected forts with Swabians. These proceedings aroused suspicion and discontent, which were increased when the emperor assembled an army, ostensibly to attack the Slavs. The Saxon nobles refused to join the host until their grievances were redressed, and in 1073 a league was formed at Wormesleben. When the insurgents under Duke Otto were joined by the Thuringians, Henry was compelled in 1074 to make various concessions to them, and in particular to release Magnus. At last Henry, having obtained help from the princes of the Rhineland, attacked and defeated the Saxons at Hohenburg near Langensalza but pardoned Otto, whom he appointed administrator of the country. The Saxons, however, were not quite subdued; risings took place from time to time, and the opponents of Henry IV. found considerable support in Saxony. During the century which followed the death of Hermann Billung, there had been constant warfare with the Slavs, but although the emperors had often taken the field, the Saxons had been driven back to the Elbe, which was at this time their eastern boundary. In 1106 Magnus died, and the German king Henry V. bestowed the duchy upon Lothair, count of Supplinburg, whose wife Richenza inherited the Saxon estates of her grandfather Otto of Nordheim, on the death of her brother Otto in 1116. Lothair quickly made himself independent, defeated Henry at Welfesholz in 1115, and prosecuted the war against the Slavs with vigour. In 1125 he became German king, and in 1137 gave Saxony to Henry the Proud, duke of Bavaria, who had married his daughter Gertrude, and whose mother Wulfhild was a daughter of Magnus Billung. The succeeding German king Conrad III. refused to allow Henry to hold two duchies, and gave Saxony to Albert the Bear, margrave of Brandenburg, who like his rival was a grandson of Magnus Billung. Albert's attempts to obtain possession failed, and after Henry's death in 1139 he formally renounced Saxony in favour of Henry's son, Henry the Lion (*q.v.*). The new duke improved its internal condition, increased its political importance, and pushed its eastern frontier towards the Oder. In 1180, however, he was placed under the imperial ban and Saxony was broken up. Henry retained Brunswick and Luneburg; Westphalia, as the western portion of the duchy was called, was given to Philip, archbishop of Cologne, and a large part of the land was divided among nine bishops and a number of counts who thus became immediate vassals of the emperor. The title duke of Saxony was given to Bernard, the sixth son of Albert the Bear, together with the small territories of Lauenburg and Wittenberg, which were thus the only portions of the former duchy which now bore the name of Saxony. Bernard, whose paternal grandmother, Eilicke, was a daughter of Magnus Billung, took a prominent part in German affairs, but lost Lauenburg which was seized by Waldemar II., king of Denmark. Dying in 1212, Bernard was succeeded in Wittenberg by his younger son Albert I., who recovered Lauenburg after the defeat of Waldemar at Bornhoved in 1227. Albert died in 1260, and soon after his death his two sons divided his territories, when the elder son John took Lauenburg which was sometimes called lower Saxony, and the younger, Albert II., took Wittenberg or upper Saxony. Both retained the ducal title and claimed the electoral privilege, a claim which the Lauenburg line refused to abandon when it was awarded to the Wittenberg line by the Golden Bull of 1356.

Saxe-Lauenburg was governed by John until his death in 1285, when it passed to his three sons John II., Albert III. and Eric I. As Albert had no sons the duchy was soon divided into two parts, until on the death of duke Eric III., a grandson of John II., in 1401, it was reunited by Eric IV., a grandson of Eric I. When Eric IV. died in 1412 he was succeeded by his son Eric V., who made strenuous but vain efforts to obtain the electoral duchy of Saxe-Wittenberg, which fell vacant on the death of the elector Albert III. in 1422. Eric died in 1436 and was followed by his brother Bernard IV., whose claim to exercise the electoral vote was quashed by the electors in 1438; and who was succeeded by his son John IV. in 1463. The next duke, John's son Magnus I., spent much time in struggles with the archbishop of Bremen and the bishop of Ratzeburg; he also assisted the progress of the Reformation in Lauenburg. Magnus, who was formally invested with the duchy by the emperor Charles V. in 1530, was the first duke to abandon the claim to the electoral privilege. After his death in 1543 his son Francis I. reigned for the succeeding 28 years, and his grandsons, Magnus II. and Francis II., until 1619. Francis, who did something to improve the administration of his duchy, was succeeded in turn by his two sons and his two grandsons; but on the death of Julius Francis, the younger of his grandsons, in 1689 the family became extinct.

Several claimants to Saxe-Lauenburg thereupon appeared, the most prominent of whom were George William, duke of Lüneburg-Celle, and John George III., elector of Saxony. George William based his claim upon a treaty of mutual succession made in 1369 between his ancestor Magnus II., duke of Brunswick, and the reigning dukes of Saxe-Lauenburg. John George had a double claim. Duke Magnus I. had promised that in case of the extinction of his family Lauenburg should pass to the family of Wettin, an arrangement which had been confirmed by the emperor Maximilian I. in 1507. Secondly, John George himself had concluded a similar treaty with Julius Francis in 1671. In 1689 the elector received the homage of the people of Lauenburg. George William, however, took Ratzeburg, and held it against the troops of a third claimant, Christian V., king of Denmark; and in 1702 he bought off the claim of John George, his successor being invested with the duchy in 1728. Since that date its history has been identified with that of Hanover (*q.v.*).

In Saxe-Wittenberg Albert II. was succeeded in 1298 by his son Rudolph I., who was followed in 1356 by his son Rudolph II. He in turn was succeeded in 1370 by his half-brother Wenceslaus, who temporarily acquired the duchy of Ldneburg for his house. He was followed in 1388 by his eldest son Rudolph III. Lavish expenditure during the progress of the council of Constance reduced Rudolph to poverty and on the death in 1422 of his brother Albert III., who succeeded him in 1419, this branch of the family became extinct.

THE ELECTORATE

A new era in the history of Saxony dates from 1423, when the Emperor Sigismund bestowed the vacant electoral duchy of Saxe-Wittenberg upon Frederick, margrave of Meissen. Frederick was a member of the family of Wettin, which since his day has played a prominent part in the history of Europe, and he owed his new dignity to the money and other assistance which he had given to the emperor during the Hussite war. The new and more honourable title of elector of Saxony now superseded his other titles, and the name Saxony gradually spread over his other possessions, which included Meissen and Thuringia as well as Saxe-Wittenberg. His new position as elector combined with his personal qualities to make him one of the most powerful princes in Germany, and had the principle of primogeniture been established in his country, Saxony and not Prussia might later have been the leading power in the German empire. He died in 1428, just before his lands were ravaged by the Hussites in 1429 and 1430. The division of his territory between his two sons, the elector Frederick II. and William, occasioned a destructive internecine war. Frederick II.'s two sons, Ernest and Albert, succeeded to their father's possessions in 1464, and for 20 years ruled together peaceably. The land prospered rapidly during this respite from the horrors of war. The childless death of their uncle William in 1482 brought Thuringia to the two princes, and Albert insisted on a division of their common possessions. The important partition of Leipzig accordingly took place in 1485, and resulted in the foundation of the two main lines of the Saxon house. The lands were never again united. Ernest, the elder brother, obtained Saxe-Wittenberg with the electoral dignity, Thuringia and the Saxon Vogtland; while Albert received Meissen, Osterland being divided between them. Something was still held in common, and the division was probably made intricate to render war difficult.

The Reformation Period.—The elector Ernest was succeeded in 1486 by his son, Frederick the Wise, one of the most illustrious princes in German history. Under him Saxony was perhaps the most influential state in the empire, and became the cradle of the Reformation. He died in 1525 while the Peasants' War was desolating his land, and was succeeded by his brother John, who was an enthusiastic supporter of the reformed faith and who shared with Philip, landgrave of Hesse, the leadership of the league of Schmalkalden. John's son and successor, John Frederick the Magnanimous, who became elector in 1532, might with equal propriety have been surnamed the Unfortunate. He took part in the war of the league of Schmalkalden, but in 1547 he was captured at Mühlberg by the Emperor Charles V. and was forced to sign the capitulation of Wittenberg. This deed transferred the electoral title and a large part of the electoral lands from the Ernestine to the Albertine branch of the house, whose astute representative, Maurice, had taken the imperial side during the war. Only a few scattered territories were reserved for John Frederick's sons, although these were increased by the treaty of Naumburg in 1554, and on them were founded the Ernestine duchies of Saxe-Gotha, Saxe-Weimar, Saxe-Coburg, Saxe-Meiningen and Saxe-Altenburg. For the second time in the history of the Saxon electorate the younger line secured the higher dignity, for the Wittenberg line was junior to the Lauenburg line. The Albertine line became later the royal line of Saxony.

Maurice, who became elector of Saxony in consequence of the capitulation of Wittenberg, was a Protestant, but he did not allow his religious faith to blind him to his political interests. He refused to join the other Protestant princes in the league of Schmalkalden, but made a secret treaty with Charles V. His fidelity to Charles V. was rewarded by the capitulation of Wittenberg. All the lands torn from John Frederick were not, however, assigned to Maurice; he was forced to acknowledge the superiority of Bohemia over the Vogtland and the Silesian duchy of Sagan. Moreover, Roman Catholic prelates were reinstated in the bishoprics of Meissen, Merseburg and Naumburg-Zeitz. Recognizing now as a Protestant prince that the best alliance for securing his new possessions was not with the emperor, but with the other Protestant princes, Maurice began to withdraw from the former and to conciliate the latter. In 1552, suddenly marching against Charles at Innsbruck, he drove him to flight and then extorted from him the peace of Passau.

Amid the distractions of outward affairs, Maurice had not neglected the internal interests of Saxony. To its educational advantages, already conspicuous, he added the three *Fürstenschulen* at Pforta, Grimma and Meissen, and for administrative purposes, especially for the collection of taxes, he divided the country into the four circles of the Electorate, Thuringia, Meissen and Leipzig. During his reign coal-mining began in Saxony. Over 200 religious houses were suppressed, the funds being partly applied to educational purposes. The country had four universities, those of Leipzig, Wittenberg, Jena and Erfurt; books began to increase rapidly, and, by virtue of Luther's translation of the Bible, the Saxon dialect became the ruling dialect of Germany.

Augustus I., brother and successor of Maurice, was one of the best domestic rulers that Saxony ever had. He increased the area of the country by the "circles" of Neustadt and the Vogtland, and by parts of Henneberg and the silver-yielding Mansfeld, and he devoted his long reign to the development of its resources. Under him lace-making began on the Erzgebirge, and cloth-making flourished at Zwickau. With all his virtues, however, Augustus was an intolerant Lutheran, and used very severe means to exterminate the Calvinists. Under John George (succeeded 1611) the country was devastated by the Thirty Years' War. After the death of Gustavus Adolphus at the battle of Lützen, not far from Leipzig, in 1632, the elector, who was at heart an imperialist, detached himself from Sweden with whom he had been allied since 1629, and in 1635 concluded the peace of Prague with the emperor. By this peace he was confirmed in the possession of Upper and Lower Lusatia. Saxony had now to suffer from the Swedes a repetition of the devastations of Wallenstein. No other country in Germany was so scourged by this terrible war. When the war was ended by the peace of Westphalia in 1648, Saxony found that its influence had begun to decline in Germany. John George's will made the decline worse by detaching the three duchies of Saxe-Weissenfels, Saxe-Merseburg and Saxe-Zeitz as appanages for his younger sons. By 1746, however, these lines were all extinct, and their possessions had returned to the main line.

The 18th Century.—The next three electors, who each bore the name of John George, had uneventful reigns. John George IV. was succeeded in 1694 by his brother Frederick Augustus I., or Augustus the Strong. This prince was elected king of Poland as Augustus II. in 1697, but any weight which the royal title might have given him in the empire was more than counterbalanced by the fact that he became a Roman Catholic in order to qualify for the new dignity. In order to defray the expenses of Poland's wars with Charles XII. Augustus pawned and sold large districts of Saxon territory, while he drained the electorate of both men and money.

From this reign dates the privy council (*Geheimes Kabinet*), which lasted till 1830. The caste privileges of the estates (Stande) were increased by Augustus, a fact which tended to alienate them more from the people, and so to decrease their power. Frederick Augustus II., who succeeded his father in the electorate in 1733, and was afterwards elected to the throne of Poland as Augustus III., was an indolent prince, wholly under the influence of Count Heinrich von Briihl (*q.v.*). Under him Saxony sided with Prussia in the First Silesian War, and with Austria in the other two. It gained nothing in the first, lost much in the second, and in the third, the Seven Years' War (1756–63), suffered renewed miseries. The country was deserted by its king and his minister, who retired to Poland. By the end of the war it had lost 90,000 men and 100,000,000 thalers; its coinage was debased and its trade ruined; and the whole country was in a state of frantic disorder. The elector died seven months after his return from Poland; Brühl died 23 days later. The connection with Poland was now at an end. The elector's son and successor, Frederick Christian, survived his father only two months, dying also in 1763, leaving a son, Frederick Augustus III., a boy of 13. Prince Xaver, the elector's uncle, was appointed guardian, and he set himself to the work of healing the wounds of the country.

THE KINGDOM OF SAXONY

Frederick assumed the government in 1768, and in his long and eventful reign, which saw the electorate elevated to the dignity of a kingdom, though deprived of more than half its area, he won the surname of the Just. As he was the first king of Saxony, he is usually styled Frederick Augustus I. When the Bavarian succession fell open in 1777, Frederick Augustus joined Prussia in protesting against the absorption of Bavaria by Austria, and Saxon troops took part in the bloodless "potato-war" The elector commuted his claims in right of his mother, the Bavarian princess Maria Antonia, for 6,000,000 florins, which he spent chiefly in redeeming Saxon territory that had been pawned to other German states. When Saxony joined the *Fürstenbund* in 1785, it had an area of 15,185 sq.m. and a population of nearly 2,000,000, but its various parts had not yet been combined into a homogeneous whole, for the two Lusatias, Querfurt, Henneberg and the ecclesiastical foundations of Naumburg and Merseburg had each a separate diet and government, independent of the diet of the electorate proper. In 1791 Frederick declined the proffered crown of Poland. Next year saw the beginning of the great struggle between France and Germany. Frederick's first policy was one of abstention but when war broke out in 1806 against Napoleon, 22,000 Saxon troops shared the defeat of the Prussians at Jena, but the elector immediately afterwards abandoned his former ally. At the peace of Posen (Dec. 11, 1806) Frederick assumed the title of king of Saxony, and entered the Confederation of the Rhine as an independent sovereign, promising a contingent of 20,000 men to Napoleon.

In 1807 his submission was rewarded with the duchy of Warsaw (to which Cracow and part of Galicia were added in 1809) and the district of Kottbus, though he had to surrender some of his former territory to the new kingdom of Westphalia. The king of Saxony's faith in Napoleon was shaken by the disasters of the Russian campaign, but when the allies invaded Saxony in the spring of 1813, he refused to declare against Napoleon and fled to Prague, though he withdrew his contingent from the French army. After Napoleon's victory at Liitzen (May 2, 1813), the Saxon king and the Saxon army were once more at the disposal of the French. During the battle of Leipzig in Oct. 1813, the popular Saxon feeling was displayed by the desertion of the Saxon troops to the side of the allies. Frederick was taken prisoner in Leipzig, and the government of his kingdom was assumed for a year by the Russians. The congress of Vienna assigned the northern portion, consisting of 7,800 sq m., with 864,404 inhabitants, to Prussia, leaving 5,790 sq.m., with a population of 1,182,744, to Frederick, who was permitted to retain his royal title. On June 8, 1815, King Frederick joined the new German Confederation.

Constitutionalism. — From the partition in 1815 to the war of 1866 the history of Saxony is mainly a narrative of the slow growth of constitutionalism and popular liberty within its limits. Its influence on the general history of Europe ceased when the old empire was dissolved. In the new German empire it was too completely overshadowed by Prussia to have any objective importance by itself. Frederick lived 12 years after the division of his kingdom. The commercial and industrial interests of the country continued to be fostered, but only a few of the most unavoidable political reforms were granted. Religious equality was extended to the Reformed Church in 1818, and the separate diet of Upper Lusatia was abolished. Frederick Augustus was succeeded in 1827 by his brother Anthony who initiated a few unimportant reforms An active opposition began to make itself evident in the diet and in the press, and in 1830, under the influence of the July revolution in Paris, riots broke out in Leipzig and Dresden, and a constitution was promised. After consultation with the diet the king promulgated, on Sept. 4, 1831, a new constitution by which the feudal estates were replaced by two chambers, largely elective, and the privy council by a responsible ministry of six departments.

While Saxony's political liberty was thus enlarged, its commerce and credit were stimulated by its adhesion to the Prussian Zollverein and by the construction of railways. Anthony had died in 1836, and Frederick Augustus II., since 1830 co-regent, became sole king. The burning questions were the publicity of legal proceedings and the freedom of the press; and on these the government sustained its first heavy defeat in the lower chamber in 1842. In 1843 the prime minister Lindenau was forced by the action of the aristocratic party to resign, and was replaced by Julius Traugott von Konneritz (1792–1866), a statesman of reactionary views. This increased the opposition of the Liberal middle classes to the Government. Religious considerations arising out of the attitude of the Government towards the "German Catholics," and a new constitution for the Protestant Church, began to mingle with purely political questions.

Warned by the sympathy excited in Saxony by the revolutionary events at Paris in 1848, the king dismissed his reactionary ministry, and a Liberal cabinet took its place in March 1848. The privileges of the nobles were curtailed; the administration of justice was put on a better footing; the press was unshackled; publicity in legal proceedings was granted; trial by jury was introduced for some special cases; and the German Catholics were recognized. The feudal character of the first chamber was abolished, and its members made mainly elective from among the highest tax-payers, while an almost universal suffrage was introduced for the second chamber. The first demand of the overwhelmingly democratic diet returned under this reform bill was that the king should accept the German constitution elaborated by the Frankfort parliament. Frederick, alleging the danger of acting without the concurrence of Prussia, refused, and dissolved the diet. The public demonstration at Dresden in favour of the Frankfort constitution was prohibited on May 2, 1849. The people seized the town and barricaded the streets; Dresden was almost destitute of troops; and the king fled to the Konigstein. The rebels then appointed a provisional Government, consisting of Tzschirner, Heubner and Todt, though the true leader of the insurrection was the Russian Bakunin. Meanwhile Prussian troops had arrived to aid the Government, and after two days' fierce street fighting the rising was quelled. The bond with Prussia now became closer, and Frederick entered with Prussia and Hanover into the temporary "alliance of the three kings"; but in 1850 he accepted the invitation of Austria to send deputies to the restored federal diet at Frankfort. The first chamber immediately protested against this step, and refused to consider the question of a pressing loan. The king retorted by dissolving the diet and summoning the old estates abolished in 1848. Beust became minister for both home and foreign affairs in 1852, and under his guidance the policy of Saxony became more and more hostile to Prussia and friendly to Austria.

The sudden death of the king in 1854 left the throne to his brother John whose name is known in German literature as a translator and annotator of Dante. His brother's ministers remained but their views gradually became somewhat liberalized with the spirit of the times. Beust, however, still retained his federalistic and philo-Austrian views. When war was declared between Prussia and Austria in 1866, Saxony took the side of Austria. On the conclusion of peace Saxony lost no territory, but had to pay a war indemnity of 10,000,000 thalers, and was compelled to enter the North German Confederation.

Franchise. — During the peace negotiations Beust had resigned and entered the Austrian service, and on Nov. 15 the king in his speech from the throne announced his intention of being faithful to the new Confederation as he had been to the old. On Feb 7, 1867, a military convention was signed with Prussia which placed the army under the king of Prussia. The postal and telegraph systems were also placed under the control of Prussia, and the representation of the Saxon cro n at foreign courts was merged in that of the Confederation. A new electoral law reformed the Saxon diet by abolishing the old distinction between the various "estates" and lowering the qualification for the franchise; the result was a Liberal majority in the lower house and a period of civil and ecclesiastical reform. John was succeeded in 1873 by his elder son Albert (1832–1902) who had added to his military reputation during the war of 1870. Under this prince the course of politics in Saxony presented little of general interest, except perhaps the spread of the doctrines of Social Democracy, which was especially remarkable in Saxony. The number of Social Democratic delegates in a diet of 80 members rose from 5 in 1885 to 14 in 1895. So alarming did the growth appear, that the other parties combined, and on March 28, 1896, a new electoral law was passed, introducing indirect election and a franchise based on a triple division of classes determined by the amount paid in direct taxation. This resulted in 1901 in the complete elimination of the Socialists from the diet. On June 7, 1902, King Albert died, and was succeeded by his brother as King George. An extraordinary situation had been created by the electoral law of 1896. This law had in effect secured the misrepresentation of the mass of the people in the diet, the representation of the country population at the expense of that of the towns, of the interests of agriculture as opposed to those of industry. The result was displayed in the elections of 1903 to the German imperial parliament, when, under the system of universal suffrage, of 23 members returned 22 were Social Democrats. This led to proposals for a slight modification in the franchise for the Saxon diet (1904), which were not accepted. In the elections of 1906, however, only 8 of the Social Democrats succeeded in retaining their seats. In 1907 the Government announced their intention of modifying the electoral system in Saxony by the adding of representation for certain professions to that of the three classes of the electorate. This was, however, far from satisfying the parties of the extreme Left, and the strength of Social Democracy in Saxony was even more strikingly displayed in 1909 when, in spite of plural voting, under a complicated franchise, 25 Socialist members were returned to the Saxon diet.

King George died on Oct. 15, 1904, and was succeeded by his son as King Frederick Augustus III., under whom the conflict about the constitution continued. The Left demanded a reform of the first chamber, the upper house, which should break the predominance of the agrarians in that house and allow to commerce, industry and handicrafts a greater influence. This was reinforced in 1917 by the agitation of the extreme Left in the diet for the early conclusion of peace.

The Revolution. — On Oct. 26, 1918, the cabinet gave place to a more liberal government under Dr. Heinze. On Nov. 9, 1918, when the revolution broke out, King Frederick Augustus abdicated, and was later compensated by a grant of 300,000 marks. A new republican constitution was adopted on Nov. 1, 1920, but the revolutionary agitation remained active. Max Holz, the most famous guerrilla leader of the communists, was at last defeated and captured early in 1921. In 1923 the strong revolutionary feeling of the Saxons was shown by the proceedings of the Zeigner ministry which depended upon an alliance of socialists and communists against the bourgeoisie and large capitalists It was expelled from office by the reich government who occupied the country with troops and replaced the ministry by a conservative coalition. In 1924 Zeigner was condemned to three years' imprisonment on a charge of bribery and destroying official documents.

The excesses of the communists and the violence of the conflicts in the alternating control by radicals and reactionaries for half a century in Saxony facilitated the seizure of power by the national socialists in 1933.

The chief authority for the early history of Saxony is Widukind, whose *Res gestae Saxonicae* is printed, together with the works of other chroniclers, in the *Monumenta Germaniae historica, Scriptores*. Collections which may be consulted are: *Codex diplomaticus Saxoniae regiae* (Leipzig. 1862–79); the *Archiv fur die sächsische Geschichte*, edited by K. von Weber (Leipzig. 1862–79); the *Biblzotlzek der sächsischen Geschichte und Landeskunde*, edited by G. Buchholz (Leipzig, 1903); and the *Bibliographie der Sächsischen Geschichte* (Leipzig, 1918, *et sqq.*, published by the *Sächsische Kommission für Geschichte*). See GERMANY. *bibliography.*

SAXOPHONE, a modern hybrid musical instrument invented by Adolphe Sax, having the clarinet mouthpiece with single reed applied to a conical brass tube. In general appearance the saxophone resembles the bass clarinet, but the tube of the latter is cylindrical and of wood; both instruments are doubled up near the bell, which is shaped somewhat like the flower of the gloxinia. The mouthpiece in both is fixed to a curved tube at right angles to the main bore. In the case of the saxophone, however, owing to its conical bore, the quality of tone materially differs from that of the clarinet. The reed mouthpiece in combination with a conical tube allows the performer to give the ordinary harmonic series unbroken, which means in practice that the octave or second member of the harmonic series is first overblown. The saxophone is therefore one of the class known as octave instruments. The fundamental note given out by the tube when the lateral holes are closed is that of an open organ pipe of the same length, whereas when, as in the clarinet family, the reed mouthpiece is combined with a cylindrical bore, the tube behaves as though it were closed at one end, and its notes are an octave lower in pitch. Hence the bass clarinet to give the same note as a bass saxophone would need to be only half as long. The quality of tone of this family of instruments is inferior to that of the clarinets and has affinities with that of the harmonium. According to Berlioz it had kinship also uith the timbre of the 'cello and cor anglais, with, however, a brazen tinge.

The saxophone has not enjoyed much favour hitherto with high-class composers. though Richard Strauss scored for a quartet of the instruments in his Sinfonia Domestica. In military bands, however. it has proved of great service and it has acquired vogue as a leading member of the jazz orchestra.

SAY, JEAN BAPTISTE (1767–1832), French economist, best known for his law of markets, which remained a central tenet of orthodox economics until the great depression of the 1930s, was born at Lyons on Jan. 5, 1767.

Say's law postulates that supply creates its own demand; hence there can be no general deficiency of effective demand to cause economic depression and unemployment. Actual depression Say attributed to temporarily misdirected production, which must automatically right itself because the overproducers of particular products will suffer losses; they must either redirect their production to conform with consumers' preferences or be forced out of business by continuing losses. An obvious implication of Say's law is the self-adjusting nature of the capitalist system. Consequently there is no need for government intervention in economic affairs.

Say was perhaps the first important economist to distinguish clearly between entrepreneur and capitalist and to assign to the former the creative role of combining the other factors of production — labour, land and capital. His career as a businessman, as well as a professor of economics. contributed to his insight into entrepreneurial activity. He died in Paris on Nov. 15, 1832.

Say's principal work is *Traité d'économie politique* (1st ed., 1803; 6th ed., 1846).

See E. Teilhac, *L'Oeuvre économique de Jean Baptiste Say* (1927); Leo Rogin, *The Meaning and Validity of Economic Theory*, ch. 6 (1956). (D. DD.)

SAY, (JEAN BAPTISTE) LÉON (1826–1896), French statesman and economist, born in Paris on June 6, 1826, was descended from a long line of well-known economists, including J. B. Say (*q.v.*), his grandfather.

After the fall of Napoleon III's empire in 1871, Say entered public life and became influential in the affairs of the third republic. As minister of finance during the 1870s, his outstanding achievement was payment of the huge war indemnity to Germany long before the prescribed time. Say sought to lower taxes and to remove all barriers to internal commerce. He repealed duties on many articles of prime utility, such as paper. and lowered postal rates to facilitate freer communication. He successfully opposed imposition of an income tax.

Say also championed free international trade and in 1880 went to England to negotiate a commercial treaty. With the revival of protectionism in France, Say organized a league against the high price of bread. He was an ardent advocate of *laissez faire* and a bitter antagonist of socialism, and he opposed every attempt at state intervention. He was elected president of the senate in 1880 but resigned from that body in 1889 in the belief that his efforts for liberalism were more urgently needed in the chamber of deputies.

Say died in Paris on April 22, 1896.

Throughout his career Say was an indefatigable writer and lecturer on economic subjects. Although he exerted a wide influence on his contemporaries, he was content with the existing framework of economic analysis and made no significant contribution to economic science. He was a prominent member of learned French academies.

A selection of his most important writings appeared posthumously under the title *Les Finances de la France sous la troisième république* (1898–1901).

See G. Michel, *Leon Say* (1900). (D. DD.)

SAY, THOMAS (1787–1834), U.S. Quaker naturalist. often termed "the father of descriptive entomology in America." was born at Philadelphia. Pa., on June 27, 1787. He was an original member of the Philadelphia Academy of Natural Sciences. founded in 1812; and after various activities. including two expeditions to the Rocky mountains. he became curator of the American Philosophical society in 1821 and was professor of natural history at the University of Pennsylvania from 1822 to 1828. During this period he took part in other expeditions, and with Robert Owen unsuccessfully attempted to found an ideal community at the village of New Harmony. Ind.. where he spent the remainder of his life. dying there on Oct. 10, 1834.

His work was almost entirely taxonomic and his writings for the most part purely descriptive. His entomological papers in various journals were collected by J. L. Le Conte and published in two volumes: *The Complete Writings of Thomas Say on the Entomology of North America* (1859). His works on conchology were collected by W. G. Binney and published in 1858 as *The Complete Writings of Thomas Say on the Conchology of the United States*, with 7j plates, many of them drawn by his wife. His paleontological writings were reprinted in 1896 by G. D. Harris in *Bulletin of American Paleontology*, vol. 1, no. v.

(ED. HE.)

SAYAD, a descendant of Ali, the son-in-law of Mohammed, by Fatima, Mohammed's daughter. Many of the Pathan tribes in West Pakistan, such as the Bangash of Kohat and the Mishwanis of the I-Iazara border, claim Sayad origin. The apostles who completed the conversion of the Pathans to Islam were called Sayads if they came from the west, and Sheikhs if they came from the east; hence doubtless many false claims to Sayad origin. In Afghanistan the Sayads have much of the commerce in their hands, as their holy character allows them to pass unharmed where other Pathans would be murdered.

The Sayads reigned at Delhi during the first half of the 15th century. Their name again figures in Indian history at the breakup of the Mogul empire, when two Sayad brothers created and dethroned emperors at their will (1714–1720).

SAYAN MOUNTAINS, in central Asia, forming the eastern continuation of the Sailyugem or Altai range, stretching from 89° E. to 106" E. They are the border ridge between the plateau of northwest Mongolia and Siberia. The geology is imperfectly known; the mountains are of the Hercynian age. The general elevation is 7,000 to 9,000 ft.; peaks, consisting largely of granites and metamorphic rocks, reach 10,000 ft. and 11,457 ft., *e.g.,* in Munku Sardyk; and the principal passes lie at 6,000 to 7,500 ft. above the sea; *e.g.,* Muztag 7,480 ft., Mongol 8,432 ft., Tenghyz 7,480 ft. and Obo-sarym 6,100 ft. In 92° E. the system is pierced by the Bei-kem or upper Yenisei, and in 106° E., it terminates above the depression of the Selenga-Orkhon valley. From the Mongolian plateau the ascent is gentle, but from the plains of Siberia it is much steeper, despite the fact that the range is masked by a broad belt of subsidiary ranges; *e.g.,* the Usinsk, Oya, Tunkun, Kitoe and Belaya ranges. Between the breach of the Yenisei and the Kosso-gol (lake) in 100° 30' E. the system bears also the name of Yerghik-taiga. The higher regions carry good forests of larch, pitch pine, cedar, birch and alder, with rhododendrons and species of *Berberis* and *Ribes.* Lichens and mosses clothe many of the boulders that are scattered around about the upper slopes.

SAYAT-NOVA (pseudonym of ARUTHIN SAYADIAN) (1712–1795), Armenian troubadour, famous for his love songs, was born at Tiflis. He worked first as a weaver and later (1750–65) became the court minstrel of Irakli II of Georgia. In 1770 he entered a monastery in Haghbat, and he was martyred in 1795 by the Persian invaders of Georgia.

Most of his extant songs are in Azeri Turkish, the rest in Armenian and Georgian. (C. J. F. D.)

SAYCE, ARCHIBALD HENRY (1845–1933), British philologist, whose services to Babylonian and Assyrian scholarship cannot be overestimated, was born at Shirehampton on Sept. 25, 1815. He was educated at Bath, and at Queen's college, Oxford, becoming a fellow in 1869.

In 1870 he was ordained. From 1891 to 1919 he was professor of Assyriology at Oxford. He was a member of the Old Testament Revision company (1874–84); deputy professor of comparative philology in Oxford (1876–90); Hibbert lecturer (1887); Gifford lecturer (1900–02 j.

Sayce died on Feb. 4, 1933, at Bath.

Among his more important works are: *Assyrian Grammar* (1872); *Principles of Comparative Philology* (1874); *Introduction to the Science of Language* (1879); *Early History of the Hebrews* (1897); *Israel and the Surrounding Nations* (1898); *Babylonians and Assyrians* (1900); and *Archaeology of the Cuneiform Inscriptions* (1907). He also contributed important articles to *Encyclopædia Britannica* and published his *Reminiscences* in 1923.

SAYE AND SELE, WILLIAM FIENNES, 1ST VISCOUNT (1582–1662), was the only son of Richard Fiennes, 7th Baron Saye and Sele, and was descended from James Fiennes, Lord Saye and Sele, who was lord chamberlain and lord treasurer under Henry VI and was beheaded by the rebels under Jack Cade on July 4, 1450.

Fiennes was educated at New College, Oxford; he succeeded to his father's barony in 1613, and in parliament opposed the policy of James I, undergoing a brief imprisonment for objecting to a benevolence in 1622, and he showed great animus against Lord Bacon. In 1624 he was advanced to the rank of a viscount. In the'early parliaments of Charles I he was in Clarendon's words "the oracle of those who were called Puritans in the worst sense, and steered all their counsels and designs." His energies found a new outlet in helping to colonize Providence Island. and in interesting himself in other and similar enterprises in America. Although Saye resisted the levy of ship money, he accompanied Charles on his march against the Scots in 1639; but, with only one other peer, he refused to take the oath binding him to fight for the king to "the utmost of my power and hazard of my life."

When the Civil War broke out, however, Saye was on the committee of safety, was made lord lieutenant of Gloucestershire, Oxfordshire and Cheshire and, raising a regiment, occupied Oxford. He was a member of the committee of both kingdoms; was mainly responsible for passing the Self-Denying ordinance through the house of lords; and in 1647 stood up for the army in its struggle with the parliament. In 1648, both at the treaty of Newport and elsewhere, Saye was anxious that Charles should come to terms, and he retired into private life after the execution of the king, becoming a privy councilor again upon the restoration of Charles II. He died at his residence. Broughton castle near Banbury, on April 14, 1662. On several occasions Saye outwitted the advisers of Charles I by his strict compliance with legal forms. He was a thorough aristocrat, and his ideas far the government of colonies in America included the establishment of an hereditary aristocracy.

Old Saybrook in Connecticut is named after Viscount Saye and Lord Brooke.

SAYERS, TOM (1826–1865), English middleweight boxing champion, was born on May 25, 1826, at Pimlico, Eng. In 1849 he left bricklaying to become a fighter. Despite his size (height 5 ft. 8½ in.; weight 155 lb.), the "Little Wonder" often fought much bigger opponents, yet he lost only one bout during the ten years he fought—that to Kat Langham on Oct. 18, 1853, in 61 rounds.

In 1860, in the first international heavyweight title match in boxing history, he fought America's great champion John C. Heenan. Although he was outweighed by 40 lb. and was nine years older, Sayers was made the 2 to 1 betting favourite over Heenan. The fight lasted 2 hr. 20 min. and after 42 rounds ended in a draw when Sayers injured his right arm. Sayers then retired from the ring, and the British raised £3,000 (about $15,000) by public subscription for him.

He died on Nov. 8. 1865. (J. D. McC.)

SAYYID AHMAD KHAN, SIR (1817–1898), distinguished Indian Moslem scholar and educationist, was born in Delhi on Oct. 17, 1817. After his father's death in 1836, against the wishes of his family, he entered the civil service. During the Indian Mutiny (1857–58) he was instrumental in saving the lives of many Europeans by sending them, at great risk to himself, into safety at Meerut. The government awarded him a pension and he was appointed a companion of the Star of India (being made knight commander in 1888). In 1869 he visited England with his two sons in order to make arrangements for their education. On his return to India he founded a college at Ghazipur in which western methods of instruction were adopted and the teaching was carried on in English. In spite of the opposition of the more conservative Moslems, he was so successful that in 1875 he opened the Mohammedan Anglo-Oriental college at Aligarh. Although he retired from public life in the following year, he accepted membership of the legislative council of India (1878–82). Until his death at Aligarh on March 2, 1898, the rest of Sir Sayyid's life was occupied by literary research and the advancement of his college, which received its first charter as a university in 1920.

See G. F. I. Graham, *The Life and Work of Sir Syed Ahnted Khan* (1909); J. M. S. Baljon, Jr., *The Reforms and Religious Ideas of Sir Sayyid Ahmad Khan* (1949). (S. J. C.)

SAZONOV, SERGHEI DMITRIEVICH (1866–1927), Russian statesman, was born in the province of Ryazan, July 29, 1866, the son of a landed proprietor, and educated at the Alexandrovsky Lyceum, St. Petersburg (Leningrad), a high school for the sons of noblemen destined mainly for the civil service. Having occupied various diplomatic posts in Rome and served six years in the Russian Embassy in London he was promoted, in 1906, to be Minister-Resident at the Vatican, where his engaging manners, frankness and taste for ecclesiastical affairs enabled him to make great headway. In 1909 he entered the Ministry of Foreign Affairs as coadjutor to Izvolsky, whom he succeeded as Minister in 1910—an appointment ascribed to the influence of his brother-in-law, Stolypin.

Sazonov's line of action was definitely traced for him by the European situation on the one hand and by the limitation of his rôle to that of confidential secretary to the Emperor on the other. His chief functions were to parry Austria's fitful thrusts at Serbia, to curb Serbia's explosive impatience, buoying her up with hopes of a vast legacy to fall due on the death of the Emperor Francis Joseph, and to bespeak the help of England. Italy, Rumania (to whom he also held out hopes of a legacy) and Bulgaria in the coming struggle. These tasks exceeded his powers, and his abortive Near-Eastern policy did not prevent Russia's ruinous collapse during World War I. Yet if his work was not to prove permanent he carried it out with considerable skill, and defended himself ably in his memoirs against the charge that he was seeking to precipitate a World War; although he admitted knowledge of the fact that Hartwig, in Belgrade, was working against his avowed aims. Meanwhile, Sazonov genuinely worked for present peace, to gain time for Stolypin's far-reaching domestic reforms and to allow Russia to consolidate her insecure domestic and military situation.

The arrangements arrived at during the tsar's visit to Potsdam (Nov. 4–5, 1910) and the kaiser's return visit to Wolfsgarten (Nov. 11) respecting the Baghdad railway, North Persia and the maintenance of Turkey, eased the strain, but failed to dispel the atmosphere of mistrust. Sazonov was suspected of a lack of straightforwardness by the kaiser. Russia's diplomatic representatives abroad were largely to blame for this. Other covert moves also lent colour to the charges of underhand dealing. For example, on the conclusion of the Balkan alliance of 1912. Sazonov decided to seek Germany's help in overawing the Balkan states and thus preserving peace. He accordingly arranged an interview between the tsar and the kaiser at Baltischport on July 4–5, 1912, which mas followed by a three days' exchange of views between the German chancellor and the members of the Russian government in St. Petersburg. Yet he concealed from Germany the existence of the Balkan alliance which had been communicated to him. Sazonov next repaired to London, Paris and Berlin and the Great Powers authorized Berchtold and him to announce their determination to uphold the *status quo,* so that if the Balkan states broke the peace their victory would be fruitless. The veto was successfully ignored by the Balkan powers, and a European crisis was the result.

Sazonov was next employed in drafting, with Bethmann Hollweg, a scheme of reforms for Armenia (Nov. 5, 1913). Immediately afterward. a fresh conflict with Germany arose over the dispatch of General Liman von Sanders to Constantinople. Sazonov gave vent to his dissatisfaction in unusually strong terms, but on the kaiser ordering Liman to lay down the command of the first Turkish army corps. while retaining his other functions, Nicholas II let the matter drop. Sazonov then drafted a memorandum to the tsar on Russia's claim to the freedom of the Straits and three months later convened a council of political and military experts to discuss the ways and means of realizing the scheme in case of a European war. But the military experts announced that in the plans of campaign no such side-problems could be included.

On learning of the Austro-Hungarian ultimatum to Serbia on July 24, 1914, Sazonov appealed unsuccessfully to Austria to extend the time limit. and advised Serbia to accept all demands except those concerning its sovereign rights. Meanwhile, Russia adopted the military measures known as "premobilization" (July 2j), the tsar and Sazonov planning a partial mobilization to follow in case Serbia should be attacked. But the general staff objected that with no plan ready for a transition from partial to general mobilization, and with war seeming unavoidable, the latter was imperative. Sazonov insisted on waiting; meanahile Berchtold declared war against Serbia (July 28), whereupon Sazonov (in the night of July 28–29) advised the tsar to sign the order.

A belated telegram. however, from the kaiser adjuring him to preserve peace for the sake of the monarchic principle moved the tsar to nithdraw the order for general, and substitute that for partial, mobilization. This command was obeyed in words but the military experts having convinced Sazonov that it would be suicidal, the minister next morning (July 30) presented himself to the tsar and obtained his consent to the radical measure advocated by the general staff. Next morning this order was posted and the catastrophe, already inevitable, broke loose.

During the war Sazonov countered all influences tending to the abandonment of the struggle by Russia, but he followed the tsar's lead in demanding first the opening of the Straits and the internationalization of Constantinople and later on the annexation of the Turkish capital. The hostility of Turkey and Bulgaria impeded assistance from the Allies, whereupon Sazonov made a bid for the help of the Poles in the shape of a Home Rule scheme, but the proposal was scouted in court circles and he was dismissed. His fall was gently broken by his appointment as ambassador to Great Britain, but before he reached his destination the revolution of hlarch 1917 had deposed the tsar. Sazonov, however, represented the government that had deposed the tsar, but it too was suddenly swept away. He was next appointed minister for foreign affairs by Admiral Kolchak; but after 1920 he retired into private life, settling at Versailles, where he occupied himself in writing his memoirs (Eng. trans., *Fateful Years,* 1928). Sazonov died at Nice. Dec 23, 1927.

SBEITLA (anc. SUFETULA), a ruined city of Tunisia, 66 mi. S W. of Kairawan. The chief ruin is the Forum. 238 ft by 198 ft., having three small and one large entrance. The great gateway is a fine monumental arch in fair preservation, with an inscription to Antoninus Pius. Facing the arch, their rear walls forming one side of the enclosure, are three temples, connected with one another by arches, and forming one design. The length of the entire façade is 118 ft.

The principal chamber of the central temple, which is of the Composite order, is 44 ft. long; those of the side temples, in the Corinthian style, are smaller. The walls of the middle temple are ornamented with engaged columns; those of the other buildings with pilasters. The porticos have been repaired, and run round the other three sides of the enclosure, which is still partly paved. The other ruins include baths, remains of a theatre, an amphitheatre, a triumphal arch of Diocletian, two churches of the priest Servas and the bishop Bellator, a chapel of the bishop Jucundus (411–419), a still serviceable bridge which also carried an aqueduct, and several square Byzantine forts.

The early history of Sufetula is preserved only in certain inscriptions. Under Antoninus and Marcus Aurelius it was a flourishing city, the district, now desolate, being then very fertile and covered with forests of olives. It was partly rebuilt during the Byzantine occupation and became a centre of Christianity. At the Arab invasion it was the capital of the exarch Gregorius.

SCABIES or ITCH, a skin disease caused by a species of mite, *Sarcoptes scabiei.* In addition to the variety that lives in the skin of man, physiological varieties of *S. scabiei* parasitize monkeys, cattle, horses, swine and certain other animals; occasionally man may receive transitory infections through contact with animals. There are also several other species of itch or mange mites that live on or in the skin of domestic and mild animals and birds. The fertilized female of S. *scabiei* burrows into the horny layer of the skin. Eggs are deposited in the burrow; the succeeding stages include the larva. nymph, adult male and female. Larvae and nymphs are found in the hair follicles. Mating occurs on the surface of the skin, and it is the newly fertilized female that passes from the infected person to a new victim. Such transmission usually results from bodily contact.

The disease is characterized by intense itching (especially at night), rash, follicular papules and vesicles. Scratching may lead to secondary bacterial infections. One remedy is to apply sulfur ointment following a hot bath. More effective treatment is obtained through application of an emulsion or lotion containing benzyl benzoate or hexachlorocyclohexane in coconut oil or in vanishing cream. Domestic animals may be treated with sprays or dips containing benzyl benzoate, hexachlorocyclohexane or tetraethylthiuram monosulfide. (L. E. R.)

SCABIOSA, a genus of about 80 species of Eurasian annual or perennial herbs belonging to the teasel family (Dipsacaceae), and commonly grown in gardens for ornament under the names of scabios, mourning bride or pincushion flower. In medieval times preparations of the plant were used medicinally, primarily to allay itching, hence the derivation of the generic name from the Latin *scabiosus,* meaning itchy, mangy or scabby.

The annual sweet scabios (*S. atropurpurea*) and its variants and the perennial pincushion flower (*S. caucasica*) are the commonest sorts: available in a wide range of colours (exclusive of brilliant red, deep yellow, orange or brown). Other perennial species frequently grown are *S. graminifolia* with grasslike leaves and lavender-blue flowers; *S. ochroleuca* with yellowish-white flowers; *S. columbaria* with lilac flowers; and *S. fischeri* with bluish-purple flowers. Most scabiosas grow to heights of 1½ to 3 ft., have toothed or lobed leaves, and produce almost globular to conical showy flower heads, usually 1 to 3 in. across. They are excellent as cut flowers.

Scabiosas are easily grown in ordinary garden soil in a sunny location. Seed may be planted in midspring; if pinched back when small the resulting bushy plants will produce blooms all summer if old flower heads are removed. The perennials, after two or three years' growth, may be increased by root division in early spring.

The garden plant known as shepherd's- or sheep's bit scabious is *Jasione perennis,* a member of the bellflower family. (G. H. M. L.)

SCAEVOLA, the name of a famous family of ancient Rome, the most important members of which were:

1. GAIUS MUCIUS SCAEVOLA, a legendary hero. who volunteered to assassinate Lars Porsena when he was besieging Rome. He reached Porsena's tent, but slew his secretary by mistake. Before the royal tribunal Mucius declared that he was one of 300 noble youths who had sworn to take the king's life, and that he had been chosen by lot to make the attempt first. Threatened with death or torture, Mucius thrust his right hand into the fire blazing upon an altar, and held it there until it was consumed. The king, deeply impressed and dreading a further attempt upon his life, ordered Mucius to be liberated, made peace with the Romans and withdrew his forces. Mucius was rewarded with a grant of land beyond the Tiber, known as the "Mucia Prata" in the time of Dionysius of Halicarnassus, and received the name of Scaevola ("left-handed"). The story is presumably an attempt to explain the name Scaevola (Livy ii. 12 ; Dion. Halic. v. 27–30). The Mucius of the legend is described as a patrician; the following were undoubtedly plebeians.

2. PUBLIUS MUCIUS SCAEVOLA, Roman orator and jurist, consul 133 B.C. during the time of the Gracchan disturbances. He was not opposed to moderate reforms, and refused to use violence against Tiberius Gracchus. After the murder of Gracchus, however, he expressed his approval of the act. He was an opponent of the younger Scipio Africanus, for which he was attacked by the satirist Lucilius (Persius i. 115; Juvenal i. 154). In 130 he succeeded his brother Mucianus as *pontifex maximus.* During his tenure of office he published a digest in 80 books of the official annals kept by himself and his predecessors. Cicero frequently mentions him as a lawyer of repute, and he is cited several times in the Digest. He was also a famous player at ball and the game called Duodecim Scripta; after he had lost a game, he was able to recall the moves and throws in their order.

See A. H. J. Greenidge, *History of Rome.*

3. QUINTUS MUCIUS SCAEVOLA, son of (2), usually called "*Pontifex Maximus,*" to distinguish him from (4), consul in 95 B.C. with L. Licinius Crassus the orator. He and his colleague brought forward the *lex Licinia Mucia de civibus regundis* which closed Roman citizenship to the allies in future, and was largely responsible for the Social War. After his consulship Scaevola was governor of the province of Asia, and dealt severely with the tax-farmers. In honour of his memory the Greeks of Asia set aside a day for the celebration of festivities and games called Mucia. He was subsequently appointed *Pontifcx Maximus,* and, in accordance with custom, dispensed free legal advice, which mas extensively sought, even by men of the standing of Servius Sulpicius. He regulated the priestly colleges, and insisted on observance of the traditional ritual, though he himself believed that religion was only for the uneducated. He was proscribed by the Marian party, and in 82, when the younger Marius, after his defeat by Sulla at Sacriportus, gave orders for the evacuation of Rome and the massacre of the chief men of the opposite party, Scaevola, while attempting to reconcile the opposing factions, was slain at the altar of Vesta and his body thrown into the Tiber. He had already escaped an attempt made upon his life by Gaius Fimbria at the funeral of the elder Marius in 86.

Scaevola was the iounder of the scientific studv of Roman law and the author of a systematic treatise on the subject, in eighteen books, frequently quoted and followed by subsequent writers. It was a compilation of legislative enactments, judicial precedents and authorities, from older collections, partly also from oral tradition. A small handbook called "Ὅροι (*Definitions*) is the oldest work from which any excerpts are made in the *Digest,* and the first example of a special kind of judicial literature (*libri definitionum* or *regularum*). *It* consisted of short rules of law and explanations of legal terms and phrases. A number of speeches by him, praised by Cicero ior their elegance oi diction, were in existence in ancient times.

4. QUINTUS MUCIUS SCAEVOLA (*c.* 159–88 B.C.), uncle of (3), from whom he is distinguished by the appellation of "*Augur.*" He was instructed in law by his father, and in philosophy by the Stoic Panaetius of Rhodes. In 121 he was governor of Asia. Accused of extortion on his return, he defended himself successfully. In 117 he was consul. He was a great authority on law, and at an advanced age he gave instruction to Cicero and Atticus. He had a high appreciation of Rfarius, and refused to vote for Sulla's motion declaring him a public enemy. Scaevola is one of the interlocutors in Cicero's *De oratore, De amicitia* and *De republica.*

For the legal importance oi the Scaevolas, *see* A. Schneider, *Die drei Scaevola Ciceros* (Munich, 1879), with full reierences to ancient and modern authorities.

SCAFELL (pronounced and sometimes written SCAWFELL), a mountain of Cumberland, Eng., in the Lake district (*q.v.*). The name is specially applied to the southern point (3,162 ft. in height) of a certain range or mass, but Scafell pike, separated from Scafell by the steep narrow ridge of Mickledore, is the highest point in England (3,210 ft.). The ridge continues northeast to Great End (2,984 ft.), which falls abruptly to a flat terrace on which lies Sprinkling tarn. The range thus defined may be termed the Scafell mass. Northwest from the pike the lesser height of Lingmell (2,649 ft.) is thrown out, and the steep flank of the range sweeps down to the head of Wastdale. On the east an even steeper wall, with splendid crags, falls to Eskdale. Above Mickledore ridge Scafell rises nearly sheer, with bold clefts.

SCAFFOLD, an elevated platform of temporary nature used to support materials and workmen in the construction or repair of a structure or machine. The term also denotes a platform used for the execution of criminals. The surface of the scaffold consists of one or more planks of convenient size and length. The method of support is varied to suit the immediate need and its form determines the type of scaffolding. Temporary built-up seats for an athletic contest are sometimes referred to as scaffolds but should be called temporary bleachers.

Timber Scaffolding. — In this type of scaffold the support for the planks is provided by a timber frame fabricated and erected at the site. The frame may consist of vertical posts, horizontal longitudinal members called ledgers, transverse members supported by the ledgers, and longitudinal and transverse cross bracing. The planks rest on the transverse members.

The posts are generally arranged in pairs with one post close to the wall and the other about 4 or 5 ft. out from the wall. Pairs of posts are placed along the wall at intervals of from 8 to 12 ft. The pairs are fastened together by ledgers running parallel to the wall and by braces. Transverse members may be cantilevered across the ledgers or may be supported by a ledger and the wall.

The posts are 2×4s for light loads and short spans or 4×4s where heavier frames are needed. The posts are usually supported on a sill resting on the ground.

As with all scaffolding, the timber must be thoroughly braced and should also be tied to the wall by suitable lashings. If a scaffold is carried up on the inside of the wall as well as on the outside, the two should be tied together through window openings to provide greater stability. The vertical spacing of the ledgers is determined by the size of lift or working space desired. The members are fastened together by nails or lashings as custom dictates.

Trestle Supports. — This type is used to carry the staging where little or no adjustment of height needs to be made for each use and where the scaffolding needs to be spread over a large area, as when plastering the ceiling of a house. The trestles may be of special design or may simply be wooden sawhorses of the type used by carpenters. Some specially designed trestles may be adjusted to provide for working heights of from 7 to 18 ft. One type of adjustable trestle is shown in fig. 1.

Putlog Trestles. — This type consists of one A-frame and adjustable vertical support similar to a single-end support of the trestle shown in fig. 1. A horizontal member, the putlog, is supported at one end by the A-frame and at the other end by the wall. Planks span across the putlogs.

Common Trestle. — This type consists of two ladders so hinged that they form an inverted V when opened; they fold together for ease in transporting or storing Two such units provide the end supports for simple or extension planks. The rungs in the ladders are spaced so that adjustments of plank heights may be made about every ten inches. The side rails of one leg of the inverted V may vary in length from 6 to 10 ft.

Extension Trestles. — The basic support unit for this type comprises two ladders similar to those of the common trestle and a third section of ladder in a vertical position and supported by the two inclined ladders forming an inverted Y. These support units may be procured in different heights and each height is adjustable. Two of the inverted Ys may support a plank for the working area or that plank may support one end of several planks to provide a wider working platform.

Scaffold Brackets. — Scaffolding is supported in frame (lumber) construction by brackets attached to the wall. A horizontal member 3 to $3\frac{1}{2}$ ft. long has one end fastened to the nall by nails and the outer end supported by a V-frame at about 45° and nailed to the timber frame. In some cases the horizontal member is so formed that it may be hooked around one of the wall studs (the

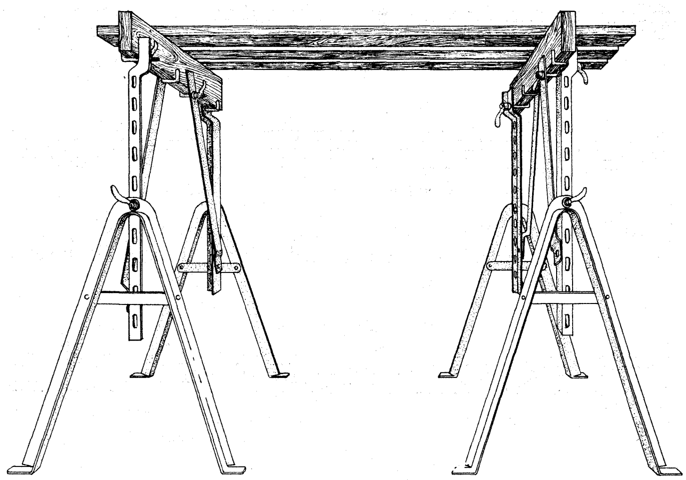

FIG. 1.— STEEL TRESTLE

vertical members in standard frame construction). The horizontal member may be manufactured with a screw end which is placed through a hole in the sheathing and fastened by a wing nut.

The diagonal support is similar in the three types. Special corner brackets are provided to turn the scaffold planks around

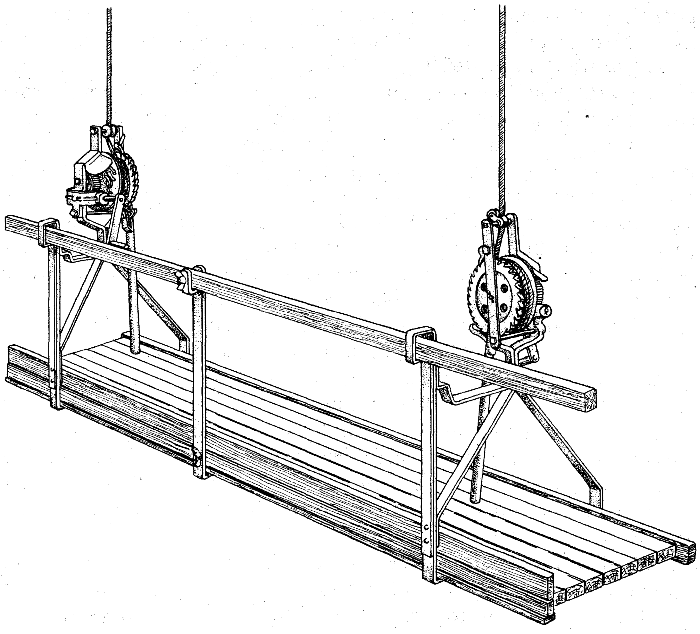

FIG. 2.— SWINGING SCAFFOLDING

a corner. The wall brackets may be folded for ease in handling and storage.

Adjustable **Roofing** Brackets. — These generally consist of a rectangular frame with one member extending beyond the rectangle so it may be held by one or more nails. Attached to the frame are two members which provide an essentially horizontal support for the plank; this triangular frame may be adjusted to provide the horizontal support on a roof of any pitch. Another type of roof bracket provides support for 2×4 staging so the 4-in dimension is normal to the roof surface. This serves as footing for shinglers.

Ladder Jacks. — A ladder jack is a Y-shaped frame with an adjustable bracket which may be placed on the rungs of a ladder to provide support for staging. Two ladders, each with a jack, are used to support one span of plank. The arms of the Y hook over a rung of the ladder and the stem generally extends to the second rung below and may be clipped to it. The bracket may be adjusted to provide horizontal support for staging for different inclinations of the ladder. The jacks may be attached above the ladder or hung underneath. An alternate type hooks around the rails of the ladder instead of around the rungs. Scaffolding provided in this manner is frequently used in painting houses.

Tubular Scaffolding. — Because of its convenience and economy, steel or aluminum tubular scaffolding has very largely replaced timber scaffolding except for installations in remote areas. Tubular scaffolding can easily be erected in any shape, length or height. Furthermore, sections of the tubular scaffolding may be mounted on casters to provide a highly mobile staging. The walkway or working platform generally consists of 2×10 or 2×12 wooden planks. The scaffolding may be enclosed with canvas for protection against the weather. Tubular scaffolding may be purchased or rented.

Two general types of tubular scaffolding are available: (1) Sectional scaffolding which is made up of standard end frames fastened together with diagonal and horizontal braces; in some cases a horizontal member, known as a bridging trestle, may be attached to the end frames. The end frames are usually about 5 ft. wide and vary in height from 3 to 10 ft. They are available in several patterns depending upon specific use. The diameter of the tubing in the end frames is about $1\frac{5}{8}$ in. (2) The second type comprises pipes or tubing of 2 to $2\frac{1}{2}$ in. diameter in lengths of 6 to 20 ft. and fastened together by couplers to form rigid frames, The standard coupler fastens members meeting at right angles and the adjustable coupler fastens members meeting at other than right angles. The scaffolding planks are supported by the "bearer." the horizontal tube connecting posts in the direction generally perpendicular to the wall. This type can easily be assembled to encompass a blast furnace or smokestack.

Suspended Scaffolding.—This type consists of a horizontal putlog attached to two drum mechanisms. Cables extend from each drum to an outrigger beam attached overhead to the structure frame. Ratchet devices on the drums permit the raising or lowering of the putlogs, which are spaced 6 to 9 ft. apart. Planks span between putlogs and provide the working surface. An outside guardrail and kick board are generally required. In some cases an attachment is provided for supporting an overhead protecting plank. The drum mechanisms are equipped with 100 to 150 ft. of $\frac{1}{2}$ in. diameter galvanized steel wire rope.

A second and lighter form of suspended scaffolding has a supporting device in the form of a stirrup about 30 in. wide with vertical legs attached to a single lifting drum. The wire rope from the drum is attached overhead to an outrigger or cornice hook. The staging, about 10 to 12 ft. long, is supported by a stirrup near each end. Guardrails and kick boards complete the assembly. The scaffolding may be raised or lowered by a ratchet mechanism on the drum and operated by the workman on the scaffolding.

Tubular Hoisting Tower.—Steel tubes or pipes about 3 in. in diameter nith standard connections may be quickly assembled into tubular hoisting towers. Pipe of different weight (standard, extra heavy or double extra heavy) is used depending upon the function of the section and its vertical position in the tower. A member may be attached to one leg to form a "Chicago boom," the leg of the tower forming the mast.

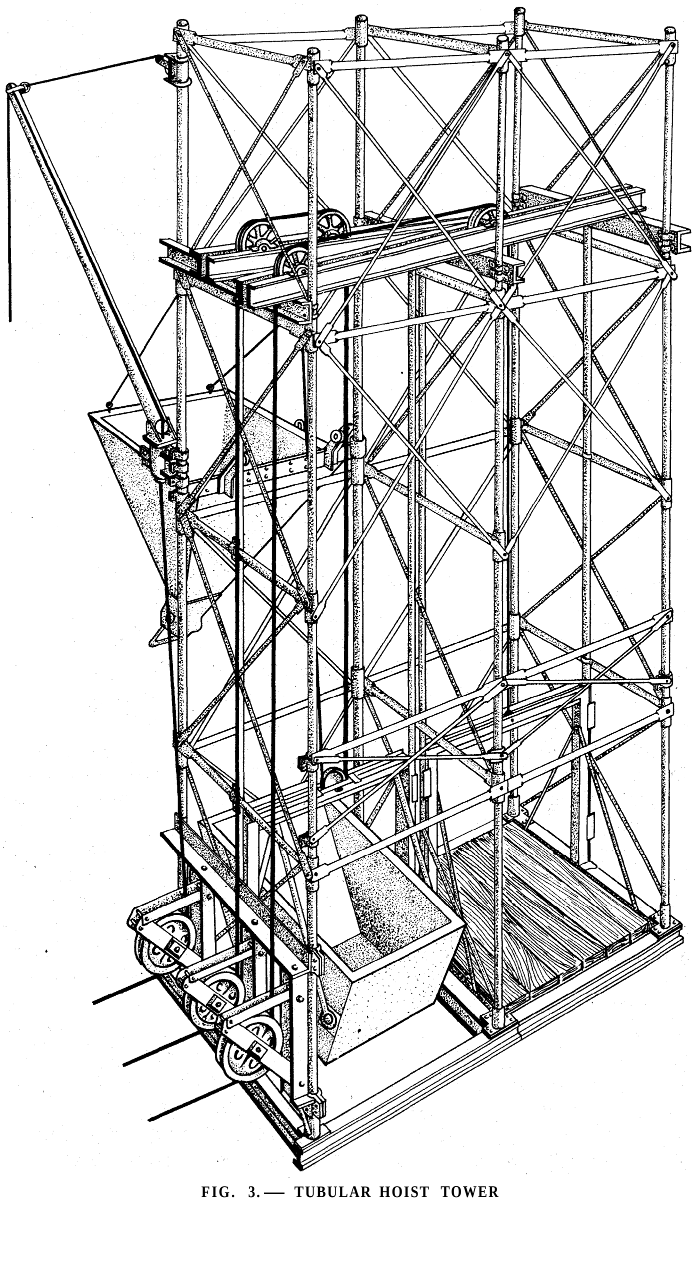

FIG. 3.— TUBULAR HOIST TOWER

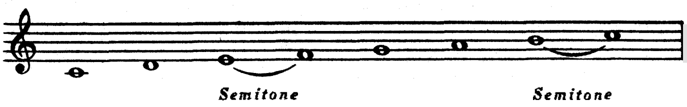
Shoring.—The sectional tubular scaffolding units may be used to form the shoring for concrete forms. The end frames are mounted on adjustable bases which rest on a timber plate or other firm support. (F. W. St.)

SCALE, in music, signifies any selected sequence of notes or intervals dividing the octave. This is a theoretical conception by which the material of an existing or a historical practice can be systematized for readier understanding and explanation. Theoretically, the octave can be divided into a number of microtones; *i.e.,* tones smaller than a semitone. In antiquity and currently in the orient. but not to any marked extent in the west. intervals smaller than a semitone were in regular use. Such a practice yields a scale that is unfamiliar to the modern western listener.

Pentatonic Scale.––Many historical and some existing traditions of music make use of five notes only (with their octave transpositions) and such a practice yields a pentatonic scale. This is a "gapped" scale: *i.e.,* a scale containing intervals of more than a tone. One of the more familiar pentatonic scales is the equivalent of the black notes of the keyboard.

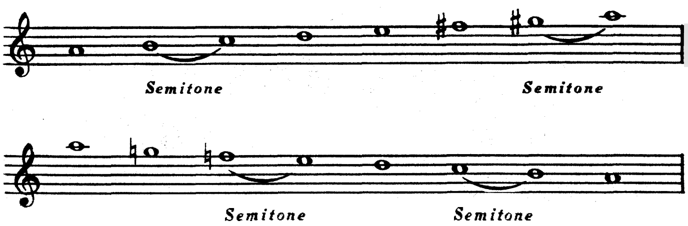
Diatonic Scale.—The division of the octave into seven notes appears very early in western music. Medieval musicians employed a variety of seven-note scales, known as modes. These contained two semitone intervals that occurred in a different relation to the "final" in each mode. Two modes, the Ionian and the Aeolian (in a slightly modified form), remain in general use as the diatonic major and minor scales. In each major and each minor scale the semitone intervals occur in the same relation to the key note (or tonic). In the major scale the semitones occur between notes 3–4 and 7–8.

Ex. 1.



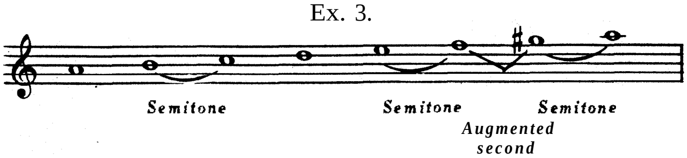
The minor scale has two forms, the "melodic minor" and the "harmonic minor." In the melodic minor the semitones occur between notes 2–3 and 7–8 ascending and between notes 6–5 and 3–2 descending.

Ex. 2.



In the harmonic minor the semitones occur between 2–3, 5–6 and 7–8, with the interval of an augmented second (a tone plus a semitone) between notes 6–7.

Ex. 3.



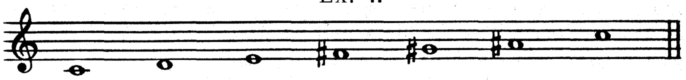
In all forms of the diatonic scale the names given to the degrees of the ascending scale are: 1. tonic; 2. supertonic; 3. mediant; 4. subdominant; 5. dominant; 6. submediant; 7. leading note.

The chromatic scale, which comprises all the 12 semitones in the octave, can be considered as a "colouring" of the diatonic scale. The medieval musician regarded the notes C and C sharp. for example, not as separate notes but as two aspects of one note. This could be written as C and altered in performance "by reason of necessity or of beauty." At a later date, owing to the practice of equal temperament, diatonic scales were built on any of the 12 notes of the octave. In the late 19th century the extreme use of chromaticism (*q.v.*) brought about the partial destruction of diatonic tonality.

The scale of "12-note," or dodecaphonic, music (*see* DODECAPHONY) uses the notes of the chromatic scale but does not permit the establishment of any tonal centre.

The whole-tone scale is often associated with Debussy, although it had been used as early as the 18th century by Mozart (in a sextet called "A Musical Joke"). As its name implies, it is a scale without semitones and consequently consists of only six notes.

Ex. 4.



Other experimental scales have been evolved by 19th and 20th century composers.

See also MUSIC.

SCALE INSECT (SOFT SCALE), the name given to insects belonging to the family Coccidae of the order Hemiptera (*q.v.*). The females are inert wingless creatures usually with reduced legs and antennae. while the males are provided with a single pair of wings and have the legs and antennae well developed. Soft scales include a number of serious plant pests. among the most injurious being the San José scale, the oyster shell scale. the scurfy scale, the purple and red scale of citrus. and the mealy bugs. On the other hand; other species have a commercial value, notably the cochineal (*q.v.*) insect. the lac (*q.v.*). insect and the so-called ground pearls.

SCALES: *see* WEIGHING MACHINES.

SCALIGER, the Latinized name of the Della Scala family. (*See* VERONA.) It has also been borne by two eminent scholars.

1. Julius Caesar Scaliger (1484–1558) was, according to his own account, a scion of the house of La Scala, born in 1484 at the castle of La Rocca on the Lago de Garda At the age of twelve his kinsman the emperor Maximilian placed him among his pages. He remained for seventeen years in the service of the emperor, distinguishing himself as a soldier and as a captain But he was unmindful neither of letters, nor of art, which he studied under Albrecht Durer. In 1512 at the battle of Ravenna, where his father and elder brother were killed, he displayed prodigies of valour, and received the highest honours of chivalry, but no substantial reward, from his imperial cousin. After a brief employment by the, duke of Ferrara, he entered (1514) as a student at the university of Bologna, where he remained until 1519 The next six years he passed in Piedmont, as a guest of the family of La Rovère, until a severe attack of rheumatic gout brought his military career to a close. Henceforth his life was wholly devoted to study. In 152j he accompanied M. A. de la Rovère, bishop of Agen, to that city as his physician. Such is the outline of his own account of his early life. It was not until after his death that his son's enemies first alleged that he was the son of Benedetto Bordone, an illuminator or school-master of Verona; that he was educated at Padua, where he took the degree of M D.; and that his story of his life and adventures before arriving at Agen was a tissue of fables. (*See* below *ad fin*)

The remaining thirty-two years of his life were passed almost wholly at Agen. in the full light of contemporary history. At his death in 1j58 he had the highest scientific and literary reputation of any man in Europe. A few days after his arrival at Agen he fell in love with Andiette de Roques Lobejac, and at forty-five he married Andiette, who was then sixteen The marriage, of which there were fifteen children, was one of almost uninterrupted happiness. In 1531 he printed his first oration against Erasmus, in defence of Cicero and the Ciceronians It is a piece of vigorous invective, displaying an astonishing command of Latin, and much brilliant rhetoric, but full of vulgar abuse, and completely missing the point of the *Ciceronianus* of Erasmus The second is even more abusive, and less successful. The orations were followed by a prodigious quantity of Latin verse, which appeared in successive volumes in 1533, 1534, 1539, 1546 and 1547; of these, a friendly critic, Mark Pattison, is obliged to approce the judgment of Huet, who says, "par ses poésies brutes et informes Scaliger a déshonoré le Parnasse." A brief tract on comic metres (*De comicis dimensionibus*) and a work *De causis linguae Latinae*—the earliest Latin grammar on scientific principles and following a scientific method—were his only other purely literary works published in his lifetime. His *Poetice* appeared in 1561 after his death.

His scientific writings are all in the form of commentaries, and it was not until his seventieth year that (with the exception of a brief tract on the *De insomniis* of Hippocrates) he published any of them In 1556 he printed his *Dialogue* on the *De plantis* attributed to Aristotle, and in 1557 his *Exercitationes* on the work of Jerome Cardan, *De subtzlitate*. His other scientific works, *Commentaries* on Theophrastus' *De causis plantarum* and Aristotle's *History of Animals,* left in a more or less unfinished state, were not printed until after his death. His *Exercitationes* upon the *De subtilitate* of Cardan (1557) is the book by which Scaliger is best known as a philosopher We are astonished at the encyclopaedic wealth of knowledge which the *Exercitationes* display, at the vigour of the author's style, at the accuracy of his observations, but are obliged to agree with G. Naudé that he has committed more faults than he has discovered in Cardan, and with Charles Nisard that his object seems to be to deny all that Cardan affirms and to affirm all that Cardan denies. Yet Leibniz and Sir William Hamilton recognized him as the best modern exponent of the physics and metaphysics of Aristotle. He died at Agen on Oct. 21, 1558.

2. Joseph **Justus Scaliger** (1540-1609), the greatest scholar of his day, was the tenth child of J. C. Scaliger. Born at Agen in 1540, he was sent when twelve years of age, with two younger brothers, to the college of Guienne at Bordeaux. An outbreak of the plague in 1j5j caused the boys to return home, and for the next few years Joseph was his father's constant companion and amanuensis. Julius daily dictated to his son from eighty to a hundred lines of Latin verse, and sometimes more. Joseph was also required each day to write a Latin theme or declamation, though in other respects he seems to have been Ieft to his own devices. He learned from his father to be an acute observer, never losing sight of the actual world, and aiming not so much at correcting texts as at laying the foundation of historical criticism.

After his father's death, he spent four years at the university of Paris, where he began the study of Greek under Turnebus. At the same time he taught himself. He read Homer in twenty-one days, and then went through all the other Greek poets, orators and historians, forming a grammar for himself as he went along. From Greek, at the suggestion of G. Postel, he proceeded to attack Hebrew, and then Arabic; of both he acquired a respectable knowledge, though not the critical mastery which he possessed in Latin and Greek. In 1563 Jean Dorat recommended him to Louis de Chastaigner, the young lord of La Roche Pozay, as a companion in his travels. A close friendship sprang up between the two young men, which remained unbroken till the death of Louis in 1595. The travellers first went to Rome. Here they found Marc Antoine Muretus, who had been a great favourite and occasional visitor of Julius Caesar at Agen. After visiting Italy, the travellers passed to England and Scotland. Scaliger formed an unfavourable opinion of the English. Their inhuman disposition, and inhospitable treatment of foreigners especially impressed him He was also disappointed in finding few Greek manuscripts and few learned men It was not until much later that he became intimate with. Richard Thompson and other Englishmen. In the course of his travels he had become a Protestant. In 1570 he proceeded to Valence to study jurisprudence under Cujas, the greatest living jurist. Here he remained three years.

The massacre of St. Bartholomew induced him to retire to Geneva, where he was appointed a professor in the academy. In 1574 he returned to France, and made his home for the next twenty years with Chastaigner. Of his life during this period we have interesting details and notices in the *Lettres françaises* *inédites de Joseph Scaliger,* edited by *M.* Tamizey de Larroque (Agen, 1881). During this period he published the books which showed that with him a new school of historical criticism had arisen. In his editions of the *Catalecta* (1575), of Festus (1575), of Catullus, Tibullus and Propertius (1577), he was the first to lay down and apply sound rules of criticism and emendation, and to change textual criticism from a series of haphazard guesses into a "rational procedure subject to fixed laws" (Pattison). But it was reserved for his edition of Manilius (1579), and his *De emendatione temporum* (1583), to revolutionize all the received ideas of ancient chronology—to show that ancient history is not confined to that of the Greeks and Romans, and that the historical narratives and fragments of Persia, Babylonia, Egypt and Palestine, and their several systems of chronology, must be critically compared, if any true and general conclusions are to be reached. It is this which places Scaliger immeasurably above any of his contemporaries. His commentary on Manilius is really a treatise on the astronomy of the ancients, and it forms an introduction to the *De emendatione temporum,* in which he examines by the light of modern and Copernican science the ancient system as applied to epochs, calendars and computations of time.

In the remaining twenty-four years of his life he at once corrected and enlarged the basis which he had laid in the *De emendatione.* With incredible patience, sometimes with a happy audacity of conjecture which itself is almost genius, he succeeded in reconstructing the lost *Chronicle* of Eusebius—one of the most precious remains of antiquity, and of the highest value for ancient chronology. This he printed in 1606 in his *Thesaurzis temporum,* in which he collected, restored and arranged every chronological relic extant in Greek or Latin. When in 1590 Lipsius retired from Leyden, the university resolved to obtain Scaliger as his successor. He declined their offer. The next year it was renewed. It was made clear that lecturing would not be required of him, and he would be entirely his own master. About the middle of 1593 he started for Holland, where he passed the remaining thirteen years of his life. He was treated with the highest consideration. His rank as a prince of Verona was recognized. His literary dictatorship was unquestioned. From his throne at Leyden he ruled the learned world; a word from him could make or mar a rising reputation; and he was surrounded by young men eager to listen to and profit by his conversation. He encouraged Grotius when only a youth of sixteen to edit Capella; Daniel Heinsius, from being his favourite pupil, became his most intimate friend.

But Scaliger had made numerous enemies. He hated ignorance, but he hated still more half-learning, and most of all dishonesty in argument or in quotation. His pungent sarcasms were soon carried to the persons of whom they were uttered, and his pen was not less bitter than his tongue. Nor was he always right. He trusted much to his memory, which was occasionally treacherous. The Jesuits, who aspired to be the source of all scholarship and criticism, perceived that the writings and authority of Scaliger whose historical methods had discredited many of their claims were the most formidable barrier in their way. It was the day of conversions. Muretus in the latter part of his life professed the strictest orthodoxy; J. Lipsius had been reconciled to the Church of Rome; Casaubon was supposed to be wavering; but Scaliger was known to be hopeless, and as long as his supremacy was unquestioned the Protestants had the victory in learning.

After several scurrilous attacks by the Jesuit party, in 1607 a new and more successful attempt was made. Scaliger's weak point was his pride. In 1594, in an evil hour for his happiness and his reputation, he published his *Epistola de vetustate et splendore gentis Scaligerae et J. C. Scaligeri vita.* In 1607 Gaspar Scioppius, then in the service of the Jesuits, whom he afterwards so bitterly libelled, published his *Scaliger hypobolimaeus* ("the Supposititious Scaliger"). The main argument of the book is to show the falsity of Scaliger's pretensions to be of the family of La Scala, and of the narrative of his father's early life. To Scaliger the blow was crushing. Whatever the case as to Julius, Joseph had undoubtedly believed himself a prince of Verona, and in his *Epistola* had put forth with the most perfect good faith, and without inquiry, all that he had heard from his father. His reply, *Confutatio fabulae Burdonum,* was not *a* success. Scaliger undoubtedly exposes many pure lies and baseless calumnies; but he could not establish the family's supposed lineage. Scioppius was wont to boast that his book had killed Scaliger. It certainly embittered the remainder of his life. The *Confutatio* was his last work. Five months after it appeared, on Jan. 21, 1609, he died.

Of Joseph Scaliger the standard biography is that of Jacob Bernays (Berlin, 1855). *See* also his *Autobiography, with selections from his letters etc,* trs. with introd. by G. W. W. Robinson (1927). *See* also *J. E.* Sandys, *History of Classical Scholarship,* ii. (1908), 199–204. For the life of J. C. Scaliger *see* the letters edited by his son, and his own writings, which are full of autobiographical matter.

SCALLOP. The popular name for a genus *(Pecten)* of marine molluscs belonging to the class Lamellibranchia. Nearly 300 living species of scallops are known and are found in all seas, from high latitudes to the tropics. Many species are important as human food. The "scallop-shell of quiet" (Sir W. Raleigh) was worn as a badge by mediaeval pilgrims.

Pecten is placed in the second order (Filibranchia) of the Lamellibranchia. This group is characterized by the possession of gills in which the filaments are doubled on themselves. forming reflected lamellae and are joined together by ciliated disks, and by the highly developed byssus. In *Pecten* the foot is rudimentary and the animal is more or less sedentary, the byssus serving to fasten it down to the sea bottom; nevertheless, they are good swimmers. The edges of the mantle are provided with highly developed eyes.

The common scallop of the British Isles (*Pecten opercularis*) is usually found in beds on a bottom composed of shell-debris with a little mud. Some of the largest beds are in the Firth of Forth and in the Irish sea. These beds are usually in water of 5–20 fathoms, though individual specimens are occasionally taken from much deeper water. The United States scallop fishery is centred on the coasts of the northeastern Atlantic states. Representatives of the subgenus *Pseudamussium* are found at greater depths (*e.g., P. neoceanicus* in 2,084 fathoms in the Pacific ocean).

(G. C. R.; X.)

SCALP, in anatomy, the covering of the top of the head from the skin to the bone.

The skin of the scalp is thick and contains a large number of hair follicles. The arteries are remarkable for their tortuosity, which is an adaptation to so movable a part; for their anastomosing across the middle line with their fellows of the opposite side, an arrangement which is not usual in the body; and for the fact that, when cut, their ends are held open by the dense fibrous tissue in which they lie, so that bleeding is more free in the scalp than it is from arteries of the same size elsewhere in the body.

The veins do not follow the twists of the arteries but run a straight course; there is often a considerable distance between an artery and its companion vein. Accompanying the veins are the larger lymphatic vessels. From the forehead the lymphatics accompany the facial vein and usually reach their first gland in the submaxillary region, so that in the case of a poisoned wound of the forehead sympathetic swelling or suppuration would take place below the jaw. From the temple the lymphatics drain into a gland lying just in front of the ear, while those from the region behind the ear drain into glands lying close to the mastoid process. In the occipital region a small gland (or glands) is found about a third of the distance from the external occipital protuberance to the tip of the mastoid process.

The nerve supply of the scalp in its anterior part is from the fifth cranial or trigeminal nerve; behind the ear the scalp is supplied with sensation by the great auricular and the small occipital nerves, while behind these. and reaching as far as the midline posteriorly, the great occipital is distributed.

Beneath the skin and fibrous tissue lies the epicranium, formed by the two fleshy bellies of the occipitofrontalis muscle and the flattened tendon or aponeurosis between them. Of these two bellies the anterior (frontalis) is the larger, and, when it acts, throws the skin of the forehead into transverse puckers. The much smaller (occipitalis or posterior) belly usually merely fixes the aponeurosis for the frontalis to act, though some people have the power of alternately contracting the two muscles and so wagging their scalps backward and forward as monkeys do.

Deep to the epicranium is a layer of very lax areolar tissue constituting a lymph space and allowing great freedom of movement to the more superficial layers; it was this layer which was torn through when an American Indian scalped his foe. So lax is the tissue here that any collection of blood or pus is quickly distributed throughout its whole area. and, owing to the absence of tension as well as of nerves, very little pain accompanies any such effusion.

The deepest layer of the scalp is the pericranium or the external periosteum of the skull bones. This, until the sutures of the skull close in middle life. is continuous with the dura mater which forms the internal periosteum, and for this reason any subpericranial effusion is localized to the area of the skull bone over which it happens to lie. Moreover, any suppurative process may extend through the sutures to the meninges of the brain. *See* also HAIR; SKULL. (F. G. P.)

SCALPING. The common term for the practice of removing, as a trophy, a portion of the skin, "shell" or "sheath," with hair attached, from an enemy's head. The custom was not unknown to the Old World, as it was mentioned by Herodotus as practised by the Scythians. It has been regarded, however, as a prevalent one among the American Indians, yet, contrary to the general belief, not all the tribes practised it by any means. Extended researches by Friederici indicate that in North America it was confined originally to a limited area in eastern United States and the lower St. Lawrence region, about equivalent to the territory held by the Iroquois and Muskhogean tribes and their neighbours. The custom was absent from New England and much of the Atlantic coast region, and was unknown until comparatively recent times throughout the interior and the Plains area; it was not practised on the Pacific coast, in the Canadian North-west nor in the Arctic region, nor anywhere south of the United States with the exception of an area in the Gran Chaco country of South America. Throughout most of America the early trophy was the head itself. The spread of the scalping practice over the greater part of central and western United States was stimulated by scalp-bounties offered by the colonial and more recent governments, the scalp itself being superior to the head as a trophy by reason of its lighter weight and greater adaptability to display and ornamentation.

The operation of scalping was painful, but by no means fatal. The impression that it was fatal probably arose from the fact that the scalp was usually taken from the head of a slain enemy as a trophy of his death, but among the Plains tribes the attacking warrior frequently strove to overpower his enemy and scalp him alive. to inflict greater agony before killing him; and frequently also a captured enemy was scalped alive and permitted to return to his people as a direct defiance and as an incitement to retaliation. The part taken was usually a small circular patch of skin at the root of the scalp-lock just back of the crown. The scalp-lock itself was the small hair braid which hung from the back of the head, as distinguished from the larger side braids. When opportunity offered, the whole top skin of the head, with the hair attached, was removed, to be divided later into smaller locks for decorating the clothing of warriors. The operation was performed by making a quick knife stroke around the head of a fallen enemy, followed by a strong tug of the scalp-lock. The scalper was not necessarily he who had killed the victim; nor was the number of scalps, but rather the number of coups (*i.e.,* "strokes" or acts of bravery in battle), the measure of the warrior's prowess. The fresh scalp was sometimes offered n-ith prayer as a sacrifice to the sun, the nater or some other divinity. When preserved for a time, as was most usual, the scalp was cleaned of the loose flesh and then stretched by means of sinew cords around the circumference within a hoop about six inches in diameter, tied at the end of a rod. When dry the skin side was painted either entirely red, or one half red and the other half black, and the hair was usually carefully braided and embellished with various ornaments. It was carried thus by the women in the triumphal scalp or victory dance on the return of a successful war-party to the home camp, and then, having served its first purpose, was retained as a bridle pendant by the warrior, deposited with the tribal "medicine," or thrown away in some secluded spot. This may be regarded as the typical treatment; but scalp customs varied from tribe to tribe, as likewise did the associated beliefs and rites. The custom is involved with that of decapitation, the severing of parts of the body, such as fingers, etc., as war trophies, and the shrinking of the heads of enemies as among the Jivaro Indians of Ecuador. (F. W. H.)

SCAMMONY, a plant. *Convolvulus scammonia,* native to the countries of the eastern Mediterranean basin; it grows in bushy waste places, from Syria in the south to the Crimea in the north its range extending westward to the Greek islands, but not to northern Africa or Italy. It is a twining perennial, bearing flowers like those of the field or corn bindweed. *Convolvulus arvensis,* and having irregularly arrow-shaped leaves and a thick fleshy root. The dried juice, "virgin scammony." obtained by incision of the living root. has been used in medicine as *scammonium,* but the variable quality of the drug has led to the use of *scammoniae resinu,* obtained from the dried root by digestion with alcohol. The active principle is the glucoside scammonin or jalapin, $C_{34}H_{56}O_{16}$; it is a ponerful purgative.

SCAMOZZI, VINCENZO (1552–1616), Italian architect and architectural theorist of the late Renaissance. was born in Vicenza and trained under his father, a pupil of Sebastiano Serlio, and in the atmosphere of the Accademia Olimpico at Vicenza. He provided designs for Salzburg cathedral, but worked mostly at Venice, Padua and in the Veneto. He designed palaces, villas and churches as well as the permanent classical stage setting for Andrea Palladio's Teatro Olimpico at Vicenza, the ducal theatre at Sabbioneta and the fortress town of Palmanova. He died in Venice in 1616. Through Scamozzi's writings (*L'Idea dell'architettura universale,* 1615) Palladianism (*q.v.*) influenced English architecture from Inigo Jones onward, but Scamozzi's theories differ in certain respects from Palladio's and he may more properly be regarded as the intellectual father of neoclassicism.

The Scamozzi Ionic order is a type of column the capital of which has four identical faces with the volutes meeting at an angle at each corner. Scamozzi was once thought to have invented it, although there are Roman precedents for the design.

See F. Barbieri, *Vzcenzo Scamozzi* (1952). (F. J. B. W.; X.)

SCANDAL, disgrace, discredit, shame, caused by the report or knowledge of wrongdoing, hence defamation or gossip, especially malicious or idle; or such action as causes public offence or disrepute. A particular form of defamation was *scandalum magnatum,* "slander of great men," words, that is, spoken defaming a peer spiritual or temporal, judge or dignitary of the realm. Action lay for such defamation under the statutes of 3 Edw. I. c. 34, 2 Rich. II. c. 5, and 12 Rich. II. c. 11 whereby damages could be recovered, even in cases where no action would lie, if the defamation were of an ordinary subject, and that without proof of special damage These statutes, though long obsolete, were only abolished in 1887 (Statute Law Revision Act).

SCANDINAVIAN CIVILIZATION. At the close of the Ice Age climatic conditions at last allowed man to enter Scandinavia; but authorities differ as to when this occurred, suggestions varying from 10,000 B.C. to 6,000 B.C.

Epipalaeolithic Period.—The earliest civilizations belong to the so-called Epipalaeolithic Period, of which two stages are at present recognised in Denmark, called after their type-stations the Maglemose and Ertebolle Periods. The former is that of a race of fishermen who lived on the shores of the Baltic while it was still a great fresh-water lake (called by geologists Ancylus lake); at Maglemose were found many tools of bone, horn and stone: the most typical being the barbed harpoon of bone or horn and a chipped flint axe known as the tranchec. Pottery was not found. In the following period (Ertebolle) a rise in sea-level had allowed the sea to flow into the Baltic (this Is called by geologists the Littorina sea). The typical remains of this age are usually found in vast rubbish-heaps or kitchen-middens (kjøkkenmøddinger). Bone and horn tools and other objects, *e.g.,* combs were still used, but flint was now the most important material. Pottery had come into use, the commonest form being a wide-mouthed bulging jar with pointed base. It is probable that in Norway and Sweden similar settlements existed, at present less fully known; for instance, remains at Nøstvet in Norway and at Limhamn in Sweden resemble and may be contemporary with those at Ertebolle. With the exception of the dog, domestic animals were unknown at this period, and agriculture was not practised.

Neolithic Period. — In the remoter districts of Norway and Sweden the epipalaeolithic people retained their primitive mode of life for a long time, untouched by the more advanced, neolithic civilizations developing to the south of them.

Our knowledge of these neolithic civilizations is almost entirely gathered from a study of the burial customs of the period. Such dwellings as are known are simple circular mud huts, containing few remains but animal bones, etc. All the more important graves of this period in Scandinavia are megalithic structures, a chronological sequence of three types being recognised (corresponding to Montelius' Periods II., III. and IV.). The earliest form of tomb was the Dolmen (*q.v.*), a small chamber enclosed by three or more rude upright stones, roofed by a single great stone slab, and often still partially covered by a mound. These graves, which usually contained several unburnt bodies, are not very richly furnished, but are characterized by the thin-butted axe (so-called celt) of flint, usually ground and polished, and by pottery, mostly ornamented flasks and vases. From these came the Passage Grave (Chamber-Tomb), a more elaborate structure in which a large megalithic chamber was approached by a passage walled and roofed with stone slabs. Such tombs are often of great size; a typical example figured by Du Chaillu, at Axvalla Heath, near Lake Venern, Vestergotland, Sweden, has a chamber 32×9 ft. and a passage 20 ft. long. These communal tombs sometimes contained as many as 100 skeletons, unburnt, and numerous associated objects. Some of the most typical are the thick-butted axe of flint, sometimes ground and polished; the perforated stone axe; transverse arrowheads and arrowheads with triangular section; oval, thick-butted daggers of chipped flint; amber beads; and pottery, usually angular or round bottomed bowls. The Passage Grave then degenerated into the Long Stone Cist. These graves also contained numerous skeletons, but are scantily furnished, the typical objects being a lunate knife of chipped flint and a beautiful, handled dagger, perhaps the finest achievement of any flint-workers. The pottery was poor and undecorated.

The civilization of the megalith-builders indicates a highly organized society of traders and farmers. Remains of domestic animals (horse, sheep, swine, cattle and dog) and traces of the cultivation of grain (barley, wheat and flax) are found round their huts; animal bones are also found in the mounds covering the tombs. Trade is proved by the occurrence of objects of Scandinavian origin in Britain (*e.g.*, perforated axes and thick-butted dagger-blades of Scandinavian workmanship in graves of the Beaker Period) and in central Europe (*e.g.*, necklaces of Baltic amber in Aunjetitz graves) and vice versa. The graves are most thickly distributed round the coastal districts of Denmark and Sweden, only in the latest (Long Stone Cist) period spreading to Norway and inner Sweden.

Contemporary with the megalithic burials a custom existed (chiefly in Jutland, S. Sweden and some of the Danish Islands) of burying each person in a small separate grave; several of these being covered by one barrow and found at different levels in it, either sunk in the earth, on the ground level or actually in the mound (bottom graves, ground graves and upper graves). These graves have pottery beakers and elaborate perforated stone axes, usually called battle axes. Axes and pottery of this type are widely distributed in Europe and these graves conceivably represent the entrance into Scandinavia of another race, who ultimately merged with the megalith-builders, since in the Long Stone Cist period there is little distinction between the furniture of the megalithic and of the separate graves.

Duration of Neolithic and Bronze Periods. — Prof. Gordon Childe, surveying the various estimates of the duration of the neolithic period in Scandinavia, suggests the following dates: Dolmen Period (Montelius Period II.), 2500–2200 B.C.; Passage-grave Period (Montelius Period III.), 2200–1650 B.C.; Long Stone Cist Period (Montelius Period IV.), 1650–1500 B.C. The last period belongs technically to the Bronze Age, since small objects of metal are occasionally found (copper and bronze pins and gold ear-rings).

Owing to the necessity of importing the metal the Bronze Age began late in Scandinavia; it probably lasted almost until the beginning of the Christian era. Here again much information is derived from burials, but hoards of objects are also of great importance. The dwelling-sites are imperfectly known.

Montelius, in his chronological classification of the Scandinavian Bronze Age, distinguishes two main periods, an Earlier and a Later, each having three subdivisions; but for a general survey the division into two periods is sufficient; the first probably ending about 1000 B.C., the second lasting till a few centuries before the Christian Era.

Earlier Bronze Period. — The sequence of metal types was much the same as in the rest of northern Europe. (See British Museum Guide, Bronze *Age,* Evolution of the Axe, Spear and Sword.) Early in the period the forms were simple, the flat and flanged axe and small knife being the commonest tools; at this time stone was probably in much commoner use than metal. But before long the innate craftsmanship of the Scandinavian asserted itself, and bronze weapons and ornaments were evolved unequalled in northern Europe for utility and elegance. That these were not importations is proved by the discovery of moulds in which such objects were cast and by the difference in technique between these objects and those of other countries.

The typical weapons were: Axes, of various forms, as, the palstave, the socketed and perforated axe; spears with riveted sockets; daggers and swords. The rapier or thrusting type of sword common throughout Europe in the middle Bronze Age was little used, being early replaced before A.D. 1000 by the heavier broad sword (leaf-shaped type), which came into use at an earlier date than in, *e.g.*, Britain. Some archaeologists hold that this type which was widely distributed through Europe, was actually evolved in Scandinavia by smiths who were, through the amber trade with Southern Europe, acquainted with the Italian bronze-handled dagger; others believe that Hungary was the place of origin. Some of the Scandinavian swords have a cast bronze hilt, others a hilt of wood or horn, etc., riveted in slabs on to a flanged bronze tang. The only defensive weapon which has survived is the circular bronze buckler, but such authorities as hold that the famous rock-carvings are of Bronze Age date deduce from these that horned helmets were worn. If the later phase of the Scandinavian Bronze Age was contemporary with the British Early Iron Age, these may well have taken the form of the bronze helmet in the British Museum found in the River Thames.

Personal ornaments were now for the first time abundant. These are usually of bronze but sometimes of gold. They include: Finger-rings, bracelets and torcs of various forms (coiled wire, cast or hammered); tutuli, *i.e.*, conical bosses apparently attached to the belt; pins, frequently disc-headed or with hanging ornaments; and brooches.

Both weapons and ornaments were commonly decorated at this time with incised designs, sometimes of chevrons, etc., but most often of spirals. This spiral ornament is often so marvellously regular as to suggest that some mechanical means was employed.

The distribution of finds suggests that there was at this time a considerable population throughout Southern Scandinavia.

The dead were at this period disposed unburnt in coffins, sometimes in the form of small stone cists but sometimes of wood, roughly hewn from a single tree-trunk. Some of these tree-trunk burials are of great interest as giving examples of the clothing worn. An oak coffin in a barrow (called Treenhøi) at Havdrup in Ribe, Denmark, contained a male skeleton with all his clothes preserved. These were: a high round cap, a wide mantle, a kind of kilt and two small fragments of leg-coverings, all of woven wool, and the remains of leather shoes. The inside of the mantle and a woollen belt which confined the kilt were fringed. A woollen shawl was rolled up to make a pillow. At the left side of the body was a sword in a sheath, and at the foot a wooden box containing a smaller box in which were another cap, a horn comb and a bronze razor. The whole contents of the grave was wrapped in an untanned hide. A complementary find at Borum-Eshoi, near Arhus, also in an oak coffin, produced a woman's dress, consisting of a long under-robe and a sleeved bodice both of woven wool, a cap of netted worsted, a tasseled belt woven of wool and cowhair, and a large mantle of woven wool and cowhair. Another cap was found in the grave, which also contained a bronze brooch, a horn comb, a finger-ring. two bracelets, a torc, three tutli and a horn-handled bronze dagger.

Later Bronze Period.—In this period cremation became general. The burnt bones were at first put in small stone cists, a number being often found under one mound; later the remains were placed in pottery urns, often still placed in cists; sometimes they were simply laid in the ground and covered with a stone. The pottery was usually in the form of plain jars and bowls, sometimes handled. Tomb furniture, especially weapons, became scantier. There is no visible break with the earlier period in the type of weapons; but gradually a new type of decoration was employed, and new kinds of household objects, ornaments, etc., were introduced. These include ornamented bronze vessels of various forms, often for hanging; a new kind of knife (so-called razor); and many personal ornaments. These are decorated with repoussé as well as with incised ornament, sometimes in the form of degenerate spirals, sometimes circles, and frequently wavy ribbon patterns and curves suggesting roughly drawn boats with bird's head terminals. Many of these were imported, being of Italian design; others are local imitations. The ornament is also foreign, being typical of the Hallstatt (earliest Iron Age) civilization of central Europe. The sword pommels are also of Hallstatt types. This period, therefore, although definitely part of the Bronze Age, was strongly influenced by the Iron Age of central and southern Europe, being contemporary with the Hallstatt Period.

At the close of this period a few iron objects of La Tène type, such as swords and brooches, occur in cremation graves otherwise indistinguishable from those of the Bronze Age, and represent the beginning of the use of iron in Scandinavia, probably dating in the first century or two B.C.

Rock Carvings.—On rocks in some districts of Sweden and Norway numerous crude carvings exist, representing scenes of fighting, husbandry, seafaring, etc. If, as most people believe, these belong to the Bronze Age, they throw a flood of light on the daily life of the time. But their dates are as yet unproved.

BOG FINDS

Although Scandinavia was always outside the Roman Empire the influence of that power was strongly shown in contemporary Scandinavian civilization. Very many objects of Roman manufacture were imported, often of good quality, showing that Scandinavia was prosperous and traded freely with the continent. Large numbers of Roman coins have been found, especially in the island of Gotland. Native art shows strong Roman influence.

At this time iron was of course in general use. Much information about the period is derived from hoards found in peat-bogs at Thorsbjerg, Vimose, Nydam and other sites in Jutland and Schleswig. These are supposed to be votive offerings following a battle. The weapons are remarkably fine, and include swords, single and double-edged, and damascened (the double-edged types having hilts resembling the Roman form); spears of various patterns, ornamented and sometimes inlaid on the blade; axes, socketed and perforated; chain-mail; helmets, one of silver; and shield-bosses. Tools of all kinds were found; also personal ornaments. Perhaps the most important find was that of a clinker-built boat 75 ft. long, at Nydam, built of oak and probably dating in the III. century A.D.; another of red pine was found.

Migration Period.—After the collapse of the Roman Empire in the west in the V. century AD. Scandinavian civilization developed gradually in harmony with the Teutonic civilizations to the south of it and in England. Again little is known of the houses of the period; the majority seem to have been four-sided huts. Burials are the chief source of information. Both inhumation and cremation were practised; the tomb furniture was rich, especially in personal ornaments and square-headed and cruciform brooches. These and other ornaments were decorated in a new style common to Scandinavia and the rest of Teutonic Europe at this period, consisting partly of geometric designs, spirals, stars, etc., and partly based on conventionalized and disintegrating animal forms, executed in a variety of techniques. The materials were sometimes bronze, occasionally silver and sometimes gold; the latter was most freely used in Sweden. In Gotland inlaid garnet ornament was popular, a technique which unlike the animal ornament occurs only sporadically in northern Europe. An ornament peculiar to Scandinavia was the bracteate, a disc-shaped gold pendant derived from barbarous copies of late Roman and Byzantine coins. The commonest weapons were the spear and shield. Swords, single and double edged, were not uncommon. Glass and wooden vessels as well as pottery are found.

Viking Period.—In the VIII. century the northern peoples, who had hitherto when restive contented themselves with local warfare and commercial ventures abroad, began to engage in piratical forays overseas. These were at first mere plundering raids resembling those of the Anglo-Saxons on the frontiers of the moribund Roman Empire in the III. and IV. centuries; but (like these) led ultimately to wide-spread colonization in England, northern France, Ireland, Scotland, the Faroes, the Orkneys, Shetland, Sicily and Russia; and to the discovery of Iceland, Greenland and America and the colonization of the two former. Their raids were pushed into almost every corner of Europe and they visited Asia Minor and North Africa.

We are fortunate in being able to examine in detail typical vessels in which they adventured, owing to their custom of burying the dead in their ships, under barrows; and it is not an exaggeration to say that all the finer developments of the sailing-ship were founded on their lines. A typical small war-vessel of the period was found at Gokstad, near Sandefjord in south Norway, and what might be described as a royal pleasure-vessel at Oseberg. Both contained a complete outfit; in the first were the chief's arms, horses, etc.; in the second the queen's bed, sledges, vessels, ornaments, etc. Lest anyone should doubt the seaworthiness of these vessels an exact model of the Gokstad ship was built and sailed across the Atlantic in 1893 and afterwards shown at the Chicago exhibition; it proved an able sea-boat.

In the Sagas, which provide a fund of information about life in those days (see SAGA) the affection of the Vikings for their ships is clearly shown, and they are often referred to by poetical names, such as Sea-skates, Elk of the Fjords, Horse of the Gull's Track, Raven of the Sea, etc.

Apart from warfare, farming was the chief occupation of the Vikings, and for this purpose slaves (thralls) were largely employed; but even kings took an active part in this pursuit. Ale-drinking, story-telling and games occupied the winter, every household having its winter store of dried meat and fish and home-brewed ale. Hospitality was practised on the grandest scale. The vivid description in the sagas of life in the halls of the northmen has been verified by excavation, "Fire-Halls" being found resembling mediaeval tithe-barns.

Typical antiquities of the period are found wherever the Vikings settled. Since paganism prevailed until about AD. 1000 in Norway and Iceland and even later in Sweden, tomb furniture was abundant in the earlier period. There was a great variety of burial customs; both inhumation and cremation were practised and the latter was not confined to the less elaborate tombs; it gradually died out, however, before the spread of Christianity. Men were often buried with a complete outfit of weapons, horse, dogs, harness, etc.; and not infrequently were buried in their boats; women had personal ornaments, household gear, etc. Boat burials were rare in Denmark, and in place of the big ship burials important persons were buried in wooden tomb chambers under mounds.

As might be expected, continual fighting led to the development of far more efficient weapons than had hitherto been known. Although the spear, used for both throwing and thrusting, still played an important part, the axe now reached an importance not seen since the Bronze Age; and the beautiful horned forms evolved (cf. Bayeux Tapestry) attest the skill of the Viking blacksmith. Splendid swords are found in the graves, frequently inlaid with gold and silver. Defensive weapons are represented by the shield, helmet and coat of ring-mail (*brynja*). From the numerous descriptions in the Sagas lve gather that a Viking's weapons were his most esteemed possessions; like the ships they are frequently described in such terms as:—for the sword, the Ice of Battle, the Dog of the Helmet, the Viper of the Host, etc.; for the spear, the Snake of the Attack, the Shooting Serpent, etc.; for the axe, the Witch of the Shield, the Wolf of the Wound; for arrows, the Bird of the Sling, the Twigs of the Corpse, etc.; for shields, the Burgh of the Swords, the Moon of Battle; for the *byrnja,* Gray clothes of Odin, the Woof of the Spear, etc. They also had personal names, as Magnus Barefoot's sword Legbiter, Skarphedin's axe, Ogress of War; and Harald Hardrada's byrnja, Emma.

Most objects are covered with decoration, the style of which at first derived from that of the end of the Migration Period (Vendel Style, conventionalized animal forms); but as a result of foreign intercourse, especially with Ireland and the Carolingian Empire, a new style of a hybrid character developed towards the close of the 8th century. Very good examples of this "Gripping beast" style are to be seen in the Oseberg Find. In the 10th century the Gripping beast style was overshadowed by the Jellinge style, in which animal forms are treated more naturalistically. This style, which in some ways resembles the Vendel style, is usually regarded as the outcome of Irish, English and Carolingian influence. The Jellinge style gave place for a time during the early 11th century to that of Ringerike, characterized by pure interlacing and conventionalized foliage, the animal motive being negligible; but later the interlaced animal of the Jellinge style reappeared in the Urnes style, at the close of which native Scandinavian art was overwhelmed by the bastard Romanesque of the Christian era.

SCANDINAVIAN LANGUAGES. This term is usually limited to the Germanic languages (*q.v.*), of the Indo-European family, spoken. and written in the Scandinavian countries, thus excluding Finnish and Lappish, mhich have most of their speakers in the same area. There are six distinct written languages in Scandinavia: the Danish language (*q.v.*), in Denmark; the Faroese language, in the Faroe Islands, a possession of Denmark; the Icelandic language (*q.v.*), in Iceland; the Norwegian language (*q.v.*), in Norway, split into two norms called Dano-Norwegian and New Norse; and the Swedish language (*q.v.*), in Sweden and Finland (only by about 9% of the population of Finland). Outside Scandinavia there are small areas of Danish speech in northern Germany and of Swedish in Esthonia, as well as among numerous emigrants in the United States and Canada. If these are estimated at about 1,000,000, the total number of Scandinavian speakers around 1950 was just over 16,000,000.

In speech there is a great deal more variation than the number of written norms would indicate. Icelandic has the least dialectal differentiation, while in the Faroes nearly every island has its own dialect

The continental countries all show a typically European cleavage into class and regional dialects. In each country there is an upper-class urban dialect mhich approaches the written norm more closely than do the rest; this is often regarded as a standard, though it varies from city to city, the speech of the capital having the greatest prestige: Oslo, Stockholm, Copenhagen. Closest to it. but by contrast regarded as vulgar, is the speech of the urban working classes; more remote, and often so different as to be mutually incomprehensible, is rustic speech. The rural dialects are divided regionally, reflecting the patterns of communication in medieval and early modern times. Every parish and village may be said to have its own dialect.

It is not known when Indo-European speech entered the north; some believe it may have come with the so-called Battle-Ax people of the Neolithic (c. 2500 B.C.). The earliest linguistic monuments bre about 100 inscriptions in the Germanic alphabet known as the older runic *futhark* (see RUNE). These date from c. A.D. 200 to 900, the earliest of which show a language close to the reconstructed proto-Germanic branch of the Indo-European languages; it may be called either North Germanic (contrasting it with East and West Germanic) or proto-Scandinavian. Between A.D 500 and 700 a radical change in the word forms led to what may be called the common Scandinavian of the Viking age (750–1050). First came a vowel assimilation known as umlaut (mutation), in which the accented vowel was coloured by the quality of the following unaccented vowel; then came a loss of unaccented vonels, ahich greatly shortened the length of the words; e g., *landa,* "land," became land, while its plural landu became *lǫnd;* similarly *katilaz* > *kætilR* > *ketill,* "kettle." Other changes were the loss of initial *j,* for example, in *ár,* "year" (corresponding to German *Jahr*), and of *w* before *u* and o, as in *ull,* "wool," and orb, "word." Our evidence for common Scandinavian consists of about 3,000 inscriptions in the younger runic alphabet of 16 characters, mostly memorial stones.

During this period Scandinavian uas carried also to Normandy, the English Danelagh, the Orkneys, Shetlands and Hebrides, to Ireland and the Isle of Man. to Greenland and the North American continent, as well as to the Swedish kingdoms in Russia; but in these areas the Scandinavian settlers were all absorbed or died out in later centuries.

Although some of the differences within the Scandinavian area undoubtedly date back to an earlier period, they do not become evident until the use of Latin writing after the introduction of Christianity. The native languages were first written in Norway, under the influence of English missionaries, in the late 11th century. From there Anglo-Saxon influences spread to Iceland also. The earliest manuscripts from Iceland and Norway date from c. 1150, while the earliest in Denmark and Sweden are nearly a century later. These show a substantially consistent form, characteristic for each centre of writing, down to about 1350; this may be called the Old Scandinavian period, in mhich fall Old Icelandic, Old Norwegian, Old Swedish and Old Danish, the two former distinguishable 'as Old West Scandinavian (also called Old Norse), the two latter as Old East Scandinavian. In the period from 1350 to 1525 a transition took place to the essentially modern forms of the present-day languages. During this Middle Scandinavian transition the manuscripts show a gradual loss of the old case system in favour of the modern analytic structure. The political and dynastic unions of the Scandinavian countries, under the hegemony of Denmark, spread Danish norms to the other countries, gradually diluting and even supplanting those which had been developing elsewhere.

The language of the royal chancery at Copenhagen eventually supplanted completely the norms of Jutland and Skåne within the Danish realm, as nell as those of Norway, mhich was united with Denmark. The last documents in pure Norwegian were written in the period 1459–1500, and the introduction of the Reformation in 1537 did not lead to a distinct Norwegian translation of the Bible. The authors who wrote in Norway after the Reformation used Danish in their literary composition; the notion of a separate Norwegian language did not arise again until the 18th century but acquired special force after the separation of 1814 In Iceland, on the contrary, the written tradition remained unbroken, though influenced by Danish. The same was true in Sneden, and the establishment of a separate Swedish state in 1525. with Stockholm as its capital, led to a strong and conscious reaction against Danish influences.

The modern Scandinavian era since the Reformation has led to three new norms as the result of modern nationalism: Faroese, established by V. U. Hammershaimb about 1850. New Norse (Landsmål, Nynorsk) by Ivar Aasen in 1853, and Dano-Norwegian (Riksmål, Bokmål), which gradually deviated from Danish in the 19th and early 20th centuries. Icelandic is the language that has most tenaciously preserved the grammar and vocabulary of the common Scandinavian period, with Faroese a not too close second; these languages have therefore become largely unintelligible to other Scandinavians. On the continent, Scandinavians are usually able to communicate with each other by speaking and writing their own languages. This is because of the common developments which the languages have undergone, including an extensive simplification of morphology and the adoption of loanwords from common sources, especially Low German. Danish is phonetically most deviant from the rest but has a large area of vocabulary in common with Dano-Norwegian; the cleavage is therefore greatest between Danish and Swedish.

Attempts have been made to promote communication by approaching the norms to one another, but with little success. Instead, an active program of mutual language teaching has been instituted in the school systems, as well as cultural exchanges under the aegis of the inter-Scandinavian society Norden.

SCANDIUM (symbol Sc), a metallic element usually classed in the cerium subgroup of rare earths (*q.v.*) and found mainly in rare ores of Scandinavia from which it derived its name. The discovery of its oxide, scandia, by L. F. Nilson in 1879 was of great scientific interest because this and other compounds of scandium had properties corresponding to those predicted by D. Mendeléyev (*q.v.*) in 1869 for the derivatives of a hypothetical element eka-boron which was needed to fill a gap in the periodical classification of the chemical elements (see PERIODIC LAW). Scandium has been found combined in a few uncommon minerals, such as thortveitite (from Saetersdalem, Nor.), wiikite (from Impilako, Fin.) in gadolinite and other rare earth bearing ores. It is also contained in small amounts in many tin and tungsten ores. Spectrographic observations have shown it to be relatively abundant in some of the stars.

Scandium has been successfully separated from the rare earths by solvent extraction of the thiocyanate complex, by anion exchange in strong HCl solutions and by cation exchange using chelating agents such as citric acid. Scandium forms many salts; these are usually colourless, diamagnetic and show scandium in the trivalent state. It .is concentrated in the soluble fractions of the usual bromate separation methods and is easily separated from other soluble salts being the least basic of the whole group.

Scandium crystallizes on the hexagonal close-packed system, $a = 3.309$ A, $c = 5.273$ A. It has an atomic number 21, atomic weight 44.96, stable isotope Sc^{45} (100%), calculated density of 3.016, melts at about 1200°–1600° C. and boils at approximately 2400° C.

SCAPA FLOW, an extensive landlocked anchorage in the Orkney Isles. about 15 mi. in length from north to south and 8 mi. in mean breadth, bounded by Pomona on the north, by South Ronaldshay on the east and southeast, and by Hoy on the west and southwest. The principal entrance is on the south from Pentland firth through Hoxa sound. Hoy sound on the west leads into the Atlantic ocean and three intricate channels on the east lead through Holm sound to the North sea.

Long before 1914 Scapa Flow was frequented by the Channel and Home fleets as its spacious and well-sheltered waters provided an excellent practice ground, and the admiralty planned that the main fleet should work from this base in wartime, to control the North sea. However, although net defenses against destroyer raids were under consideration, nothing had been done by the time war broke out beyond mounting a fen old guns. The strong tides and intricate navigation of the entrances were considered sufficient defense against enemy submarines.

Accordingly, on Aug. 4, 1914, the Grand fleet was at its base in Scapa Flow, which continued to be its base for the greater part of World War I. On Sept. 1, however, as a result of an unfounded report of an enemy submarine having entered the Flow the fleet put to sea, proceeding first to Loch Ewe on the west coast of Scotland and later to Lough Swilly in Northern Ireland. But these places were too far from the danger area so the fleet returned to Scapa Flow early in November. Temporary net defenses were rigged until permanent ones could be installed.

In Nov. 1914 an enemy submarine was destroyed in the outer approaches. Four years later, after the mutiny in the German fleet, one of their U-boats perished in a last desperate attempt to achieve success, but no U-boat managed to enter the Flow during World War I.

The battle cruiser force with its attendant flotillas moved to the Firth of Forth as soon as adequate antisubmarine defenses had been provided and in the latter part of the war Lord Beatty based the whole Grand fleet there.

After the surrender of the German fleet in 1918 the Allies would not agree to Britain's definitely taking over the German vessels but. in spite of Britain's protests, the most important units of what had been the High Sea fleet were interned in Scapa Flow with skeleton German crens on board, but not handed over. They were therefore only under distant observation by the British, and the result was that on June 21, 1919, the ships were scuttled by their German crews and the majority sank. They were later raised, broken up and sold as scrap.

The story of Scapa Flow during 1939–40 bears a striking resemblance to that of 1914–15. Once more the main fleet was at anchor there when war broke out. and once more it had to abandon the base in the early days because of lack of defenses. In 1914 there were none, in 1939 there were only single lines of antisubmarine nets and a few antiaircraft guns. This time. however, the evacuation was due to no false alarm but to the sinking of H.M.S. "Royal Oak" by a German submarine which had entered the Flow through the eastern entrance. where the tide rushes through at a speed of 9 to 12 knots. This disaster was quickly followed by the bombing of the depot ship, and once more the fleet had to move west, farther from the danger zone.

A new defense scheme was immediately prepared and work proceeded with feverish activity. Eighty-eight heavy antiaircraft guns, together with many light ones. and more than 100 searchlights, were mounted. Coast defense artillery was installed and three large controlled mine fields were laid in the entrances. All antisubmarine nets were doubled and additional inner lines were laid. Aerodromes had to be constructed on the most unpromising sites, and there was much anxiety over the gaps continually occurring in the line of block ships closing the eastern entrance. This problem was eventually solved by joining the islands concerned with concrete emplacements, a tremendous engineering undertaking. To the north the defense of Kirkwall as a large convoy assembly port had to be organized, with canteen and recreational facilities—all during a winter of extreme severity, with only six hours of daylight in midwinter. Accommodation difficulties were acute and many men working on the defenses had to be accommodated under canvas.

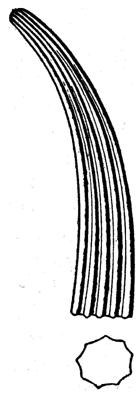
A most farseeing part of the defense was the installation of the first really efficient radar operation near Kirkwall by Sept. 1939. This proved of immense value, and an efficient balloon barrage was installed. Early in 1940 the defenses were sufficiently advanced for the fleet to return.

A successful air attack on the anchorage took place at the end of March 1940 when H.M.S. "Norfolk" was hit by a bomb. Two further air attacks were made early in April, but after this air attacks were never resumed. The efficiency of the defenses was proved by the fact that for five years the fleet's main base, although situated only 250 mi. from enemy aerodromes, was not again attacked. (R. N. BA.)

After World War II little activity took place there except for basic maintenance of the channels and anchorage. The home fleet visited it occasionally and fleet regattas were held there, but it was no longer the busy and important base it had been during World Wars I and II.

In June 1956 the admiralty announced that all naval establishments in the Orkneys would be closed in a program to streamline the naval forces to meet the conditions of nuclear warfare. On March 29, 1957, the Royal Navy ensign was hauled down for the last time and Scapa Flow was abandoned except for an oil storage depot. (X.)

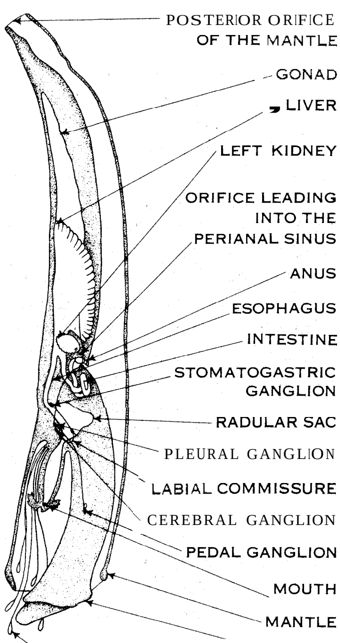
SCAPHOPODA. A group of marine invertebrate animals, popularly called elephant's-tusk or tooth-shells and constituting a class of the Mollusca (*q.v.*). There are four genera (of which *Dentalium* is the most familiar), and more than 350 species. They are the second smallest molluscan class. Their structure is quite distinct from that of other mollusks. They are bilaterally symmetrical, elongate animals, in which the right and left edges of the mantle are joined in the mid-ventral line except at the anterior and posterior ends. The visceral mass is thus enclosed in a tubular sheath open at both ends. The shell secreted by the mantle is correspondingly tubular and has anterior and posterior orifices. The head is imperfectly developed and bears numerous long filaments. The foot is cylindrical, and the animal is devoid of gills.



FROM PILSBRY, "MANUAL OF CONCHOLOGY"

FIG. 1.— TUSKLIKE SHELL OF DENTALIUM ELEPHANTINUM: BELOW. OUTLINE OF CROSS SECTION

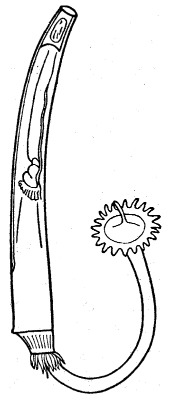
The Scaphopoda are exclusively marine. The foot is adapted for digging and burrowing into sand, in which they lie with the posterior extremity of the shell projecting from the surface. They were originally placed in the same class (Acephala) as the Lamellibranchia; but beyond the conformation of the mantle and the digging foot there is no close resemblance to that group, whereas their possession of a radula, mandible and buccal bulb and of a stomatogastric system in their nervous organization point to affinities with the Gastropoda.



FROM LANKESTER, "TREATISE ON ZOOLOGY"

FIG. 2.—DIAGRAM OF INTERNAL ANATOMY OF DENTALIUM, SHELL REMOVED

Bionomics, Evolution, Etc. —The Scaphopoda are sedentary, and in the adult stage live on the sea bottom, into the surface layers of which they burrow and usually remain with part of the shell projecting from the surface. They are carnivorous and feed upon such small animals as Foramenifera, young bivalves, etc. The majority live in fairly deep water and (*e.g.*) in the North sea are entirely absent in the littoral zone. *Dentalium peruvianum* has been found at a depth of 2,235 fathoms (U.S.S. "Albatross"). Many of the bathyal species are cosmopolitan in distribution. The earliest representatives of the class appear in the Devonian period. about 300 fossil species being known.



FROM ' VAN BENTHEM JUTTING, "TIERWELT DER NORD-UND OST-SEE"

FIG. 3.—SIPHONODENTALIUM LOFOTENSE SHOWING EXPANDED FOOT AND ANTERIOR END OF SHELL

External Form. — The shell of *Dentalium* is able to contain the whole animal and is elongate, conical and slightly curved. There are two apertures in all the Scaphopod shells, a larger anterior one from which the foot projects and a smaller posterior one. The hinder end bearing this orifice is kept clear of the sand and thus admits water for respiration and allows the excreta and feces to be discharged when the animal is buried. The mantle cavity is continuous from one end of the body to the other. The head and foot lie at the anterior end, the former above the latter. The head is cylindrical and bears two lobes beset with long filaments (captacula). These are mainly sensory but also serve to capture the small organisms on which the animal feeds. The foot is elongated and capable of considerable extension. Its expansible end is of great service in digging.

Internal Anatomy. — All Scaphopoda have a well-developed buccal mass with mandible and radula. From the esophagus the food passes into the stomach, which is little differentiated and receives the ducts of a bilobed liver and a pyloric caecum. The intestine is provided with an anal gland. The circulation and respiratory system is extremely simple. The heart is rudimentary, and there are no proper blood vessels. There are no specialized respiratory organs (gills), and the blood is oxygenated in the inner surface of the mantle. There are two kidneys in the mid-ventral region of the body, which open to the exterior, one on each side of the anus. The nervous system consists of the same pairs of ganglia, with their commissures. as in the Gastropoda. The cerebral and pleural ganglia are joined to the pedal ganglia by a long connective. These animals have only three kinds of sensory organs—the captacula, apparently tactile and olfactory; the subradular organ, probably an organ of taste; and the organs of balance (statocysts), situated in the foot. The sexes are separate. The ovary and the testis are unpaired and open into the right kidney, as in the aspidobranchiate Gastropoda.

Development.—This has been studied in *Dentalium.* The eggs are laid singly, and segmentation is unequal and irregular. A gastrula arises through invagination, as in most Mollusca. and subsequently develops into a floating trochophore larva. A veliger stage succeeds. and after five or six days the velum (girdle of cilia) atrophies and the young *Dentalium* abandons its floating life and starts to creep about on the sea bottom. Interesting experiments have been done on this form.

III (1920). (G. C. R.; W. K. E.)

SCAPOLITE, a group of rock-forming minerals, which are silicates of aluminum with calcium or sodium but containing more or less chlorine, carbonate or sulfate radicals. The name is from the Greek for "rod" and "stone" after the shape of some crystals. Scapolite also is known as wernerite.

Mineralogy.— The species of the scapolite group, ranging from marialite to meionite, must be regarded as variable isomorphous mixtures of the following five components:

Ma = $3NaAlSi_3O_8.NaCl$—chloride-marialite
MaS = $3NaAlSi_3O_8\ Na_2SO_4$—sulfate-marialite
MaC = $3NaAlSi_3O_8\ Na_2CO_3$—carbonate-marialite
MeC = $3CaAl_2Si_2O_8\ CaCO_3$—carbonate-meionite
MeS = $3CaAl_2Si_2O_8\ CaSO_4$—sulfate-meionite

It seems likely that in marialite. NaCl. etc . may be replaced to a limited extent by KOH. and in meionite, $CaCO_3$. etc., may be similarly replaced by CaF_2. The close relation which this group of minerals bears to the plagioclase feldspars is apparent in the formulas indicated above (see FELDSPAR: The *Plagioclases*). The scapolites crystallize in the tetragonal system, the crystals being prismatic hemihedral. The dominant cleavage is (100). The hardness is j–6. while the specific gravity varies with the composition. pure chloride marialite being 2.j60 and carbonate-meionite 2.772. The colour is usually white or gray. Between the end members, marialite and meionite. there are mixtures which have been given definite names. These include dipyre and mizzonite, and may. as in the case of the plagioclase feldspars, be arbitrarily fixed as follows:

marialite $Ma_{100} \rightarrow Ma_{80}$
dipyre $Ma_{80}Me_{20} \rightarrow Ma_{50}Me_{50}$
mizzonite $Ma_{50}Me_{50} \rightarrow Ma_{20}Me_{80}$
meionite $Ma_{20}Me_{80} \rightarrow Me_{100}$

The scapolites show varying resistance to acids, the meionite-rich members being most readily attacked, CO_2 being released by HCl-HF mixtures from the carbonate meionite, while marialite is only slightly attacked. None of the scapolites had been synthesized by the late 1950s. They are destroyed by fusion, the lime-rich members giving plagioclase feldspar on cooling. The commonest alteration products are calcite kaolin, white mica and zeolites. The scapolites are essentially metamorphic minerals, appearing very commonly in metamorphosed limestones.

Well-developed glassy crystals of scapolite occur in the ejected blocks of limestone of Monte Somma. Vesuvius, and large crystals occur in the apatite deposits of Bamle, southern Norway, where they arise from alteration of plagioclase feldspar in gabbro. The mode of occurrence of scapolite is referred to in detail below.

(C. E. T.)

Scapolite **Rocks.**—Scapolites have three principal types of occurrence in rocks:

1. Scapolites are common in crystalline limestones and in calc-silicate hornfelses near igneous contacts. Even marialite, the variety richest in sodium, occurs in this manner as small crystals lining cavities in ejected blocks of limestone at Vesuvius and the Eifel craters in Germany. The scapolite may occur as small inconspicuous grains or as large, well-formed crystals. Minerals found with it in rocks of this sort include calcite: diopside, grossularite garnet, tremolite, wollastonite. sphene and idocrase. In the Pyrenees, scapolite is common in limestone and calcareous shale where these rocks are in contact with diabase and peridotite.

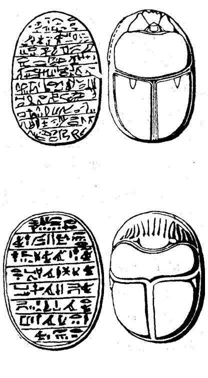
2. Scapolite is also common in beds of marble and calc-silicate granulite associated with gneiss and mica schist. The scapolite is characteristically associated with calcite, diopside. garnet, wollastonite or amphibole. Rocks of this sort have formed by metamorphism. on a regional scale: of impure limestones and calcareous shales. Examples are numerous in the Pre-Cambrian rocks of Canada and Fennoscandia (the Baltic shield) as well as in areas of crystalline schist formed in more recent geologic times. Some scapolite-bearing amphibolites and pyroxene-gneisses are probably metamorphosed igneous rocks. At Bolton, Mass.. coarsely crystalline scapolite and scapolite-quartz rocks occur as dikelike bodies, several feet thick. cutting across dolomitic marble. These masses resemble in texture the pegmatite dikes cutting the adjacent mica schists and their origin may be similar.

3. In gabbros and related rocks: plagioclase feldspars may be wholly or partly converted to scapolite. Excellent examples occur in Norway and Sweden; in the Pyrenees; in Ontario, Can.; and in the Adirondack mountains of New York. The pyroxenes in these rocks are altered in some occurrences to a uralitic hornblende. and the rock may have a spotted appearance with white. rounded patches of scapolite in a granular matrix of green hornblende. Chlorine-bearing apatite is commonly associated with such occurrences and it has been suggested that the scapolitization has been brought about by the action at depth of aqueous solutions rich in chlorides and phosphates, presumably from an igneous source.

(J. B. T.)

SCARAB (Lat. scarabaeus, connected with Gr. *capabos*), literally "a beetle," and derivatively an Egyptian symbol in the form of a beetle. The Egyptian hieroglyph  pictures a dung beetle (*Scarabaeus sacer*), which lays its egg in a ball of dung, and may be seen on sandy slopes in hot sunshine compacting the pellet by pushing it backward uphill with its hind legs and allowing it to roll down again, eventually reaching a place of deposit. Whatever the Egyptians may have understood by its actions, they compared its pellet to the globe of the sun. The beetle is common on both shores of the Mediterranean; the Egyptian name was *kheperer,* kheperi, and the sign spelled the verb *khopi(r)* meaning "become" and perhaps "create," also the substantive "phenomenon" or "marvel." The insect was sacred to the sun-god in his form *kheperi* at Heliopolis, and has been found mummified. A colossal scarabaeus of granite in the British museum probably came from the temple of Heliopolis. The scarabaeus was much used in Egyptian religions, appearing sometimes with outstretched wings or with a ram's head and horns as the vivifying soul. It is often seen in this guise on coffins of the New Kingdom and later. when it also became the custom to place in the bandages of the mummy a large stone scarab engraved with a chapter of the Book of the Dead. This chapter. the 64th, identified the object with the heart of the deceased and conjured it not to betray him in the judgment before Osiris. A winged scarab might also be laid on the breast; and later a number of scarabs were placed about the body. These are often of hard stone and of fine workmanship. Another and even more important class of Egyptian antiquities is in the form of scarabs pierced longitudinally for a swivel or for threading, and having the bases flat and engraved with designs. These were intended principally for seals. but might also be used as beads or ornaments. They are thus found, engraved or plain, strung on necklaces, and amethyst scarabs with plain bases are common articles of Middle Kingdom jewelry. But the employment of scarabs as seals is proved by the impressions found on sealed documents of the Middle and New Kingdoms; on several occasions the impressed clay seals alone have been found hardened and preserved by the fire which had destroyed the archives themselves.

The seal type of scarabaeuses is extremely abundant, and the designs engraved beneath them show endless variety. Some have inscriptions carefully executed, but frequently corrupted by illiterate copying until they became meaningless. The inscriptions are sometimes "mottoes" having reference to places, deities, etc., or containing words of good omen or friendly wishes; *e.g.,* "blemphis is mighty for ever," "Ammon protecteth," "Mūt give thee long life," "Bubastis grant a good New Year," "May thy name endure and a son be born thee." Such are of the New Kingdom or later. Names and titles of officials appear, most commonly in the Middle Kingdom.



FROM PETRIE, "SCARABS AND CYLINDFRS" (HAZELL, WATSON & VINEY)

EGYPTIAN HEART SCARABS OF THE 18TH DYNASTY

Historically the most valuable class is that which bears royal names, ranging from Senusret I of the 12th dynasty to the end of the 26th dynasty. Certain great kings are commemorated on scarabs of periods long subsequent to them. Thus Cheops (Khufu), of the 4th dynasty. appears on examples of the latest Pharaonic age, scarabs having been unknown in his time, and Tuthmosis III is found at all times after the 18th dynasty. But after the 12th dynasty the royal names are of contemporary workmanship. and the differences of style and pattern make it possible to group unknown kings with those who are known historically; the names of the Hyksos kings have been principally recovered from collections of scarab seals. Scarab-shaped seals are traceable as far back as about the 6th dynasty. They became abundant under the 12th and continued until almost the end of the native rule. As seals they took the place of the earlier cylinders and "button-seals." Considering the life history of the scarabaeus and its meaning as a hieroglyph, it may well be that the scarab impressing the clay had a symbolic significance; however that may be, the oval form was well adapted for seal stones and for the bezels of finger rings. In this situation the scarabs were often mounted with a rim of gold or silver round the edge.

Rings of stone, glass or metal. with engraved bezels of the same material, and eventually Greek gem rings, gradually displaced the scarabs.

A series of exceptionally large scarabs was engraved in the reign of Amenophis III, *c.* 1450 B.C., all being inscribed with his name together with that of Queen Tiye and her parentage. At present five varieties are known. The simplest commemorates his queen and the north and south limits of his empire; another dated in the 1st year. a great battue of mild cattle; the third. the arrival of the princess Gilukhipa of Mitanni in the 10th year; the fourth (many specimens), the number of lions slain by the king down to his 10th year; the last, the cutting of the lake of Zarukhe in the 11th year.

Egyptian scarabs were carried by trade to most of the islands and shores of the eastern Mediterranean and to Mesopotamia. The Greeks, especially in their Egyptian colony of Kaucratis, imitated them in soft paste. The finest Etruscan gems of the 6th and 5th centuries B.C. are in the form of scarabs, perhaps suggested by the Egyptian.

See EGYPT.

SCARAMOUCH, properly a buffoon. used later colloquially for a ne'er-do-well. The name was that of a stock character in the 17th-century Italian farce. *Scaramuccia* (*i.e.*, literally. "skirmish"). who. attired usually in a black Spanish dress. burlesquing a "don," was beaten by Harlequin for his boasting and cowardice.

SCARBOROUGH, a municipal borough in the Scarborough and Whitby parliamentary division of the North riding of Yorkshire, Eng., 41 mi. N.E. of York by road. Pop. (1951) 43,985. Area 6.2 sq.mi. It is the largest holiday town on the northeast coast of Yorkshire. where a hammer-shaped peninsula of high land, crowned by a ruined castle, projects eastward, separating the North and South bays. The modern town fringes both bays and extends a considerable distance inland, its southern limits being dominated by Oliver's Mount (said to have been named after Oliver Cromwell) on which the war memorial. a gigantic obelisk, stands. In the southern curve of the peninsula is the harbour, less important than formerly as a fishing centre. The origin of the modern town was the discovery in 1620 of a medicinal spring in consequence of which Scarborough became a much-frequented spa. In 1660 a native of the town. Dr. Wittie, advocated sea bathing and the town added salt-water cures to those of the inland waters and became a very popular health resort. Catering for holiday makers and other visitors is still its chief industry.

There was no direct evidence of early settlements until 1919, when excavations on the seaward side of the castle hill revealed three distinct types of early remains: a late Bronze Age village, a Roman signal station on the castle hill and three chapels. The signal station was one of a series built along the Yorkshire coast about A.D. 370. In the 10th century, Scarborough was founded (and named) as the result of an invasion by a Scandinavian. Thorgils "Skarthi" (hare-lipped). The castle was built by William le Gros. earl of Albemarle, in the 12th century. about 70 years after the town had been raided by Harald Hardrada. Edward I held court there in 1275; it was beseiged in 1312 and five times subsequently. It was damaged in the Civil War, after which it gradually fell into decay. It was in this state when George Fox. the founder of the Society of Friends (the Quakers) was imprisoned in the Charles tower of the castle for more than a year in 1665–66. He suffered great hardships before being released by Charles II. The castle was damaged again in World War I when the German fleet bombarded the town. The present ruins, occupying an area of about 19 ac.. include a lofty Norman keep and a dyke or moat on the landward side. A wall with towers also protected the castle on this side.

The first charter was given to Scarborough by Henry II in 1181 when the town was given the same liberties as those of York. In 1251 Henry III granted a charter for a new port. Authority was also given to Scarborough fishermen to land fish in Sormandy free of toll. Elizabeth I rebuilt the harbour in 1564 and George II enlarged it in 1732 when Vincent pier was built at the end of which was later added a lighthouse. East and West piers were built in 1752 and 1822 respectively. A floating dock was built in 1849 and at the beginning of the 19th century Scarborough was a leading shipbuilding centre on the east coast.

Close to the castle is the parish church of St. Mary, occupying the site of a 12th-century Cistercian monastery. It is transitional Norman and Early English, with later additions. and was much damaged during the siege of the castle in 1644. the tower and other parts having to be rebuilt. In the churchyard is the grave of Anne Bronte (d. 1849). Skirting the foot of the castle hill and serving as a sea-defense work is a marine drive linking the two bays. Old houses are still to be found in Sandside and other steep winding lanes at the back of the harbour which is enclosed by the East and West piers and divided into two basins by the Vincent pier. King Richard III house (1350) is a tall gabled building where the king is said to have stayed in 1484. Running inland south of the harbour is a deep valley crossed by bridges and laid out as Wood End gardens. The house, formerly the home of the Sitwells, is a museum devoted to natural history and including a vivarium; there is also a collection of books. mss.. etc.. connected with the Sitwell family. South of this park are the modern buildings of the spa—the ballroom, theatre, etc.—connected with the promenade above by one of the four cliff tramways. The pump room at the northern end of the present spa promenade is the direct descendant of the original wooden hut and platform which were built over the spring in 1770. There are splendid beaches with bathing and boating in both bays and boating in two of the many beautifully kept gardens and parks. On an island in the lake of Korthstead Manor gardens is the stage of an open-air theatre while the auditorium (for 7,000 spectators) rises up the facing hillside. The stage is illuminated by 40,000,000 candle power. The stewardship of the ancient manor of Northstead, which lies under the lake in the nearby Peasholm gardens. is given alternatively with that of the Chiltern Hundreds to members of parliament who have applied for the latter. There is an annual cricket festival and tennis and golf tournaments, the latter played on the championship course at Ganton. 9 mi. southwest.

Scarborough is the British centre for tunny fishing. the British Tunny club having its headquarters on the Sandside. A residential as well as a holiday town, it has also a number of small industries which include sheet metal and spring works. clothing and hosiery manufactories, motor coach body building, and market gardening. It is a quarter sessions borough and has a separate court of summary jurisdiction.

Scarborough returned two members to parliament from 1295–1885 when the number was reduced to one.

SCARLATTI, ALESSANDRO (1659–1725), Italian musical composer, was born in Sicily in 1659. He is generally said to have been a pupil of Carissimi in Rome, and he probably had some connection with northern Italy, since his early works show the influence of Stradella and Legrenzi. The production at Rome of his opera *Gli equivoci nel sembiante* (1679) gained him the protection of Queen Christina of Sweden, and he became her maestro di capella. In Feb. 1684 he became maestro di capella to the viceroy of Naples, and there he produced a long series of operas, remarkable chiefly for their fluency. In 1702 he left Naples and did not return until the Spanish domination had been superseded by that of the Austrians. In the interval he enjoyed the patronage of Ferdinand III. of Tuscany, for whose private theatre near Florence he composed operas, and of Cardinal Ottoboni, who made him his maestro di capella, and procured him a similar post at the church of S. Maria Maggiore in Rome (1703). After visiting Venice and Urbino in 1707, he took up his duties at Naples again in 1708, and remained there until 1717. It was at the Teatro Capranica in Rome that he produced some of his finest operas (Telemaco, 1718; *Marco* Attilio *Regolo,* 1719; Griselda, 1721), as well as some noble specimens of church music, including a mass for chorus and orchestra, composed in honour of St. Cecilia for Cardinal Acquaviva in 1721. His last work on a large scale appears to have been the unfinished serenata for the marriage of the prince of Stigliano (1723); he died at Naples on the 24th of October 1725.

Scarlatti's music forms the most important link between the tentative "new music" of the 17th century and the classical school of the 18th, which culminated in Mozart. His early operas (Gli *equivoci* nel sembiante [1679]; *L'Honestà negli* amori [1680]; *Pompeo* [1683], containing the well-known airs "O cessate di piagarmi" and "Toglietemi la vita ancor," and others down to about 1685) retain the older cadences in their recitatives. By 1686 he had definitely established the "Italian overture" form (second edition of *Dal* male il bene), and had abandoned the ground bass and the binary air in two stanzas in favour of the ternary or *da capo* type of air. His best operas of this period are La *Rosaura* (1690, printed by the Gesellschaft *für Musikforschung*), and *Pirro* e Demetrio (1694), in which occur the songs "Rugiadose, odorose," "Ben ti sta, traditor." *Mitridate Eupatore,* composed for Venice in 1707, contains music far in advance of anything that Scarlatti had written for Naples, both in technique and in intellectual power. The later Neapolitan operas are *L'Amor volubile* e *tiranno* (1709); La *Principessa* fedele (1712); Tigrane, 1715.

Scarlatti's claim to remembrance rests on the fact that he practically created the language of classical music. He extended the old forms, and filled them with melody unrivalled for purity and serenity, based on a far-reaching foundation of modern harmony and tonality, combined with great power of thematic development.

SCARLATTI, DOMENICO (1685–1757), eldest son of Alessandro Scarlatti, also a composer, was born at Naples on the 26th of October 1685. Presumably he studied first under his father, but he was in all probability also a pupil of Gaetano Greco. In 1704 he remodelled Pollaroli's Irene for performance at Naples. In 1709 Domenico entered the service of Marie Casimire, queen of Poland, then living in Rome, and composed several operas for her private theatre. He was Maestro di Cappella at St. Peter's from 1715 to 1719, and in the latter year came to London to direct his opera *Narciso* at the King's Theatre. In 1720 or 1721 he went to Lisbon, where he taught music to the princess Magdalena Theresia. He was at Naples again in 1725, but in 1729 went to Madrid as music master to the princess, who had married into the Spanish royal house. He is supposed to have died in 1757.

SCARLET FEVER (Scarlatina) is an acute infectious disease caused by certain types of the haemolytic streptococcus. The first clear description is credited to the German physician. Daniel Sennert (1619), although Michael Doering probably first observed the disease in Breslau, Ger. Thomas Sydenham in 1676 gave a clear differentiation of scarlet fever as follows: "The skin is marked with small, red spots, more frequent, more diffuse, and more red than in measles. These last two or three days. They then disappear, leaving the skin covered with brawny squamulae, as if powdered with meal." The disease appeared in North America about 1735 and was described by Benjamin Rush.

Although many agents have been proposed as the cause of scarlet fever, the streptococcus has been associated with the disease from the early days of bacteriology and is now regarded as the cause. E. Klein, in 1885, in a study of an outbreak of scarlet fever associated with the distribution of milk, isolated an organism which he termed the sfreptococcus scarlatinae. A. Baginsky and P. Sommerfeld, after studying a large group of cases in 1900, stated, "Many points seem to be in favor of the streptococcus being causally related to scarlatina." Ludwig Hektoen in 1903 isolated streptococci from the blood in 12% of a series of cases. C. Krumweide, N. Nicoll and Josephine Pratt in 1914 described a typical case of the disease in a laboratory worker who had accidentally aspirated a suspension of living streptococci into her mouth. In 1923 George and Gladys Dick experimentally reproduced scarlet fever in volunteers by swabbing their throats with suspensions of haemolytic streptococci.

Practically all strains of the organism capable of producing the disease belong to Lancefield's group A and are serologically distinguished from other groups of streptococci on the basis of a specific group antigen, the C substance which is carbohydrate in nature. Within group A many types of haemolytic streptococci have been identified on the basis of their M substance which is protein in nature. In an outbreak of 345 cases at Camp Borden, Ont., in 1943, W. R. Feasby and E. T. Bynoe isolated type 19 in 68%, and type 3 in 22% of the cases. Occasionally scarlet fever is caused by streptococci belonging to a group other than A.

Under suitable growth conditions the haemolytic streptococcus elaborates a number of toxic substances. some of which seem to be important factors in its disease-producing mechanism. These are the erythrogenic toxin, streptocolysin, fibrinolysin, leukocidin, and the spreading factor, an enzyme called hyaluronidase. The erythrogenic toxin causes the toxic manifestations of the disease such as the eruption. rapid pulse, fever and delirium. Injection of a small amount of this toxin into the skin to determine susceptibility to the disease is known as the Dick test. Since fibrinolysin, hyaluronidase and leukocidin are products of freshly isolated strains, they are probably important factors in the septic aspects of the disease.

Symptoms.— The onset of the disease begins from two to seven days after exposure The first symptoms are fever, sore throat, headache and, in children, vomiting. From two to three days later the rash appears as a diffusely fine erythema which begins on the neck, in the arm pits, groins and upon the chest. The face is flushed, with a ring of pallor around the lips. The throat is inflamed and red spots appear upon the palate. The tongue is coated, but the edges are deeply inflamed. After four days the coating on the tongue disappears, leaving a swollen, deeply injected surface with prominent papillae (strawberry tongue).

The eruption lasts for a week or more, and in about one-third of the cases is followed by desquamation, or peeling off of portions of the skin. The glands of the body are usually swollen, those of the neck may be tender and painful to touch. The eruption may be very faint; indeed. it may never occur in persons who have immunity to the toxin (scarlatina sine exanthemata). Such individuals represent important agents in the spread of the disease to others. The fever may last for a week or more.

Various clinical patterns. such as mild, moderately severe, severe, toxic, septic. and malignant scarlet fever have been described. Such classifications merely denote variations in the degree of severity and are a matter of opinion. The clinical manifestations may be regarded as primary and secondary. The primary infection usually occurs in the pharynx; the secondary features are the result of toxic and septic reactions. Toxic reactions include headache. fever, vomiting, rapid pulse, delirium, eruption, and disturbances in the heart and kidneys. The septic reactions result from invasion of the tissues by the haemolytic streptococcus and include cellulitis, swollen glands, infections of the ear, mastoid, sinuses, blood and brain.

Complications are frequent. The sinuses probably are always secondarily involved, frequently remain infected during convalescence and constitute an important focus in which the organism remains to cause the patient to become a carrier. Abscesses of the ear and mastoiditis are common. Infection of the glands of the neck frequently result in abscess formation. In certain instances the streptococcus enters the blood stream and is carried to various parts of the body where localized areas of infection develop. Among the late complications are nephritis (which occurs in 0.5% to 1.0% of all cases), arthritis and rheumatic fever. The urine should be tested frequently during the course of the disease.

Diagnosis is based upon the characteristic symptoms and signs. As a general rule, a child who becomes ill with fever, sore throat, headache and vomiting and who develops a fine generalized rash within 24 to 72 hr. after the onset of symptoms presumably has scarlet fever until proved otherwise. The diagnosis may be confirmed by isolation of the streptococcus from the throat or from some other region of the body, which may be the focus in so-called surgical scarlet fever. When an injection of a small amount of immune serum (0.1 c.c. to 0.3 c.c.) is made into the skin while the rash is at its height, a blanched area results at the point of injection within 18 hr. if the rash in question is caused by scarlet fever toxin. This reaction is known as the Schultz-Charlton test. Another confirmatory test consists in the reversal of the Dick test from positive to negative during the course of the disease.

Second attacks of scarlet fever are relatively rare but the recovered patient may subsequently experience other types of streptococcal infection. Treatment should include bed rest for at least ten days, adequate fluids and a diet commensurate with the patient's desire should be offered.

Penicillin, to which the streptococcus is highly sensitive, was the treatment of choice at mid-20th century. Sulfadiazine was also effective. In addition, the injection of serum, obtained from individuals recently recovered from the disease, or of refined antiserum prepared by injecting horses with the streptococcus or its toxin was beneficial in certain cases. Gamma globulin, prepared from human serum, was also effective.

Epidemiologically scarlet fever is extremely variable in its severity not only in different countries but in different outbreaks occurring in the same country. In the U.S. it is relatively mild, with a mortality rate of less than 1%. In the Balkans and in China severe forms of the disease exist. It is found principally in the temperate zones, rarely in the tropics. It is primarily a disease of childhood; half the cases occur between the ages of two and eight years. Most cases of scarlet fever occur during the winter and spring months, with an increase of incidence in September when schools open. Nonwhite people are less susceptible than white, and slightly more males than females develop the disease. Certain families are especially susceptible, but in general the communicability rate among susceptibles in a given family is between 5% and 15%.

The disease is spread chiefly by droplet infection but may be disseminated by contaminated dust particles and by contaminated hands, food, drinks and fomites. Contaminated milk may give rise to an outbreak. Surgical scarlet fever may result from infected wounds and bums. Convalescent cases and persons harbouring the organism in discharges from infected ears, sinuses and wounds may act as carriers, constituting an important factor in the spread of the disease. Control measures include isolation of the active case and the treatment of carriers, many of whom become free of streptococcus after treatment with penicillin.

In certain institutions active immunization is carried out by the injection of susceptible individuals (those with positive Dick tests) with the toxin of the streptococcus. Persons thus immunized may be protected against the toxic, but not necessarily against the septic, features of the disease. In certain instances the prophylactic administration of sulfadiazine had restricted the spread of the disease to closely exposed contacts; but this procedure sometimes resulted in the particular strain of streptococcus becoming resistant to the drug. Because of the fact that scarlet fever is only one of several related types of infections caused by the haemolytic streptococcus (designated by some as streptococcosis), quarantine and isolation procedures alone did not prove to be adequate measures in the prevention of the disease. (W. L. Bd.)

SCARPANTO: *see* KARPATHOS.

SCARRON, PAUL (1610–1660), French writer whose burlesque poems set him among the wits of the age, whose plays show a gift of lively comedy that immediately foreshadows Molière and whose major novel is a masterpiece of the picaresque genre. The son of a counselor in the *parlement* of Paris, he was baptized July 4, 1610. Becoming an abbé in 1629, he entered the service of Charles de Beaumanoir, bishop of Le Mans, in 1633. After a visit to Rome with him in 1635, Scarron returned to Le Mans and there, in 1638, was attacked by a disease which in 1640 became so much worse that the rest of his life was spent in pain and progressive deformity.

His life up to this point had been dissolute but he now found consolation in the chaste sympathy of Louis XIII's former favourite, Marie de Hautefort (the future maréchale de Schomberg), temporarily exiled at Le Mans. Returning to Paris, he was further troubled by lawsuits with his stepmother after his father's death (1643).

For some time Scarron enjoyed the patronage of the future cardinal de Retz (*q.v.*), and during the Fronde he eventually published a violent pamphlet against Mazarin (early in 1651). In 1652, almost entirely paralyzed, he married a beautiful but poor young girl, Françoise d'Aubigné, who later became world-famous as Madame de Maintenon (*q.v.*). He died in the night of Oct. 6–7, 1660.

Scarron's first book, *Recueil de quelques vers burlesques* (1643; supplemented by *Suite des oeuvres burlesques*, 1644) had some success, but his burlesque epic, *Typhon, ou la gigantomachie* (1644) was less well received. His play *Jodelet, ou le maître valet* (1645), named after the comedian Jodelet for whom the principal role was destined, inaugurated that tradition of developing the valet's role in comedy which Molière was to exploit so brilliantly.

The work for which Scarron was most famous in his own day, *Virgile travesty* (7 books, 1648–53), a parody of the *Aeneid*, seems rather deplorable to modern readers, but his *Roman comique* (*Le Romant comique*, 2 vol., 1651–57, unfinished; 3rd vol. by other hands, 1659) is recognized as of great merit and interest. The desultory story of a troop of strolling actors (in the style of the Spanish picaresque romances), it depicts manners and character in a singularly vivid way that makes it a landmark in the development of the French novel. Scarron's other works include eight more comedies (the most notable was *Don Japhet d'Arménie*, c. 1647) and a series of five tragicomical tales in the Spanish manner (1655–57). Of the latter, Molière drew on *La Précaution inutile* as a main source for *L'École des femmes* and on *Les Hypocrites* to a lesser extent for *Tartuffe*.

Scarron was at the centre of the literary activity of his time. He knew all the young men who were putting new life into the French drama—Jean Mairet, Tristan L'Hermite, Corneille and Rotrou. His own plays show a gift for realistic comedy that is the nearest thing to Molière before 1650. He was moreover a most important representative of the critical strain in French literature. While his burlesque verses parody contemporary epic, the vivid scenes of the *Roman comique* seem to be meant as an antidote to idealistic and pretentious novels. The vigour and wit of his writing reveal a talent as remarkable as the personality that, in the opinion of many who knew him, triumphed over years of pain. A critical edition of Scarron's collected works began with *Le Romant comique*, edited by H. Bénac (1951).

SCAUP DUCK, a diving duck (*Aythya marila*), so called because it feeds upon scaup (broken shellfish), especially oysters and mussels. This handsome waterfowl winters round the coasts of most of the northern hemisphere; it repairs inland in spring to breed in Iceland, Lapland, Siberia and the fur countries of North America. The scaup has considerable likeness to the pochard (*q.v.*), both in habits and appearance; but it more generally inhabits salt water and the head of the male is black, glossed with green; in North America a smaller species of more southerly distribution is also found, the lesser scaup N. *affinis*. The female scaup can be distinguished from the female pochard by her broad white face. Scaups are expert divers, powerful swimmers and rapid flyers. Because of their dietary (about 50% animal matter), they are not So prized as are the stricter vegetarian ducks.

SCAURUS, MARCUS AEMILIUS, the name of two Roman politicians. father and son.

MARCUS AEMILIUS SCAURUS (c. 162–c. 89 B.c.) was a leader of the Optimates. Having acquired wealth by discreet methods, he turned from business to public life, reaching the consulship in 115 B.C., when he defeated some Alpine tribes and gained a triumph. Chosen *princeps senatus,* he held this position until his death. Sent to check Jugurtha in 112, Scaurus was alleged in 111 to have been bribed by him. but neatly avoided trouble by getting himself selected as one of the presidents of the Mamilian commission appointed to inquire into such allegations (109). In 109, as censor, he constructed a Via Aemilia through Pisa to Dertona and repaired the Mulvian bridge. In 104. as corn commissioner at Ostia he replaced Saturninus. whose sedition in 100 he helped to suppress. Accused of extortion by Caepio in 92. he managed to get the trial postponed. He supported his friend the younger M. Livius Drusus in 91 and was accused in 90 under the Varian commission of intriguing with the Italian allies, but was acquitted. He married Caecilia Metella, later Sulla's wife, and was the father of Aemilia, later Pompey's wife. He wrote three books De vita *sua,* which Sallust may have used in his *Bellum Jugurthinum.* A conservative who moved with the times, Scaurus exercised great influence: Cicero (Pro Fonteio, 24) said that the world was almost ruled by the nod of his head; Sallust gives a less flattering portrait.

See G Bloch, "M Aemilius Scaurus," in *Mélanges* d'hzstoire ancienne (1909); E Pais, *Dalle* guerre *puniche* a Cesare *Augusto,* i, pp. 91 ff. (1918); J. Carcopino, *Histoire* romaine, ii, p 269 (1929)

MARCUS AEMILIUS SCAURUS, son of the foregoing, served as Pompey's quaestor and proquaestor in the third Mithradatic War (66–61 B.C.). Sent to Judaea and Nabataea, in return for large bribes he decided the quarrel between Hyrcanus and Aristobulus in the latter's favour in 64 (Pompey later reversed this) and allowed the king Aretas to retain Nabataea in 62. The settlement nith Aretas was commemorated on a coin which Scaurus issued as curule aedile (58), when he staged public games of unusual magnificence. Having been praetor (56) and propraetor in Sardinia (55), he was accused of provincial extortion in 54, was defended by Cicero and by Hortensius and was acquitted. Accused de *ambitu,* he nent into exile in 52. He married Mucia, formerly Pompey's wife.

See josephus, *Antiquitates,* xiv, 3–5, and *Bellum Judaicum,* 1, 7; Appian, Syriaca, 51, and Bellum *Civile,* ii, 24; Pliny, *Historia Naturalis,* xxxvi, 24; Cicero, Pro Sestio, 54; fragments of Pro *Scauro,* and many references in the Epistulae; Asconius In Scaurianam; E. A. Sydenham, Coinage of the *Roman* Republic, no. 912 (1952)

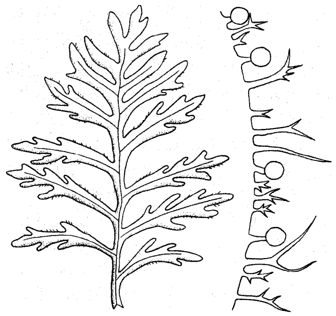
(H. H. SD.)

SCAVENGER'S DAUGHTER (corruption of Skevington's or Skeffington's daughter), an instrument of torture in use during the 16th century in England. It was invented by Sir W. Skevington, lieutenant of the Tower in the reign of Henry VIII. It consisted of a wide iron hoop which by means of screws was tightened round the victim's body until the blood was forced from the nose and ears, and sometimes from the hands and feet.

SCENTED PLANTS. The supreme joyous notes of plant life are colour and fragrance. Colour is shared with many animal groups, among them birds, fishes and butterflies, but fragrance is the openly broadcast gift of plant life. Natural animal fragrances are rare, but it is worth noting that certain floner-visiting butterflies and moths produce a flowery fragrance composed of essential oils, the same group of substances that produces redolence in flowers.

Fragrance and colour. so welcome to the aesthetic sense, have been the practical guideposts to food, consisting of pollen and nectar, for certain insects for thousands of centuries. There are many wind-pollinated and bird-pollinated flowers, none of which possess fragrance, and of the many flowers dependent on insects for pollination, only some are fragrant.

The sweet scents of flowers are nearly always associated with the showy parts of the blossom, being released by the petals or by sepals or bracts when there are no petals, but there are a few plants with small inconspicuous flowers, such as the pussy tvillow and a few others, that are fragrant. In the mint family (Labiatae) the pleasant refreshing scent comes from the green parts of the flower cluster and especially from the leaves and stems.



A LEAF OF LAVENDER (LAVANDULA MULTIFIDA) ABOUT ½ ACTUAL SIZE, WITH OUTLINE OF THE EDGE OF THE SAME LEAF. ENLARGED ABOUT 50 TIMES

Globe-tipped glandular or oil-secreting hairs are present on the edge of the leaf; thousands of smaller glandular organs are on both leaf surfaces

The attractive odours of flowers and foliage are predominantly attributable to the presence of essential oils (*q.v.*). These volatile substances are found in about one plant family out of five. An essential oil is a complex secretion product, apparently a normal part of the functioning of the plant and not an isolated end in itself. The essential oils are rather powerful substances and often appear in minute quantities and perhaps never constitute more than about 2% of the floral plant material. The violet can be taken as an example, 15 tons of the flowers being needed to produce a pound of oil. The essential oils of flowers are more complicated than those of leaves—the former may consist of a dozen components while the simplest of leaf essential oils may have but one.

Both flower and leaf fragrances are much used in the manufacture of perfumes. Outstanding flowers for this purpose are rose, tuberose, hyacinth, jasmine, acacia (Acacia farnesiana), lily-of-the-valley and ylang-ylang (an Asiatic tree, Cananga odovata); leaves (and green sepals) used in perfumery include those of geranium (*Pelargonium* species), lavender, rosemary, patchouli (*Pogostemon* cablin), clary sage and even a few species of grass (of the genus *Cymbopogon*), which produce citronella, lemon grass and palmarosa oils.

Fragrance occurs not only in flowers and leaves but also in fleshy fruits of many kinds. This odour attracts mammals which help disseminate the seeds contained within the fruit. The same scents found in fruits, or very similar ones. are found in flowers and even in leaves of unrelated species. Thus one finds apple-scented (apple mint, sweetbriar rose) among other fruit-scented leaves, and peach, lemon, raspberry and quince odours among others in flowers of plants totally unrelated to those fruits.

The particular sweetness of a flower is usually not the result of the presence of a single chemical compound, but often includes one or more unrelated compounds that closely imitate the dominating odour. The types of compounds which are constituents of the volatile oils are esters, alcohols, aldehydes, ketones, etc. The dominating ester can be accompanied by a closely related set of esters, making for overtones, and the final fragrance results from an intricate combination and proportion of volatile substances characteristic of the species.

The oil secretion of flowers takes place in the epidermal cells of the coloured part, usually on the upper side, but occasionally on both sides. as in the rose. Additional petallike parts, interior to the normal ring of petals, which make for doubling of flowers may also secrete oils, causing many double flowers to have that much more scentedness (violets, roses). Sometimes. however, doubling results in reduction of fragrance over that in single forms of the same kind of flower (lily-of-the-valley, poet's narcissus). In some leaves odours originate in hairs projecting from the surface or recessed in tiny depressions.

In the mint family (lavender, thyme, basil, marjoram, sage, etc.) the short-stalked glandular hairs uhich secrete the oil appear among several other kinds of hairs. They have rounded heads consisting of 1 to 16 or more cells. Other families, such as citrus (Rutaceae), myrtle (Myrtaceae) and laurel (Lauraceae), produce the fragrant oils in tough sacs in the interior of the leaf. These can be readily seen with a hand lens by holding a leaf up against the light.

There has been extensive neglect in maintaining fragrance in a large number of cultivated flowers. It has been customary to think of a flower as being beautiful because of its colour, size and form, and hybridists have been concentrating on this ideal. In the course of extensive hybridization workers have drawn parents from many sources, and when unscented flowers are crossed with scented ones, the progeny will include some without fragrance. As an example, the group of yellow rose species (of Asiatic origin) have no rose scent. When they are bred even with fragrant kinds, many of their progeny will be unscented One large grower of sweet peas finds that after considerable hybridizing his crimson and scarlet kinds are practically devoid of fragrance. It is extremely rare for any flower to lose its scent in nature, as this factor is so fundamental in the maintenance of the species. A fragrant plant introduced into cultivation and given conditions approaching its natural habitat should retain its fragrance.

A pronounced impetus to interest in scented plants has been given by the establishment in several large cities of fragrance gardens for the blind. The first such garden was founded in Exeter, Eng , in 1939; the first in the United States at Lima, Pa., in 1949. Fragrance gardens located in large cities—*e.g.*, one (started in 1955) at the Brooklyn Botanic garden in New York city. and another (started in 1956) at the Lighthouse for the Blind in Chicago—are, because of their locations, much visited. In these gardens the blind can "view" trees. flowers and herbs by their fragrance and texture. Braille markers are placed so that the plants can be readily identified. The gardens are so designed that the sightless can guide themselves through the paths and experience the only realities of plants that are available to them—the furry leaf, the prickly stem, the juice of crushed leaves, the softness and fragility of the petals and above all the faint bouquets and the incense of the unseen blossoms.

Among plants grown for their fragrance and texture—and therefore essential in gardens for the sightless—are those with light and elusive bouquets: wallflower, cottage pink, flowering tobacco, sweet william, alyssum, heliotrope and violet; those with characteristically heavy redolence, hyacinth, rose, tuberose, jonquil, lily-of-the-valley, lilac and mock orange. Plants with pungent piercing scent, to be tasted and bruised with the fingers are thyme, dill, laurel, sage, lemon balm, rosemary, lavender, marigold and the astringent witch hazel and mints; and those to be touched and held in the hand, plants of interesting texture as well as unique odour, the hairy leaves of many herbs (mint, lavender, geranium), the unfolding leaves of the pungent balm-of-Gilead, the apple-scented foliage of sweet brier rose and especially most needle-leaved and some broad-leaved evergreens with their aromatic resins.

SCEVE, MAURICE (1500?–1564), French poet, was born at Lyons, where his father practised law Besides follo ing his father's profession he was a painter. architect. musician and poet. He was the centre of the Lyonnese group that elaborated the theory of spiritual love, derived partly from Plato and partly from Petrarch. which was enunciated in Antoine Héroet's *Parfaicte Amye*. Scève's chief works are *Délie, objet de plus haulte vertu* (1544); two eclogues. *Arion* (1536) and *La Saulsaye* (1547); and Le *Microcosme* (1562), an encyclopaedic poem beginning with the fall of man. *Délie* (an anagram for *l'idée*) set the fashion of a series of poems addressed to a mistress real or imaginary, followed by Ronsard in *Cassandre* and by Du Bellay in *Olive*. For the Lyonnese school of which Scève was the leader *see* LABÉ, LOUISE CHARLIN PERRIN.

SCHACHT, (HORACE GREELY) HJALMAR (1877–), German financier, the "German Talleyrand" who occupied high official positions successively under monarchy, the Weimar republic and Naziism, was born at Tingleff, in Schleswig-Holstein, on Jan. 22. 1877. He received his elementary education in the United States, his higher education upon returning to Germany. He became a bank statistician, bank director and then financial administrator of occupied Belgium (until 1916). Appointed president of the *Reichsbank* after World War I, Schacht, as chief German spokesman at reparations conferences. obtained for Germany more money in loans than the country paid in reparations. When in 1930 the Young plan (*see* GERMANY), intended to fund German war indebtedness, came into force, Schacht resigned his official positions in protest. He aided Adolf Hitler's ascent and as economics minister under the Nazi regime forged, by extraordinary methods, the financial sinews of German rearmament. The Nürnberg war crimes tribunal ruled, in 1946. that this central role in German rearmament did not make Schacht a party to Nazi planning for war. After 1950 he advised, among others, the governments of Syria, Indonesia, Iran and Egypt on financial matters. (G. W. Z.)

SCHADOW, a family of German artists.

JOHANN GOTTFRIED SCHADOW (1764–1850), sculptor, was born in Berlin on May 20, 1764. He learned his craft under the court sculptor J. P. A. Tassaert and perfected it in Rome from 1785–87 in the studios of A. Trippel and A. Canova. In Nov. 1787 he returned to Berlin, and a year later succeeded Tassaert as director of the royal school of sculpture.

His first monumental work is the tombstone for Count Alexander von der Mark (1790, Berlin); his best known is the quadriga on the Brandenburger Tor (1793). Among his finest work is the group of the princesses Louise and Frederike of Prussia (1797, Berlin). He was also responsible for the statue of Frederick the Great at Stettin (1793) and the Luther memorial at Wittenberg (1821). From 1800 on Gottfried Schadow was increasingly surpassed by Christian Rauch. After 1807 he executed a series of busts for the Bavarian crown prince's "Valhalla." He was one of the chief representatives of classicism in Germany, but he largely replaced the idealistic by a rigorous realism. In the last three decades of his life his sight became affected; he then stood out primarily for his writings on the theory of art and for his genius as a draftsman. He died on Jan. 27, 1850, in Berlin. The exemplary significance of his work was not recognized during his lifetime.

See H. Mackowsky, *Johann Gottfried Schadow,* with full bibliography (1951).

RUDOLF SCHADOW (1786–1822), eldest son of Gottfried, also a sculptor, was born on July 9, 1786, in Rome and was first taught by his father in Berlin. In 1811 he went to Rome, where he came into contact with the J. F. Overbeck and P. von Cornelius circle. He became the pupil of B. Thorvaldsen and A. Canova and took over C. Rauch's studio in Rome. From 1812 he was a member of the S. Luca academy. Of his youthful, versatile work must be mentioned "The Spinner" (1816, Berlin and Budapest), the "Girl Binding on her Sandals" (1817, Munich) and the model for the monumental group in Berlin "Achilles Defends the Dying Penthesilea" (1821). Rudolf Schadow died in Rome on Jan. 31, 1822.

WILHELM VON SCHADOW-GODENHAUS (1788–1862), painter, founder of the Dusseldorf school, second son of Gottfried, was born in Berlin on Sept. 6, 1788. He was the pupil of his father and later of the painters J. F. Weitsch and W. Wach. He went to Rome in 1811 with his brother Rudolf, becoming a member in 1813 of the "Lukasbund" founded by F. Pforr and J. F. Overbeck. From 1816 to 1817 Wilhelm, together with P. von Cornelius, Overbeck and P. Veit, painted the frescoes in the Casa Bartholdi. From 1819 to 1826 he was professor at the Berlin academy and then succeeded Cornelius as director of the Diisseldorf academy. The Diisseldorf school, which he founded, soon departed completely in its special type of painting and in its anecdotal, religiously-determined realism from the artistic ideas of Overbeck and his Nazarenes. Wilhelm died in Dusseldorf on March 19, 1862. His chief works are: a portrait of Gabriele von Humboldt (1818, Berlin); "Adoration of the Shepherds" (1823, Potsdam); and the fresco of "The Wise and Foolish Virgins" (1842, Frankfurt). He educated a generation of painters, including K. F. Lessing (1808–80).

See Anton Fahne, *Die Düsseldorfer Malerschule in den Jahren 1834, 1835 and 1836,* new ed. (1937); Julius Hiibner, *Schadow und seine Schule* (1869). (J. C. JE.)

SCHAFF, PHILIP (1819–1893), U.S. theologian, church historian and pioneer in church union, was born in Chur, Switz., Jan. 1, 1819. He was educated at the *Gymnasium* of Stuttgart and at the universities of Tubingen, Halle and Berlin. At Berlin he was deeply influenced by the historian J. A. W. Neander, and became *Privatdozent* there in 1842. His brilliant scholarship early attracted favourable attention. In 1844 he became professor of church history and biblical literature in the Theological seminary of the German Reformed Church at Mercersburg, Pa. His inaugural address on *The Principle of Protestantism,* published in both German and English editions, viewed the history of the Christian Church as a divinely appointed development leading to a higher form of church life in which the values of Roman Catholicism and Protestantism would be blended in an evangelical Catholicism. This address, with its prophetic interest in church union, provoked charges of heresy, from which he was exonerated. Schaff, together with the theologian John W. Nevin (1803–86), shaped the Mercersburg theology, which resisted revivalist theology and emphasized the doctrine of the church. In 1864 Schaff began a six-year term as secretary of the New York Sabbath association, becoming a widely known Protestant leader. He became professor at Union Theological seminary, New York city, in 1870, serving until the year of his death. An inveterate traveler, he continued active leadership in Protestant affairs, especially in .the interests of church unity through the Evangelical alliance. He won a secure place as one of America's great theological scholars, both through the quality and remarkable quantity of his work as author and editor.

Outstanding among his many productions are the seven-volume *History of the Christian Church* (1858–92) and the three-volume *Bibliotheca Symbolicae Ecclesiae Universalis: The Creeds of Christendom* (1877). He edited the translation and revision of Lange's massive *Commentary* (1864–80), the great Schaff-Herzog *Encyclopaedia of Religious Knowledge* (1884) and other biblical and historical works. He participated actively in the preparation of the Revised Version of the Bible. He founded the American Society of Church History in 1888 and served as its first president. He was an originator and general editor of the American Church History series.

Schaff's last public address was a remarkable utterance on the reunion of Christendom, delivered at the World's Parliament of Religions.

He died in New York a month later. Oct. 20, 1893.

See David S. Schaff, *Life of Philip Schaff (1897).* (R. T. H.)

SCHAFFHAUSEN, the most northerly Swiss canton. lying almost wholly north of the Rhine, which, in part, separates it from the cantons of Zurich and Thurgau. On the other sides it is surrounded by Baden, portions of ahich separate the canton into three detached portions; the largest is the region near the chief town, Schaffhausen. Southward, the small lowland isolated district of Riidlingen and Buchberg was purchased in 1520, and Zurich. in 1798, ceded a slightly more extensive eastward tract around the old town of Stein. The territory contains two tiny Baden "enclaves." of which the village of Büsingen and the small tract of land surrounding it is the larger and more important. The total area of the canton is 115 sq.mi., of which the high proportion of about 95% is classed as "productive" (forests covering about 45 sq.mi., and vineyards about 1 sq mi.). The dominant land feature is the plateau of Randen—Hohe Randen summit, 2,998 ft., is on the northern boundary—sloping gently southward to the Rhine and intersected by short glens such as Klettgau (west of Schaffhausen) which carry intermittent water torrents. The Rhine 1½ mi. below the capital is a stream 370 ft. wide. interrupted by the famous falls (Laufen), which, though of small height (j6 ft.), are of considerable grandeur; they are exploited for hydroelectric power. The capital is an important railway junction. It is on the main line from Constance to Basel which traverses the canton, and also has normal railway linkages with Friedrichshafen (Lake of Constance), and Zürich (2 lines). Schleitheim (northwest) is connected to it by a light railway.

The population (57,515 in 1950) is devoted chiefly to agriculture and to vine growing; the forests are also a considerable source of revenue. The manufacture of watches and jewelry is also of considerable importance. Schaffhausen (pop. 25,971) is the only large town. Neuhausen (7,969) near the Rhine falls has an important aluminum works. There are six administrative districts containing 36 communes. The Cantonal constitution dates from 1876. The legislature *(Grossrat)* is composed of 76 members elected (by the system of absolute majority) for four years in the proportion of one to every 700 residents. The executive *(Regierungsrat)* of five members is also elected for four years by a popular vote, as are the two members of the federal *Standerat* and the two members of the federal *Nationalrat.* Since 1876, any 1,000 electors have the right of "initiative," both for legislative projects and for the revision of the Cantonal constitution. Since 1895 the "obligatory referendum" for all legislative projects and financial resolutions has prevailed. Taxation is light, for the public cantonal property, *e.g.,* forests, is the most considerable in Switzerland and the area is particularly prosperous.

The canton, admitted into the Confederation in 1501, arose from acquisitions made at various dates by the town; the chief of these were the outlying estates of the ecclesiastical foundations suppressed at the time of the Reformation. Of historical interest in this connection is the little town of Stein am Rhein (pop. 2,352) with its Benedictine monastery (1005–1526)—now restored to form a museum of antiquities—and Hohenklingen—the castle of the feudal lords of Stein—towering above it.

SCHAFFHAUSEN (Fr. SCHAFFHOUSE), the capital of the Swiss canton of that name, situated on rising ground above the right bank of the Rhine, and 31 mi. by rail W. of Constance. The population in 1950 was 25,971. Villa Scafhusun was first mentioned in 1045. About 1050 the counts founded the Benedictine monastery of All Saints, which henceforth became the centre of the town. Perhaps as early as 1190, certainly in 1208, it was an imperial free city, while the first seal dates from 1253. The powers of the abbot were gradually limited, and in 1277 the emperor Rudolf gave the town a charter of liberties. The Habsburgs held the town from 1330 to 1415, its freedom being finally purchased in 1418, while from 1411 the trade guilds ruled the town.

In 1454 the city made an alliance with six of the Swiss confederates, by whom it was received as an ally, being finally admitted a full member in 1501. The Reformation was adopted in 1524, finally in 1529. The town suffered much in the Thirty Years' War from the passage of Swedish and Bavarian troops.

Schaffhausen is a city of contrasts, medieval architecture of the true Swabian type and modern manufactures mingling curiously together. The chief ancient building in the town is the *Münster* (now Protestant) of All Saints, formerly a Benedictine monastery. It was consecrated in 1052, and is a specimen of the sternest and plainest Romanesque. Close to it is deposited the famous 15th-century bell that suggested Schiller's *Song of the Bell* and the opening of Longfellow's *Golden Legend.* The castle of Unnoth, above the town, dates in its present form from the second half of the 16th century. There are a number of factories in the town. At Neuhausen, a suburb, are aluminum works.

SCHAFFNER, JAKOB (1875–1944), Swiss novelist and story writer, was born at Basel on Nov. 14, 1875, was educated in a charity school, and worked as a shoemaker until his 30th year. He won the Schiller prize for the autobiographical novel *Johannes* (1922), followed later by *Die Jünglingzeit des Johannes Schattenhold* (1930), and *Eine deutsche Wanderschaft* (1933). He was a master of the short story, as may be seen in *Die Goldene Fratze* (1912), *Verhangnisse* (1927), and *Föhnwind* (1928). He also published an unconventional and lively *History of Switzerland* (1915), and a collection of poems (Der *Kreislauf,* 1927). His style was marked by freshness, geniality, imagination and humour, often recalling Gottfried Keller (*q.v.*). In later years he wrote favourably of national socialism, though not uncritically *(Volk zu Schiff,* 1936). He died in Strasbourg, France, in Sept. 1944.

SCHAPPE. A term denoting a particular type of yarn spun from schappe waste silk from which the natural gum, termed sericin, has not been entirely removed or discharged either by boiling-off by the English system of degumming raw silk, or by the alternative continental system of fermentation, known as schapping. The waste silk so treated is soft and lustrous, with the fine silk filaments free from each other, yet retaining some of their natural gum. Schappe silk varies from a white to a bright yellow tone according to the amount of gum still present.

Schappe also denotes a particular type of silk fabric sold under that trade name and produced from two-ply schappe spun silk yarn which, before bleaching, has a somewhat yellow tone owing to the presence of the natural gum. A schappe silk fabric is a fairly strong and firm texture of medium weight, woven on the principle of the plain calico weave, but having a slightly fine ribbed effect somewhat similar to that of a fine poplin (*q.v.*) texture but with the ribs or cords much less pronounced. This fine ribbed effect is developed by employing warp yarn of finer denier or counts than that of the weft, and also by inserting a greater number of warp threads than picks of weft, per inch, in the fabric. Thus, one example of schappe silk fabric contains 104 warp threads of 52's/2, and 72 picks of 40's/2 weft, per inch.

These denominations of yarn counts are equivalent to 52's and 40's counts of single cotton yarn respectively. They are produced by folding and doubling together two silk threads each of 50 denier silk (approximately) to produce the 52's/2 silk thread, and two threads each of 65 denier silk (approximately) to produce the 40's/2 silk thread. (H. N.)

SCHARNHORST, GERHARD JOHANN DAVID VON (1755–1813), Prussian general, was born at Bordenau near Hanover, on Nov. 12, 1755. In 1778 he received a commission in the Hanoverian service. He designed, and in part published, a *Handbuch fur Offiziere in den anwendbaren Theilen der Kriegswissenschaften.* He also published in 1792 his *Militiirische Taschenbuch fur den Gebrauch im Felde.* His first campaign was that of 1793 in the Netherlands, in which he served under the duke of York with distinction. In 1794 he took part in the defence of Menin and commemorated the escape of the garrison in his *Vertheidigung der Stadt Menin* (Hanover, 1803), which, next to his paper *Die Ursachen des Glücks der Franzosen in Revolutionskrieg,* is his best-known work. Shortly after this he was promoted to major and employed on the staff of the Hanoverian contingent.

In 1801 he entered the service of the king of Prussia, who gave him a patent of nobility, and the rank of lieutenant-colonel. Scharnhorst was employed at the War Academy of Berlin, where he had Karl von Clausewitz (*q.v.*) as one of his pupils, and he was the founder of the Berlin Military society. In the mobilizations and precautionary measures of 1804 and 1805, and in the war of 1806, Scharnhorst was chief of the general staff (lieutenant-quartermaster) of the duke of Brunswick, and received a slight wound at Auerstedt. He attached himself to Gebhard von Blucher in the last stages of the disastrous campaign, was taken prisoner with him at the capitulation of Ratkau, and, being shortly exchanged, bore a prominent part in the leading of L'Estocq's Prussian corps which served with the Russians. For his services at Eylau, he received the order *pour le mérite.*

Educated in the traditions of the Seven Years' War, Scharnhorst had by degrees divested his mind of antiquated forms of war, and come to realize that a national army and a policy of fighting decisive battles alone responded to the political and strategical situation created by the French Revolution. The steps by which he converted the professional long-service army of Prussia, wrecked at Jena, into the national army, based on universal service, were slow and laboured. He was promoted major-general a few days after the peace of Tilsit, and placed as the head of a reform commission, to which were appointed Gneisenau, Grolman, Boyen and others. Stein himself became a member of the commission and secured for Scharnhorst free access to the king by causing him to be appointed aide-de-camp-general. But Napoleon's suspicions were quickly aroused, and the king had repeatedly to suspend or to cancel the reforms recommended. By direct application to Napoleon, Scharnhorst evaded the decree of Sept. 26, 1810, commanding all foreigners to leave the Prussian service forthwith, but when in 1811–12 Prussia was forced into an alliance with France against Russia and dispatched an auxiliary army to serve under Napoleon's orders, Scharnhorst left Berlin on unlimited leave of absence. In retirement he wrote his *Über die Wirkung des Feuergewehrs* (1813). But the retreat from Moscow at last sounded the call to arms for the new national army of Prussia. Scharnhorst was recalled to headquarters, and was made chief of staff to Bliicher. The first battle, Liitzen or Gross-Gorschen, was a defeat, but a very different defeat from those which Napoleon had hitherto been accustomed to inflict. Scharnhorst was wounded, and died from the effects of his wound on June 8, at Prague, where he had been sent to negotiate with Schwarzenberg and Radetzky for the armed intervention of Austria.

SCHAUMBURG-LIPPE, a former component part of the German empire, from 1922 a free state of the German republic, from 1933 a *Land* of the Third Reich, and from 1945 a district *(Kreis)* of the Lower Saxony *Land* of Germany. It consists of the western half of the old countship of Schaumburg. Area, 131 sq.mi.; pop. (1939) 54,168; (1950) 85,443. Its northern extremity is occupied by a lake named the Steinhuder Meer. The southern part is hilly (Wesergebirge), but the remainder consists of a fertile plain. Besides agriculture the inhabitants practise yarn-spinning and linen-weaving, and the coal mines of the Bückeburg, on the southeastern border, are very productive. The great bulk of the population is Lutheran. The capital is Buckeburg, and Stadthagen is the only other important town.

SCHECHTER, SOLOMON (1847–1915), U.S. Jewish theologian and Talmudist, president (1902–15) of the Jewish Theological Seminary of America and for many years the leading spokesman for Conservative Judaism in the U.S. Born on Dec. 7, 1847, in Fokshan, Rum., he pursued advanced studies in Vienna and Berlin and was one of the first scholars to study the Talmudic literature of Judaism in the light of modern critical research. Schechter's *Some Aspects of Rabbinic Theology,* published while he was still a lecturer in rabbinics at Cambridge university, and other writings led to a sympathetic reappraisal of the teachings of the Pharisees. In 1902 Schechter went to New York city to serve as president of the Jewish Theological Seminary of America, which he developed into a foremost institution for Jewish research and for the training of rabbis and teachers. The United Synagogue of America, which he founded in 1913, had grown, by the early 1960s, from an original membership of 23 Conservative congregations to about 650 congregations.

In 1896 Schechter discovered the Genizah (archive) in the old synagogue in Cairo, containing over 90,000 manuscripts, many of them of great significance for biblical and rabbinic research. Among them was a copy of the original Hebrew text of Ecclesiasticus (*q.v.*), one of the important books in the Apocrypha. Schechter's identification of another manuscript as relating to an ancient Jewish sect in pre-Christian times was confirmed almost 50 years later, by the discovery among the Dead Sea scrolls of the Manual of Discipline, which is very similar in content to what Schechter identified as a Zadokite document. He died on Nov. 19, 1915, in New York city. (M. AT.)

SCHEELE, CARL WILHELM (1742–1786), Swedish chemist, who anticipated by several years Joseph Priestley's discovery of oxygen, was born at Stralsund, the capital of Pomerania, which then belonged to Sweden, on Dec. 9, 1742. He studied the elements of chemistry during his apprenticeship to an apothecary in Goteborg, Swed., with whom he stayed for eight years. In 1765 he took a similar position in Malmo and again in Stockholm in 1768. He read chemistry avidly and experimented constantly during his free time. In 1770 he settled at Uppsala, where he made the acquaintance of Torbern O. Bergman (*q.v.*). A friendship sprang up between the two, and it has been said that Scheele was Bergman's greatest discovery. In 1775, the year in which he was elected into the Stockholm Academy of Sciences, he left Stockholm for Koping, a small place on Lake Malaren, where he became proprietor of a pharmacy. Frederick the Great tried to induce him to accept a chair of chemistry at Berlin, but this flattering offer, as well as one from England, was refused.

He found time for an extraordinary amount of original research, and every year he published two or three papers, most of which contained some discovery or observation of importance. It is said that his unremitting work, especially at night, and in a poorly ventilated laboratory, together with his handling of the most toxic materials and also with the habit of tasting and smelling materials indiscriminately, induced illness which brought about his death in Koping at the age of 43 on May 21, 1786.

Scheele's record as a discoverer of new substances is probably unequaled, in spite of his poverty and lack of ordinary laboratory conveniences. His work touched every province of the chemistry of his time. His first paper was published in 1770 in conjunction with his friend Anders Retzius; it dealt with the isolation of tartaric acid from cream of tartar (see TARTARIC ACID). Analysis of manganese dioxide in 1774 led him to the discovery of chlorine and baryta, to the description of various salts of manganese itself, including the manganates and permanganates, and to the explanation of its action in colouring and decolourizing glass. He showed that iron, copper and mercury exhibit various degrees of oxidation. In 1775 he investigated arsenic acid and its reactions, discovering arsine and Scheele's green (copper arsenite). (See ARSENIC.) Papers published in 1776 were concerned with quartz, alum and clay and with the analysis of calculus vesicae (bladder stones), from which for the first time he obtained uric acid.

Scheele's only book, Air and Fire, was published in 1777 but was written some years before. One of the chief observations recorded in it is that the atmosphere is composed of two gases—one which supports combustion and the other which prevents it. The former, "fire-air," or oxygen, he prepared from acid of nitre, from saltpetre, from black oxide of manganese, from oxide of mercury and other substances, and there is little doubt but that he obtained the gas two years before Priestley. Owing to the delay in the publication of his results he is rarely given credit for this discovery. In all, he described ten methods of preparing oxygen. He showed that it played an essential part in the life processes of aquatic animals and plants. as well as those that live in air. Scheele remained in favour of the phlogiston theory (see CHEMISTRY: History of *Chemistry*) until his death; he apparently thought that hydrogen, which he had obtained by the action of certain acids on iron or zinc, was pure phlogiston.

In 1777 Scheele prepared sulfureted hydrogen by a variety of methods and noted the chemical action of light on silver compounds and other substances. (See SULFUR.) In 1778 he proposed a new method of making calomel and powder of algaroth, and he got molybdic acid from mineral molybdaena *nitens,* which he carefully distinguished from ordinary molybdena (graphite or black lead of commerce). In the following year he showed that graphite consists essentially of carbon, and he published a record of estimations of the proportions of oxygen in the atmosphere, which he had carried on daily during the whole of 1778—three years before Henry Cavendish (*q.v.*). In 1780 he proved that the acidity of sour milk is due to what was afterward called lactic acid, and by boiling milk sugar with nitric acid he obtained mucic acid.

His next discovery, in 1781, was in connection with the mineral scheelite (calcium tungstate), from which he obtained tungstic acid. In 1782 he published some experiments on the formation of ether and in 1783 examined the properties of glycerine, which he had discovered seven years before. About the same time, in the course of some work on Prussian blue, he described the composition, properties and compounds of prussic (hydrocyanic) acid and even ascertained its smell and taste. quite unaware of its poisonous character. In the last years of his life he returned to the vegetable acids. He isolated and investigated citric, malic, oxalic and gallic acids.

BIBLIOGRAPHY.—O. F. Zekert, *C. W. Scheele, Sein Leben und seine Werken* (1931–33); E. Thorpe, *Essays in Historical Chemistry* (1923); W. Tilden, *Famous Chemists* (1921); G. Bugge (ed.), *Buch der grossen Chemiker* (1929–30).

SCHEELITE, a mineral consisting of calcium tungstate, is an important ore of tungsten. Before the development of high-speed tool steels around 1900, the ore had little commercial value. Since then, however, consumption has increased greatly as a source of tungsten for use in the manufacture of alloy steel. Tungsten is also used as a pure metal, in carbides and as filaments in electric lights and electronic equipment, Synthetic sheelite has the same uses. Named after C. W Scheele, a Swedish chemist, it is the mineral in which he discovered tungstic acid. Scheelite is commonly found in heavy, compact and granular masses, but tetragonal, dipyramidal crystals occasionally occur. It is white, yellow, brown or green and has a vitreous to adamantine lustre. The hardness is 4.5 to 5 and the specific gravity 5.9 to 6.1. Most scheelite fluoresces, the colour ranging from blue-white or white to yellow, depending upon the amount of molybdenum present. The formula is $CaWO_4$. $CaO = 19.4\%$; $WO_3 = 80.6\%$. The high density, high lustre and fluorescence are distinguishing characteristics.

Scheelite is found in contact metasomatic deposits, high-temperature veins and in granite pegmatites. Associated minerals include cassiterite, fluorite, topaz, apatite, wolframite and certain sulfides. In the United States scheelite has been mined in quantity in North Carolina, California, Nevada and in smaller amounts in a number of other western states. It also occurs in Cornwall and Cumberland, Eng.; and in Bolivia, New South Wales. New Zealand and Tasmania. See also TUNGSTEN. (A. F. HR.)

SCHEEMAKERS, PETER (1691–1781), a sculptor who worked almost entirely in the classical tradition and may be considered one of the founders of modern sculpture in England, was born at Antwerp in 1691. He studied in the workshop of his father and a orked in Rome. Copenhagen and, about 1720, in London, first with P. D. Plumier and later with F. Bird. After another stay in Rome and at Antwerp he came back to London about 1735 and worked there until about 1770. He spent the last years of his life in Antwerp, a-here he died in 1781.

Scheemakers is responsible for a great deal of work in England, and monuments signed by him are to be found in churches all over the country. His most famous work is the monument to Shakespeare, which was designed by William Kent and erected in Westminster abbey in 1741. (J. A. DR.)

SCHEER, REINHARD (1863–1928), German admiral, who commanded the High Seas fleet at the battle of Jutland (*q.v.*), was born at Obernkirchen, Hesse-Nassau, on Sept. 30. 1863. After serving in the Cameroons and east Africa, in 1903 he was given command of the 1st torpedo division. In 1910 he became chief of staff of the High Seas fleet under Henning von Holtzendorff and in 1913 became commander of a battle squadron. At the outbreak of World War I he was stationed at Kiel with his squadron. Scheer introduced many important improvements in submarine tactics. In Jan. 1916 he was placed in command of the German High Seas fleet, which he led at the battle of Jutland. On July 2, 1918, he succeeded Von Holtzendorff as chief of the admiralty staff. On Nov. 14, 1918, he was placed on the retired list and took up residence in Marktredwitz, where he died on Nov. 26, 1928. Scheer's account of the battle of Jutland appears in his book *Deutschlands* Hochseeflotte *im Weltkriege* (1919).

SCHEFFEL, JOSEPH VIKTOR VON (1826–1886), German poet and novelist, was born at Karlsruhe on Feb. 16, 1826. He studied at Munich, Heidelberg and Berlin, entered the state judicial service, and for four years (1848–52) held an official position at Sackingen. There he wrote his poem Der Trompeter von Sackingen (1853), a romantic and humorous tale which immediately gained extraordinary popularity. It has reached more than 250 editions. In 1854 he quitted the government service and settled at Heidelberg, with the intention of joining the teaching staff of the university. His studies were interrupted by eye disease, and he went to live on the Lake of Constance. There he elaborated the plan of his famous historical romance *Ekkehard* (1857), the scene of which is laid in the monastery of St. Gall in the 10th century; (Eng. trans. by S. Delffs, 1872). The first ideas for this work he got from the *Monumenta* Germaniae. In 1901 *Ekkehard* had reached the 179th edition. Scheffel next returned to

Heidelberg, and published *Gaudeamus, Lieder aus dem Engeren und Weiteren* (1868), a collection of joyous and humorous songs; the matter for which is taken partly from German legends, partly from historical subjects. Scheffel was custodian (1857–59) of the library of Prince Egon von Furstenberg at Donaueschingen; he eventually settled at Karlsruhe, where he died on April 9, 1886.

Scheffel's *Gesammelte Werke* have been published in 6 vol. (1907). *See* also A. Ruhemann, *Joseph Victor von Scheffel* (1887).

SCHEFFER, ARY (1795–1858), French painter of German parentage, was born at Dordrecht, Holland, Feb. 12, 1795; his father was court painter at Amsterdam. He studied in Paris with Pierre Narcisse Guerin and, like his great fellow student Delacroix, painted the defense of Missolonghi. His "Gretchen Spinning" (1831) was the subject of a chapter by Heinrich Heine, and from this time Scheffer devoted himself to romantic narrative and religious paintings. His "Paolo and Francesca" (Wallace collection, London) and "Mount of Olives" (Dordrecht) show his mature style; his early free and bold handling gave place to a manner dependent on precise contour and smooth modeling. Scheffer's best known work in the Louvre is "St. Augustine and St. Monica." He died June 15, 1858, at Argenteuil. He enjoyed immense popularity in his lifetime and was drawing master to the children of Louis Philippe. (D. C. T. T.; X.)

SCHEIDEMANN, PHILIPP (1865–1939), German politician, was born at Kassel on July 26, 1865, the son of a carpenter and upholsterer. He became a printer and later a journalist and editor of Socialist papers. In 1903 he was elected to the *Reichstag* as Social Democratic deputy for Solingen. He became secretary of the Social Democratic party in 1911, and led the party in active support for the war in 1914, a policy he continued to follow as leader of the party in the *Reichstag* after the Independent Socialists, who opposed the war, had broken away, although he demanded a "peace without annexation or indemnities." On Oct. 3, 1918, after some hesitation, he entered Prince Max of Baden's government as secretary of state. He became convinced of the need for the kaiser's abdication; and it was he who, on Nov. 9, proclaimed the republic outside the *Reichstag* building. He joined the provisional government as finance minister, and, together with Friedrich Ebert and Gustav Noske, was active in suppressing attempts at revolution by the Independent Socialists and Communists. He was elected to the national assembly in Jan. 1919, and in February became head of the government, a post he held until June when he resigned because he and some of his colleagues refused to sign the treaty of Versailles. From 1920 to 192j he was *Oberbiirgermeister* of Kassel. He sat in the *Reichstag* from 1920 to 1933 as a deputy for Hesse-Nassau. In 1933 he emigrated to Czechoslovakia and then to Denmark, where he died on Nov. 29, 1939.

Scheidemann published two volumes of recollections, *Der Zusammenbruch* (1921) and *Memoirs of a Social Democrat* (1929). (J. B. Jl.)

SCHELDT (Fr. ESCAUT; Flem. SCHELDE), a river rising near Catelet in France, entering Belgium near Bleharies in Hainaut, and flowing past Tournai, Oudenarde, Ghent and Termonde till it reaches Antwerp. Some distance below Antwerp, in front of the island Beveland, where the river divides into two channels, respectively north and south of the island, both banks belong to Holland. Of the two channels named, the southern, De Hout, which reaches the sea at Flushing, is used for ocean commerce. The Scheldt has a length of 270 mi., of which, by a skillful arrangement of locks, not less than 248 mi. are navigable. Its breadth is 1.640 ft. at Antwerp and 5,905 ft. where it leaves Belgium. The principal tributaries are the Lys, the Dender and the Rupel. By the treaty of Munster in 1648 the Dutch obtained the right to close the Scheldt to navigation, and they clung tenaciously to it for over two centuries. In 1839 on the final dissolution of the kingdom of the Netherlands, Holland gave definite form to this right by fixing the toll, and by obtaining the assent of the powers to the arrangement which fettered the trade of Antwerp. In 1863 after long negotiations Belgium bought up this right—each of the powers interested in the trade contributing its quota—and the navigation of the Scheldt was then declared free.

SCHELER, MAX (1874–1928), German philosopher, born in Munich on Aug. 22, 1874, began teaching philosophy at Jena in 1902, when he had already come under the influence of Edmund Husserl (*q.v.*). From 1907 to 1910 he taught at Munich. Finally, after some work for the German foreign office in Geneva (1917) and at The Hague (1918), he was in 1919 appointed professor of philosophy at Cologne. He died at Frankfurt am Main on May 19, 1928.

Throughout his work Scheler's method is phenomenological, that is to say, he tries to discover what is essentially involved in mental attitudes and their objects; he differs from Husserl in his readiness to accord an independently real status to the objects of such attitudes.

In ethics Scheler's main work is *Der Formalismus in der Ethik und die materiale Wertethik* (Halle, 1913–16), in which, after severely criticizing the formalistic ethics of Kant, he pleads for a teleological ethics of value not unlike British ideal utilitarianism. Values are ranged in an objective order of higher and lower, which are presented a priori through our feelings: Scheler builds largely on Pascal's "order" or "logic of the heart." In philosophical psychology Scheler's most interesting work is *Wesen und Formen der Sympathie* (1923; Eng. trans. by P. Heath as *The Nature of Sympathy*,.1954). In the work entitled *Vom Ewigen im Menschen* (1921) Scheler gives a penetrating analysis of the religious consciousness (called by him the "religious act") and of the kind of object to which it is essentially directed; *i.e.,* an object self-sufficient, all-performing, holy, etc. The theistic flavour of this work yields to a more pantheistic attitude in the later *Die Stellung des Menschen im Kosmos* (1927, 1928). Scheler's principal contribution to philosophical sociology is *Die Wissensformen und die Gesellschaft* (1926), where he passes criticism and attempts to improve on Marxist and Comtist accounts of the relation of ideas and beliefs to social structure and development.

See the collected *Werke* (1954–); also the special issue of *Philosophy and Phenomenological Research,* vol. 2, *no.* 3 (1942), devoted to Scheler. (J. N. F.)

SCHELLING, FRIEDRICH WILHELM JOSEPH VON (1775–1854), German philosopher who, following a departure from Fichte's ethical philosophy, formulated a system of metaphysics based on the philosophy of nature. He was born on Jan. 2j, 1775, at Leonberg, a small town of Württemberg. He was educated at the cloister school of Bebenhausen, near Tubingen, where his father, an able orientalist, was chaplain and professor. In 1790 he entered the theological seminary at Tubingen. Among his (elder) contemporaries were Hegel and Holderlin. He shared in the revolutionary sentiments common among his fellow students. In 1792 he graduated. Meanwhile he was a close student of Kant, Fichte and Spinoza, more especially of Fichte. Schelling had no sooner grasped the leading ideas of Fichte's amended form of the critical philosophy than he put together his impressions of it in his *Uber die Moglichkeit einer Philosophie überhaupt* (Tubingen, 1795). The more elaborate work, *Vom Ich als Prinzip der Philosophie, oder iiber das Unbedingte im menschlichen Wissen* (Tübingen, 1795), while remaining within the limits of the Fichtean idealism, exhibits a tendency to give the Fichtean method a more objective application and to amalgamate with it Spinoza's more realistic view.

After two years as tutor to two youths of noble family, Schelling was called as extraordinary professor of philosophy to Jena, the centre of the poets and philosophers of the Romantic sch'ool, in midsummer 1798. He had already contributed articles and reviews to F. I. Niethammer's *Philosophisches Journal* (Neustrelitz, 1795–96; Jena. 1797–98), to which his *Philosophische Briefe über Dogmatismus und Kritizismus* (a critique of the ultimate issues of the Kantian system) and his *Neue Deduction des Naturrechts* (the composition of which, in 1795, to some extent anticipated Fichte's *Grundlage des Naturrechts)* had been sent. His studies of physical science bore rapid fruit in his *Ideen zu einer Philosophie der Natur* (Leipzig, 1797) and in the treatise *Von der Weltseele* (Hamburg, 1798); and these were followed by his *Erster Entwurf eines Systems der Naturphilosophie* (Jena and Leipzig, 1799), by the *Einleitung zu dem Entwurf eines Systems der Naturphilosophie* (Jena and Leipzig, 1799), by the *System des transzendentalen*

Idealismus (Tiibingen, 1800), by the *Darstellung meines Systems der Philosophie* (in the *Zeitschrift fur spekulative Physik,* ii, Jena, 1801), by *Bruno, oder uber das natiirliche und gottliche Prinzip der Dinge* (Berlin, 1802) and by the *Vorlesungen iiber die Methode des akademischen Studiums* (Tiibingen, 1803). The philosophical renown of Jena was at its height during Schelling's years of residence there (1798–1803). His intellectual sympathies, moreover, united him closely with some of the most active literary tendencies of the time. With Goethe he was on excellent terms, but he was repelled by Schiller's less speculative philosophy. In Schelling, essentially a self-conscious genius, eager and rash, yet with undeniable power, the Romanticists hailed a personality of the true Romantic type. With August Wilhelm von Schlegel and his wife Caroline, herself the embodiment of the Romantic spirit, Schelling's relations were intimate, and a marriage between Schelling and Caroline's young daughter by a previous marriage, Auguste Bohmer, was perhaps contemplated by both. Auguste's death in 1800 drew Schelling and Caroline together. Schlegel divorced his wife, and in June 1803 she married Schelling. This marriage marks the end of Schelling's life at Jena.

From 1803 to 1806 Schelling was professor at the new university of Wiirzburg. In 1804 he published the essay *Philosophie und Religion* (Tiibingen). During this period, however, he not only broke with Fichte and with Hegel but also embroiled himself with his colleagues and with the government. In 1806, then, he moved to Munich, where he was to remain until 1841. There Schelling enjoyed ease and leisure, thanks to state appointments: he was made an associate of the academy of sciences, secretary of the academy of arts and then secretary of the academy of sciences. These appointments, moreover, did not prevent his lecturing for a short time at Stuttgart and annually over a seven-year period at Erlangen (1820–26). Finally, in 1827, he became professor at Munich. Caroline's death (1809) was followed by his marriage in 1812 to one of her closest friends, Pauline Gotter, in whom he found a faithful companion.

The early years of Schelling's Munich period were marked by several publications. The aphorisms on *Naturphilosophie* in the *Jahrbiicher der Medicin als Wissenschaft* (Tubingen, 1806–08) are for the most part extracts from lectures delivered at Wiirzburg; but the treatise *Uber das Verhältniss der bildenden Kiinste zu der Natur* (Munich, 1807; Eng. trans. by A. Johnson, *The Philosophy of Art,* London, 1845) and the *Philosophische Untersuchungen iiber das Wesen der menschlichen Freiheit* (first published in *Philosophische Schriften,* Landshut, 1809; Eng. trans. by J. Gutmann, Of *Human Freedom,* Chicago, 1936) represent interesting developments in his thought. Subsequently, however, his literary activity came gradually to a standstill. The *Denkmal der Schrift von den'gottlichen Dingen des Herrn F. H. Jacobi* (Tiibingen, 1812) was called forth by the incident of Jacobi's book. The tract *Uber die Gottheiten von Samothrake* (Stuttgart and Tübingen, 181j) was ostensibly part of a great work, *Die Weltalter,* which was frequently announced as ready for publication but which was never finished *(cf.* the fragment trans. by F. de Wolfe Bolman, *The Ages of the World,* New York, 1942).

The dominance of Hegel in the German schools appears to have silenced Schelling. It was only in 1834, after the death of Hegel, that, in a preface to a translation of a work by Cousin, he expressed in writing the antagonism in which he stood to the Hegelian and to his own earlier conceptions of philosophy. The antagonism certainly was not new: it was evidenced in his Erlangen lectures of 1822 on the history of philosophy *(Siimmtliche Werke,* x, 124–125); and Schelling had already begun the treatment of mythology and religion which in his view constituted the true positive complement to the negative of logical or speculative philosophy. The writings of D. F. Strauss. L. Feuerbach and other members of the Hegelian left having alarmed the religious element, Frederick William IV invited Schelling to Berlin in 1841 in the hope that he would lecture at the university and counteract the Hegelians. But the latter were too strongly entrenched, and in 1845 Schelling ceased to lecture. No authentic information as to the nature of the new positive philosophy was made generally available till after Schelling's death, which took place on Aug. 20, 1854, at Ragaz. His Berlin lectures were then printed in the first four volumes (1856–58) of the 2nd section of his collected works, setting forth his "philosophy of mythology" and his "philosophy of revelation."

Philosophy.—Schelling indicated the turning points of his philosophical career as follows: (1) the transition from Fichte's method to the more objective conception of nature — the advance, in other words, to *Naturphilosophie;* (2) the definite formulation, in the *Identitätsphilosophie,* of that which implicitly, as Schelling claims, was involved in the idea of *Naturphilosophie,* that is to say the thought of the identical, indifferent, absolute substratum of both nature and spirit; **(3)** the opposition of negative and positive philosophy, an opposition which is the theme of the Berlin lectures, though its germs may be traced back to 1804.

Schelling's philosophy of nature, though first conceived as a supplement to Fichte's mainly ethical position, soon developed into an entirely different outlook. Whereas Fichte's *Wissenschaftslehre* made the knowing and willing subject the centre of existence altogether, Schelling emphasized the self-existence of the objective world. Nature is not to be understood only from the perspective of empirical observation and scientific theory; it is rather a reality of its own which speculative or intellectual intuition has to interpret. Such an interpretation discloses that nature is a universal organism endowed with a world soul, as Plato taught. In nature as in the human ego the same original tendencies operate: the one finite and material, the other infinite and ideal.

In his system of transcendental idealism (1800) Schelling tried to unite his philosophy of nature with epistemology and ethics, the objective and the subjective aspect of speculation. He subordinated nature to mind, but he denied that morality is the zenith of subjective activity (as Kant and Fichte had assumed). Mind reaches its consummation rather in the creative act of the artist. On the one hand, the genius works as nature does, but consciously and intentionally; on the other, nature works as the genius, but unconsciously and unintentionally. This magnificent solution of the basic problem of reconciling nature and mind to one another corresponded best to the Romantic spirit of the epoch.

But impressive and fascinating as the solution was, it could not fully satisfy the thinking intellect just because it was too Romantic and not rational enough. In 1801 Hegel began his academic career in Jena, and it was probably under the influence of Hegel's more rational thinking that Schelling hastily conceived of a new scheme in which he concentrated upon the original identity of the opposites, the finite and the infinite, the objective and the subjective, the real and the ideal. This identical ground cannot be comprehended in itself, but can be known indirectly by the relative balance of the antagonistic polarity in both the objective and the subjective sphere open to our experience. This scheme was not carried out, but remained a sketch.

The objective tendency, which was dominant in Schelling, soon led him to a Platonic conception of the subjective sphere: he renewed the time-honoured doctrine of the ideas. But the ultimate unity out of which the opposites arise could not be expounded unless the realm of the ideas was understood as being the origin of the finite self and the finite world. Schelling took a new step in 1804 when he wrote his essay *Philosophie und Religion* in order to explain this most hidden relation. Like Coleridge, he longed "to know metaphysically the Spirit of God." The ideas have their absolute unity in that spirit. But since it is the nature of the ideas to be both necessary (objective) and free (subjective), they are able to fall away from their origin and centre. This defection is possible because of the absolute freedom of the ideas; but for the same reason it cannot be accounted for. Schelling here renews the doctrine of Origen. Slowly he is going back to Christian speculation. Through debasing themselves the ideas transform themselves into the phenomenal world in which we live. The original unity of ideas and God can be restored only through the return of man to his creator.

These half-religious, half-speculative conceptions were further modified under the influence of the Catholic Romantic F. X. von Baader (who in turn was inspired by Jacob Boehme) in Schelling's work on human freedom (1809). Schelling now carried the ground of the apostasy of the ideas back into the nature of God himself: in God there is an original abyss, a kind of absolute and non-rational will, which is the ultimate source of the independence and contingency of the finite world, or of its existence in contrast to its divine essence. But the final and definitive form of Schelling's speculation was gained only in the Berlin lectures.

According to these lectures, God cannot be known by any speculative effort whatsoever ("negative philosophy"): God has to be experienced. This position Schelling calls metaphysical empiricism. The experience of the absolute ground of all things is impossible apart from the self-manifestation of God. We learn his nature from the history of myth and revelation. which is at the same time God's own spiritual history ("positive philosophy"), culminating in the Incarnation and Resurrection of Christ. These lectures, which, as has been said, had no success when Schelling delivered them, were to arouse the interest of existentialists in the 20th century.

SCHENECTADY, a city of New York, U.S., is located 16 mi. N.W. of Albany on the Mohawk river, the seat of Schenectady county. It was established in 1661 when the Mohawk Indians sold the title to the wide, flat river plain immediately above the falls of the river to Arent van Curler and his associates. The site was only 14 mi. by easy portage from the seaport of Albany; the place name is of Indian origin. In 1690 the little village was virtually extinguished by the Schenectady massacre, occurring when a war party of French and Indians walked by the snowmen which the overconfident citizens had erected as sentries. About 1700 there was an influx of English settlers. Schenectady was chartered as a borough in 1765 and as a city in 1798. Its location on the portage between the Hudson and Mohawk rivers assured it of a prosperous business in the transshipment of goods. In the period after the American Revolution a vast tide of New England immigrants moved into the Mohawk valley, and Schenectady, being the transfer point, was further stimulated by new business. With the opening of the Erie canal in 1825, however, the canal boats carried their cargoes directly into Albany, and Schenectady suffered a decline. Recovery began with the manufacture of brooms and brushes during the next decade.

New forms of transportation and industry came to Schenectady when the Mohawk and Hudson railroad began to operate in 1831. The railroad was a forerunner of the New York Central, and the consequent demand for locomotives led to the establishment of the Schenectady Locomotive works in 1848. This firm, which has built tanks as well as steam and diesel locomotives, became the American Locomotive company (later Alco Products, Inc.) in 1901.

In 1886 the Edison Machine works were moved to Schenectady and in 1892 mergers created the General Electric company, with its main administrative offices there and later establishing plants manufacturing gas turbines, motor generators and electronic equipment, and experimental laboratories which provided research facilities for many famous scientists, including Charles Steinmetz, Willis Whitney, William David Coolidge and Irving Langmuir. The Atomic Energy commission's Knolls Atomic Power laboratory, established to provide facilities for the investigation of uses of nuclear power, and its nearby establishment at West Milton, Saratoga county, are operated by the company.

Manufactures include varnish, mica products, wire and cable equipment and athletic and sporting goods.

Union college. a private liberal arts college for men, established in 1795. is in Schenectady; the college and its affiliated professional schools in Albany form Union university.

The city has a council-manager form of government, in effect since 1936.

The population of Schenectady in 1960 was 81.682 (for comparative population figures see table in NEW YORK: Population). It is a part of the Albany-Schenectady-Troy standard metropolitan statistical area (see ALBANY). (H. S. PR.)

SCHERER, EDMOND HENRI ADOLPHE (1815–1889), French theologian, critic and politician. was born in Paris on April 8, 1815. After a course of legal studies he spent several years in theological study at Strasbourg, where he graduated doctor in theology in 1843, and was ordained. He held a theological chair in a Protestant seminary at Geneva for a brief period, but developed liberal opinions on religious matters, and eventually settled in Paris as a journalist.

He at once attracted attention by brilliant critical work, at first chiefly on great foreign writers, contributed to the Revue des deux *mondes*. He was elected municipal councillor at Versailles in 1870. deputy to the National Assembly for the department of Seine-et-Oise in 1871 and senator in 1875. He supported the Republican party.

Scherer was for many years one of the ablest contributors to Le Temps. He was a frequent visitor to England, and took a lively interest in English politics and literature. He died at Versailles on March 16. 1889.

Among his works are: *Etudes critiques sur la littdrature contemporaine,* 10 vol. (1863–89), *Études critiques de littdrature* (1876), *Dzderot* (1880), *La Démocratie et la France* (1883), *Etudes sur la littérature au XVIII^e siècle* (1891).

SCHERZO (Italian for "a joke"); in music, a quick movement evolved from the minuet and used in the position thereof in the sonata forms (*q.v.*). The term is also used as a mere character name. Haydn first used it and its adverb scherzando, for the middle movement of an early sonata in C sharp minor, and afterwards in place of the minuet in the set of six quartets known sometimes as "Gli Scherzi," and sometimes as the "Russian quartets" (op. 33). He never used the term again, though his later minuets are often in a very rapid tempo and sometimes on alarger scale than any of the earlier scherzos of Beethoven. Haydn wished to see the minuet made more worthy of its position in large sonata works; but he did not live to appreciate (though he might possibly have heard) the fully-developed scherzos of his pupil, Beethoven.

The formal essence of the minuet and trio lies in their combination of melodic forms with an exact da *capo* of the minuet after the trio. No other movement in the sonata has leisure for so purely decorative a symmetry. Beethoven's typical scherzos purposely exaggerate this quality. He does not follow Mozart's example of minuets with two trios, for the style of his mature scherzos is so continuous that a second trio would give it an elaborate rondo character unlike that of a dance-movement. But after Beethoven's scherzo has run through the stages of scherzo, trio and scherzo da capo, it goes through the same trio and da capo again; and then tries to do so a third time, as if it could not find a way out, so that it has to be abruptly stopped. Modern players and listeners are impatient of these grotesque repetitions; but the art-form is true to its own nature, and we should be the better for leisure to understand it. Apart from the wonderful little A flat bagatelle—No. 7 of the set written at the age of 15 and published (presumably with extensive revision) as op. 33—Beethoven first used the double repetition in his 4th symphony (with a shortening of the last da capo); and his last example is in the C sharp minor quartet (op. 131).

The scherzo of the 9th symphony is so enormous that its main body differs from a complete first movement of a sonata only in its uniformity of texture and its incessant onrush, which not even the startling measured pauses and the changes from 4-bar to 3-bar

Outline of SCHERZO of Beethoven's 7th Symphony.

(The phrasing given here is the most natural; but any phrasing whatever will prove that the themes change their accents in the course of the movement.)

rhythm can really interrupt. Beethoven directs as many repetitions of its subsections as possible, and his coda consists of an attempt to begin the trio again, dramatically cut short. The scherzo of the C minor symphony was originally meant to go twice round; and a certain pair of superfluous bars, which caused controversy for 30 years after Beethoven's death, were due simply to traces of the difference between the *prima volta* and *seconda volta* being left in the score.

Beethoven does not use the title of scherzo unless the music is humorous. Thus in the sonata in E flat (op. 31, No. 3) it is applied to a sonata-form lively movement which is technically the slow movement. while the following slow minuet is the dance-movement. The second movement of the F major quartet (op. 59, No. 1) is a unique example of scherzo-style in a most elaborate sonata-form.

Perhaps this gigantic movement may have been the inspiring source of the Mendelssohnian scherzo, one of the most distinct new types of movement since Beethoven, and quite independent of the notion of an alternating trio. The scherzos in Mendelssohn's *Midsummer Night's Dream* music, in the Scotch symphony and in the string quartets in E minor and E flat major (op. 44, Nos. 2 and 3) are splendid examples. Even Berlioz shows their influence in the "Queen Mab" scherzo of his *Roméo et Juliette.*

Of Brahms' scherzos there are several distinct types, ranging from a quiet allegretto and trio in melodic forms to the sonata-form *Presto giocoso* of the 4th symphony, which within seven minutes accomplishes the most powerful scherzo since Beethoven. Every degree of lyric beauty and dramatic passion is comprised in the various movements that Brahms puts into the position of scherzo in his sonata works.

Chopin produced a new type of independent scherzo; obviously inspired by Beethoven, but with a slightly macabre tendency of his own, except in the very diffuse and light 4th scherzo. The majority of classical scherzos are in a quick triple time with only one countable beat to a bar; and this custom is the last vestige of the derivation of the scherzo from the minuet.

Of modern scherzos there is nothing specific to be said; the term still applies to lively intermediate movements in cyclic instrumental works, and is otherwise a mere character-name.

(D. F. T.)

SCHEVENINGEN (Schāv'nĭng-ẹn), fishing port and watering-place, the Netherlands, on the North sea, province of South Holland, about 2 mi. N. of The Hague, of which it is a part. It is situated in the dunes at the extremity of the woods which separate it from The Hague proper. The development of Scheveningen as a seaside resort dates from modem times, but the fishing village is of ancient origin and once stood farther seaward. To prevent coast erosion a stone wall was built along the sea front in 1896–1900, and below this lies the fine sandy beach stretching for miles on either side. The first bathing establishment there dates from 1818, and was also the first in the Netherlands. There is a large harbour. During the winter of 1942–43 the Germans destroyed large sections of Scheveningen. Pop. (1947) 13,781.

SCHIAPARELLI, GIOVANNI VIRGINIO (1835–1910), Italian astronomer and senator of the kingdom of Italy, was born March 14, 1835, at Savigliano, Piedmont. He entered Turin university in 1850, and graduated in 1854. Two years later he went to Berlin to study astronomy under Encke, and in 1859 was appointed assistant observer at Pulkova, a post he resigned in 1860 for a similar one at Brera, Milan. On the death of Francesco Carlini in 1862, Schiaparelli succeeded to the directorship, which he held until 1900. He died at Milan July 4, 1910.

Schiaparelli possessed exceptional powers as an observer—his first discovery was of the asteroid Hesperia in 1861—and his considerable mathematical ability is shown in his papers. In 1866 he showed the connection between meteor streams and cometary orbits, giving, in particular, the identity of the orbits of the Perseids and Comet III., 1862, and of the Leonids and Comet I., 1866. These discoveries were subsequently amplified in his Le *Stelle cadenti* (1873) and in his *Norme per le osservazioni delle-stelle cadenti dei bolidi* (1896). He observed double stars, and the results of his measures are published in 2 vols., the first containing those made between 1875–85, and the second those between

1886–1900. He made extensive studies of Mercury, Venus and Mars. In 1877 he observed on Mars the peculiar markings, which he called *canali,* the nature and origin of which is still controversial. *(See* MARS.) From his observations of Mercury and Venus he concluded that these planets rotated on their axes in the same time as they revolved about the sun. On his retirement he turned to the astronomy of the Hebrews and Babylonians; his earlier results are given in his *L' Astronomia nell' antico Testamento* (1903), which has been translated into English and German, whilst later ones are to be found in various journals, the last being in *Scientia* (1908).

SCHICHAU, FERDINAND (1814–1896), German engineer and shipbuilder. was born at Elbing, the son of a smith and ironworker, on Jan. 30, 1814. He started works of his own at Elbing in 1834, and was soon employing some 8,000 men. He began by making steam engines, hydraulic presses and industrial machinery, and, by concerning himself with canal work and river or coast improvement, came to the designing and construction of dredgers, in which he was the pioneer (1841), and finally to the building of ships.

His "Borussia," in 1855, was the first screw-vessel constructed in Germany. Schichau began to specialize in building torpedo-boats and destroyers (at first for the Russian Government) at an early date. From 1873 he had the co-operation of Carl H. Ziese, who married his daughter. Ziese introduced compound engines into the first vessels built by Schichau for the German navy, the gunboats "Habicht" and "Möwe," launched in 1879, and also designed in 1881 the first triple-expansion machinery constructed on the continent, supplying these engines to the torpedo-boats built by Schichau for the German navy in 1884, the first of some 160 that by the year 1909 were provided by the Elbing yards. Torpedo-boats were also built for China, Austria and Italy. Meanwhile Elbing had become insufficient for the increased output demanded. In 1889 Schichau established a floating dock and repairing shops at Pillau, and soon afterwards, by arrangement with the Government, started a large yard at Danzig. He died on Jan. 23, 1896.

SCHICKELE, RENÉ (1883–1940), Alsatian writer, was born in Oberehnheim, Alsace, Aug. 4, 1883. He was educated in Zabern and Strasburg, and afterward lived in Paris and Berlin. His first works were poetic; they include the volumes *Sommernachte* (1902), *Der Ritt urns Leben* (1906), *Mein Herz mein Land* (1915). His first prose work was *Der Fremde* (1907). He also wrote dramas. which were of less importance; but *Hans im Schnakenloch* (1916) was performed in both Paris and Berlin during World War I. Schickele was essentially an Alsatian in both style and thought. He blended in his work, which unites warmth with strength in a remarkable degree, the essence of the Germanic and the Latin cultures. His life was largely a revolt against the crushing of Xlsace's individuality by either German or French. Before World War I he was in revolt against Germany. During the war, against which he protested strongly, he lived in Switzerland; but later he made his home in Germany, in the Black Forest. The most notable novels of his maturity were *Wir wollen nicht sterben* (1922), *Maria Capponi* (192j, English trans. 1928), and *Blick auf die Vogesen* (1927). He died Jan. 31, 1940, in Nice, France.

SCHIEDAM, a town and river port of the Netherlands, in the province oi South Holland, on the Schie, near its confluence with the Maas, and a junction station 3 mi. W. of Rotterdam by rail. Pop. (1957 est.) 77,383 (mun.). The public buildings of interest are the Groote or Janskerk, the old Roman Catholic church, the synagogue, the town hall, the exchange, the concert-hall and a ruined castle. Schiedam is famous as the seat of a great gin manufacture, which, carried on in more than three hundred distilleries, gives employment besides to malt-factories, cooperages and cork-cutting establishments, and supplies sufficient yeast to form an important article of export.

SCHIFF, JACOB HENRY (1847–1920), American banker and philanthropist, was born at Frankfurt-on-Main, Germany. Jan. 10, 1847. He studied in the schools of Frankfurt and for a time worked in a bank. In 186; he went to New York city and organized the brokerage firm of Budge. Schiff and Co. In 1875 he was taken into the firm of Kuhn, Loeb and Co., and, on Loeb's retirement in 1885, took his place. In 1897 his house assisted E. H. Harriman in reorganizing the Union Pacific Railway, and in 1901 aided him in his struggle with James J. Hill and J. P. Morgan for the control of the Northern Pacific Railway. In his later years he gave much personal attention to charities. He was a founder and president of the Montefiore Home for chronic invalids, New York city. In 1903 he presented a Semitic museum building to Harvard university. He died in New York city Sept. 25, 1920.

SCHILL, FERDINAND BAPTISTA VON (1776–1809), Prussian soldier, was born in Saxony. Entering the Prussian cavalry at the age of twelve, he was still a subaltern of dragoons when he was wounded at the battle of Auerstadt. At Kolberg he played a very prominent part in the celebrated siege of 1807. After the peace of Tilsit he was given the command of a hussar regiment. In 1809 the political situation in Europe appeared to Schill to favour an attempt to liberate his country from the French domination. Leading out his regiment from Berlin under pretext of manoeuvres, he raised the standard of revolt, and marched for the Elbe. At Dodendorf (May 5, 1809) he had a brush with the Magdeburg garrison, but was soon driven northwards, where he hoped to find British support. With little more than his original force Schill was surrounded by 5,000 Danish and Dutch troops in the neighbourhood of Wismar. He escaped by hard fighting (action of Damgarten, May 24) to Stralsund. The Danes and Dutch soon hemmed him in, and by sheer numbers overwhelmed the defenders (May 31). Schill himself was killed.

See L. K. C. von Liliencron, *Schilliana* (a vols., 1810); Haken, *Ferdinand von Schill* (Leipzig, 1824); Barsch, *Ferdinand von Schill's Zug und Tod* (Leipzig, 1860), and F. *von Schill, ein Charakterbild* (Potsdam, 1860); Francke, *Aus Stralsunds Franzosenzeit* (1890).

SCHILLER, JOHANN CHRISTOPH FRIEDRICH VON (1759–1805), German poet, dramatist and philosopher, was born at Marbach on the Neckar, on Nov. 10, 1759. His father, Johann Kaspar (1723–96), was an army-surgeon, and the vicissitudes of his profession entailed a constant change of residence; but at Lorch and at Ludwigsburg, where the family was settled for longer periods, the child was able to receive a regular education. In 1773 the duke Karl Eugen of Wurttemberg claimed young Schiller as a pupil of his military school at the "Solitude" near Ludwigsburg, where he was obliged to devote himself to law. On the removal of the school in 1775 to Stuttgart, he was, however, allowed to take up medicine. The strict military discipline of the school lay heavily on Schiller, and intensified the spirit of rebellion, which burst out in the young poet's first tragedy. In 1776 some specimens of Schiller's lyric poetry had appeared in a magazine, and in 1777–78 he completed his drama, *Die Rauber.* In 1780 he left the academy qualified to practise as a surgeon, and was at once appointed by the duke as doctor to a regiment garrisoned in Stuttgart. His discontent found vent in the passionate lyrics of this period. Meanwhile *Die Rauber,* which Schiller had been obliged to publish at his own expense, appeared in 1781 and made an impression on his contemporaries hardly less deep than Goethe's *Götz von Berlichingen,* eight years before. The strength of this remarkable tragedy lay, in spite of its inflated tone and exaggerated characterization, in the sure dramatic instinct with which it is constructed and the directness with which it gives voice to the most pregnant ideas of the time. In this respect, Schiller's *Rauber* is one of the most vital German dramas of the 18th century. In January 1782 it was performed in the Court and National Theatre of Mannheim, Schiller himself having stolen secretly away from Stuttgart in order to be present. The success encouraged him to begin a new tragedy, *Die Verschwörung des Fiesco zu Genua,* and he edited a lyric *Anthologie auf das Jahr 1782,* to which he was himself the chief contributor. A second surreptitious visit to Mannheim came, however, to the ears of the duke; he had Schiller put under a fortnight's arrest, and forbade him to write any more "comedies" or to hold intercourse with any one outside Württemberg. Schiller resolved on flight, and took advantage of some court festivities in Sept. 1782 to put his plan into execution. He hoped in the first instance for material support from the theatre in

Mannheim and its intendant, W. H. von Dalberg; but nothing but rebuffs and disappointments were in store for him. He did not even feel secure against extradition in Mannheim, and after several weeks spent mainly in the village of Oggersheim, where his third drama, *Kabale und Liebe,* was in great part written, he found a refuge at Bauerbach in Thuringia, in the house of Frau von Wolzogen, the mother of one of his former schoolmates. Here *Kabale und Liebe* was finished and *Don Carlos* begun. In July 1783 he received a definite appointment for a year as "theatre poet" in Mannheim, and here both *Fiesco* and *Knbale und Liebe* were performed in 1784. In the latter play Schiller's powers as a realistic portrayer of people and conditions familiar to him are seen to best advantage. Although Schiller failed to win an established position in Mannheim, he added to his literary reputation by the publication of the beginning of *Don Carlos* (in blank verse) in his journal, *Die rheinische Thalia* (1785). He had also the opportunity of reading the first act of the new tragedy before the duke of Weimar at Darmstadt in Dec. 1784.

In April 1785 Schiller accepted the Invitation of four unknown friends—C. G. Korner, L. F. Huber, and their *fiancées* Minna and Dora Stock—with whom he had corresponded, to pay a visit to Leipzig. He spent a happy summer mainly at Gohlis, near Leipzig, his jubilant mood being reflected in the *Ode an die Freude;* and in September of the same year he followed his new friend Korner to Dresden. As Korner's guest in Dresden and at Loschwitz on the Elbe, Schiller completed *Don Carlos,* wrote the dramatic tale, *Der Verbrecher aus verlorener Ehre* (1786), and the unfinished novel, *Dcr Geisterseher* (1789). Körner's interest in philosophy also induced Schiller to turn his attention to such studies, the first results of which he published in the *Philosophische Briefe* (1786). *Don Carlos,* meanwhile, appeared in 1787, and added to Schiller's reputation as a poet. It was unfortunate, however, that in seeking a model for this higher type of tragedy he turned rather to the classic theatre of France than to the English drama.

A new chapter in Schiller's life opened with his visit to Weimar in July 1787. Goethe was then in Italy, and the duke of Weimar was absent; but the poet was kindly received by Herder and Wieland. Not very long afterwards he made the acquaintance at Rudolstadt of the family von Lengefeld, the younger daughter of which subsequently became his wife. Meanwhile the preparation for *Don Carlos* had interested Schiller in history, and in 1788 he published the first volume of his chief historical work, *Geschichte des Abfalls der vereinigten Niederlande von der spanischen Regierung.* It obtained for him, on the recommendation of Goethe, a professorship in the university of Jena, and in Nov. 1789 he delivered his inaugural lecture. Schiller's other historical writings comprise a *Sammlung historischer Memoires* and *Geschichte des dreissigjahrigen Krieges* (1791–93). The latter is written for a wider public than his first history, but the narrative is dramatic and vivid and the portraiture is sympathetic.

Before, however, this work was finished, Schiller had turned from history to philosophy. A year after his marriage he had been stricken down by severe illness, from the effects of which he was never completely to recover; financial cares followed, which were relieved unexpectedly by the generosity of the hereditary prince of Holstein-Augustenburg. who conferred upon him a pension of 1,000 talers a year for three years. Schiller devoted the leisure of these years to the study of philosophy. In the summer of 1790 he had lectured in Jena on the aesthetics of tragedy, and in the following year he studied carefully Kant's *Kritik der Urteilskraft,* which had just appeared and appealed powerfully to Schiller's mind. The influence of these studies is to be seen in several essays, as well as in his correspondence with his friend Korner. Here Schiller arrives at his definition of beauty, as "Freiheit in der Erscheinung," which marked the beginning of a new stage in the history of German aesthetic theory. *Uber Anmut und Würde,* published in 1793, was a further contribution to the elucidation and widening of Kant's theories; and in the eloquent *Briefe über die ästhetische Erziehung des Menschen* (179j), Schiller proceeded to apply his new standpoint to the problems of social and individual life. These remarkable letters were published in *Die Horen,* a new journal, founded in 1794, which was the occasion for his gaining the friendship of Goethe. An immediate outcome of the new friendship was Schiller's admirable treatise, *Uber naive und sentimentalische Dichtung* (1795–96). Here Schiller applied his aesthetic theories to that branch of art which was most peculiarly his own, the art of poetry; it is an attempt to classify literature in accordance with an a priori philosophic theory of "ancient" and "modern," "classic" and "romantic," "naïve" and "sentimental"; and it sprang from the need Schiller himself felt of justifying his own "sentimental" and "modern" genius beside the "naive" and "classic" tranquillity of Goethe's.

For Schiller himself this was the bridge that led back from philosophy to poetry. Under Goethe's stimulus he won fresh laurels in that domain of philosophical lyric ahich he had opened with *Die Künstler;* and in *Das Ideal und das Leben, Die Macht des Gesanges, Würde der Frauen,* and *Der Spaziergang,* he produced masterpieces of reflective poetry. These poems appeared in the *Musenalmanach,* a new publication which Schiller began in 1796. Here were also published the *Xenien* (1797), a collection of distichs by Goethe and Schiller, in which the two friends avenged themselves on their critics. The *Almanach* of the following year was even more noteworthy, for it contained a number of Schiller's most popular ballads, *Der Ring des Polykrates, Der Handschuh, Ritter Toggenburg, Der Taucher, Die Kraniclze des Ibykus* and *Der Gang nach dem Eisenhammer; Der Kampf mit dem Drachen* following in 1799, and *Das Lied von der Glocke* in 1800. As a ballad poet, Schiller's popularity has been hardly less great than as a dramatist; his bold and simple outlines, his terse dramatic characterization appealed directly to the popular mind. The supreme achievement of the last period of Schiller's life was the series of master dramas which he gave to the world between 1799 and 1804. Just as *Don Carlos* had led him to the study of Dutch history, so now his occupation with the history of the Thirty Tears' War supplied him with the theme of his trilogy of *Wallenstein* (1798–99). The plan of *Wallenstein* was of long standing, and it was only towards the end, when Schiller realized the impossibility of saying all he had to say uithin five acts, that he decided to divide it into three parts, a descriptive prologue, *Wallensteins Lager,* and the two dramas *Dze Piccolomini* and *Wallensteins Tod.* Without entirely breaking with the classic method he had adopted in *Don Carlos, Wallenstein* shows how much Schiller's art had benefited by his study of Greek tragedy; the fatalism of his hero is a masterly application of an antique motive to a modern theme. The success of *Wallenstein,* with which Schiller passed at once into the front rank of European dramatists, was so encouraging that the poet resolved to devote himself uith redoubled ardour to dramatic poetry. Towards the end of 1799 he took up his residence permanently in Weimar, not only to be near his friend, but also that he might have the advantage of visiting regularly the theatre of which Goethe was director.

Wallenstein was followed in 1800 by *Maria Stuart,* a tragedy, which, in spite of its great popularity in and outside of Germany, is not one of his best. Finer in every way is the "romantic tragedy," *Die Jungfrau von Orleans* (1801) The resplendent mediaeval colouring of the subject, the heroic character of Joan of Arc, gave Schiller an admirable opportunity for the display of his rich imagination and rhetorical gifts; and by an ingenious alteration of the historical tradition he uas able to make the drama a vehicle for his own moral idealism. Between this drama and its successor, *Die Braut von Messina,* Schiller translated and adapted to his classic ideals Shakespeare's *Macbeth* (1801) and Gozzi's *Turandot* (1802). With *Die Braut von Messina* (1803) he experimented with a tragedy on purely Greek lines, this drama being as close an approximation to ancient tragedy as its mediaeval and Christian *milieu* permitted. The introduction of a chorus detracted from the value of the tragedy for the theatre, but it appealed particularly to Schiller's genius. In the poet's last completed drama, *Wilhelm Tell* (1804), he once more, as in *Wallenstein,* chose a historical subject involving wide issues. *Wilhelm Tell* is the drama of the Swiss people; its subject is less the personal fate of its hero than the struggle of a nation to free itself from tyranny. It was an attempt to win for the German drama a new field, to widen the domain of dramatic poetry. Besides writing *Tell*, Schiller had found time in 1803 and 1804 to translate two French comedies by Picard, and to prepare a German version of Racine's *Phèdre*; and in the last months of his life he began a new tragedy, *Demetrius*, which gave promise of being another step forward in his poetic achievement. But *Demetrius* remains a fragment of hardly two acts.

Schiller died at Weimar on May 9, 1805. His last years were darkened by constant ill-health; and indeed it is marvellous that he was able to achieve so much. A visit to Leipzig in 1801, and to Berlin in 1804, were the chief outward events of his later years. He was ennobled in 1802. Schiller's art, with its broad, clear lines, its unambiguous moral issues, and its enthusiastic optimism, has appealed with peculiar force to the German people, especially in periods of political despondency. But since the re-establishment of the German empire in 1871 there has been a certain waning of his popularity, the Germans of to-day realizing that Goethe more fully represents the aspirations of the nation. In point of fact, Schiller's genius lacks that universality which characterizes Goethe's; as a dramatist, a philosopher, an historian, and a lyric poet, he was the exponent of ideas which belong essentially to the Europe of the period before the French revolution.

BIBLIOGRAPHY.—The first edition of Schiller's *Samtliche Werke* appeared in 1812–15 in 12 vols. Of the countless subsequent editions mention need only be made here of the *Historisch-kritische Ausgabe* by K. Goedeke (15 vols., 1867-76). Good modern editions are the *Säkularausgabe*, edited by E. von der Hellen and others (17 vols., 1904–05) and that edited by O. Güntter and G. Witkowsky (20 vols., 1904–11). A critical edition of Schiller's *Briefe* was published by F. Jonas (7 vols. 1892–96).

The chief biographies of Schiller are the following: T. Carlyle, *Life of Friedrich Schiller* (1824, German translation with an introduction by Goethe, 1830); E. Palleske, *Schillers Leben und Werke* (1858–59, 14th ed. 1894, Eng. trans 1885); H. Viehoff, *Schillers Leben* (1875, new ed. 1888); J. Sime, *Schiller* (1882); R. Weltrich, *F. Schiller* (vol. i., 1890); O. Brahm, *Schiller* (vols. i. ii., 1888–92); J. Minor, *Schiller, sein Leben und seine Werke* (vols. i.–ii., 1890); O. Harnack, *Schiller* (1898, 2nd ed. 1905); C. Thomas, *Life and Works of Schiller* (1901); K. Berger, *Schiller* (1905–09: 9th ed., 1917); E. Kühnemann, *Schiller* (1905: Eng. transl., 1912). *See* further: V. Basch. *La Poétique de Schiller* (1902); L. Bellermann, *Schillers Dramen: Beiträge zu ihrem Verständnis* (2 vols., 1888–91; 4th ed., 1908); A. Köster. *Schiller als Dramaturg* (1891); K. Fischer, *Schiller-Schriften* (1891–92); J. W. Braun, *Schiller im Urteile seiner Zeitgenossen* (3 vols., 1882); J. G. Robertson, *Schiller after a Century* (1905); Schiller's *Gespräche*, ed. by J. Petersen (1911); M. Hecker and J. Petersen, *Schillers Persönlichkeit*, 3 vols. (1907–09); A. Ludwig, *Schiller und Die Deutsche Nachwelt* (1909). (J. G. R.)

SCHILTBERGER, JOHANN or **HANS** (1381–1440?), German traveller and writer, was born of a noble family in 1381, probably at Hollern near Lohof, half way between Munich and Freising. In 1394 he joined the suite of Lienhart Richartinger, and went off to fight under Sigismund, king of Hungary (afterwards emperor), against the Turks on the Hungarian frontier. At the battle of Nicopolis (Sept. 28, 1396) he was wounded and taken prisoner; Sultan Bayezid I. *(Ilderim)* then took him into his service as a runner (1396–1402). During this time he accompanied Ottoman troops to Asia Minor and Egypt. On Bayezid's overthrow at Angora (July 20, 1402), Schiltberger passed into the service of Bayezid's conqueror Timur: he now visited Samarkand, Armenia and Georgia. After Timur's death (Feb. 17, 1405) his German runner became a slave of various successors. He next accompanied Chekre, a Tatar prince living in Abu Bekr's horde, on an excursion to Siberia, of which name Schiltberger gives us the first clear mention in west European literature. He followed Chekre in his attack on the Old Bulgaria of the middle Volga. Wanderings in south-east Russia; visits to Sarai, the old capital of the Kipchak Khanate on the lower Volga and to Azov or Tana, still a trading centre for Venetian and Genoese merchants; travels in the Crimea, Circassia, Abkhasia and Mingrelia; and finally escape (from the neighbourhood of Batum) followed; he lay hid at Constantinople for a time, then returned to his Bavarian home (1427) by way of Kilia, Akkerman, Lemberg, Cracow, Breslau and Meissen. After his return he became a chamberlain of Duke Albert III.

Schiltberger's *Reisebuch* contains not only a record of his own experiences and a sketch of various chapters of contemporary Eastern history, but also an account of countries and their manners and customs. First come the lands "this side" of Danube, where he had travelled; next follow those between the Danube and the sea, which had now fallen under the Turk; then the Ottoman dominions in Asia; last come the regions from Trebizond to Russia and from Egypt to India. Schiltberger is perhaps the first writer of Western Christendom to give the true burial place of Mohammed at Medina; he contributed to fix Prester John, at the close of the middle ages, in Abyssinia.

Four mss. of the *Reisebuch* exist: (1) at Donaueschingen in the Fürstenberg library, No. 481; (2) at Heidelberg, university library, 216; (3) at Nuremberg, city library, 34; (4) at St. Gall, monast. library, 628 (all of 15th century, the last fragmentary). The work was first edited at Augsburg, *c.* 1460; four other editions appeared in the 15th century, and six in the 16th; in the 19th the best were K. F. Neumann's (Munich, 1859), P. Bruun's (Odessa, 1866, with Russian commentary, in the *Records of the Imperial University of New Russia*, vol. i.), and V. Langmantel's (Tübingen, 1885); "Hans Schiltbergers Reisebuch," in the 172nd volume of the *Bibliothek des literärischen Vereins in Stuttgart*. *See* also the English (Hakluyt Society) version, *The Bondage and Travels of Johann Schiltberger . . .*, trans. by Buchan Telfer with notes by P. Bruun (1879); C. R. Beazley, *Dawn of Modern Geography* (1897, etc.) iii. 356–378, 550.

SCHIMPER, ANDREAS FRANZ WILHELM (1856–1901), German botanist best known for his work on the ecology of tropical plants, was born at Strasbourg on May 12, 1856 a member of a celebrated family of botanists. He received his doctorate at Strasbourg in 1878, and afterward studied under H. A. de Bary. From 1880 to 1881 he was a fellow at Johns Hopkins university. Upon returning to Europe he became *Privatdozent* ("official but unpaid lecturer") and professor (1886) at Bonn Botanical institute where he remained until 1898. From 1898 to 1901 he was professor at Basel, Switz. Schimper's botanical travels took him to the West Indies (1881, 1882–83), to Brazil (1886), to Ceylon and Java (1889–90) and to the Canary Islands, Cameroons, East Africa, Seychelles and Sumatra with the "Valdivia" deep-sea expedition (1898–99).

Schimper died on Sept. 9, 1901 at Basel.

Schimper's ecological studies included important papers on epiphytes, strand vegetation and myrmecophilous plants. His *Pflanzengeographie auf physiologischer Grundlage* (1898; 3rd ed., 1935; English trans., *Plant-Geography Upon a Physiological Basis*, 1903), ranks with Johannes Warming's *Plantesamfund* (1895) as one of the foundation works of modern plant ecology. The book is divided into three sections: the first considering factors that affect plant life; the second presenting Schimper's influential classification of world vegetation; and the third containing a systematic account of this vegetation. Schimper was instrumental in the establishment of a truly scientific and comprehensive method of ecological investigation. Apart from ecology, he made significant contributions to other branches of botany. He showed (1881) that starch grains are not formed in cytoplasm as previously maintained, and concluded (1883) that plastids do not arise through anything but the division of pre-existing plastids.

See notice on Schimper, with a bibliography, in *Ber. Dtsch. Bot. Ges.*, xix, pp. 54–70 (1901).
(J. W. Tr.)

SCHINKEL, KARL FRIEDRICH (1781–1841), German architect and city planner, was born near Brandenburg on March 13, 1781. He studied with Friedrich Gilly and at the Academy of Architecture, Berlin. Two years in Italy, 1803–05, completed his studies.

As state architect of Prussia, Schinkel executed many commissions for King Frederick William III and other members of the royal family. His designs were based on the revival of various historical styles of architecture, his Greek revival buildings including the Royal theatre, Berlin, 1818–21, and the Altes museum, Berlin, 1822–30. His design for a monument to Queen Louise, 1810, and the Werdersche church, Berlin, 1824–30, are two of the earliest Gothic revival designs in Europe. The St. Nicholas church, Potsdam, 1826–49, is based on Italian Renaissance prototypes.

The industrial scene in Manchester, Eng., provoked him to inquire why the modern age had not yet developed its own style, and he gave an intimation of his answer in the building he designed for the Bauakademie at Berlin. His work as city planner resulted in new boulevards and squares in Berlin.

Schinkel also is remembered for his paintings of romantic landscape scenes. stage and scenery designs and his designs for furniture, decorative ironwork, etc.

BIBLIOGRAPHY.—Designs published in *Sammlung architektonischer Entwürfe* (Berlin, 1819–40, 1866), *Werke der höheren Baukunst* (1840–42, 1878). Complete bibliography in P O Rave, K. F. Schinkel (1935). *See* also "K. F Schinkel, Das Lebenswerk" series by various authors, ed by Rave (1942–56). (E B. MACD)

SCHINZNACH, a small spa in the canton of Aargau, Switz. It is situated 3 mi. from Brugg, in the lower valley of the Aar river. at the southwest foot of the small but steep, well-wooded hill mass of Wülpelsburg (1.683 ft. altitude). The village (1,165 ft alt.; pop.. 1950, 1.083) is famed for its strongly sulfurous and saline medicinal springs (90°–95° F.), and during the period May to September, annually, it is much patronized, principally by French visitors. Other popular spas, such as Mullingen and Birmenstorf, lying eastward in the valley of the Reuss river, are in its immediate vicinity.

The Wulpelsburg is crowned by the ruins of an 11th-century castle. Tradition claims that the count of Altenburg discovered his strayed hawk (Ger, habicht) on the hill summit, and the naturally defended site resulted in its selection for the erection of the castle of Habichtsburg — the first important stronghola of the subsequently famous Habsburg dynasty of Austria.

SCHISM, a division, especially used of a formal separation from a church or religious body; a sect or church formed by such separation

The dispute which led to the separation of the Latin and Greek churches is known as the "Great Eastern Schism." For the Great Western Schism see PAPACY.

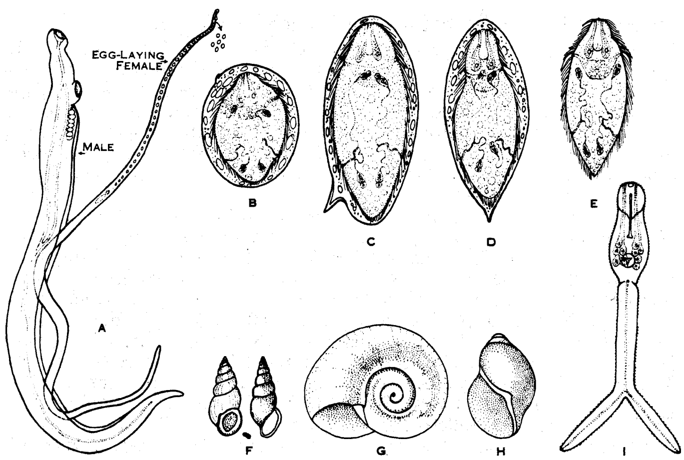
SCHISTOSOMIASIS (BILHARZIASIS), a group of diseases caused by a genus of parasitic microorganisms called blood flukes, produces symptoms primarily referable to the intestine and liver, with associated dysentery, or to the urinary bladder, with passage of blood in the urine.

Oriental schistosomiasis is endemic in Japan, central, west and south China, the Philippines and Celebes. Manson's schistosomiasis occurs in northern Egypt and many other parts of Africa, Yemen and other places in Arabia. Puerto Rico and several islands of the Lesser Antilles, Venezuela, Dutch Guiana and extensive areas in Brazil. Vesical schistosomiasis exists throughout practically all of Africa, the southern tip of Portugal, Cyprus, Palestine, Arabia, Iraq and Iran.

Causative Organisms. — They are commonly called blood flukes or schistosomes because they live in the blood vessels of their definitive host. They belong to the trematodes, a class group of flatworms (Platyhelminthes). The adult blood flukes are delicate, elongated organisms measuring about 10 to 25 mm. in length The sexes are separate. The male holds the delicate female in his ventral sex canal during the long period of egg laying. Oriental (or Asiatic or Japanese) schistosomiasis is produced by Schistosoma japonicum, Manson's (or intestinal) infection by *S.* mansoni and vesical (or urinary) schistosomiasis by S. haematobiurn. The former two reside in the mesenteric-portal venous circulation and S. *haematobium* principally in the vesical and pelvic venous plexuses

The Life Cycle. — Eggs deposited by the female worms in the smaller venules contain rapidly maturing ciliated larvae which secrete digestive substances, aiding the eggs to escape from the blood vessels through the tissues into the lumen of the intestine or urinary bladder. When the fully embryonated eggs reach fresh water they soon hatch and the ciliated larvae (miracidia) actively swim about. In case there are appropriate species of snails near by (species of Oncomelania for *S. japonicum,* Planorbis for *S.* mansoni and Bulinus or Physopsis for *S. haematobium*), the miracidia attack and penetrate the soft tissues of the mollusk and transform into simple hollow sacs (sporocysts). Each of these produces several second-generation sporocysts, which in turn give rise to numerous fork-tailed larvae, the cercariae. Broods of mature cercariae escape at frequent intervals from the snail, swim about in the water and, on contact with mammalian skin, become attached and proceed to penetrate the tissues. Man is the only natural host of S. haernatobium; man and occasionally monkeys are natural hosts of S. mansoni; and almost any mammal is susceptible to infection with *S.* japonicum. Before penetrating exposed skin (or mucous membrane) the cercaria drops its tail. Upon reaching a venule it is passively carried to the pulmonary arterioles, slowly squeezes through the capillaries into the pulmonary venules and passes into the systemic circulation. It will survive only if it reaches a mesenteric artery and proceeds through the capillaries into the portal blood vessels, where it feeds on glycogen in the blood plasma and grows. On reaching adolescence the worms work their way against the venous current: S. *japonicum* migrates to the mesenteric vessels draining the small bowel, S. mansoni to those draining the large bowel and *S.* haematobiurn down the inferior mesenteric venules and through the hemorrhoidal and pudendal anastomoses into the vesical venules. In these localities the worms complete maturity and mate, and the females begin to lay eggs.

From skin exposure until egg deposition the minimum time for *S.* japonicurn is about 4 weeks, for S. rnansoni 6 to 7 weeks and for *S.* haematobiurn 10 to 12 weeks.



BY COURTESY OF DR E C FAUST

STAGES IN THE DEVELOPMENT OF THE THREE SPECIES OF SCHISTOSOMA RESPONSIBLE FOR SCHISTOSOMIASIS

(A) Adult schistosomes in blood vessels (magnified 2.50 times). (B–D) Mature eggs (X 180): *Schistosoma japonicum, Schistosoma mansoni, Schistosoma haematobium.* (E) Miracidium hatched from egg invades snail. (F–H) Snail hosts (X 0.70): Oncomelania (*Schistosoma japonicum*), *Planorbis* (*Schistosoma mansoni*), *Bulinus* (*Schistosoma haematobium*). (I) Cercaria in water invades skin, causing disease (X 90)

Pathogenesis and Symptoms. — There are three recognized clinical stages in schistosomiasis, namely (1) incubation period, (2) acute stage and (3) chronic stage. The incubation period begins with the penetration of the cercariae and is terminated when egg deposition begins. During this time and continuing during the life of the worms (20 or more years if the patient survives) the byproducts of the worms produce local and systemic irritation of an allergic nature. (See PARASITIC DISEASES.) There is inflammation and marked to profound eosinophilia, with a nonproductive cough, late afternoon fever, giant urticaria, together with swelling, pain and tenderness of the liver. In the intestinal types (S. *japonicum* and S. mansoni), diarrhea occurs toward the end of the incubation period. With the beginning of egg deposition the acute stage of the disease is initiated, resulting from trauma caused by eggs escaping from blood vessels through the tissues into the lumen of the intestine or the urinary bladder, typically accompanied by hemorrhages. As the chronic stage gradually develops, eggs become impacted in the walls of the organs and provoke pseudotubercle formation around themselves. This leads to fibrous thickening of the organs, with greatly diminished function. The intestine gradually develops the consistency of an old, nonelastic garden hose, and the bladder becomes impregnated with phosphatic deposits and possesses a gritty surface. Moreover, in the intestinal types, eggs in increasing numbers are carried in the portal current into the liver, filter out and initiate hepatic cirrhosis. This tends to block the flow of blood through the liver, produces abdominal fluid (dropsy) and indirectly causes enlargement of the spleen.

In the vesical type, eggs in the lumen of the bladder become centres for concretions ("stones"); meanwhile the fibrosis extends to the pelvic organs. In all types, eggs are frequently swept through the accessory venous circulation to the lungs where they set up centres of tissue reaction. Occasionally nests of eggs reach the brain and other organs where they produce granulomatous tumours.

Diagnosis and Prognosis.—Diagnosis is accomplished by recovery of the characteristic eggs from the stool or by rectal biopsy (*S. japonicum, S. mansoni)* and from the sediment of the urine or by bladder biopsy (*S. haematohium).*

Prognosis depends on the species of *Schistosoma* involved (*S. japonicum* is most dangerous), on the amount of exposure, on the chronicity of the disease and to a considerable degree on the patient's reactiveness to the infection. Unless exposure is overwhelming, early diagnosis and persistent effective treatment usually provide a good prognosis.

Treatment.—The only drugs which have consistently proved helpful in the eradication of human blood flukes are the antimony compounds. Potassium antimony1 tartrate (tartar emetic), first employed in 1917, proved on the whole satisfactory, although it must be administered intravenously and is rather poorly tolerated in concentrations higher than 0.5%. Certain synthetic antimonials, particularly stibophen and lithium antimony thiomalate, are administered intramuscularly and are better tolerated, but their cure rate is considerably lower than that of tartar emetic. Miracil D is useful in infection with *S. haematohium.*

Prevention.—There is no immunization against schistosomiasis. Theoretically, education in hygiene, and public health measures to keep viable eggs from reaching fresh water constitute first-line prevention. This is impractical, however, both because of social and economic practices and, in *S. japonicum* areas, because the disease would be perpetuated by reservoir hosts. Mass chemotherapy in endemic areas likewise proved unsatisfactory. Concentrated attack on the molluscan host by naturalistic methods and by using copper sulfate in the water was moderately successful in reducing the snail population in endemic spots in Egypt, with a comparable decrease in the incidence of the disease. Molluscicides also showed considerable promise. *See* also FLUKE.

SCHIST, in geology, a crystalline rock that splits easily. Schists are widely distributed in all major mountain ranges The name is from the German *schizein,* "to split." The ease of splitting is caused by a parallel arrangement of scaly, tabular or prismatic minerals. Nearly all schists are metamorphic rocks, and micas are the most common minerals composing them. Micas are a large family of minerals that have highly perfect cleavage, and tend to form sheetlike crystals. They are hydrous aluminum silicates with various combinations of iron, magnesium, calcium, manganese, lithium, potassium and sodium. Muscovite (white), biotite (brown to black), chlorite (green) and phlogopite (light brown) are the most common micas.

Where the earth's crust is being deformed, physicochemical conditions at depths of a few miles are such as to favour the growth of micas as stable minerals in any rock that has the requisite bulk composition. Elevated temperatures, intense shearing of the rock fabric and solutions circulating through pore spaces are probably the most important factors. Siliceous ashes or lavas (rhyolite), granitic rocks or shales may be converted to schists if the deformation is intense enough. Basaltic rocks and gabbros may be converted into greenish-gray chlorite schists, or hornblende schists, composed of combinations of the minerals hornblende (a prismatic calcium-magnesium-iron-aluminum silicate), epidote, magnetite, garnet, several members of the mica family and other silicates.

However, calcareous shales have a bulk composition similar to that of basalts and gabbros, and can also be converted into chlorite schists or hornblende schists. It may be impossible to determine the parent rock. Igneous rocks high in magnesia and iron but low in silica (peridotites) yield, under metamorphic conditions, aggregates of the fibrous mineral antigorite. Under intensive shear stress, these rocks develop talc and become talc schists. However, certain dolomites (magnesian limestones) may also be metamorphosed to talc or talc-tremolite schists (tremolite is a hydrous calcium-magnesium silicate).

Schists split easily even if mica is a subordinate constituent. Slightly muddy sandstone, metamorphosed and sheared, becomes a quartz-muscovite schist that flakes easily. Slightly muddy limestones turn into calcareous schists, composed of calcite, muscovite, phlogopite or other micas that induce fissility of the rocks. Tabular minerals, such as feldspar, or prismatic minerals like hornblende, tremolite and antigorite may under special conditions arrange themselves in parallel planes and give rise to a crude schistose structure of the rock.

The mineral hematite (ferric oxide) possesses a direction of good cleavage. Larger masses of this mineral, recrystallized under strong shear stress, may slip along the cleavage planes and become schistose (specular hematite, "iron mica"). Some of these rocks contain red jasper beds, and surfaces displaying these scarlet laminae intermixed with the silvery hematite flakes in intricately crumpled beds are extremely beautiful.

Metamorphic processes coarsen the grains of shaly sediments and lead to a series from shale (finest) through slate and phyllite (from the Greek *phyllon,* "leaf, sheet") to schist (coarsest). The grain size of schist averages over one millimetre. If feldspar equals or exceeds the amount of mica, the rock is called a gneiss. Other minerals commonly found in schists are quartz, garnet, tourmaline, feldspar, magnetite, staurolite, hornblende, kyanite, sillimanite, andalusite, epidote and graphite.

The origin and structure of schists discloses many interesting details of rock deformation. Nearly all larger mountain ranges of the earth have gone through a period of preparation during which a major depression in the crust received large volumes of muddy sediment. Subsequently, these large mud-filled depressions have been violently compressed, the strata folded and the folded complex uplifted to form the mountains. At depths of several miles, mud tends to recrystallize into mica aggregates. But simultaneously, the layers are being folded. Thus it can happen that these rocks, having reached their yield strength during the folding, were intimately dissected by slip planes or slip cleavage. If solutions circulate actively along them, the planes will become coated with newly grown mica flakes, extending across the truncated layers of deposition. Along the slip cleavage planes the entire mass of rocks can be further deformed, developing planes of movement unrelated to the layers of deposition. Perhaps some of the longest slip planes in the solid crust of the earth are those that connect major bodies of easily yielding schist.

Unless they contain many nonmicaceous minerals, schists weather readily, and tend to underlie smooth slopes and gentle land forms, yielding fairly good, clayey soils.

Mica crystals in schists are usually too small to be of commercial use. However, the accompanying minerals of some schists (kyanite, sillimanite. andalusite, talc, garnet, graphite and others) are important as raw materials for high-grade ceramic wares, abrasives, lubricants and other nonmetallic mineral industries.

For a more detailed discussion of the metamorphic processes and concepts referred to in this article *see* METAMORPHISM.

(R. BK.)

SCHIZOPHRENIA is a term (replacing the older designation "dementia praecox") to indicate a group of psychological disturbances or mental disorders occurring in different combinations and degrees of symptoms but generally having in common disturbances of feeling, thought and relationship to the outside world. Neither dementia praecox (early progressive insanity) nor schizophrenia (splitting of the mental functions) is entirely satisfactory as a term to cover the various patterns of disturbances usually included in the group. In the 20th century there have been alternating trends to consider the term schizophrenia as denoting a single disease process or a number of similar patterns of psychological reactions to life situations.

Four major types of schizophrenia are generally differentiated. (1) The simple type is characterized mainly by an insidious and gradual reduction in external relationships and interests. Emotions are lacking in depth, ideation is simple and referring to concrete things, there is relative absence of activity, progressively less and less use of inner resources and retreat to simpler or stereotyped forms of behaviour. (2) The hebephrenic type is characterized mainly by shallow, inappropriate affective reactions, silly or bizarre behaviour, false beliefs (delusions) and false perceptions (hallucinations). (3) The catatonic type is characterized mainly by striking motor behaviour. The patient may be in a state of almost complete immobility, often assuming statuesque positions. Mutism, extreme compliance and removal of almost all voluntary actions are also common. This state of inactivity is at times preceded or interrupted by episodes of excessive motor activity and excitement, generally of an impulsive, unpredictable kind. (4) The paranoid type (see also PARANOID REACTIONS), usually arising later in life than the other types, is characterized primarily by unrealistic, illogical thinking, delusions of being persecuted or of being a great person and hallucinations.

Hallucinations, although not constantly found, are perhaps the most conspicuous symptom in the hebephrenic and paranoid types. The commonest are auditory — the patient hears "voices," although nobody is there to say what he hears. The patient, however, does not understand the abnormal character of the voices and believes in their reality. Visual hallucinations are also relatively ccmmon, especially in acute episodes, and olfactory and gustatory hallucinations as well as abnormal bodily perceptions also occur in a smaller number of cases. (See also HALLUCINATION.)

The symptom common to all types, although at times only minimally present and difficult to detect, is a thinking disorder characterized by an impairment in the use of abstract concepts and a withdrawal into a concrete frame of reference, as Kurt Goldstein demonstrated.

These types of schizophrenia are by no means mutually exclusive. Mixtures are to be found especially in the early acute phases but also in some later chronic phases. In the latter also may be found patients who show few of the original symptoms of their earlier phases and whose present symptom picture is indeterminate. In addition to mixtures within schizophrenia itself, there may be mixtures of schizophrenic symptoms with those of other psychoses, notably with those of the manic-depressive group. Such patients are ordinarily referred to as of the "schizo-affective" type.

In the U.S.. schizophrenia is considered the most important of the major psychoses, schizophrenics constituting 20% to 25% of first admissions to public hospitals for mental disease. Because of the relative youth at admittance and the relatively long stay per patient, the group niakes up about 55% of the residual population of these hospitals. It has been estimated that schizophrenics comprise between 2.5 and 3 per 1,000 of the general population. The maximum incidence of first admissions in men comes between the ages of 20 and 24 and in women between the ages of 35 and 39. About 45% of schizophrenics who are admitted to public mental hospitals or clinics recover or improve greatly. Of those patients who are committed and improve, about 80% leave the hospital within the first year of residence.

Causation. — Many theories have been proposed as to the origin of the condition. They vary from anatomical and biochemical to psychological, from hereditary to environmental causes. Probably the best opinion in the 1960s was that the schizophrenic reaction types are faulty adjustment reactions to a variety of underlying conditions which may be either somatic or psychological, or both.

Psychological Theories. — Emil Kraepelin (1856–1926) was the first author who differentiated this mental disorder from the other psychiatric conditions. He gave to it the name dementia praecox (a term which had already been used by the Belgian psychiatrist B. A. Morel in a more restricted sense) and described all the characteristics of the disorder. He held that the varied manifestations of dementia praecox are all different signs of a single disease process, either a degenerative disease of the brain or metabolic disturbances causing autointoxication. He held a rather pessimistic view of the disorder, inasmuch as he believed that all cases end in a dementia1 state.

Eugen Bleuler (1857–1939), early influenced by Freudian ideas, developed more dynamic notions than Kraepelin about the psychological aspects of the disturbance, and it was he who coined the term schizophrenia. Bleuler emphasized the importance of the impairment of association of ideas, and saw most of the symptoms as a direct or indirect result of this impairment. He did not deny, however, the possibility that a toxin may be involved in the causation of this psychosis.

Adolf Meyer (1866–1950) considered schizophrenic reactions to be habit disorganizations resulting from progressive maladaptations. The background for the development of these habit disharmonies and deteriorations he believed could be both physiological and psychological. Meyer emphasized the psychobiological integrity of the organism and preferred not to separate the mental from the physical.

Although Sigmund Freud (1856–1939) was not primarily interested in the study of this psychosis, his psychoanalytic theories and investigations have clarified many aspects of schizophrenia. Many schizophrenic symptoms can be interpreted as symbolic manifestations (similar in form, content and motivation to dreams of normal people) and therefore susceptible of psychoanalytic interpretation. The psychoanalytic view emphasizes also two aspects of schizophrenic behaviour — the regressive and the restitutive. The regressive symptoms are seen as a retreat by the person to less mature levels of the ego (the reality-testing portion of the psyche). The restitutive symptoms are attempts to replace the existing world, from which the patient has retreated, by such phenomena as hallucinations, delusions, world reconstruction phantasies or peculiarity of language.

Carl Jung (1875–1961) thought that schizophrenia is caused by an unusual strength of the unconscious, so that an abnormal number of atavic tendencies do not adjust to modern life. He saw the symptoms not only as the result of the past life of the patient but also as manifestation of the resurging collective unconscious (that is, of that inherited part of the psyche which according to him stores the primordial images, or archetypes, that have been deposited as a result of numerous recurrences of identical situations in previous generations).

Harry Stack Sullivan (1892–1949) considered schizophrenia as a result of faulty interpersonal relations, especially poor parent-child relationship. Anxiety and lack of self-esteem, originating in these early relationships, lead the patient to distortions in his way of living (parataxic distortions), to lack of consensual validation (that is to less and less recognition from others of the patient's way of seeing the world) and finally to schizophrenic panic.

Silvano Arieti (1914–) accepts to a large extent Sullivan's dynamic interpretation of schizophrenia. He emphasizes, however, the importance of the special formal mechanisms that the conflicts and the way of living of the patient must assume. It is especially in the realm of cognition that these special formal mechanisms are found. The patient follows a particular form of logic called by Arieti "paleologic," a different form of causality, of symbolization and of volition. Arieti feels that the schizophrenic process also may be interpreted psychosomatically, inasmuch as intensely disturbing emotional factors may bring about the resurgence of obsolete functional and neuronal patterns.

Biological Theories. — Franz Kallmann, as a result of many investigations, especially on twins, concluded that the cause of schizophrenia is hereditary but that the factor is recessive and therefore manifested only in some cases. According to Robert Heath, schizophrenia is a disorder of metabolism and hinges on the formation of a substance he and his collaborators isolated and called taraxein.

The series of substances which have been thought to engender schizophrenia is very long. Great interest has been shown to the experimental use of some substances, which reproduce a picture similar to schizophrenia. One of them is bulbocapnine, which brings about in experimental animals a picture similar but not identical to catatonia. Mescaline and lysergic acid have reproduced in human beings abnormal perceptions and thought disorders similar to those seen in schizophrenia. (*See* also NEUROPHARMACOLOGY AND PSYCHOPHARMACOLOGY.)

Treatment. — Although at one time there was considerable pessimism about the outlook in schizophrenic cases and in their treatment, this attitude changed markedly, beginning about the fourth decade of the 20th century. Even psychoanalytic therapy, about which Freud himself was skeptical in the treatment of psychoses, began to be applied, after modifications were made on the original orthodox technique. These modifications, mainly introduced by the pioneer work of Paul Federn, Harry Stack Sullivan, Frieda Fromm-Reichmann, John Rosen and Marguerite Sechehaye, include the abolition of the couch, direct intervention with adoption of the symbolic language of the patient and much less reliance on free association. But application of psychotherapeutic techniques to schizophrenia is limited by the fact that relatively few psychiatrists are experienced with this type of treatment.

By far the majority of patients are treated with physical methods, the most important being: (1) insulin therapy, which was devised by Manfred Sakel and consists in the artificial production of comas by administration of large doses of insulin; (2) electric convulsive therapy, which was devised by U. Cerletti and L. Bini, and which consists of the artificial production of convulsions, and (3) drug therapy, which consists in the administration of large doses of pharmaceutical products, called ataractic or tranquilizers, the most important of which are reserpine and chlorpromazine. (*See* also TRANQUILIZING DRUGS.) So-called psychosurgery—separation of certain areas of the brain—has been carried out in the most recalcitrant cases of schizophrenia. The commonest operation, that devised by Antonio Egas Moniz, consists of prefrontal lobotomy, or surgical interruption of bundles of nervous fibres between the thalamus and the frontal lobes. Interest in this type of operation developed especially in the late 1940s, but by the middle 1950s a great decline of interest uas already evident, as less drastic therapies came to be preferred even for the most difficult cases.

Although some cases of schizophrenia are mild and may be treated outside hospitals, the majority of patients diagnosed as schizophrenics are hospitalized, especially during acute episodes. In the hospital the patient may receive various forms of treatment. Whereas almost all psychiatric hospitals are equipped to provide the above-mentioned physical treatments and occupational therapy, only a minority of them provide psychotherapy. In many cases, what seems most important is to provide the patient with an environment in which he is protected and in which he can gradually work through his periods of confusions and disturbance away from the disturbing influences of his ordinary environment.

The success of treatment seems definitely to vary with the stage of the disease in which it is introduced. If the illness has been permitted to go on for a long time, successful treatment is more difficult to attain. Other signs that have been found related to good outcome are acute, sudden onset of a confused, excited kind of disturbance; absence of schizophrenic history in the family; presence of an admixture of symptoms usually found in manic-depressive psychosis; and presence of some fairly clear psychological conflict which precipitated the disturbance. Statistical studies of the effects of therapy indicate in general that shock treatment (insulin and electric convulsive) seems to some extent to improve the prognosis in those cases which already have a good outlook and in some proportion of those with a poor outlook. However, shock treatment is not so generally effective in this disorder as it is in manic-depressive psychosis.

Prevention. — Without a clear-cut understanding of the etiology of the illness, of course, specific preventive measures are not available. A number of authorities, influenced largely by the psychoanalytic points of view, believe that the relationship with the family, particularly the mother, in the early years of life plays a most important role in the development of schizophrenia. Their recommendations for prevention therefore centre largely in the provision of security for the child through warm, understanding relationships in the family.

There seems also to be a relation between the type of society and the incidence of schizophrenia. There are indications that urban areas and in particular the very large cities have a larger incidence of this disorder. An industrial society seems also to predispose to the condition more than an agricultural. Accurate statistical research is difficult because not all patients are hospitalized and because the diagnostic criteria vary in different places. Schizophrenia, however, is found among all cultures and all societies.

SCHLEGEL, AUGUST WILHELM VON (1767–1845), German poet, translator and critic, was born on Sept. 8, 1767, at Hanover, where his father, Johann Adolf Schlegel (1721–93), was a Lutheran pastor. He mas educated at the Hanover *Gymnasium* and at the University of Gottingen. Having spent several years as a tutor in the house of a banker at Amsterdam, he nent to Jena, where, in 1796, he married Karoline Michaelis, the widow of the district medical officer Bohmer, and in 1798 was appointed extraordinary professor. There he began his translation of Shakespeare, which was ultimately completed, under the superintendence of Ludwig Tieck, by Tieck's daughter Dorothea and W. H. Baudissin. This rendering is one of the best poetical translations in German, or indeed in any language. At Jena Schlegel contributed to Schiller's periodicals the *Horen* and the *Musenalmanach;* and with his brother Friedrich he conducted the *Athenaeum,* the organ of the romantic school. He also published a volume of poems, and carried on a rather bitter controversy with Kotzebue. The brothers were the leaders of the new romantic criticism. A volume of their joint essays appeared in 1801 under the title *Charakteristiken und Kritiken.* In 1802 Schlegel went to Berlin, where he lectured on art and literature; and in the following year he published *Ion*, a tragedy in Euripidean style, which gave rise to a suggestive discussion on the principles of dramatic poetry. This was followed by *Spanisches Theater* (2 vol., 1803–09), in which he presented admirable translations of five of Calderon's plays; and in another volume, *Blumensträusse italienischer, spanischer und portuguesischer Poesie* (1804), he gave translations of Spanish, Portuguese and Italian lyrics. In 1807 he attracted much attention in France by an essay in the French language, *Comparaison entre la Phèdre de Rncine et celle d'Euripide*, in which he attacked French classicism from the standpoint of the romantic school. His lectures on dramatic art and literature (*Über dramatische Kunst und Literatur,* 1809–11), which were translated into most European languages, were delivered at Vienna in 1808.

Meanwhile, after a divorce from his wife Karoline in 1804, he traveled in France, Germany, Italy and other countries with Madame de Stael, who owed to him many of the ideas which she embodied in her work *De l'Allemagne*. In 1813 he acted as secretary to the crown prince of Sweden. Schlegel was made a professor of literature at the University of Bonn in 1818, and during the remainder of his life occupied himself chiefly with oriental studies, although he continued to lecture on art and literature, and in 1828 he issued tno volumes of critical uritings (*Kritische Schriften*). In 1823–30 he published the journal *Indische Bibliothek* (3 vol.) and edited (1823) the Bhagavad-Gita nith a Latin translation and (1829) the Ramayana. These works mark the beginning of Sanskrit scholarship in Germany. After the death of Madame de Staël, Schlegel married (1818) a daughter of H. E. G. Paulus of Heidelberg; but this union was dissolved in 1821. He died at Bonn on May 12, 184j. As an original poet Schlegel is unimportant, but as a poetical translator he has rarely been excelled.

In 1846–47 Schlegel's *Siimtliche Werke* were issued in 12 vol. by E. Böcking. Editions were also published by the same editor of his *Œuvres écrites en français,* 3 vol. (1846), and *Opuscula Latine scripta* (1848). Schlegel's Shakespeare translations have been often reprinted; the edition of 1871–72 was revised with Schlegel's manuscript by M. Bernays. *See* M. Bernays, *Zur Entstehungsgeschichte des Schlegelschen Shakespeare* (1872); *R.* Genee, *Schlegel und Shakespeare* (1903); J. Koerner, *Romantiker und Klassiker. Die Brüder Schlegel in ihren Beziehungen zu Schiller und Goethe* (1924). Schlegel's Berlin lectures of 1801–04 were reprinted from manuscript notes by J. Minor (1884). A selection of the writings of A. W. and F. Schlegel, ed. by O. F. Walzel, was printed in Kiirschner's *Deutsche Nationalliteratur,* 143 (1892). *See* especially R. Haym, *Romantische Schule,* and the article in the *Allg. deutsche Biographie* by F. Muncker.

SCHLEGEL, FRIEDRICH VON (1772–1829), German poet, critic and scholar, was the younger brother of August Wilhelm von Schlegel. He was born at Hanover on March 10, 1772. He studied law at Gottingen and Leipzig, but ultimately devoted himself entirely to literary studies. He published in 1797 the important book *Die Griechen und Romer,* which was followed by the suggestive *Geschichte der Poesie der Griechen rind Romer* (1798). Goethe and Schiller looked to the Greeks for form and objectivity; Schlegel's Hellenism was romantic and lyrical. At Jena, where he lectured as a *Privatdozent* (official but unpaid lecturer) at the university, he contributed to the *Athenäum* the aphorisms and essays in which the principles of the romantic school are most definitely stated. This journal formed the centre for the first group of romanticists at Jena. There also he wrote *Lzicinde* (1799), an unfinished romance, which is interesting as an attempt to transfer to practical ethics the romantic demand for complete individual freedom, and *Alarcos,* a tragedy ('1802) in which, without much success, he combined romantic and classical elements. In 1802 he went to Paris, where he edited the review *Europa* (1803), lectured on philosophy and carried on oriental studies. some results of which he embodied in *Über die Sprache und Weisheit der Zndier* (1808). In the same year in which this work appeared. he and his wife Dorothea (1763–1839), a daughter of Moses Mendelssohn. joined the Roman Catholic Church, and from this time he became more and more opposed to the principles of political and religious freedom. In 1809 he was appointed imperial court secretary at the headquarters of the archduke Charles at Vienna; later he was councilor of legation in the Austrian embassy at the Frankfurt diet. but in 1818 he returned to Vienna. Meanwhile he had published his collected *Gedichte* (1809) and two series of lectures, *Über die neuere Geschiclzte* (1811) and *Geschichte der alten und neuen Literatur* (1815). After his return to Vienna from Frankfurt he edited *Concordia* (1820–23), and began the issue of his *Samtliche Werke.* He also delivered lectures: which were republished in his *Philosophie des Lebens* (1828) and in his *Philosophie der Geschichte* (1829). He died on Jan. 11, 1829, at Dresden. Friedrich Schlegel's wife, Dorothea, was the author of an unfinished romance, *Florentin* (1801), a *Sammlung romantischer Dichtungen des Mittelalters* (2 vol., 1804), a version of *Lother und Maller* (1805) and a translation of Madame de Stael's *Corinne* (1807–08)—all of which were issued under her husband's name.

Friedrich Schlegel's *Samtliche Werke* appeared in 10 vol. (1822–25); a 2nd ed. (1846) in 15 vol. His *Prosaische Jugendschriften* (1794–1802) were edited by J. Minor (1882; 2nd ed., 1906); also reprints of *Lucinde,* and F. Schleiermacher's *Vertraute Briefe iiber Lucinde, 1800* (1907). *See* I. Rouge, *F. Schlegel et la genèse du romantisme allemand* (1904), *Erläuterungen zu F. Schlegels Lucinde* (1905); M. Joachimi, *Die Weltanschauung der Ronzantik* (1905); *W.* Glawe, *Die Religion F. Schlegels* (1906); *E.* Kircher, *Philosophie der Romantik* (1906); *R.* Volpers, *Friedrich Schlegel als politischer Denker und deutscher Patriot* (1917). On Dorothea Schlegel *see* J. M. Raich, *Dorothea von Schlegel und deren Söhne* (1881); F. Diebel, *Dorothra Schlegel als Schriftsteller im Zusammenhang mit der romantischen Schule* (1905).

SCHLEICHER, AUGUST (1821–1868), German philologist, the first linguist to study an Indo-European language not from texts; but directly from living speakers, was born at Meiningen, on Feb. 19, 1821. He became professor of Germanic and classical philology in Prague in 1850, and in 1857 was appointed to the chair of comparative linguistics at Jena. His *Handbook of the Lithuanian Language* (1856–57) marks an epoch in linguistic history; and his *Compendium of Comparative Grammar of Indo-European* (1861) was the first to emphasize the regularity of phonetic correspondences between the related languages, and the first to attempt reconstructions of proto-Indo-European. His work well sums up the first half century of comparative linguistics, and, methodologically, indicates the direction of much subsequent scholarship.

Schleicher died on Dec. 6, 1868, at Jena. (M. S. Br.)

SCHLEIERMACHER, FRIEDRICH DANIEL ERNST (1768–1834), German theologian and philosopher. one of the most influential thinkers of 19th-century Protestantism, was born in Breslau on Nov. 21, 1768, the son of a Prussian army chaplain of the Reformed confession. He was educated at schools belonging to the Moravian Brethren and was to have become a Moravian pastor. Under the influence of the literature of the time, however. he began to doubt Christianity in its transmitted form; and he exacted from his father permission to study at Halle university, where at the time rationalism reigned.

He early became a student of Kantian philosophy, though from the first a critical one. In 1796 he was appointed chaplain to the Charité hospital in Berlin. He then became influenced by Spinoza and still more by Plato and by Fichte. Entering the circle of the early Berlin romantics. he formed a great friendship with Friedrich Schlegel, whom he defended in his *Vertraute Briefe iiber Schlegels 'Lucinde'* (1800). Schleiermacher established his fame with the *Reden iiber die Religion* (Berlin, 1799; new ed. by R. Otto, 1926) in which he maintained religion to be independent of knowledge and morality. The *Monologen* (1800; new ed. by F. M. Schiele and H. Mulert, Leipzig, 1914) contain the first statements of his ethical system, which does not take a general moral law as its starting point but claims to establish the particularity of the individual.

From 1802 to 1804 Schleiermacher was pastor at Stolp. During these years he began his translation of Plato and published his first strictly philosophical work, the *Grundlinien einer Kritik der bisherigen Sittenlehre* (Berlin. 1803). In 1804 he became professor of theology at Halle; and it was there that. in 1806, he published *Die Weihnachtsfeier,* an important dialogue for his Christology. In the same year appeared the second. heavily revised edition of his *Reden,* already containing his final conception of religion.

From 1809 until his death (Feb. 12, 1834) Schleiermacher lived in Berlin, becoming professor in the newly founded university there in 1810. He took part in the national movement against Napoleon and did much to promote the union of the Lutheran and Reformed churches in the Church of Prussia (1817). His *Kurze Darstellung des theologischen Studiums* (Berlin. 1811; rev. ed, 1830), an encyclopaedia of theological disciplines, already presupposes the final form of his philosophical-theological system, which had built itself up by the independent use of borrowed stimuli (especially from Schelling). His chief theological work, *Der christliche Glaube nack den Grundsätzen der ecangelischen Kirche,* 2 vol. (Berlin. 1821–22), became basic for evangelical theology in the 19th century. Schleiermacher expressed the principles of the second, heavily revised. edition of this work in two letters to his friend Friedrich Liicke (in the periodical *Theologische Studien und Kritiken,* 1829; ed. separately by H. Mulert. 1908); in these he defended his theological position in general and his book in particular. His metaphysic of knowledge, the *Dialektik,* was left incomplete at his death. His lectures on philosophical and theological ethics. as well as those on practical theology, were also printed posthumously.

Theoretical Philosophy.—In Berlin Schleiermacher was overshadowed by Hegel as a philosopher, and the significance of his fragmentary philosophical works was seldom fully appreciated in the century following his death. Although his point of departure was that of the idealist philosophy of identity, he took a critical view of the limits of our knowledge. All knowledge arises from a conflict of thoughts (hence the title Dialektik), as knowledge is the agreement which ends the conflict: but the content of all conflicting thoughts lies between a chaotic multiplicity of sense impressions and the general principles of reason; and only through the unity of real and ideal, that is, through the complete mutual interpenetration of these opposites, could perfect knowledge be attained. In the case of such an absolute knowledge, the one "transcendent cause" of all being. God, mould be simultaneously apprehended. But the reconciliation of the opposites is never more than approximate; our perception of God is likewise confined to various approximate formulas reached by a differential method; and our knowledge remains incomplete. Nonetheless. God as transcendent cause is already presupposed in all partial knowledge. God cannot be comprehended in a definition; but is immanent to all existing beings, constituting their connection with all other existence. In immediate self-consciousness (or, as Schleiermacher calls it, feeling) God is present as the basis of the unity of the self in the transition from thinking to willing and vice versa. Although immanent in all existence, God is not identical with the world but is its origin. As such, He is not conceivable to our thought apart from the world.

Ethics. — The subject of ethics is the striving of the mind to unite physical nature with itself and to fashion that nature into its instrument and symbol. This ethical striving must presuppose that nature and reason are in principle one in the transcendent cause (in God). that nature is preordained to be the organ and symbol of the mind, just as there is an impulse in the mind working toward this same unity. This impulse is not a general moral law but expresses itself differently in each individual. It always leads the individual to participate in society, however—for example in the forms of family, state, school and church.

Theology. — While philosophy, from perception of the world, constructs approximate formulas for the transcendent cause, theology contemplates immediate self-consciousness—or feeling. which mirrors the divine unity. Since man in his self-consciousness knows that he does not exist from himself, he feels himself absolutely dependent. This feeling is the source of all religion. All religious language is its expression, and dogmatic theology states in explicit terms what are actual religious assertions within the religious consciousness. So-called natural religion, or the religion of reason, as something distinct from positive religion, is a pure abstraction. All religion is positive because religious feeling is experienced only in conjunction with sense consciousness, and consequently every religious expression has its own particular character. The great religious communions arise through religious heroes, who awake the religious life in others by communicating their special religious experience and who found religious communities, churches, for the cultivation of this religious life. Christianity belongs to the highest, monotheistic stage of religion and is of the ethical type of religion insofar as it regards every deficiency in consciousness of God as sin and any strengthening of this consciousness as grace. The specific feature of Christianity is the relation to Christ as mediator, in whom the consciousness of God was realized prototypically and superlatively, so that one must speak of "God's being in Him." Christians are conscious of having been redeemed by their experience of Christ's religious perfection from a situation in which their religious consciousness was overpowered by their sense consciousness: they have been transplanted from this condition into one where everything is subordinated to the religious feeling. The work of Christ is now carried on in a natural way by the church; but its founder, Jesus, was a completely new and original factor in the process of religious development and was to that extent, like every new and higher stage of being, a supernatural revelation. Schleiermacher believed that this conception of Christianity overcame both the one-sidedness of rationalism and the contrary one-sidedness of supernaturalism. As he assigned to dogmatic theology the task of justifying all Christian teaching as an expression of Christian consciousness, he nas compelled to exclude from that theology much that does not seem to be a necessary expression of it; *e.g.*, all historical events. the whole of the Old Testament and also the doctrine of the Trinity. Likewise, he had to offer a considerable reinterpretation of the doctrine of sin and justification and of Christological and eschatological teaching.

BIBLIOGRAPHY.—The collected edition of Schleiermacher's works, 30 vol. (Berlin, 1834–64), comprises three groups of writings, (1) theology, (2) sermons and (3) philosophy and miscellanea. To these must be added the *Aesthetik*, ed. by R. Odebrecht (Leipzig, 1931). *See* also the *Dialektik*, new ed. by R. Odebrecht (Leipzig, 1942), in conformity with the lecture of 1822.

F. Ueberweg, *Grundriss der Geschichte der Philosophie*, iv (Berlin, 1923), gives a bibliography of the secondary literature. For more recent works see F. Flückiger, *Philosophie und Theologie bei Schleiermacher* (Zürich, 1947). (W. U. P.)

SCHLESINGER, FRANK (1871–1943), U.S. astronomer, "the father of modern astrometry." was born in New York city May 11, 1871, of Silesian parentage. Upon graduation from City college in 1890, Schlesinger practised surveying four years before preparing for the Ph.D. degree at Columbia (1898). After a period with the International Latitude service in California. he became astronomer at the Terkes observatory (1903–05). There he demonstrated the effectiveness of long-focus telescopes for photographic measurements of distances of stars. His highly accurate method proved epoch making. As others followed his procedure, the number of stars with measured distances increased from a few dozen to over 6.000 during Schlesinger's lifetime, and the measurements became basic to knowledge of the scale of the universe beyond the solar system.

In 1905 Schlesinger accepted the directorship of the Allegheny observatory in Pittsburgh. From 1920 until his retirement in 1941 he was director of the Yale university observatory. For Allegheny he acquired the 30-in. Thaw refractor; for Yale the 26-in. refractor in the southern hemisphere. These instruments contributed a large share of the known stellar distances. He also pioneered in the use of wide-angle cameras for determining photographically positions and proper motions of stars formerly measured by laborious visual methods. Fifteen volumes of Yale Zone Catalogues give results for about 150,000 stars.

Schlesinger's contributions were recognized by many honours: medals, lectureships. election to the National Academy of Sciences and the presidency of the International Astronomical union.

He died in Lyme, Conn., July 10, 1943. (D. BR.)

SCHLESWIG, capital of the former Prussian province of Schleswig-Holstein, and after World War II in the *Land* of the same name, is in the German Federal Republic on the narrow arm of the sea called the Schlei, 30 mi. N.W. of Kiel on the railway from Hamburg to Flensburg. Pop. (1950) 36,247. The town consists mainly of a single street: 3½ mi. long, forming a semicircle round the Schlei. The church of St. Peter (1100), renewed in the Gothic style in the 1jth century, contains a fine carved oak reredos by Hans Brueggemann. The former commercial importance of the town has disappeared, and the Schlei now affords access to small vessels only. Fishing, tanning, flour milling and gardening are the chief industries.

History.—Schleswig (ancient forms Sliesthorp, Sliaswic, *i.e.*, the town or bay of the Slia or Schlei) seems to have been a place of importance in the 9th century, as a medium of trade between the North sea and the Baltic. The first Christian church was built there by Xnsgarius (d. 865), and it became the seat of a bishop about a century later. The town, which obtained civic rights in 1200, also became the seat of the dukes of Schleswig, but its commerce gradually dwindled as a result of the rivalry of Lubeck, the wars in which the district was involved and the silting up of the Schlei. At the partition of 1j44 the old castle of Gottorp, built in 1160 for the bishop, became the seat of the Gottorp line of the Schleswig-Holstein family, which remained there till expelled by the Danish king Frederick IV in 1713.

From 1731 to 1846 Schleswig was the seat of the Danish governor of the duchies.

For later history see SCHLESWIG-HOLSTEIN QUESTION.

SCHLESWIG-HOLSTEIN, a *Land* of the German Federal Republic, formerly a province in the northwest of Prussia, formed out of the once Danish duchies of Schleswig, Holstein and Lauenburg, and of part of the lands of the former free city of Lubeck. Schleswig-Holstein is bounded west by the North sea, north by Denmark, east by the Baltic sea, Lubeck and Mecklenburg and south by the lo er course of the Elbe (separating it from Hanover). It thus consists of the southern half of the Cimbric peninsula. As a result of the plebiscite taken in accordance with the treaty of Versailles in 1920, the northern zone of the existing German province of Schleswig-Holstein was restored to Denmark, while the southern zone remained part of German territory. The boundary line ran just north of Sylt, south of Tønder and north of Flensburg. In addition to the mainland, which decreases in breadth from south to north. the province included several islands, the most important being Fehmarn in the Baltic and Heligoland, Sylt and Fohr in the North sea. The total area of the Land of Schlesmig-Holstein is 6,054 sq.mi.

The more ancient geological formations are seldom found in Schleswig-Holstein. The contrast between the two coast lines of the province is marked. The Baltic coast has generally steep, well-defined banks and is irregular, being pierced by numerous long and narrow inlets (*Föhrden*) which often afford excellent harbours. The North sea coast is low and flat, and its smooth outline is interrupted only by the estuary of the Eider and the peninsula of Eiderstedt.

Dunes or sand hills, though rare on the protected mainland, occur on Sylt and other islands, while the small flat islands called *Halligen* require protection by dikes.

The climate of Schleswig-Holstein is mainly determined by the proximity of the sea, and the mean annual temperature, varying from 45° F. in the north to 49" in the south, is rather higher than is usual in the same latitude. Rain and fog are frequent, but the climate is on the whole healthful. The Elbe forms the southern boundary of Holstein for 65 mi., bpt the only river of importance within the province is the Eider, which rises in Holstein and after a course of 120 mi. falls into the North sea, forming an estuary 3 mi. to 12 mi. in breadth. It is navigable from its mouth as far as Rendsburg. which is on the Riel-Elbe canal, which intersects Holstein. There are numerous lakes in northeast Holstein, the largest of which are the Plöner See (12 sq.mi.) and the Selenter See (9 sq.mi.).

The ordinary cereals are all cultivated with success and there is generally a considerable surplus for export. Rape is groun in the marshlands and flax pn the east coast. while large quantities of apples and other fruit are raised near Altona for the Hamburg and English markets. The marshlands afford admirable pasture, and great numbers of cattle are reared for export. The Holstein horses are also in request. but sheep raising is comparatively neglected. Beekeeping is a productive industry. The hills skirting the bays of the Baltic coast are generally pleasantly wooded, but the forests are nowhere of great extent except in Lauenburg. The fishing in the Baltic is productive; Eckernforde became the chief fishing station in Prussia. The oysters from the beds on the west coast of Schleswig are widely known under the misnomer of "Holstein natives." The mineral resources are almost confined to a few layers of rock salt near Segeberg. The more important industrial establishments, such as iron foundries, machine works, tobacco and cloth factories. are mainly confined to the large towns, such as Rendsburg, Kiel and Flensburg. The shipbuilding of Kiel and other seaports, however. is important. The commerce and shipping of Schleswig-Holstein. stimulated by its position between two seas. as well as by its excellent harbours and waterways, are much more prominent than its manufactures. Kiel is one of the chief seaports of the area. while overseas trade ordinarily is carried on by Flensburg. Kiel (254,449) is the largest town and is the capital of the *Land*. The exports include grain, vegetables, meat, fish and oysters.

The population of the Land in 1950 was 2,594,648. The peninsula of Angeln, between the Gulf of Flensburg and the Schlei, is supposed to have been the original seat of the English, and observers profess to see a striking resemblance between this district and the counties of Kent and Surrey. The peasants of Dithmarschen in the southwest retain many of their ancient peculiarities. The chief educational institution in Schleswig-Holstein is the University of Kiel.

SCHLESWIG-HOLSTEIN QUESTION, the name given to the whole complex of diplomatic and other issues arising in the 19th century out of the relations of the two "Elbe duchies," Schleswig and Holstein, to the Danish crown on the one hand and the German confederation on the other, which came to a crisis with the extinction of the male line of the reigning house of Denmark by the death of King Frederick VII on Nov. 1j, 1863. The central question was whether the two duchies did or did not constitute an integral part of the dominions of the Danish crown, with which they had been more or less intimately associated for centuries. This involved the purely legal question, raised by the death of the last male heir common to both Denmark and the duchies, as to the proper succession in the latter, and the constitutional questions arising out of the relations of the duchies to the Danish crown, to each other, and of Holstein to the German confederation. There was also the national question: the ancient racial antagonism between German and Dane, intensified by the tendency, characteristic of the 19th century, to the consolidation of nationalities. Lastly, there was the international question: the rival ambitions of the German powers involved, and beyond them the interests of other European states, notably that of Great Britain, in preventing the rise of a German sea power in the north.

Early History. — From time immemorial the country north of the Elbe had been the battleground of Danes and Germans. Danish scholars point to the prevalence of Danish place names far southward into the German-speaking districts as evidence that at least the whole of Schleswig was at one time Danish; *i.e.*, place names according to popular usage, not the official names given in German maps (*e.g.*, Haderslev for Hadersleben). German scholars claim it, on the other hand, as essentially German. That the duchy of Schleswig, or South Jutland (Sonderjylland), had been from time immemorial a Danish fief was. indeed, not in dispute, nor was the fact that Holstein had been from the first a fief of the Germano-Roman empire. The controversy in the 19th century raged round the "indissoluble" union of the two duchies, the principle of which had been secured by the charter of Ribe, signed by the Danish king Christian I in 1460, after his election by the respective estates as count of Holstein and duke of Schleswig. The "Eider Danes" (*i.e.*, the party at Copenhagen which aimed at making the Eider, the southern boundary of Schleswig, the frontier of the Danish kingdom proper) claimed Schleswig as an integral part of the Danish monarchy, which. on the principle of the union, involved the retention of Holstein also; the Germans claimed Holstein as a part of Germany and, therefore, on the same historic principle, Schleswig also.

The congress of Vienna, instead of settling the questions involved in the relations of the duchies of Denmark once for all, sought to stereotype the old divisions in the interests of Germany. In 1806, after the dissolution of the Holy Roman empire, the duchies had been virtually incorporated in Denmark. This settlement was reversed by the congress, and while Schleswig remained as before. Holstein and Lauenburg were included in the new German confederation. The opening up of the Schleswig-Holstein question thus became sooner or later inevitable. The Germans of Holstein, influenced by the new national enthusiasm evoked by the War of Liberation, resented more than ever attempts to treat them as part of the Danish monarchy and, encouraged by the sympathy of the Germans in Schleswig, tried to reassert in the interests of Germanism the old principle of the unity of the duchies. The political atmosphere, however. had changed at Copenhagen also; and their demands were met by the Danes with a nationalist temper as intractable as their own. Affairs were ripe for a crisis, which the threatened failure of the male heirs common to the kingdom and the duchies precipitated.

CRISIS OF 1848–49

When Christian VIII succeeded his half-cousin Frederick VI in 1839 the elder male line of the house of Oldenburg was on the point of extinction, the king's only son and heir having no children. To German opinion the solution of the question of the succession seemed clear. The crown of Denmark could be inherited by female heirs; in the duchies the Salic law had never been repealed and, in the event of a failure of male heirs to Christian VIII, the succession would pass to the dukes of Augustenburg. Danish opinion, on the other hand, clamoured for a royal pronouncement proclaiming the principle of the indivisibility of the monarchy and its transmission intact to a single heir, in accordance with the royal law. To this Christian VIII yielded so far as to issue in 1846 letters patent declaring that the royal law in the matter of the succession was in full force so far as Schleswig was concerned. As to Holstein he stated that he could not give so clear a decision, but the principle of the independence of Schleswig and of its union with Holstein were expressly reaffirmed.

An appeal against this by the estates of Holstein to the German diet received no attention. The revolutionary year 1848 brought matters to a head. On Jan. 28 Christian VIII proclaimed a new constitution which, while preserving the autonomy of the different parts of the country, incorporated them for common purposes in a single organization. The estates of the duchies replied by demanding the incorporation of Schleswig-Holstein, as a single constitutional state, in the German confederation. Frederick VII, who had succeeded his father at the end of January, declared (March 4) that he had no right to deal in this way with Schleswig, and, yielding to the Eider-Danish party, withdrew the rescript of January (April 4) and announced to the people of Schleswig (March 27) the promulgation of a liberal constitution under which the duchy, while preserving its local autonomy, would become an integral part of Denmark.

Prussian Intervention. — Meanwhile the duchies had broken out into insurrection; a provisional government had been established at Kiel; and the duke of Augustenburg had hurried to Berlin to secure the assistance of Prussia in asserting his rights. This was at the crisis of the revolution in Berlin, and the Prussian government saw in the proposed intervention in Denmark in a popular cause an excellent opportunity for restoring its damaged prestige. Prussian troops were marched into Holstein and, the diet having on April 12 recognized the provisional government of Schleswig and commissioned Prussia to enforce its decrees, Gen. Friedrich von Wrangel was ordered to occupy Schleswig also. Prussia, as the mandatory of Germany, endeavoured to enforce the principle that the states were independent, indissolubly united and hereditary only in the male line. But the Germans had reckoned without the European powers, which were united in opposing any dismemberment of Denmark, even Austria refusing to assist in enforcing the German view.

Convention of **Malmö**.—Prussia was now confronted on the one side by the German nation urging it to action, on the other side by the European powers threatening the worst consequences should it persist. Frederick William chose the lesser of two evils and, on Aug. 26, 1848. Prussia signed at Malmo a convention which yielded practically all the Danish demands. The Holstein estates appealed to the German parliament, but it was soon clear that this had no means of enforcing its views, and the convention was ratified at Frankfurt.

The convention was only in the nature of a truce establishing a temporary modus vivendi. and the main issues continued to be hotly debated. A conference held in London failed to arrive at a settlement, and on April 3, 1849, the war was renewed. But the European situation, and notably the attitude of the emperor Nicholas I of Russia—who looked on Augustenburg as a rebel and Russia as bound in honour to safeguard the interests of the Danish crown—decided Prussia to conclude peace with Denmark on the basis of the *status quo* ante *bellum*.

Treaty of Berlin, 1850.—The treaty was signed at Berlin on July 2, 1850. Both parties reserved all their antecedent rights; but for Denmark it was enough, since it empowered the king-duke to restore his authority in Holstein with or without the consent of the German confederation. Danish troops marched in to coerce the duchies; but, meanwhile, negotiations among the powers continued, and on Aug. 2, 1850, Great Britain, France, Russia and Norway-Sweden signed a protocol, to which Austria subsequently adhered, approving the principle of restoring the integrity of the Danish monarchy. On Jan. 28, 1852, King Frederick VII issued a royal letter announcing the institution of a unitary state which, while maintaining the fundamental constitution of Denmark, would increase the powers of the estates of the two duchies. This was approved by Prussia and Austria, and by the German federal diet insofar as it affected Holstein and Lauenburg.

The Protocol **of** London, 1852.—The question of the succession was next approached. The main obstacle to an agreement among the powers was removed when, on March 31, 1852, the duke of Augustenburg resigned his claim in return for a money payment. Further adjustments followed. After the renunciation by the emperor of Russia (who represented the elder, Gottorp line) and others of their eventual rights, Charlotte, landgravine of Hesse, sister of Christian VIII. and her son Prince Frederick transferred their rights to the latter's sister Louise, who in her turn transferred them to her husband Prince Christian of Gliicksburg. This arrangement received international. sanction by the protocol signed in London on May 8, 1852, by the five great powers and Norway and Sweden. On July 31, 1853, King Frederick VII gave his assent to a law settling the crown on Prince Christian, "prince of Denmark," and his male heirs. The protocol of London, while consecrating the principle of the integrity of Denmark, stipulated that the rights of the German confederation in Holstein and Lauenburg should remain unaffected. It was, in fact, a compromise which satisfied neither the Danes nor the Germans; and when in Oct. 1855 King Frederick issued a parliamentary constitution for the whole monarchy, its legality was disputed by the two German great powers, on the ground that the estates of the duchies had not been consulted, and the diet of the confederation refused to admit its validity so far as Holstein and Lauenburg were concerned (Feb. 11, 1858).

The question was now once more the subject of international debate; but the situation was no longer so favourable to the Danish view. The Crimean War had crippled Russia, and Nicholas I was dead. France was prepared to sell the interests of Denmark in the duchies to Prussia in return for "compensations" to itself elsewhere. Great Britain alone sided with the Danes; but the action of British ministers, who realized the danger to British supremacy at sea of the growth of German sea power in the Baltic, was hampered by the natural sympathy of Queen Victoria and the prince consort with the German point of view.[1] The result was that the German diet, on the motion of Bismarck, having threatened federal intervention (July 29), Frederick VII abolished the general constitution so far as it affected Holstein and Lauenburg, while retaining it for Denmark and Schleswig (Nov. 6).

CRISIS OF 1863-64

Though even this concession violated the principle of the "indissoluble union" of the duchies, the German diet, fully occupied at home, determined to refrain from further action till the Danish parliament should make another effort to pass a law or budget affecting the whole kingdom without consulting the estates of the duchies. This contingency arose in July 1860, and in the spring of the following year the estates were once more at open odds with the Danish government. The German diet now prepared for armed intervention; but it was in no condition to carry out its threats, and Denmark decided, on the advice of Great Britain, to ignore it and open negotiations directly with Prussia and Austria as independent powers. These demanded the restoration of the union between the duchies, a question beyond the competence of the confederation. Denmark replied with a refusal to recognize the right of any foreign power to interfere in its relations with Schleswig; to which Austria, anxious to conciliate the smaller German princes, responded with a vigorous protest against Danish infringements of the compact of 1852. Lord John Russell now intervened, on behalf of Great Britain, with a proposal for a settlement of the whole question on the basis of

[1] *See* Queen Victoria to Lord Malmesbury, May 1, 1858, in ***Letters,*** iii, 280, pop. ed. (1908). Compare the letters to Palmerston of June 21, 1849, ii, 222, and June 22, 1850, ii, 279, with Palmerston to Russell, June 23, 1850, and Queen Victoria to Russell, ii, zjo.

the independence of the duchies under the Danish crown.[1] This was accepted by Russia and by the German great powers, and Denmark found itself isolated. The international situation, however. favoured a bold attitude, and Denmark met the representations of the powers with flat defiance. The retention of Schleswig as an integral part of the monarchy was to it a matter of life and death; the German confederation had made the terms of the protocol of 1852, defining the intimate relations between the duchies, the excuse for interference in the internal affairs of Denmark: and on March 30, 1863. a royal proclamation was published at Copenhagen repudiating the compacts of 1852, and, by defining the separate position of Holstein in the Danish monarchy, negativing the claims of Germany upon Schleswig.[2]

Danish Constitution of 1863.—The reply of the German diet was a note to Copenhagen (July 9) demanding, on pain of federal execution. the withdrawal of the proclamation and the grant of a constitution based on the compacts of 1852 or on the British note of Sept. 24, 1862. Instead King Frederick VII issued, on Sept. 28, 1863, a new constitution for "our kingdom of Denmark-Slesvig." which. encouraged by the hesitating attitude of the German diet, the Danish parliament passed on Nov. 13. Two days later Frederick VII died.

The "protocol-king." Christian IX, who now ascended the throne, was in a difficult position. The first act he was called upon to perform was to sign the new constitution. To sign was to violate the terms of the very protocol which was his title to reign; to refuse to sign was to defy the sentiment of his Danish subjects. He chose what seemed the remoter evil. and on Nov. 18 signed the constitution. The news was received in Germany with violent manifestations of anger. Frederick, duke of Augustenburg, son of the prince nho in 1852 had renounced the succession to the duchies, now claimed his rights on the ground that he had had no share in the renunciation. In Holstein an agitation in his favour had begun from the first, and this was extended to Schleswig on the terms of the new Danish constitution becoming known. His claim was enthusiastically supported by the German princes and people, and in spite of the negative attitude of Austria and Prussia the federal diet decided to occupy Holstein "pending the settlement of the succession." On Dec. 24 Saxon and Hanoverian troops marched into the duchy in the name of the German confederation and, supported by their presence and by the loyalty of the Holsteiners. the duke of Augustenburg assumed the government under the style of Duke Frederick VIII.

Attitude of Austria and Prussia.—With this "folly"—as Bismarck roundly termed it—Austria and Prussia, in the teeth of violent public opinion. would have nothing to do. for neither wished to risk a European war. It was clear to Bismarck that the two powers, as parties to the protocol of 1852, must uphold the succession as fixed by it. and that any action they might take in consequence of the violation of that compact by Denmark must be so "correct" as to deprive Europe of all excuse for interference. The publication of the new constitution by Christian IX was in itself sufficient to justify a declaration of war by the two powers as parties to the signature of the protocol. As to the ultimate outcome of their effective intervention, that could be left to the future to decide. Austria had no clear views. King William wavered between his Prussian feeling and a sentimental sympathy with the duke of Augustenburg. Bismarck alone knew exactly what he wanted, and how to attain it. "From the beginning," he said later (*Reflections,* ii, 10), "I kept annexation steadily before my eyes."

The protests of Great Britain and Russia against the action of the German diet helped Bismarck to persuade Austria that immediate action must be taken. On Dec. 28 a motion was introduced in the diet by Austria and Prussia, calling on the confederation to occupy Schlesnig as a pledge for the observance by Denmark of the compacts of 1852. This implied the recognition of the rights of Christian IX, and was indignantly rejected; whereupon the diet was informed that Austria and Prussia would act in the matter as independent European powers. The agreement between them was signed on Jan. 16, 1864. One article stated that the two powers would decide only in concert on the relations of the duchies, and that they would in no case determine the question of the succession save by mutual consent.

At this stage, had the Danes yielded to the necessities of the situation and withdrawn from Schleswig under protest, the European powers would probably have intervened, a congress mould have restored Schleswig to the Danish crown and Austria and Prussia, as European powers, would have had no choice but to prevent any attempt upon it by the duke of Holstein. To prevent this possibility Bismarck made the Copenhagen government believe that Great Britain had threatened Prussia with intervention should hostilities be opened, "though, as a matter of fact, England did nothing of the kind." The cynical stratagem succeeded; Denmark remained defiant; and on Feb. 1, 1864, the Austrian and Prussian forces crossed the Eider.

The Danish War.—An invasion of Denmark itself had not been part of the original program of the allies; but on Feb. 18 some Prussian hussars, in the excitement of a cavalry skirmish, crossed the frontier and occupied the village of Kolding. Bismarck determined to use this circumstance to revise the whole situation. He urged upon Austria the necessity for a strong policy, so as to settle once for all not only the question of the duchies but the wider question of the German confederation; and Austria reluctantly consented to press the war. On March 5 a fresh agreement was signed between the powers, under which the compacts of 1852 were declared to be no longer valid, and the position of the duchies within the Danish monarchy as a whole was to be made the subject of a friendly understanding. Meanwhile, honever, Lord John Russell on behalf of Great Britain, supported by Russia. France and Sweden, had intervened with a proposal that the whole question should once more be submitted to a European conference.[3] The German powers agreed on condition that the compacts of 1852 should not be taken as a basis, and that the duchies should be bound to Denmark by a personal tie only. But the proceedings of the conference, which opened at London on April 25, only revealed the inextricable tangle of the issues involved. Beust. on behalf of the confederation, demanded the recognition of the Augustenburg claimant; Austria leaned to a settlement on the lines of that of 1852; Prussia, it was increasingly clear. aimed at the acquisition of the duchies. The first step toward the realization of this latter ambition was to secure the recognition of the absolute independence of the duchies, and this Austria could only oppose at the risk of forfeiting its nhole influence in Germany. The two poners. then, agreed to demand the complete political independence of the duchies bound together by common institutions. The next move was uncertain. As to the question of annexatian Prussia would leave that open, but made it clear that any settlement must involve the complete military subordination of Schleswig-Holstein to itself. This alarmed Austria. which had no wish to see a further extension of Prussia's already overgrown power. and it began to champion the claims of the duke of Augustenburg. This contingency, however, Bismarck had foreseen and himself offered to support the claims of the duke at the conference if he would undertake to subordinate himself in all naval and military matters to Prussia, surrender Kiel for the purposes of a Prussian war harbour, give Prussia the control of the projected North sea canal and enter the Prussian customs union. On this basis. with Austria's support, the whole matter might have been arranged without—as Beust pointed out (*Mem.,* i, 272)—the increase of Prussia's power beyond the Elbe being any serious menace to Austrian influence in Germany. Fortunately, however. for Bismarck's plans. Austria's distrust of Prussia led it to oppose this settlement and at its instigation the duke of Augustenburg rejected it.

Treaty of Vienna, 1864.—On June 25 the London conference broke up without having arrived at any conclusion. On the 24th. in vien of the end of the truce, Austria and Prussia had

[1]Note of Sept. 24, 1862. For the diplomatic correspondence on the duchies see *Parl. Papers,* lxxiv (1863).

[2]For this and later correspondence see *Parl. Papers,* lxiv, p. 40 *et seq.* (1864).

[3]*Parl.* Papers, lxv, 124 *et seq.* (1864). Beust (*Mem.,* i, 252) says that Queen Victoria personally intervened to prevent British action in favour of Denmark.

arrived at a new agreement, the object of the war being now declared to be the complete separation of the duchies from Denmark. As the result of the short campaign that followed, the preliminaries of a treaty of peace were signed on Aug. 1, the king of Denmark renouncing all his rights in the duchies in favour of the emperor of Austria and the king of Prussia. The definitive treaty was signed at Vienna on Oct. 30, 1864. By art. xix a period of six years was allowed during which the inhabitants of the duchies might "opt" for Danish nationality and transfer themselves and their goods to Denmark; and the right of "indigenacy" was guaranteed to all, whether in the kingdom or the duchies, who enjoyed it at the time of the exchange of ratification of the treaty.[1]

SETTLEMENTS OF 1866 AND 1920

The Schleswig-Holstein question from this time onward became merged in the larger question of the general relations of Austria and Prussia. So far as Europe was concerned it was settled by the decisive result of the Austro-Prussian war of 1866. (*See* SEVEN WEEKS' WAR.) It survived, however, as between Danes and Germans, though narrowed down to the question of the fate of the Danish population of the northern duchy.

By art. v of the treaty of Prague (Aug. 23, 1866) Schleswig was ceded by Austria to Prussia with the reservation that "the populations of the North of Schleswig shall be again united with Denmark in the event of their expressing a desire so to be by a vote freely exercised." But the plebiscite never came, and by the treaty of Vienna of Oct. 11, 1878, the clause relating to the plebiscite was formally abrogated.

To incorporate Schleswig in the German empire, however, was one thing; to absorb its people into the German nation quite another. South Schleswig was already German; but for 50 years Germanism, backed by all the weight of the empire and imposed with the weapons of official persecution, had not held its own in north Schleswig. But the scattered outposts of Germanism could hardly be expected to acquiesce without a struggle in a situation that threatened them with social and economic extinction. Fifty years of dominance, secured by official favour. had filled them with a double measure of aggressive pride of race, and the question of the rival nationalities in Schleswig, like that in Poland, remained a source of trouble and weakness within the frontiers of the German empire.

During the years preceding World War I, the efforts to Germanize the Danish inhabitants of Schleswig continued, but only succeeded in strengthening their Danish national consciousness. In Aug. 1914 the effects of this spirit were so feared in Germany that a number of prominent Danes were imprisoned, and during the war the aspirations for union with Denmark were silenced.

On Oct. 23, 1918, however, H. P. Hanssen, a Danish representative, raised the demand for reunion in the German *reichstag;* on the same day the Danish *rigsdag* passed a resolution in favour of a readjustment of the frontier on the principles of nationality. On Nov. 28 the Danish government communicated its wishes to the Allies, and in Feb. 1919 a united Danish north Schleswig delegation was sent to the peace conference in Paris to present the Danish point of view: a plebiscite en *bloc* in north Schleswig (zone 1); a community ballot in central Schleswig and Flensburg (zone 2) and voting rights to all those born in the voting district. The peace treaty presented May 7 further provided for a plebiscite in a third zone, but this was later dropped.

On the treaty coming into force (Jan. 10, 1920) an international commission took charge of the plebiscite district. Zone 1 gave 75,431 votes for Denmark, 25,329 for Germany (Feb. 10); zone 2, 48,148 votes for Germany, 13,029 for Denmark (March 14). The frontier established by the treaty of July j, 1920, gave effect to this verdict, and restored to Denmark that part of Schleswig which lies north of the Flensburg fiord, and of a line drawn approximately west from it. On July 7 the executive power in zone 1 was handed over to Denmark.

Subsequent elections showed the line to be fairly drawn. The Danish vote polled in Germany in 1924 was 7,700—insufficient to return a Danish representative. The German votes for the *rigsdag* in 1921 and 1924 totaled 7,500, returning one member under the system of proportional representation. The treaty of Versailles imposed no special obligations upon Denmark with regard to its German minority, since the Danish constitution offered adequate safeguards; on the same grounds the Danish government declined the proposal for a special treaty with Germany for reciprocal protection of the minorities, as this might lead to interference by the government of one country in the affairs of another. The Danish government, however, offered the German minority every facility to develop its own culture, the school system of north Schleswig being reorganized with this view; parents were allowed to decide whether their children would be educated in German or Danish at primary schools, and German private schools received state grants. (W. A. P.; X.)

[1]The full text of the treaty is in La *Question du Slesvig,* p. 173 *et seq.*

SCHLEY, WINFIELD SCOTT (1839–1911), U.S. naval officer, was born at Richfields, near Frederick, Md., on Oct. 9, 1839. He graduated at the U.S. Naval academy in 1860, and during the Civil War was in active service as a lieutenant until July 1863.

In Feb. 1884 Schley was appointed to command the third Greely relief expedition, and on June 22 near Cape Sabine rescued Greely and six companions. In 1898 he was put in command of the flying squadron, with the "Brooklyn" as his flagship, for service in the war with Spain. The command of the fleet off Santiago de Cuba was taken from Schley by Acting Rear Adm. W. T. Sampson. In the battle of Santiago on July 3, Schley, in Sampson's absence, was the senior officer. In 1901 he retired from active service. At his request, because of charges made against him, a court of inquiry investigated Schley's conduct before and during the battle of Santiago; in 1901 the court pronounced Schley guilty of delay in locating Cervera's squadron, of carelessness in endangering the "Texas" by a peculiar "loop" movement or turn of the "Brooklyn" which blanketed the fire of other American vessels and of disobedience to a departmental order of May 25, but it recommended that no action be taken. He died in New York city, on Oct. 2, 1911.

SCHLICK, MORITZ (1882–1936), German philosopher and leader of the group of neopositivists who composed the Vienna circle, was born in Berlin on April 14, 1882, the son of a manufacturer. After attending the *Realgymnasium* in Berlin, he studied physics at Heidelberg, at Lausanne and at Berlin where, as a pupil of Max Planck, he obtained his doctorate of philosophy in 1904 with a thesis on physics. In 1911 he qualified for a teaching post in Rostock with a dissertation on "The Nature of Truth According to Modern Logic." In 1921 he was appointed to a post in Kiel. In 1922 Schlick went to Vienna as professor of the philosophy of the inductive sciences. His predecessors in this chair included Ernst Mach and Ludwig Boltzmann. In Vienna he gathered around him a group of philosophers, such as Rudolf Carnap, Otto Neurath and Friedrich Waismann, and of mathematicians and scientists, such as Kurt Gödel, Philipp Frank. Karl Menger and Hans Hahn, which met regularly to discuss problems of common interest. The group, the Vienna circle, was characterized by its hostility to metaphysics, by its radical empiricism, by its faith in the techniques of modern symbolic logic and by its belief that the future of philosophy lay in its becoming the logic of science. Claiming to continue the positivist tradition of Mach and Boltzmann, it was much influenced also by Bertrand Russell and by Ludwig Wittgenstein (*q.v.*). Its views were publicized in a series of books. *Schriften zur wissenschaftlichen Weltauffassung* (Vienna, 1928 ff.); and the manifesto *Wissenschaftliche Weltauffassung: der Wiener Kreis* (1929) served to organize it on a more formal basis. Making contact with philosophers of similar tendencies in other countries, it launched the international movement in philosophy which has come to be known as logical positivism. Schlick went to California in 1929 for a short period as visiting professor at Stanford university. On his return he continued to direct the activities of the Vienna circle and wrote regularly for its review *Erkenntnis.* On June 22, 1936, as he was entering the university to give his lecture, he was shot by a demented student and killed.

In his philosophical view Schlick belonged to what may be called the right wing of the Vienna circle. He did not agree with Carnap and Neurath that statements which appeared to be about mental events were all translatable into statements about physical events, nor did he accept their contention that it was metaphysical to talk of comparing statements with reality. On the contrary, he insisted always that the individual's private experience was the ultimate test of the truth of any assertion of fact. To the objection that this made it impossible to account for there being a public language, he replied that while the content of one's experience was incommunicable, its structure was not. He was thus led to the implausible conclusion that all empirical statements, insofar as they are publicly intelligible, are statements about structure. In his early days he was influenced by Kant, but he believed that the discoveries of modern physics, which he was one of the first to interpret philosophically, showed Kant's views of space and time and causality to be untenable. He also appealed to modern physics in support of the fundamental principle of the logical positivists that "the meaning of any statement turns entirely on the possibility of its empirical verification." It was from this principle that he drew the conclusion that metaphysical statements were meaningless. Metaphysics for him did not include ethics; he took a utilitarian view of ethical statements, which allowed them to be empirically verifiable. It did, however, include any attempt to characterize a transcendent reality. The philosopher, therefore, should not try to compete with the scientist. The object of philosophy was not to establish a body of philosophical propositions, but to make other propositions clear.

See also LOGICAL POSITIVISM: *Characteristic Views of the Vienna Circle.*

Schlick wrote a great many essays, of which some were collected in the posthumous *Gesammelte Aufsätze* 1926–36 (1938). His most important books were *Raum und Zeit in der gegenwärtigen Physik* (1917), 2nd ed. (1919), Eng. trans. (1920); *Allgemeine Erkenntnislehre* (1918), 2nd ed. (1925); *Fragen der Ethik* (1930); and the posthumous *Grundziige der Naturphilosophie* (1948) and *Natur und Kultur* (1952). (AD. J. A.)

SCHLIEFFEN, ALFRED, COUNT VON (1833–1913), Prussian soldier, was born on Feb. 28, 1833, in Berlin. He served in the war of 1866 against Austria and in that of 1870–71 against France as a general staff officer. In 1891 he was appointed chief of the general staff of the army. He promoted the training of general staff officers in the leading of armies, urged on technical equipment and threw his energies into the effort to equip the army with mobile heavy artillery.

On his retirement in 1907, Schlieffen put his views in writing. He was a disciple of Clausenitz, nho in his turn had deduced his doctrine of strategy from Napoleon. The essence of their doctrine is that the enemy forces should be not merely defeated but destroyed. To this end it seemed to them necessary that not only the front but the flanks and if possible the rear should be attacked. Schlieffen pushed this system to its logical conclusion. He saw Germany surrounded on all sides by enemies who, together, were far more powerful than itself. It seemed to him that the only salvation lay in opposing one of the enemies with a superior force, inflicting on him a decisive defeat, and then, using a well-developed network of railways and maneuvering on inner lines, turning upon the other enemy against whom until then a defensive attitude would have been maintained.

Schlieffen died in Berlin on Jan. 4, 1913, but in 1914—seven years after his retirement—he still played his part in the world's history; for on retiring, he had bequeathed to his successor, General Moltke the younger, the plan for deployment against France. This plan embodies his strategic convictions. It is at once immensely bold and also simple. Only the bare minimum was to remain facing the Russians; in the West the left flank was to be held back and the troops in Alsace were to withdraw behind the Rhine and face attack on the line Metz-Strasbourg. The bulk of the army was to deploy on the right flank and, pivoting on Metz, to drive forward against the line Dunkirk-Verdun. In this way the strongly fortified east front of France would be turned and the French army forced to give battle with a reversed front. The German army commander of 1914 considerably diluted the Schlieffen plan and, particularly in its execution, followed other courses. And so it was that the inspired scheme of Schlieffen did not bear the fruits which were expected.

How armies are to be handled in the Schlieffen spirit the war on the Eastern front showed. The battle of Tannenberg has very justly been called a super-Cannae, and the campaign of Lodz, the German attack against the Warsaw-Thorn line—the best-conceived operation of the whole War, which was directed solely against the right flank of the Russians—rests upon Schlieffen's ideas. The field marshal's influence on the German leadership in World War I is incontestable.

See Graf Schlieffen, *Gesammelte Schriften (1913)*; *Cannae,* selection from the above (1925). (K. VON O.)

SCHLIEMANN, HEINRICH (1822–1890), German archaeologist, was born on Jan. 6, 1822, at Neu Buckow in Mecklenburg-Schwerin. He made a fortune at the time of the Crimean War, partly as a military contractor. Happening to be in California when made a state of the union, in 1850, he became a U.S. citizen. He took his large fortune to Greece in 1868 and proceeded to visit Homeric sites. In an ensuing *book—Zthaka, der Peloponnes und Troja—he* propounded two theories: that Hissarlik, not Bunarbashi, was the site of Troy, and that the Atreid graves at Mycenae, lay within the citadel wall.

Two years later he took up Calvert's work on the former site, and, convinced that Troy must be on the lowest level, hewed his way down. regardless of the upper strata, wherein lay unseen the remains of which he was really in search. By 1873 he had laid bare considerable fortifications and other remains of a burned city of very great antiquity, and discovered a treasure of gold jewelry. We now know this city to have belonged to the middle pre-Mycenaean period, long prior to the generation of Homer's Archaeans, but Schliemann proclaimed it Troy.

Trying to resume his work in Feb. 1874, he found himself inhibited by the Ottoman government, whose allotted share of the gold treasure had not been satisfactory, and it was not till April 1876 that he obtained a *firman.* During the delay he issued his *Troy and Its Remains* (1875), and betook himself to Mycenae. There in Aug. 1876 he began work in the dome tombs and by the Lion Gate, and opened a large pit just within the citadel. The famous double ring of slabs and certain stone reliefs came to light. Schliemann, thinking it was only a platform leveled as a place of Achaean assembly, paused, and did not resume till November. Then he cleared away some three feet more of earth and stones, and lighted on the five shaft graves.

A sixth grave was found immediately after his departure. The immense treasure of gold, silver, bronze, fine stone and ivory objects. which was buried with the 16 corpses in this circle, is worth intrinsically more than any treasure trove known to have been found in any land, and it revealed once for all the character of a great civilization preceding the Hellenic. The discoverer, publishing his *Mycenae* in English in 1877, had his full share of honours and fame. He had now settled in Athens.

In 1878 he dug unsuccessfully in Ithaca, and in the same year and the following resumed work at Hissarlik, and summed up his results in *Ilios,* upon which a sequel, *Troja* (1884) was a considerable improvement. In 1880 and 1881 Schliemann cleared out the ruined dome tomb of Orchomenus, finding little except remains of its beautiful ceiling; in 1885, with W. Dorpfeld, he laid bare the upper stratum on the rock of Tiryns, presenting scholars with a complete ground plan of a Mycenaean palace.

While Tsountas, for the Greek Archaeological society, picked up his work at Mycenae in 1886, and gradually cleared the Acropolis with notable results, Schliemann tried for traces of the Caesareum at Alexandria, of the palace of Minos at Knossos, in Crete, and of the Aphrodite temple at Cythera (1888); but he was not successful.

In 1889 he entertained at Hissarlik a committee of archaeological experts, deputed to examine Botticher's contention that the ruins represented not a city, but a cremation necropolis. He was planning a new campaign on the site when he became ill at Naples and died on Dec. 25, 1890. (D. G. H.)

SCHLÖZER, AUGUST LUDWIG VON (1735–1809), German historian, was born at Gaggstedt, in the county of Hohenlohe-Kirchberg, on July 5, 1735. He went in 1755 to Stockholm, and afterward to Uppsala; while in Sweden he wrote in Swedish an *Essay on the General History of Trade and of Seafaring in the Most Ancient Times* (1758). In 1759 he returned to Göttingen. From 1761 to 1767 he occupied academic posts in Russia; he returned to Göttingen, retired in 1805 and died Sept. 9, 1809.

Schlözer's most important works were his *Allgemeine nordische Geschichte*, 2 vol. (1772) and his translation of the Russian chronicler Nestor to the year 980, 5 vol. (1802–1809).

SCHLÜSSELBURG (PETROKREPOST), a town of the U.S.S.R. in the Leningrad *oblast*, at the point where the Neva river issues from Lake Ladoga. Opposite the exit of the Neva are two islands, on the larger of which is a fortress, erected after its capture by Peter the Great in 1702. It received its name because Peter considered it the key (*Schlüssel*) to the sea. After the final defeat of the Swedes in his reign, it was converted into a prison for political offenders. Founded by the Novgorodians in 1323, it changed hands many times during the wars between Russia and Sweden, and after its recapture by the Swedes in 1661 was called Noteborg.

SCHLÜTER, ANDREAS (1660–1714), German sculptor, the first important baroque native master and a favourite of the Hohenzollern, was probably born in Danzig in 1660. His most remarkable work is the well-known equestrian monument of the Great Elector in Berlin (1696–1703). The general effect is closely related to the French classical style of the reign of Louis XIV. The motif of the four corner slaves is Italianate and the sculptor might have derived the ideas for their attitudes from figures of Michelangelo and Bernini. The most famous example of his religious work is the pulpit in the Marienkirche (1703) in Berlin. The sarcophagi of King Frederick I (1713) and his queen (1705) in the cathedral are also monumental works of Schlüter's who finished them with extraordinary dispatch. A good deal of room decoration in a style bordering between the baroque and rococo is attributable to Schlüter. Schlüter, who was also an architect, designed the old post office in Berlin (1701/2–04) which was torn down in 1889. He died at St. Petersburg in 1714.

SCHMIDT, BERNHARD VOLDEMAR (1879–1935), Estonian optical instrument maker whose invention of the telescope named after him was an outstanding development in astronomical optics for the increase in dimension which it gave to the useful field and for its fine image definition (*see* PHOTOGRAPHY, CELESTIAL: *Photographic Telescopes*). Schmidt was born on the island of Naissaar near Reval (Tallin), Estonia, on March 30, 1879. After little schooling, he worked until 1898 as a telegraph operator, photographer and designer, meanwhile continuing independent studies and experiments with increasing interest in astronomy and optics. After a short period at the Chalmers institute in Goteborg, Swed., he went in 1901 to the engineering school at Mittweida in Germany for a few terms' study, but remained until 1926, installing a small workshop and observatory there. The parabolic mirrors which he made during this period and his 16-in. horizontal telescope of 1909 established his reputation as an optical technician, and he obtained several patents. In 1926 Schmidt joined the staff of the Hamburg observatory at Bergedorf. During the far eastern solar eclipse expedition of 1929, he conceived the idea of a coma-free mirror system, and after initial difficulties, the first 14-in. Schmidt telescope (1:1.75) was begun at Bergedorf in 1930 and completed in 1932. *See* his "Ein lichtstarkes Komafreies Spiegel-system," *Mitteilungen der Hamburger Sternwarte in Bergedorf*, no. 36 (1931). Schmidt died at Bergedorf on Dec. 1, 1935. His optical system has proved its efficiency in various technical fields, including that of television projection.

SCHMIDT, WILHELM (1868–1954), German Roman Catholic priest and anthropologist, the leader of an influential school of ethnology, was born, Feb. 16, 1868, in Horde, Westphalia. He was educated at a seminary in the Netherlands and at the universities of Berlin and Vienna. A member of the Society of the Divine Word, Father Schmidt taught ethnology and linguistics at St. Gabriel's seminary at Wien-Mödling, Aust., 1895–1938, and at the universities of Vienna and Fribourg (Switz.). He began his career in linguistics and soon broadened it to include ethnology, joining the culture-historical (*Kulturkreis* or "culture circle") movement founded by F. Ratzel, F. Graebner and B. Ankermann, of which he eventually became leader. Schmidt vigorously opposed the evolutionism of L. H. Morgan, E. B. Tylor and H. Spencer. Following the lead of Andrew Lang, Schmidt challenged the evolutionists' theory of the development of religion, and maintained in *Der Ursprung der Gottesidee* ("The Origin of the Idea of God," 12 vol., 1912–55), his principal work, and in *The Origin and Growth of Religion* (1931), that the most primitive peoples believed in a supreme being. In 1906 he founded the Anthropos institute and its journal, *Anthropos*. His philosophy of ethnology was expounded in *The Culture Historical Method of Ethnology*, translated by S. Sieber (1939).

Schmidt died on Feb. 10, 1954, in Fribourg, Switz.

W.)

SCHMIDT-ROTTLUFF, KARL (1884–), German painter and graphic artist and an important figure in the Expressionist movement, was born in Rottluff near Chemnitz on Dec. 1, 1884. Originally a student of architecture, Schmidt-Rottluff turned to painting in Dresden where he became one of the founders of *die Brücke* ("the bridge")—an influential group of artists in the initial years of Expressionism. His finest work is characterized by a dynamism of brilliant colour and boldness of cubic form. His religious woodcuts, done immediately after World War I, were inspired by African sculpture. They are characterized by a power of religious statement that could not have been achieved with traditionalistic liturgical art forms.

See Will Grohmann, *Karl Schmidt-Rottluff* (1956). (P. H. S.)

SCHMITT, FLORENT (1870–1958), French composer, known for his orchestral works, was born at Blâmont, Meurthe-et Moselle, Sept. 28, 1870. He studied at Nancy and in 1889 entered the Paris Conservatoire, where he was a pupil of Massenet and Fauré. In 1900 he won the Prix de Rome with his lyric scene *Sémiramis* and later traveled throughout Europe. His reputation was established with the *Psaume XLVI* (1906) for chorus and orchestra, the ballet, *La Tragédie de Salomé* (1907) and a piano quintet (1908). Between 1894 and 1950 he wrote many orchestral works, showing a bold sense of orchestral colou., and including *Antoine et Cléopâtre* (1920), *Mirages* (1924) and *Salammbô* (1927). Among his piano works, several of which he orchestrated, are the *Reflets d'Allemagne* (1905). He wrote unaccompanied choral works and chamber works, including the *Suite en rocaille* (1935), *A tour d'anches* (1947), quartets for woodwind instruments and for brass, and a sextet for clarinets. He died, Aug. 17, 1958, at Neuilly-sur-Seine.

See Yves Hucher, *Florent Schmitt* (1953).

SCHMOLLER, GUSTAV VON (1838–1917) noted German economist, was born in Heilbronn, Württemberg, June 24, 1838. He taught successively at the universities of Halle, Strassbourg and Berlin and became the leader of the "younger historical school," which emphasized empirical research and the historical background of contemporary economic phenomena, wanting to give economics an ethical foundation. He stood in contrast to the neoclassical school that emphasized deductive reasoning, searched for timeless economic laws and refrained from making value judgments. Moderately liberal in his views on policy, Schmoller criticized the socialists while asserting that the socialist movement must be understood as a reaction to the evils of unregulated capitalism. As an academic teacher, Schmoller inspired a great deal of valuable research, especially in economic history; on the other hand, his influence was largely responsible for the neglect of economic theory at German universities up to the 1920s. Next to economic history, Schmoller's favourite object of research was the administrative technique of the Prussian state. Schmoller was a co-founder and guiding spirit of the largest professional organization of German economists, the Verein für Sozialpolitik ("Association for Social Welfare Policy"). He was also a member of the Prussian Academy of Sciences and of the upper chamber of the Prussian diet. He died in Bad Harzburg on June 27, 1917.

Among Schmoller's numerous writings are the following: *Zur Geschichte der deutschen Kleingewerbe im 19. Jahrhundert* (1869); "Zur Methodologie der Staats- und Socialwissenschaften" (against Menger) in *Jahrbuch für Gesetzgebung und Verwaltung* (1883); *Über einige Grundfragen der Sozialpolitik und der Volkswirtschaftslehre,* a collection containing the article against von Treitschske (1898); *Grundriss der allgemeinen Volkswirtschaftslehre* (1901). He was co-editor of *Acta Borussica.*

See Richard Bahr, *Gustav Schmoller* (1909). (C. L.)

SCHMUCKER, SAMUEL SIMON (1799–1873), U.S. theologian, a leading theologian of the American Lutheran Church during the period of the development of an indigenous type of liberal Lutheranism, was born at Hagerstown, Md., on Feb. 28, 1799. He was educated at first under private tutors and then at the University of Pennsylvania and at Princeton seminary. Schmucker fostered a strongly pietistic emphasis, moving on to a prophetic ecumenical spirit. He was a pioneer in the establishment of a first united Lutheran Church of district synods in America, the General Synod (1820); he became the first theological professor in Gettysburg seminary, an institution he helped to promote; and he founded a classical school that later became Gettysburg college.

Constitutions for churches and district synods, liturgies, hymnbooks and editions of Luther's catechisms (with his own freer interpretations) were only a few of his numerous works. In 1834 appeared his *Elements of Popular Theology,* a first systematic treatment in English of Lutheran theology in America. In 1838 was published his *Appeal to the American Churches,* outlining a plan of church fraternity, a forerunner of the Federal Council of Churches which came years later. When the Evangelical Alliance was organized in 1846 he played a major role.

What has been called the crisis in American Lutheran theology centred about Schmucker's name, particularly in an anonymous pamphlet which he caused to circulate entitled *Definite Synodical Platform* in 1855. This document proposed an amended and abridged form of the Augsburg Confession as a confessional statement for the American Lutheran Churches. The incentive to its publication lay in the pressure groups of conservative Lutheran immigrants, who, in increasing numbers, began to flood the American scene, calling for a return to a stricter allegiance to the Lutheran Confessions of the 16th century. Schmucker went down to defeat, and with him the tender plant of "American Lutheranism," the term given to the liberal movement he had so strongly nurtured. He died on July 26, 1873. (V. F.)

SCHNABEL, ARTUR (1882–1951), Austrian-born pianist and composer, known for his masterly interpretations of Beethoven, was born at Lipnik, near Bielitz-Biala, Aust., April 17, 1882. From about 1892 to 1897 he studied the piano with T. Leschetizky and theory with E. Mandyczewski in Vienna. His first performance was given in 1893 at Bielitz. After giving recitals in Vienna and Berlin he became the accompanist of the singer Therese Behr, whom he married in 1905. From 1919 to 1933 he taught at the Hochschule für Musik at Berlin. During this period his performances throughout Europe and the United States of the works of Beethoven, particularly the late sonatas, became known for their intellectual grasp of Beethoven's forms. His repertory also included Mozart, Schubert, Schumann and Brahms. He settled in London in 1934 and moved to the United States in 1939, becoming naturalized five years later. His own compositions, which show the influence of Schoenberg, include three symphonies, an orchestral rhapsody, five string quartets and some piano pieces. He also edited Beethoven's sonatas and published books on musical aesthetics. He died at Axenheim, Switz., on Aug. 15, 1951.

See C. Saerchinger, *Artur Schnabel* (1957).

SCHNEIDEMÜHL (Polish PILA), the capital town of the former Prussian province of Grenzmark, Ger., now in state of Poznan, Pol., on the Cüddow, 60 mi. N. of Posen and 145 mi. N.E. of Berlin on the main line to Königsberg, and at the junction of lines to Stargard and Thorn. Pop. (1950) 21,100. Schneidemühl has a trade in wood, grain and potatoes and possesses iron foundries, a brewery and machine shops, and manufactures cement, starch and bricks. It is the seat of the provincial law courts.

SCHNITZLER, ARTHUR (1862–1931), Austrian playwright and novelist, was born in Vienna on May 15, 1862. He took a medical degree, and practised for a time as a physician. Schnitzler's first and one of his most characteristic pieces was his *Anatol* (1893, Eng. trans. 1911), a series of sketches of the love adventures of a rich young Viennese. Nearly all Schnitzler's gifts are revealed in this series: a limpid style, a strong but never exaggerated sense of humour, an inimitably light touch and above all, a gift of characterization. Other plays in the same style are *Liebelei* (1895, Eng. trans. 1914) and *Freiwild* (1896), each striking a more tragic note in the fate of the "sweet little girl" round whom Viennese romance centres, and *Reigen* (1920), a series describing Viennese amours in great detail. The best of his early stories are *Sterben* (1895), describing the decline of a tubercular, and *Leutnant Gustl* (1901), portraying the kindly but stupid soul of the Austrian subaltern with deadly accuracy. His one long novel *Der Weg ins Freie* revealed his limitations, still more marked in his long romantic play *Der junge Medardus* (1920). Notable are the stories *Die griechische Tänzerin* (1904), *Casanovas Heimfahrt* (1918, Eng. trans. 1922) and *Fräulein Else* (1924, Eng. trans. 1925) and the play *Professor Bernhardi* (1913). In his later period, Schnitzler at times left Vienna to deal with such subjects as the life and adventures of Casanova, but he remained happiest in describing his Viennese. His verse, while polished and brilliant, gives less scope to his talents than his prose. Among his later works are *Beatrice* (Eng. trans. 1926), *Buch der Sprüche und Bedecken* (1927) and *Daybreak* (Eng. trans. 1928). (C. A. M.)

SCHNORR VON CAROLSFELD, JULIUS (1794–1872), German painter, was born on March 26, 1794, at Leipzig, where he received his earliest instruction from his father, Hans Veit Schnorr (1764–1841), a draftsman, engraver and painter. In 1818 he followed the founders of the new school of German Pre-Raphaelites in the general pilgrimage to Rome. This school of religious and romantic art abjured modern styles and set itself to recover fresco painting and "monumental art." Together with Cornelius, Overbeck and Veit, Schnorr received a commission to decorate the entrance hall of the Villa Massimi with frescoes after Ariosto. In 1825 he left Rome, settled in Munich, entered the service of King Ludwig and transplanted to Germany the art of wall painting learned in Italy. Schnorr published a pictorial Bible, with about 200 pictures, in 1852–60; it does not bear comparison with Raphael's Bible. He also made designs, carried out in the royal factory at Munich, for windows in Glasgow cathedral and in St. Paul's cathedral, London. He died on May 24, 1872.

His son, LUDWIG SCHNORR VON CAROLSFELD (1836–1865), was a singer, well known for his interpretation of Wagnerian parts. He created the role of Tristan.

SCHOBER, JOHANN (1874–1932), Austrian politician, was born and educated in upper Austria, entering the Imperial Austrian police service as a young man, and became the Austrian president of police in 1918, some months before the revolution. On the proclamation of the Austrian republic (Nov. 12, 1918), Schober immediately placed his force at the disposal of the new government, and by this action and by his moderate conduct in general did much to ensure a peaceful and bloodless change of regime. At the same time, he succeeded in securing the safety of the ex-imperial family, whose departure from Vienna he supervised. During the two years of social democratic government which followed, Schober's force was reproached by extremists with being reactionary, quite unjustly, as he aimed at strict impartiality. his administrative ability, and above all, his conspicuous honesty, gained him the confidence of all moderate opinion in Austria, and especially of the inter-allied missions and advisers. Because he was known to enjoy this confidence it was expected that if he were chancellor, the Allied and Associate Powers would be willing to grant the loan necessary to restore Austria's chaotic finances, and he was selected to form a non-party ministry in June 1921. He took the first step toward establishing friendly relations between Austria and its neighbours when he concluded the pact of Lana with Czechoslovakia on Dec. 16, 1921 (*see* AUSTRIA). This move aroused the hostility of the pan-Germans, who formed a part of the Government coalition, and resented any pact with Czechoslovakia as putting difficulties in the way of the ultimate *Anschluss* with Germany. They withdrew from the Government coalition. The Christian Socialists were not strong enough to govern alone against the opposition of the Social Democrats. On May 24, 1922, Schober resigned the chancellorship and returned to the post of president of police.

Sre O. Kleinschmied, *Schober* (Wien, 1930).

SCHOBERT, JOHANN (*c.* 1720–1767), German composer and harpsichord player, was brought up at Strasbourg but settled in Paris in 1760, where he held an appointment under the Prince de Conti. He was one of the most popular players of the harpsichord of his time, and is praised by Mozart and by Grimm. He left a large number of agreeable "sonatas" for harpsichord, with and without the accompaniment of other instruments; also six "sinfonies" for clarinet and two horns. These were published and much played in London as well as in Paris. A selection is included in vol. xxxix., of *Denkmäler deutscher Tonkunst* (1909).

See also the article *Jean Schobert* by Georges de Saint-Fois in the *Revue musicale* of Aug 1922.

SCHOFIELD, JQHN MCALLISTER (1831–1906), American soldier, was born at Gerry, Chautauqua county (N Y.), on Sept. 29, 1831. He graduated at West Point in 1853, served for two years in the artillery. and was an assistant professor of philosophy at West Point in 1855–60. When the Civil War broke out he became a major in a Missouri volunteer regiment and served as chief of staff to Maj.-Gen. Nathaniel Lyon until the death of that officer. In 1864, as commander of the Army of the Ohio, he took part in the Atlanta campaign under Maj -Gen. W. T. Sherman. In Oct. 1864 he was sent to Tennessee to join Maj.-Gen G. H. Thomas in opposing Gen. J. B. Hood, and on Nov. 30 he fought with Gen. Hood the desperate indecisive battle of Franklin He was awarded the rank of brigadier-general (Nov. 1864) and the brevet rank of major-general (March, 1865) in the regular army. He co-operated with Sherman in North Carolina in the spring of 1865 with great skill and distinction.

After the war he was sent on a special diplomatic mission to France, on account of the presence of French troops in Mexico. From June 1868 to March 1569 he served as secretary of war under President Andrew Johnson, after the retirement of E. M. Stanton (*q.v.*). From 1876 to 1881 he was superintendent of the Military Academy at West Point, and from 1888 until his retirement in 1895 he was commanding general of the United States Army He died at St. Augustine (Fla.) on March 4, 1906. Gen. Schofield published *Forty-Six* years in *the Army* (1897).

SCHOLASTICISM, the name usually employed to denote the most typical products of mediaevai thought, and commonly employed with differing shades of meaning down to modern times when its application has become fixed in accordance with the latest views of modern philosophy. These views are so far-reaching and complicated that the present article will be confined to an historical sketch of Scholasticism merely, and the reader is referred to the bibliography for details of modern publications on the subject.

After the centuries of intellectual darkness which followed upon the closing of the philosophical schools in Athens (529), and the death of Boetius, the last of the ancient philosophers, the first symptoms of renewed intellectual activity appear contemporaneously with the consolidation of the empire of the West in the hands of Charlemagne. He endedvoured to attract to his court the best scholars of Britain and Ireland, and by imoerial decree (787) commanded the establishment of schools in connection with every abbey in his realms. Peter of Pisa and Alcuin of York were his advisers, and under their care the opposition long supposed to exist between godliness and secular learning speedily disappeared. Besides the celebrated school of the Palace, where Alcuin had among his hearers the members of the imperial family and the dignitaries of the empire as well as talented youths of humbler origin, we hear of the episcopal schools of Lyons, Orleans and St. Denis, the cloister schools of St. Martin of Tours, of Fulda, Corbie, Fontenelle and many others, besides the older monasteries of St. Gall and Rcichenau. These schools became the centres of mediaeval learning and speculation, and from them the name Scholasticism is derived (*cf.* Sandys, *Hist. of Class. Schol.*, i. 471, 1906). They were designed to communicate instruction in the seven liberal arts which constituted the educational curriculum of the middle ages (*See* TRIVIUM) The name *doctor scholasticus* was applied originally to any teacher in such an ecclesiastical gymnasium, but gradually the study of dialectic or logic overshadowed the more elementary disciplines, and the general acceptation of "doctor" came to be one who occupied himself with the teaching of logic. The philosophy of the later Scholastics is more extended in its scope; but to the end of the mediaeval period philosophy centres in the discussion of the same logical problems which began to agitate the teachers of the 9th and 10th centuries.

Chronological Limits.—Scholasticism in the widest sense thus extends from the 9th to the end of the 14th or the beginning of the 1 jth century—from Erigena to Occam and his followers. The belated Scholastics who lingered beyond the last mentioned date served only as marks for the obloquy heaped upon the schools by the men of the new time. Erigena is really of the spiritual kindred of the Neoplatonists and Christian mystics rather than of the typical Scholastic doctors, and, in fact, the activity of Scholasticism is mainly confined within the limits of the 11th and the 14th centuries. It is divisible into two well-marked periods—the first extending to the end of the 12th century and embracing as its chief names Roscellinus, Anselm, William of Champeaux and Abélard, while the second extended from the beginning of the 13th century to the Renaissance and the general distraction of men's thoughts from the problems and methods of Scholasticism. In this second period the names of Albertus Magnus, Thomas Aquinas and Duns Scotus (qq *v.*) represent (in the 13th century and the first years of the 14th century) the culmination of Scholastic thought and its consolidation into system.

Prnntl says that there is no such thing as philosophy in the middle ages; there are only logic and theology. The remark overlooks two facts—firstly that the main objects of theology and philosophy are identical, though the method of treatment is different, and secondly that logical discussion commonly leads up to metaphysical problems, and that this was pre-eminently the case with the logic of the Schoolmen. But the saying draws attention to the two great influences which shaped mediaeval thought—the tradition of ancient logic and the system of Christian theology. Scholasticism opens with a discussion of certain points in the Aristotelian logic; it speedily begins to apply its logical distinctions to the doctrines of the church; and when it attains its full stature in St. Thomas it has, with the exception of certain mysteries, rationalized or Aristotelianized the whole churchly system. Or we might say with equal truth that the philosophy of St. Thomas is Xristotle Christianized. The Schoolmen contemplate the universe of nature and man not with their own eyes but in the glass of Aristotelian formulae Their chief works are in the shape of commentaries upon the writings of "the philosopher" (Aristotle). Their problems and solutions alike spring from the master's dicta—from the need of reconciling these with one another and with the conclusions of Christian theology.

Reason and Authority.—The fact that the channels of thought during the middle ages were determined in this way is usually expressed by saying that reason in the middle age is subject to authority. It has not the free play which characterizes its activity in Greece and in the philosophy of modern times. Its conclusions are predetermined, and the initiative of the individual thinker is almost confined, therefore, to formal details in the treatment of his thesis. To the church, reason is the handmaid of faith (*ancilla fidei*). But this principle of the subordination of the reason wears a different aspect according to the century and writer referred to. In Scotus Erigena, at the beginning of the Scholastic era, there is no such subordination contemplated, because philosophy and theology in his work are in implicit unity. "Conficitur inde veram esse philosophiam veram religionem, conversimque veram religionem esse veram philosophiam" (De *divina praedestinatione,* Proem). Reason in its own strength and with its own instruments evolves a system of the universe which coincides, according to Erigena, with the teaching of Scripture. For Erigena, therefore, the speculative reason is the supreme arbiter; and in accordance with its results the utterances of Scripture and of the church have not infrequently to be subjected to an allegorical or mystical interpretation. But this is only to say again that Erigena is more of a Neoplatonist than a Scholastic. Hence Cousin suggested in respect of this point a threefold chronological division—at the outset the absolute subordination of philosophy to theology, then the period of their alliance, and finally the beginning of their separation. In other words, we note philosophy gradually extending its claims. Dialectic is, to begin with, a merely secular art, and only by degrees are its terms and distinctions applied to the subject-matter of theology. The early results of the application, in the hands of Berengarius and Roscellinus, did not seem favourable to Christian orthodoxy. Hence the strength with which a champion of the faith like Anselm insists on the subordination of reason. To Bernard of Clairvaux and many other churchmen the application of dialectic to the things of faith appears as dangerous as it is impious. Later, in the systems of the great Schoolmen, the rights of reason are fully established and acknowledged. The relation of reason and faith remains external, and certain doctrines—an increasing number as time goes on—are withdrawn from the sphere of reason. But with these exceptions the two march side by side; they establish by different means the same results. For the conflicts which accompanied the first intrusion of philosophy into the theological domain more profound and cautious thinkers with a far ampler apparatus of knowledge had substituted a harmony. "The constant effort of Scholasticism to be at once philosophy and theology" seemed at last satisfactcrily realized. But the further progress of Scholastic thought consisted in a withdrawal of doctrine after doctrine from the possibility of rational proof and their relegation to the sphere of faith. Indeed, no sooner was the harmony apparently established by Aquinas than Duns Scotus began this negative criticism, which is carried much farther by William of Occam. But this is equivalent to a confession that Scholasticism had failed in its task, which was to rationalize the doctrines of the church. The Aristotelian form refused to fit a matter for which it was never intended; the matter of Christian theology refused to be forced into an alien form. The end of the period was thus brought about by the internal decay of its method and principles quite as much as by the variety of external causes which contributed to transfer men's interests to other subiects.

BIBLIOGRAPHY.—Besides the numerous works quoted in articles on the individual philosophers, *see* Haureau, *Histoire de la philosophie scolastique* (2 vols., 1850; revised and expanded in 1870 as *Histoire de la phil. scol.),* Kaulich, *Geschichte d. schol. Philosophie* (1863); Stockl, *Gesch. der Phil. des Mittelalters* (3 vols., 1864–66); Karl Werner, *Die Scholastik des spateren Mittelalters* (4 vols., 1881–87); and, on a smaller scale, de Wulf's *Histoire de la phil. médiévale* (1900; 5th ed., 1924–25). Supplementary details are given in Hauréau's *Singularités historiques et litte'raires* (1861) and in R. L. Poole's *Illustrations of the History of Mediaeval Thought* (1884), while much light is thrown upon the minuter history of the period by the *Chartularium Universitatis Parisiensis* edited by Denifle and Chatelain in 1894, by Hauréau's *Notices et extraits de quelques MS. latins de la Bibliothlque Nationale* (6 vols., 1890–1895) and by the *Beiträge zur Geschichte d. Phil. d. Mittelalters.* The accounts of mediaeval thought by Ritter, Erdmann, Ueberweg and Windelband are very good. There are also notices of the leading systems in Milman's *History of Latin Christianity* (6 vols., 1854–55). The psychology of the Scholastic writers is ably dealt with in Siebeck's *Die Psychologie von Aristoteles bis zu Thomas von Aquino* (1885). Jourdain's *Recherches critiques sur l'âge et l'origine des traductions latines d'Aristote* (1819; 2nd ed. 1843); Rousselot's *Études sur la philosophie dans le moyen âge* (1840–1842), Cousin's Introduction to his *Ouvrages inédits d'Abélard* (1836), and Prantl's *Geschichte der Logik im Abendlande* (4 vols., 1855–1870) are invaluable aids in studying the history of mediaeval thought. For modem views *see* C. Baeumker, *Abhandlungen zur Geschichte der Philosophie des Mittelalters* (1923); G. Ritter, *Studien zur Spätscholastik* (1921, etc.); A. C. A. Schneider, *Die Erkenntnislehre bei Beginn der Scholastik* (1921); H. O. Taylor, *The Mediaeval Mind,* 2 vols. (1925); O. Wichmann, *Die Scholastiker* (1921); N. de Wulf, *Histoire de la philosophie médiévale* (1924, etc.).

SCHOLIUM (to be distinguished from *Scolium,* an after-dinner song), the name given to grammatical, critical and explanatory notes, extracted from existing commentaries and inserted on the margin of the m.s. of an ancient author. These notes were altered by successive copyists and owners of the m.s. and in some cases increased to such an extent that there was no longer room for them in the margin, and it became necessary to make them into a separate work. The name of "the first scholiast" has been given to Didymus of Alexandria (see DIDYMUS CHALCENTERUS), and the practice of compiling scholia continued till the 15th or 16th century A.D. The word σχόλιον itself is first met with in Cicero (Ad Att. xvi, 7). The Greek scholia we possess are for the most part anonymous, the commentaries of Eustathius on Homer and Tzetzes on Lycophron being exceptions. Although frequently trifling, they contain much information not found elsewhere, and are of use for the correction and interpretation of the text. The most important are those on Homer (especially the Venetian scholia on the *Iliad,* discovered by Villoison in 1781 in the library of St. Mark), Hesiod, Pindar, Sophocles, Aristophanes and Apollonius Rhodius; and, in Latin, those of Servius on Virgil, of Acro and Porphyrio on Horace, and of Donatus on Terence.

SCHOMBERG, FRIEDRICH HERMANN (or FREDERIC ARMAND), DUKE OF (1615–1690), marshal of France and English general, was born Dec. 6, 1615, at Heidelberg, Ger.. the son of Hans Meinard von Schonberg (1582–1616) and Anne Sutton. daughter of the 5th Lord Dudley. He was educated by various friends, among whom was the "Winter King." Frederick V of the Palatinate. in whose service his father had been. He began his military career under Frederick Henry prince of Orange. and entered about 1633 into the Swedish service, and that of France in 1635. After a time he retired to his family estate at Geisenheim on the Rhine, but in 1639 he re-entered the Dutch army, in which he remained until about 1650. He then rejoined the French army as a volunteer in May 1652, served under Marshal Turenne in the campaigns against the prince of Condé, and became a lieutenant general in 1655.

After the peace of the Pyrenees (1659) Schomberg was sent as military adviser to Lisbon to assist the Portuguese in their struggle for independence from Spain. He nent with the secret approval of Charles II of England and Louis XIV, who, in order not to infringe the treaty just made with Spain, deprived Schomberg of his French offices. By winning the victory of Montes Claros on June 17. 1665, over the Spaniards under the prince of Parma he assured the independence of Portugal. He then helped to depose the reigning king in favour of his brother Dom Pedro, and then returned to France, became a naturalized Frenchman and bought the lordship of Courbet near Paris. In 1673 he was invited by Charles to England and was appointed lieutenant general to Prince Rupert. He soon returned to the French service. In 1674 his operations in Catalonia were unsuccessful because of the disobedience of subordinates and the rawness of his troops, but he retrieved this failure by retaking Bellegarde in 1675. For this he was made a marshal in the promotion that followed the death of Turenne.

The tide had now set against the Huguenots, and Schomberg's merits had been long ignored on account of his Protestantism. The revocation of the edict of Nantes (1685) compelled him to quit France, and he became in 1687 general in chief of the forces of the elector of Brandenburg. At Berlin he was the acknowledged leader of the Huguenot refugees.

In 1688. with the elector's consent, he joined the prince of Orange on his expedition to England, as second in command to the prince. The following year he was made a knight of the garter, took the naturalization oath, was created successively baron, marquess and duke in the English peerage, was appointed master general of the ordnance, and received compensation for the loss of his French estates. of which Louis had deprived him. In Aug. 1689 he commanded the expedition to Ireland against James II. After capturing Carrickfergus he marched unopposed through a country desolated before him to Dundalk, but decided not to risk a battle with his undisciplined troops, and entrenching himself at Dundalk declined to be drawn beyond the circle of his defenses. Shortly afterward pestilence broke out, and when he retired to winter quarters in Clster his forces were severely shattered. His conduct was criticized in ill-informed quarters, but the facts justified his inactivity. In the spring he began the campaign with the capture of Charlemont, but no advance southward was made until the arrival of William. At the Boyne (July 1. 1690) Schomberg gave his opinion against the determination of William to cross the river in face of the opposing army. In the battle he commanded the centre, and while riding through the river without his cuirass to rally his men. was killed by Irish horsemen. (R. B. WM.)

SCHOMBURGK, SIR ROBERT HERMANN (1804–1865), British explorer and surveyor whose "Schomburgk line" marked the boundary of British Guiana from 1841 to 1895 (*see* GUIANA: *British* Guiana), was born at Freiburg, Lower Saxony, Ger., on June 5, 1804. In 1829 he went to the United States and from there in 1831 visited Anegada, one of the British Virgin Islands. He surveyed it and noted the frequency of the wrecks, particularly of U.S. ships. which occurred upon it. In 1835 the Royal Geographical society sent Schomburgk to explore British Guiana. On this trip he discovered the giant water lily, *Victoria regia,* and in 1840 produced his *Description* of *British* Guiana. In 1841 he surveyed the colony and fixed its boundary, being knighted on his return to England in 1844. He continued his geographical surveys as British consul to Santo Domingo, non the Dominican Republic (1848), and to Bangkok (1857). Schomburgk died at Berlin on March 11, 1865.

SCHÖNBEPN, CHRISTIAN FRIEDRICH (1799–1868), German-Swiss chemist who discovered ozone, guncotton and collodion, was born at Metzingen, Swabia, on Oct. 18. 1799, and died at Sauersberg, near Baden-Baden, on Aug. 29, 1868. After studying at Tübingen and Erlangen. he taught chemistry and physics, first at Keilhau, Thuringia, and then at Epsom, Eng., but most of his life was spent at Basel, where he began to lecture on chemistry and physics in 1828 and was appointed full professor in 183j. His name is chiefly known in connection mith ozone (*q.v.*), which he discovered in 1839; with guncotton, which he prepared and applied as a propellant in firearms early in 1846; and with his discovery of collodion (1846). He also worked on the passivity of iron. the properties of hydrogen peroxide and catalysis. He was a most prolific writer. 364 papers appearing under his name in the Royal society's *Catalogue.*

Many of his letters together with a life will be found in G. W. A. Kahlbaum, *Monographien aus der Geschichte der Chemie,* vol. iv and vi (1899 and 1901). *See* also E. Farber, essay, in G. Bugge, *Buch der grossen Chemiker* (1955).

SCHÖNBERG, ARNOLD (1874–1951), Austrian composer, was born in Vienna on Sept. 13, 1874. He began to study violin and cello at an early age and to compose chamber music. In musical theory he was practically self-taught. His earlier works include songs, the string sextet, *Verklarte Nacht,* opus 4 (revised later for string orchestra with six soloists), the symphonic poem *Pelléas et Mélisande* and the *Gurrelieder,* a ballad cycle for chorus and full orchestra (first produced in Vienna 1912–13), written under the influence of the Wagner tradition.. Schonberg then came into touch with Kokoschka and other leaders of the new movement in art and literature, and entered upon an experimental period in which he put romanticism behind him and went back to Bach and the earlier polyphonic writers for inspiration. With the 2nd chamber symphony and particularly the 2nd string quartet (1908), into the last two movements oi which he introduces a soprano part to words by Stephan George, he definitely broke away from tradition; and with the piano pieces, opus 11, his mature period may be said to begin, although he continued to strike out new paths with each successive mork. In 1911 he went to live in Berlin and in the same year produced his *Harnzonielehre* (rev. ed., 1922). (*See* also HARMONY.)

An eventful performance was that of *Pierrot Lunaire* in Berlin in 1923 with Xlbertine Zehme in the spoken part. This cycle of 21 poems for recitation with piano, flute, clarinet, violin, and violoncello in constantly changing combinations, is, after the *Gurrelieder,* his best-known mork. In 1918, having returned to Vienna, Schonberg founded there a society for private musical performances. A revival of *Die glückliche Hand,* opus 18, at Breslau, Ger., in 1928 aroused much interest. This dramatic piece was, in spite of its early date, perhaps the most daring of Schonberg's experiments and that in which his psychology finds its clearest expression. He wrote the libretto and ordered every detail of the staging. Essentially a pioneer, he never made concessions to the ordinary listener, but the tenseness and extreme compression of this work make quite unprecedented demands on the concentrative powers of his audiences. In all his later writing the combination of a tersely dramatic and fragmentary style with complete atonality leaves an impression of complication and strain. He was, nevertheless, sincerely striving toward simplicity and compactness, and his reversion to a smaller or chamber orchestra led to a general adoption of this medium by younger composers. He also adopted a simplified method of scoring, in which duplication of parts is avoided and the whole is compressed onto a few staves. He went to the U.S. in Oct. 1933 and mas professor of music at the University of California at Los Angeles, 1936–44. He died near Los Angeles, July 13, 1951.

Other important works are: 6 songs with orchestra, opus 8 (1911); chamber symphony for 15 solo instruments, opus 9 (1912); serenade ior clarinet, bass clarinet, mandolin, guitar, three strings and (low) male voice, opus 24 (1924); *Thenze and Variations,* opus 43b (1943); *Fantasie* for violin and piano (1949). *See* E. Wellesz, *Arnold Schonberg,* Eng. tr. by W. H. Kerridge (1925); René Leibowitz, *Schoenberg and His School,* Eng. tr. by Dika Newlin (1949).

SCHÖNEBECK, a town of Germany, in the district of Magdeburg, on the left bank of the Elbe, 9 mi. S. of the city of Magdeburg by the railway to Halle and Leipzig. Pop. (1950) 46,426. It contains manufactories of chemicals, machinery, bicycles, rubber, explosives and various other articles, but is chiefly noted for its extensive salt works. Its harbour on the Elbe and factories were objects of aerial bombardment in World War II.

SCHÖNEBERG, an administrative district of Berlin, Ger., which it adjoins on the southwest. Pop. (1950) 189.260. The foundation of Alt-Schoneberg is ascribed to Albert the Bear, margrave of Brandenburg, in the 12th century, while Neu-Schöneberg was founded by Frederick the Great in 1750 to accommodate some Bohemian weavers exiled for their religion. Its chief manufactures are railway material, cigars, soap, paper and chemicals.

SCHONGAUER, MARTIN (called MARTIN SCHÖN and HIPSCH [Hubsch] MARTIN) (1445/50–1491), German engraver and painter of the early German school, was born in Colmar, Alsace, a son of the goldsmith. Caspar Schongauer from Augsburg, where the family, originally from Schongau. had been prominent for two centuries. Dates of his birth proposed in German literature after 1941, range from 1425 to 1453. In 1465 he was registered at the University of Leipzig. but apparently remained there only one semester. In view of the variance of opinion on his age, it is not clear whether he was there as a student or as a visiting artist, enjoying the university's protection from interference of the local painters' guild. That he was a student appears more likely because no work of his has ever been discovered which could with certainty be dated earlier than 1469, and because the wide distribution of his work did not get under way until the late 1470's, judging from the flood of copies mhich are dated. In 1469 his name is mentioned for the first time in the Colmar register of property. The same date appears also on three of his drawings, all obviously early works, but these dates and signatures were added by Albrecht Dürer, who may have received them from Schongauer's brothers when he arrived in Colmar the year after Martin's death. In 1488 Schongauer left Colmar and moved to Breisach, Baden. He died a bachelor in Breisach on Feb. 2. 1491, being survived by three brothers, the goldsmiths Jorg and Paulus and the painter Ludwig.

According to contemporary sources, Schongauer was a prolific painter, whose panels were sought in many countries. Few paintings by his hand survive. Among them the "Madonna in a Rose Garden" of 1473, altarpiece of the church of St. Martin in Colmar, ranks first in importance. This work strikingly combines monumentality with tenderness and is the only painting in which Schongauer approached the heights of the great Flemish painter Rogier van der Weyden by whom he was so profoundly influenced Other paintings by Schongauer include two wings of the Orliac altar (Colmar museum); six small panels among which the "Nativity"

(Berlin) and the "Holy Family" (Vienna) are the most mature; and finally the murals of the "Last Judgment" in the cathedral of Breisach, probably his last work (uncovered in 1932). The 24 panels depicting the "Joys of Mary" and the "Passion of Christ." painted for the church of the Dominicans (Colmar museum), appear to be mainly the work of his assistants.

As an engraver, however, Schongauer stands without rival in northern Europe in his time. His engraved work, consisting of about 115 plates, all signed with his monogram, is a final, highly refined and sensitive manifestation of the late Gothic spirit. Technically he brought the art of engraving to maturity by expanding its range of contrasts and textures, thus introducing a painter's viewpoint into an art which had been primarily the domain of the goldsmith's shop. The larger and more elaborate engravings,. such as the "Temptation of St. Anthony" or the "Death of the Virgin," belong to his earlier period. In his later years, he preferred smaller plates, even for subjects as the "Passion of Christ," a set of twelve engravings. Some of his most eloquent plates are single figures, such as the "Madonna in a Courtyard" or "St. Sebastian." Within the diversity of trends in German art in this period, Schongauer represents the most idealistic and aristocratic element. devoting his art mainly to Christian subjects and shunning the gross and often bawdy humorous realism of some of his fellow engravers. The sensitive grace of his work became proverbial even in his lifetime and gave rise to such names as "Hübsch Martin" or "Schon Martin" ("Bel Martino" in Italian), whereby the adjective "Schon" became often confused with the artist's real family name. Schongauer's engravings are well represented in the print rooms of the larger museums of Europe as well as numerous C.S. museums (New York, Boston, Chicago, Cincinnati, Cleveland and Washington, D.C.).

(H. JM.)

SCHÖNHERR, KARL (1867–1943), Austrian dramatist, was born at Axams, Tirol, Feb. 24, 1867. His first works were published in 1895. These were dialect poems of an unassuming nature and short stories; in 1897 he turned his attention to drama and the stage with *Der Judas von Tirol* (revised in 1927). Schonherr stood midway between realism and symbolism and expressed himself in a vigorous and original style. His accomplished technique, applied frequently to peasant or medical life, enabled him to evolve successful dramas with a limited number of characters. In his plays simple emotions and the problems and crises arising out of them are presented with inexorable consistency. His most famous drama *Glaube und Heimat* (1910), dealing with the time of the Counter-Reformation, and also *Der Weibsteufel* (1914), aroused religious controversy. Schonherr's other important works include *Die Bildschnitzer* (1900); *Erde* (1908); *Volk in Not* (1915); *Frau Suitner* (1916); *Vivat academia* (1922); *Es* (1923); *Hungerblockade* (1925). Most of his dramas were first produced in the Burgtheater and in the Deutsches Volkstheater in Vienna. Later dramas included *Der Armendoktor* (1927), *Passionsspiel* (1933) and *Die Fahne weht* (1938). His tales and sketches, *Caritas* and *Aus meinem Merkbuch,* express much the same trend of thought and motif as his dramas. His *Gesammelte Werke* appeared from 1928 onward. He died in Vienna March 16, 1943.

SCHOOL ADMINISTRATION. School administration deals with the control, management and direction of all matters affecting the school, including organization, finances, policies, personnel, curriculum and methods, standards and related areas.

In this article school administration is treated under the following headings: types of administration; national systems; local systems; joint local and national systems; sectarian systems; political party control; and trends. For information concerning school administration in various countries, states and provinces, etc., not treated here, *see* the articles on those political divisions. *See* also EDUCATION, HISTORY OF.

Types of Administration.—The schools of the world are organized and administered for the most part by four agencies functioning separately or in combination: the church, the state, the political party and the private group. Of these, the church and private groups have become less powerful. In fact, the last named is now concerned almost exclusively with private schools.

Most school systems of the world are centralized; that is, they are administered by the national government. Decentralized types of administration may be classified under such headings as provincial (state), county, township, community, etc. In Communist countries much administration is determined by local or regional cultural preference. but over-all policy is governed by directives issued from party headquarters in accordance with the prevailing political philosophy.

Administration differs also with the level of education. In centralized systems of education much responsibility for the early stages of schooling is granted to local authorities, whereas secondary education tends to gravitate toward centralized control. Higher education defies generalization. Publicly controlled universities in the United States and Canada may be either local or state in nature; at the same time they are supported to a very small degree, if land-grant colleges, by the federal government. In Great Britain both private and civic universities are dependent upon public funds but remain autonomous. Governmental influences are strong in French, Spanish, Italian and Latin-American universities, while in countries similar to the Soviet Union, universities are controlled by the Communist party, trade and professional unions, and various governmental departments.

National *Systems.* — *France.* — *The* classic example of a national system of education is that of France. Its administrative structure was originated by Napoleon in 1802. The country is divided into politico-educational units decreasing in size from *académies* to *départements* to communes. Each of the 17 *académies* is headed by a university. The chief administrator of both the university and the *acade'mie* is called a rector, who is appointed from the ranks of university professors by the president of France on recommendation of the national minister of education. He is responsible primarily for secondary and higher education within his *académie;* he nominates candidates for administrative positions in his area, appoints examination committees, supervises examination content and procedures and presides over a sort of personal cabinet called an academic council. Unlike political divisions in such countries as Australia, Canada, the United States and west Germany, the *académies* have little power or authority of their own; rather, they are administrative arms of the national ministry of education; they represent a devolution rather than a delegation of power from the central government. The 97 *départements* are likewise administrative units governed by prefects who are appointed in Paris. The prefect heads the elementary school system, acting in a manner similar to the rector. The prefect, too, has an advisory council, appointive in nature, and by no means equivalent to local boards of education in such countries as the United States and Canada. *Départements* are empowered to levy subsidiary school taxes as approved by the national government; in the early 1960s about half the cost of *département* schooling was met by local taxation. *Départements* are also permitted to provide further school services, on approval of higher authorities, including additional emoluments for teachers. There are about 38,000 communes, varying in size from the smallest community to the city of Paris. The chief officer of the commune is the mayor, who is likewise the president of the commune school board. Again, these school boards are largely advisory in nature; they also see to it that national and *département* educational procedures and policies are carried out in their particular area; they have only minor administrative responsibilities and can initiate very little school legislation and practice. In practice, the *département* prefect assumes much of the control over education in the commune, as such control is derived from higher authorities.

The French educational system is also characterized by a pyramid of bureaus which reach their apex in the ministry of national education in Paris. As in all national systems, even including Great Britain, the minister of education is a political appointee of the prime minister, and he usually falls when his government falls. Practical control is exercised by a powerful and permanent civil service, which remains relatively unaffected by political changes. The ministry of education consists of five directorates: general administration; elementary; secondary; technical; and higher education. The minister is assisted by a higher council of national education, consisting of 56 members appointed in part by the president of the republic and the minister of education and elected in part by the universities and representatives of elementary and secondary education. Although its primary function is advisory in nature, the higher council is really a sort of educational parliament, in that the minister is required to consult its members and secure their approval in nearly all major matters of educational policy and procedure. A corps of inspectors general. appointed by the ministry of education, reports on progress and needs in all areas. Although some determination of school practices is allowed local governments, especially in matters involving purely internal conduct. the responsibility for education is actually not delegated, as in such countries as the United States. Great Britain and Canada. Administration is a sort of "line and staff" arrangement ordered in such a way that directives may readily be executed by subordinate officers.

Other National Systems.—National systems of education prevail in Belgium, the Netherlands. Greece. Scandinavia and other countries where centralized controls are geographically practical and strategic; the middle east (Turkey, Iraq, Syria. Egypt. etc.); most Latin-American countries; and other political systems not federal in nature. In most national systems, however, local control over educational administration increased after World War II.

An example of a different type of centralized control is Uruguay. The highest administrative agency is the ministry of public education and social welfare. but the ministry concerns itself primarily with welfare services. Educational administration falls within the province of four national autonomous educational councils: the Xational Council for Primary and Teacher Education; the National Council for Secondary and Preparatory Education; the Higher University council; and the National Council for Industrial Education, which occupies itself with agricultural, vocational and industrial schools of all types. but it is divorced from the political and ideological overtones which characterize labour educational administration in such a country as Mexico. The coexistence of these four councils in one sense illustrates a form of decentralization; since the councils operate on a national basis, however, and since their functions interlock, the resulting organization might be conceived as a type of pluralistic centralized control.

Local Systems. — Included in local systems are state. provincial. county and community types of school administration. Local emphases in administration are to be found in countries where public schooling originated in grass roots or separatist movements, or where political unity was achieved out of a confederation of sovereign states. In some instances of federalization. as in Italy and to some extent Switzerland, a central ministry has been granted administrative as well as advisory power. As a rule, however, cultural and political units have jealously guarded their control over education. Characteristics of local control may be generalized thus: (1) weak central ministries or bureaus of education. which are largely advisory in character; (2) financial support for education locally derived. aid from central authorities being mostly in the form of supplementary or emergency funds accepted with a minimum amount of control; and (3) administrative power lodged in local boards of education, sometimes appointed. sometimes elected. In countries like Canada. west Germany and Australia. where the separate states are sovereign, state ministers of education are appointed and state systems of inspection prevail. In the United States the state executive officer of education becomes either a commissioner of education (if appointed) or a state superintendent of schools, each with less power than his counterpart abroad.

United States. — The United States is an outstanding example of local control on state, county and community levels. The decentralization of education characteristic of U.S. schooling is a source of bewilderment to foreign observers. who seek to understand not only the many different types of state-controlled education but yet another system in the District of Columbia, administered by the federal government.

The whole is complicated by the myriads of local county, township or community units of education, by types of schooling directly supported and controlled by the federal government, and by the great variation among the states as regards internal administration and relations with local organizations. Some states, like Delaware: tend toward centralization. Massachusetts is an example of decentralization. Even in the support of education. the amount of funds provided can vary from the practice in such a state as Nebraska; where in 1955, for example, about 90% of expenditures were underwritten by local authorities, to states like New Mexico where, in the same year, state rather than local revenues paid for most public schooling. In addition to the various state public-school systems, there exist, outside these systems, parochial schools which are administered by church groups and a large variety of privately supported schools.

Although no mention is made of education in the United States constitution, the federal government has been mindful of the need to support formal schooling. exemplified in the Land ordinances of 1785 and 1787, by which part of the national domain was set aside for school purposes. and in the numerous federal statutes which have supported types of education (technical, military, agricultural, etc.) necessary to national welfare. The earliest federal statutes, enacted in accordance with traditional educational practices, gave control of lands and resources to local townships: but by 1804, with the Ohio Territory act, the states had accepted custodianship and assumed control of school endowments.

Education in the United States mas originally conceived as a private or local affair. If not undertaken by the family or the church, schooling became the concern of charity groups. Hence, education was considered a matter of public welfare. But the federal government did not relinquish its responsibility; acting by authority of the "general welfare clause" of the constitution (sec. 8. art. i), it required of all states joining the union that satisfactory provision for public education be stipulated in the state's constitution. By a series of supreme court decisions the federal government settled local educational disputes and in part guided the course of education in its national implications. The federal government has also supervised the educational welfare of territories. trusts and dependencies. and assumed the responsibility for educational agencies supplying the federal government with the kind of personnel and services it requires. Included in this category are the various academies and institutes which train officers and specialists for such areas as national defense, diplomacy. internal security and technology. The federal government has also supported educational relief programs, such as the National Youth administration and the Civilian Conservation corps in the 1930s.

The United States office of education was established by congress in 136;. In 1939 it was transferred from the department of the interior to the Federal Security agency. It became a branch of the department of health. education and welfare when that department was established in 1953. It is not an administrative agency in essence. although it has assumed control over certain projects supported by the federal government. such as certain programs of vocational education, exchange of students and teachers with other countries, certain aspects of land-grant college administration and the general promotion of educational thought and practice throughout the country. Specifically, its functions involve the collection, interpretation, publication and dissemination of factual information on education, not only in the U.S. but abroad. Its specialists may be drawn upon for counsel by any educational group in the country. Similar agencies exist in India, Canada. Australia, west Germany and other nations where federated governments and local controls determine educational administration.

Responsibility for education in the United States rests with the individual states. The states delegate this responsibility to the local communities, not simply as a devolution of power. as in France and other centralized systems, but as a matter of self-determination under fairly liberal state school codes. It is commonly claimed that the three levels of educational organization and administration in the U.S.—federal, state and local—are in matter of fact actually interdependent rather than hierarchic. Hence, a system of checks and balances is said to prevail in educational as well as other governmental matters. In practice. however, administration rests heavily on the shoulders of local communities and operates in accordance with local decisions, assuming such decisions accord with federal and state statutes.

On the state level. educational administration generally is headed by a state board of education, sometimes appointed by the governor or the state legislature, sometimes elected. As a rule, state boards of education are less powerful than state ministries of education in other countries, largely because local communities in the United States assume much more administrative responsibility.

However, the board of education of the state of New York, for example, exercises powerful control over educational standards through a system of state-wide examinations. The extensive ramifications of its operations are seen in the fact that its staff consists of over 500 full-time professionals. State boards range in size from 3 to 19 members. They are largely composed of laymen but in some instances professional educators may become members.

Again, the duties of these state boards vary from state to state, but in general they all concern themselves with the distribution of state or federal funds (allotted to the states), the enforcement of educational statutes, the determination of basic courses of study, the adoption or recommendation of textbooks. the certification of teachers, the approval of building and maintenance standards, the provision of library services and the operation of teachers' colleges. State boards likewise interest themselves in the improvement of education as a function of government. the equalization of educational opportunity, the provision of educational leadership and the improvement of local operations. The functions of state departments of education were defined by the White House Conference on Education, Nov. 1955, in which general agreement was reached on the following recommended types of services to be provided local districts: (1) establishment of minimum standards for an adequate educational program; (2) advisory or consultative services in such areas as population trends, transportation, school construction, financial planning. curriculum development and special services; (3) research and statistical studies of a nature to assist in long-term planning; (4) certification of teachers and professional staffs; (5) provision of "dynamic" leadership. Included in a minority report were the following recommended types of services: (1) provision of scholarships for qualified students in financial need; (2) establishment of a sound, equitable tax base among administrative units; (3) assumption of desirable services above or beyond the capabilities of local districts to provide,

Inspection of local schools and school systems by inspectors responsible to state boards or other authorities is found in many states but is not so highly developed as in most other countries. School and classroom supervision is provided by local systems through specialists who do not function as inspectors but rather "helping teachers." In one state they are officially so designated.

The genius. but also the weakness, of the U.S. educational system lies in its more than 60.000 school districts, each exercising an amount of freedom unequaled in any other country. Administrative authority is assumed by a local board of education, which in about 90% of cases is elected by the people. Boards of education are usually independent of other agencies of local government; in fact, school funds voted by boards of education are for the most part not subject to rejection by other bodies. In cases of dispute over budgets between boards of education and boards of finance, the courts have ruled almost exclusively in favour of the former. In most communities, school taxes have first priority; usually they are independent of other sources of revenue.

The duties of a local board of education are limited to community needs. The local board selects the superintendent of schools, who in turn recommends personnel for appointment by the board. In nearly all cases. boards of education have the power directly to appoint nonteaching employees. The local school board also determines the educational policy for the district, acting usually on professional advice, secured by way of the superintendent of schools and in accordance with the wishes of the community at large. The board assists the superintendent in the preparation of the budget. approval of which obligates the local board to see that tax funds are provided.

India.—India may be used as an example of local control strongly exercised by the various provinces under provincial or state ministries of education. Unlike the United States constitution, the Indian counterpart of 1947 states that the federal government will endeavour to provide free, compulsory education for all children till they reach the age of 14. Partly because the central government did not have sufficient funds to implement this ideal and partly because of the natural diversity of India's population, considerable responsibility for education has been delegated to the states. The functions of the Indian ministry of education approximate those of the United States office, but whereas the United States commissioner of education is appointed by the president, the Indian minister of education is elected by parliament and is directly responsible to that body. The state ministry of education has five divisions: (1) administration and cultural relations; (2) bureau of development; (3) general education; (4) technical education; and (5) scholarships. Delegation of authority by the states to the local communities is restricted to elementary education, as is the case in most countries. while secondary education is subject to state control. State ministers of education. like their federal counterparts, are both elected and appointed and are responsible to state legislative bodies. Indian state governments are responsible for educational policy, the local units being conceived largely as administrative and taxation units. Control over education is exercised through an inspection system.

Advising the Indian state minister of education is the director of public education, who is a permanent executive head of the ministry. He controls the inspectorial staff, the teachers and the government-recognized private schools, and is responsible for executing the policies of the ministry of education, principal among which is the inculcation of basic education through productive activity and local crafts to all children between the ages of 6 and 14.

There are great inequalities of educational opportunity in India, where population distribution, linguistic diversity and the caste system aggravate an already difficult educational situation. The Indian central government has confessed its inability to assist adequately in fostering school development, not for want of desire but from sheer financial inability. It has confined its efforts to supporting higher education and technical education, research in the interest of national welfare, experiments in educational methods, the production of suitable literature. the training of specialized personnel and the translation of important works into Indian languages. The administrative problem in India is therefore not one of where control ideally may be located but of securing the kind of educational organization and administration which will best serve a country which is as yet economically undeveloped, and where the many religions and sects insist upon tying public education to their own particular beliefs.

West Germany.—West Germany (the German Federal Republic) is another example of decentralization of administration. Art. 7 of the Basic law of the German Federal Republic (1949) places schools under the supervision of the respective states (Lander). The various states exercise fairly complete control over all schools and commit themselves to a program of close supervision in major activities. Local boards of education function everywhere. but with less power than in the United States. Again, as in similar systems, the highest administrative agency is the state ministry of education, headed by a minister of education (*Kultus*-minister), who is a political appointee. The state minister of education might be compared with the state superintendent of schools in the United States, but he also absorbs some of the duties reserved for the U.S. local superintendent of schools, exemplified by his right of control and jurisdiction over internal school practices. Co-ordination among the state school systems is achieved in part by the Conference of Educational Ministers which meets several times a year in Bonn. In 1953 a federal educational council was established to advise the Conference of hlinisters. The west German local school superintendent is appointed by the state minister of education on recommendation of the *Kultusminister*. Local school boards are not elected but are chosen by local legislatures; they are responsible only for those phases of school administration not assumed by the state. External university administration, including certain financial, academic, examination and other aspects, is exercised by the division of higher education of the state ministry of education, though the universities enjoy a large amount of autonomy.

Joint Local and National Systems.—Examples of national and local systems working co-operatively, or in partnership, are to be found in England and. to some extent, Japan.

Great Britain.—Educational administration in England was fixed by the Education act of 1944, which lodged final authority in the central ministry of education but which placed immediate administrative responsibility upon local educational authorities (L.E.A.s). (See EDUCATION, HISTORY OF: *Great* Britain *and the* Commonwealth *of Nations:* The 1944 *Act.)* The Education act sets the structure of administration and control but allows local authorities to interpret policies in accordance with local need, preference. and internal school conditions. Central authority is vested in three bodies: the ministry, the central advisory councils and the civil service: representing the political. the advisory and the professional elements of education respectively. The minister of education. appointed by the prime minister, is responsible for broad educational policy and practice within the framework of existing legislation as approved by parliament. The two Central Advisory councils (for England and Wales) advise the minister on internal matters of administration. The civil service is responsible for the communication and interpretation of broad policy at the local level. The permanent education secretary guarantees continuity of policy and operations. The "eyes and ears" of the ministry are her majesty's inspectors, better known as H.M.I.s, who are members of the civil service. The H.M.I.s have four major duties: (1) to ensure that government appropriations are being spent wisely; (2) to see that educational legislation is being complied with; (3) to act as missionaries disseminating enlightened educational thought; and (4) to keep the ministry informed on what transpires at the grass roots of education.

The L.E.A.s are not elected directly by popular vote but are appointed by county and borough councils. which are in turn elected directly by the people. Actual supervision is, however, delegated to education committees, which are appointed by the L.E.A.s out of their own membership plus a minority of non-L.E.A. members who are interested in education. One of the committee's functions, like that of a local board in the United States, is to appoint a chief education officer, usually called a director of education. The director of education enjoys less power and independence of action than the U.S. superintendent of schools, his chief function being to present proposals to his committee for decision and action, to record decisions and to carry them out. On the other hand, the headmaster of an English school, especially on the secondary level, is a more powerful and influential person than his U.S. colleague; he is given wide latitude in the formulation and execution of internal policy. As the power of the headmaster increases. it is natural that the power of the director of education decreases. Nevertheless, with the aid of a corps of local inspectors and advisers, the director of education commands a post of considerable weight, which takes on added importance in view of the director's responsibility to the national ministry of education, as well as to his local education committee.

In general. it may be said that in contrast with other leading nations, England presents an educational system which not only operates co-operatively on both local and national levels but unites with private endeavour and voluntary organizations to spread the responsibility for control throughout the entire political and social structure of the nation.

Japan.—After World War II, in Japan educational administration tended to follow directives issued by the United States as the occupying power. Organization is on three levels: national; prefectural or county: and local community. The central ministry of education, though stripped of much of its power, is still, as in England. the chief administrative authority. The ministry has a secretariat and five divisions: elementary and secondary education: higher education and science; social education; research; and administration. Advice on general policy is afforded by 18 councils on education, including a central council for education. The national ministry of education is entitled to draft laws in the interest of national educational standards but its power to instruct local boards is limited by parliament. Since the ministry allots much financial aid to local systems. especially for school buildings, considerable indirect control is added to that which may be exercised directly. In consideration also of the weakness of local boards, due in part to educational tradition in Japan and in part to insufficient funds for vigorous programs at the local level, the ideal of a weak central ministry of education advocated by the United States educational mission failed to materialize. Concrete evidence is seen in such developments as the assumption by the central ministry of responsibility for the nine years of compulsory schooling and the security of teachers' salaries and emoluments. Also, the recommended transfer of university control to local authorities has failed, so that since 1954 universities have fallen within the province of the national educational administration.

Unlike England, the roots of local self-determination, especially in educational matters, are not deep in Japan, so that local controls are in a stage of growth rather difficult to delineate. Local boards of education are responsible. legally, for the establishment and maintenance of elementary and lower secondary schools; while the county (prefectural) board of education administers upper secondary and special schools, the certification of teachers, certain aspects of private schools and the choice of textbooks. Originally. too, these boards were supposed to be elected, but because educated and desirable Japanese people did not wish to run for the office (or could not afford campaign expenses), and because the Japanese themselves did not feel a strong affinity for the elective process, board members became appointive. Another difficulty with implementing the ideal of local controls in Japan has been the traditional method of collecting taxes. It has not been possible to establish a system of special school taxes, so that local boards must depend upon general local revenues, supplemented by allotments from the central ministry. Although the trend is back to a centralized administration in Japan, local authorities still exercise far more control than before the war, so that a modified type of partnership in educational administration may therefore be said to prevail in Japan, in principle if not always in practice.

Sectarian Systems.—Religious and denominational influences control school administration in Spain, Ireland, certain provinces in Canada and certain Latin-American countries. The Spanish state guarantees the teaching of the Catholic religion as a regular and compulsory subject in all educational institutions, whether state controlled or not, and no matter what their level and purpose. Publications of any type may be banned or suppressed if contrary to Catholic dogma and morals. Also, in tests for the selection of teachers, for example. examining boards are composed of five members, three of whom, including the chairman, must be church officers. In Ireland local boards of education, hence local school systems, are controlled by the prevailing local religious denomination.

Canada.—For the most part, educational administration in Canada is similar to that of the Cnited States. The national government delegates the responsibility to the provinces and local communities. In the provinces of Quebec and Newfoundland, administration is sectarian in nature, but the schools are otherwise "public." Education is free and compulsory but children must attend the school of their denomination, unless an "outsiders fee" is paid. Control of schooling in Quebec dates from 1826, when the province was divided into two distinct groups: the Protestant English and the Catholic French, each group demanding the right to educate its members. There is no minister of education in Quebec, as in other provinces. Instead, the titular head of the department of education is the superintendent of education, appointed by the government, who is chairman of a council of education which is divided into two committees, Catholic and Protestant, each having a secretary. School districts may be organized by minorities in any community, if there are a sufficient number of pupils to justify the procedure and a sufficient number of taxpayers capable of assuming the responsibility. This principle of "dissent" is guaranteed by law. Individual taxpayers may also designate the school system to which their taxes must be paid. The French-speaking school districts in Quebec are generally coterminous with the Catholic parishes; otherwise, it is obvious that political districts and school districts are not necessarily identical.

In Newfoundland, where early settlement took place along denominational lines, nearly every local community has a majority of one or another of the various denominations. This situation has produced a sectarian system of education, whereby the churches of the various groups have built and in large part control their own schools. Directors of education are nevertheless responsible to the provincial ministry of education. Increasingly the schools of Newfoundland are becoming consolidated, however, especially at the secondary level, reflecting a national trend.

Certain general observations may be made about the rest of Canada. There is neither a central ministry of education, as in England, nor an office of education, as in the United States. Instead, the dominion bureau of statistics publishes an *Annual* Survey of Education in Canada; the Canadian Education association collects and pubiishes research studies and disseminates information on procedures and practices in the various provinces; and a national research council assists materially in advanced research and investigation at the university level. The dominion government is not without authority, however, in educational matters. For one thing, it is empowered to overrule any act of a provincial government. It protects the educational rights of minorities; it has provided crown lands for the support of education; it is responsible for the operation of schools within the territories, it grants a limited amount of aid for vocational and higher education; it supports research and other types of educational investigation; it provides special grants to increase staff salaries in universities; it supports school broadcasts. (Pressures upon the dominion government to support education at the federal level are similar to those in the United States.)

The provincial departments of education exercise control over such matters as courses of study. teacher education, examinations, textbooks, school buildings and legislative grants. The provincial minister of education is a member of the provincial legislature and hence of the political party in power, and he is responsible to the legislature in matters involving broad educational policy. The deputy minister of education (called the superintendent of education in Quebec and by other titles in other provinces) is the chief permanent officer of the provincial department of education.

The most persistent administration problem in Canada is how to find the means of providing larger and more efficient units of organization and administration, at the same time preserving local control of schooling in a sparsely settled, widely diversified, heterogeneous nation.

Political Party Control. — The Soviet Union and its satellites, Communist China and, to a limited extent, Spain, are examples of educational administration as controlled by a single political party.

U.S.S.R.—Art. 121, revised, of .the U.S.S.R. constitution reads as follows:

All citizens of the U.S.S.R. have the right to education. This right is insured by universal compulsory seven-year schooling, by extensive developments of secondary education, by the fact that all forms of education, both secondary and higher, are free of charge, by a system of state stipends for students who have distinguished themselves in higher schools, by education in the schools in the students' native language, and by organization at plants, state farms, machine tractor stations, and collective farms of free, technical, industrial, and cultural training for the working people.

The Soviet Union resembles India and China in its multiplicity of cultural, national and linguistic groups. There are nearly 200 such groups incorporated into the union; more than 100 different languages are spoken. Under such circumstances, the U.S.S.R. could not help but organize as a federal state; indeed, one secret of Soviet success may be traced to the willingness of the central government to cater in part to national and cultural differences, including instruction in vernacular languages at primary and secondary levels, with Russian the compulsory second language. After World War II the union consisted of 16 union republics, 16 autonomous republics, 9 autonomous regions and 10 national areas, listed in order of size of population and area. The Russian Soviet Federated Socialist Republic, with Moscow as its capital, is by far the largest union republic; within its boundaries are no less than 100 cultural and linguistic groups.

In the Soviet Cnion, as in other federated political systems, education is the responsibility of the individual republic. The U.S.S.R. goes one step further in providing no central ministry of education, relying instead upon ministries of education of the various republics to unify their activities in accordance with educational directives emanating from Communist party headquarters and the central government in Moscow. There is, however, a central ministry of higher educational institutions, which is part of the ministry of culture; and this agency controls all universities, most of the secondary schools (technicumr) and most of the teachers' institutes. Another sample digression occurs in the fact that the national ministry of labour reserves is in charge of the factory schools and certain vocational institutes, even though it does not contribute materially to their support. Budgets are drawn up by local agencies and the ministries of education of the republics for approval by central authorities, who, in turn, advance direct grants for specified areas and make up deficits. Despite the apparent decentralization of administration. uniformity is guaranteed, as no decision of any consequence, certainly none contravening party directives, is made at levels lower than the republican ministry of education. Policies may originate locally, but they have to be submitted to the republican ministry for approval, or, if of sufficient importance, to the council of ministries for general agreement. The philosophy underlying all agreements and hence all policy and practice is that of the Communist party and party principles are the same for the entire nation. Under the sixth five-year plan (1956–60), for example, the goal in all republics was ten years of compulsory education for ages from 7 to 1;.

Control by the Communist party is guaranteed by the central government, which administers the entire economy and the fiscal policies of the nation. In a planned economy, education becomes simply another agency of government and national life, so that all school practices must be co-ordinated with activities planned for other phases of the country's existence. Freedom is allowed only when no directives exist to the contrary. Though directives are many and detailed, the individual republics have been able to exercise a number of prerogatives which give the air of self-determination. In Georgia, for example, the compulsory study of Russian (in addition to the Georgian vernacular) was found to interfere so greatly with the time allotted to other subjects that primary schooling was extended one more year.

Because they are tied to other segments of the government, the republican ministries of education are far more complex in organization than counterparts in other nations. For one thing, the minister of education is also a member of the union republic council of ministers. so that, contrary to practice in other nations, he belongs not only to his republic but also to the central government. He therefore has a multiplicity of divided duties to perform. The following departments exist in a Soviet republican ministry of education: organization and administration (including teacher training, buildings, finance. elementary and secondary educational methods, etc.) ; vocational education; adult education; social and polytechnic education; literature and publications; science and art institutes; research agencies; and certain commercial trusts. such as the state publishing house, the state motion-picture enterprises and the state supply board. An inspectorial system, under control of the ministry, interests itself in the improvement of teaching and classroom management. Although inspectors must see that party policies are carried out, in practice, they interest themselves primarily in modern pedagogical methods and in supervision; they also teach demonstration classes. Inspectors co-operate closely with school principals; they do not "rate" teachers, except to recommend awards or special honours for particular tasks well done.

Local school boards are appointed by local executive committees of the local council (soviet) concerned. The local director of education is likewise appointed. by the executive committee of the council. School principals are, however, named by local school boards and principals in turn select the teachers, subject to approval of the school board. The school principal is also in charge of school purchases; but he must buy all supplies from government houses. The internal duties of local school boards resemble those of most countries but they must look to higher authorities for the determination of over-all policy and practice and have no authority to levy taxes. Each school is guided by a council consisting of parents, teachers, Communist party members and others connected with school life, including clerks and janitors. These councils occupy themselves vigorously with the ongoing activities of the school, uniting with parent-teachers associations in physical (as well as ideational) projects, such as cleaning and redecorating classrooms and providing benefits and perquisites not forthcoming from governmental sources.

The Communist party not only establishes policy but also determines who may be elected to office. Education therefore has the task of preparing future leaders, for whom special party schools are established. In all schools the party exerts its influence in the organization of pupils in various types of political youth leagues. from Pioneer groups for ages 9 to 14 to the Komsomol, or Young Communist league for youth over 14. Members of these youth groups are specially chosen for their loyalty to party principles and their actual or potential capacity for leadership. In sum, administrative policies in the Soviet Union may originate in local areas but to become effective they must be approved at the top. Approved policy then sifts down through the various levels and its enactment is overseen by party members or affiliates, who penetrate every phase of public and educational life.

Communist China.—Similar practices prevail in China. In fact, following World War II Chinese schools were reorganized under the aegis of Russian counselors and modeled after the educational ideals of the Soviet Union. Art. 41 through 47 of ch. v of the Common Program contain the core of Chinese educational policy. Education, according to this program, shall be "national, scientific, and cultural." It shall promote the five "loves": fatherland, people, labour, science and public property. Education and politics become inseparable, so that educational leaders are either members of the Communist party or pledged to support its principles. The entire nation is organized under such centralized ministries as finance, trade, labour, heavy industry, fuel industry, textiles, foods, light industries. railways, communications, agriculture, conservation, forestry and land reclamation. The listing of these ministries is not merely a verbal duty; it reveals the nature of Communist China; and the school system is charged with providing trained personnel for all these ministries.

Contrary to the Soviet Union, China has a central ministry of education, which concerns itself not only with elementary and secondary education but also with the establishment and administration of institutes of higher learning. Hence. it might be said that China is an example of an educational system which is controlled not only by a political party but also by highly centralized administrative agencies. School administration is said to be democratized by the organization of educational councils, in which teachers, students and workmen enjoy equal voting status. The democratic way is also said to be practised in all kinds of meetings and discussion groups, findings of which are transferred for action to higher authorities, on the basis of "discussion by the many but decisions by the few." Heading these educational discussions, or influential in their operation, are members of the party. When one compares two such highly nationalized systems as China and France, political preference is readily discerned as perhaps the chief agent for ordering educational ends, even though the means of administration are similar.

Trends. — While trends in educational administration differ among nations, certain generalizations may be made:

(1) Nationalized or centralized systems (France, Mexico, India, etc.) are advocating the assumption of greater responsibility at the local level; conversely, local school systems (the United States, Canada, Great Britain, etc.) are looking toward centralized authorities for assistance in the support of schools. Thus, a greater co-operation among all governmental groups is becoming evident, influenced by two forces: more liberal sociopolitical democratic practices and the need to derive the cost of schooling from more and wider sources of revenue. (2) School-leaving ages are being raised, so that few countries remain in which children are allowed to leave school before the age of 14; only financial and material limitations prevent the fullest application of laws on compulsory education. (3) Administration is rapidly being democratized, largely in co-ordination with greater democratic practices in other phases of a culture, as evidenced in the breakdown of hierarchic controls, in less rigid forms of student selectivity, in the establishment of single-ladder (open to all regardless of class) school systems, in the insistence upon basic education for all children up to school-leaving age and in provisos for secondary education for more and more young people. (4) State interest in the education of all citizens is resulting in greater provisions for scholarship help to those in economic need, so that meritorious students will be afforded the necessary impetus to continue their education at state expense. (5) The single-ladder system of school organization is slowly gaining favour, though in countries like France and Germany. where entrance to secondary school has traditionally been highly selective, the *école unique* and the *Einheitsschule* are meeting considerable opposition, partly in reaction to general reforms of a socializing nature and partly because of the power of the universities over secondary school policy. Otherwise, secondary education for all, wherever physically possible, is becoming fundamental to educational progress. (6) Although more and more money is being spent on education year by year, and although more and more students are attending the world's schools, the proportion of most government budgets allotted to education is either static or actually decreasing. Teachers' salaries have not increased commensurately with the rising cost of living and with salaries paid in other professions or vocations. Problems of administration are everywhere aggravated by the lack of funds and of suitably trained, talented personnel. *See* ELEMENTARY EDUCATION; SECONDARY EDUCATION. *See* also Index references under "School and Curriculum" in vol. 24.

SCHOOL AND CURRICULUM. Prior to the opening of the 20th century, traditional curricula were accepted in the United States without serious question. During the colonial period they were dominated by British practices and traditions. Textbooks used in the United States were printed in England, and British courses of study were only slightly modified for use in American schools. Even when America began to print its own textbooks following the American Revolution. their content was not materially changed until the 20th century.

In the first two decades of the 20th century. the term curriculum was used interchangeably with course of study. It later became generally agreed, however, that the curriculum consists of all the experiences of the pupils under the guidance of the school. The teachers' guide or course of study is an aid to be used voluntarily by teachers, not a prescribed syllabus to be followed rigidly.

Logically organized subject matter formulated by scholarly specialists resulted in the subdivision of knowledge into smaller units. This accounted for the expansion of elementary subjects after

1890 in the following sequence:

1890: Drawing, civics, history, language and grammar, reading, spelling, writing, arithmetic, nature study, geography, music and physical exercises.

1900: Hygiene, literature, sewing and manual training.

1925: Instrumental music, health and safety.

1950: Social studies, art, crafts and science.

The typical U.S. child learns to read, write and figure in the first six grades. In most schools developmental reading is supplemented by reading for pleasure in books borrowed from a classroom or a school library. Spelling is learned separately from books in which the words appear in context as well as in an isolated list. The children begin manuscript (print) writing in the first grade and change to cursive writing toward the end of the second grade. The addition, subtraction, multiplication and division of integers are learned in the first four grades in the order of difficulty. Fractions are learned in grade five and decimals in grade six. The applications of numbers to real situations have been increasingly used in the classroom and in the textbooks.

At mid-20th century there was still considerable variation from school to school in the content of the social studies. The first three grades were usually devoted to the study of home and community life. The pupils studied state and local history and geography most commonly in grade four; U.S. history and geography in grade five; and European backgrounds and world geography in grade six. Elementary science, usually taught in the middle grades, was undergoing a transition from nature study to the broader phases of science. The topics of study were being drawn from the physical and biological environment to include the heavenly bodies, the earth. living things, simple phenomena and man's use of the soil, power and minerals. Health and physical education were being taught incidentally in the first three grades and somewhat more directly in the upper three elementary grades. Art, studied both separately and as an outgrowth of other studies, had broadened to include the crafts.

The number of subjects in the high school curriculum also multiplied rapidly after 1890. At the turn of the 20th century, the high schools reported 18 subjects to the United States office of education. At mid-century, 70 common subjects were listed on the official blank of the same agency. The appearance of new subjects is most conveniently shown in the follo ing sequence:

1890: Latin, Greek, French, German, algebra, geometry, physics, chemistry and history (U.S., ancient, mediaeval, modern).

1898: Trigonometry, astronomy, physical geography, geology, physiology, rhetoric, English literature and civics.

1922: Spanish, zoology, botany, agriculture, home economics, general biology, industrial training, drawing, vocal music, bookkeeping, typewriting, shorthand, office practice, social studies, shop subjects, hygiene, general science, economics and physical education.

1934: World history, problems of democracy, United States government, military drill, art appreciation, band and orchestra.

1950: Music appreciation, general shop, sheet and art metal, printing, machine shop, electrical work, auto mechanics, aeronautics, general mathematics, general business education, consumer economics, retailing and home management.

In 1934 the typical high school youth completed a course of fairly conventional subjects. In the seventh and eighth grades a pupil studied English and social sciences; he took one year of mathematics and perhaps a second year; he studied science and music for one year and may have taken drawing for one year. A girl took at least one year of home economics and a boy one year of shopwork. As the youth progressed through the four remaining years of the secondary school he studied three years of English, three years of social science, two years of science, two years of commercial work, two years of mathematics, two years of physical education and one year of music. The girl took one year of home economics and she also may have taken a year of industrial training; the boy was likely to have taken a year of shop or industrial work.

During the years following World War II the pattern of education underwent a few changes. The pupil in the seventh and eighth grades added one year of general science and two years of physical education. In grades 9-12 the youth had one more year of English and three more years of physical education. He was required to take one year of United States history in grades 7 and 8 and another year in grades 9–12. He probably elected one year of art or music. In addition to these courses the student chose two years of commercial education, two years of industrial education or two years of homemaking, depending upon his field of specialization.

Influences on U.S. Curriculum Development. — In teaching the school subjects the textbook remains the most dominant influence in the life of the classroom. The course of study is frequently built before selecting a textbook, but as it actually works out in the classroom, the textbook and not the course of study determines what is learned by the children.

One must not conclude that all schools require their pupils to follow a program of isolated subjects. Over a period of years, there is evidence of considerable effort to reduce the number of unrelated studies and to unify learning. When the junior high school movement began in 1910 it gave impetus to a wave of fused or broad courses such as general mathematics, social studies, general science and general language.

In a nation-wide study of representative schools in 1944, about 25% of the elementary schools reported social studies for grades three to eight, an indication of the trend toward fusion of related subjects. About half of the schools had combined two or more subjects into broader areas, the language arts and social studies being the most frequently combined fields. Arithmetic, art, language, geography, handnriting, health, music, reading, science and spelling stood out predominantly as separate subjects in all grades.

Another step in overcoming the limitations of organized knowledge was to functionalize it, that is, to make it useful in life. A large number of practical subjects such as social and economic mathematics. consumer science, everyday physics and living chemistry made, their appearance. The introduction of practical courses led to a more lifelike organization of content. For example, the conventional outline of physics is: matter, force, heat, sound, light, magnetism, electricity, etc. The organization of the same subject for the improvement of living would be based upon problems of living such as water, fuels, weather, transportation and home equipment.

The still potent influence of the college preparatory requirements was gradually breaking down at mid-20th century. Studies made in 1948 showed that the high school was exerting a groaing independence from the domination of the college. There was a sharp decline in the number of colleges requiring a specific number of units for college entrance. For example, 61% of the colleges in nine states required no units of foreign languages and 48% required no units of mathematics. Conversely, the high school requirements were more rigid than the college entrance requirements. For example, 45% of the high schools in the nine states studied required three or four units in mathematics and science although no college imposed this requirement in science and only 2% had prescriptions in mathematics.

Interested groups outside of the schools were exerting pressure on the curriculum through direct influence on the teacher and by school legislation. Nearly every subject in the curriculum had been regulated in some way by state legislation. A study of legislative control in the northwest made in 1948 showed that the number of curricular prescriptions increased from 233 in 1900 to 5j2 in 1947. These prescriptions pertained most frequently to health and safety, state and national history and vocational education. Many of the materials advocated by pressure groups had been of fundamental educational value. A number of educational foundations had made generous grants for the advancement of wise use of resources, better intergroup relations and the improvement of health

Curriculum-Making Movement. — For convenience, the curriculum-making movement may be said to have begun with the first of the reports on minimal essentials made by the National Society for the Study of Education in 1915. In 1920, spurred by the leadership of this organization, the department of superintendence of the National Education association appointed a curriculum commission which produced a series of five successive yearbooks. These brought the need for curriculum revision forcibly to the attention of more than 5,000 superintendents of schools in the U.S. and led to the most phenomenal output of courses of study in the history of public education to that date. While the improvement of the curriculum was most extensively organized in the local schools. nearly all the states also conducted elaborate long-range programs of curriculum development.

The first ten years of the curriculum-making movement were marked by the appearance of several important germinal books, the most significant of which was Franklin Bobbitt's *The* Curriculum. The principal contribution of the universities at that time was to encourage investigators to study what should be learned. Several thousand curriculum studies were produced as a result and helped to transform the content of the common school subjects.

The principle of selection with which the schools of the United States were experimenting was that of usefulness. But to U.S. thought the concept of usefulness was given a meaning sufficiently broad to include aesthetic, social, moral and intellectual, rather than merely vocational and financial uses. Utility was not always of major importance in curriculum construction. For centuries educators assumed that the organized fields of knowledge—grammar, history, botany, mathematics and the like—were appropriate for instructional purposes. The practical value of these courses of study was based upon the doctrine of transfer of training, expounded by John Locke in the 17th century. In 1901 and 1902, Edward Thorndike's studies on the transfer of training appeared, causing educators to question the adequacy of the text materials to train students in abilities useful outside school.

The exploration of the concept of usefulness had taken several directions in the United States. One approach was through activity analysis; another was by way of the long-familiar organized fields of knowledge. The investigators interested in discovering the activities, needs, problems or interests of the persons to be educated were divided into two groups, one interested in exploring children's activities and the other adult activities. The former group, which asserted that the school is life, not preparation for life, to use John Dewey's phrase, more or less consciously analyzed child activities and interests to discover the most important of these; and upon them they based the curriculum. Numerous studies of children's spelling vocabularies, their errors in language, their use of mathematics, etc., were made. A second group, which assumed that the school is an agency established by the state to teach the young the patterns of behaviour which a good citizen should follow, analyzed the activities, interests and problems of adults. and based the selection of their curriculum on the results of such analyses, with adaptation of the material to children's interests and activities. Careful studies were made by this group of adult vocabularies and errors, of the use of mathematics, geography, history and the like. The second group was interested also in the analysis of vocations as a basis for the selection of materials for vocational curricula. Analyses of the activities of pharmacists, secretaries! machinists and a wide variety of other occupations were made in constructing a curriculum for each.

As the concept of usefulness was developed further, theories of learning introduced from psychology were utilized. With the acceptance of the theory that purposeful learning in solving problems felt to be valuable by pupils is superior to the learning of systematized information, the usefulness of which is not appreciated, the project had been evolved. The project curriculum is one in which significant problems, as nearly like life situations as may be, were selected as units of instruction, and such subject matter as was needed was drawn from the organized fields of knowledge in a form appropriate to the completion of the project.

Interest in the project as a learning unit gave rise to a number of experimental centres commonly referred to as activity schools. These contributed largely to a better understanding of children and to a somewhat more general introduction of purposeful learning in an informal atmosphere. The teachers were given more freedom to adjust their work to the interests and needs of the learners. Creative expression in art, music, literature, drama and the dance were encouraged. Pupils worked together in small groups toward the achievement of the goal which the class had chosen and accepted as its own. As centres of experimentation increased in number, many schools were induced to pioneer in breaking down the barriers between subjects.

Interest in curriculum research continued for the next two decades. New techniques of research developed and extensively applied in the 1920s were concerned with the discovery of the objectives of subjects and areas of living. The study of social and civic deficiencies was accelerated during the depression years of 1929–33. This gave rise to a wave of elaborate studies on the social basis of the curriculum. Extensive experimentation was carried on with various plans of reorganization of the curriculum in which broad areas of social experience replaced the conventional subjects.

The years immediately preceding entry of the United States into World War II were notable for experimentation with activity and core curricula. The war dealt a harsh blow to these frontier programs and led to a decline in significant curricular research. During the war period the investigation~in secondary education were centred on the study of the needs and interests of youth. The critical problems revealed by the war led to increased research in curriculum planning and to a renewal of interest in curriculum change.

Basic Reorganization of Curriculum.— Dissatisfaction with a classroom procedure in which subjects were taught with little relation to each other and in short, disconnected periods of time led to a search for a more satisfactory organization of learning. It was natural to turn to life for learning experiences which possessed unity. This led to the formulation of the concept of the unit of work.

A unit of work is a large ongoing experience having a purpose which the pupils have accepted as their own. It is a purposeful learning enterprise in which the pupils work together to solve a problem of individual or community living. The pupils have a part in deciding in what direction their learning shall move. They help to outline the inquiry and, therefore, step by step, they know where they are going. It is a continuing and developing enterprise which goes more deeply into the problem which the learners have set for themselves.

The basic skills of reading, writing and figuring were learned as needed in solving the learners' problem. Additional periods were provided daily for acquiring the tool subjects and for practice in attaining mastery of the skills in reading, writing, speaking and figuring.

The unit of learning was the smallest subdivision of the curriculum. The sequence of units over a period of years derived unity and coherence by continuous reference to broad areas of living and to the progressive stages of child growth. These furnished the framework of the curriculum.

Many schools and school systems departed from tradition and accepted areas of living instead of systems of knowledge as fundamental to the development of the new curriculum. They represented a unity of design and a continuity of purpose which gave clear direction to all the work of the school.

Generally speaking, the proposals for basic reorganization of the curriculum were built on one axis showing the areas of living, and on a second axis showing the progressive levels of child development. Together they formed the framework of the curriculum. The areas of living had been identified by many working groups and put into practice by a considerable number of schools and school systems. The specific areas of living varied from group to group but the following pattern is suggestive of the most common practice: protecting life and health, engaging in recreation, expressing aesthetic impulses, communicating and transporting goods and people, producing and consuming goods and services, making a home, governing and getting a living.

The levels of maturation furnished the sequence of learning activities year by year. These were more difficult to isolate, and therefore the available suggestions were fewer in number. The grade centres or themes were committee generalizations made to simplify and to facilitate the planning of the curriculum. The most common grade themes proposed were:

Grades 1–2: the immediate environment
Grades 3–4: the expanding environment

Grades 5–6: invention and discovery
Grades 7–8: adjustment to physical and biological environment
Grades 9–10: adjustment to social and economic institutions
Grades 11–12: building a democratic society.

Education for Good Living.— During the 20 years ending in mid-century, the expansion of interest in the improvement of the curriculum resulted from a number of long-term projects of several nation-wide commissions. The Commission on Relation of School and College of the Progressive Education association. established in 1930, made agreements with institutions of higher learning which freed 30 experimental schools from the rigid requirements for college entrance. The so-called eight-year study demonstrated that the traditional patterns of prescribed courses were not essential and that secondary schools could be given greater freedom in planning the curriculum. The work of the commission, ending in 1942, led the way to about a dozen other regional and state projects, all of which resulted in some adjustments of the curriculum to the needs of youth.

In 1936 the American Association of School Administrators took the initiative in organizing the Educational Policies commission which represented the full scope of public education in the United States. The commission proceeded to prepare several significant reports on the purposes, structure and content of education which had great influence on the plans and policies of the schools.

An intensive study of the social aspects of democratic living yielded four major objectives of education: the development of the learner; the improvement of home. family and community life; fulfilment of economic needs; and performance of civic and social duties. This led to formulation of a detailed program of education for living which was issued in a volume entitled *Education for All American Youth.* The commission recommended that the secondary school curriculum should be divided into four major divisions: (1) personal and individual interests; (2) vocational preparation; (3) common learnings in personal and social living, and (4) health and physical fitness.

In co-operation with the National Association of Secondary-School Principals. the Educational Policies commission gave wide circulation to what was called the ten imperative needs of youth. These goals indicated the direction which the scope of secondary education was taking. Briefly stated and roughly following the language of the commission, all youth need: to develop salable skills; to develop good health; to understand the significance of the family; to purchase and use goods and services intelligently; to understand the influence of science on human life; to enjoy literature, art, music and nature; to use leisure time well; to develop respect for other persons; and to grow in the ability to think rationally.

Core **Curriculum.**—The area of common learnings correspondcd to the core curriculum which was an outgrowth of the eight-year study of the Progressive Education association. Together they constituted a phase of widespread interest in general education which is that part of the curriculum designed to meet the common needs of good living in a democracy. In 19jo the United States office of education reported that 3.5% of the nation's approximately 24.000 public high schools had adopted a core curriculum in some form.

The transition to the core mas usually made by scheduling English and social studies in two successive periods. Thus a larger block of time was devoted daily to the study of the problems of living. Information from several subjects was drawn upon as needed. The students took a part in selecting the goal and in planning the learning activities: working in groups and coming together from time to time to share their findings.

The core was prescribed for all pupils but the special interests were most commonly organized as elective courses and voluntary activities. The block of time devoted to them increased from year to year as the pupil progressed from the 1st to the 12th grade. The special interests included college preparatory courses, vocational studies, creative and expressive arts and informal activities. The latter were usually voluntary, self-governing groups called, in common parlance, extracurricular activities.

In 1948 the Educational Policies commission turned its attention to the education of children on the assumption that elementary education was entering a period of significant change. Its report. *Education for All American Children,* recommended that all school faculties should engage in continuous curriculum improvement. This process was designed to keep pace with changing social demands and to introduce new learnings built upon familiar backgrounds. drawing upon experiences in the local community as starting points for broader understandings. This was a downward extension of the core curriculum to the elementary grades.

Impact of World War **II** on the U.S. **Curriculum.**—The trend for some time prior to World War II was to make the study of mathematics courses elective. At the same time social and economic arithmetic was introduced into the junior high school and a somewhat more advanced course of a similar nature was offered in the senior high school. The advent of World War II temporarily reversed this trend. Some schools rashly added required courses in algebra, geometry and trigonometry. At mid-century the pendulum began to swing back to the prewar policy of making pure mathematics elective and prescribing functional and useful mathematics.

The war brought new emphasis on science which continued in the postwar period. Pure science had always had sufficient emphasis as a college preparatory subject but the application of physics, chemistry and biology to problems of everyday living had been neglected. Physical science courses for noncollege preparatory students were spreading rapidly until they were temporarily displaced by the courses given prior to induction into the armed services. but later such courses began once more to increase in number. The mobilization of industry gave greater impetus to rapidly expanding opportunities for vocational education. Yocational schools were established in industrial centres and all new high schools added the shops and equipment for training in a variety of industrial occupations.

Greater attention was given to understanding the free institutions of democracy. Racial and religious tolerance was stressed in many schools. On the high school level, particularly, the school continued to function as a little community in which the self-governing activities offered the most effective apprenticeship in citizenship. In the postwar years the emphasis upon development of a global outlook was continued.

Curriculum Development in School Systems.— In the first quarter of the 20th century there was a strong tendency to assign the task of educational planning to the expert, particularly as it applied to the curriculum. Although this survived in practice in many places, professional leadership completely repudiated the old view in favour of broad participation of teachers in group planning.

Experience in co-operative programs of curriculum development had demonstrated that the greatest amount of individual growth comes from active participation in planning, experimenting with and evaluating teaching and administration. This discovery revolutionized the process of curriculum development. Indeed, it accounted for adoption of the term curriculum development instead of curriculum making which had been in vogue during the 1920s.

Co-operative effort continued to characterize long-term curriculum development in state and local school systems. The program usually begins with a period of study which leads to the acceptance of the need for a fundamental approach to instructional improvement. The teachers working as a group develop a common educational point of view; they study the needs of the children and the community; they formulate the broader goals of education. The teachers continue their study and experimentation with a balanced curriculum, a more fundamental framework and large ongoing learning units. A tentative course of study is prepared which stimulates widespread experimentation with improved learning activities. The curriculum is continually adjusted to the changing needs of good living. The production of the course of study is one of a series of steps in the ongoing process of curriculum development.

The emphasis upon curriculum development as a process is reflected in the contents of courses of study which show that policies are made by committee procedure. Varied and lifelike activities are suggested. The importance of formulating meaningful goals is recognized. Units of work are organized around social experiences or lifelike interest centres and integration of courses begins to emerge as a significant trend.

Following the interruption caused by World War II a number of U.S. states and cities resumed long-range programs for instructional improvement. In the southeast and northwest, regional groups were organized with special emphasis upon the development of the human and natural resources. Several significant reports produced during the war years portended a renewal of study of the total pattern of the curriculum.

GREAT BRITAIN

A curriculum is a course of study laid down for students of a university or school or for schools of a certain type; *e.g.,* primary, secondary. In Great Britain education is compulsory between the ages of 5 and 15. The primary stage, for children up to 11 years of age, includes nursery schools for children between 2 and 5 years old. The secondary stage, while compulsory for pupils between 11 and 15, can be continued up to the age of 18 or 19.

The Primary Stage—It is usual to regard this stage as consisting of three parts—nursery, infants and junior, although because of the exigencies of accommodation or small numbers two or three parts are often combined in one school. The nursery school has a long history if the nurseries and kindergartens set up in the 19th century may be regarded as prototypes. They were established mainly as an antidote to bad housing conditions or to assist mothers going out to work; and nurseries were later widely used in wartime to meet the needs of women warworkers. The true nursery school, however, bears little relation to such expedients and owes its origin rather to pioneers like Rachel and Margaret Macmillan who, concerned about the falling birth rate and high infant mortality, sought to bring about a more enlightened conception of our responsibility to very young children. The purpose of the nursery school is not only to make good deficiencies in the home but especially to co-operate with the parent so as to ensure for the child the best possible early upbringing. The Education act of 1944 made it a duty of the local education authority to make provision for these younger children, where it is likely to be needed, by means of nursery schools or, where such schools are considered to be inexpedient, by means of nursery classes.

The aims of the nursery school are to provide the medical care which such young children need, to afford a training in good habits and right behaviour and to supply an environment in which children can learn the things appropriate to their age. It would be difficult to define the curriculum of a nursery school. The physical needs of the child demand a balanced diet, adequate rest and sleep, play within doors and in the open air, suitable clothing and careful training in healthy habits. An important part of the curriculum consists in helping children to adjust themselves to their environment and to behave socially; and a great deal depends upon the quality of the teacher, her influence with the parents and her guidance within the school. Although there is no curriculum in the ordinary sense, the child's day is carefully planned in stages to secure a balance of rest and of activities, the child himself being, of course, unaware of this: as the Scottish Advisory council's report observed: "The child is taught; the objects he handles, the things he sees, the projects he plans. the actions he performs, the companionship he shares, the atmosphere of affection and security by which he is surrounded—all these are his teachers." The infant school (ages 5–7) has forged for itself a certain tradition; and it has been claimed that as an institution it is peculiar to Britain. The first school in Great Britain founded specially for the teaching of infants was established at New Lanark by Robert Owen in 1816 and his aim was that the children should grow up happily in a healthy environment. By making school attendance compulsory at five, a lower age than that adopted in any other country, the legislation of the 1870s perpetuated a type of school already in existence: and as a nation therefore the British have had a long experience of infant teaching. Although the history of the infant school contains many bad patches, it is true to say of it that Robert Owen's keynotes of health and happiness predominate. But it is difficult to speak with precision about the curriculum at the infant stage, for as the consultative committee in their report on infant schools remarked: "It would be entirely inappropriate to translate it [the life of the school] into any rigid or logically ordered curriculum." It is characteristic of children at this age that their interests emerge during play, and that is why the "play-way" constitutes an important element in the teaching of infants. Opportunities are thereby provided for children to discover by their own experiences answers to the questions which arise in their minds as they play. For this reason many individual occupations are arranged for them and they are also encouraged to engage in co-operative "work" in small groups. Thus in any good infant school can be seen children doing things together most energetically and freely talking and puzzling about the business in hand. That is how they learn to think, and how the desire to read, write, measure and count grows. The curriculum usually embraces: (1) natural activities, including physical exercises, open-air life, rest and play; (2) expression training, comprising speech, dancing, singing, handwork and drawing; and (3) in the later age groups, formal instruction in the three R's. Opinions differ as to when formal instruction should begin but Sir Cyril Burt's view, that there should be little or no formal teaching before the age of six, came to be widely adopted.

The important junior stage (7–11) formerly fared badly. Too often it had formed part of an all-age school or, when the seniors had been removed as a result of reorganization (*i.e.,* the establishment of a separate senior school as recommended in the Hadow report), the juniors had been left to make the best of it in the old building. It suffered also from the intense competition for admission to grammar schools, serving as a preparatory establishment, although about 90% of its pupils never entered the grammar school. This had an adverse influence on its curriculum, and for this and other reasons it became difficult for the junior school to become an entity with a soul of its own. Because of the inevitable delay in giving effect to the Education act of 1944, these handicaps remained but the sense of frustration and despair was less evident when it was appreciated that as the act came into effective operation the junior school would acquire a new status. One function assigned to it was that of assessing the aptitude and ability of children, all of whom were expected to pass forward to an appropriate secondary education. If then the junior stage had been a Cinderella of the educational system, it now had a bright prospect before it. "The junior school," to quote the ministry of education, "is at the beginning of its history. Its tradition has yet to be made, and all those who care for young children have a part to play in the making. It is our task to create in our time a junior school not only with fair buildings, not only with small classes, but giving a happy and healthy growth to all children from seven to eleven." Thus the junior school was visualized as a little commonwealth of children mainly between the ages of 7 and 11, but some might continue to the end of the term in which they reach 12 while there would also be bright children going forward to the secondary stage from about 10½ years old onward.

To some extent: therefore, the curriculum and methods of the junior school had to be thought out afresh, taking full advantage of the experience gained by enterprising teachers of juniors. The Scottish Advisory Council for Education urged strongly that "curriculum and methods should follow the child's natural line of development." and that "we should not destroy or needlessly impair those primitive powers and graces, those qualities of initiative, curiosity, ingenuity, and self-dependence" that are an essential part of a child's heritage. This also expressed the opinion prevailing in other parts of the United Kingdom; the general tendency was for the curriculum of this junior stage to move rapidly away from the former restrictive influences. In place of this emphasis on the three R's the aim was to awaken interest and create alertness by the stimulus of activity and experience. The curriculum was therefore devised not only as a means of imparting knowledge or facts to be stored but also as a source of opportunities whereby the child might grow in mental, moral and physical stature through the media of activity and experience. In addition to religious education, the main phases of the curriculum are English, especially spoken English; art and various crafts; music; counting and measuring; physical exercises including. of course, games and dancing. "We regard," the Scottish Advisory council remarked?"hand-and-eye training not as a 'frill' but as forming along with oral expression ('tongue-ear-and-eye training') the core of the primary curriculum." An intensely active education of this kind makes a considerable demand upon the teacher; much depends in the application of the curriculum upon his or her sympathetic understanding of children 'at this vital junior stage.

Here it may be well to note that in all stages of education the co-operation of the home is of crucial importance if full value is to be derived from the curriculum: and among the techniques of education it became more and more realized that one of the most effective is that of finding ways of knowing parents and attracting their support.

The Secondary Stage.—The Education act of 1944 gave a new meaning to the term "secondary school." Formerly it was applied only to public, grammar and high schools, but now became a generic expression embracing every kind of school attended by pupils of 11 and over. The educational world was therefore confronted with an entirely new concept of secondary education, and as required by the act was engaged in the difficult task of evolving courses of study appropriate to the "different ages, aptitudes and abilities" of the pupils, bearing in mind also the "different periods for which they may be expected to remain at school." This process of reconstruction was still in the experimental stage at mid-20th century and it would be premature to indicate as standard any of the numerous courses of study being followed at that time.

The problem of providing secondary education for all children is fundamentally different from that of providing a particular kind of secondary education for a few selected children. The task of those concerned with secondary education was not, therefore, one of giving to all children the education previously available for a fen-, but rather one of mapping out a variety of alternative courses so as to ensure that different aptitudes and abilities would be catered for. Nor indeed was it as straightforward as that, for the educational needs of children vary greatly; and it is also impossible to regard aptitude or range of ability as a constant factor during the school life of any individual pupil.

The concept of secondary education for all had received long years of consideration before its acceptance by parliament, and the decision to provide it with due regard to age, aptitude and ability was a direct consequence of recommendations made in various official reports—the Hadow report on the education of the adolescent (1926), the Spens report on secondary education (1938) and the Norwood report on curriculum and examinations (1943). In all these reports emphasis was laid on the importance of ensuring that the curriculum fitted the pupil and on the inadequacy of an educational system which in its provision of secondary education met the needs only of the pupil with an academic bent. Indeed the first official warning that a secondary education which ignored the nonacademic pupil was ill-conceived was given as early as 189j by the influential Bryce Commission on Secondary Education; "no definition of technical instruction," it contended, "is possible that does not bring it under the head of secondary education."

The regulations for secondary education prescribed under the Education act of 1902 disregarded the opinion of the Bryce commission, enunciating a curriculum that was mainly academic. Criticizing them, the Spens committee observed that "they failed to take note of the comparatively rich experience of secondary curricula of a practical and quasi-vocational type which had been evolved in the higher grade schools, the organized science schools and in the technical day schools. The new regulations were based wholly on the tradition of the grammar schools and the public schools." Under these secondary regulations the admirable service of grammar and high schools was built up to a high level, but apart from a comparatively few junior technical schools all other postprimary education was administered under the regulations for elementary schools. Fortunately many central and senior schools succeeded in providing much excellent teaching of a nonacademic character within the elementary school system, some of them reaching a high standard in spite of the discouraging auspices under which they worked. It remained true however that in providing secondary education for all the major task was to establish on a nation-wide basis schools that would adequately meet the needs of pupils—the great majority—for whom the academic curriculum of the grammar and high schools is inappropriate.

Much consideration had been given as to how this should be done before the Education act of 1944 gave statutory sanction to the principle of secondary education for all. The Hadow committee envisaged secondary education as consisting of two broad types: grammar (with an academic bias) and modem (with a practical bias). The Spens committee added a third type, the technical high school, while the Norwood committee confirmed this tripartite division. "Such, then." said the White Paper on *Educational Reconstruction* submitted to parliament in 1943, "will be the three main types of secondary schools to be known as grammar. modern, and technical schools. It would be wrong to suppose that they will necessarily remain separate and apart. Different types may be combined in one building or on one site as considerations of convenience and efficiency may suggest. In any case the free interchange of pupils from one type of education to another must be facilitated." Wide differences of opinion as to the best way of organizing secondary education revealed themselves as soon as the act became law and its implementation a practical issue. These found expression in the development plans prepared by local education authorities in pursuance of the act, some preferring the tripartite arrangements, others one type of comprehensive school, others a multilateral school; while several sought a solution by means of the establishment of bilateral schools; *e.g.*, grammar and technical or modern and technical. The London county council came out strongly in favour of a comprehensive school catering for all abilities and aptitudes. The upshot of all this divergency of view was a reorientation of official policy with the result that when the ministry of education published its leaflet on The *New Secondary Education* (1947), the stress was laid on variety. flexibility and experiment.

Meanwhile the Scottish Advisory Council for Education had been considering how the problem could best be resolved in Scotland, having regard to its educational history and tradition. The tripartite organization was found to be unsuitable for Scotland because: (1) it was unrelated to the existing system; (2) the age of 12 was considered too early to distinguish grammar, technical and modern types; (3) evidence was lacking that the "modern" school would have adequate status; and (4) the segregation of types at 12 would be opposed to the conception of school as community. One difficult question yet to be determined was that of size; *e.g.*, could a school foster a sense of community if it were large? On this the ministry of education made this comment: "In order to ensure that a school providing secondary education for all the senior children in a given area offers proper scope and opportunity for all its pupils, it will have to be a very large school. It is doubtful whether a school with less than a ten-form or eleven-form entry (that is, a total of 1.500 to 1,700 pupils) is capable of offering the necessary variety of suitable courses."

The future of the curriculum was largely bound up with that of organization, and so far the tendency had been to give precedence to a consideration of the latter. Some, however, maintained that by doing so the cart had been put before the horse. One reason for the emphasis on organization was the optimistic belief that the new schools would be built fairly soon and accord with the development plans; and there was a tacit assumption that once the organization had been settled the curriculum would be made to fit. The prolongation of economic difficulties, however, thrust the idea of the rapid completion of a vast building program into the background and as a result problems of organization lost their original urgency. Consequently the issue of the curriculum began to assume priority; and much thoughtful research and experiment was undertaken in colleges and schools as to what kind of secondary education was best suited to children of different ages, aptitude and ability.

Official opinion as to the content of the secondary curriculum was clearly expounded in the ministry of education's pamphlet *The New Secondary Education*, the needs of grammar, modern and technical schools being dealt with separately. The grammar-school course was then represented as a whole, covering the years 11 to 18, and it was regarded as incomplete if it ended at 16 and lacked two years future study in the sixth form. In the general course up to 16 "the treatment of all subjects and groups of subjects, but notably languages (classical and modern), mathematics and science, follows a predominantly logical development" and the subsequent intensive course in the sixth form covers "a narrower range of subjects, which for many boys and girls leads naturally on to studies at the university level." The distinguishing feature of the grammar-school curriculum lies in its length, the scholarly treatment of its content and the intellectual discipline that it affords. The duration of the modern school course was to be four or five years. From April 1, 1947, school attendance was compulsory up to 15 and it was official policy that as soon as practicable it would be raised to 16. As modern schools developed it was to be expected that the tendency for children to remain at school beyond the compulsory age would increase, but meanwhile the normal modern school course would extend from 11 to 15 with provision for those who remained at school longer.

The modern school curriculum includes English (or English and Welsh), mathematics, history, geography and science. In many modern schools a modern language is taught, and there is a growing interest in social studies. Art, music, handicraft, housecraft and various kinds of crafts are strong features of the curriculum and, wherever possible, gardening and animal husbandry. Physical education has an important place throughout the secondary stage, and the teaching of health principles is assuming more and more a positive quality.

The technical secondary school had behind it the tradition and experience gained by the junior technical schools established from 1905 onward; but the latter were handicapped by their truncated age range, normally from 12 or 13 to 15 or 16. The technical secondary school would have its pupils from 11 to 16, and after the age of 16 there would be various lines of development open to keen pupils; *e.g.*, combination of training in industry with part-time attendance at a college for further education, or full-time study at such a college, or in some technical secondary schools courses at the sixth-form level with some degree of vocational specialization. The curriculum of these schools would, however, during the first two years not differ much from that of other secondary schools; in the third year some vocational teaching might be included, introducing applications of basic principles. In the fourth and fifth years the bias would be increased and the work more deliberately related to a future vocational purpose.

Religious Instruction.— It should be noted that under the Education act of 1944 it was a requirement that in all primary and secondary schools the school day should begin with a corporate act of worship and that religious instruction should be given. The former provision in previous acts, restricting religious instruction in elementary schools to the beginning and end of the school session, no longer applied; and now the instruction might be given at any time during the session One consequence of this was that it became possible in many schools, formerly prevented from doing so by the timetable restriction, to arrange for the religious teaching to be given by a teacher who had made it a special study.

In the voluntary aided schools a syllabus appropriate to the particular denomination is followed and in the county schools use is made of an "agreed syllabus" drawn up by a conference of biblical scholars and teachers convened by the local authority in each area. Much care has also been taken in many areas in the preparation or selection of suitable service books.

SCHOOL ARCHITECTURE: *see* EDUCATIONAL ARCHITECTURE.

SCHOOLCRAFT, HENRY ROWE (1793–1864), U.S. ethnologist and explorer, one of the earliest of important writers on the American Indian. was born on March 28, 1793, in Albany county, New York. He was educated at Union and Middlebury colleges, where he showed a predilection for mineralogy. His *View of the Lead Mines of Missouri* (1819) was based upon a collecting trip through the Indian country of Missouri and Arkansas and led to his appointment as topographer on the Lewis Cass expeditions to the upper Mississippi and Lake Superior copper regions, where he became increasingly interested in Indian life. In 1822 he was appointed Indian agent to the tribes of the Lake Superior region and shortly afterward married a girl of Chippewa extraction. Her tribe became the subject of his special study. From 1836 to 1841 he was superintendent of Indian affairs for Michigan; in this capacity he supervised the treaty of March 28, 1836, by which the Chippewa ceded much of northern Michigan to the United States. Schoolcraft's contribution to ethnology was made in his *Historical and Statistical Information Respecting the History, Condition, and Prospects of the Indian Tribes of the United States*, 6 vol. (1851–57). Repetitious and disorganized, the work nevertheless remains an invaluable source of information gathered by the author from Indians, missionaries, traders and agents. The publication of F. Nichols' *Index to Schoolcraft's "Indian Tribes of the United States"* by the Bureau of American Ethnology (1954) greatly enhanced the value of the original volumes.

Schoolcraft continued his exploratory trips, the most important of which was in 1832, when he discovered Lake Itasca, the source of the Mississippi. Among many books was *Algic Researches* (1839; 1856 ed., *The Myth of Hiawatha),* which Longfellow used for *Hiawatha.* He died on Dec. 10, 1864, in Washington, D.C.

See also Chase S. Osborn and Stellanova Osborn, *Schoolcraft-Longfellow-Hiawatha* (1942). (V. Kz.; X.)

SCHOOL HYGIENE AND PHYSICAL EDUCATION form important branches of public hygiene in the United States. The school, since practically all the children are collected there, furnishes the great opportunity for caring for the health of all the people.

School Hygiene.— School hygiene may be divided into four main branches: (1) Sanitation of schoolhouses and school grounds. (2) The hygiene of the school child. including prevention of contagious and other diseases, health examinations both physical and mental, the prevention and treatment of defects and positive training for the development of habits of health. (3) The hygiene of school teachers. (4) The hygiene of school instruction together with mental hygiene.

The Schoolhouse.—This branch of school hygiene is concerned first of all with the best conditions of workshop for growing children occupied in brainwork. Architectural and artistic considerations, although usually considered important, are secondary. First of all the health of the workers should be considered. For example, the unit in a schoolhouse is the schoolroom and the size of the room should be determined by consideration of the average limits of normal sight and hearing, etc.

Hygiene of the School Child.—Child hygiene is based upon the character of the child's body and the laws of growth. It seeks to determine the needs and to avoid the dangers of each stage of development. Among its important contributions have been many scientific studies of development, the diseases and abnormalities of school children, the defects of the sense organs, the incidence of disease by years, seasons, months of the school year, the relation of defects to school progress and studies also in detecting and controlling contagious diseases.

Hygiene of Teachers—A new branch of school hygiene relates to the health of teachers. The few studies made emphasize the great importance of the health of the great army of teachers. It appears that the members of the teaching profession are prone to respiratory diseases and to nervous disorders. Thus it is seen to be a matter of importance to make conditions healthful for the work and the life of the teachers as well as of the pupils.

Hygiene of Instruction.—This emphasizes the hygienic importance of the mental habits formed by education, the secondary effects of instruction; and it studies every educational principle and method, the relations of teacher and pupil, the problems of the period of study, from the point of view of hygiene.

The importance of this newer field of school hygiene is seen when one considers the fact that an important means of cure for nervous and mental disorder is re-education, the development of healthy habits of mental activity—wholesome interests, habits of attention, self-control and orderly association—in fact, the very habits that are essential for hygienic school work. More and more scientific investigation and observation are showing the hygienic importance of mental hygiene both for pupil and teacher.

School Legislation.—The development of school hygiene is shown by the growth of medical inspection as well as by the training of teachers, the legislation in regard to the health of children and the sanitation of school buildings. By mid-20th century most states had laws making medical examination of school children practically compulsory. There was a wide divergence in practice, however; some of the states required annual examinations, some biennial or even less frequent, and some specified no definite period.

Most U.S. cities likewise had laws requiring annual health examinations of children, and many had adopted mental hygiene programs as well. Increased attention had been paid to physical defects as well as to contagious disease, and health inspection had been placed largely under the direction and control of the educational authorities.

Physical Education.—Physical education in the school may be divided as follows: (1) General physical exercise including play and training in health habits; (2) systematic physical training, gymnastics (*q.v.*), callisthenics, and the like; (3) athletics (see ATHLETIC SPORTS); (4) the higher aims of physical education. Special treatment of gymnastics, athletics and mental hygiene is given under separate articles. Only general aspects of the subject are discussed here.

The importance of physical education in relation to health has been emphasized in recent years in a twofold way: first, because of its significance for the normal development of children and the maintenance of general physical health; second, because of its significance for mental health. The minimum amount of physical exercise for the maintenance and development of physical health has been suggested by Hetherington as follows: Four hours of muscular activity at the age of 5 years, five hours from the ane of 7 to 9, six hours from 9 to 11, five hours from 11 to 13, four hours from 13 to 16, three hours from 16 to 18, and two hours daily from 18 to 20.

The slogan of physical education from the days of the Greeks until the present has been *mens* sana in *corpore sano* (the sound mind in the sound body), with the implication that the sound body is a condition of mental sanity. In modern times, under the influence of the great teachers of physical training in Europe, Johann Christoph Friedrich Guts-Muths, Friedrich Ludwig Jahn and others in Germany, Pehr Henrik Ling and the founders of Swedish gymnastics, the training has naturally centred much more upon physical education. While the mental factor in this twofold aim has often been neglected, in recent times the emphasis has been placed largely on the mental aspects of physical training. In a report of a special committee to the Society of Directors of Physical Education in Colleges made in 1921 the committee emphasized right mental attitudes, self-sacrifice, loyalty and co-operation, and mentioned some of the more generic of these mental attitudes as their first group of aims. Thus by mid-20th century there was growing the theory that physical education affords opportunity for important training in mental hygiene as well as for physical health. While no claim was made, like that of Plato, that God gave men music and gymnastics for mental culture alone, emphasis was placed on the development of healthy mental attitudes and interests as the culminating value of such training.

With the development of physical education in relation to somatic and mental health, it became a subject ior scientific research as well as a practical art, as indicated by recent literature. In the practice of hygiene the best schools supplemented instruction by actual training in health habits; and in the colleges the highest ideal was the acquisition of health intelligence as demonstrated by health habits. (See also PHYSICAL EDUCATION, and for English legislation on the subject see EDUCATION, HISTORY OF.) (W. H. B.)

SCHOOLS, ANCIENT. This article deals with the history of Greek and Roman schools, from which modern schools are derived. For modern schools see SCHOOL AND CURRICULUM and for a general historical sketch see EDUCATION, HISTORY OF.

GREEK SCHOOLS

First Phase.—The term and the institution date, not from the great or what may be called the Hellenic age of Greece, but from the later Macedonian or Hellenistic period. The account given by K. I. Freeman in his *Schools* of *Hellas* (1907) may be summed up in the statement, "There were no schools in Hellas." That is, there were no schools in the modem sense, where, during boyhood and youth, boys spent their whole time in a continuous course of instruction. There were professional teachers of three kinds: (1) the grammatistes, who taught reading, with writing and perhaps arithmetic, in the grammateion; (2) the *citharistes,* who taught music, *i.e.,* playing and singing to the cithara; (3) the paedotribes, who taught gymnastic, wrestling, boxing, running, jumping, throwing the javelin, etc., in the *palaistra.* To these teachers the boys were taken by slaves, called boy-leaders (παιδαγωγοί, whence our pedagogues), as single pupils, and were not taught in classes.

Roughly, the age for the grammar-school and song-school was 7 to 14, for the gymnastic school 12 to 18. A certain amount of literature was imparted, and especially in the song-school, Homer and other early poets, the very Bibles of Hellas, were learnt by heart. In later days, under the Sophists, and Socrates, "the greatest of the Sophists," 450–400 B.C., something approaching secondary education was developed. But it was wholly unorganized. The itinerant orators or rhetoricians taught oratory, and the learning that was considered necessary to the political orator, a smattering of Greek history, constitutional law and elementary logic. The philosophers, such as Protagoras, discoursed vaguely on natural science, "things in the heavens above and the earth beneath," and divinity, "whether there are gods or not," mathematics and ethics, or any subject which attracted them, while the lawyers, in the same unsystematic way, taught what law was necessary in a State where the Constitution was at the mercy of chance majorities in a sovereign assembly of 30,000 people, and trials at law were settled by 600 jurymen-judges.

Second **Phase.—In** the next generation, the orators and the philosophers, by settling down in fixed places, began to establish something more like schools. Plato, though like his master Socrates he taught without asking fees, was the first to give a regular educational course extending over three or four years, and in a fixed place, the Academy. The gymnasium was originally a parade or practice ground for the militia or conscript army of the State, which derived its name from the exercises being in that climate performed naked (γυμνός). At the age of 15 or 16 the boys left the palaestra, or private gymnasium, for this public training school, maintained at the public expense, preparatory to their admission as youths (ἔφηβοι), to take the oath of citizenship and undergo two years' compulsory training in regiments on the frontier. After those two years were over, they still required continuous exercise to keep themselves in training; consequently men of all ages, from 16 to 60, were to be iound in the gymnasium. Though the gymnasium was free, the teachers and trainers in gymnastics were paid, and as the poorer citizens had to earn their own living, the Athenian gymnasium, like the modem university, was for educational purposes chiefly frequented by the well-to-do. So the Academy became a fashionable lounge, and here developed the walking and talking clubs, which became the Platonic or Academic Schools. Logic and ethics, built on a foundation of geometry and mathematics, seem to have been the staple subjects. An inner circle met, and dined together in Plato's private house and garden, close to the Academy. Plato devised the house and garden to his successor Speusippus, who passed them on to Xenocrates. They thus became the first endowment of the first endowed college, which grew very rich and lasted till the disestablishment and disendowment of the old learning by Justinian in A.D. 529. Aristotle, a pupil of Plato for 20 years, set up a school of his own in the Lyceum, another public gymnasium, where he lectured twice a day, in the morning esoterically to the inner circle of regular attendants, in the afternoon to the public. From these two institutions three nations of Europe have derived three different terms for a school, the Germans their gymnasium, the French their lycée, and the Scotch their academy. Yet none of the originals was a school in any real sense of the word. In the days of their founders they were like discussion forums; at the most, courses of lectures. In later years, the gilded youth whb flocked to Athens from the whole Graeco-Roman world were enrolled among the ephebi, and the so-called "university of Athens" was evolved.

Third Phase.—It is to the Alexandrines, either to Antiodorus or to Eratosthenes, c. 250 (J. E. Sandys, *Hist.* of Classical *Scholarship,* 7), that grammar, as a term and a science, which included literary criticism and scholarship, and the grammar school are due. The earliest extant treatise on grammar is by Dionysius of Thrace (born c. 146), a pupil of the Homeric critic, Aristarchus. It defines grammar as "the practical knowledge of the usage of writers of poetry and prose" and includes exegesis or explanation of the author in the widest sense as well as mere verbal or syntactical grammar. It was from the term thus understood that the grammar school (*scola* grammaticalis), the term which described the typical secondary school from that day to 1869, derived its denotation and its connotation. Throughout the 13 centuries which intervened between Dionysius Thrax and Dr. Kennedy, Dionysius's grammar was the standard work and the foundation, directly or indirectly, of all other grammars, while the grammar school has always meant, and, in the hands of the better class of teachers, has always been, not a gerund-grinding machine, but a place for the training and exercise of the mind by the study of literature. The word "school," as well as the word "grammar," seems to be due to Alexandria. The first known use of it in that sense seems to be in Dionysius Halicarnassus' Letter to Ammaeus, *c.* 30 B.C. But as Plautus (c. 210) uses the corresponding Latin term, ludus *literarius,* some two centuries earlier, we may safely infer that he used it as a translation of grammar school.

ROMAN SCHOOLS

First Stage.—At Rome schools began under influence of the Greeks. According to Suetonius. the emperor Hadrian's secretary, who wrote *The* School *Masters* (De *grammaticis*) about A.D. 140, literary teaching and the science of grammar began with Livius Andronicus, a Greek from Magna Graecia in the south of Italy, who, being brought to Rome as a slave in 272 B C, became a freedman, translated the Odyssey into Latin, and taught both Greek and Latin. Ennius, the first Latin poet, was also half-Greek, and came to Rome in 209 B C, where he also taught both languages. According to Plutarch (Quaest. Rom 59) the first grammar school (*grammatodidaskaleion*) was opened by Spurius Carvilius, a freedman of Carvilius, about 230 B.C. According to Suetonius, Crates, who about 169 B C came to Rome as ambassador from Attalus, king of Pergamum, a great centre of learning, and was kept there by a broken leg, occupied himself in giving lectures His example was soon followed by Romans. Schools of grammar, in which, even as late as Cicero's time, the Laws of the Twelve Tables were the chief text-book and were learnt by heart, were kept by Greeks or freedmen. These seem to have been of the nature of elementary schools. But at Rome, as at Athens, the working-classes were for the most part slaves; and elementary schools were like English preparatory schools rather than public elementary schools. Schools of rhetoric, which were more like secondary schools, were also opened after the model of that of Isocrates at Athens In 92 B C schools of Latin rhetoric were put down as an innovation. Yet among the treatises written by Cato, the praiser of the past at the expense of the present, was one on public speaking, the chief rule in uhich was "take care of the sense. and the sounds will take care of themselves." Neither the gymnasium or palaestra, nor the music school, flourished at Rome. As at Athens, so at Rome the boys were sent to school in charge of a slave, a *pedagogus,* comes or *custos.* But it would seem that at Rome the pedagogus generally a Greek slave, often himself gave elementary instruction In Varro's much-debated phrase, "Educat nutrix, instituit pedngogus, docet magister," "the nurse brings up, the pedagogue instils the elements. the master teaches" *Magister*, which in English became "maister" and then "master," remained the term for the teacher of the public school from that day to this, though attempts were made at the time of the Reformation to introduce the Greek word *didascalus* in its place

The Roman school was very much like the modem school. All the methods of torture which have made the service of the Muses for most boys a veritable slavery were in full vogue. Instruction was now in a foreign language, and grammar became prominent. Early rising, loud speaking and hard flogging were in the ascendant. The staple of instruction in the Roman schools was the works of the poets, Greek and Latin, Homer and Virgil, Hesiod and Aesop, Menander and Terence. Horace says (*Ep.* i. 19. 40) "that he was not thought worthy of going the round of the schoolmasters' desks"; but it was a fate not long delayed, and the writings of the poets of the silver age, Lucan and Statius, became school-books in their own lifetimes.

Our knowledge of the Roman curricula is mainly due to Quintilian's *Institutio* oratoria, C. A.D. 91. Fabius Quintilianus, born on the banks of the Ebro, was not only the son of a man who kept a rhetoric school, but himself kept one, and is said by St. Jerome to have been the first who kept a public school, in the sense that he was the first who received a stipend from the emperor. In endeavouring to create the perfect 'orator, Quintilian discusses the whole of education from the cradle upwards.

Second Stage.—The first definitely endowed school we hear of is one founded by Pliny the younger, a pupil of Quintilian, at his native place Como. Later historians say that the emperor Antoninus Pius (138–161) assigned offices and salaries (honores et *salaria*) for rhetoricians throughout the provinces; and that Alexander Severus did the same, and also established exhibitions for poor boys, with the limitation, curiously repeated a thousand years later in the statutes of All Souls College and of Eton, modo *ingenuos, i.e.,* provided only that they should be free-born.

There were complaints that the masters were ill-paid. Quintilian made a fortune by his school, but Juvenal calls him in this respect a white crow.

Later Schools.—Grammar and rhetoric schools spread throughout the Roman world and continued substantially unchanged in method and subject to the days of Gregory the Great and Augustine the apostle of the English. The Confessions of St. Augustine of Hippo, a schoolmaster at Carthage, Rome and Milan, before his baptism in the year 387, and the poems of his contemporary Ausonius, educated in the grammar school at Toulouse, and himself a schoolmaster at Bordeaux before becoming prefect of Illyria and of Gaul, show that the schools were much the same in the 4th century as in the first. Ausonius celebrated in verse all the Bordeaux schoolmasters, some coming from schools at Athens, Constantinople, Syracuse and Corinth, one the son of a Druid at Bayeux, others schoolmasters from Poitou, Narbonne, Toulouse, who went to Lerida and other places in Spain. Ausonius had for his pupil the emperor Gratian, who in 376 established a legal tariff for schoolmasters' salaries. "In every town which is called a metropolis, a noble professor shall be elected" The rhetoric master (rhetor) was to have at least 24 annonae (an annona being a year's wages of a working man); while the grammar masters were to receive half that. But at Trier, then the capital of the Western empire, the rhetor was to have 30, the Latin grammarian 20, and the Greek grammarian, if one could be found, 12 annonae (Cod. *Theod.* xiii. 3. 11). The same century saw Priscian, a schoolmaster at Constantinople, compose the Latin grammar which, itself for the most part a mere translation from Greek, reigned without a rival till the Reformation. and is represented by over 1,000 mss.

Venantius Fortunatus, educated in the grammar school at Treviso, wrote in 570 a life of St. Martin of Tours in three books of hexameter verse, and lives of saints and bishops. His era was one of transition, and marks the passing of the schools from secular to ecclesiastical control. His contemporary Pope Gregory in a letter to Desiderius, "bishop of Gaul." at Vienne commends the monks whom Gregory was sending with Laurence the priest and Mellitus the abbot to Augustine of Canterbury, thus bringing the grammar-school-teaching bishop into direct connection with the conversion of the English, and the foundation of the first English school.

SCHOOLS, EVENING, schools open in the evening to enable those working during the day to continue their education. Evening schools in Great Britain are discussed under ADULT EDUCATION and TECHNICAL EDUCATION. The following article describes the work in the United States.

Evening schools in the United States for apprentices and others were opened in New York (1833) and Louisville, Ky. (1834). Ohio (1839) enacted legislation requiring towns to provide evening schools for males over 12 years of age. Massachusetts (1847) permitted towns to appropriate money for instructing adults in reading, writing, English grammar, arithmetic and geography.

By 1862 Cincinnati, San Francisco, St. Louis, Chicago, New Orleans and other cities to the number of at least 15 had conducted free public evening schools. Thirty-two cities reported such schools in 1881, and the report of the United States bureau of education for 1887–88 showed a total enrolment in cities of 8,000 or more of 135,654. Thereafter the growth was even more rapid, enrolment being approximately 1,400,000 at mid-20th century.

Classes are maintained in Americanization work, elementary, high school and vocational subjects. The objectives of Americanization work are to teach immigrants to speak, read and write English, to aid them to get an understanding of American institutions and to prepare them to take out citizenship papers. Many employers co-operate helpfully in this work, and sometimes pay part or all of the expenses of these classes. Elementary classes are for those who wish to obtain further instruction in subjects usually covered in day grade schools. High school classes enrol pupils who wish to pursue work of high school grade in English, history, mathematics, science and classical or modern languages, and also offer courses in such fields as choral singing, dancing, art work and business law. Vocational courses range from work which appeals to an avocational interest in fancy work or manual arts to specific vocational training for office workers, housekeepers and apprentices and journeymen in the industrial trades. Of the total evening school enrolment of 1,475,104 provisionally reported for 1951 by the U.S. office of education, 319,096 students were taking agricultural courses. 228,173 courses in distributive occupations, 659,551 courses in home economics and 268,284 courses in trades and industry.

Pupils usually attend evening school two hours per night for two or three evenings per week, from Oct. 1 to April 1. By increasing the time allotment, Cincinnati, Chicago, Boston, Philadelphia and other cities offered an evening school diploma equivalent to that of the day high school. Rural evening schools also developed large enrolments. This work is essentially for adult men, and is strictly vocational.

The evening school in the United States, excepting Americanization classes, is chiefly for young working people. The pupils average about 19 years in age and are about equally divided as to sex. (O. D. E.; X.)

SCHOOLS OF ART. As institutions, art schools are comparatively recent. The first signs of organization were perhaps in the middle ages when the arts and trades were controlled by guilds. Courses of instruction, promotions, competitions and general advisory councils were in existence at that time in the more important art centres of England, France, Germany and, especially, Italy.

However, such organizations did not take the place of personal instruction by the masters of the arts, fine and applied. It was to the great artists that pupils looked for supervision, and the term "school" as applied to these masters (such as the school of Michelangelo) had no connection with organized institutions. The 19th and early 20th centuries saw the birth and development of innumerable art schools, especially in countries where the government made appropriations for such educational work. The development of art schools saw the evolution of the art teacher, a phenomenon new to the 19th century, since he was a man trained to teach art as distinct from the artist who only taught incidentally.

In recent times there has been a marked tendency to encourage an individual approach among students. There is less emphasis on the teaching of traditional techniques and more on making students aware of contemporary idioms and ways of expression, but this advancement did not mean the obliteration of personal instruction under pre-eminent artists. It is not uncommon to find students who have never attended an art school. This "personal supervision" system of study has its weaknesses, the chief among which is the tendency toward imitation oh the part of the student.

With the development of museums where design could be studied from the collections of art work, more importance was given to observation classes. In many of the municipal museums, especially in the U S., an art school was established in connection with the museum. For those wanting industrial arts. most schools have branches for technical instruction in that field, such as interior design, graphic design and dress design Since 1934, in Great Britain, there has been an attempt to restrict the industrial subjects offered at individual art schools to the special requirements of the main industries of the area in which the schools are situated.

Public exhibitions. local and international. were perhaps the greatest stimulus in the development of art schools in Europe and the United States. About the middle of the 19th century considerable competition in the industrial arts was started among the European countries, and later spread to the United States, making itself manifest also in local exhibitions in the larger cities.

UNITED STATES

Schools of art which provide opportunities for specialized study in one or more of the various areas of art in the U.S. are set up largely on the postsecondary level. Most high schools of sufficient size to employ specialized teaching personnel, however, offer major programs in art. Such an arrangement enables talented or interested students to enroll in art courses continuously throughout their secondary schooling, usually for one period a day. although occasionally more. Sometimes these courses are highly specialized and of a terminal nature.

On the postsecondary level, schools of art are numerous. The *American Art Directory*, compiled by the American Federation of Arts, includes a listing of almost 600 institutions offering professional training. With few exceptions, these fall into three categories: professional art schools, colleges and universities and the schools of individual artists who conduct classes of professional standards. Only those colleges and universities were included that offered a major in art, including the fields of architecture and landscape architecture. In many instances, one university may have several independent departments and colleges where various major curriculums can be pursued.

New York state headed the list with more than 100 different institutions offering professional training. California, Massachusetts and Pennsylvania each had more than 30.

In addition to the institutions listed by the American Federation of Arts, there are hundreds of other colleges and universities that offer courses in art, either as a minor subject or as an essential part of the training of students (for example, to elementary teachers) or as an elective that does not have "minor" status. A very large number of communities, through such agencies as museums or school systems, offer instruction in art to interested adults and children on afternoons, evenings and Saturdays. There are also many artists who carry on private instruction or who conduct an occasional class in art. Although the art instruction covered in this paragraph is not set up as professional instruction, it generally includes some individuals who have a professional interest. But, more important, it exerts an enormous influence in maintaining a widespread interest in art.

There is great diversity among the art schools in practically all the factors which characterize them. A large number have no entrance requirements, being open to any interested student. Entrance requirements on both academic background and art ability and achievement are set up by those schools that offer programs of study over a period of several years leading to diplomas or degrees. Many are set up around one man, generally an artist of distinction who gives instruction to small groups of students. In such cases the character of instruction and the reputation of the school itself are dependent on the reputation and the stature of the artist who conducts the school.

Many art schools have large and permanent faculties and offer programs of study in varied fields. A goodly number, such as the Brooklyn Museum Art school, are connected with museums of art. One, the Massachusetts School of Art, Boston, is state supported. Some, such as the Art Students league of New York city, are best known for their training in painting. as the staff of that organization includes many gifted contemporary artists. Others. such as the art school of Pratt institute. also in New York city. are best known for their courses in such fields as advertising design. illustration and industrial design. Many art schools. particularly the small ones. enroll only part-time students. Most enroll both full-time and part-time students.

There has been a strong trend among the large and established art schools to become degree-granting institutions. This development has been the result of the continued increase in numbers of college graduates in all fields and the increasing status of college degrees generally, but also to meet the competition from regularly established colleges and universities where. increasingly. courses in studio work in the various fields of art are counted toward a degree along with academic subjects.

For the art schools this has meant offering the liberal arts courses themselves that are required for the degree; or working out some arrangement with a nearby college or university as. for example, the Rhode Island School of Design. Providence. with Brown university. or the Pennsylvania Academy of the Fine Arts. Philadelphia, with the University of Pennsylvania; or accepting academic work from any accredited institution where the student wishes to take it. A number of art schools, such as the school of the Art Institute of Chicago and the Kansas City Art institute. offer master's as well as bachelor's degrees.

A partial list of other outstanding art schools. besides those already mentioned, includes the Cleveland School of Art; Cooper union of New York city, which is tuition-free; the Art Center school and the Chouinard Art institute. both of Los Angeles; Parsons School of Design in New York city; and the Moore Institute of Art. Science and Industry in Philadelphia.

Colleges and universities are all degree-granting institutions and the colleges, schools and departments of art that are within them are governed hy the same general policies as other sections of the institution. The staffs of the art departments, in most instances, however, have considerable freedom in determining the character and direction of the art program.

A large number of colleges and universities offer art programs, either for the preparation of professionals in such fields as painting, sculpture, architecture, advertising art and industrial design, or as a cultural subject for interested students.

Although art history and aesthetics were at one time considered the only kinds of art courses academically acceptable at the college level, there is an increasing acceptance of studio work toward meeting degree requirements. Bachelor's degrees in a wide variety of art fields are common. Many institutions offer either master of fine arts or master of arts degrees for students specializing in such fields as painting, sculpture or education. In a few institutions, as, for example, Teachers college. Columbia university, and the State University of Iowa. Iowa City, doctor's degrees are ofiered which include courses in studio work toward meeting the degree requirements. In fact. the considerable expansion and acceptance of productive work in the arts in higher education during the 20th century is a most significant development in art. The presence of art departments in the college and university milieu is of great educational and cultural importance.

The placement and organization of art departments within higher education varies considerably from one institution to another. In some large universities offerings in art appealing to differing groups of students are available in a number of places. At Columbia university, for example. there are six separate departments offering courses and programs of art. These include such fields as art education, art history. painting and medical illustration. In other universities the various art offerings have been brought together. Yale. for example, has a school of fine arts with departments of architecture, drama, design and history of art. The department of design offers curriculums in painting. sculpture and graphic arts. In some universities, such as the University of California at Los Angeles and the University of Illinois. Urbana, the various art departments form a college.

Most frequently, the art departments are placed in the college of liberal arts, such as at the University of Minnesota, Minneapolis. and the State University of Iowa. At Ohio State university, Columbus, however. the school of fine and applied arts, which does not include architecture and landscape architecture, is placed within the college of education.

A partial list of the other universities with important art programs includes: the universities of Arkansas, Fayetteville, and Nebraska. Lincoln. Syracuse university, N.Y., and the Carnegie Institute of Technology. Pittsburgh, Pa.

Although one or more college degrees are necessary for many art teaching positions in colleges and universities, professional accomplishment alone is a basis for employment in a considerable number of instances.

In the teaching of the arts in the U.S., emphasis is being placed on the development of individual expression. Basic courses are offered, but in them. also. experimentation and the development of unique and personal interpretation are encouraged. The role of the instructor is to guide and develop the student rather than to encourage imitation. (See also ART EDUCATION.) (E. Z.)

GREAT BRITAIN

Apart from one or two small private academies of the early 18th century, the first British art school was that which still forms a part of the Royal Academy of Art, founded in 1768. This school gives instruction to an average of 60–70 students in painting, sculpture and architecture at Burlington house.

In 1835 a parliamentary commission was appointed to inquire into "the best means of extending a knowledge of the arts and of the principles of design among the people (especially the manufacturing population) of the country." The immediate outcome of the commission's report was the establishment, in London, of the Normal School of Design, later to be called the Royal College of Art. A radical reorganization of this college was undertaken in 1948, as a result of which it became for the first time the main centre in the country for the training of industrial designers. It also has departments of painting, sculpture. stained glass, engraving and graphic design.

A further result of the report of the commission of 1835 was the foundation of other schools of design—the first in 1842—which were to become the foundation of the British system of public art education. By 1890 there were 200 such schools of art, and in 1902 their work became a part of the national system of higher education.

Immediately after World War II the number of art students increased, but dropped after a few years. Consequently the ministry of education, in consultation with local authorities, carried out an active policy of closing art schools in many parts of the country. In the late 1950s there were about 200 art schools in England and Wales recognized by the ministry. The ministry of education administers its own system of art examinations.

The universities of Oxford, London, Reading and Durham and University college. Aberystwyth also maintain schools of art, of which the most famous is the Slade School of Fine Arts, of London university. Another London school of considerable importance is the London county council's Central School of Arts and Crafts, founded in 1896. This had some influence on the development of art education on the continent of Europe in the early years of the 20th century.

There are, besides, a number of private schools, mainly in London: for example, the Byam Shaw school and Heatherley's.

CONTINENT OF EUROPE

Germany.— It has been in Germany that many important experiments in art education have taken place since the beginning of the 19th century. It was the Nazarene painters such as Peter von Cornelius, for example, who made the first serious attack upon the authority and curriculum of academies and who put forward the idea of *Meisterklassen,* training based upon the talents and personality of outstanding teachers with whom the student could enter into a more intimate and inspiring relationship than had been possible under the academic system of fixed instruction. Between the 1890s and the end of World War I much was done to prepare the way for a reunion of the fine and applied arts and to consider the particular problems of industrial design.

This movement found its fulfillment in the work of Walter Gropius; his Bauhaus, established at Weimar in 1918 and later moved to Dessau, aimed, in its instruction, to achieve a union of all the branches of art. This fruitful amalgamation of the fine and applied arts was also achieved in the 1920s at the Berlin Hochschule der Freien Kiinste. Most of the main centres of Germany have their *Kunstakademien, Kunstgewerbeschulen* or *Werkakademien.*

France. — In the 17th century France created the most famous and the most influential of all art academies, the Académie Royale de Peinture et Sculpture. It established the form of art education in Europe for many generations. In modern times the official art schools of France are administered by the Ministère de l'Instruction Publique et des Beaux Arts; there are not only the many municipal schools maintained by the state throughout the country but also those at Lyons and Dijon modeled directly upon the chief state school, the École Nationale des Beaux Arts in Paris.

Italy. — In Italy, where the first academies of art were established in the 17th century, no public system of art education existed until the time of the Fascist state. The fine arts are catered for in the *licei artistici;* and for more advanced studies there are *accademie di belle arti* in Rome, in Bologna, in Florence, in Milan, in Naples, in Palermo, in Turin and in Venice.

Training in arts and crafts is given in *scuole d'arte,* in *istituti d'arti* and in *istituti superiori per le arti industriali,* the last being found in Venice, in Florence, in Naples and in Palermo.

(B. Tr.)

SCHOONER, a sailing vessel having two or more masts and only fore-and-aft rigged sails. The masts have the same names as those of square-rigged ships and the sails forward of the foremast are similar to those of a square-rigged ship. Each mast carries a single gaff-headed sail which takes the name of the mast supporting it; gaff topsails may be carried above these sails. *(See* also RIGGING ; SAILS.)

In two-masted schooners the mainmast is higher and carries more sail than the foremast. In schooners having more than two masts the masts are the same height and carry nearly equal sail areas.

Modern schooners are generally used as yachts and have but two masts. The sails on the after side of the masts of schooner yachts are triangular in shape and slide up and down the mast on metal tracks. (M. R. D.)

SCHOPENHAUER, ARTHUR (1788–1860), German philosopher. primarily important as the exponent of a metaphysical doctrine of the will in immediate reaction against Hegelian idealism, was born at Danzig on Feb. 22, 1788, the son of a merchant, Heinrich Floris Schopenhauer, and of his wife Johanna. H F. Schopenhauer was a liberal-minded man who disliked authoritarian and absolutist governments and moved to Hamburg in 1793 when Danzig surrendered to Prussia; he was also cultivated and cosmopolitan in his tastes and acquainted with French and English literature. Johanna shared her husband's literary interests and herself wrote novels; but otherwise they seem to have been temperamentally unsuited, and the marriage was not a happy one.

Arthur Schopenhauer's education was intermittent. After spending two years (1797–99) at Le Havre to learn French, four years in a private school at Hamburg and another two years traveling in England, France. Switzerland and Austria, he entered a merchant's office at Hamburg

After the unexpected death of Heinrich Floris in 1805 (he fell, or threw himself, into a canal), Johanna Schopenhauer moved to Weimar. Schopenhauer eventually joined her there and studied classical literature until 1809. when he entered the University of Gottingen, reading first medicine and then philosophy. The pears 1811–13 he spent at the University of Berlin, attending the lectures of J. G. Fichte, for whose philosophy he was later to express considerable contempt.

At the time of the uprising of the German states against Napoleon, Schopenhauer, who disliked all forms of militarism and was not much moved by appeals to national sentiment, retired to Rudolstadt, where he published his doctoral thesis, *Uber die vierjache Wurzel des Safzes vom zureichenden Grunde* (1813; Eng. trans.. *On the Fourfold Root oj the Principle of Sufficient Reason,* London. 1889).

After his thesis had appeared Schopenhauer returned to Weimar, where in his mother's salon he met the orientalist F. Mayer, who introduced him to Indian philosophical literature. He also met Goethe. The latter having in 1810 published an essay on colours, Schopenhauer took up the same subject and sent his manuscript "On Vision and Colours" (*Über das Sehn und die Farben,* Leipzig, 1816) to Goethe in 1815; it was not, however, very enthusiastically received.

Schopenhauer had meanwhile left Weimar for Dresden, having quarreled with his mother (May 1814); they were never to see one another again. At Dresden he wrote his principal work, *Die Welt als Wille und Vorstellung* (Leipzig, 1819; Eng. trans., *The World as Will and Idea,* 3 vol., London! 1883.) Schopenhauer expected that this would at once be recognized as a book of first-class importance; but neither was it well-received nor did it sell. More successful at this time were his efforts to save the family fortunes when the firm in Danzig in which they had been invested went bankrupt.

After the publication of his book, Schopenhauer started lecturing in the University of Berlin (1820), but this too was a failure. Philosophy in Berlin was dominated by Hegel, and Schopenhauer's disdain for Hegelian ideas met with a poor response. He went to Italy in 1822 and to Munich in 1823; there he stayed for nearly a year. sick and isolated. From 1825 to 1831 he lived in Berlin, partly in order to defend himself against a seamstress who was suing him for injuries sustained when Schopenhauer, annoyed by her chatter, had driven her downstairs from a landing outside his room. He was eventually condemned to pay her regularly a certain sum of money until her death. which took place in 1841.

In 1831 Schopenhauer settled in Frankfurt-am-Main. He seems to have lived very well there: he enjoyed food and wine; he was fond of the theatre and music (he himself played the flute); and he read widely in French, Italian and English literature. Happy, however, he was not. By'nature misanthropic, he was also by this time profoundly embittered by lack of recognition, and his bitterness was only exacerbated by his contempt for the official Hegelian philosophy. He expressed his opinions on this score with great vigour. both in *Uber den Willen in der Natur* (Frankfurt, 1836; Eng. trans., "On the Will in Nature," in *Two Essays,* London, 1889) and in his preface to the second edition (1844) of *Die Welt als R'ille und Vorstellung:* he regarded Hegel as a charlatan who had corrupted the minds of an entire generation with bombastic sophistry and meaningless verbiage. Nor was his resentment alleviated when an essay of his, the sole entry for a competition instituted by the Danish academy of science, received no award. This essay was subsequently published in *Die beiden Grundprobleme der Ethik* (Frankfurt, 1841; Eng. trans., *The Basis of Morality,* London, 1903).

Schopenhauer's later writings added little that was new to what he had already written. In the second edition of his main work he added 50 supplementary chapters. including a section on sexual love in which there is only a suggestion of the misogynistic sentiment that coloured his later well-known essay "On Women."

With the publication of *Parerga und Paralipomena, 2* vol. (Berlin. 1851; selective Eng. trans., *Essays From the Parerga and Paralipomena,* London. 1951), a collection of essays on a variety of topics. Schopenhauer at last began to acquire fame. Articles on his system appeared in English. French and Italian as well as German periodicals; in 1856 the University of Leipzig offered a prize for the best exposition and criticism of his ideas; and by 1857 his doctrines were the subject of lectures at Jena, Bonn and Breslau. His reputation quickly spread beyond the confines of the academic field, and he gradually became the object of a kind of cult, with admirers in England, Russia and the U.S. He died at Frankfurt on Sept. 21, 1860.

PHILOSOPHY

The main philosophical influence upon Schopenhauer, and one that he freely acknowledged, was undoubtedly Kant. But although he never questioned Kant's greatness, *Die Welt als Wille und Vorstellung* contains a long "Criticism of the Kantian Philosophy" in which Kant's theories are subjected to a severe analysis. Other influences were Plato (particularly noticeable in Schopenhauer's references to eternal "ideas" in his account of artistic experience), Schelling, oriental philosophy and, to a lesser extent, the British empiricists: Schopenhauer speaks with respect of Locke and shared Kant's admiration for Hume.

Theory of **Knowledge.**—Schopenhauer accepted the Kantian distinction between the phenomenon, or the appearance that a thing presents to the perceiving mind, and the noumenon, or the thing as it is in itself. Thus in perception the mind is aware only of phenomena: what lies behind them, being beyond all possible experience, is unknowable; and the pretensions of traditional metaphysics to provide knowledge of a supra-empirical kind must accordingly be rejected. Again. Schopenhauer derived from Kant his view that the mind makes an important contribution to the general nature of our experience. The human sensibility is such that sense-data can only appear to us as spatially and temporally ordered; further, all phenomena are subject to the a priori category of cause and effect. Time, space and causality. Schopenhauer declares, are "nothing more than functions of the brain."

Schopenhauer went on to argue that we reflect upon and communicate our experience through concepts, or general terms. By means of these we are able to classify together different things in virtue of those common features which are of interest or importance to us. The function of conceptual thinking is thus essentially practical: without it what we learn from our experience could not be retained or put to use. But it is impossible to dissociate it—as some philosophers have tried to do—from the perceptual experience on which it is based: "Conceptions and abstractions which do not ultimately refer to perceptions are like paths in the wood that end mithout leading out of it." In saying this, Schopenhauer acknowledged his debt to the English empiricist philosophers.

Metaphysical theories that profess to be able to describe the nature of the world a priori and without reference to observed facts "move in the air without support." In the end they do no more than elicit by deductive steps the implications of the highly abstract concepts from which they start. and such a procedure can yield no more than a system of tautologies. Schopenhauer regarded Hegel's work as a prime example of such "trifling and paltry" philosophizing.

Metaphysics. — The basic tenets of Schopenhauer's theory of knowledge would seem to impugn the validity of all metaphysical speculation considered as a source of information about the world. He felt. however, a deep dissatisfaction with the purely empirical type of knowledge represented by the natural science of his time. Scientific explanation. he believed, always ultimately presupposes what is itself inexplicable in scientific terms: it may tell us how things as a matter of fact behave under certain conditions, but it cannot in the final analysis explain why things happen as they do and not otherwise; it is like "a sum which never comes out." Thus metaphysics has, after all, a genuine function, viz., to resolve certain fundamental problems which, although necessarily beyond the scope of science, seem naturally to arise. But how are these problems to be tackled in the light of what Schopenhauer, following Kant. has already said concerning the limitations of human knowledge?

The answer, for Schopenhauer, lay in the nature of our own intimate experience of ourselves. Although, from one point of view, I am as much a "phenomenal" object as a rock or a tree, self-consciousness reveals that I am more than this. For, apart from my awareness of myself as a perceivable bcdy, occupying space, enduring through time and causally responding to stimuli, I also know that in my overt behaviour I express my will. And just as my own activity is ultimately only explicable as the expression of my will, so it is with everything else in nature. Will is the concept in terms of which all that exists and manifests itself in the world can finally be understood. In this way Schopenhauer believed that he had arrived at a fundamental metaphysical truth by a method which escaped Kant's objections, although the reasons for his confidence are not very clear.

The picture which Schopenhauer thus drew of the inner character of the world was not—and was not intended to be—a pleasant or consoling one. For him the "real" was not, as it was for Hegel, the rational, but the irrational: the metaphysical will is "blind," an insatiable force without conscious purpose or direction. Human beings may deceive themselves into thinking that they are acting from considerations dictated by reason alone, but this is never in fact the case: the function of the intellect is only to assist the will to achieve its ends. From this the conclusion is drawn that all participation in the world is to be avoided. Schopenhauer's final remedy being not, as might be expected, suicide. but quietism.

Theory of Art. — The importance that Schopenhauer assigned to artistic experience is understandable in the light of his general theory. The scientist's attitude to the world is practical: he is concerned with phenomena only with a view to discovering the laws which govern their behaviour; and the sole value of his findings lies in the use to which they can be put in securing the objectives of the will. By contrast, the concern of art is with what Schopenhauer calls "contemplation," or "will-less" perception: the aesthetic frame of mind is characterized by a complete absence of desire or practical interest. What is perceived in artistic apprehension and what the artist strives to communicate through his works are certain archetypal "ideas," described as "the permanent essential forms of the world and all its phenomena." These "ideas" are not to be confused either with concepts or with the objects of everyday perceptual awareness to which concepts are applied: they occupy, in fact, an intermediate place in Schopenhauer's system between phenomenal appearances and the underlying noumenal reality of will. The position is further complicated by the fact that a different account is provided of music, which is regarded as directly exhibiting the inner workings of the will itself. Yet. whatever obscurities surround his theory of the ideas, the general significance of Schopenhauer's discussion of art is plain: the Romantic conception of the artist, as one who can withdraw from the material exigencies of life and reveal aspects of the world to which those dominated by considerations of practical interest are blind, could not fail to appeal to him; and the "knowledge" so achieved seemed to him to be correspondingly superior to any that could be acquired in response to the demands of the will.

Psychology and **Ethics.**—Schopenhauer's deterministic theory of human action and motivation is consistent with the rest of his system. Whatever a man does is necessarily an expression of his inner will, and this is fixed and unalterable. The knowledge of what we are comes to us as a result of seeing what we do: a man cannot "resolve to be this or that, nor can he become other than he is; but he *is* once and for all, and he knows in the course of his experience *what* he is." The common-sense belief in the freedom of the will is consequently an illusion: in our so-called "free" choices we merely exhibit the nature of our innermost unchangeable character. This belief did not, however, prevent Schopenhauer from distinguishing on moral grounds between different sorts of action. A wrong act is an act by which a man, in expressing his own will, "denies" or inhibits the will of another. Moreover, if justice consists in refraining from such injurious acts, goodness consists in treating the welfare of others as being as important as one's own: thus the good man acts from motives of benevolence and sympathy.

Influence and **Originality.**—Schopenhauer's philosophy achieved a wide popularity on the continent of Europe in the latter half of the 19th century: both Friedrich Nietzsche and Richard Wagner, for instance, were in different ways profoundly impressed by his ideas. In England. however, his influence on philosophical thinking was small: the dominant school of "absolute idealism," for example, was largely inspired by Hegel's doctrines, against which Schopenhauer had directed his most bitter attacks; and little attention was paid to his writings by British philosophers in the first half of the 20th century, when belief in the validity of metaphysical speculation was declining.

Such neglect is somewhat unjustified. Schopenhauer was not a rigorous thinker, and his theory lacks the tight, connected structure and logical ingenuity characteristic of the systems of men like Spinoza and Leibniz. Yet he compares favourably in a number of ,respects with other 19th-century metaphysicians — Hegel and his followers. for instance. He recognized, as they did not, the force of Kant's criticisms of metaphysics, and he had a much clearer conception of the relations holding between language and the world and, consequently, of the limitations of a priori knowledge. Moreover, he wrote with great distinction and style and with a natural clarity of expression that prevented him from camouflaging his inconsistencies beneath obscure phraseology and jargon. He showed acute psychological insight, particularly into the metaphysical urge; and his doctrine of the will foreshadowed, in metaphysical form, new categories of thought that were to emerge with advances in the nonphysical sciences — especially psychology. His avowed dissatisfaction with science can in fact be seen — partially at least — as a dissatisfaction with the mechanistic models of explanation and interpretation which theorists of the 17th and 18th centuries, fascinated by the achievements of physics. had sought to extend to all departments of human life and experience. Both here and in his rejection of the optimistic rationalism of the Enlightenment, Schopenhauer showed an originality and a prescience which it is difficult to ignore.

Bibliography.—The earlier collected editions of Schopenhauer's works, by J. Frauenstadt, 6 vol. (Leipzig, 1873–74), M. Brasch, 2 vol., 3rd ed. (Leipzig, 1891) and E. Grisebach, 6 vol. (Leipzig, 1892; supplemented by *Arthur Schopenhauers handschriftlicher Nachlass*, 4 vol., 1895), were superseded by A. Hubscher's rehandling of Frauenstadt's ed., 7 vol., 2nd ed. (Wiesbaden, 1946–50). *See* also *W.* L. Hertslet, *Schopenhauer-Register* (Leipzig, 1890); and G. F. Wagner, *Encyklopadisches Register zu Schopenhauers Werken* (Karlsruhe, 1909). For selections in Eng. trans. see *The Living Thoughts of Schopenhauer, From the World as Will and Idea,* presented by Thomas Mann (New York, London, 1939).

For a bibliography of the earlier studies *see* F. Laban, *Die Schopenhauer-Literatur* (Leipzig, 1880). Modern biographies are: W. Schneider, *Schopenhauer: eine Biographie* (Vienna, 1937); and *A.* Hubscher, *Schopenhauer: ein Lebensbild* (Leipzig, 1938). For a study of his philosophy in English, *see* F. Copleston, *Arthur Schopenhauer, Philosopher of Pessimism* (London, 1946). (P. L. G.)

SCHORL, in mineralogy the name given to coarse black varieties of tourmaline (*q.v.*). Schorl was originally a mining term applied both to black tourmaline and to hornblende.

Schorl rocks are crystalline aggregates of quartz and tourmaline and occur almost always in association with tourmaline-bearing granites or pegmatites. They originate by the action of gases and vapours on granites, porphyries and other rocks. Sometimes direct pneumatolytic derivatives of the granite itself, they are also frequent as replacement products of the country rock into which the granite is intruded (*see* also Greisen). The altered granite known as luxullianite, from its occurrence near Luxullian, a village in Cornwall. is a tourmalinized granite in which a progressive replacement of biotite and feldspar by quartz and tourmaline can be traced. The rock still contains pink feldspars in large porphyritic feldspars set in a dark tourmaline matrix, giving polished specimens a handsome appearance. By impregnation with boron-bearing vapours, the slates and sandstones surrounding granites are locally converted into schorl rock, schorl schist or tourmaline hornfels consisting almost wholly of quartz and tourmaline. Banding, lamination or cleavage of the original slates, etc. is frequently preserved. (C. E. T.)

SCHOULER, JAMES (1839–1920), U.S. lawyer and historian of Scottish descent, was best known as a legal writer and for his seven-volume history of the United States. Born in West Cambridge (now Arlington), Mass., on March 20, 1839, he graduated at Harvard in 1859, taught a year at St. Paul's school in Concord, N.H., studied law in Boston and was admitted to the bar in 1862. His legal practice was interrupted by service in the Union army, and in 1869 he moved to Washington, where he opened a branch office and for several years published the *United States Jurist.*

After his return to Boston, he devoted himself to office practice and to literary pursuits, lecturing also at Boston university, the National university law school, Washington, D.C., and Johns Hopkins university, Baltimore, Md. In 1896–97 he was president of the American Historical association. He died at Intervale, N.H., on April 16, 1920. His legal publications include treatises on domestic relations (1870), bailments (1880) and wills (1887).

Schouler is best known, however, as a historian, his most important work being a *History of the United States Under the Constitution* (1880–1913) covering events from 1783 to 1877. Among his other publications are *Historical Briefs* (1896), which contains his biography up to that period; *Constitutional Studies* (1897); lives of Thomas Jefferson (1893) and Alexander Hamilton (1901); *Americans of 1776* (1906); and *Ideals of the Republic* (1908).

SCHREINER, OLIVE (1855–1920), pen name of Mrs. Cronwright-Schreiner, was born in Basutoland, the daughter of a German missionary. In 1881 she brought to England the manuscript of her first novel, *The Story of an African Farm,* a vivid and penetrating study of the life. she knew well, and submitted it to George Meredith, then reader for Chapman and Hall. It was published in 1883 by this firm over the pseudonym "Ralph Iron," and proved an immediate success, entirely surpassing any of her subsequent writings in literary merit. Her later work included *Dreams* (1891); *Trooper Peter Halkett of Mashonaland* (1897), a much-criticized attack on the first settlers in Rhodesia; *An English South African's View of the Situation* (1899); and *Woman and Labour* (1911), a fragment of an earlier manuscript which had been burned during the South African war. She died at Cape Town, U. of S.Af., in Dec. 1920. She had married in 1894 S. C. Cronwright. a member of the Cape parliament. who afterward took the name of S. C. Cronwright-Schreiner. He wrote *The Life of Olive Schreiner,* which appeared in 1924.

SCHREINER, WILLIAM PHILIP (1857–1919), was born in the district of Cape Colony. After studying law at Cape Town, and at Cambridge and London universities, he was called to the bar (Inner Temple) in 1882 and on returning to South Africa in the same year was admitted as an advocate of the Cape supreme court.

He was for many years leader of the Cape bar; in 1887 he entered Cape politics as attorney general in the second Rhodes ministry. He was prime minister on the outbreak of the South African war (1899). In 1914 he was appointed high commissioner for the Union in London, and he died at Llandrindod Wells, Wales, on June 28, 1919.

SCHREYER, ADOLF (1828–1899), German painter, especially esteemed as a painter of horses, of peasant life in Wallachia and Moldavia, and of battle incidents, was born at Frankfurt am Main on May 9, 1828. He studied art first at the Staedel institute in his native town and then at Stuttgart, Munich and Diisseldorf; but he formed his style in Paris, while he found his favourite subjects in his travels in the near east. In 1862 he settled in Paris, but returned to Germany in 1870, settling at Cronberg near Frankfurt, where he died in 1899. Schreyer's work may be seen at the Museum of Art in Toledo, O., at the Metropolitan Museum of Art, New York city, and at other galleries.

SCHRODER, FRIEDRICH LUDWIG (1744–1816), German actor, manager and dramatist, was born in Schwerin on Nov. 3, 1744. In 1764 he appeared with the Ackermann company (K. E. Ackermann was his stepfather) in Hamburg, playing leading comedy parts; but his most famous performances were in the tragic roles of Hamlet. Lear and Philip in Schiller's *Don Carlos.* After Ackermann's death in 1771 Schröder and his mother took over the management of the Hamburg theatre, and he began to write plays — largely adaptations from the English, making his first success with the comedy *Die Arglistige.* In 1780 he left Hamburg, and after a tour with his wife, Anna Christina Hart, accepted an engagement at the Court theatre in Vienna. In 1785 Schroder again took over his Hamburg management and conducted the theatre with marked ability until his retirement in 1798. In 1811 he returned to it for one year. He died on Sept. 3, 1816.

As an actor Schroder abandoned the stilted style of former tragedians; as a manager he first brought Shakespeare before the German public. Schroder's *Dramatische Werke,* with an introduction by Tieck, were published in four volumes (1831).

See B. Litzmann, Friedrich Ludwig Schroder (Hamburg, 1890–94); R. Blum in the *Allgemeines* Theater-Lexikon (1842); and Brunier, Friedrich Ludwig *Schröder* (Leipzig, 1864).

SCHRODINGER, ERWIN (1887–1961), Austrian physicist who, with Paul A. M. Dirac (*q.v.*), was awarded the Nobel prize for physics in 1933 for work on wave mechanics and its applications to atomic structure. His discoveries agreed with those made independently by Werner Heisenberg (*q.v.*).

Schrodinger was born in Vienna on Aug. 12, 1887. He was educated at the University of Vienna, Aus., and was subsequently professor of physics in Stuttgart, Ger., Breslau, Pol., and Ziirich, Switz. He succeeded Max Planck as professor of physics at the University of Berlin in 1927. and in 1940 he became professor at the Institute for Advanced Studies in Dublin. Ire. He returned to Vienna in 1956 and died there on Jan. 4, 1961.

His work. which was mainly in the field of mathematical physics and especially in the physics of the atom, was an extension of the ideas of Louis de Broglie (see BROGLIE, DE). Niels Bohr (*q.v.*) had pictured the atom as consisting of a nucleus about which electrons rotated in fixed orbits, radiation being absorbed or emitted only when an electron changed from one orbit to another, the energy change involved being therefore discrete! and the atom regarded as being in a series of what were called "stationary states." De Broglie's theory of wave mechanics, or matter waves, had modified this by supposing that a wave, with a wave length an exact submultiple of the length of the orbit, is associated with the electron circulating about the nucleus. Schrodinger extended these ideas further to the problem of atomic structure by supposing that such waves could be superposed on each other. The emission and absorption frequencies were thus related to the orbital frequencies and were represented by the differences of the frequencies of two standing waves. The mathematical application of these ideas was confirmed by experimental observations of spectral lines. Schrodinger wrote several works on wave mechanics and also developed a new field theory. (D. McK.)

SCHUBERT, FRANZ PETER (1797–1828), Austrian composer, was born on Jan. 31, 1797, in the Himmelpfortgrund, a small suburb of Vienna. His father, Franz, son of a Moravian peasant, was a parish schoolmaster; his mother, Elizabeth Fitz, had before her marriage been cook in a Viennese family. Of their 14 children nine died in infancy. The father, a man of worth and integrity, possessed some reputation as a teacher, and his school, in the Lichtenthal, was well attended. He was also a fair musician.

At the age of five Schubert began to receive regular instruction from his father. At seven he was placed under the charge of Michael Holzer, the Kapellmeister of the Lichtenthal Church. Holzer's lessons seem to have consisted mainly in expressions of admiration, and the boy gained more from a friendly joiner's apprentice, who used to take him to a neighbouring pianoforte warehouse and give him the opportunity of practising on a better instrument than the poor home could afford.

In Oct. 1808 he was received as a scholar at the Convict, which, under Salieri's direction, had become the chief music-school of Vienna, and which had the special office of training the choristers for the Court Chapel. Here he remained until nearly 17, profiting little by the direct instruction, which was almost as careless as that given to Haydn at St. Stephen's, but much by the practices of the school orchestra, and by association with congenial comrades. Many of the most devoted friends of his after life were among his schoolfellows: Spaun and Stadler and Holzapfel, and a score of others who helped him out of their slender pocket-money, bought him music-paper which he could not buy for himself, and gave him loyal support and encouragement.

EARLY COMPOSITIONS

Meanwhile his genius was already showing itself in composition. A pianoforte fantasia, 32 close-written pages, is dated April 8–May 1, 1810: then followed in 1811, three long vocal pieces written upon a plan which Zumsteeg had popularized, together with a "quintet-overture," a string quartet, a second pianoforte fantasia and a number of songs. His essay in chamber-music is noticeable, since we learn that at the time a regular quartet-party was established at his home "on Sundays and holidays," in which his two brothers played the violin, his father the violoncello and Franz himself the viola. It was the first germ of that amateur orchestra for which, in later years, many of his compositions were written. During the remainder of his stay at the Convict he wrote a good deal more chamber-music, several songs, some miscellaneous pieces for the pianoforte and, among his more ambitious efforts, a Kyrie and Salve Regina, an octet for wind instruments — said to commemorate the death of his mother, which took place in 1812—a cantata, words and music, for his father's name-day in 1813, and the closing work of his school-life, his first symphony.

At the end of 1813 he left the Convict, and, to avoid military service, entered his father's school as teacher of the lowest class. For over two years he endured the drudgery of the work, which, we are told, he performed with very indifferent success. There were, however, other interests to compensate. He took private lessons from Salieri, who annoyed him with accusations of plagiarism from Haydn and Mozart, but who did more for his training than any of his other teachers; he occupied every moment of leisure with rapid and voluminous composition. His first opera —*Des* Teufels Lustschloss — and his first Mass — in F major — were both written in 1814, and to the same year belong three string quartets, many smaller instrumental pieces, the first movement of the symphony in B flat and 17 songs, including such masterpieces as *Der* Taucher and Gretchen am *Spinnrade*. But even this activity is far outpaced by that of the *annus* mirabilis 1815. In this year, despite his school-work, his lessons with Salieri and the many distractions of Viennese life, he produced an amount of music the record of which is almost incredible. The symphony in B flat was finished, and a third, in D major, added soon afterwards. Of church music there appeared two Masses, in G and B flat, the former written in six days, a new Dona *nobis* for the Mass in F, a *Stabat* Mater and a Salve Regina. Opera was represented by no fewer than five works, of which three were completed —*Der Vierjährige Posten,* Fernando and Claudine von Villabella — and two, Adrast and Die *beiden Freunde von Salamanca,* apparently left unfinished. Besides these the list includes a string quartet in G minor, four sonatas and several smaller compositions for piano, and, by way of climax, 146 songs, some of which are of considerable length, and of which eight are dated Oct. 15, and seven Oct. 19.

In the winter of 1814–15 Schubert made acquaintance with the poet Mayrhofer: an' acquaintance which, according to his usual habit, soon ripened into a warm and intimate friendship. They were singularly unlike in temperament: Schubert frank, open and sunny, with brief fits of depression, and sudden outbursts of boisterous high spirits; Mayrhofer grim and saturnine, a silent man who regarded life chiefly as a test of endurance.

As 1815 was the most prolific period of Schubert's life, so 1816 saw the first real change in his fortunes. Somewhere about the turn of the year Spaun surprised him in the composition of Erlkonig — Goethe's poem propped among a heap of exercise-books, and the boy at white-heat of inspiration "hurling" the notes on the music-paper. A few weeks later Von Schober, a law-student of good family and some means, who had heard some of Schubert's songs at Spaun's house, came to pay a visit to the composer and proposed to carry him off from school-life and give him freedom to practise his art in peace. The proposal was particularly opportune, for Schubert had just made an unsuccessful application for the post of Kapellmeister at Laibach, and was feeling more acutely than ever the slavery of the class-room. His father's consent was readily given, and before the end of the spring he was installed as a guest in Von Schober's lodgings. For a time he attempted to increase the household resources by giving music lessons, but they were soon abandoned and he devoted himself to composition. "I write all day," he said later to an inquiring visitor, "and when I have finished one piece I begin another."

The works of 1816 include three ceremonial cantatas and two new symphonies, No. 4 in C minor, called the Tragic, with a striking andante, No. 5 in B flat, as bright and fresh as a symphony of Mozart; some numbers of church music, fuller and more mature than any of their predecessors, and over a hundred songs, among which are comprised some of his finest settings of Goethe and Schiller. There is also an opera, *Die Burgsckajt*, spoiled by an illiterate book.

All this time his circle of friends was steadily widening. Mayrhofer introduced him to Vogl, the famous baritone, who did him good service by performing his songs in the salons of Vienna; Anselm Hiittenbrenner and his brother Joseph ranged themselves among his most devoted admirers; Gahy, an excellent pianist, played his sonatas and fantasias; the Sonnleithners, a rich burgher family whose eldest son had been at the Convict, gave him free access to their home, and organized in his honour musical parties which soon assumed the name of Schubertiaden. The material needs of life were supplied without much difficulty. No doubt Schubert was entirely penniless, for he had given up teaching, he could earn nothing by public performance, and, as yet, no publisher would take his music at a gift; but his friends came to his aid with true Bohemian generosity—one found him lodging, another found him appliances, they took their meals together and the man who had any money paid the score. Schubert was always the leader of the party and was known by half-a-dozen affectionate nicknames, of which the most characteristic is *"kann er 'was?"* his usual question when a new acquaintance was proposed.

The year 1818, though, like its predecessor, comparatively unfertile in composition, was in two respects a memorable year. It saw the first public performance of any work of Schubert's—an overture in the Italian style written as an avowed burlesque of Rossini, and played in all seriousness at a Jäll concert on March 1. It also saw the beginning of his only official appointment, the post of music-master to the family of Count Johann Esterhazy at Zelesz, where he spent the summer amid pleasant and congenial surroundings. On his return to Vienna in the autumn he found that Von Schober had no room for him, and took up his residence with Mayrhofer. He made his first public appearance as a song-writer on Feb. 28, 1819, when the *Schäfers Klagelied* was sung by Jager at a Jall concert. In the summer of the same year he took a holiday and travelled with Vogl through Upper Austria. At Steyr he wrote his brilliant piano quintet in A, and astonished his friends by transcribing the parts without a score. In the autumn he sent three of his songs to Goethe, but, so far as we know, received no acknowledgment.

MATURITY

The compositions of 1820 are remarkable, and show a great advance in development and maturity of style. The unfinished oratorio *Lazarus* was begun in Feb.; later followed, amid a number of smaller works, the 23rd Psalm, the *Gesang der Geister,* the quartettsatz in C minor and the great pianoforte fantasia on *Der Wanderer.* But of almost more biographical interest is the fact that in this year two of Schubert's operas appeared at the Karnthnerthor theatre, *Die Zwillingsbrüder* on June 14, and *Die Zauberharfe* on Aug. 19. Still, however, publishers held obstinately aloof, and it was not until his friend Vogl had sung *Erlkönig* at a concert in the Karnthnerthor (Feb. 8, 1821) that Diabelli hesitatingly agreed to print some of his works on commission. The first seven opus-numbers (all songs) appeared on these terms; then the commission ceased, and he began to receive the meagre pittances which were all that the great publishing houses ever accorded to him. Much has been written about the neglect from which he suffered during his lifetime. It was not the fault of his friends, it was only indirectly the fault of the Viennese public; the persons most to blame were the cautious intermediaries who stinted and hindered him from publication.

The production of his two dramatic pieces turned Schubert's attention more firmly than ever in the direction of the stage; and towards the end of 1821 he set himself on a course which for nearly three years brought him continuous mortification and disappointment. *Alfonso und Estrella* was refused, so was *Fierrabras; Die Verschworenen* was prohibited by the censor (apparently on the ground of its title); *Rosamunde* was withdrawn after two nights, owing to the badness of its libretto. Of these works the two former are written on a scale which would make their performances exceedingly difficult (*Fierrabras,* for instance, contains over 1,000 pages of manuscript score), but *Die Vsrschworenen* is a bright, attractive comedy, and *Rosamunde* contains some of the most charming music that Schubert ever composed. In 1822 he made the acquaintance both of Weber and of Beethoven, but little came of it in either case, though Beethoven cordially acknowledged his genius. Von Schober was away from Vienna; new friends appeared of a less desirable character; on the whole these were the darkest years of his life.

In the spring of 1824 he wrote the magnificent octet, "A Sketch for a Grand Symphony"; and in the summer went back to Zelesz, when he became attracted by Hungarian idiom, and wrote the *Divertissement à l'Hongroise* and the string quartet in A minor. Most of his biographers insert here a story of his hopeless passion for his pupil Countess Caroline Esterhazy; but whatever may be said as to the general likelihood of the romance, the details by which it is illustrated are apocryphal, and the song *l'Addio,* placed at its climax, is undoubtedly spurious. A more debatable problem is raised by the grand duo in C major (op. 140) which is dated from Zelesz in the summer of this year. It bears no relation to the style 'of Schubert's pianoforte music, it is wholly orchestral in character, and it may well be a transcript or sketch of the "grand symphony" for which the octet was a preparation. If so, it settles the question, raised by Sir George Grove, of a "symphony in C major" which is not to be found among Schubert's orchestral scores.

Despite his preoccupation with the stage and later with his official duties he found time during these years for a good deal of miscellaneous composition. The Mass in A flat mas completed and the exquisite "Unfinished Symphony" begun in 1822. The *Müllerlieder,* and several other of his best songs, were written in 1825; to 1824, beside the works mentioned above, belong the variations on *Trockne Blumen* and the two string quartets in E and E flat. There is also a sonata for piano and arpeggione, an interesting attempt to encourage a cumbersome and now obsolete instrument.

The mishaps of the recent years were compensated by the prosperity and happiness of 1825. Publication had been moving more rapidly; the stress of poverty was for a time lightened; in the summer there was a pleasant holiday in Upper Austria, where Schubert was welcomed with enthusiasm. It was during this tour that he produced his "Songs from Sir Walter Scott," and his piano sonata in A minor (op. 42), the former of which he sold to Artaria for £20, the largest sum which he had yet received for any composition. Sir George Grove, on the authority of Randhartinger, attributes to this summer a lost "Gastein" symphony which is possibly the same work as that already mentioned under the record of the preceding year.

From 1826 to 1828 Schubert resided continuously in Vienna, except for a brief visit to Graz in 1827. The history of his life during these three years is little more than a record of his compositions. The only events worth notice are that in 1826 he applied for a conductorship at the opera, and lost it by refusing to alter one of his songs at rehearsal, and that in the spring of 1828 he gave, for the first and only time in his career, a public concert of his own works. But the compositions themselves are a sufficient biography. The string quartet in D minor, with the variations on the song *Der Tod und das Mädchen,* was written during the winter of 1825–26, and first played on Jan. 25. Later in the year came the string quartet in G major, the "Rondeau brilliant," for piano and violin, and the fine sonata in G which, by some pedantry of the publisher's, is printed without its proper title. To these should be added the three Shakespearian songs, of which *Hark! Hark! the Lark* and *Who is Sylvia?* were written on the same day, the former at a tavern where he broke his afternoon's walk, the latter on his return to his lodging in the evening. In 1827 he wrote the *Winterreise* songs, the fantasia for piano and violin, and the two piano trios; in 1828 the *Song of Miriam,* the C major symphony, the Mass in E flat, and the exceedingly Beautiful *Tantum Ergo* in the same key, the string quintet, the second Benedictus to the Mass in C, the last three piano sonatas, and the collection of songs known as *Schwanengesang.* Six of these are to words by Heine, whose *Buch der Lieder* had recently appeared. Everything pointed to the renewal of an activity which should equal that of his greatest abundance, when he was suddenly attacked by typhus fever, and after a fortnight's illness died on Nov. 19 at the house of his brother Ferdinand. He had not completed his 32nd year.

HIS ACHIEVEMENT

Some of his smaller pieces were printed shortly after his death, but the more valuable seem to have been regarded by the publishers as waste paper. In 1838 Schumann, on a visit to Vienna, found the dusty manuscript of the C major symphony and took it back to Leipzig, where it was performed by Mendelssohn and celebrated in the *Neue Zeitschrift*. The most important step towards the recovery of the neglected works was the journey to Vienna which Sir George Grove and Sir Arthur Sullivan made in the autumn of 1867. The travellers rescued from oblivion seven symphonies, the *Rosamunde* music, some of the Masses and operas, some of the chamber works, and a vast quantity of miscellaneous pieces and songs. Their success gave impetus to a widespread public interest and finally resulted in the definitive edition of Breitkopf and Härtel.

Schubert is best summed up in the well-known phrase of Liszt, that he was "le musicien le plus poète qui fut jamais." In clarity of style he was inferior to Mozart, in power of musical construction he was far inferior to Beethoven, but in poetic impulse and suggestion he is unsurpassed. He wrote always at headlong speed, he seldom blotted a line, and the greater part of his work bears, in consequence, the essential mark of improvisation: it is fresh, vivid, spontaneous, impatient of restraint, full of rich colour and of warm imaginative feeling. He was the greatest song-writer who ever lived, and almost everything in his hand turned to song. In his Masses, for instance, he seems to chafe at the contrapuntal numbers and pours out his whole soul on those which he found suitable for lyrical treatment. In his symphonies the lyric and elegiac passages are usually the best, and the most beautiful of them all is, throughout its two movements, lyric in character. The standpoint from which to judge him is that of a singer who ranged over the whole field of musical composition and everywhere carried with him the artistic form which he loved best.

Like Mozart, whose influence over him was always considerable, he wrote nearly all the finest of his compositions in the last ten years of his life. His early symphonies, his early quartets, even his early Masses, are too much affected by a traditional style to establish an enduring reputation. It is unfair to call them imitative, but at the time when he wrote them he was saturated with Mozart, and early Beethoven, and he spoke what was in his mind with a boy's frankness. The andante of the Tragic symphony (NO. 4) strikes a more distinctive note, but the fifth is but a charming adaptation of a past idiom, and the sixth, on which Schubert himself placed little value, shows hardly any appreciable advance. It is a very different matter when we come to the later works. The piano quintet in A major (1819) may here be taken as the turning-point; then come the Unfinished symphony, which is pure Schubert in every bar; the three quartets in A minor, D minor and G major, full of romantic colour; the delightful piano trios; the great string quintet; and the C major symphony which, though diffuse, contains many passages of surpassing beauty.

His larger operas are marred both by their inordinate length and by their want of dramatic power. The slighter comedies are pretty and tuneful, but, except as curiosities, are not likely to be revived. We may, however, deplore the fate which has deprived the stage of the *Rosamunde* music. It is in Schubert's best vein; the *entr'actes*, the romance, and the ballets are alike excellent, and it is much to be hoped that a poet will some day arise and fit the music to a new play.

Of his pianoforte compositions, the sonatas, as might be expected, are the least enduring, though there is not one of them which does not contain some first-rate work. On the other hand his smaller pieces, in which the lyric character is more apparent, are throughout interesting to play and extremely pleasant to hear. A special word should be added on his fondness for piano duets, a form which before his time had been rarely attempted.

His concerted pieces for the voice are often extremely difficult, but they are of a rare beauty which would well repay the labour of rehearsal.

Of the songs it is impossible, within the present limits, to give even a sketch. They number over 600, excluding scenas and operatic pieces, and they contain masterpieces from the beginning of his career to the end. *Gretchen am Spinnrade* was written when he was 17, *Erlkönig* when he was 18; then there follows a continuous stream which never checks or runs dry, and which broadens as it flows to the *Müllerlieder*, the Scott songs, the Shakespearian songs, the *Winterreise*, and the *Schwanengesang*. He is said to have been undiscriminating in his choice of words. Schumann declared that "he could set a handbill to music," and there is no doubt that he was inspired by any lyric which contained, though even in imperfect expression, the germ of a poetic idea. But his finest songs are almost all to fine poems. He set over 70 of Goethe's, over 60 of Schiller's.

In his earlier songs he is more affected by the external and pictorial aspect of the poem; in the later ones he penetrates to the centre and seizes the poetic conception from within. But in both alike he shows a gift of absolute melody which, even apart from its meaning, would be inestimable. Neither Händel nor Mozart—his two great predecessors in lyric tune—have surpassed or even approached him in fertility and variety of resource. The songs in *Acis* are wonderful; so are those in *Zauberflöte*, but they are not so wonderful as *Litanei*, and *Who is Sylvia?* and the *Ständchen*. To Schubert we owe the introduction into music of a particular quality of romance, a particular "addition of strangeness to beauty"; and so long as the art remains his place among its supreme masters is undoubtedly assured.

SCHÜCKING, WALTER (1875–1935), German jurist, was born on Jan. 6, 1875, at Munster, Westphalia. He taught at the universities of Breslau and Marburg 1900–21, and in 1921 was appointed a professor at the Berlin commercial high school. In 1919 he was appointed a member of the National Assembly and chief German delegate to the Peace Conference at Versailles. In 1919 he became a member of the permanent court of arbitration at The Hague. In 1920 and again in 1924 he was elected to the Reichstag and became one of the leaders of the German Democratic party.

His works include: *Das Küstenmeer im internationalen Recht* (1897), "Die Verwendung von Minem im Seekrieg" (in Niemeyer's *Zeitschrift*, vol. 16), *Die Organisation der Welt* (2nd ed. 1909), *Der Staatenverband der Haager Conferenzen* (1912) (Eng. trans. 1918), *Neue Ziele der staatlichen Entwicklung* (3rd ed. 1913), *Internationale Rechtsgarantien* (Hamburg, 1918), *Die Satzung des Völkerbundes* (2nd ed. 1924), *Garantiepakt und Rüstungsbeschränkung* (1924), *Das Genfer Protokoll* (1924).

SCHULZE-DELITZSCH, FRANZ HERMANN (1808–1883), German economist, was born at Delitzsch, in Prussian Saxony, on Aug. 29, 1808. The suffix Delitzsch was added in 1848 to distinguish him from other Schulzes in the National Assembly. He studied law at Leipzig and Halle, became an assessor in the court of justice at Berlin in 1838, and three years later was appointed *Patrimonialrichter* at Delitzsch. Entering the parliament of 1848, he joined the Left Centre, and, acting as president of the commission of inquiry into the condition of the labourers and artisans, became impressed with the necessity of co-operation to enable the smaller tradespeople to hold their own against the capitalists. He was a member of the Second Chamber in 1848–49; but a quarrel with the minister of justice led him to throw up his public appointments in October 1851, and withdraw to

Delitzsch. Here he devoted himself to the organization of co-operative societies, and of Vorschussvereine (people's banks). In 1859 he promoted the first *Genossenschaftstag,* or co-operative meeting, in Weimar, and founded a central bureau of co-operative societies. In 1861 he again entered the Prussian Chamber. The next few years were given to the formation of local centres, and the establishment of the Deutsche Genossenschafts-Bank, 1865.

The spread of these organizations led to legislation on the subject, and this too was chiefly the work of Schulze-Delitzsch. As a member of the Chamber in 1867 he was mainly instrumental in passing the Prussian law of association, which was extendec! to the North German Confederation in 1868, and later to the empire. Schulze-Delitzsch also contributed to uniformity of legislation throughout the states of Germany, in 1869. by the publication of *Die Gesetzgebung über die privatrechtliche Stellung der Erwerbs- und Wirthschaftsgenossenschaften,* etc. His remaining years were spent in consolidating his work. He died on April 29, 1883, at Potsdam.

His works include: *Kapitel zu einem deutschen Arbeiter-Katechismus* (1863); *Soziale Rechte und Pflichten* (1867); and *Die Entwicklung des Genossenschaftswesen in Deutschland* (1870). *See* also A. Bernstein, *Schulze-Delitzsch* (1879); B. Rampal, *Esquisse Biographique* (1874).

SCHUMANN, **ROBERT** ALEXANDER (1810–1856), German musical composer, was born on June 8, 1810, in Zwickau, Saxony, the son of a publisher. He tells us that he began to compose before his seventh year. At fourteen he wrote an essay on the aesthetics of music and also contributed to a volume edited by his father, entitled *Portraits of Famous Men.* While still at school in Zwickau he read, besides Schiller and Goethe, Byron (whose *Beppo* and *Childe Harold* had been translated by his father) and the Greek tragedians. But the most powerful and permanent of the literary influences exercised upon him, however, was that of Jenn Paul Richter. This influence may clearly be seen in his youthful novels *Juniusabende* and *Selene,* of which the first only was completed (1826). In 1828 he left school, and after a tour, during which he met Heine at Munich, he went to Leipzig to study law. His interest in music had been stimulated when he was a child by hearing hfoscheles play at Carlsbad, and in 1827 by the works of Schubert and Mendelssohn. But his father, who had encouraged the boy's musical aspirations, had died in 1826, and neither his mother nor his guardian approved of a musical career for him. Nevertheless, both at Leipzig and at Heidelberg, whither he went in 1829, he neglected the law for the philosophers, and began composing songs. At Easter 1830 he heard Paganini at Frankfurt. In December 1830 he returned to Leipzig, taking piano lessons with his old master, Friedrich Wieck. In his haste to acquire a perfect execution he permanently injured his right hand. His ambitions as a pianist being thus suddenly ruined, he began a course of theory under Heinrich Dorn, conductor of the Leipzig opera. About this time he contemplated an opera on the subject of *Hamlet.*

The fusion of the literary idea with its musical illustration, which may be said to have first taken shape in *Papillons* (op. 2), is foreshadowed in an essay on Chopin's variations on a theme from *Don Juan,* which appeared in the *Allgemeine musikalische Zeitung* in 1831. Here the work is discussed by the imaginary characters Florestan and Eusebius (the counterparts of Vult and Walt in Jean Paul's novel *Flegeljahre*), and Meister Raro (representing either the composer himself or Wieck) is called upon for his opinion. By the time, however, that Schumann had written *Papillons* (1831) he had gone a step farther. The scenes and characters of his favourite novelist had now passed definitely and consciously into the written music, and in a letter from Leipzig (April 1832) he bids his brothers "read the last scene in Jean Paul's *Flegeljahre* as soon as possible, because the *Papillons* are intended as a musical representation of that masquerade." In the winter of 1832 Schumann visited his relations at Zwickau and Schneeberg, when the first movement of his symphony in G minor mas performed. In Zwickau the music was played at a concert given by Wieck's daughter Clara. then only thirteen. The death of his brother Julius and of his sister-in-law Rosalie in 1833 affected Schumann with profound melancholy. By the spring of 1834, however, he started *Die neue Zeitschrift fur Musik,* the paper in which appeared the greater part of his critical writings. The journal effected a revolution in the taste of the time, when Mozart, Beethoven and Weber were neglected, and the genius of Chopin and of Berlioz unappreciated.

During the summer of 1834, Schumann became engaged to Ernestine von Fricken, a girl of sixteen, the adopted daughter of a rich Bohemian, from whose variations on a theme in C♯ minor Schumann constructed his own *Études symphoniques.* The engagement was broken off by Schumann, for reasons which have always remained obscure. In the *Carnaval* (op. 9=1834), Schumann commenced nearly all the sections with the musical notes signified in German by the letters that spell Asch, the town in which Ernestine was born, which also are the musical letters in Schumann's own name. By the sub-title "Estrella" to one of the sections in the *Carnaval,* Ernestine is meant, and by the sub-title "Chiarina" Clara Wieck. In the *Carnaval* Schumann went farther than in *Papillons,* for in it he himself conceived the story of which it was the musical illustration. On Oct. 3, 1835, Schumann met Mendelssohn at Wieck's house in Leipzig, and his appreciation of his great contemporary was shown with the generous freedom that distinguished him in all his relations to other musicians.

In 1836 Schumann's acquaintance with Clara Wieck, already famous as a pianist, ripened into love, and a year later he asked her father's consent to their marriage, but was met with a refusal. The series of *Phantasiestücke* for the piano (op. 12) once more illustrates the fusion of literary and musical ideas as embodied conceptions in such pieces as "Warum" and "In der Nacht." In the *Kreisleriana,* written in 1838, the composer's realism is again carried a step farther. Kreisler, the romantic poet brought into contact with the real world, was a character drawn from life by the poet E. T. A. Hoffmann (*q.v.*), and Schumann used him as a mouthpiece for the recital in music of his own personal experiences. The *Phantasie* (op. 17), written in the summer of 1836, is a work of the highest quality of passion. With the *Faschingschwank aus Wien,* his most pictorial work for the piano, written in 1839, after a visit to Vienna, this period of his life comes to an end. As Wieck still withheld hi: consent to their marriage, Robert and Clara dispensed with it, and were married on Sept. 12 at Schonefeld, near Leipzig.

Until now Schumann had written almost solely for the pianoforte, but in 1840 he wrote about a hundred and fifty songs. Schumann's biographers represent him as caught in a tempest of song, the sweetness, the doubt and the despair of which are all to be attributed to varying emotions aroused by his love for Clara. Yet it would be idle to ascribe to this influence alone the lyrical perfection of "Friihlingsnacht," "Im wunderschonen Monat Mai" and "Schone Wiege meiner Leiden." His chief song-cycles of this period were his settings of the *Liederkreis* of J. von Eichendorff (op. 39), the *Frauenliebe und Leben* of Chamisso (op. 42), the *Dichterliebe* of Heine (op. 48) and *Myrthen,* a collection of songs, including poems by Goethe, Riickert, Heine, Byron, Burns and Moore. The songs "Belsatzar" (op. 57) and "Die beiden Grenadiere" (op. 49), each to Heine's words, show Schumann at his best as a ballad writer, though the dramatic ballad is less congenial to him than the introspective lyric. As Grillparzer said, "He has made himself a new ideal world in which he moves almost as he wills." But in his lifetime the sole tokens of honour bestowed upon Schumann were the degree of Doctor by the University of Jena in 1840, and in 1843 a professorship in the Conservatorium of Leipzig In 1841 he wrote two of his four symphonies. The year 1842 was devoted to the composition of chamber music, and includes the pianoforte quintet (op. 44). In 1843 he wrote *Paradzse and the Peri,* his first essay at concerted vocal music. He had now mastered the separate forms, and from this time forward his compositions are not confined during any particular period to any one of them. In Schumann, above all musicians, the acquisition of technical knowledge was closely bound up with the growth of his own experience and the impulse to express it. The stage in his life when he was deeply engaged in his music to Goethe's Faust (1844–1853) was a critical one for his health. The first half of the year 1844 had been spent with his wife in Russia. On returning to Germany he had abandoned his editorial work, and left Leipzig for Dresden, where he suffered from persistent nervous prostration. As soon as he began to work he was seized with fits of shivering, and an apprehension of death which was exhibited in an abhorrence for high places, for all metal instruments (even keys) and for drugs. He suffered perpetually also from imagining that he had the note A sounding in his ears. In 1846 he had recovered, and in the winter revisited Vienna, travelling to Prague and Berlin in the spring of 1847 and in the summer to Zwickau.

To 1848 belongs his only opera, Genoveva. It is interesting for its attempt to abolish the recitative, which Schumann regarded as an interruption to the musical flow. The music to Byron's *Manfred* is pre-eminent in a year (1849) in which he wrote more than in any other. The insurrection of Dresden caused Schumann to move to Kreischa, a village near the city. In August, on the occasion of the centenary of Goethe's birth, such scenes of Schumann's Faust as were already completed were performed in Dresden, Leipzig and Weimar, Liszt as always giving unwearied assistance and encouragement. The rest of the work was written in the latter part of the year, and the overture in 1853. From 1850 to 1854 the text of Schumann's works is extremely varied. In 1850 he succeeded Ferdinand Hiller as musical director at Düsseldorf; in 1851–1853 he visited Switzerland and Belgium as well as Leipzig. In January 1854 Schumann went to Hanover, where he heard a performance of his Paradise and *the* Peri. Soon after his return to Diisseldorf, a renewal of the symptoms that had threatened him before showed itself. Besides the single note he now imagined that voices sounded in his ear. One night he suddenly left his bed, saying that Schubert and Mendelssohn had sent him a theme which he must write down, and on this theme he wrote five variations for the pianoforte, his last work. On Feb. 27 he threw himself into the Rhine. He was rescued by some boatmen, and taken to a private asylum in Endenich near Bonn, where he remained until his death on July 29, 1856.

His wife, CLARA SCHUMANN (1819–1896), extended her own reputation as a pianist beyond the borders of Germany, and it was thanks to her efforts that Schumann's compositions became generally known in Europe. From 1865 onward she was a regular visitor in London. In 1878 she was appointed teacher of the piano at the Hoch Conservatorium at Frankfurt, a post which she held until 1892, and in which she contributed greatly to the modern improvement in technique. As an artist she is remembered, together with Joseph Joachim, as one of the first executants who really played like composers. She was herself the composer of a few songs and of some charming music, mainly for the piano, and the authoritative editor of her husband's works for Breitkopf and Härtel.

The following are the chief compositions of Robert Schumann.

Pianoforte Works.

Papillons (op. 2)	1829–31
Etudes symphoniques (op. 13)	1834
Carnaval (op. 9)	1834–35
Sonata in F sharp minor (op. 11)	1835
Sonata in G minor (op. 22)	1833–35
Kinderszenen (op. 15)	1836
Fantasia in C (op. 17)	1836
Fantasiestücke (op. 12)	1837
Kreisleriana (op. 16)	1838
Novelletten (op. 21)	1838
Faschingschwank aus Wien (op. 26)	1839

Songs and Choral Works

Songs:—"Liederkreis" (Heine), nine songs (op. 24)	1840
"Myrthen," twenty-six songs (4 books) (op. 25)	1840
"Liederkreis" (Eichendorff), twelve songs (op. 39)	1840
"Frauenliebe und Leben" (Chamisso), eight songs (op. 42)	1840
"Dichterliebe," sixteen songs from Heine's *Buch der Lieder* (op. 48)	1840
"Belsatzar," ballad (Heine) (op. 57)	1840
Song, "Tragödie" (Heine) from op. 64	1841
Ballad, "Der Handschuh" (Schiller)	probably 1851
Songs from Wilhelm Meister and Requiem for Mignon for chorus (op. 98)	1849
Spanische Liebeslieder (op. 138)	1849
Choral *and* Dramatic Works:—"Paradise and the Peri," for solos, chorus and orchestra (op. 50)	1843
Faust music	1844–1853
"Genoveva," opera	1848
Manfred music	1849
"Der Rose Pilgerfahrt" (Moritz Horn), for solos, chorus and orchestra (op. 112)	1851
"Der Königssohn" (Uhland), for solos, chorus and orchestra (op. 103)	1851
"Des Sängers Fluch" (Uhland) for solos, chorus and orchestra (op. 139)	1852
Mass for four part chorus and orchestra (op. 148)	1852
"Vom Pagen und der Königstochter," four ballads (Geibel) for solos, chorus and orchestra (op. 135)	1852
"Das Gliick von Edenhall," ballad (Uhland), for solos, chorus and orchestra (op. 143)	1853
Festival overture on the *Rheinweinlied* for orchestra and chorus (op. 123)	1853

Chamber Music

Three quartets for strings in A minor, F and A (op. 41)	1842
Quintet for pianoforte and strings in E flat (op. 44)	1842
Quartet for pianoforte and strings in E flat (op. 47)	1842
Fantasiestucke for pianoforte, violin and violoncello (op. 88)	1842
Andante and variations for two pianofortes (op. 46)	1843
Trio for pianoforte and strings in D minor (op. 63)	1847
Trio for pianoforte and strings in F (op. 80)	1847
Fantasiestucke for clarinet and pianoforte (op. 73)	1849
Five "Stiicke im Volkston" for piano and violoncello (op. 102)	1849
Three Romances for oboe and piano (op. 94)	1849
"hlarchenbilder" for pianoforte and viola (op. 113)	1851
Sonata for pianoforte and violin in A minor (op. 105)	1851
Trio for pianoforte and strings in G minor (op. 110)	1851
Sonata for pianoforte and violin in D minor (op. 121)	1851
"Marchenerzahlungen," four pieces for clarinet, viola and pianoforte, probably written in	1853

Orchestral *Works*

B flat Symphony (op. 38)	1841
Fourth Symphony in D minor (op. 120)	1841
Overture, Scherzo and Finale	1841
Second Symphony in C (op. 61)	1846
Third or "Rhenish" Symphony in E flat (op. 97)	1850

Concertos *and* Concert-Stucke

For Pianoforte in A minor (op. 54)	1841–1845
Concert-stiick for four horns (op. 86)	1849
Introduction and Allegro-appassionato for Pianoforte (op. 92)	1849
concerto for Violoncello (op. 126)	1852

W. Patterson, *Schumann* (1935).

SCHUMANN-HEINK, ERNESTINE (1861–1936), contralto, was born at Leiben, near Prague, June 15, 1861. After making her début as Azucena, Oct. 13, 1878, at the Court theatre, Dresden, she was engaged at the Stadt theatre, Hamburg, where she remained until she went to the Royal theatre, Berlin. After appearing with success at Bayreuth, in 1896, she made her American début in *Lohengrin,* at Chicago in 1898. Her London début was at Covent Garden, in Das *Rheingold,* 1902.

See Mary Lawton, *Schumann-Heink* (1929).

SCHUMPETER, JOSEPH ALOIS (1883–1950), economist whose work bridges the static equilibrium theory of Léon Walras and modern dynamics (see ECONOMICS: The Marginal Utility Analysis), was born in Triesch, Moravia (now in Czechoslovakia), on Feb. 8, 1883. In Vienna he was a pupil of Friedrich von Wieser and Eugen Bohm-Baaerk and he taught at Czernoaitz, Graz and Bonn (1909–32) when he went to the U.S. where he taught at Harvard university until his death.

Schumpeter's *Theorie der wirtschaftlichen Entwicklung* (1912; Eng. trans., *The Theory of Economic Development*, 1934) contained the seeds of his later work. The central idea is that of the creative entrepreneur whose activities as an "innovator" prevent the capitalist system from settling down into the monotonous circular flow of a static state. The phenomena of interest, held to be nonexistent in a static economy (a view for which he was much criticized), and profit emerge as the results of dynamic change. Business cycles are also the indirect product of innovation, and the capitalist system generates the forces of its own decline into socialism. Schumpeter was consistently hostile to Keynesian economics. He exalted mathematics in economic theory and was a founder of the Econometric society. He died in Taconic. Conn.. Jan. 8, 1950; his monumental *History of Economic Analysis* (1954) was published posthumously.

See for bibliography of Schumpeter's writings *Quarterly Journal of Economics* (Aug. 1950); evaluations of his work are in *Schumpeter, Social Scientist*, ed. by Seymour Harris (1951). (E. H. Cn.)

SCHURMAN, JACOB GOULD (1854–1942), U.S. educator and diplomat. was born at Freetown, P.E.I.. on May 22. 1854, of Dutch descent, his loyalist ancestors having left New York in 1784. He secured his B.A. and M.A. degrees at the University of London (1877 and 1878) and studied for several years in Paris, Edinburgh and Germany. After teaching appointments at Acadia, Wolfville, N.S., (1880–82) and Dalhousie, Halifax. N.S., (1882–86) colleges. he went to Cornell university as professor of philosophy. He became dean of the Sage school of philosophy in 1891 and president of the university in 1892, holding that post until 1920. Like his predecessor. Andrew Dickson White (*q.v.*), he united a diplomatic with an educational career. He was president of the first U.S. Philippine commission in 1899; he served as minister to Greece and Montenegro and to China. becoming in 1925 ambassador to Germany. He edited the *Philosophical Review* (of which he was a cofounder) and wrote *Kantian Ethics and the Ethics of Evolution* (1881), *The Ethical Import of Darwinism* (1888), *Belief in God* (1890), *Agnosticism and Religion* (1896), *The Balkan Wars, 1912–1913* (1914) and *Why America Is in the War* (1917). He died on Aug. 12. 1942.

SCHURZ, CARL (1829–1906), German-American statesman and reformer, was born in Liblar. near Cologne, on March 2, 1829, the son of a school-teacher. He studied in the Jesuit gymnasium of Cologne in 1840–46, and then entered the University of Bonn, where he became a revolutionary and assisted Gottfried Kinkel, professor of literature and history, in editing the *Bonner Zeitung*. On the outbreak of the revolution of 1848 he took the field. but when Rastatt surrendered he escaped to Ziirich. In 1850 he returned secretly to Germany, rescued Kinkel from prison and helped him to escape to Scotland. Schurz went to Paris. but the police forced him to leave France on the eve of the *coup d'état*, and until Aug. 1852 he lived in London, making his living by teaching German. He married in July 1852 and removed to America. living for a time in Philadelphia.

In 1856 after a year in Europe he settled in Watertown, Wisconsin, and immediately became prominent in the Republican Party. In the Illinois campaign of the next year between Abraham Lincoln and Stephen A. Douglas he took part as a speaker; and later in 1858 he began to practise law in Milwaukee. In the State campaign of 1859 he made a speech attacking the Fugitive Slave Law and in the same year he delivered in Faneuil Hall, Boston, an oration on "true Americanism," which coming from an alien was intended to clear the Republican Party of the charge of "nativism." In the Republican national convention of 1860 Schurz was chairman of the delegation from Wisconsin. Lincoln sent him in 1861 as minister to Spain. He returned to America in Jan. 1869, was commissioned brigadier-general of volunteers in April. and in June took command of a division under Frémont, and then in Sigel's corps, with which he took part in the second battle of Bull Run. He was promoted major-general of volunteers on March 14, and was a division commander at Chancellorsville of the 11th Corps, under Gen. O. O. Howard. He was at Gettysburg and at Chattanooga and was then put in command of a corps of instruction at Nashville; he was with Sherman's army in North Carolina in the last months of the war and resigned immediately after the close of hostilities. In 186j President Johnson sent him through the South to study conditions; but Schurz's valuable report, suggesting the readmission of the States with complete rights and the investigation of the need of further legislation by a Congressional committee, n·as not heeded by the president. In 1866–67 he was chief editor of the Detroit *Post* and then became editor and, joint proprietor with Emil Praetorius (1827–1905) of the *Westliche Post* of St. Louis.

In 1869–75 he was U.S. senator from Missouri, and made a great reputation by his speeches on financial subjects. During this period he broke with the administration: he started the Liberal Republican movement in Missouri in 1870 and in 1872 he presided over the Liberal Republican convention. He opposed Grant's Santo Domingo policy, his Southern policy, and the Government's selling arms and making cartridges for the French army in the Franco-Prussian War. But in 1875 he campaigned for Hayes, as the representative of "sound money," in the Ohio gubernatorial campaign. In 1876 he supported Hayes in the contest for the presidency, and Hayes made him in 1877 his secretary of the interior. Upon his retirement in 1881 he removed to New Tork city, and from 1881 to 1883 was editor-in-chief and one of the proprietors of the *New York Evening Post*. In 1884 he was a leader in the Independent (or Mugwump) movement against the nomination of James G. Blaine for the presidency and for the election of Grover Cleveland. In 1892 he succeeded George William Curtis as president of the National Civil Service Reform League and held this office until 1901. He succeeded Curtis as editorial writer for *Harper's Weekly* in 1892–98, in which he did much for civil service reform and for Cleveland's nomination and election in 1892. He opposed W. J. Bryan for the presidency in 1896, speaking for sound money; in 1900 on the anti-imperialism issue he supported Bryan. He died in New York city on May 14, 1906.

Schurz published a volume of *Speeches* (188j); *Henry Clay* (1887) in the "American Statesmen" series; *Abraham Lincoln* (1889); and *Reminiscences* (1907–08).

SCHUYLER, MONTGOMERY (1843–1914), U.S. journalist. writer and architectural critic. an exponent of modern American architecture. was born in Ithaca, N.Y.. Xug. 19, 1843. and died in New Rochelle. N.Y., July 16. 1914. Schuyler spent 42 years on the staffs of the *New York World* (1865–83) and the *New York Times* (1883–1907) and was also managing editor of *Harper's Weekly* (1885–87). His editorials and features were urbane. dignified and punctuated with sophisticated literary allusions. Schuyler's architectural criticism was no less accomplished than his editorials. though grace and elegance of phrasing were sometimes replaced by polemics and ridicule. He helped found the *Architectural Record* (1891) and from then on his architectural writings had an increasing effect on the architectural profession. *Studies in American Architecture* (1892). a collection of his earlier architectural writings, contains a magnificent essay on the Brooklyn bridge. Though late in life Schuyler praised skyscraper Gothic, he was among the first to recognize and evaluate the significance of the works of Louis Sullivan and Frank Lloyd Wright.

His other published works include *Westward the Course of Empire* (1906), a collection of descriptive essays, and *The Woolworth Building* (1913).

See E. R. Smith, "Montgomery Schuyler and the History of American Architecture," *Architectural Record* (Sept. 1914), for a bibliography of Schuyler's architectural writings. (H. Mn.)

SCHUYLER, PHILIP JOHN (1733–1804), American soldier, mas born at Albany, N.Y., on Nov. 11, 1733. The Schuyler family was established in the new world by Philip Pieterse Schuyler (d. 1683), who migrated from Amsterdam in 1650, and whose son, Peter (1657–1724), was the first mayor of Albany. The family was one of the wealthiest and most influential in the colony and was closely related by marriage to the Van Rensselaers, Van Cortlandts and other representatives of the old Dutch aristocracy. Philip Schuyler served in the Provincial army during the Seven Years' War, first as captain and later as major, taking part in the battles of Lake George (1755), Oswego river (1756), Ticonderoga (1758) and Fort

Frontenac (1758). From 1768 to 1775 he represented Albany in the New York assembly, and he was closely associated with the Livingston family in the leadership of the Presbyterian or Whig party. He was a delegate to the Second Continental congress in May 1775, and on June 19, was chosen one of the four major generals in the Continental service. Placed in command of the northern department of New York, he made preparations for an invasion of Canada. Soon after the expedition started he was prostrated by rheumatic gout, and the actual command devolved upon Gen. Richard Montgomery. On the death of Montgomery and the failure to take Quebec the army retreated to Crown Point, and its commander, Gen. John Sullivan, was superseded by Gen. Horatio Gates. Gates claimed precedence over Schuyler and, on failing to secure recognition, intrigued to bring about Schuyler's dismissal. The necessary withdrawal of the army from Crown Point in 1776 and the evacuation of Ticonderoga in 1777 were magnified by Schuyler's enemies into a retrograde movement, and, on Aug. 19, 1777, he was superseded. A court martial appointed in 1778 acquitted him on every charge. He resigned from the army in April 1779. In 1788 he joined his son-in-law Alexander Hamilton, John Jay and others in leading the movement for the ratification by New York of the federal constitution. He served in the United States senate as a Federalist in 1790–91 and mas again elected in 1797. He was also active for many years as Indian commissioner and surveyor general and helped to settle the New York boundary disputes with Massachusetts arid Pennsylvania. In 1792–96 he carried to a successful conclusion a project for connecting the Hudson with Lake Ontario by way of the Mohawk, Oneida lake and the Onondaga river. He died on Nov. 18, 1804.

SCHWANN, THEODOR (1810–1882). German physiologist known as one of the originators of the cell theory, and the first to use this term, was born at Neuss in Rhenish Prussia on Dec. 7, 1810. After studying at Cologne, Bonn and Würzburg, he graduated in medicine at Berlin in 1834. There he assisted Johannes Peter Muller (*q.v.*) with his experimental work in physiology. Schwann in 1838 was called to the chair of anatomy at the University of Louvain. and in 1847 went as professor to Liège, where he continued until his death, at Cologne, on Jan. 11, 1882. While working with Müller, Schwann's attention was directed to the physicochemical basis of life. Between 1825 and 1837 several workers demonstrated that yeasts of beer and wine are cells that multiply by budding.

In 1839 Schwann was the first to observe internal spores of yeasts, and demonstrated the necessity to digestion of the presence of a ferment which he called pepsin. In 1837 he began to investigate the laws of muscular contraction, discovering the striated muscle in the upper part of the esophagus, and, later, the myelin sheath, covering the peripheral axons, which now bears his name (*see* REGENERATION: *Nerve Regeneration*). Schwann's *Microscopic Investigations on the Accordance in the structure and Growth of Plants and Animals* (1839; Eng. trans., 1847) set forth his hypothesis that both animal and vegetable tissues are to be traced back to cells and that the cells of each are identical in character. His cell theory was taken up by Rudolf Virchow (*q.v.*), who disproved Schwann's hypothesis of the discontinuity of cell formation.

SCHWANTHALER, LUDWIG VON (1802–1848), German sculptor, who was in style a belated neoclassicist, m s born in Munich on Aug. 26, 1802. He studied in Munich and in Rome, where he adopted the neoclassical manner. After 1834 in the new palaces and museums built in Munich by Ludwig I he was probably kept so busy doing pediments, friezes and the like that he had no opportunity to fulfill his real capabilities. Some of his work was on a colossal scale, *e.g.*, a 60-ft. figure of Bavaria, and twelve 10-ft, bronze figures. He supplied the Alte Pinakothek with 25 marbles commemorative of painters. Outside Munich he executed groups for both pediments of the Walhalla in Ratisbon, and also numerous portrait statues, including those of Mozart, Jean Paul Richter and Goethe. Schwanthaler died at Munich on Nov. 14, 1848, and left to the Munich academy his models and studies (about 200), which now form the Schwanthaler museum.

(A. K. McC.)

SCHWARZENBERG, FELIX, PRINCE. ZU (1800–1852), Austrian statesman, was born on Oct. 2, 1800.

After six years' service in the Austrian army, Felix espoused a diplomatic career at the instance of Metternich, and underwent a period of probation (1824–48) at various European courts, which confirmed his aristocratic aversion to popular government. In 1848 he took an active part in the war against Piedmont and the insurgents in Vienna. On Nov. 21, 1848, he was appointed head of a reactionary ministry, at the instance of his brother-in-lam, Prince Windischgratz. Himself a soldier, he aimed at the restoration of the absolute monarchy by means of the army. He supervised the abdication of Ferdinand and proclamation of Francis Joseph as emperor, and although at first he held out prospects of constitutional government, he dissolved the Kremsier *reichstag* at the earliest opportunity (March 7. 1849) and late in November called in the Russians to end the war in Hungary. He then turned his attention to Germany. His refusal to incorporate only the German provinces of the monarchy in the proposed new German empire had thrown the German parliament into the arms of Prussia. His object was to restore the *status quo ante* of the confederation, with the old predominance of Austria. His success in this respert was partly due to exterior circumstances, notably the mistimed exaggerations of the German revolutionists, but largely to his diplomatic skill, unscrupulousness and iron tenacity of purpose with which the weakness of Frederick William IV and his ministers was unable to cope. His triumph came with the restoration of the old federal diet in May 1850 and the signature of the convention of Olmütz Nov. 29, 1850 (*See* GERMANY *History.*) Schwarzenberg was also mainly responsible for Francis Joseph's suspension of the last remnants of the constitution on Dec. 31, 1851. He died on April 5, 1852.

See Berger, *Felix, Fürst zu Schwarzenberg* (1853); A. Beer, *Fürst Schwarzenberg's Deutsche Politik bis zu den Dresdener Konferenzen* (Historisches Taschenbuch, 1891); A. Schwarzenberg, *Prince Felix zu Schwarzenberg, Prime Minister of Austria* (1946).

SCHWARZENBERG, KARL PHILIPP, PRINCE ZU (1771–1820), Austrian field marshal, was born on April 15. 1771, at Vienna. He entered the imperial cavalry in 1788, fought in 1789 under Count Lacy and Baron von Loudon against the Turks, distinguished himself by his bravery and became major in 1792. At Cateau Cambresis in 1794 his brilliant charge at the head of his regiment, vigorously supported by 12 British squadrons, earned him the cross of the Maria Theresa older. After taking part in the battles of Amberg and Würzburg in 1796 he was promoted major general, and in 1799 lieutenant field marshal At Hohenlinden in 1800 his promptitude and courage saved the right wing of the Austrian army from destruction, and he afterward commanded the rear guard. In 1805 he commanded a division under Mack, and when Ulm was surrounded by Napoleon in October he was one of the brave band of cavalry, under the archduke Ferdinand, which cut its way through the hostile lines.

In 1808 he was sent on a mission to St. Petersburg (Leningrad) but returned in time to take part in the battle of Wagram, and was soon afterward promoted general of cavalry. After the peace of Vienna he was sent to Paris to negotiate the marriage between Napoleon and the archduchess Maria Louisa The prince gave a hall in honour of the bride on July 1, 1810, which ended in the tragic death of many of the guests, including his own sister-in-law, in a fire. Napoleon held Schwarzenberg in great esteem, and it was at his request that the prince took command of the Austrian auxiliary corps in the Russian campaign of 1812. In 1813 Schwarzenberg, recently promoted field marshal, was appointed commander in chief of the allied Grand Army of Bohemia against France. As such he was the senior of the allied generals who conducted the campaign of 1813–14 to the final victory before Paris and the overthrow of Napoleon. He died at Leipzig on Oct. 15, 1820.

SCHWARZSCHILD, KARL (1873–1916), German astronomer,. whose researches were of great range and versatility, was born on Oct. 9. 1873, at Frankfurt am Main, Ger. His exceptional ability in science was evident in a paper on the theory of celestial orbits he wrote at the age of 16. As a student, Schwarzschild came under the inspiration of the astronomer Hugo von Seeliger at Munich. In 1901 he became professor and director of the observatory at the University of Gottingen. leaving in 1909 to become director of the Astrophysical observatory at Potsdam. He served actively in World War I, during which he contracted an illness of which he died on May 11, 1916, at Potsdam.

Schwarzschild's contributions to physical science are significant in several fields. In observational astronomy, he was the first to introduce and apply precise methods in photographic photometry; the first to employ a coarse grafting in front of the telescope objective for photometric and astrometric work; and he developed certain basic methods of analysis of solar spectra taken during eclipses. In theoretical astronomy Schwarzschild introduced the concept of radiative equilibrium in astrophysics and was the first clearly to recognize the role of radiative processes in the transport of heat in the atmospheres of the stars. He also initiated some basic mathematical methods for the treatment of these problems.

Schwarzschild laid the foundations of modern statistical methods in astronomy, and also made the most important contributions, after Carl Friedrich Gauss, to geometrical optics and the theory underlying the design of optical instruments.

Although generally considered an astronomer, Schwarzschild also made fundamental contributions to theoretical physics and to relativity. In the former, he was one of the great pioneers in developing Niels Bohr's theory of atomic spectra. In a great paper, the proofs of which he read on his deathbed, Schwarzschild developed (independently of Arnold Sommerfeld) the so-called general "rules of quantization" and gave the complete theory of the Stark effect and initiated the quantum theory of molecular spectra. Similarly, in developing the general theory of relativity, Schwarzschild gave the first exact solution of Einstein's general gravitational equations leading to the discovery of what is now called Schwarzschild's line element describing the geometry of space in the neighbourhood of a mass point. (Su. C.)

SCHWEINFURT, a German town of Bavaria, on the Main, 27 mi. N.E. of Wiirzburg. Pop. (1950) 46,140. Schweinfurt is mentioned in 790, and in the 10th century was the seat of a margrave. Receiving civic rights in the 13th century, it maintained its independence as a free imperial city with few interruptions until 1803, when it passed to Bavaria. In the Thirty Years' War it was occupied by Gustavus Adolphus, who erected fortifications, remains of which are extant. The chief manufactures are paint, beer, sugar, machinery, ball bearings, bicycles, brushes, soap and other drysalteries, basketwork and vinegar. Schweinfurt is the seat of an important sheep and cattle market.

SCHWEINFURTH, GEORG AUGUST (1836–1925), German botanist and traveler who made his name as the explorer of the Bahr el Ghazal region of the west Nile basin, was born in Riga on Dec. 29, 1836, the son of a German wine merchant who had settled in Riga. He studied botany at Heidelberg and Berlin and early became interested in the plants of Africa. In 1863 he traveled down the Red sea to Suakin and overland to Khartoum, botanizing as he went. On his return to Berlin in 1866 he interested the Royal Academy of Science in the botanical exploration of the hitherto little-known region watered by the Bahr el Ghazal, for which he received a grant from the Humboldt institute. Arriving at Suakin in Sept. 1868 and at Khartoum in Jan. 1869, he ascended the White Nile and traveled westward by way of Lake No with a party of ivory traders.

Primarily a botanist, Schweinfurth had also a good knowledge of zoology and ethnology; he spent nearly three years in the region, visiting the Niam-Niam, the Bongo and the Mangbettu peoples; and his is the first authoritative account of the Congo pygmies. Crossing the Nile-Congo watershed he reached, in March 1870, the westward-flowing Uele, later discovered to be an affluent of the Congo. He received the Royal Geographical society's Founder's medal for 1874. his discovery of the Uele having helped toward a final estimate of the extent of the Nile System.

From 1875 to 1888 Schweinfurth lived in Cairo, traveling each winter, notably to the Lebanon in 1880, Socotra in 1881 and the Yemen in 1888, interesting himself in botany. geology, paleontology and archaeology. In 1876 he attended the African conference summoned to Brussels by King Leopold, and in 1888 moved to Berlin where his herbarium was housed. Until 1914 he went to Africa frequently, visiting Eritrea three times between 1891 and 1894. He died in Berlin on Sept. 19. 1925. Schweinfurth was a keen observer and an accurate and humorous recorder; *The Heart of Africa* (1873) is excellent reading and a reminder of the part played by German explorers in African discovery.

See S. Passarge, *Mitteilungen der Geographischen Gesellschaft in Hamburg*, vol. 37 (1926); and an unsigned obituary in *Geogr. J.* vol. 67 (1926). (D. Mn.)

SCHWEITZER, ALBERT (1875–), philosopher, theologian, musician, mission doctor and winner of the Nobel peace prize of 1952, was born on Jan. 14. 1875 the eldest son of the Lutheran pastor of Kaysersberg in Upper Alsace. He studied at the universities of Strasbourg. Paris and Berlin.

Schweitzer's first original academic work was a treatise *Die Religionsphilosophie Kants* (1899), which gained him a doctorate of philosophy at the age of 24. Already however his mind was turning to the problems of the Synoptic Gospels and to that independent line of investigation into the life of Jesus which. despite a multiplicity of other labours, he has pursued ever since, unmoved by controversy. In 1901 appeared *Das Abendmahlsproblem auf Grund der wissenschaftlichen Forschung des 19. Jahrhunderts und der historischen Berichte* and *Das Messianitäts-und Leidensgeheimnis Jesu* (Eng. trans., *The Mystery of the Kingdom of God*, 1914), preparing the way for the publication in 1906 of *Von Reimarus zu Wrede: eine Geschichte der Leben-Jesu-Forschung* (Eng. trans., *The Quest of the Historical Jesus*, 1910), which at once established Schweitzer as a world figure in theological studies. In these two books he made a radical and exhaustive demonstration of the eschatological view of Our Lord's life, the view that Jesus' whole ministry was dominated by His knowledge of His Messiahship and of the imminent end of the world. In two books on Paul and in later and briefer writings he continued to expound the hypothesis that the New Testament is pervaded by eschatological expectation.

Having achieved the second of his three doctorates, in theology, and being already engaged upon *Von Reimarus zu Wrede,* Schweitzer in 1902 agreed to write for his organ instructor, the renowned C. M. Widor of Paris, a study of the life and art of J. S. Bach. Widor recognized in the young Schweitzer not only an unusually gifted organist hut also a Bach interpreter of rare and original perception. As so often in Schweitzer's literary undertakings, an intended essay grew into a substantial book, *Jean Sébastien Bach: le musicien-poète* (1905), written while he was lecturing and preaching in German at Strasbourg. Its publication brought him immediate acclaim from the highest musical circles in France and Germany. Called upon for a German translation, Schweitzer instead entirely rewrote the book in German and at twice the length, and it was from this edition (1908) that the English translation was made (1911). Following his usual practice, he gave the reader a thorough historical and analytical background of the subject, of the origins of the chorale, of the cantata and of the Passion music; he reviewed the forms of music and art within the philosophy of the history of thought and presented Bach as a deeply religious mystic whose music was impersonal and unselfconscious, as cosmic as the forces of nature. In a literary style matching his theme, he described the composer as a musician-poet and the supreme pictorial artist in sound; and he gave detailed and copiously illustrated instructions for the playing of his works. His *J. S. Bach* remains the classic study, for the depth and breadth of its interpretation and for its rich spiritual content.

In 1905, principal of the theological faculty at the university and a pastor in Strasbourg, a scholar and an organist of more than continental repute with an unbounded academic future before him, Schweitzer made known to his protesting friends his intention to realize a decision made on the threshold of manhood. He resigned his university appointments and became a humble medical student to qualify himself as a mission doctor to the primitive natives oi equatorial Africa. Later, in *Zwischen Wasser und Urwald* (1921; Swedish text 1920; Eng. trans., *On the Edge of the Primeval Forest*, 1922), he explained that he had found his simple motive in the parable of Dives, the white man endowed with all the benefits of culture and science, and Lazarus, the Negro exploited and oppressed and lacking even medical treatment for his disease and pain. With characteristic thoroughness he took the full six years' course in medicine and surgery, continuing meanwhile with almost superhuman energy some of his major literary work. In 1912 he married Hélène Bresslau, daughter of a well-known Strasbourg historian and herself an accomplished scholar, who became a trained nurse to share her husband's renunciation and adventure in discipleship. In 1913 they went out to the Gabon province of French Equatorial Africa. The site for Schweitzer's hospital at Lambaréné on the forested banks of the Ogowe river was provided by the Paris Missionary society, which had declined his services because of his unorthodox theological views; but in all else his was an entirely independent enterprise. He established, equipped and maintained his hospital from the proceeds of organ recitals and lectures on his occasional visits to Europe and irom royalties on his books (later also irom unsolicited gifts and grants from private individuals and foundations in many countries).

Building his hospital with his own hands and native help, operating far into the night under the most primitive conditions and entering his long fight with leprosy, with sleeping sickness and with the host of tropical diseases, Schweitzer began at the same time to turn his ever-active intellect to the problem of world civilization. Opportunity for the development of his thought was given by the brief internment at Lambarene in 1914 of himseli and his wife as German subjects, and he continued to work more intensively on his thesis when brought back to a prison camp in Prorence. The outcome was the publication in 1923 of the first two volumes of his *Kulturphilosophie*. The first, *Verfall und Wiederaufbau der Kultur* (Eng. trans., *The Decay and the Restoration of Civilization*, 1923), is a brief introduction, while the second, *Kultur und Ethik* (Eng. trans., *Civilization and Ethics*, 1923), is a brilliant review of the history of ethical thought leading to his own original and positive contribution of reverence for life as the true and effective basis for a civilized world.

Early in 1925 Schweitzer returned to Africa to rebuild his derelict hospital and to renew its work. Famine, pestilence, floods and lack of adequate help made this fresh start even more formidable than the first beginning, and after a couple of years he decided to move to a better site about two miles further up the Ogowe. Here his impressive practical powers of planning and building were devoted to the creation of a larger and more efficient hospital. For more than a quarter of a century the hospital village grew under his hand and, with the discovery of new drugs for the treatment of leprosy, a large leper colony came into being near by.

Beside this principal preoccupation, Schweitzer published *Die Mystik des Apostels Paulus* (1930; Eng. trans., *The Mysticism of Paul the Apostle*, 1931), more massive and mature than his previous pieces of original New Testament scholarship, and *Die Weltanschauung der indischen Denker: Mystik und Ethik* (1935; Eng. trans., *Indian Thought and its Development*, 1936), a book that grew from a single chapter of the draft of the continuation of his *Kulturphilosophie*. He returned for a number of brief visits to his home at Günsbach and to give lectures and organ recitals in Germany, Great Britain, the Netherlands, Scandinavia and France and accepted an invitation to take a leading part in the Goethe bicentenary celebrations at Aspen, Colo., in 1949; and he made gramophone recordings and resumed his editing of Bach's music begun with Widor in 1911. Intermittently he returned to the third volume of the *Kulturphilosophie*, which he was reluctant to publish until he thought its iorm and content satisfactory and world conditions iavourable ior its effective acceptance.

Schweitzer's astonishing capacity for arduous physical and mental labour all his life and into old age was supported by a physique of exceptional strength. Tall and broad, of relentless energy and acute concentration, his iace at once iorceful and strikingly compassionate, his charm ior all who met him proved immediate and magnetic. A peasant shrewdness is evident in his business arrangements and administration of his hospital settlement, together with an almost patriarchal feeling in his retention of control over every detail of its work and management. The practical thoroughness underlying his powers of creation and interpretation is reflected no less clearly in his passion for the building and repair of organs than in his exhaustive mastery of the work of his predecessors in theology and philosophy. He can be regarded as above all an artist striving with humility to become as nearly perfect as possible in his Christian discipleship and in all the manifestations of his many-sided genius.

N. Mozley, *The Theology of Albert Schweitzer* (London, 1950, New York, 1951). (J. D. N.)

SCHWENKFELD, KASPAR (1490–1561), of Ossing, German theologian, entered the service of the duke of Liegnitz, over whom he had great influence. In 1522 he visited Wittenberg, where he made the acquaintance of Andreas Carlstadt and Thomas Münzer. On his return to Liegnitz he helped to spread the principles of the Reformation in the principality and in Silesia, while warning his colleagues against the abuse of the doctrine of justification by faith. The controversy on the Eucharist (1524) revealed his disagreement with Luther on that critical point. He sought to establish a via *media* between the doctrines of Luther and Zwingli, and vainly hoped to obtain for it Luther's acceptance. He as vainly sought to secure Luther's adoption of a strict rule of church discipline, after the manner of the Moravian Brethren. Meanwhile the Anabaptists obtained a footing in Silesia, and suspicions of Schwenkfeld's sympathy with them were aroused. Letters and writings of his own (1527–1528) proved him to hold strongly anti-Lutheran views, and both Catholics and Lutherans urged the duke of Liegnitz to dismiss him. He voluntarily left Liegnitz in 1529, and lived at Strasbourg for five years amongst the Reformed clergy there. In 1533, in an important synod, he defended against Martin Bucer the principles of religious freedom as well as his own doctrine and life. But the heads of the church carried the day, and Schwenkfeld left Strasbourg for a time. The publication (1j39) of a book in proof of his most characteristic doctrine — the deification of the humanity of Christ —led to active persecution by the Lutherans and his expulsion from the city of Ulm. The next year (1540) he published a refutation of the attacks upon his doctrine with a more elaborate exposition of it, under the title Grosse Confession. The book emphasized the differences between the Lutherans and Zwinglians on the doctrine of the Eucharist at a moment when efforts were being made to reconcile them. An anathema was accordingly issued from Schmalkald against Schwenkfeld (together with Sebastian Franck); his books were placed on the Protestant "index"; and he himself was made a religious outlaw. Schwenkfeld went into hiding. He and his followers withdrew from the Lutheran Church, declined its sacraments, and formed small societies of kindred views. He died at Ulm, on Dec. 10, 1561.

Schwenkfeld left behind him a sect (who were called subsequently by others Schwenkfeldians, but who called themselves "Confessors of the Glory of Christ") and numerous writings to perpetuate his ideas. His writings were partially collected in four folio volumes, the first of which was published in the year 1564, containing his principal theological works. His adherents were to be found at his death scattered throughout Germany. In Silesia they formed a distinct sect, which persisted. In the 17th century they were associated with the followers of Jacob Böhme, and were undisturbed until 1708, when an inquiry was made as to their doctrines. In 1720 a commission of Jesuits was despatched to Silesia to convert them by force. Most of them fled from Silesia into Saxony, and thence to Holland, England and North America. Frederick the Great of Prussia, when he seized Silesia, extended his protection to those who remained in that province. Those who had fled to Philadelphia in Pennsylvania (1734) formed a small community under the name of Schwenkfelders; and Zinzendorf and Spangenberg, when they visited the United States, endeavoured, but with little success, to convert them to their views. This community still exists in Pennsylvania and their views appear to be close to those of the Quakers.

Schwenkfeld distinguished between an outward word of God and an inward, the former being the Scriptures and perishable, the latter the divine spirit and eternal. In his Christology he departed from the Lutheran and Zwinglian doctrine of the two natures by insisting on what he called the Vergotterung des Fleisches Christi, the deification or the glorification of the flesh of Christ. His peculiar Christology was based upon profound theological and anthropological ideas, which contain the germs of some recent theological and Chiistological speculations.

Kriebel, "The Schwenkfelders in Pennsylvania," *Pa.-German Soc. and Addresses*, vol. xiii. (1904); and S. K. Brecht, *The Geneological Record of the Schwenkfelder Families* (1923).

SCHWERIN, KURT CHRISTOPH, Count von (1684–1757), Prussian general field marshal, was born at Löwitz, Pomerania. He served in the Dutch army and then in the Mecklenburg-Schwerin armies during the War of the Spanish Succession. In 1713 he was with Charles XII. of Sweden in his captivity at Bender, and in 1718 was made major-general. In 1719 he opposed the Hanoverian army which invaded Mecklenburg (in the course of which he fought a brilliant action at Walsmühlen on March 6, 1719), and in 1720 entered the Prussian service. In 1730, as a major-general, he was a member of the court-martial which tried the crown prince of Prussia (afterwards Frederick the Great) for desertion, and in 1733, at the head of a Prussian army, conducted with great skill the delicate and difficult task of settling the Mecklenburg question. Frederick promoted Schwerin to the rank of general field marshal and made him a count. At the battle of Mollwitz (April 10, 1741) his brilliant leading converted a doubtful battle into a victory. In the Second Silesian War (1744–1745) Schwerin commanded the army which, marching from Glatz, met the king's army under the walls of Prague and contributed 'to the capture of that place. In the first campaign of the Seven Years' War (1; j6) he conducted the war on the Silesian side of Bohemia; and in 1757, following the same route as in 1744, again joined Frederick at Prague. On May 6, leading on a regiment of the left wing to the attack with its colour in his hand, the old field marshal was shot dead.

See Varnhagen von Ense, *Biographische Denkmale*, vol. vi. (3rd ed., Leipzig, 1873), and *Leben Schwerins* (Berlin, 1841).

SCHWERIN, from Jan. 22. 1953, chief town of a district in the German Democratic Republic, at the southwest corner of the Lake of Schwerin 129 mi. N.W. by rail of Berlin. Population: (1925) 48,157; (1950) 93,576. Schwerin is mentioned as a Slavonic stronghold in 1018, its name (*Zwierin*) signifying "game preserve." The town. founded in 1161 by Henry the Lion in opposition to this Slavonic fortress, received civic rights in 1166. From 1167 to 1648 it gave name to a bishopric; and it was also the capital of the duchy of Schwerin, which formed the western part of the grand duchy of Mecklenburg-Schwerin.

Destructive fires. the hardships of the Thirty Years' War and the removal of the court to Ludwigslust in 1756 seriously depressed the town.

The town is closely surrounded and hemmed in by a number of lakelets. Though Schwerin is the oldest town in Mecklenburg, its aspect is comparatively modern, a fact attributable to destructive fires which swept away most of the ancient houses. The most conspicuous of the many fine buildings is the former ducal palace built in 1844–57 in the French Renaissance style. It stands on a small round island between Castle lake and the lake of Schwerin, formerly the site of a Slavonic fortress and of a later mediaeval castle.

The older palace, the government buildings and the museum all stand in the "old garden," an open space at the end of the bridge leading to the new palace. Among the other secular buildings are the former palace of the heir apparent and the library. The cathedral was originally consecrated in 1248, though the present building—a brick structure in the Baltic Gothic style, with an unfinished tower—dates for the most part from the 15th century.

The chief industry is the making of furniture, and there are also some manufactures of dyes, pianos, wool yarn, sugar, cement and soap.

SCHWERTE, a to n in North Rhine-Westphalia, Ger., 7 mi. N.E. of Hagen, at the junction of the lines Aachen-Holzminden and Schwerte-Münster. Pop. (1950) 22,940. Schwerte received civic rights in the 12th century.

It has a Romanesque church. with a carved altar of 1523 and stained glass of the 14th and 15th centuries; and there is a 16th-century toun hall.

The industries are practically confined to the manufacture of iron and steel goods.

SCHWIEBUS or SWIEBODZIN, a town formerly in the Prussian province of Brandenburg. Ger.. 47 mi. E. of Frankfurt-on-Oder by the railway to Posen. It was incorporated into Poland in 1945. Pop. (1946) 6,144.

The territory originally belonged to the principality of Glogau, and in the 16th and 17th centuries mas a bone of contention betneen the electors of Brandenburg and the emperors. In 1686 the elector received the lordship of Schwiebus on renouncing his claims to certain other principalities. Frederick III, however, restored Schwiebus to the emperor Leopold I in 1695, receiving £40,000 in exchange. By the peace of 1742, Frederick the Great regained Schwiebus with the rest of Silesia. The town is still in part surrounded by its medieval wall, and has an old market place, a castle and many old houses.

Cloth, machinery and bricks are manufactured, and there are flour mills, breweries and lignite mines.

SCHWIND, MORITZ VON (1804–1871), Austrian painter and engraver, remembered mainly for his illustrations, was born in Vienna on Jan. 21, 1804. His early art training was rudimentary, and at 17 he entered the circle of artists who gathered around Schubert in Vienna and became a friend and admirer of the composer.

In 1827 Schwind went to Munich, where he came under the influence of Schnorr and Cornelius, and in 1834 was commissioned to decorate Ludwig II's new palace with wall paintings after Tieck. Later he also designed the wall paintings for the castle of Hohenschwangau in the Bavarian Tirol and for the Wartburg. The revival of art in Germany was favourable to the development of his fanciful genius, and he became popular through his illustrations of Goethe and other poets. From 1844–47 he lived in Frankfurt, where he painted the "Singers' Contest in the Wartburg" (1846), made the designs for the Goethe celebrations and did numerous book illustrations, including those for Robinson Crusoe. In 1847 he became professor at the Munich academy. He published a cycle of the Seven Ravens from Grimm in 1857.

Many of his water colours, etc., of the early Vienna days, and the Schubert sketches, are in Vienna. Schwind died at Munich on Feb. 8. 1871.

SCHWOB, MARCEL (1867–1905), French author. Many of his novels have a historical setting, but his art is extraordinarily versatile and includes tales of imagination, of the future, legends, psychological essays and many short stories.

In the prefaces to *Coeur* double, Roi *au* masque d'or (1893) Schmob makes an attempt to analyze his art. In spite of his unusual historical, linguistic and scientific knowledge, and his crowded canvas, his style is simple and straightforward. His work includes translations of Shakespeare and Defoe. He had a wide and close knowledge of English literature. He was a friend of Oscar Wilde, who dedicated *Salome* to him. The Vies *imaginaires* (1896; reprint, 1922) is a series of sketches in a-hich the *légendes* of various famous people are the basis, rather than their actual lives.

His works include *Spicilège* (1896) ; *La Croisade des enfants* (1896) ; *La Lampe de Psycht* (1903) ; *La Guerre commerciale,* 2 vol. (1896 and 1904).

SCHWYZ, one of the ancient forest cantons of central Switzerland. Its total area is 351 sq.mi., of which roughly three-quarters is reckoned as "productive" (forests covering about 75 sq.mi. and vineyards about 30 ac.), while of the rest, 18.1 sq.mi. is occupied by the larger lakes (chiefly several square miles of Zurich and of Lucerne, together with a small area of Zug and the whole of Lowerz—1.2 sq.mi. draining into Lucerne); about 0.5 sq.mi. is covered by glaciers. Its loftiest point is the Boser Faulen (9,199 ft.), while the two highest summits of the Rigi (the Kulm, 5,909 ft., and the Scheidegg, 5,463 ft.) are within its borders, but, on the whole, the land is hilly rather than mountainous.

Its title as the "core of Helvetia" is more appropriate in respect of its position, for though much below average size for a Swiss canton. no fewer than seven other cantons touch its borders. It has two main valleys, the Muota, receiving the waters of Lake Lowerz and draining into Lucerne, and the Sihl. which receives the river Alp on which Einsiedeln stands; the reinforced stream, though formed near the head of the Lake of Zurich, flows for a long distance roughly parallel to it and enters the river Limmat below the lake.

The canton has few main-line railways, the principal being a portion of the main St. Gothard line between Sisikon and Kiissnacht. Arth-Goldau (memorable for the great landslide of 1806) is a railway junction of some importance, with a line to Zug and another past Biberbrücke (junction for Einsiedeln and the waterfalls) toward Wadenswil. A mountain railway also terminates at Arth-Goldau for the ascent of the Rigi-Kulm, with a branch to Rigi-Scheidegg. Of other mountain lines in the canton the most important is the electric cogwheel railway from Brunnen to Axenstein.

Population in 1950 was 71,082. In 1930 the population was 62.337, of whom 60,571 were German-speaking, 1.261 Italian-speaking and 371 French-speaking, showing during the 20th century a substantial increase of the German tongue and a reduction in the other elements. There were 59,793 Catholics, 3,450 Protestants and 11 Jews. Schwyz is in the diocese of Choire. The largest towns in 1950 were Einsiedeln (pop. 8,423), a great pilgrimage centre noted for its black Virgin and its Benedictine monastery, and Schwyz (pop. 10.259), which is the political capital and is connected with Brunnen, its port on Lucerne. The canton is essentially a pastoral one, its local breed of brown cattle being much esteemed, particularly in north Italy, but some industrial activity (textiles) also takes place near the Lake of Zurich and the home weaving of silk is still general. The 30 cantonal communes are grouped into six administrative districts. The constitution, dating mainly from 1876, was revised in 1898. The legislature (Kantonsrat) is composed of 103 members elected in the proportion of 1 for every 600 residents, and the elections, since 1907, take place according to the principles of proportional representation. The executive (Regierungsrat) of seven members is elected by a popular vote and, as is the case with the larger body, holds office for four years. The two members of the federal *Ständerat* and the three of the federal *Nationalrat* are also chosen by a popular vote. Since 1876 the "obligatory referendum" has prevailed in the case of all laws and financial resolutions approved by the legislature, while 2,000 electors may claim a popular vote as to any remaining decrees or resolutions. Any 2,000 electors have also the right of "initiative" as to the revision of the cantonal Constitution or as to legislative matters.

History. — The valley of Schwyz is first mentioned in 972 as "Suittes." Later, a community of freemen settled at the foot of the Mythen, subject only to the count of the Zurichgau, as representing the German king. In 1240 the community obtained from the emperor, Frederick II., the privilege of being subject immediately to the empire. Its territory then included only the district round the village of Schwyz and the valley of the Muota. But in 1269 it bought from Count Eberhard, of Habsburg-Laufenburg, Steinen and Rothenthurm. Schwyz took the lead in making the famous everlasting league of Aug. 1, 1291, with the neighbouring districts of Uri and of Unterwalden, its position and political independence specially fitting it for this prominence. An attack by Schwyz on Einsiedeln was the excuse for the Austrian invasion that was gloriously beaten back in the battle of Morgarten (Nov. 15, 1315). In the history of the league Schwyz was always to the front, so that its name in a dialectal form (Schweiz) was from the early 14th century onwards applied by foreigners to the league as a whole, though it formed part of its formal style only from 1803 onwards. After the victory of Sempach (1386) Schwyz greatly extended its borders. An "alliance" with Einsiedeln in 1397 ended in 1434 with the assumption of the position of "protector" of that great monastery; between 1386 and 1436 the whole of the "March" (the region near the upper lake of Zürich) was acquired; in 1402 Küssnacht was bought, and in 1440 the "Höfe," the parishes of Wollerau, Feusisberg, and Freienbach, situated on the main lake of Zurich. All these districts were governed by Schwyz as "subject lands," the supreme power resting with the *Landsgemeinde* (or assembly of all male citizens of full age). Schwyz joined the other forest cantons in opposing the Reformation, and took part in the battle of Kappel (1531), in which Zwingli fell. In 1798 Schwyz, including Gersau (free from 1390), formed part of the République Telliane (or Tellgau), set up by the French, which a week later gave way to the Helvetic republic. In 1803 the separate canton of Schwyz was again set up. Schwyz joined, in 1832, the league of Sarnen, and in 1845 the Sonderbund, which was put down by a short war in 1847. In 1832 the outer districts (Einsiedeln, the March, Kussnacht, and Pfaffikon) formed themselves into a separate canton, an act which brought about a federal occupation of the old canton in 1833, this ending in the dissolution of the new canton, the constituent parts of which were put on an equal political footing with the rest. In 1838 strife broke out in the older portion of the canton between the richer peasant proprietors (nicknamed the "Horns," as they owned so many cows) and the poorer men (dubbed the "Hoofs," as they possessed only goats and sheep) as to the use of the common pastures, which the "Horn" party utilized far more than the others. The "Horn" party finally carried the day at the Landsgemeinde held at Rothenthurm. The cantonal constitution of 1848 put an end to the ancient Landsgemeinde; it was revised in 1876 (when membership of one of the 29 communes became the political qualification), and in 1898.

SCHWYZ, the capital of the Swiss canton of that name, a picturesque little town, admirably situated, amid fruit trees, on a mountain terrace (at a height of 1,706 ft.), at the north-west foot of the conical peak of the Gross Mythen (6,240 ft.). Including the neighbouring hamlets of Ibach, Rickenbach, etc., the parish had 10,259 inhabitants in 1950, practically all German-speaking and Roman Catholics. The town is about 3 m. from Brunnen, its port on the lake of Lucerne.

Besides a stately 18th century parish church and several convents, it contains a 16th century town hall (housing various precious mss.), as well as several curious old patrician houses.

SCIACCA (Arabic, *Sciaqqak),* a town and episcopal see of Sicily. Italy, on the south coast, in Agrigento province, 52 mi. N.W. of Girgenti by rail, and 30 mi. direct. Pop. (1951) 22,333. It is surrounded by walls erected about 1330, and has two ruined castles, belonging to the Luna and Perollo families, whose hereditary feuds lasted from 1410 to 1529, some fine mediaeval and 18th-century palaces, and several interesting churches. The convent of Sta. Maria delle Giummare, with its battlemented walls, occupies the former palace of the Saracen governors, and contains a painting of the foundation of the convent by Count Roger. The town has only an open roadstead. Three miles E. of the town is the Monte San Calogero (the ancient Mons Cronius) with sulphurous and saline springs and vapour baths, known in Roman times as Aquae Larodes or Thermae Selinuntiae (after nearby Selinus). The town is the birthplace of Tommaso Fazello (1498–1570), father of Sicilian history. Sciacca was bombed by the Allies in World War II.

See I. Scaturro, *Storia della cittd di Sciacca* (1925–26).

SCIALOJA, VITTORIO (1856–1933), Italian jurist and statesman, son of the eminent Neapolitan scientist, patriot and statesman, Antonio Scialoja, was born at Turin on April 24, 1856, and after graduating in jurisprudence was appointed professor of civil law at the University of Camerino when only 23 years of age. In 1880 he was transferred to the University of Siena, and in 1884 to that of Rome. Many of the most distinguished jurists and political men in Italy were his pupils, and through his teachings and writings he exercised a wide influence on juridical thought and practical legislation. In 1904 he was nominated senator. In 1909 he was appointed minister of justice, and during World War I he was minister (without portfolio) in the Boselli and Orlando cabinets. In the autumn of 1919, on the resignation of Senator Tittoni. Senator Scialoja became minister of foreign affairs in the Nitti cabinet, and in this capacity he attended various meetings of the peace conference, either as assistant Italian delegate under Sig. Nitti or as first delegate. He left office on the fall of the cabinet in June 1920, and in the autumn of that year became a member of the Italian delegation at the League of Nations assembly. In 1925 he became president of the Italian delegation at the assembly and Italian representative on the council of the League. He, in fact, collaborated in the drafting of the covenant.

He is the author of a large number of books, pamphlets and articles on legal subjects, of which the most important are the following: *Sopra il precarium nel diritto rontano* (1878); *Degli atti di emulazione nell' esercizio dei diritti* (1878); *Del diritto positivo e dell' equità* (1880); *Responsabilità e volontà nei negozi giuridici* (1885); Italian translation, with an introduction, of Savigny's *System of Roman Law* (8 vols., 1886–98); *Sul diritto al nome e allo stemma* (1889); *Sulla teoria dell' interpretazione della iegge* (1898); *Dizionario pratico del diritto privato* (1899, etc.); *Sulle condizioni impossibili nei testamenti* (1901); *Sulle funzioni della IV. Sezione del Consiglio di Stato* (1901).

SCIATICA, a form of neuralgia or inflammation of the sciatic nerve, or its roots and characterized by pain, along the course of the nerve, running down the back of the thigh and the leg. *(See* NEURALGIA.)

SCIDMORE, ELIZA RUHAMAH (1856–1928), U.S. traveller and author who wrote some of the first guidebooks to Alaska and the Orient, mas born in Madison, Wis., on Oct. 14, 1856. She was educated in boarding schools, and for one year (1873–74), at Oberlin (O.) college. She served her newspaper apprenticeship as a Washington, D.C., society correspondent for the *New York Times* and the *St. Louis Globe-Democrat,* after which she went to Alaska to gather material for newspaper articles and travel books.

Her Alaskan trip was the beginning of her world travel during which she spent many years in Japan. China, India, Java and the

Philippines in the far east and in Europe. Active in the National Geographic society as a member from its earliest days, she served successively as corresponding secretary, associate editor, foreign secretary, and was the first woman to serve on the board of managers. She served as a secretary at two Oriental congresses at Rome in 1897 and at Hamburg in 1902. She contributed to many magazines and while studying the actions of the League of Nations in Geneva, Switz., in 1925 decided to make her home in that city, where she died on Nov. 3. 1928. Her last book. *As The Hague Ordains* (1907), so impressed the Japanese emperor with its sympathetic account of Japanese treatment of prisoners of war in the Russo-Japanese war that at her death the Japanese government asked and received permission to transport her ashes to Japan for interment.

Her books include: *Alaska: its Southern Coast and the Sitkan Archipelago* (1885, republished as *Journeyings in Alaska,* 1889); *Westward to the. Far East* (1890); *From East to West* (1890); *Appleton's Guide-book to Alaska and the Northwest Coast* (1893) ; *Java, the Garden of the East* (189;) ; and *Winter India* (1903).

SCIENCE. Is it possible to define what we mean by science? Perhaps not, for science is one of the major activities of our minds. in this sense resembling art, religion or philosophy. None of these can be understood unless we consider them in relation to their past history. Science may perhaps be regarded as a mood in which we consider our world. No man is always in the same mood, and no man of science remains permanently in the scientific mood. In estimating the value of the judgments of men of science outside their own scientific department it is nell to remember this, for these judgments are sometimes to be rated very low.

As soon as we attempt to discuss science as a whole. a host of difficulties appear. The Latin word *scientia* meant nothing more definite than "knowledge," but the modern usage covers only certain kinds of knowledge. The area of these is now so vast that no man can have a grasp of more than a minute fraction of them. Moreover, even the kinds of knowledge regarded as "scientific" are extremely diverse. They extend from subatomic reactions to mental processes; from mathematical laws of thermodynamics to the economics of race relations; from the births and deaths of stars to the migration of birds; from the study of ultramicroscopic viruses to that of extragalactic nebulae: from the rise and dissolution of cultures and of crystals to the rise and dissolution of atoms and of universes. They include both knowledge of the workings of living bodies and knowledge of the laws of thought, together with that of the nature of their disturbances. Can these innumerable and endlessly diverse topics be brought under any one formula?

These very different activities and disciplines all involve systematic and unbiased observations; the due examination of the records of these by trained minds leads to classification; from such classifications general rules or "laws" are deduced; these laws may be applied to further observations; failures in correspondence between new observations and accepted laws may result in alterations of the laws; and these alterations lead to yet further observations; and so on. This chain of activities is usually held to constitute the "method" of science.

Admittedly this chain is not followed invariably. It may be short-circuited by some sort of mental process of which we know little; but even in such cases the final appeal is to observation, often in that specialized form known as experiment. Further, science is, of its nature, always developing and not a mere body of knowledge. To summarize, science is a search for judgments to which universal assent may be obtained—universal, that is, on the part of those who understand the judgments and their bases. It is a search that never ends and is never satisfied.

It is always dangerous to infer the semantic value or range of meaning of a word on its etymological basis. Nevertheless, it cannot be disregarded that in English, as in other languages with vocabularies even more largely Latin-derived, the complex adjectival form of the word *science,* namely *scientific* (*i.e.,* "knowledge-making"), has been steadily displacing simpler, shorter and more natural formations, such as *sciential, scientic* and their variants, since the beginning of the 17th century. The acceptance of our usage of *scientific* follows closely the growing prestige of what has come to be called "science" (earlier it was known as "natural philosophy"). This correlation of concept and adjective becomes intelligible if me consider the spread of the awareness that science is the making of knowledge and is not knowledge as such. Science has thus become constantly more nearly equated with "research" and has come to connote a process and not a static body of doctrine. This situation is evident enough and can be illustrated by many examples showing that when the process of making knowledge ceases, science subsides into static or recessive tradition. But it is highly important that this should not be taken to mean that science excludes tradition. The reverse is the case, for science necessarily involves a developing tradition. Not a few persons active in advancing science have persuaded themselves that they had no need of tradition, that is. of the history of their subject. Some have at times refrained from studying the work even of their contemporaries and have prided themselves thereon. These men have all deceived themselves, for the man of science cannot forsake his tradition however he strive. Doubtless atomic physics, for example. may be advanced without exact knowledge of the careers, achievements and mental processes of Max Planck and Albert Einstein. Moreover there are episodes of research wherein the researcher is wise to confine himself temporarily to his own thoughts. But those thoughts have been shaped by the scientific tradition. To forget that tradition for a moment does not change the fact that the man of science inherits an age-old way of thinking and that his research is but part of an ever-growing body of knowledge based on tradition. Only by extending knowledge previously won can he build new knowledge. He can no more free himself from the millennial tradition of science than from the language that he speaks or from the civilization in which he has been reared. *"L'histoire de la science,"* said Auguste Comte, *"c'est la science même"* ("The history of science is science itself.").

Despite their philosophical importance controversy on the nature of knowledge, on the question of whether our knowledge is real or whether there is another and deeper reality to which we cannot reach and the even more pressing debate as to how or whether science can give certitude are of no aid in defining, delimiting or understanding the nature of science (*see* KNOWLEDGE, THEORY OF). Science can treat the outer world solely on its own level, that is, the level of *phenomena* (.'things that appear," "appearances"). These can appear only to the senses that we possess. It may be that our senses yield results that are ultimately contradictory or, at least, that our minds find no rest in them. or—which is much the same thing—that our minds can repose only in a sensation of harmony. But the quieting of our minds on such things is ultimately a task of philosophy or religion or both. Science, as such. can have only an indirect share in this.

Evidently, in the study of phenomena our senses often deceive us. But science seeks ever to correct. aid. extend and supplement our senses by technological devices. With these the sphericity of the earth. the discontinuity of matter and of forces. the movements of atoms, the bending of light by the sun's mass and even the mutual convertibility of mass and energy may be demonstrated to our senses. It is also true that science frequently leaves phenomena altogether, to mount into an atmosphere of abstract symbols, usually of a mathematical kind. But science takes such flights only to descend again to the prediction or demonstration of phenomena. Phenomena must ultimately be sensed, and mathematical considerations, however recondite, and scientific instruments, however intricate, are but delicate, remote and specialized ways of extending sense-experience, though sense-experience may for some sciences (and perhaps eventually for all) be ultimately reducible to scale readings.

The Method of Science.—The first modern philosopher of science, Francis Bacon (*q.v.;* 1561–1626), set forth in his *Advancement of Learning* the belief that in any field of knowledge the facts might be collected, according to an accepted and prearranged plan, and then passed through an automatic logical process from which correct judgments would inevitably emerge. This method cannot be applied in practice, since phenomena are beyond number. Therefore, when we seek to explore any field of knowledge, we must somehow choose from among the phenomena—often called facts. The question then arises as to how the man of science can best choose the phenomena to be observed and recorded.

The history of science shows that only those with a knowledge of how their predecessors have succeeded or failed have chosen profitably. In other words, the process of choosing phenomena is an act of judgment on the part of a learned or experienced chooser, a scientist; and the most learned is often modestly unconscious of the depth of his own learning.

But is not this also the case with the choosing of words by that word-chooser whom we call a poet or the choosing of colours by that colour-chooser whom we call an artist? The choice of scientist, of poet, of artist, is necessarily controlled by his knowledge of his special field. his "subject." as we are wont to call it. Perhaps it would be more true to say that the choice is controlled by his experience of the scientific, of the poetic or of the artistic mood. The scientist, like the poet and the artist, exercises his judgment to select those things which bear to each other certain relations which he has himself conceived or which he seeks. He may find something which he has not conceived or does not seek. This discovery may lead him to further search and so to further discovery. And yet no experience of the scientific mood, however profound. no acquaintance with the history of his science: however complete, no reasoning, however deft, will make a man a scientific discoverer. Nor, for that matter, will any knowledge of metre. or of colour, or of the nature and history of verse or perspective make a poet or an artist. Successful scientific men, like poets and artists: may be directed by training and are always moulded by tradition. But they must also possess that incommunicable power of judgment, as necessary in science as in the arts. Thus in the end science, like the other great human activities, comes up against the impenetrable mystery of mind.

We therefore return to phenomena. The scientific man, in practising his art of discovery, has to exercise a series of quite different mental activities. These may be classified as, first, collecting observations; second. forming an hypothesis that links the observations; third, testing the truth or falsehood of the hypothesis; and, fourth, using the hypothesis in examination of further observations or re-examination of those already considered. When the hypothesis answers suitably to repeated or sufficiently delicate tests, our scientist has made a "discovery." It is true that the four processes of choosing, of drawing an hypothesis: of testing it and demonstrating its validity and. lastly, of using it to guide further observational activity are often inadequately distinguished by the scientist in his own thinking. Often, too, the exposition of his discovery helps him! more or less unconsciously, to new acts of judgment, these to a new selection of facts, and so on in endless complexity. But essentially the processes are separable, and the power to wield one of them may be developed while the others are in relative abeyance. It would be easy to select men of science more skilled in some of these processes and less in others. But for due display of nature's ways all these powers must be at work.

On this matter, scientific articles (and especially textbooks) commonly give a false impression. They are composed to convince the reader of the truth of certain views or to put him in possession of certain knowledge. In doing this, such works normally obscure the process by which the views were reached. That process, as vie have seen, usually consists of a series of improvised judgments or working hypotheses, interspersed with a provisional series of observations. Many such judgments are normally found untenable and many observations irrelevant, ill-chosen: badly made or needing further test. An article or book is necessarily and rightly silent on these side issues and false starts: otherwise it would be diffuse beyond all toleration. Nevertheless, these omissions conceal the tracks of the investigator. For this reason, among others, science can never be learned from books, but only by contact with phenomena.

The relationship between the process of discovery and that of demonstration is often missed or glossed over, even by men of science. During the middle ages it was almost consistently avoided. On this point Francis Bacon remained in darkness. He rightly emphasized the importance of systematic fact collection but failed to perceive how deeply the act of judgment must be involved in it. No important discovery has ever been made along Baconian lines, though some discoverers have thought that they were following them. Some of the founders of the Royal society, in the middle decades of the 17th century, regarded themselves as followers of Bacon. Investigation, however, has repeatedly revealed that each great discoverer has worked out his own line of research in a way suited to that line and to his own way of thinking, with little reference to any theory of the nature of science itself.

Study of the philosophy and history of science illumines our view of the world and makes it more worth investigation. It absorbs the reader and raises the status of the man of science. But such study will never be a direct instrument of discovery. The characteristic of the modern scientific scene that separates it from the mediaeval outlook is less possession of a method than constant devotion to and even obsession with observation as the demonstrative test. This point is often missed by those who seek scientific elements among mediaeval activities. Such elements existed; but, with little devotion to observation, they bore little fruit.

From all this it is apparent that the scientific process can be yet further reduced to two main activities: discovery and demonstration. As regards discovery, there is hardly any faculty or power that has not, from time to time, been used by scientific men in their inquiry into nature's ways. But how his ideas reach the man of science is of relative insignificance. They may come in a dream or in an illuminating flash, or follow painful calculation, or be suggested by an analogy (often a false one). In all this the unconscious mind cannot be disregarded. In the end these things are matters of temperament. But it is in the processes of demonstration that we discern the man's efforts as scientific. Discovery is an art, demonstration makes the science. In the series of processes involving investigation, these two kinds of activity are inevitably mingled, but they can often be disentangled by study of accounts that men of science have given of their own experience.

Scientific knowledge is a developing thing. As with other developing things, its structure and functions can be understood only through its history, nhich is, of its nature, "progressive." The "idea of progress" has many implications, mathematical, philosophical, biological, social. spiritual, with which we are not here concerned, but there can be no true science that does not extend its range. Science. of course, may perish, but, in so far as it is alive, it can build only on the science that has gone before. There were indeed periods of history and episodes of civilizations in which scientific progress was retarded. or in uhich its records were corrupted or forgotten or destroyed. These periods and episodes have their special interest because of the fragments of the great tradition that survived them. but examination of them cannot reveal the processes of development of science.

ANCIENT SCIENCE

The traceable history of progressive science divides naturally into tno main periods. One is the active Greek period from about 600 B.C. to about A.D. zoo. The other is the active modern period from about 1450 onward, in the full flood of which we live. Since of Greek science only is the full course known—even in outline—it is related here as the sole possible exemplar of our own. This is not to foretell disaster; but appreciation of the history of Greek science may help to avert dangers from our own. The Greek achievement can be examined in its entirety with steady and unbiased vision.

The Age of Anonymous Science.—When then did science begin? Something remotely resembling it is discernible very early, long before the Greeks. With very slowly increasing skill men of the Old Stone Age fashioned neapons or tools—the two were at first undifferentiated. Perhaps 400.000 years ago these began to assume a symmetrical form involving some mental image of the object before it was wrought. This form implied an adaptation of means to ends, based primarily on trial and error, a crude form of experiment used even by lower animals. Again and again in the succeeding millennia men have made such adaptations. When they became conscious that trial and error is a may to solve problems. men took a great step on the road to science. Some 30.000

years ago they succeeded in portraying animals in positions of movement and in the chase. A further passage to exact observation and record of nature occurred when men ceased to be food gatherers and began to become food growers some 13,000 years ago. There then arose the need to choose the right time to sow and to reap. Apart from day and night, the obvious way to reckon lapse of time is by changes in the moon. Months or moon cycles cannot be made to correspond to any exact fraction of the solar year or sun cycle. But in the earlier agricultural stages the one set was given some temporary approximation to the other.

As men gathered in aggregates, forming cities, and began to be civilized, more exact divisions of time were needed. It became necessary to number the days in the year and in its seasons. This soon became a task for specialists, men who could enjoy the new social surplus. Moreover, the settled agricultural life needed more tools, at first of stone. Thus a professional technology developed.

The age of stone passed into that of metals. The treatment of ores and the extraction and working of metals called for new groups with special knowledge and special leisure. The development of rights in land demanded some sort of survey. Tradition has it that the annual Nile flood rendered necessary an annual remeasurement of the fields of Egypt. Thus geometry (literally "earth measurement") was born. The cutting-up of animals for food and the examination of their entrails for divination yielded, especially in Mesopotamia, some knowledge of bodily structure. These activities are among the sources of what we now call metallurgy, mathematics and anatomy.

As society became yet more complex, commerce increased. The stewards and priests of palaces and temples needed records. Thus systems of numerical notation were invented. Ultimately writing developed from pictographs. The ancient world presents numerous examples of such inventions, fathered by necessity and mothered by experience. All have some claim to be considered in a history of science. Early civilizations united men into larger and ultimately into imperial units. But those who share our Judaeo-Graeco-Roman culture, when they examine the records of the earliest civilizations, are impressed by the failure to stress human individuality.

Investigation of the ancient empires, notably of the Babylonian, has revealed a far more extensive and systematic accumulation of astronomical and mathematical information than was formerly suspected. Science can therefore no longer be called a Greek product. Cumulative records began in the 4th millennium B.C. in the river valleys of both Egypt and Rfesopotamia and perhaps elsewhere. Nevertheless our records of these are still so discontinuous that, while it would be possible to write an account of what we know of them, to reconstruct the history of science in the ancient empires is still impossible. It is, however, important to recall that to the Babylonians we owe exact measurement of the lunar and solar cycles, the tracing of the paths of the planets, the division of the circle into 360 degrees and the designation of constellations, notably those of the zodiac.

Science First Conscious of Itself (c. 600–c. 300 B.C.).—The figure traditionally associated with the beginning of science among the Greeks is Thales of Miletus (*q.v.*) in Asia Minor, who flourished in the first half of the 6th century B.C. The Greek alphabet is thought to have first emerged (from the Phoenician) in Miletus, about 200 years before Thales. He was a merchant, son of a Greek father and of a Phoenician mother! and had visited Mesopotamia and Egypt. He made certain geometrical discoveries, though the Greeks no more invented geometry than they did astronomy. The elements of the latter came to them from Mesopotamia; those of the former, according to their own traditions, from Egypt. The Egyptians, however, had not generally reached beyond an empirical use of certain special relations of such figures as triangles and rectangles, pyramids and spheres.[1] Thales or his Greek contemporaries succeeded in generalizing such special cases and, moreover, made other discoveries familiar in what is now regarded as very elementary mathematics.

[1]The question as to how far the Egyptians generalized mathematical conceptions is still under discussion. On the other hand, there is evidence from their art that they knew and constantly practised the "golden section."

By the 6th century B.C., Greek-speaking peoples had founded colonies in the west, namely in southern Italy and in Sicily. The intellectual activity in these settlements was significant for science, especially that of the "Pythagoreans." Born about 582 B.C., their founder, Pythagoras (*q.v.*) established a brotherhood or sect the influence of which has been very persistent. The Pythagoreans developed what seems now a peculiar teaching on numbers. These were held to have a real and separate existence. The use by the Greeks, as by the Phoenicians and Hebrews, of letters to express numbers encouraged this conception, which has often been given mystical and magical application. But the Pythagoreans gave to the word *mathematics*—which first meant simply "learning"—its special relationship to number. Aristotle in his *Metaphysics* tells that they saw in numbers many resemblances to "the things that exist and are coming into being," almost all things being numerically expressible—in particular the attributes and ratios of the musical scale; and that they therefore regarded numbers as being the elements of all things and saw the whole heaven as a musical and numerical scale. This conception seems very fanciful now, but fancies of this type have repeatedly been of value to science. The human mind, it seems, is somehow attuned to the processes of nature or, as some would say, has attuned itself, perhaps under the guidance of Pythagoreans and others. Certainly we live in a world the major phenomena of which are susceptible of mathematical expression. And it has many times happened that the theoretical developments of mathematicians have been found to bear a relation to observations.

Why and how this should be so are mysteries. Yet consciousness that there is a correspondence between the working of our minds and the working of nature is a conclusion most important for the development of science. We owe this idea to the Pythagoreans. Their conception of the "harmony of the spheres"—on which Aristotle touches—proceeded from the observation that the pitch of musical notes depends on a simple numerical ratio in the length of the chords struck. It was not unnatural that, having made this great discovery, they should have suggested that this ratio might correspond to the distances of the heavenly bodies from their common centre.

A Pythagorean of the 5th century B.C. launched another doctrine which has had repercussions to our time and is still embedded in our language. He supposed that Love and Strife held sway over all things, even material things. In matter itself, in which he distinguished the four elements, water was opposed to fire but allied to earth, while air was opposed to earth but allied to fire. By arranging these elements in pairs, four primary qualities were evolved: namely heat (air and fire), dryness (fire and earth), cold (earth and water) and moisture (water and air). The conception was later extended to the living body. This was held to be composed of four "humours," blood, phlegm, yellow bile (or choler) and black bile (or melancholy), characteristic of the four "temperaments," of which we still speak (sanguine, phlegmatic, choleric, melancholic). This was the first attempt to trace the rules of the external world to the working of man's body.

By the middle of the 5th century both eastern and western schools of Greek thought were becoming overshadowed by the Athenian. In Athens the systematic accumulation of knowledge was rendering old-fashioned those who "took all knowledge to be their province." Something like specialization thus began to appear and has characterized science ever since. It resulted immediately in the recognition of mathematics and of medicine as independent disciplines. The two near contemporary exemplars of these disciplines both bore the name Hippocrates and came from islands of the eastern Aegean.

Hippocrates of Chios, the mathematician (*fl. c.* 450 B.C.), was the first to compose a work on the elements of geometry. One of his discoveries was that the lune bounded by an arc of 90° and by a semicircle on its chord has an area equal to that of a triangle having the chord for base and the centre of the arc for apex. Thus the area of the lune, a figure bounded by curves, can be equated with a figure bounded by straight lines. Of course, this is not equivalent to squaring the circle nor even an approach thereto; but it is the first known introduction of the circle into geometric construction and thus had a great future.

The name of Hippocrates of Cos (*q.v.*) the physician (*fl.* c. 400 B.C.), has been attached to many works. Probably none is his. but the earliest of them are significant for the expression, with religious intensity, of a faith in the constant sequence of cause and effect. Thus in the work called The *Divine Disease (sc.,* epilepsy), we find:

As for this disease called divine, surely it has its nature and causes, as have other diseases. It arises—like them—irom things which enter and quit the body, such as cold, the sun and the winds, things ever changing and never at rest. Such things are divine or not—as you will, for the distinction matters not—and there is no need to make such division anywhere in nature, for all are alike divine or all are alike human. All have their antecedent causes which can be found by those who seek them. (Slightly paraphrased.)

The intellectual history of the 4th century B.C. is filled by the gigantic figures of Plato and Aristotle. They are considered here only in their relation to science.

Plato regards mathematics as yielding that type of certitude to which other studies should conform. Mathematics for him relies for its material upon something of the nature of his "ideas." Many of his thoughts assume a mathematical guise, and he tended to respect a science in the degree to which it had progressed to a mathematical stage. Following his Pythagorean teachers, he regarded the motions of the heavenly bodies as being examples of perfect geometric forms. For astronomy—especially on this theoretic side—Plato had a high regard, and by his followers mathematics became identified with astronomy. We think of astronomy as a field for the application of mathematics; to the Platonists it was rather a field for its exemplification.

Plato regarded the mathematical form of the universe as evidence of the rational mind of its Creator. "God," he is said to have said, "ever geometrizes." To deny the existence of mind as a separate entity was, he held, to assume the universe to be the result of accident. To suggest such a universe was a denial of the validity of philosophy. It is not inconsistent with this view that Plato respected Hippocrates the physician, who "was the first who separated science from philosophy." But the trend of Platonism in general and of ancient Platonism in particular was usually away from observational activity. There have been many evident exceptions, and Platonism has often been helpful to science both in stressing its quantitive aspect and in opposing an entrenched and static Aristotelianism. It was from Pythagorean teachers that Plato derived the so-called "Platonic bodies," the five regular polyhedra which have equal sides and equal angles *(see* SOLIDS, GEOMETRIC). Many centuries later mathematicians proved that the possible number of regular bodies is only five. Moreover, it was from a consideration of these bodies that Kepler developed the first unitary scheme of the universe (A.D. 1596).

Aristotle devoted his incomparable genius to systematizing and organizing the whole area of knomledge. His earliest and, from the modern scientific point of view, his best efforts were on biological topics. The whole of his science and indeed the whole cast of his mind was deeply influenced by his first-hand observations on living things. In his *Parts* of *Animals,* he sets forth his view of the relation between biology and "physics," the latter being for him a general description of the universe. He says:

Of the things constituted by nature some are ungenerated, imperishable, eternal; others subject to generation and decay. The former are excellent beyond compare and divine, but less accessible to knowledge. The evidence that might throw light on them and on the problems which we long to solve respecting them is furnished but scantily by our senses. On the other hand, we know much of the perishable plants and animals among mhich we dwell. We may collect information concerning all their various kinds, if we but take the pains. (Somewhat paraphrased.)

Living things are for Aristotle the type of existence. and existence as a whole presents. according to him, evidence of design. He attempted to analyze the nature of generation. of heredity and of sex. He treated many other topics now discussed by naturalists. There is a profundity in his biological thought which gives it a permanent value. He was a first-class observing naturalist in the modern sense.

Aristotle, like Plato, had Pythagorean tendencies, which he exhibits in his physical scheme. He emphasized the "perfection" of the circle and of the sphere, on which therefore the world is modelled. For him the heavens are a series of concentric spheres arranged round our earth as a central body. These spheres he described, however, as crystalline, mechanizing them from the schemes of certain of his older Athenian mathematical contemporaries.

The mechanical scheme of the universe set out by Aristotle and his successors suggests a series of geared wheels and may have come to the minds of the Greeks through some such complex apparatus. This view of Aristotle was the basis of the theory of the universe that held men's minds for 2,000 years. We may thus summarize it:

1. Matter is continuous.
2. All mundane things are made up of four "elements," which in their turn manifest the four "qualities."
3. Stars and planets move with uniform circular velocity, embedded in crystalline spheres, centred round the earth. Each sphere is subject to the influence of those beyond.
4. Circular, changeless, eternal movement is perfect order. It contrasts with the rectilinear movement which prevails on our changing and imperfect earth.
5. The universe is limited in space and within an outmost sphere. It is unlimited in time, being subject as a whole neither to creation nor to destruction.

Alexandrian Science: First Period, 300–30 B.C.—For the 500 years after Aristotle the scientific centre of the world was Alexandria. There mathematics assumed a prominent position. Among its first exponents was Euclid (*fl. c.* 300 B.C.), whose *Elements of Geometry* determined instruction in the subject for the next 22 centuries.

Another Alexandrian teacher, Aristarchus of Samos (*fl. c.* 270 B.C.), made the first scientific attempt to measure the distances of the sun and moon from the earth and their relative sizes. He estimated the sun as 18 times more distant than the moon (instead of more than 346 times). That he thought the sun far larger than the earth may have suggested to him that it was improbable that a large body would revolve round a relatively minute one. At any rate. he held that the earth rotates on its own axis and revolves round the sun.

Hipparchus (*fl.* 146–127 B.C.) was the greatest astronomer of antiquity. He erected at Rhodes the first recorded observatory. He rendered a great service in developing trigonometry by which numerical calculations can be applied to figures drawn on either plane or spherical surfaces. He made numerous observations and collated the records of earlier Greek astronomers and of their Babylonian predecessors to see if astronomical changes had taken place in the course of the ages. These comparisons led him to two brilliant conceptions:

One was that of the precession of the equinoxes. In 134 B.C. Hipparchus observed a new star in the constellation Scorpio. This discovery suggested the preparation of a catalogue of star positions, of which he recorded the celestial latitude and longitude of more than 1.000. The constellations to which Hipparchus referred these are generally accepted today. He showed great foresight in recording cases in which three or more stars were in a line, so that later astronomers might detect changes in their relative positions. He compared his own positional observations with others of about 150 years earlier and found that there had been changes of a kind that could be explained only by a rotation of the axis of the earth in the direction of the apparent daily motion of the stars. This rotation causes the equinoxes to fall a little earlier each year. Knowledge of this precession and of its rate was necessary for the progress of astronomical theory. The complete cycle of precession takes 26,000 years.

The other great achievement of Hipparchus was his theory of the motion of the planets. When he came to examine the apparent movement of the planets, he had before him two theories, the epicyclic and the eccentric. According to the former, each planet moves on a circle. the epicycle. the centre of which moves on another circle. the centre of which is the centre of the earth. Some of his predecessors had set forth the eccentric view, in which the planet is said to move around the earth but in a circle whose centre is not at the centre of the earth. This secondary centre may also be represented as moving on a circle. Hipparchus explained the behaviour of the sun by a fixed and the moon by a moving eccentric. (The geometric results of moving eccentric and epicycle are identical.)

The epicyclic view was to become the primary basis of astronomy through the mediation of Ptolemy of Alexandria *(see* below), whose works were influential for the next 1,400 years. Ptolemy and his successors, however, invoked also eccentrics. The eccentric theory particularly of the moon and to a less extent of the sun was of service in that calculations based on it accorded more closely with actual observations. From Hipparchus onward. eclipses of the moon could be predicted within an hour or two and those of the sun somewhat less accurately.

At Alexandria. anatomy and physiology became recognized disciplines. The first medical teachers of the school. contemporaries of Euclid, began the practice of dissecting the human body publicly. They compared its structure with that of animals and opposed both Plato and Aristotle by regarding the brain as the sole seat of the intelligence. They observed that arteries, unlike veins, pulsate, but did not ascribe this to the heart's action. thinking that it was an activity of the arteries themselves. They thought of the nerves as hollow and believed that through them was conveyed the hypothetical "nervous fluid." They distinguished between the main brain, or *cerebrum,* and the lesser, or *cerebellum,* observed the cerebral convolutions of both man and animals and associated their greater complexity in man with his intelligence. Their experiments on animals led them to distinguish between the posterior nerve roots of the spinal cord. which convey sensations, and the anterior, which convey the motor impulses.

From about 400 B.C. the doctrine of atoms was current in the Greek world. It was rejected by Aristotle. Later. though important philosophically. it had on the whole a retarding influence on the course of Greek science. It had, however, some influence on Alexandrian anatomy and physiology. Some Alexandrian anatomists supposed that nonatomic "air," equivalent to *pneuma* (πνεῦμα) (see below), is taken in by the lungs and passes to the heart. Here. they supposed, it enters the blood and is changed into a peculiar kind of pneuma or spirit—the "vital spirit"—which is sent to the various parts of the body by the arteries. It is thus carried to the brain. where it is further altered into another pneuma, the "animal spirit." This. they believed, reaches different parts of the body through the hollow nerves.

An Alexandrian school considered the pneuma that circulates in the body to be ultimately drawn from the air, or world-pneuma. This assumption gave a physiological basis to the philosophical conception of the spirit of man as part of the world-spirit. Such a conception is frequent in later writings of the Stoic school *(see* STOICS) and also perhaps in Philo Judaeus and in the Fourth Gospel. Physiology and philosophy thus reacted on each other.

We cannot leave the biological work of the early Alexandrian school without reference to the pupil of Aristotle, Theophrastus (*c.* 372–287 B.C.), who lived well into Alexandrian times. His botanical writings are the best-arranged ancient biological treatises. Among his many acute and accurate observations is his clear distinction between monocotyledons and dicotyledons. Interesting too is his attempted distinction of sex in plants, an attempt successful only for palms. His splendid botanical works had a definite influence on modern biology.

The greatest of the Alexandrian school was Archimedes (c. 287–212 B.C.) of Syracuse, constantly recalled in the mathematical construction of the Archimedean spiral *(see* CURVES, SPECIAL: *Section 38)* and in the mechanical construction of the screw of Archimedes *(see* ARCHIMEDES, SCREW OF) for raising water. The screw as a means of applying mechanical force was perhaps suggested by one of these devices. The familiar story of Archimedes and the crown of Hiero *(see* ARCHIMEDES) shows that he had obtained the relative specific weights of gold, of silver and of a mixture of the two by comparing the relative amount of water displaced by the same weight of the three substances. The scientific aspect of the subject is set forth in his treatise *On Floating Bodies.* This work contains the first record of what we now call "specific weights." Consideration of the scientific use, or development, or exact definition of common knowledge has often thrown light on the nature of the scientific process. Thus to Archimedes the ancient world owed a general exposition of the doctrine of levers. To say this does not mean that Archimedes invented the lever any more than that he had discovered some bodies to be heavier than others. But it is one thing to use or even to contrive a device and another to display its principles and to follow them to their theoretical applications and mathematical analyses. Science owes to the Greeks its first formal. conscious and organized development. just as to Archimedes the doctrine of levers owes its first formal and systematic exposition.

Perhaps the earliest existing work of Archimedes is *On Plane Equilibria.* It sets forth certain fundamental principles of mechanics as rigorous geometric propositions. The work opens with his famous "postulate": "Equal weights at equal distances are in equilibrium; equal weights at unequal distances are not in equilibrium but incline toward the weight at the greater distance." This postulate developed into the principle of the steelyard *(see* WEIGHING MACHINES), and led Archimedes in the end to the discovery of the centre of gravity in a variety of geometric figures.

Among the achievements of Archimedes is his method of measuring the areas of curved figures and surfaces. The simplest expression of this is the effort to "square the circle." His predecessors had broached the idea of "limits"; Archimedes, however, employed limits systematically: a doctrine of great historical and practical importance.

The principle can be expressed simply. A square can be inscribed within a circle. It is evident that the sum of its sides is less than the circumference and that its area less than that of the circle. The number of sides can be doubled to make an eight-sided figure within the same circle. The proposition remains true, however many the sides; but as their number is increased the discrepancy decreases. "In the limit," when its sides become no more than points, the polygon may be conceived as becoming the circle. Archimedes realized that this limit can be approached as nearly as we wish *(see* LIMIT).

Archimedes proved that the area of a circle is equal to that of a triangle of base equal to the circumference of the circle and of height equal to its radius. To calculate this area it is necessary to find the ratio between circumference and diameter. In estimating this ratio Archimedes sought the limit approached by the sides of regular polygons both inscribed in and circumscribed on the circle. The limits for their ratio to that of the diameter he found to lie between $3\frac{10}{71}$ and $3\frac{10}{70}$. The latter has, since his day, been generally accepted as a good approximate value of the quantity known as π.

He applied a comparable process to other curves. In his treatise *The Quadrature of the Parabola* he brings both an inscribed and a circumscribed rectilinear figure into relation with the curve under investigation. The two rectilinear figures, as it were, compress the curve, one from within and the other from without, until they coincide with it. This procedure, together with the use of mechanics for solutions subsequently demonstrated by geometry, leads to the consideration of his extremely important treatise *On Method.*

For the most part, Archimedes, like other Greek men of science, gives his proofs but does not tell how he reached them. In the *Method,* however, addressing Eratosthenes *(see* below) he recalls the discoveries which he had sent to his friend on a former occasion and then says that he is now explaining how he made them.

In essence the *Method* is the application of two principles: (1) that a plane figure may be regarded as an aggregate of an infinite number of parallel lines; and (2) that consideration of the respective weights of two plane figures, one curved and one rectilinear, may reveal the approximate area of the curved figure. The same process may be applied to demonstrate relationship between the volumes of solid curved figures considered as aggregates of an infinite number of parallel plane figures. It amounts to a practical solution of problems of the relation between areas or volumes by analysis. mechanical or other. after which the investigator returns to a synthetical mathematical process. He thus gains by experience some estimate of the solution before he seeks its mathematical demonstration.

An Alexandrian successor of Archimedes. Apollonius of Perga (*fl.* 220 B.c.), developed the knowledge of conic sections. Our familiar terms parabola, ellipse and hyperbola derive from him. The subject has a peculiar interest here since the idea of conics was for more than 1,500 years a purely intellectual exercise. Generations of mathematicians discussed the mathematical properties of these curves, which were not known in nature. Then in 1618 Kepler discovered that planets move in elliptical orbits. Surely here the distinction between pure and applied science was artificial. The human mind is somehow attuned to nature, whose ways it had unwittingly explored for all these ages.

Among the Alexandrian luminaries was Eratosthenes (c. 276–*c.* 194 B.C.), the greatest scholar of his age. His most important achievement was the measurement of the globe of the earth, performed by an operation of beautiful simplicity. He started with these propositions: (1) that at Syene (the modern Aswan) on the tropic and on the Nile, at noon on midsummer day an upright rod casts no shadow; (2) that Syene is 5,000 stadia due south of Alexandria.

The problem is to determine the angle at the centre of the earth subtended by 5,000 stadia. But if on midsummer day the shadow cast by an upright rod at Alexandria is measured, then the angle which the sun's ray makes with the rod can be estimated. Since, however, the sun is so far distant from the earth, its ray at Alexandria is effectively parallel to its ray at Syene. Therefore the angle that it makes with the rod is equal to the angle subtended by 5,000 stadia at the earth's centre (alternate angles). Thus an estimate can be made of the one unknown in the equation, that is, the earth's circumference. His result was reasonably accurate.

Having measured the earth, Eratosthenes proceeded to consider the known parts of it. Here, like all his predecessors, he had self-imposed limitations. He regarded the habitable world as wholly within the northern hemisphere and forming only about one-third of that. He considered that the land-surface of the world was longer from east to west than from north to south and estimated the distance from the Atlantic to the Eastern ocean as 78,000 stadia (about 7,800 geographical miles) and the distance from the parallel of the Cinnamon land (Ceylon) to that of Thule as 38,000 stadia. As he estimated the circumference or equator at 250,000 stadia. Eratosthenes could also estimate the circumference at the parallel of the Pillars of Hercules (Strait of Gibraltar), which he knew was also that of Rhodes. This fundamental parallel (latitude 36°) passed through other important points—the westernmost point of Spain. for example, and the southern points of Italy and of Greece—and along the Taurus mountains. At this parallel the total circumference of the world Eratosthenes estimated at 200,000 stadia. All but 78,000 stadia of this was sea.

At right angles to the parallel of Rhodes. Eratosthenes determined a north-south line between Alexandria and Syene. This, produced northward, he regarded as passing through Byzantium and thence to the river Dnieper. Southward, he considered that it passed to Meroë and then along the Nile.

These fundamental lines, together with those on other parallels of latitude and lines of longitude, are sufficiently accurate for constructing an outline world map in which the Mediterranean area is recognizable.

Alexandrian Science under the Roman Empire, 30 **B.C.–A.D.** 200.—Despite the dominance of Rome, science remained Greek in spirit and language. Its final syntheses are provided by two pupils of the Alexandrian school, Ptolemy (*fl.* c. A.D. 140) for cosmology and geography and Galen (*c.* 130–*c.* 200) for anatomy and biology.

Ptolemy's *Almagest* was of the highest significance for later astronomical development. Its basic cosmic conceptions come from his predecessors but are expounded with the utmost skill. Ptolemy (*q.v.*) invoked epicycles to explain the movements and behaviour of the planets, employing them to resolve some errors and inconsistencies of Hipparchus. He retained, however, eccentrics to explain certain elements in the movements of the planets.

Ptolemy possessed a series of astronomical instruments, the existence of which proves the high degree of mechanical skill evolved during generations in exact metalwork. With these he could determine the date of the equinoxes, the midday altitude of the sun, the zenith distance of the moon at its meridian passage, the meridian transit of stars, the apparent diameter of sun or moon and the latitude and longitude of the moon or of a fixed star. Among his greatest achievements is the determination of the distance of the moon by parallax: the method is in principle that still in use. Ptolemy estimated the moon's distance to be 59 earth radii, which is not very far from the truth. Working on an eclipse method of Hipparchus, he estimated the sun, however, to be only 1,210 earth radii distant, which is one-twentieth of the truth. He had no way of estimating the distances of the lesser planets but followed tradition in accepting apparent speed as the main test of nearness. The resulting scheme passed to the middle ages.

Ptolemy's other great work, his *Guide to Geography,* was a product of knowledge brought to him by Roman imperial expansion. He developed his own manner of representing on a plane surface the curved surface of the earth. In his "projection" the parallels of latitude are arcs of concentric circles. Chief among the parallels are the equator and the circles passing respectively through Thule, through Rhodes and through Meroë. The meridians of longitude are converging straight lines.[1]

The great biological synthesis of antiquity was made by Galen (*q.v.*), a native of Pergamum in Asia Minor. Galen studied at Alexandria but spent most of his active life in Rome. He elaborated a complete physiological scheme which was generally accepted until modern times. Three kinds of pneuma or spirit are involved in addition to the world-pneuma or air. The basic principle of life he believed to be drawn from the air by breathing. Entering the body through the windpipe, it passes, he thought, to the lung and thence to the left ventricle of the heart, where it encounters the blood. His view as to the changes that then take place in the blood was most ingenious and was based on experiments, but the errors that it involved remained current till the 17th century and beyond.

Galen's scientific works are among the most influential of all time. Nevertheless he established no school and had neither disciples nor direct followers. On his death anatomical and physiological inquiry ceased abruptly. Mathematical and mechanical research continued a little longer than biological, but they pass into a silver period in the 3rd century. For science in general the middle ages begin effectively about A.D. 200.

MEDIAEVAL SCIENCE

There followed a period well-nigh barren in positive scientific results until versions of the Greek scientific works appeared in Arabic in the 10th and 11th centuries and in Latin, mostly from Arabic: in the 13th and 14th. Though these later "middle ages" added little to the growth of our scientific heritage, they did something for its coherence and presentation. Consideration of this is best treated for the eastern and for the western share separately.

Islamic Science, c. 850–c. 1200.—After the fall of the western Roman empire, science disappeared with it. In the eastern Roman empire, which mas Greek-speaking, a disintegration began that was never effectively arrested. Much valuable Greek scientific literature was, however: translated into Syriac, the language of the heretical Nestorian Christians. Between 750 and 850 these versions were revised and many others added. From 850 to 950 Nestorian translators at Baghdad rendered the Syriac versions into Arabic. This presentation of Greek science in Arabic is the primary source of "Arabian science" which was to leave a deep impress on the Latin world.

The Arabic language and culture spread afar: to Portugal in the west and to the frontiers of China in the east and over many degrees of latitude. The most characteristic Arabic scientific developments were in alchemy, in mathematics, in astronomy and in medicine.

Alchemy is a term used to describe very diverse kinds of literature; most of it highly mystical. From Egypt, from Byzantium

[1] He has another scheme of projection in which the meridians are also curved.

and perhaps from China, however. Arabic-speaking "alchemists" derived many recipes and methods for industrial processes, and their experiments demanded special apparatus. The greatest Arabic-writing alchemist. Rhazes (d. *c.* 930), who completed his work by goo, makes the earliest known suggestions for furnishing a chemical laboratory. Industrial technology and alchemical apparatus of Arabic origin had an important role in the rise of modern chemistry.

In mathematics, of all peoples of antiquity, none except the Greeks attained so high a standard as the Hindus. Nevertheless. it is impossible to fix dates and hardly even possible to establish sequences for the Indian mathematical works. By the 9th century, however, the Islamic peoples were using the Indian system of numerical notation, the so-called "Arabic numerals." The most influential work that conveyed this was by the Persian Mohammed ibn Mûsâ al-Khowârizmî (c. 825), from whose name the mediaeval word for arithmetic. algorism, was formed. The title of the Latin version of his Algebra is the first western use of the word in the mathematical sense: it means "rectification," that is, transposition of negative terms of an equation to the opposite side. The Arabic speakers also inherited and considerably developed the geometrical and optical works of the Greeks.

Astronomy and with it astrology were constant preoccupations of the Islamic world. They were specially developed in Spain. where schools or groups of experts in these subjects were formed both at Córdova and at Toledo. The tables of positions of stars known as Toledan were drann up in 1080. Their authors sought to replace the Ptolemaic by a strictly concentric system.

In medicine, as in alchemy, the first and greatest original Moslem writer was Rhazes, the type of the oriental man of science whose erudition was all-embracing. He made the first distinction between measles and smallpox. It is impossible to mention Arabic medicine without recalling Avicenna (979–1037), whose work was for centuries standard in Latin as it still is in Arabic. He was scientifically much inferior to Rhazes. The physiology and anatomy of the Arabic writers as typified by Avicenna was a grossly deteriorated version of the Greek. The great Arabic contribution to medicine is the introduction of new vegetable drugs, many of which are still in use.

Science in the Latin West, 1100–1450.—Until the 11th century no western scientific movement needs consideration, since Spain in those earlier centuries must be regarded as within the orbit of eastern culture. In the 11th century the west began to come into relation with the nisdom of the east through Latin translations of Arabic works. These, during the following three centuries, came mostly from Spain but also from Sicily, from Provence and from Syria.

Mediaeval Latin had at first no technical scientific vocabulary. The translators therefore often transliterated Arabic words, and thus many Arabic names of stars, of chemical substances. of apparatus, of plants and even of anatomical parts passed into Latin. Some have survived in modern vernaculars. Moreover, Aristotle's views of the structure of the universe as conveyed in these Arabic-Latin translations from his works and from Ptolemy provided the mediaeval world-picture. The recovery of the works of Aristotle was a major factor in the 13th-century revival of intellectual coherence and gave to scholastic science its essential character. This "mediaeval Aristotle" was later modified by a slow infiltration of direct translation from the Greek.

It is remarkable that the accumulation of knowledge derived from the Arabic, involving rapid development in the whole mental life of Europe, did not arouse a more passionate faith in the value of progress in knowledge. The test of such faith must be the direct appeal to nature. But there was remarkably little of this until the 15th century.

Great emphasis has often been placed on mediaeval "forerunners" of science, notably of Roger Bacon (c. 1214–94). Research on Roger Bacon and on his times has shown that his scientific contribution was small. Comparable investigations of several other mediaeval writers who sought to outline a philosophy of science have yielded new and interesting but basically comparable results. There have been many able attempts to display the experimental achievements of the age. It is true that there were experiments with the compass (perhaps under Arabian influence); that the problem of the path of light within a spherical lens was partially solved on a mathematical basis; that a parabolic burning mirror was constructed or at least attempted; and that a solitary genius made a workable astronomical clock of great complexity. These achievements, scattered over two or three centuries, are minute compared with those of the best Greek or Arabic centuries. They hardly justify a revision of the standard view that modern science arose in the 15th and 16th centuries, primarily as a recovery of Greek science. But the new science had two advantages: first it had a better empirical technology, the product of the mediaeval centuries; secondly, it was aided by a method of exposition that was a real contribution of scholastic thought.

Astronomy—which cannot at this stage be distinguished from astrology—was certainly the main scientific interest of the scholastic age. The practical results of scholastic astronomical activity are. however, meagre. Western knowledge of astronomy was largely based on the activity of Alphonso the Wise (d. 1284), king of Castile. He collected at Toledo a body of scholars, mostly Jews, who had access to Arabic sources and calculated a set of astronomical tables (1252). These spread rapidly through Europe. They contain few new ideas, but certain of their numerical estimates, notably the length of the year. were calculated with very remarkable accuracy. Alphonso is also responsible for a vast encyclopaedia of astronomical knowledge compiled from Arabic sources by a similar group.

In pure mathematics the original achievement of the scholastic age was small, though a borrowed element, the so-called "Arabic" notation, was later to prove of the highest significance. The *Liber* abaci of Leonardo of Pisa (c. 1170–*c.* 1245), which advocates this system with great skill, appeared in 1202. The first book by a Latin Christian to employ this system, it is the essential source of our modern method of numeration, which, however, was extremely slow of general adoption. Other works of Leonardo were much more original, but being before their time had less influence. He was undoubtedly a mathematician of extraordinary ability, but his positive contributions are as nothing compared to his importance as the carrier of the new method.

THE RENAISSANCE AND EARLY MODERN SCIENCE

The Humanistic Century, 1450–1550.—It is not necessary to recount the western recovery of the Greek classics from surviving Greek traditions and texts. This "humanistic" movement was in full action by 1450, and the scientific heritage had been fully recovered by 1550. The intervening 100 years saw also the introduction and spread of the arts of printing and illustration, both of great importance for scientific development. From these general considerations we turn to the specific scientific achievements of the humanistic century. The first practical Latin exponent of the value of experiment is the German cardinal Nicolaus Cusanus (1401–64), whose recorded careful experiment on a growing plant, proving that it absorbs something of weight from the air, is the first modern formal biological experiment and the first experimental proof that air has weight. Carried to its logical conclusion it would have ended the old doctrine of the pneuma. Nicolaus wrote a book on the use of the balance and showed in several ways that he could apply the experimental method in detail. His theoretical views led him to believe that the earth moves, though he reached no formal astronomic theory.

Copernicus (1473–1543), despite the vast scientific change introduced in his name (see ASTRONOMY: History of Astronomy) was a conservative scholar rather than an observer. Induced to seek a new theory of the heavenly bodies by finding that mathematicians differed among themselves on this subject, he concluded that some essential factor had been missed. He found his hint in the surviving traditions of the thought of the Pythagoreans and of Aristarchus and perhaps also in the thought of Nicolaus Cusanus. The renovated scheme set up by Copernicus assumed that the universe is spherical and finite. limited by the sphere of the fixed stars, and that the movements of the celestial bodies are always circular and always with uniform velocities. It invoked epicycles and demanded eccentrics. John Milton gives a description of the Ptolemaic world that fits this attempt to "save the phenomena" when he makes the archangel Raphael tell of those who would

"model Heaven
And calculate the stars: how they will wield
The mighty frame; how built, unbuild, contrive
To save appearances; how gird the sphere
With Centric and Eccentric scribbled o'er,
Cycle and Epicycle, Orb in Orb."
(Paradise Lost, viii, 79–84.)

An important aspect of the humanistic century is the impact of the main technical instrument of Renaissance art, namely perspective. This new device, though it rapidly became a convention, is truly scientific because, given certain conditions, its truth can be demonstrated experimentally and at will and its accuracy estimated Leonardo da Vinci (1452–1519) was its greatest scientific exponent, but it was the product of many minds.

Perspective deeply influenced many sciences. It produced sounder and simpler plans of engines of all kinds and was of great aid in many technical arts. All developments involving geometry in three dimensions became more easily intelligible. Above all it made possible the adequate representations of living things and their parts. Thus Leonardo could both illustrate many devices of his age and make clear on paper, for the first time, many details of the structure of human and animal bodies.

The same movement which linked the study of nature with scientific perspective produced in the first half of the 16th century many exact studies of plant form. Its most characteristic product was the masterpiece of Andreas Vesalius (1514–64), the first great scientific monograph in the modern manner. This appeared in 1543, within a few weeks of the work of Copernicus, his senior by 41 years. Copernicus is essentially a mediaeval figure. Vesalius a modern who employed all the resources of the art of his age to illustrate personal observations. Nevertheless it is important to remember that the researches of Vesalius were solidly and consciously based on a sound knowledge of the 1.300-year-old findings of Galen.

The New Status of Greek Science.—Mediaeval thought on the material world was essentially based on that of the Greeks and especially on Aristotle. By 1500 the whole works of Plato and almost the whole of Aristotle were available in reliable Latin translations direct from Greek. The Renaissance saw a revival of Platonic thought. Moreover, from about 1550 an accumulation of biological works based on Aristotle tended to confirm him as "the master of those that know" in that particular field. At about the same time, however, in the fields of mechanics and of cosmology cracks were beginning to appear in Aristotle's system. These were brought out clearly by Simon Stevinus (1548–1620) in the last years of the 16th century. He investigated the Aristotelian theory of the fall of bodies. His name is associated with the method of resolution of forces, with the distinction of stable and unstable equilibrium and, above all, with the law of equilibrium on an inclined plane in a famous demonstration of the impossibility of perpetual motion. He perceived that science could not well advance until its mathematical framework had been improved. This was facilitated by his introduction of decimal fractions. Several other contemporary devices helped in the same direction: for example, the employment of letters to represent quantities (1591), the conception of conic sections as stages in a series from the line pair to the circle (1604) and the invention of logarithms (1614). With such equipment and with the improvement in the technique of instrument-making, notably of lenses, the great exponents of scientific method of the earlier part of the 17th century —Galileo (1564–1642), Kepler (1571–1630), Descartes (1596–1650)—could proceed with their work. By the middle of that century Aristotle's physics and cosmology had fallen, while his biology was on its way to being rebuilt on his own lines; mathematics had become a recognized instrument of research in the physical sciences; the contributions of Archimedes were recognized, even when applied in the biological field; alchemy had effectively been replaced by a chemistry built mainly on the technological traditions of craftsmen but aided by the apparatus of the alchemists; the exploration of the structure and function of the human body had become a profession. Science itself had emerged as a vocation supported by its specialized philosophers, by its specialized exponents in the arts of discovery in various departments and by its skilled instrument-makers. Science had thus become consciously mature and was prepared for its formal organization in the period which followed. All this was exemplified in the brilliant personality of Galileo (*q.v.*).

The outlook of the first half of the 17th century thus involved on the negative side a rapid waning of the scholastic reliance on ratiocination, and on the positive a new reliance on experience and especially on experiment as a way to make knowledge. A man of science of the 20th century could converse freely with one of 1650, with a very few of 1600, with a handful of 1550, but hardly with one of 1500. What had happened in this first and critical half-century of modern science, from 1600 to 1650?

In cosmology, the explanation of planetary movements by Kepler (*q.v.*) and Galileo's discoveries with the telescope had destroyed geocentric thinking. They had done away with the moral connotation of physical events expressed in the idea of the perfection of the sphere. Incidentally they had destroyed astrology.

There was a new view of the nature of matter. The systematization of mineralogical knowledge and the increased literacy of industrial technicians had given birth to chemistry and destroyed alchemy, removing there too a moral significance from material phenomena.

To express his findings in mathematical terms became the ideal of the physical experimenter. Broadly, this was acceptance of a relation between number and form, for which Descartes (*q.v.*) is still commemorated in the term "Cartesian co-ordinates."

The idea of acceleration is a development of that of mathematical expression but one of such significance that it demands special mention. Its introduction by Galileo was a great seminal idea for all aspects of physics and notably for celestial physics.

Physiology set physics as its ideal. The discovery of the circulation of the blood by William Harvey (1578–1657) and the chemical investigation of the bodily processes by J. B. van Helmont (1577–1644) made possible the first comprehensive treatment of the subject by Descartes.

Living forms, by reason of their great variety, did not yield (and still hardly yield) to physical, chemical or mathematical consideration. The period saw an extension of Aristotelian methods to the classification of animals and of plants. "Natural history" perhaps first achieved this status at the hands of Joachim Jung (1587–1657).

From this point on it is harder to consider science as a whole, even if we avoid considering the applications of science. Scientific thought became specialized. At its dawn about 400 B.C., we saw it dichotomize into mathematics and medicine. So from 1650 we must consider the physico-chemical view on the one side and the biological on the other. Soon there will be much more complex division and recombination.

DETERMINISM AND POSTDETERMINISM

From the second half of the 17th century to the end of the 19th men lived in a world of which the material framework had been outlined by Isaac Newton (1642–1727). The attitude of mind called "scientific determinism," sometimes rashly equated with "scientific materialism," is not quite as old as that. Newton's great work, *Philosophiae Naturalis Principia Mathematica,* was published in 1687. It had little immediate effect: it could at first be read only with difficulty even by mathematicians, and its demonstrations were intelligible to a mere handful of Newton's contemporaries, none of whom moreover was interested in introducing them to less scientific readers. Its wider influence began to be felt after Newton's death. The impact of "Newtonism" on general thought can perhaps be dated from the publication of Voltaire's admirably clear essay on Newton's system (1737).

Though Newton wrote what he called "philosophy" and habitually called himself a "philosopher," he meant by those words just what we mean by "science" and "scientist"; cf. the *Philosophical*

Transactions of the Royal society (over which Newton used to preside), from which anything that we would now call "philosophy" is invariably excluded. Let us therefore consistently render his word "philosophy" by our word "science," which is almost exactly what he meant.

Newton left no doubt as to what he regarded as the principles of science and his hopes for it.' All its difficulties, he held. "seem to consist in this—from the phenomena of motions to investigate the forces of nature, and then, from our knouledge of these, to demonstrate other phenomena." And he goes on: "I wish I could derive all phenomena of nature by some kind of reasoning from mechanical principles; for I have many reasons to suspect that they all depend upon certain forces by nhich the particles of bodies are either mutually attracted and cohere in regular figures or are repelled and recede from each other." Thus he hoped to fit all material events into a framework of relatively simple and mathematically expressible rules. That is what he regarded as the task of his "philosophy" and what for two centuries was regarded as the task of "science."

Newton's marvellous genius ran at its ease only along the line of demonstration to the senses. and it was as a means for such demonstration that his superb mathematical apparatus was designed. He was indeed much interested in theology and spent much time on it; but for philosophy he had a definite distaste. The influence of his science on philosophy (and doubtless through it on religion) has mostly been unwitting, though no less important on that account.

Newton was more gifted with the power of scientific demonstration than any man. He is rightly regarded as the very type of the modern man of science. and we may treat him as the modern scientific exemplar. But this scientific giant presents a different figure when he works in a field ill-suited to his trained talents and works with tools the use of which he has not learned in the best tradition. Newton's incursions into chemistry make a depressing story of waste of most precious effort. His chemical. that is, his alchemical record provides the classical warning that the task of the man of science is demonstration and that his opinions, where unrelated to demonstration, are of little more value than those of other men.

In spite of all this Newton formulated, more clearly than any of his predecessors, those primary statements on which others came to build that comprehensive system which later became known as "scientific determinism." The term was introduced about the middle of the 19th century, but the passages just quoted from Newton's *Principia* contain the essential elements in the determinist faith. Some of the exponents of that faith have, however. extended the conception of "phenomena" far beyond anything that Newton intended. They have, for example, ranked as phenomena events within the mind itself, and they have treated them also as determinate.

The conception that mental events are determinate has been much more revolutionary for religion than anything in the Newtonian system proper. That man's body works on ascertainable mechanical principles had indeed seemed obvious to Descartes before Newton and as long ago as 1627. The followers of Descartes directed the thought of the age for about a century. The Cartesians, however, recognized with their master that men are something more than mechanical systems. Man thinks as well as acts. Only if man's entire nature, including his thinking, could be fitted as links into a long chain of causal development could his actions and his mind be treated as truly determinate. It was in this very way that the conceptions of Descartes and Newton were extended in the middle and later years of the 19th century, especially after 1859, in which year appeared both Darwin's *Origin of Species* and Marx's *Zur Kritik der politischen Oekonomie*. The former contains the germ of biological determinism, the latter that of psychological determinism. Both are sources of the doctrine of social determinism.

Years before Darwin and Marx, the seer William Blake (1757–1827) had seized on the apparently unoffending figure of Newton as the type of those who deny free will—which in fact Newton did not. Blake could not read any part of Newton's science, but echoes of the scientific discussions of his age reached his limited circle. Despite his misunderstandings, Blake had a remarkable vision of scientific determinism. But he was not the first. There were certain schools of thought in the 18th century that followed the determinist path. Such were the French encyclopaedists and some of the first English utilitarians. With these may well be classed certain heretical groups during Renaissance and mediaeval times. Behind these again were strains of Stoic and of Epicurean thought in classical antiquity. Further back, too, at the very dawn of philosophy, we see a cleavage on determinism between the thought of Socrates and that of his rival Anaxagoras. Through all the ages these attitudes have opposed each other. Neither had or could then have demonstrational backing. It was Newton who first demonstrated a law of physical movement the writ of which ran equally on earth as in the heavens, a law which seemed wholly unrelated to any spiritual order. It was this that gave to the conception of determinance an immediacy as well as a practical workaday aspect that it had never previously worn.

Newton sought always to cast his scientific conclusions into a mathematical form. From the time of Galileo, or indeed from the time of Plato, many men have held that the scientific value of any collection of observations can be estimated by the degree to which they are susceptible of arrangement under mathematical formulas. Were this the case, mathematics would be the yardstick by which alone the maturity of a science could be judged. That "science is measurement" is widely held and even more widely tacitly accepted. Yet in fact much science is not, or has not yet become, mathematical.

So far as the 19th century is concerned, it was the conclusions of certain nonmathematical sciences that impinged most directly on philosophical and religious thought. It was the geologists and the evolutionary biologists who raised most acutely the issues primarily responsible for "the conflict between religion and science," by demonstrating that man's place in nature is very different from that which had been taught. Evolutionary doctrine quickly affected historical, social, linguistic and even literary studies. No line of scientific thought has ever so rapidly seized so many minds as that associated with the name of Charles Darwin (1809–82). Now, however, the thunders of the evolutionary conflict rumble only from the further frontiers of philosophical discussion, and the air has long cleared in the area of the original disturbance. Scientific men, though still busy discussing the nature of the evolutionary process, do not spend time answering such remote and ineffectual persons as may deny the demonstrated evolutionary sequences.

But in considering this and other great seminal ideas it must ever be borne in mind that science never considers and cannot consider the world as a whole. It is essential to any science that it proceed by abstracting a part of the universe, to be considered by and for itself. This fragmentation carries with it the secret of the scientific triumph and the secret of a common philosophic fallacy. While one science may combine with another to form a new science with its own technique (for example, entomology and psychology have together produced insect psychology) and while one science can use the results of another, yet each science can describe only its own little bit of the universe in its own terms. These terms are derived by a comparison of yet smaller bits of the universe with other smaller bits. Such terms have little or no application outside the particular science for which they were devised. The technical terms of the sciences have no universal application or value. Their use outside the field for which they were invented is a very frequent source of misunderstanding.

Gross errors have been made, even by scientific men, through transference of scientific terms from their original field of reference. Consider, as examples, the mass of fruitless disputation that has arisen around such words as "evolution," "instinct," "element"; or the employment of the words "race," "tradition," "heredity," "nationality," "value" to give a scientific appearance to nonscientific judgments; or, again, the endless confusion between the scientific, the philosophic and the theological usages of such terms as "substance," "theory," "idea,'! "cause," "purpose," "function." The language of the sciences is a peculiarly difficult subject, for language is a product of complex and ever-changing social conditions. Words cannot be fixed or stabilized and they carry with them a history that needs to be traced right up to the moment of usage.

To enter into the difficult and disputable region of definition of terms would take us right back to a discussion of the very nature of knowledge. Here it must suffice to indicate that there cannot be a "science" of the whole universe. Specifically, it is impossible to reach that end—or perhaps any end—by just adding the sciences together. Even apart from the many difficulties and objections intrinsic to such a process. there are vast regions of experience—those occupied, for example, by art, by literature and by philosophy—that are refractory to scientific treatment. In any event, there is no such thing as a universal science, a scientific treatment of the entire universe. It is, moreover, certain that there never can be.

Nevertheless a science must not be mistaken for a mere fragmentation of knowledge. The necessary minuteness of scientific analysis may give those untrained in the sciences an impression of triviality. That the restriction of the field of experience of scientific men should be a favourite theme for humorists is both legitimate and highly praiseworthy. There are many useful men of science who spend their lives absorbed in minute scientific details and who never learn the importance or significance of their own studies. But, despite such dull, obstinate, timid or temperamentally limited beings, science is a great deal more than exploration of ever minuter details. The objective of scientific analysis is to reach a series of points—a natural frontier—from which the mind can return along its tracks to arrange its findings into some pattern. Such patterns are scientific theories or generalizations. They frequently involve a reunion of the findings of workers in different departments. Often these findings become the starting places for new analytic explorations and the bases of yet further generalizations and thus of new sciences.

The impressiveness of the great scientific generalizations must not deceive us as to their essentially abstractive nature. Each science is as much a consideration of an artificially separated fragment of the universe as is the minutest entomological research. Whether we are discussing the galactic circle, or the antennae, of a beetle or the "expanding universe,'! we are dealing with an artificially separated bit of the world. We often speak of the "field" of a science, and the term is peculiarly applicable to such an area of experience. The essential character of a field is that it is separated from the surrounding country by a fence or hedge. It does not make up the whole landscape. though it contributes to its character. A science, to be such, must have its set limitations.

The term "expanding universe" itself here merits a little consideration, since it is often the subject of a naïve confusion between scientific, philosophic and religious conceptions. The expanding universe of the relativists is, of course, not at all the universe of ordinary thought, but simply a technical term of astronomical and mathematico-physical science. It refers to something the existence of which must be assumed in order to fit together the mathematical deductions from certain physical measurements. For these deductions to fit each other, it is necessary to assume a field that is ever growing larger. This is the expanding universe of the astronomers. The universe: without an adjective, includes many things that are insusceptible not only of measurement but of any sort of mathematical treatment or expression. To such things the term expanding is wholly inapplicable. Csing a verbal, though not a real, paradox, we may say that the expanding universe is part of the universe.

There is an aspect of the necessary conditions of scientific observation that has forced itself upon the attention of men of science during the 20th century. It became more apparent to them that their studies demand for their prosecution certain basic data, that is to say, things "given," or taken for granted. To express the same thought in other words, we say that physical science has its metaphysical foundations. A famous saying of Archimedes brings out this point: "*Give* me a place on uhich to stand," said he. "and I can move the world." His difficulty was, of course. that there is no such place, unless it be, as he says. "given"—that is, taken for granted and imagined for the purpose of his discussion.

Men of science have now come to perceive, more clearly than before, that for scientific observation to have any meaning, certain things must be assumed, accepted, taken for granted, given. The point came into high relief early in the 20th century in connection with the interpretation of certain observations of the behaviour of light from the stars. These observations formed the basis of the physical theory of relativity associated with the name of Albert Einstein (1879–195j), the essence of which may be expressed by saying that the very act of observation affects that which is observed. Within a few years a similar point arose in connection with the intra-atomic physics. It was found that the more accurately the position of a particle could be specified, the less accurately could its velocity be predicted: and vice versa. This is the principle called "indeterminancy" or "uncertainty" (see UNCERTAIKTY PRINCIPLE, THE), which, like relativity, runs athwart the whole view of scientific determinism.

Relativity and indeterminancy are of the utmost importance not only in the specific fields in which they first came into view, but also for any consideration of the ultimate validity of scientific demonstration. In this connection, however, a serious misunderstanding has arisen. It has been assumed that. because the most minutely exact prediction may be impossible to us human beings, physical action is ultimately indeterminate. But the one thing does not follow from the other. Whether nature is indeterminate or not is an entirely different question from whether we can or cannot ascertain all her determinate elements. The indeterminate element may be in ourselves.

Fortunately, it is unnecessary to discuss here in detail physical relativity or physical indeterminancy. Since neither principle is involved in those separate observational sciences which admittedly treat only of artificially separated fragments of the sensually appreciable universe, a scientific "theory" can generally be safely launched regardless of these principles. however important they are for any general consideration of science.

The universe as a whole, meanwhile. is not explained by gravitation plus particulate doctrine of matter plus relativity plus evolution plus subconscious mind plus the doctrine of marginal values plus e'nergetics and so on, even though we should eventually muster all the great scientific generalizations. Such things cannot all be added together. To attempt to do so is to pass into absurdity. Some of them are incommensurate with others of them. And, moreover, such of them as can be added together provide thereby not a goal, but rather a starting place for further exploration (as exemplified in "insect psychology"). The vastness of the territory which has been considered by men in their scientific mood must not blind us to this essentially partial or temporary character of their conclusions. There is a limit beyond which the mood cannot be applied, maintained or endured. The sciences can, at best, describe only a part of the universe.

Thus to the oft-asked question "What does science say about religion?" the strictly true answer is "Nothing whatever" if by religion is meant a general view of the universe and of man's place in it. Notably that must be the answer if religion is to include that inner factor in man's consciousness by which he integrates himself into the universe. Science can say something of scarabs and stars and mountains and, maybe, of the relations of all these things to each other. It may treat of the operation of minds, both individually and collectively, at any rate as judged by an assumed—though unintelligible—parallelism between mind and body. And as regards a religion, science may analyze it into abstracted parts and tell us something about, let us say, the psychology of Buddhism or the debt of Islam to Byzantine Christianity. It may display the influence of a religion on the conduct not only of a society but even of an individual. But science can neither, on the one hand, bring all the diverse parts of the universe into relation with each other nor, on the'other, touch the essential nature of existence of which we are aware through something that we call "consciousness."

Consciousness is the ultimate datum, the thing taken for granted. Consciousness is, as it were. the judge before whom science must recite its piece, which is its narrative of experience of phenomena. These experiences are arranged in a series of acts or scenes each of which bears the name of a particular science. The scenes may be altered, amalgamated, enlarged, increased in number; but external things, seen, heard and felt, they remain. Their recital, and that alone. is the role of science. (C. SI.)

SCIENCE, TEACHING OF. In most countries. science instruction begins in the elementary school. The teacher at this level cannot be a specialist in science teaching, for he must also teach the other subjects of the curriculum, but there is a growing tendency to employ specially trained science consultants who do demonstration teaching in science and who assist the regular teachers in their work.

The teaching of science as a separate subject generally begins with the middle or junior high school (typically, grades six to eight or seven to nine; *i.e.,* second to fourth or third to fifth form). Instruction at this level in Great Britain, the United States and many other countries offers.under the heading of general science, all major aspects of the subject. Many countries, however, follow the French system of offering separate courses in physics, chemistry and biology, starting with simple and descriptive accounts in the sixth or seventh grade (second or third form). The instruction in these fields is typically cyclical, and the instruction continues throughout the secondary school. The Anglo-U.S. pattern of general science is followed by courses in physics, chemistry and biology in the later secondary-school years. Less rigorous courses such as physical science are sometimes offered for less capable students.

Postsecondary-school science courses are many and diverse. Universities offer sequences in each major field of science. from introductory and general courses to highly specialized courses which provide intensive instruction in restricted fields leading to research or to technical vocations. Technical schools provide specialized training for industrial work; science instruction in such schools is focused more on the practical than on the theoretical aspects of science.

Goals of Science Teaching.— The modern world requires a very large number of skilled technicians and practitioners as well as of persons who can add to the store of fundamental knowledge through their own research. A primary responsibility of the science teacher, therefore, is to foster the development of the scientist. But there is a second goal, no less important, which is that of educating each person, to the degree of his capabilities, in scientific understanding to enable him to cope intelligently with his environment and to contribute both to his own well-being and to that of society. Another way of looking at goals is to examine the nature of science itself. Science is. first, a body of tested facts and concepts that satisfactorily interpret natural phenomena and disclose causal relationships, and. second. a means for discovering such facts and principles and for applying them in the solution of problems. There is no single "scientific method," but there are general procedures which distinguish the scientific methodology as a discipline from the methodologies of other fields such as art or philosophy. This aspect of science, heavily emphasized in graduate programs of universities, formerly had little attention at lower levels, particularly in European schools, but emphasis on scientific attitudes and methods as an instructional goal is increasing.

Methods of Science Teaching.— Methods are a reflection of goals. For example, the development of knowledge sufficient to pass the rigorous governmental examinations has been a chief instructional goal in the French *lycées.* As these examinations emphasize detailed memory of facts and principles (and, at least formerly, largely ignored reflective analysis of data, applications of principles, and so forth), instruction has placed a premium on memorization. The formal lecture method is widely employed, and students are expected to take notes and to remember what the teacher has taught. Laboratory work is seldom used, and even demonstrations are generally neglected in favour of a systematic and highly verbal treatment of a logically organized body of scientific facts. Practice in the U.S., as another example, has tended in the opposite direction. The secondary schools have placed a much stronger emphasis on individual laboratory work, demonstrations, problem solving and informal lecturing and discussion. About the middle of the 20th century, however, an American trend toward greater rigour and systematic instruction was paralleled by a European trend toward greater flexibility with less emphasis on strictly memory work. (R. W. Bu.)

SCIENCE FICTION deals with the human drama, the conflicts and adventures, arising out of scientific discovery in the future. There are two basic types. Science fiction proper, an almost step-by-step development of possibilities from known scientific or social data, is exemplified by Arthur C. Clarke's *The Sands of Mars* (1952), which works out the conditions encountered by the first explorers on that planet; by Hal Clement's *Mission of Gravity* (1954), which deals similarly with an entirely alien world and its beings in another solar system; and by George Orwell's *1984* (1949), which presents an uncannily perceptive extrapolation from contemporary totalitarian social patterns. Science fantasy, on the other hand, can leap directly to whatever farfetched assumptions may be necessary to the story. Obeying the sole requirement of dramatic plausibility, it permits the imagination not only to go beyond the known and proved but to contradict it when that is necessary, as exemplified by Alfred Bester's *The Demolished Man* (1953), Ray Bradbury's *The Martian Chronicles* (1950) and Edward E. Smith's *Lensman* series (various dates). Needless to say, the two basic types are frequently combined.

The major themes of science fiction are: (1) space travel to and from other planets, solar systems and galaxies, including the exploration, settlement and exploitation of other worlds as well as encounters with, or between, extraterrestrial life forms; (2) time travel to the future or the past and, similarly, travel to "alternate universes" which are usually different versions of our own; (3) psychological and biological changes in man, brought about by nature or science, and similar changes in other species; (4) "supernormal" powers and talents, achieved either through technology or the advancement of such "fringe sciences" as parapsychology; (5) science applied, directly or indirectly. to human relations for either constructive or destructive purposes. These themes are clearly illustrated in such short-story anthologies as Groff Conklin, *The Best of Science Fiction* (1946) and *A Treasury of Science Fiction* (1948); August Derleth, *Beyond Time & Space* (1950); and Raymond J. Healy and J. Francis MacComas, *Famous Science Fiction Stories, Adventures in Time and Space* (1957).

History.— Even in ancient times certain science-fiction themes were used as vehicles for social satire and criticism and for tales of wonder. These treatments dealt with what was then admittedly impossible. True science fiction, however, assumes a "this *can* happen" attitude which could not exist until the scientific method was defined and until the mechanization of everyday life made great numbers of people aware of science. It was not until the latter part of the 19th century, especially in the works of such writers as Jules Verne and H. G. Wells (*qq.v.*), that science fiction began to acquire its 20th-century forms and its functions not only of entertainment but of speculation and prophecy. In this last it has been more accurate technologically than socially

As a separate and self-aware literary form, science fiction may be said to date in the United States from Hugo Gernsback's founding in 1928 of the magazine *Amazing Stories.* In 1937 it entered a new epoch when John W. Campbell, Jr., took over the editorship of *Astounding Science Fictzon* and established a story pattern emphasizing not only the element of scientific speculation but those of character and human drama as well. Advances in nuclear power and rocketry during and after World War II increased its popularity tremendously. In the United States the number of specialized magazines rose from 8 in 1945 to more than 30 a few years later, and the number of novels and anthologies increased even more rapidly. Serious journals of comment and opinion took note of science fiction. The general magazines, motion pictures, radio and television began to use it much more often. A specialized critical literature came into being.

This phenomenon was especially marked in the United States and the rest of the English-speaking world; however, in varying degrees it took place in most civilized nations—for science fiction had accomplished something unique in the history of literature. The central technological achievements of the period—radar, television, automation, electronic brains, atomic power for peace and war, rockets and eaith satellites—had been science-fiction commonplaces for a generation before their practical realization. With a remarkable degree of general accuracy science fiction had heralded and defined the electronic age, the atomic age and the age of space.

Influence.—Through its readers science fiction had considerable sociological influence. Surveys showed that many of the readers of the better science-fiction magazines were young scientists and technologists or students destined for these fields. Similarly, many science-fiction writers, such as Arthur C. Clarke, Isaac Asimov, Robert Heinlein, John Taine and Edward E. Smith, were themselves scientists or engineers. Science fiction influenced many young people to choose the sciences as a career; it stimulated the imaginations of many scientists in the forefront of discovery; it helped to orient many intelligent laymen to the scientific world of the present and the future.

Nevertheless, science fiction did not break with literary tradition. The same artistic rules apply to it. Its characters must be as fully developed as any others; its plot structures must be as coherent; its emotional impacts must be just as strong. That is why, with the infinite variation of its themes, it holds at its best so much for readers and writers alike.

SCIENTIFIC MANAGEMENT, a movement once popular (prior to the 1930s) with businessmen and a rather distinct theory of business management.

The movement began with Frederick W. Taylor's experiments in management methods at the Midvale Steel company, Philadelphia, Pa., around 1880. The theory was forged largely by Taylor from his observations and experiences and was not set forth in formal fashion until 1903. Taylor did so then in a paper entitled "Shop Management" and, in clearer fashion in 1911, in a book, *The Principles* of *Scientific Management.*

The Theory.—The basic theory of scientific management is that business managers have an inescapable responsibility for eliminating "waste" and improving the efficiency of the industrial system. Efficiency, in the physical output-input sense, is the end and aim of scientific management.

Taylor stated specifically that managers are responsible for: (1) defining the task which the worker is to perform; (2) selecting the proper worker for the job; and (3) motivating the worker to a high level of performance. When managers properly perform these tasks efficiency increases.

In the late 19th century these ideas were revolutionary. For centuries, the knowledge of methods in various trades had been passed from one generation of workmen to another. Furthermore, workmen over the years had established informal quotas of work which they regarded as fair. Management efforts were largely in the direction of trying to exhort workers to produce more without having any clear idea of how much the worker should or could produce. Taylor believed this state of affairs to be nothing less than a defection on the part of managers. Over a period of years he worked out specific techniques for managers to follow to bring the situation into proper order.

Management Duties and Techniques.—In order to accomplish the primary job of properly defining the worker's task managers must: (1) prescribe the exact order and method of work; (2) prescribe the tools and equipment to be used; and (3) establish the time in which the task is to be accomplished. The first two duties are accomplished through use of motion study. The last duty Taylor accomplished through the technique of time study. This technique became clearly identified with scientific management and became the centre of much controversy. Time study involves the observation of a "good worker" who is using prescribed methods and equipment for the purpose of determining the time in which his task should be performed. Taylor contributed the technique of timing component parts of the total task with a decimal minute watch.

The "good worker" concept is an important one. Managers, in accordance with this philosophy, must seek out and use those men peculiarly well-fitted for the particular job under consideration. This necessitates application of knowledge contributed by engineers, psychologists and physiologists. An important characteristic of the good worker (or "first-class worker," as Taylor put it) is his willingness to accomplish the amount of work which management establishes as proper. (The worker, of course, is picked as physically capable of performing this work.) From these selection duties the modern personnel department of the business firm evolved.

The willingness on the part of the worker to accomplish the prescribed task results from an incentive being offered for such accomplishment. Taylor proposed a piece payment plan which rewarded rather poorly for performance below the task standard set, and handsomely (in terms of accepted rates of pay) for performance above standard. As Taylor strongly emphasized, this system of management is eifective only if standardized job conditions are established and rigorously maintained. The techniques described are aimed at standardization.

Others, following Taylor, contributed refinements of his ideas and techniques. Frank and Lillian Gilbreth devised an extremely thorough method of studying the motions of workers. They sought to reduce working time and effort through discovery of the most effective sequence of motions, and through proper design of the workplace. H. L. Gantt devised a useful visual aid to planning of production (the Gantt chart) in addition to refining concepts of accounting for costs. Still others devised various incentive pay systems.

Status of Scientific Management.—Examination of Taylor's ideas reveals that his philosophy turns on several crucial assumptions. The prime assumption is that the dominant, if not exclusive, motivation of the individual worker is economic. The "normal" man, in the work situation, is interested above all else in increasing his money earnings. Another assumption is that men working individually are interested in doing a good job, but that working in groups they are concerned only with not working harder than others. Group incentives are thus generally ineffective. A further assumption is that in removing the responsibility for planning methods from the worker, and turning that task over to a specialist, a net gain in efficiency results.

These assumptions were attacked sharply during the years following the publication of Taylor's ideas. In particular, critics adduced evidence that men are motivated in working by a number of factors, of which money earnings may be only one. In enumerating these other motivating factors critics inevitably found themselves questioning the additional assumptions implicit in the theory of scientific management. For example, in the years following the depression of the 1930s a popular body of thought developed in which a prime factor in the motivation of the individual worker was conceived to be the degree to which he continues to experience satisfying relationships with other members of a work group. This idea. a product of the "human relations" school, became so widely accepted that the scientific management concept of motivation appeared, superficially, to have been abandoned.

Furthermore, a group of critics argued that removing the planning function from the worker destroyed any opportunity for creativeness on his part. If the individual finds no outlet for creative activity in his work, the argument goes, he becomes no more than an automaton. The worker is restless, dissatisfied, unhappy; labour turnover will be high, strikes frequent. Thus, it is argued, efficiency will decline; the gain from using planning specialists will disappear. This argument was advanced by many thoughtful observers, and there was evidence in the 1950s that it was beginning to receive consideration by some managers.

One might wonder if, since the arguments noted attack critical assumptions in the scientific management theory, this means that the theory was being superseded by some superior system of management.

In evaluating the status of scientific management in the 1950s it is important to remember that a basic change in the labour force had occurred after the late 19th century. In the United States, where scientific management and later criticisms of it had been most discussed, the formal education of the average worker had been phenomenally increased since 1880

The worker tended to be better informed, more critical and more vocal with respect to management methods than was true in Taylor's time. This, together with the great increase in per capita wealth (and hence. perhaps, a lesser preoccupation with the grim task of earning the necessities of life), might well mean that the worker's pattern of motivation had become more complex than it was in the early days of the scientific management movement. Hence, there was reason to believe that scientific management stops short of providing a complete answer to management problems.

But the separation of planning from performance, the chief heritage of scientific management, remained in full effect everywhere. Moderate and thoughtful critics of the theories of Taylor and his followers usually argued only that management had gone too far along the scale from complete control of the job by the worker to complete lack of worker control of anything save the quantity of his output.

The latter-day management problem was to put back into the job something of interest other than earnings. Few questioned the arrangement whereby management determines performance standards, basic work methods. worker qualifications and incentives. The critics merely pointed out the necessity for more intelligent planning of these factors (especially work methods and incentives) in the light of advances in knowledge (particularly psychological) in the mid-20th century.

Taylor's revolution had been accomplished. Scientific management had changed from a movement to an accepted way of managing.

Whether or not a counterrevolution would become necessary depended upon the ability of 20th-century practitioners of scientific management to distinguish theory from techniques; *i.e.,* to continue to accept the responsibility for intelligent planning while adapting specific management procedures to accord with changes in the working population, and in society in general.

See Management Sciences.

Bibliography.—Frederick Winslow Taylor, *Scientific Management* (1947); William R Spriegel and Clark E. Myers (eds), *The Writings of the Gilbreths* (1953). (T. L. W.)

SCIENTIFIC METHOD is a description now reserved for the procedure by which we gain knowledge in empirical studies such as physics, chemistry and physiology. At one time the word "science" was applied to all systematic studies or organized bodies of knowledge, including mathematics and theology. There was a tradition derived from Plato and Aristotle that the system to be expected in a science should be such as we have in mathematics; that is, that all the asserted propositions which are not themselves self-evident should be derived from others that are self-evident. In accordance with this usage the word "scientific." first introduced in its Latin form as a rendering of ἐπιστημονικός in Aristotle's *Posterior Analytics*, i, 2. was applied only to reasoning which produced knowledge like that which we have in mathematics. For many centuries it remained a synonym for "demonstrative." Thus John Locke says in his *Essay Concerning Human Understanding,* iv. 3, § 26, "How far soever human industry may advance useful and experimental philosophy in physical things, *scientifical* will still be out of our reach"; and he explains his meaning later in the paragraph by the remark "*Certainty* and *demonstration* are things we must not in these matters pretend to."

The modern use of "scientific" noticed above appears to have been established in England about the middle of the 19th century. At the beginning of that century physicists and chemists were still called philosophers, and the tools of their trade philosophical instruments. The word "scientist" was invented by William Whewell in 1840, and the earliest evidence in the *Oxford English Dictionary* for an acknowledged particularization of the word science in its special modern sense comes from 1867.

Clearly there may be many different methods by which scientists gain knowledge in different fields of research. Thus Archimedes found a way of determining specific gravities, and A. H. L. Fizeau found a way of measuring the speed of light. In modern times the special methods of research used in the various sciences have become more numerous and more complicated. so that a large part of the training of a future scientist is the imparting of techniques. Knowledge of these is important not only because it is necessary for one who is to make new contributions as an experimenter but also because it is an indispensable link between observation and theory.

A physiologist may use a cathode ray oscillograph without being an expert in electronics, but it will not help him to get evidence for or against a hypothesis about the working of nerves unless he understands its own working at least in outline. Since such a special method involves application of scientific results already attained, it cannot be expounded without an exposition of science. But when me speak of scientific method in the singular, we ordinarily mean some pattern of reasoning common to all empirical sciences, and that is the subject of this article.

Traditional Views: From Aristotle to J. S. Mill.—If there is any common method of the sciences it must obviously be related to what is common in the aims of the various kinds of scientists. Aristotle gives two accounts of the matter which had great influence on subsequent thought. In the first place he introduces the notion of ἐπαγωγή, or induction, as a way of learning distinct from demonstration and logically prior because it provides the premisses needed for demonstration. But in his *Prior Analytics,* ii 23, he talks of induction as a kind of syllogism in which we reach a universal conclusion from an exhaustive survey of the cases it covers; and in his *Posterior Analytics*, i, 1 and 18, he talks of induction as the establishment of a universal truth by consideration of an instance or instances which reveal to thought the necessity of the connection asserted. In modern times these two distinct procedures have been called summative and intuitive induction respectively. Neither can be identified with the procedure of ampliative induction, by which universal propositions are in fact established in the empirical sciences. For scientists do not claim to have proved that copper is a good conductor of electricity by examining every specimen of copper, nor do they claim to have discovered the necessity of the connection by careful reflection on some single experiment. Secondly, Aristotle says in various places (*e.g.,* in *Posterior Analytics,* i, 2) that science is knowledge of αἰτίαι, or causes. Perhaps he meant by αἰτίαι in this context much the same as we mean by "explanations," but his detailed account of the various kinds of causes that he recognized would not be accepted by modern scientists as a statement of their objectives, and the doctrine is not in any case connected with either of the accounts of induction noticed above.

For more than 2.000 years, however, these two pronouncements of Aristotle determined the course of discussion about scientific method even among those philosophers who professed hostility to his doctrines. Thus Francis Bacon. David Hume and J. S. Mill all assumed that the business of the empirical scientist was to establish universal propositions about causal connection, though they differed from Aristotle in the accounts that they gave of causes.

Some part of scientific activity may indeed be described as a search for causes of kinds of phenomena, but it now seems clear that this is not a satisfactory description of all that scientists try to do. (*See* Causality; Induction.)

We need consider here only the general outline of the doctrine which was introduced by Francis Bacon in his *Novum Organum* of 1620 and accepted for a long time after as a correct account of the method of the new science.

According to Bacon it is the business of the scientist to discover the "forms" of phenomena, but in his usage this word "form" (derived presumably from Aristotle's theory of formal causes) means what would now be called a necessary and sufficient condition.

Thus F is the form of P if and only if P never occurs without F but always occurs with F. If either is capable of varying in degree, it is required also that the other should vary in similar fashion. For the discovery of forms in this sense the proper procedure is to digest our information about the phenomenon in three tables showing presence, absence and degrees: the first includes positive instances of the phenomenon, the second negative instances (*i.e.*, cases which are in most respects like known positive instances but do not in fact exemplify the phenomenon under investigation) and the third instances which vary in degree. Together they should enable us to refute all false suggestions put forward in reply to the question "What is the form?" and so to reach the true answer by elimination.

We can say, for example, that anything which does not vary in degree when the phenomenon under investigation varies cannot be its form. It is assumed, of course, that every phenomenon must have a form, or necessary and sufficient condition.

J. S. Mill, whose System of **Logic** (1843) had great influence in the 19th century, wrote of causes rather than forms but defined a cause as an invariable antecedent and modelled his account of induction on Bacon's. He spoke of it, however, as employing a number of different methods: for example, a method of agreement, in which the cause of a phenomenon is revealed by the consideration that it is the only circumstance (other than the phenomenon itself) in which positive instances agree; and a method of difference, in which the cause is revealed by the consideration that it is the only circumstance (other than the phenomenon itself) in which a positive and a negative instance differ.

This doctrine of scientific method could not have obtained the popularity that it once enjoyed if it corresponded to nothing at all in scientific inquiry. Mill's method of agreement is indeed used in the purely observational sciences and his method of difference in the experimental sciences. But the doctrine does not cover the whole field of scientific activity and moreover is misleading in its suggestion that the business of discovery can be reduced to rules. Even when the work of a scientist can be described without distortion as a search for necessary and sufficient conditions, it is not correct to assume that he can find these by application of a standard procedure.

Thus it is that Bacon and Mill both take for granted without warrant that there is no serious difficulty in drawing up an exhaustive list of circumstances which deserve consideration in a search for the necessary and sufficient condition of a phenomenon; yet there is in fact nothing to indicate what should be considered in this connection as a single circumstance. When we single out for attention half-a-dozen distinct features of events, say A, B, C, D, E and F, why should we not also take account of their conjunctions and disjunctions, that is to say, of complex features such as might be represented by "A and B", "C or D" or even more complicated formulas like "[A or (B and C)] and [(D and E) or F]"? And if we allow for all this complication what assurance can there be that the half-dozen features with which we started are the only elementary features that deserve consideration? Mill admits in a somewhat half-hearted way that there may be what he calls plurality of causes. but he does not recognize that his methods are defective in general for lack of any systematic enumeration of possibilities.

Varieties of Scientific Activity.— It is very difficult indeed and perhaps not very profitable to find a formula which will adequately characterize all scientific activity. For while some scientists are concerned for all or most of their time with the making of generalizations from experience, others are concerned more with the elaboration of deductive systems in which such generalizations may be derived from hypotheses that cannot themselves be tested directly because they deal with unobservable entities such as electromagnetic waves. And apart from these two groups, whose methods may be called primary and secondary induction respectively, there are others whose interest in nature is more like that of a historian. Thus the palaeontologist who tries to trace the biological evolution of man wants to discover what happened in certain places at certain times, and the geologist and the cosmologist are equally interested in the course of past events. All use generalizations, but none of them is primarily interested in these for their own sake. If such inquiries are to be called scientific (and that is how they are ordinarily described), it is not even correct to say that all empirical science is inductive, unless indeed the meaning of the word "inductive" is stretched to cover not only the secondary induction noticed above but also any reasoning concerned in any way with generalizations from experience. Perhaps the best we can say is that the pursuit of science is the search for knowledge and understanding through formulation of the laws of nature. This excludes the collection of disconnected scraps of information and draws attention to the special importance of natural laws in our conception of science.

Whatever can be said usefully about scientific method in general must be related to these.

The beginning of science is classification (*q.v.*). Whatever we recognize must be of some kind, and language even at its lowest level is full of general words. But the same things may be classified in many different ways; *e.g.*, according to size, to shape, or to colour. Each classification is based on real characters of the things classified, and each may be useful for some human purpose. There are, however, some that seem more important than others: those, namely, for which the classifying terms of our most primitive language are nouns as distinct from adjectives. Thus "grass," "tree," "stone," "cow," "horse" and "dog" are said sometimes to mark natural kinds, whereas "red," "square" and "hard" serve only for artificial grouping. The point of the distinction is not that we can make anything red or square or hard by calling it so but rather that recognition of a thing as a piece of grass or as a tree or as a stone is the gaining of an important clue to what may be expected of it. If the thing before us is a blade of grass, then it will probably grow bigger, but not to a height of more than a few feet; when touched, it will bend; after a few months it will turn brown and gradually decay; and so on. It is not necessary, however, that I should satisfy myself of the thing's behaviour in all these respects before venturing to call it grass: fortunately I can recognize grass by its appearance and then make a number of prophecies about it with fair confidence. There is very little, on the other hand. that I can safely assume about the future behaviour of a thing merely because it is red.

Here, then, in the classifications called natural, we have the beginning of our intellectual mapping of nature. Long before there was any conscious pursuit of science men took it for granted that there were bounds of natural possibility; *i.e.*, that not all the conceivable combinations of characters were realized in nature. We cannot discard all their assumptions without abandoning also the language we have inherited from them; but we can and do improve on their classifications. Many of the terms for metals. which our children learn with ease because of the great practical importance of metals in modern life, have been added to the vocabulary of men within historic times.

Primary induction is the deliberate attempt to find more laws about the behaviour of the things that we can observe and so to draw the bounds of natural possibility more narrowly. In so far as it is successful. it enables us to make more inferences from the observed to the unobserved and, in particular, more predictions by which we may guide our conduct. But this is not its only value. Already at this stage there is intellectual satisfaction to be had in the discovery of laws: we have a beginning of explanation when we can say that a piece of wire has melted in a candle flame because it is lead and lead always melts at the heat of a candle flame.

Sometimes scientists or writers on science who are interested chiefly in the more advanced stages of science speak of primary induction as though it scarcely deserved to be called scientific. And it would indeed be a great mistake to suppose that science is never anything more than the making of generalizations in the fashion of 17th-century naturalists. But generalization from experience is an indispensable feature of science. In the more advanced sciences such as physics and chemistry, observations are directed by an interest in theory; but what the scientist deduces from his theory and then tries to test by observation or, if possible, by experiment (*i.e.*, observation in circumstances over which he has control) is always some universal proposition. Here primary induction comes late in the temporal order of a scientist's activities, but it is still primary in the sense that it is basic in his final argument and logically independent of the superstructure of the theory. For a generalization which has been confirmed by experience only after it has been deduced from a theory is not invalidated by the discovery of a flaw in the theory, though it may perhaps lose something in reliability when it is no longer linked with other generalizations through the theory.

With primary induction we may conveniently include arguments of the kind sometimes called proportional generalizations. If we have observed many A things and found that the frequency of B things among them has remained fairly constant in the neighbourhood of a fraction *f*, we are inclined to say in general terms that the proportion of **A** things which are B is about f. Unless the class of *A* things is known to be finite. we cannot take this remark as an ordinary statement of proportion; but in practice we may use it as a guide to expectation, when we wish to know whether something which is *A* is .likely to be also B. Often it is said to be a statement of the probability (*q.v.*) of an *A* thing's being B.

Secondary induction is the attempt to incorporate the results of primary induction in an explanatory theory (*q.v.*) covering a large field of inquiry. At this level in science it may be impossible to make progress without the introduction of concepts far removed from those used by primitive men in their classification of perceptible objects. In retrospect we can see that physical theory has contained such concepts for a long time (*e.g.*, the concept of energyj ; but until the 20th century the fact could be ignored because it was still possible to provide in imagination some sort of model for the interpretation of the statements of physical theory. When it was supposed that electromagnetic waves were transmitted through an ethereal jelly, the model was already inappropriate in some features but not in so obvious a way that it could not still be taken seriously by great scientists. Since then the difficulty of bridging the gap between theory and common sense has become more obvious. Modern views on this subject are discussed in the article EXPLANATION.

The Role of Hypothesis. — From the nature of the scientific enterprise it is clear that the reasoning by which it proceeds cannot be reduced to validating schemata like those of deduction; that is, to patterns of inference which guarantee the truth of the conclusion provided only that the premisses are true. There may of course be deductive arguments in natural science, but the laws and theories which are said to be established by scientific research are not deduced from observations. On the contrary, each is put forward first as an hypothesis (*q.v.*) which together with certain initial data entails the facts of observation. Our effort is to construct a deductive system "from the wrong end up" but not, of course, a trivial system in which the hypothesis itself could be deduced from the facts of observation. To be worth consideration a hypothesis of law must restrict the field of possibility more than that field is already known or assumed to be restricted; and similarly a suggested theory must be more restrictive than the set of laws which it is supposed to co-ordinate and explain; in other words, it must have some consequences other than those we already accept.

For these reasons it has been said that the conclusions of ampliative induction are never more than probable; but this pronouncement is unfortunate in some ways. The word "probable" is ordinarily used to recommend propositions when we are not completely satisfied about them; but we do in fact claim to know some results of induction (for example, that arsenic is poisonous), and adoption of the suggestion that we should apply the word "probable" to all results of induction would therefore lead to a blurring of a useful distinction. On the other hand, it is important to appreciate that the cases in which we say that we know some result of induction differ only in degree from cases in which we are not prepared to commit ourselves by use of the word "know"; and this is at least part of what philosophers have tried to convey by saying somewhat paradoxically that the results of induction are never more than probable. In mathematics, a general proposition such as C. Goldbach's conjecture of 1742 that every positive even integer is the sum of two primes (see NUMBERS, THEORY OF) may perhaps be regarded as highly probable because it has so far survived all attempts to find a counter-example. But no accumulation of evidence of this kind would ever justify a claim to knowledge of the truth of the generalization: for that, it would be necessary to produce an argument of a totally different kind, and the possibility of such an argument is at least conceivable. In natural science: however. there can be nothing corresponding to mathematical proof, and the customary requirement for the use of the word "knowledge" is therefore different.

The theory of statistics (*q.v.*) supplies principles for the marshalling of complex evidence in many different inductive studies, but if we take "scientific method" to mean a rule or set of rules by obedience to which any fairly intelligent person can make discoveries in natural science whenever he wishes, we must admit that there is no scientific method. For the all-important act in scientific discovery is the finding of a hypothesis that will survive testing, and this cannot be reduced to a routine. When we are looking for a necessary and sufficient condition of a phenomenon, or, less exactingly, for a sufficient condition only, we naturally consider only circumstances which are to be found accompanying some instance; and attempts were made by Bacon and by Mill to formulate rules of primary induction on this basis.

But the notion of accompanying is not very precise, and it is in fact impossible to set out any exhaustive list of circumstances that deserve consideration, because an intellectual search of this kind admits of no device like the systematic quartering of the ground by which we can make sure of success in a search for some material object that has been lost. An argument from analogy (*q.v.*) may perhaps suggest an interesting hypothesis here or in secondary induction, but again there is no infallible procedure for discovering fruitful analogies. In short, the finding of the right hypothesis is always a problem, rather than a task. But in this it resembles the finding of proofs in most parts of mathematics, and it must not be thought that success in either case is just a matter of luck.

If we take "scientific method" in the looser sense of a program or policy, then undoubtedly there is a scientific method, namely the policy of making hypotheses for the purposes of primary and secondary induction as described above. Once formulated, this seems to be obviously rational, and some philosophers of modern times are inclined to talk of such scientific activity as though it were nothing but the commonest of common sense. But the deliberate pursuit of knowledge by this method is a comparatively recent enterprise of mankind: at the beginning of the 17th century. when Bacon wrote his *Novum Organum,* it was a novelty not very well understood; and a thinker as great as Descartes could maintain that there was no essential difference between physics and geometry. A hundred years later, after the founding of the Royal Society and the great triumphs of Newton, the method was still something that could arouse debate among intelligent men, as may be seen from the curious remarks of Newton in the General *Scholium* that he added at the end of his *Principia.* In 1739 Hume, who thought Newton "the greatest and rarest genius that ever rose for the ornament and instruction of the species," found himself driven nevertheless to the conclusion that induction could be nothing but customary association of ideas (which Locke had called "a sort of madness") because it was clearly not to be justified as a form of deduction. If the method or policy now seems obviously wise, that is because we understand our situation better than our predecessors did and are therefore no longer inclined to think we can get what we want in any other way.

The Scope of Scientific Method. — The prestige acquired by physics, chemistry and physiology from the middle of the 19th century became so great that there have been many attempts to apply the methods of these sciences in other fields. These efforts have in turn provoked attempts to erect barriers beyond which scientists should not presume to go. In particular there has been much talk of demarcating a boundary between the proper spheres of science and of religion. It is desirable therefore to consider the scope of scientific method; *i.e.,* whether there are any limits to its application.

Because the various special sciences have all been separated successively from the matrix of philosophy (*q.v.*) much as colonies are separated from their mother country, those who advocate the application of scientific method to new fields sometimes think of themselves as liberators and champions of enlightenment against obscurantism. At times the attitude of professional philosophers toward science may perhaps have given some justification for this view; but in general it is a mistake to think of philosophy as opposed to science. For in the past the word "philosophy" was used, as we have seen, to cover all' that is now called science. and in its more restricted modern usage it signifies the search for clarity by the study of the relation of concepts. So long as scientific advance does not involve the asking of any questions about the relations of concepts of high generality science has little. if any, contact with philosophy in the modern sense, and those who are actively engaged in the advance may come to think of philosophical inquiries as fruitless and even perverse. This was the situation in chemistry, for example, at the beginning of the 20th century. But when the development of scientific theory leads to suggestions which are at variance with common sense or at least so far removed from the realm of common sense that they cannot he illuminated by familiar analogies. scientists themselves say that their work has a philosophical aspect; *i.e.*, that it involves clarification of concepts. This happened in physics with the appearance of the relativity and quantum theories.

Conversely. philosophers of the 20th century who are especially interested in the progress of science have sometimes described their work as scientific. Bertrand Russell. for example. published in 1914 a book entitled Our *Knowledge* of *the External World as a Field for Scientific Method in Philosophy,* and thereafter the phrase "scientific philosophy" occurred often in philosophical literature. This way of speaking seems. however. to involve an unjustified extension of the use of the word "scientific." Those who adopt it wish no doubt to convey the impression that the philosophy which they favour is a permanent intellectual acquisition and not merely the product of a fashion or the expression of personal attitude. But there is usually no difficulty in distinguishing the conceptual inquiries of the philosopher from the empirical researches of the natural scientist, and there is nothing to be gained from a blurring of the distinction.

When we say that psychology and sociology are empirical sciences, rather than departments of philosophy in the modern sense of that word, what we have chiefly in mind is the possibility of using primary induction in these studies. But those who issued the first declarations of independence on behalf of these studies sometimes revealed in their claims an extravagance like that which is too often found in political nationalism. Thus Émile Durkheim maintained in his *Règles de la méthode sociologique* (1894) that sociological laws were not reducible to those of any other science; and in psychology also it has sometimes been held that explanation can be achieved only by the introduction of hypotheses which are themselves purely psychological. It is clear that for research to be practicable there must be a division of academic labour and that there can be no specialization without the distinction of one science from another. But this does not entail the denial of all possibility of co-operation or require that the distinction between primary and secondary induction, which is of the greatest importance in physics, should reappear separately in all other branches of science. There may of course be principles of explanation other than those of physics, but the question whether the laws of one department of science can be explained by reference to those of another is to be settled in each case by scientific inquiry, not by a priori pronouncements from separatists or universalists.

Since psychology and sociology have been recognized as sciences it is sometimes asked whether scientific method can be applied in history. This is a confusing question. Those who ask it may perhaps mean by "scientific method" no more than the use of modern techniques such as the radio-carbon method of dating a wooden object. Or again they may mean simply a dispassionate and unprejudiced approach to controversial issues. In either case the answer is "Yes." If, however, the questioners wish to know whether history can become a branch of science, the answer seems to be that history cannot be a science like physics, chemistry or even sociology. since it deals with individual persons and events, but that it may be scientific in the same sense as astronomy and geography, which also apply generalizations to individual objects.

In all ages history has in fact exhibited the patterns of explanation favoured by its authors. When men believed in magic: their history was full of magical causation. When it was the ideal of explanation to relate everything to the divine purpose, history was conceived as theodicy or the tracing of God's plan. When in the second half of the 19th century the principle of the survival of the fittest was thought to be the supreme principle of explanation in all biology, there were soon historians ready to apply it in their accounts of the vicissitudes of men and societies.

In all this there is nothing to indicate any need for drawing a boundary to the application of scientific method. On the contrary, it seems absurd even to suggest that there might be such a boundary within the realm of fact as opposed to value. For whenever we make an assertion that cannot be checked either by hard thinking alone or by observation alone, we commit ourselves to judgment by scientific method. This is not to say that we cannot reasonably support any of our statements by appeal to authority, but rather that in this field all rationality. including the rationality of relying on any authority, depends in the last resort on the rationality of scientific method as described above. For even those who cite miracles as evidence of the reliability of their authority assume premisses derived from induction, as for example that events of certain sorts do not happen without divine intervention.

Valuations as opposed to statements of fact are not established by scientific method. This is indeed a truism, and if we wish to speak of a limit to the applicability of scientific method me may perhaps say that we have found it here. But we must be cautious in the way in which we draw the boundary. For discoveries made by scientific method are undoubtedly relevant to some of our valuations. Although chemical analysis of an artist's materials does not contribute to an aesthetic judgment of his work, scientific knowledge about the consequences of a man's act may be of the greatest importance for a moral judgment of its rightness. What we must guard against here is the suggestion that moral distinctions are meaningless unless they can he identified completely with distinctions of the sort that scientists can study.

SCILLA, a large genus of mostly small bulbous herbs of the lily family, native to temperate regions of the old world and commonly known as squill, wild or wood hyacinth and bluebell. Several are grown for ornament, mainly for early spring bloom. Their flowers are few to many in terminal racemes, and blue, purple, rose or white. The cultivated forms are hardy and should be left undisturbed for a number of years, but should be given an occasional top dressing of well-rotted manure. *See* SQUILL; BLUEBELL. (J. M. BL.)

ROCHE

SIBERIAN SQUILL (SCILLA SIBERICA)

SCILLITAN MARTYRS, a company of early north African Christians who suffered under Marcus Aurelius in A.D. 180 and whose *Acta* are at once the earliest documents of the church of Africa and the earliest specimen of Christian Latin. The martyrs take their name from Scilla (or Scillium), a town in Numidia. Their trial and execution took place in Carthage on July 13, A.D. 180. In this martyrdom is an excellent example of "Acts of Martyrs" properly so called. The document is in brief legal form, beginning with the date and the names of the accused, and giving the actual dialogue between them and the judge, and may well be a transcript of the official report of the trial proceedings.

The Scillitan sufferers were 12 in all—7 men and 5 women. Six had already been tried; of the remainder, to whom these "Acts" primarily relate, Speratus is the principal spokesman. He claims for himself and his companions that they have lived a quiet and moral life, paying their dues and doing no wrong to their neighbours. But when called upon to swear by the genius of the emperor, he replies: "I recognize not the empire of this world; but rather do I serve that God whom no man hath seen, nor nith these eyes can see."

SCILLY ISLES, a group of about 140 small islands and islets, off Cornwall, Eng., 25 mi. W. by S. of Land's End. The origin of their name has never been authoritatively settled. The islands, none of which is more than 160 ft. high, are wild and picturesque, with sheer cliffs and many large caves hollowed out by the Atlantic. Because of the reefs and shoals by which these shores are surrounded, navigation becomes perilous in rough weather. A local proverb tells that for every man who dies a natural death on the islands the sea takes nine.

On an outlying rock to the southwest is Bishop Light. first built, with infinite difficulty, in 1858, and other lighthouses are on Round Island and Penninis head (St. Mary's). The islands are part of an almost submerged granite mass that has been broken up by the sea. This mass was probably joined to the mainland between the Armorican folding and the Upper Cretaceous periods. During Pliocene times it was submerged, since when there has been an elevation from time to time as can be seen in the raised beaches and the terracing of the rocks.

Some of the islands, *e.g.*, St. Agnes and Gugh, are joined together by bars of shingle and blown sand, and the tops of the larger ones have been flattened by erosion. According to legend. the Scilly Isles are the only visible remains of the land of Lyonesse. Olaf I Tryggvesson in his saga tells of his visit to the Scillies in the 10th century and his conversion there to Christianity which he then introduced to Scandinavia.

The climate of the islands is unusually mild, snow being rarely seen and the range of temperature being from 46° to 58° F. Fuchsias, geraniums and myrtles attain an immense size, and aloes, cactus and prickly pear flourish in the open. The gardens of the governor on Tresco Island are subtropical in character.

Great flocks of sea birds haunt the remoter parts, and rare land birds, such as the golden oriole, are occasional visitors. On some of the islands there are deer, and Tean has a warren of white rabbits.

The raising of early asparagus, spring vegetables and flowers is the principal industry. From its start in 1881 and its figure of 65 tons of cut flowers in 1885, this trade had expanded to over 1,200 tons, representing 60,000 blooms by the mid 1950s. Grown in the open air in winter, protected from the Atlantic gales by hedges, the Scilly flowers are more popular than those forced under glass.

The true islands number about 40, with a total area of 6.3 sq.mi., but only 5 are inhabited—St. Mary's, Tresco, St. Martin's, St. Agnes and Bryher. The total population in 1951 mas 2,154, of which 1,625 lived on St. Mary's. Hugh Town in St. Mary's is the capital. occupying a sandy peninsula. The town possesses a harbour and a roadstead where large vessels can lie at anchor. Governed by a county council, the islands are part of the St. Ives parliamentary division of Cornwall.

The islands are served by steamers from Penzance and by air from St. Just, and there is radio, telephone and telegraph communication with the mainland.

On Tresco there are ruins of an abbey and of two fortifications called Oliver Cromwell's tower and King Charles's tower. Rude pillars and circles of stones and barrows are common, the most remarkable being a barrow on the Isle of Samson, 58 ft. in girth, and containing a very perfect "kistvaen," or sepulchral chamber of stone.

It is not until the reign of Henry I that we have written evidence concerning the Scillies. The king gave the isles to the abbot and church of Tavistock and secular priests were temporarily substituted for regulars by the abbot in 1345. Sharing the dignity of lords of Scilly with the abbot was the family of Blanchminster (de Albo Monasterio) in the reign of Edward I.

Ralph de Blanchminster held of the earldom of Cornwall lands in Scilly at a yearly service of 300 puffins in 1345. In 1484 value of the lands was estimated at 40s. in time of peace and nothing in time of war. The Blanchminsters resisted and imprisoned the coroner of Cornwall and in 1319 were granted a coroner of their own. In 1547 Silvester Danvers, a coheir of the Blanchminsters, sold his moiety of Scilly to Sir Thomas Seymour, by whose attainder in 1549 it fell to the crown, which already possessed the church land and revenues.

In 1571 Elizabeth I leased the islands for £10 a year to Francis Godolphin, uho built Star castle above Hugh Town in 1593. During the Great Rebellion Hugh Town gave shelter to Prince Charles until his escape to Jersey in 1646. The islands were occupied by Roundheads for two years but in 1648 declared for the king nith Sir John Grenville as governor. After his surrender to Admiral Blake in 1651, Cromwell's tower mas built on Tresco.

Early a haunt of pirates, the islands were afterward notorious for smuggling. In 1834 Augustus Smith succeeded the Godolphins as lessee and introduced compulsory education and other measures to improve the condition of the inhabitants. His nephew T. A. Smith-Dorrien-Smith succeeded him in 1872 and in 1933 A. A. Dorrien-Smith. his son, surrendered to the duchy of Cornwall the four islands of St. Mary's, St. Martin's, St. Agnes and Bryher, retaining the others on a 59-year lease.

SCIPIO (originally meaning "staff"), the name of a patrician branch of the Cornelian gens in ancient Rome, whose most important historical representatives are separately noticed.

SCIPIO, PUBLIUS CORNELIUS, consul in 218 B.C., sailed with an army to southern Gaul to prevent Hannibal's advance on Italy (see HANNIBAL). Having arrived too late, he himself returned to Italy, but boldly sent his army on to Spain under his elder brother Gnaeus to check the Carthaginian forces still there. In northern Italy he hoped to fight delaying actions against Hannibal along the tributaries of the Po. Being repulsed and wounded at the Ticinus, he retired to the Trebia where he was joined by his colleague Ti. Sempronius Longus, who insisted on fighting and was defeated (Dec. 218).

In 217 Scipio was sent as proconsul to Spain; he and his brother smashed near the Ebro Hasdrubal's attempt to break through to Italy (215), and by 212 they had captured Saguntum.

From this base they could move farther south; advancing separately, however, they both met disaster and death, Publius on the upper Baetis, Gnaeus in the hinterland of Carthago Nova (211). But for seven years they had denied Hannibal the resources of Spain.

See Polybius, iii; Livy, **xxi–xxxv;** for the Spanish campaigns *A.* Schulten, *Fontes Hispaniae antiquae,* iii *(1935).* (H. H. SD.)

SCIPIO AEMILIANUS AFRICANUS, PUBLIUS CORNELIUS, the younger (185/4–129 B.C.), was the younger son of L. Aemilius Paullus, under whom he served at the battle of Pydna (*q.v.*) in 168 B.C. He was adopted by the elder son of Scipio Africanus, P. Cornelius Scipio, whose name he assumed. His early years are described by Polybius (xxxi, 23–29), who gained his friendship. In 151, when the Romans had met with defeats in Spain, he volunteered for service there as military tribune; his integrity, personal bravery and honest diplomacy, reminiscent of the qualities of his adoptive grandfather, were appreciated by Spanish tribes long sickened by Roman treachery.

In 150, when on a military mission to Massinissa (Masinissa), he nas asked by the Carthaginians to mediate in their war against Massinissa, but he achieved no result. In the following year, after Rome had declared war on Carthage, he served in Africa as military tribune with conspicuous ability, and in 148 Massinissa, at the point of death, asked him to arrange the future of Numidia: Scipio divided it between the king's three sons. Returning to Rome to stand for the aedileship, he was by a special vote of the people elected to the consulship of 147 and was granted the command against Carthage.

Scipio returned to Africa with his friend Gaius Laelius and possibly also Panaetius he blockaded Carthage and, in 146, destroyed the city, enslaving the survivors and establishing the province of Africa. He celebrated a triumph and received the name of Africanus (Minor).

His censorship in 142 was marked by traditional sternness. Ti. Claudius Asellio. whom he demoted from the equites, prosecuted him in 140. For two years (140–139; less probably 136–135) he served on an embassy to Egypt, Syria, Pergamum and Greece. On his return he prosecuted L. Aurelius Cotta for extortion (138) and supported a measure to introduce secret ballot in judicial assemblies of the people (137). Military disasters and inefficiency in Spain required the dispatch of a capable soldier: to this end, since re-election to the consulship had been forbidden in 151, by special dispensation he was elected consul for 134. After reestablishing discipline in the Roman army he brought the war in Spain to an end by the blockade and destruction of Numantia in 133 (traces of his camps and earthworks there still survive): he received the additional cognomen Numantinus.

He returned to Rome after the death of his brother-in-law Tiberius Gracchus, but expressed disapproval of his unconstitutional behaviour, quoting the Odyssey (i, 47): "So perish all who do the like again." He opposed a proposal of the tribune C. Papirius Carbo to allow the re-election of tribunes (131 or 130), thus increasing his unpopularity with the masses who naturally had resented his attitude to Gracchus. In 129 he carried a measure which affected the working of the Gracchan land commissioners, probably however only warning them off public land held by the allies in order to avoid "international" issues. The night before he was to have spoken on the agrarian laws he died in mysterious circumstances: various persons were later suspected of murder, or even Scipio himself of suicide, but very probably he died a natural death.

An admirer of Greek literature and learning, he gathered around him the so-called "Scipionic circle," a coterie which included Polybius, Panaetius, C. Lucilius, Terence and Laelius and aimed at blending the better elements of Greek and Roman life. Upright himself, he tried to revive and uphold earlier Roman standards of conduct. His thought, Stoic in philosophy. moved on traditional lines, and he tried to maintain Rome's accustomed relations toward the Italian allies and the provinces. An able soldier and orator, he acted as a moderating influence on the constitutional difficulties of his day which increased after his death. Cicero, who made him the chief speaker in his De *Republica,* regarded his era as the golden age of aristocratic government. (H. H. Sd.)

SCIPIO AFRICANUS, PUBLIUS CORNELIUS, the elder (236–184/3 B.C.), son of P. Cornelius Scipio (*q.v.*), is said to have saved his father's life at the engagement on the Ticinus and, as military tribune, to have strengthened Roman resistance to Hannibal after Cannae (216). After his curule aedileship (213), though only a *privatus,* he was, without constitutional precedent, appointed by the Roman people to a proconsular command in Spain (210). There all south of the Ebro was in Carthaginian hands, but he boldly continued his father's offensive strategy.

By a brilliant swoop Scipio captured the enemy's headquarters, Carthago Nova, from which all three Carthaginian armies in Spain happened to be ten days' distant (209); there he gained stores and supplies, Spanish hostages, the local silver mines, a splendid harbour and a base for advance farther south. After training his army in new tactics he defeated Hasdrubal Barca at Baecula (Bailén) in Baetica (208); whereas normally the two rear ranks of a Roman army closely supported the front line, Scipio here, under a screen of light troops, divided his main forces, which fell on the enemy's flanks. When Hasdrubal broke away, ultimately to join his brother Hannibal in Italy, Scipio wisely declined the impossible task of trying to stop him and decided rather to accomplish his mission in Spain, the defeat of the other two Carthaginian armies still there. This he brilliantly achieved in 206 at the battle of Ilipa (*q.v.;* Alcalá del Rio, near Seville), where he held the enemy's main forces while the wings outflanked them. After quelling a disturbance among some troops on his lines of communication and bringing some restless Spanish allies to heel, he secured Gades, thus making Roman control of Spain complete.

Elected consul for 205, Scipio boldly determined to disregard Hannibal in Italy and to strike at Africa. Having beaten down the political opposition of Q. Fabius and other senators, he crossed to Sicily with an army consisting partly of volunteers. In 204 he landed with perhaps 35,000 men in Africa. where he besieged Utica. Early in 203 he burned the camps of Hasdrubal Gisco and his Numidian ally Syphax. Then. swooping down on the forces which the enemy were trying to muster at Campi Magni (Souk el-Kremis) on the upper Bagradas, he smashed their army by a double outflanking movement. After his capture of Tunis the Carthaginians sought peace terms, but Hannibal's subsequent return to Africa led to their renewing the war in 202. Scipio advanced southwestward to join the Numidian prince Massinissa (Masinissa) who was bringing his invaluable cavalry to his support. Then he turned eastward to face Hannibal at the battle of Zama (*q.v.*); his outflanking tactics failed against the master from whom he had learned them, but the issue was decided when the Roman and Numidian cavalry, having broken off their pursuit of the Punic horsemen, fell on the rear of Hannibal's army. Victory was complete and the long war ended; Scipio granted comparatively lenient terms to Carthage. He was named in honour Africanus. (See also PUNIC WARS.)

In 199 Scipio was censor and became *princeps senatus.* Though he vigorously supported a philhellenic policy, he argued during his second consulship (194) against a complete Roman evacuation of Greece after the ejection of Philip V of Macedon. fearing that Antiochus III of Syria would invade it; his fear was premature, but not unfounded. In 193 he served on an embassy to Africa and perhaps also to the east. After Antiochus had advanced into Greece and been ejected by a Roman army, Scipio's brother Lucius was given the command against him, Publius serving as his legate (190); together the brothers crossed to Asia, but Publius was too ill to take a personal part in Lucius' victory over Antiochus at Magnesia. Meantime in Rome Scipio's political opponents, led by the elder Cato, launched a series of attacks on the Scipios and their friends. Lucius' command was not prolonged; the generous peace terms which Africanus proposed for Antiochus were harshly modified; and the "trials of the Scipios" followed. On the trials the ancient evidence is confusing: in 187 an attack on Lucius for refusing to account for joo talents received from Antiochus (as war indemnity or personal booty?) was parried; and Africanus himself may have been accused: but not condemned, in 184. Anyhow. his influence was shaken and he withdrew from Rome to Liternum, where, embittered .and ill, he died soon afterward (184/3).

Scipio married Aemilia, daughter of the L. Aemilius Paullus who fell at Cannae. He had two sons (Publius, debarred by ill-health from a public career, and Lucius, praetor in 174) and two daughters, one of whom became the mother of the Gracchi. A man of wide sympathies, cultured and magnanimous, Scipio easily won the friendship of such men as Philip of Macedon and native princes in Spain and Africa, while he secured the devotion of his own troops. Though essentially a man of action, he was also something of a mystic in whom contemporary legend saw the favoured of Juppiter Capitolinus as well as a spiritual descendant of Alexander the Great. One of the greatest soldiers of the ancient world, by his tactical reforms and strategic insight he created an army which defeated even Hannibal and asserted Rome's supremacy in Spain, Africa and the Hellenistic east. His philhellenic sympathies led him to champion Rome's imperial and protective mission in the world. For ten years (210–201) he had commanded a devoted army at the people's wish; but, though convinced of his own powers, he offered no challenge to the dominance of the Roman nobility ensconced in the senate, except by normal political methods (in which he showed no outstanding ability). Reaction against his generous foreign policy and against his encouragement of Greek culture in Roman life led to his downfall amid personal and political rivalries, but his career had shown that Rome's destiny was to be a Mediterranean, not merely an Italian, power.

SCLATER, JOHN ROBERT PATERSON (1876–1949), Canadian clergyman, who was an early leader in the United Church of Canada, was born in Manchester, Eng., on April 9, 1876. Ordained in the Presbyterian Church of England in 1902, he was minister of the Greenhill Presbyterian church, Derby (1902–07), and of the New North church, Church of Scotland, Edinburgh (1907–23). He was chaplain to the 9th Royal Scots (Highlanders) and the Royal Scots (territorial forces) (1909–23) and in World War I served on the Forth defenses and in the chaplain's department of the Y.M.C.A. in France (1916–17). In 1923 he went to Canada and after serving as minister of the Parkdale church in Toronto (1923–24) became minister of Old St. Andrews church, a position he held until his death. He had been Warrack lecturer at the Scottish Theological colleges in 1921 and became well known throughout Canada and the United States as a lecturer, serving as Lyman Beecher lecturer at Yale in 1927 and as Dudleian lecturer at Harvard in 1936. At the last university he was also select preacher and a member of the board of preachers at various periods in the 1930s and 1940s. He was moderator of the United Church of Canada (1942–44). Among his published works are *Modernist Fundamentalism* (1926) and *The Public Worship of God* (1927). He died in Scotland on Aug. 24, 1949.

SCOLECITE, a zeolite mineral of the natrolite group. It is a hydrated silicate of lime and alumina. It commonly occurs as bundles of radiating fibres and when heated sometimes curls up like a worm; the name is derived from the Greek word meaning a worm, It is usually colourless or white and more or less transparent. It crystallizes in the monoclinic system, with angles very near those of the cube. Scolecite occurs frequently with other zeolites in the western isles of Scotland, Iceland, in the Deccan trap area in India and at Table mountain, Colo., among many other localities.

For composition, structure, etc., *see* ZEOLITE.

SCOLOPACIDAE: *see* SNIPE; WOODCOCK; SANDPIPER.

SCONE, a civil parish of Perthshire, Scot., containing Old Scone, the site of a historic abbey and palace, and New Scone, a modern village, about 2 mi. N.N.E. of Perth, near the left bank of the Tay. Pop. (1951) 3,014.

According to tradition Scone became the capital of "Pictavia" in succession to Forteviot in the 8th century and remained that of Alban after the union of Picts and Scots. In 906 Constantine III and Bishop Cellach held a council concerning the church on the Mote hill of Scone, hence also called Hill of Worship. Kenneth MacAlpin is said to have brought from Dunstaffnage the Stone of Destiny, on which Scottish kings were crowned until its removal to Westminster abbey by Edward I of England. A Culdee foundation which existed there from early times was superseded by an Augustinian house founded by Alexander I *c.* 1115. Scone remained the normal place of the coronation of Scottish kings, the last being that of Charles II in 1651. It was also the scene of many medieval parliaments.

At the Reformation the abbey was burned by a mob from Perth and the lands were given to the earl of Gowrie. On the Gowrie forfeiture in 1600 these were granted to Sir David Murray of Gospertie, afterward Viscount Stormont, to whose descendant, the earl of Mansfield, the estate still belongs. Sir David completed the mansion begun by Gowrie, but it was pulled down in 1803 to make room for the present house.

A church built on the Mote hill in 1604 was demolished in tde late 18th century, except for one aisle. Scone was visited by James Edward Stewart in 1716 and by Prince Charlie in 1745. The old cross of Scone stands in the park, which also contains a racecourse. (E. W. M. B.-M.)

SCOPAS of Paros, sculptor and architect, was considered by ancient writers one of the greatest artists of the 4th century B.C. He is said by Pliny to have worked on the sculptures of the mausoleum of Halicarnassus (c. 350 B.C.) together with Bryaxis, Timotheus and Leochares, and to have carved the reliefs on one of the columns of the temple of Artemis at Ephesus; and by Pausanias to have been the architect of the temple of Athena Alea at Tegea. Unfortunately, though sculptural remains of all three buildings have survived. none can with certainty be associated with Scopas. In the case of the mausoleum. there is the difficulty of apportioning the extant reliefs to four different artists of whose style little is known. In the case of the Ephesian temple only three of the 36 columns that Pliny says were decorated have survived. And the few battered pieces that remain of the pedimental sculptures of the temple at Tegea are not necessarily the work of Scopas, for Pausanias attributes to him only the cult statues of Asclepius and Hygieia. Nevertheless, since Scopas was the architect of the temple, it is possible that he also at least sketched the designs for the pediments; and since the extant heads show a highly individual and forceful style, they may give an idea of Scopas' work. The squarish form, the deep-sunk eyes and a strongly emotional quality have, therefore, been thought to be characteristic of Scopas.

Pausanias, Pliny, Strabo and other ancient writers mention and sometimes briefly describe a number of statues made by Scopas for Asia Minor, the Peloponnesus and Attica, and some of these works have been tentatively identified in Roman marble copies and in the reliefs on Roman coins. Among them are a bronze Aphrodite seated on a goat, an Apollo Smintheus, an Apollo Citharoedus, a Maenad, a group of Eros, Himeros and Pothos, and a large group of Achilles, Nereids and Tritons.

Scanty though our knowledge of Scopas is, it can be surmised from the little which remains that he, together with Praxiteles and Lysippus. were the outstanding sculptors of the middle and second half of the 4th century B.C., who imparted to their work a new grace and emotional quality and whose influence was felt for many generations.

(G. M. A. R.)

SCOPES TRIAL, beginning July 10, 1925, at Dayton, Tenn., and lasting 11 days. was one of the most widely publicized legal cases in 20th-century U.S. history. The charge was that John Thomas Scopes, a teacher of science in Rhea high school in Dayton, had violated the Tennessee state law prohibiting the teaching in public schools of any theories that deny the divine creation of man as taught in the Bible. Scopes, a biologist, had been teaching evolution. The basis for the sensational nature of the trial was laid by the increasing alarm of a Christian movement, known as Fundamentalism (*q.v.*), over the challenge of science and evolutionary theory to a literal interpretation of the Scriptures.

The legislature of the state of Tennessee was the first to pass an antievolution law, by an overwhelming majority (95–11), and the measure was signed by the governor on March 13, 1925. The essential section stated that it was "unlawful for any teacher in any of the universities, normals and all other public schools of the state, to teach any theory that denies the story of the divine creation of man as taught in the Bible, and to teach instead that man has descended from a lower order of animals."

When the American Civil Liberties union in New York city heard of the passage of the Tennessee law, the executive director Roger N. Baldwin sent a news release to leading Tennessee newspapers offering the services of the union to defend any teacher who would personally test the constitutionality of the statute by his classroom teaching. Baldwin soon received a telephone call from George Rapplyea, proprietor of a drug store in Dayton, stating that he had been discussing the offer with John Scopes. Assured of support. Scopes formally violated the law, and the public prosecutor in Dayton secured an indictment.

The leading lawyers on both sides of the case were probably the most famous and the most appropriate who could have been produced for the occasion. William Jennings Bryan (*q.v.*) came to Dayton to assist the local prosecutor. The defense counsel was headed by Clarence S Darrow (*q.v.*), the most famous criminal lawyer of his generation. He was assisted by Dudley Field Malone, a liberal Catholic and one of the great courtroom orators of the time, and by Arthur Garfield Hays, the outstanding civil liberties attorney of the day.

The dramatic nature of the case and the fame of the lawyers assured extended newspaper coverage. Each day an average of about 175,000 words were telegraphed out of Dayton during the 11 days that the case was in court. The case was followed daily by tens of millions of readers in both the United States and Europe.

The rulings of the judge prevented any testing of the civil liberties issue of the constitutionality of the law or any testimony as to the validity of the doctrine of evolution The sole relevant question, said the judge, was whether Scopes had actually taught the doctrine of evolution. The defense freely admitted that he had.

The case might, thus, have closed more rapidly had not Bryan made the serious mistake of permitting Darrow to get him on the stand and subject him to a long and grueling cross-examination as to his beliefs relative to the Fundamentalist attitude on science and biblical authority The process, perhaps Darrow's most animated and sarcastic courtroom performance. was a devastating experience for Bryan; many believed it hastened his death which occurred five days after the close of the trial. Darrow had adroitly used the judge's rulings on the irrelevance of the validity of the doctrine of evolution in the case to prevent Bryan from delivering a long oration he had prepared.

Scopes was convicted and fined $100. The defense appealed the case to the state supreme court which, in 1927. upheld the constitutionality of the 1925 law, but cleared Scopes on a technicality. It thus turned out that the Scopes trial was more a contribution to public education on science and religion than a test of civil liberties.

SCOPIDAE: see HAMMERKOP.

SCOPOLAMINE (HYOSCINE) is one of the belladonna alkaloids. It is obtained from a number of solanaceous plants including the deadly nightshade, henbane and Jimson weed. On racemization (see STEREOCHEMISTRY: Racemization), atropine is obtained.

Scopolamine is the most active of the belladonna alkaloids, partly because of its greater solubility, which permits more rapid passage to the site of action Like atropine. it has a depressant action on parasympathetic nerves and in larger doses on autonomic ganglia. It also has a marked depressant action on the central nervous system, and this is the basis of its main therapeutic uses.

Combined with morphine it produces "twilight sleep," a state of analgesia and amnesia. This drug combination became popular for use during childbirth since the patient remains more or less conscious but does not usually recall later the unpleasant circumstances of the event. This and similar combinations are used for preoperative medication.

Scopolamine taken orally is an effective remedy for seasickness, probably because of its central depressant and its antispasmodic action It also finds use in controlling the rigidity and tremor of Parkinson's disease. It is a toxic drug and is administered only in minute quantities.

See also ALKALOIDS; ATROPIYE. (V. E.)

SCORE (French. partition; Italian, *partitura;* German. *Partitur*) is the name given to the copy of a work of music containing the notation for one or many performers, and is so called from the way in which the music is divided by bars scored through the series of staves on which the music is written. In a solo work the score is the only copy of the notation. In concerted works the notation of each performer constitutes a part—*e.g.,* violin part, flute part—and a score shows the vertical alignment of each of the parts. Indications of both individual and simultaneous performance are thus provided for the principal performer, the conductor and the listener.

The word score is used in several specialized senses. The arrangement or reduction of an orchestral score for piano is commonly known as the piano score. A vocal score (of operas and choral morks), consists of the vocal parts set out as in the full score, but with the orchestral score reduced for the piano. A short score is the sketch made by a composer for a full score, showing the main features set out on a few staves. An open score shows the parts, usually of a contrapuntal exercise, written on separate staves for greater clarity. A miniature score (or pocket score) is the published version of a full score reduced in size so as to be more convenient for study or following an orchestral work in performance.

The practice of writing music in score dates from the schools of polyphonic music in the early middle ages It was replaced at the beginning of the 13th century by the choirbook—a large-size manuscript in which the soprano and alto parts usually faced each other on the upper halves of two opposite pages with the tenor and bass parts occupying the lower halves. This arrangement was considered economical since the upper parts, which sang the texts required more space than the slow-moving lower parts. The music was read by the entire choir grouped around the choirbook set on a stand.

In the 15th and 16th centuries vocal and instrumental music was published in partbooks. These partbooks contained the notation of only single parts. The parts of madrigals were sometimes published crosswise on single sheets, which allowed each of the singers seated around a rectangular table to sing from his particular part.

The modern form of score, in which the bar lines are scored vertically throughout the parts, appeared in the 16th century in the madrigals of Cipriano de Rore and the orchestral music of Giovanni Gabrieli. In scores of all kinds the arrangement of the parts follons accepted schemes. In vocal works the arrangement from top to bottom is. soprano, alto, tenor bass. Scores for unaccompanied choir in four parts are sometimes known as SATB scores In scores of chamber works for string instruments the arrangement follons the compass of the instruments first and second violins. viola. cello, double bass, nith the part of a figured bass or a supporting keyboard instrument below. Parts for wind instruments in chamber norks are placed above the strings in the same arrangement as that in the orchestral score, known as the full score.

The full score is divided from top to bottom into five main sections: woodwind instruments, brass. percussion, harps and keyboard instruments, and strings. The order followed for the woodwind is: flutes, oboes, clarinets and bassoons, with the higher and lower members of their families placed appropriately. In a work using a nide variety of instruments the woodwind section would thus be set out in this order: piccolo. flutes, bass flute: oboes, oboe d'amore. cor anglais. heckelphone; clarinet in E flat, clarinets in B flat or A, bass clarinet; bassoons. double bassoon. The order for the brass instruments is: horns, trumpets, trombones. tuba. The percussion section is headed by the part for timpani followed by the keyboard percussion instruments (glockenspiel, xylophone and vibraphone) and the instruments of indefinite pitch (triangle cymbals. etc.). the latter requiring only a single line. The next section shons parts in double staves for harps, piano or organ. At the bottom of the score the string section is aligned as in chamber works.

In concertos the part of the solo instrument is placed immediately above the strings. In choral norks the choral parts may appear either above the strings or, as in the illustration from the finale of Beethoven's Choral Symphony, betneen the viola and cello parts. In full scores of operas and oratorios solo parts appear above the choral parts. In military band scores the woodwind and brass are followed, in descending order, by string basses and percussion instruments. Brass band scores are usually arranged in the order of cornets, horns, baritones, trombones, euphonium and basses, and drums.

Score reading, which is part of the equipment of conductor, consists of reproducing the essential features of a full score at

SCORE OF THE FINALE OF THE CHORAL SYMPHONY (NO. 9 IN D MINOR) BY BEETHOVEN the piano. It demands the ability to read simultaneously in the alto and tenor clefs as well as the treble and bass clefs, and to transpose parts of many of the woodwind and brass instruments Score reading of complex modern works is sometimes undertaken in the form of a piano duet.

Students of the orchestra and listeners generally find that the ear can be greatly helped by the eye in following the performance of orchestral and choral works with the score. This enables the general design of the work to be more easily grasped and ingredients of orchestral effects to be readily identified.

See G Jacob, *How to Read a Score* (1944). (E LR.)

SCORESBY, WILLIAM (1789–1857), English arctic explorer, scientist and clergyman, who contributed particularly to the knowledge of terrestrial magnetism, was born near Whitby, Yorkshire, Oct. 5, 1789. His father William Scoresby (1760–1829), made a fortune in the arctic whale fishery. The son made his first voyage with his father when he was 10 years old, but on his return he was sent back to school until he was 14. After this he was his father's constant companion, and was with him on May 25, 1806, in the whaler "Resolution," when he reached 81° 30′ N. lat. (19° E. long.), then the highest latitude attained by a freely navigating ship.

Scoresby then attended the natural philosophy and chemistry classes at Edinburgh university and in his voyage of 1807 he began to study the meteorology and natural history of the polar regions. In 1811 his father resigned to him the command of the "Resolution," and in the same year he married. In a voyage two years later he established the fact that the temperature of the polar ocean is warmer at great depths than at the surface. He was elected a fellow of the Royal Society of Edinburgh in 1819 and about the same time he communicated a paper to the Royal Society of London "On the Anomaly in the Variation of the Magnetic Needle." In the following year he published *An Account of the Arctic Regions and Northern Whale Fishery,* in which he gathered the results of his own observations, as well as those of previous navigators. His voyage of 1822 to Greenland, during which he surveyed and charted 400 mi. of the east coast, between 69° 30′ and 72° 30′ was the last of his arctic voyages, for his wife had died while he was away and on his return he entered the church.

In 1824 the Royal society elected him a fellow and after two years at Cambridge he took his degree (1825) and was appointed to the curacy of Bassingby, Yorkshire. The discharge of his clerical duties at Bassingby, and later at Liverpool, at Exeter and at Bradford did not prevent him from continuing his interest in science to which he added social questions, especially the improvement of conditions in factories. When crossing the Atlantic in 1848 he made some valuable observations on the height of waves and he voyaged to Australia in 1856 in order to obtain magnetic data.

Scoresby died at Torquay on March 21, 1857.

See R. E. Scoresby-Jackson, *The Life of William Scoresby* (1861) (L. M. Fs.)

SCORIA, in geology, lava that is moderately frothy or vesicular and has a structure like that of a clinker. The name is from the Latin word meaning "slag." Ejected masses of scoria are often called cinders, a term conveniently used for all lumps of vesicular lava.

See VOLCANO.

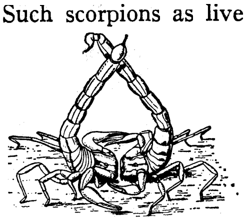
SCORPIO or SCORPIUS (the Scorpion), in astronomy, a constellation and sign of the zodiac. The constellation appears rather low in the south in the early evenings of summer for observers in middle northern latitudes. The stars outline a sprawling figure that might seem to suggest a scorpion or perhaps a kite with a long tail. The brightest star, Antares, is a supergiant at the distance of something like 170 light-years. This red star has several hundred times the sun's diameter and is intrinsically 1,000 times as luminous as the sun.

The region of the heavens from Scorpius eastward to Sagittarius and northward into Ophiuchus surrounds the direction of the centre of our galaxy. This region exhibits a spectacular display of star clouds of the Milky Way, star clusters including great globular clusters, and bright and dark nebulae. In photographs the dark cosmic dust is frequently illuminated by involved stars in patches of reflection nebulae, remindful of the glows around street lamps on a foggy night. (R. H. BR.)

SCORPION, a common name applied to any representative of the order Scorpiones of the class Arachnida (*q.v.*). Although different in size, all scorpions are more or less alike in appearance and are easily distinguished from other Arachnida by a combination of characters which are never wanting. Their pedipalpi, always held forward, are powerfully developed and provided with pincers resembling the claws of a crayfish or lobster. The first portion of their abdomen is as wide as the cephalothorax, while the last five annular segments forming the "tail," or postabdomen, are much more slender and sharply set off from the preceding seven segments of the preabdomen. At the end of the tail is a sting, somewhat curved and pointed. Its base is enlarged and contains a pair of poison glands which open near the tip of the sting. The curvature of the sting is such that the sting may be used only when the tail is raised above the preabdomen and thrust forward. Finally, on the ventral side of the abdomen, immediately behind the genital opercula, a pair of combs is situated, an organ not found in any other animals but scorpions.

The carapace or shield covering the dorsal surface of the cephalothorax bears a pair of median and from three to five pairs of lateral simple eyes. The mouth is ventral in position and is situated between an anterior and a posterior lip. In front of the mouth and above the base of the pedipalpi a pair of short appendages, the chelicerae, are used for mashing and shredding of food, for which purpose they are provided with small, but strong pincers. The first two of the four pairs of walking legs have maxillary plates and harbour glands secreting digestive enzymes. When a scorpion wants to eat, it grasps an insect with the pincers of the pedipalpi, stings it, mashes it with the chelicerae, injects digestive enzymes into the wound and when all tissues of the insect have become fluid under the influence of the enzymes, pumps the insect dry with the aid of its own pharynx, which acts both as a pump and as a strainer. Nothing but the chitinous empty shell remains of the insect. The liquid food is passed into the midgut and its immense digestive glands, where it is further subjected to the action of enzymes and absorbed by special cells, while the unused remnants are excreted through the anus situated at the end of the tail, just in front of the sting. Insects form the chief food of scorpions, but spiders and millipedes are also eaten. However, food requirements are not very great and scorpions can endure hunger for more than a year without dying.

Such scorpions as live usually in moist localities require water for their existence, but species living in deserts may go without water for many months.



FROM "CAMBRIDGE NATURAL HISTORY," BY PERMISSION OF THE MACMILLAN COMPANY, PUBLISHERS

FIG. 1.—MATING OF BUTHUS OCCITANUS (AFTER FABRE)

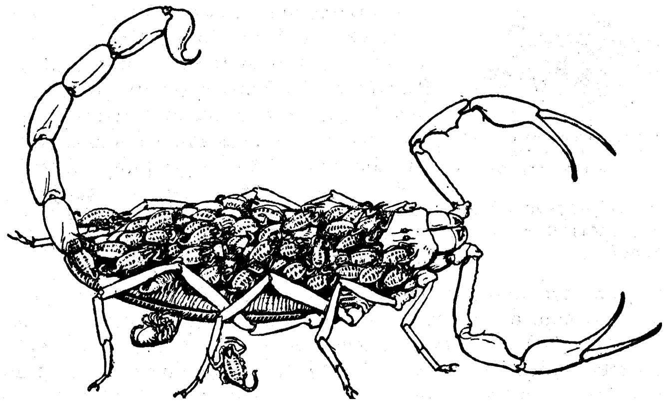
Scorpions live in hot and tropical countries. On the American continent they are found from the southern United States to Patagonia. In Europe several species are found in Greece, Italy and Spain, and at least one species goes as far north as southern Germany. The geographical distribution of scorpions was made the subject of several special studies and recalls in a general way the distribution of mammals. On many islands, including New Zealand, scorpions are wanting. On the other hand, cosmopolitan species may be found occasionally even in countries not suited for their life. The author of this article has in his collection (1945) a specimen which he caught in Connecticut, running on a lawn and evidently imported with lumber. In their natural habitat scorpions live under stones and under bark, in crevices of rocks, under dead leaves and rubbish, in open fields and in forests, in stone walls, in barns and stables, in outhouses and deserted buildings, in thatched roofs and in dark basements.

In countries where the dwellings are poorly screened, scorpions are common visitors in the rooms. Having a natural tendency to get into crevices, scorpions manage to get even into well screened homes by passing under a screen door. The author has repeatedly captured scorpions in such buildings and is also able to substantiate a number of reports of individuals who were stung by scorpions in bed. Although common in some countries with very dry climate, scorpions are sensitive to moisture. During the dry season they hide regularly in the ground and may not be easily seen. But as soon as the rainy season begins and the ground becomes soaked with water, the scorpions find their way to the surface and stay under loose stones where they are quite commonly found.

The life of scorpions is comparatively simple. Even the most primitive forms of animal association are not known among scorpions. All species lead strictly individual lives and avoid each other or else fight to death, the victor usually devouring the victim. In very large cages several individuals may be kept together because they have enough room not to encroach on one another. But in smaller containers not more than one scorpion may be kept alive. Growth is accompanied by moulting, as in all arthropods. The old skin cracks around the carapace and is shed completely, including the lining of the foregut and hindgut and of the four pairs of book-lungs situated on the ventral side of the third to sixth preabdominal segments. The total number of moults is not exactly known and may vary somewhat even in the same species. When the state of maturity is reached the sexes show visible differences in the relative proportions of the body. The male is more slender and has a longer "tail." It also has a pair of organs used in copulation, but visible only when the specimen is turned over on its back. On finding a female the male engages in a primitive sort of courtship, consisting mainly in grasping the hands of the female with his own hands and rubbing his tail against her tail. After copulation the male is often attacked by the female and devoured unless he manages to escape.

The fertilized eggs develop inside the mother and the young are born alive. At this stage they already possess all the characters of scorpions, but the proportions of their bodies are very different from those of their parents. Moreover, they are quite helpless and incapable of eating because their midgut is completely filled with embryonic yolk.

Unable to take care of themselves they climb on the back of their mother often completely hiding from view the body of the latter so that nothing but the appendages and the tail remain visible. The mother carries her young around, but does not feed them. They exist for a while on the nourishment which they derive from digesting the embryonic yolk. After the first moult, while the young still cling to the back of the mother, the body becomes in appearance more like that of the adult, only many times smaller. The yolk is now digested. The creatures become more active, often drop off their mother's back, and begin soon to leave her for good to start their own individual existence.



BY LISBETH KRAUSE

FIG. 2.— MATERNAL CARE IN SCORPIONS. FEMALE CENTRUROIDES INSULANUS WITH YOUNG SCORPIONS ON HER BACK

The most interesting feature of a scorpion is of course its poison. Prabably because of their poisonous qualities, scorpions were known and feared already in ancient times. Observations on the effect of their poison have been made many times in the past, but scientifically correct data are only few and comparatively recent. One of the sources of error is the same as in all similar observations, namely the lack of knowledge of the physiological state of the animal on which the observation was made and of the quantity of poison injected by the scorpion into the wound and its relation to the total weight of the victim. Another, often even more serious, error is due to the fact that many observations refer simply to "a scorpion," whereas there are some 500 species of scorpions in the world and in many localities several species may occur close to each other. It is known that different species vary a great deal in the degree of virulence and type of their poison. Exact knowledge can therefore be had only under carefully controlled laboratory experiments, while general observations may only supplement such knowledge when the offending species is determined by an expert. Such observations have led to the conclusion that at least two types of scorpion poison exist. One of these is local in effect and comparatively harmless to man. It is exemplified by the European *Euscorpius italicus* and the American *Centruroides vittatus*. The other type is neuro-toxic, resembles the venom of some snakes and produces serious effects on the organism often resulting in death. This type is represented in the United States by *Centruroides sculpturatus* and its close relative, *Centruroides gertschi.* Poison for experiments may be obtained in pure form without injury to the scorpion by electric stimulation. It is soluble in water, in glycerin and in physiological salt solution. The poison of *Buthus australis* of North Africa contains some 20% to 25% of a substance which becomes solid on drying. This substance seems to be neither of protein nor lipid nature, retains its virulence for a long time in the dry state, but is destroyed when boiled for half an hour. The amount of poison produced by the glands of a scorpion depends largely upon the size of the specimen.

Buthus occitanus of southern France produces at one time about 8 milligrams of fluid poison. The weight of dried poison of *Buthus quinquestriatus* of North Africa, Syria and Palestine was estimated at a minimum of 2 milligrams.

The symptoms caused by scorpion poison of the less virulent type consist mostly in sudden sharp pain followed by numbness of the limb and local swelling. The symptoms pass within an hour or two. There is no more danger to man from this type of scorpion poison than there is from the sting of a wasp or a hornet. The author observed in his laboratory the effect of the poison of *Vejovis spinigerus* of Arizona on the large centipede *Scolopendra polymorpha.* The sting produces almost instantaneously paralysis of the legs of the segment which was stung and of two adjoining ones.

A few moments later one more segment on each side becomes paralyzed, so that altogether five segments are affected. The paralysis lasts for some time, but disappears in a few hours. Besides *Centruroides vittatus* and *Vejovis spinigerus,* to this type belong also the formidable-looking *Hadrurus hirsutus* and *Hadrurus spadix* of Arizona and Utah.

It seems that the Central American *Centruroides margaritatus,* which reaches the length of 95 mm. ($3\frac{3}{4}$ in,), is equally harmless.

Sot so with species whose poison is neuro-toxic. Here the symptoms resemble poisoning with strychnine. The sting produces a sharp pain, followed by numbness of the limb; speech becomes difficult; discharge of saliva is copious; the patient becomes restless; breathing is hard and death is not uncommon. The numerous deaths from scorpion sting in Durango, Mexico, seem to be all caused by *Centruroides suffusus,* the most common scorpion in that state. The injection into a vein of a middle-sized dog of a solution containing between 1 and 1.5 milligrams of dried poison of the European *Buthus occitanus* is sufficient to cause death.

The effect of the poison on different animals varies a great deal. The European hedgehog is practically immune to scorpion poison, as it is also to the venom of European snakes. African rodents of the genus *Gerbillus* are nearly 300 times less sensitive than guinea pigs. Dogs are very sensitive to the poison of *Buthus australis,* but *Canis cerdo* (=*Vulpes zerda),* the fennec, of North Africa is immune. Birds are quite sensitive. Sparrows and pigeons are easily killed with the poison of *Scorpio maurus*. Frogs are easily killed, and fish of the species *Motella tricirrata* succumb in less than two hours after a subcutaneous injection. It has been shown that the poison has a haemolytic action, destroying red blood corpuscles, and in this respect is also comparable to the venom of snakes.

The story that scorpions commit suicide by stinging themselves, when surrounded by a ring of fire, is based on misinterpretation of their behaviour and has long since been disproved. However, the generally accepted idea that all animals are immune to their own poison is not quite correct. Scorpions possess a certain degree of immunity. This is true of *Palamnaeus scaber (=Scorpio afer)*, according to older statements. But *Buthus australis* may be killed by injections of its own poison provided the dose contains at least 0.25 to 0.5 mgm. of dry weight, *i.e.*, provided that the dose is nearly 200 times greater than the one necessary to kill a guinea pig. Scorpions are very sensitive to heat and die easily when exposed to the rays of the sun in a closed container. What happens when a scorpion is subjected to heat is simply this: first it tries to escape and failing in this, begin3 to strike frantically with its tail as if in an attempt to sting. Finally it becomes insensitive, overcome by heat, and dies unless removed and allowed to recuperate. The treatment against scorpion poison consists in an application of cold, administration of barbiturates, and injections of a special scorpion serum. The latter is made in Brazil, Mexico, London and Algeria.

Notwithstanding their poison, scorpions have some enemies which destroy them. In the tropical rain forests of Mexico and Central America one can often see army ants disturbing scorpions in the progress of their own raids. Many times the size of their tormentors, scorpions succumb rapidly to their attacks, are overpowered and dismembered. African baboons have been observed catching scorpions of large size, tearing off their tail and greedily devouring the rest of the body. Remnants of scorpions were found in the stomach of a large lizard, *Varanus griseus,* in Transcaucasia. It has been also reported that certain natives of Algeria enjoy eating live scorpions. The author has seen chickens in Arizona dismembering scorpions with their bills. Artificial combats staged by otherwise ignorant people have little scientific value, but they have shown that scorpions entangled in the web of the black widow spider succumb to the poison of the latter. Of course, under normal conditions, scorpions never get into webs of any spiders, while those spiders which scorpions occasionally use for their own food never make webs. It is not yet quite clear whether scorpions of one species are immune to the poison of another species. But it is certain that the blood of scorpions acts as an antitoxin in the case of the same species. In combats between two individuals of the same species, the weaker one is killed, not by poison, but by brute force.

Some of the symptoms produced in man and animals by neuro-toxic scorpion poison stand in direct relation to its effect on various tissues. Both transversely striated and smooth muscles contract under direct influence of weak solutions. Intravenous injections raise the blood pressure considerably. Serous exudation is produced in kidneys. Liver cells undergo fatty degeneration within a few minutes, the liver acquiring a yellowish colour. Necrosis of the liver may take place within 30 minutes after the injection of a large dose of scorpion poison.

The size of scorpions varies considerably. Some species are only 13 mm. ($\frac{1}{2}$ in.) long, while the largest attain 175 mm. ($6\frac{7}{8}$ in.). Although even the smallest scorpions are large enough to be easily studied under lo power, the identification of species is not a simple matter. There is a great deal of variation in most characters so that even a specialist often has difficulty in assigning a specimen to its proper species. The six recent families into which scorpions are divided. as nell as the genera, are easily determined. Their distinction is based on structural characters such as sternum, combs, spines, rows of granules on fingers and on the surface of the body. etc. Being physiologically of the least importance these characters were less subject to functional modifications and remained more or less stationary throughout long geological periods, this being one of the reasons why palaeozoic scorpions are so much like recent ones in appearance. Specific characters are finer and less stable. The species found in Europe and those in the United States are well known and have been described many times. Of the four families represented in the United States, the Buthidae alone have been so far shown to contain dangerously poisonous species, namely the two species of the genus *Centruroides,* mentioned above. Four other species belonging to this genus are found in the U.S. In view of the fact that, of the 30 species known to occur in the U.S., less than a quarter have been studied with a view of ascertaining the type and virulence of their poison, caution in handling scorpions is advisable.

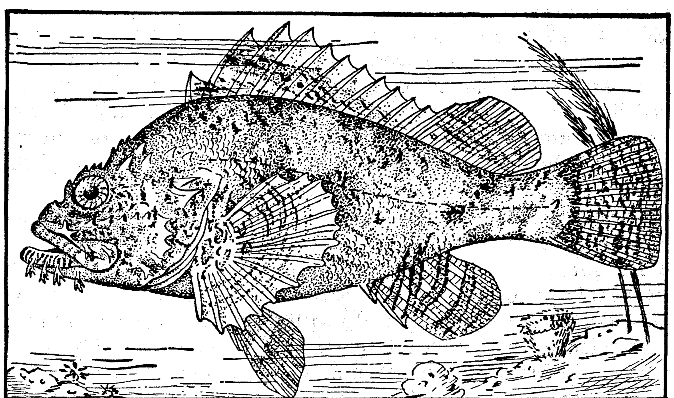
(A. Ph.)

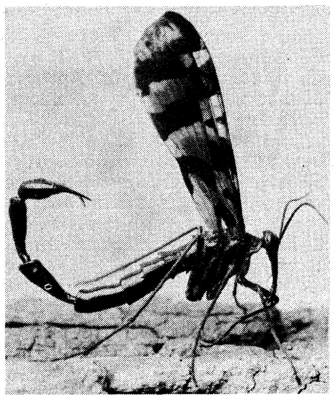
SCORPION FISHES (Scorpaenidae), a family of spiny, marine fishes, characterized as are other families of the order Cataphracti (the Cottidae, etc.), by a bony stay across the cheek. The name is particularly used for the many mostly small (a foot or less long), bottom species in the shore waters of all warm seas (*Scorpaena,* etc.). These usually have mottled colours and are found on rough bottoms or among seaweed. In cooler, coastal waters of the North Pacific, there are larger (the largest two or



SCORPION FISH (SCORPAENOPSIS CACOPSIS), FROM HAWAII AND TAHITI; MANY SIMILAR SPECIES OCCUR ON THE SHORES OF ALL WARM SEAS

three feet long), freer-swimming, less spiny species (*Sebastodes,* etc.), commonly known as rockfish, and of greater market value In the cold waters of the North Atlantic there is a bright red one, the rosefish (*Sebastes marinus*), which is excellent for the table. So far as known all members of the family are good to eat, but persons handling the warm-water ones, especially, should use care, as wounds from their sharp spines may be very painful and cause swelling. In the cool-water species, the small eggs hatch within the body of the mother as a rule, broods of hundreds if not thousands of tiny fishes being spawned. (J. T. N.)

SCORPION FLY, the common name for insects of the family Panorpidae, order Mecoptera (*q.v.*), and by extension often applied to the order as a whole (*see* below). The name refers to the fact that in male panorpids the abdomen terminates in a bulb-like segment which is held over the back, after the manner of a scorpion. In both sexes the chewing mouth parts are borne at the tip of a stout beak, the antennae are long and many-segmented, and there are two pairs of membranous, net-veined wings, which in many species are darkly spotted or banded. The largest genus, *Panorpa,* comprising about 170 species, is widely distributed in forested areas of the northern hemisphere. Adult scorpion flies, usually found on the wing in summer, feed on dead animals, especially insects, but the larvae are thought to be predaceous on minute soil animals. The immature stages of only a few species are known; the larvae resemble caterpillars, and pupation occurs in a cell in the soil.



ROSS E. HUTCHINS
A MALE SCORPION FLY (PANORPA) COMMON IN THE SOUTHERN UNITED STATES

Besides Panorpidae, the order includes the hanging flies, family Bittacidae, which hang by their forelegs and catch insect prey with their raptorial hind feet; and the tiny, blackish snow scorpion flies, family Boreidae, with greatly reduced wings.

Snow scorpion flies are occasionally seen walking over the surface of snow; both the adults and larvae are said to feed on mosses. The order is small, numbering about 350 known living species, but it is very widespread in distribution and is of great antiquity.

Scorpion flies are altogether harmless to man and serve a useful function in nature as scavengers.

See INSECT: *Classification: Mecoptera.* (G. W. Bs.)

SCORZONERA (*Scorzonera hispanica*), a hardy perennial, native to central and southern Europe, and cultivated in gardens as a vegetable for its fleshy cylindrical roots, which resemble those of salsify (*q.v.*) except in being black outside. They should be treated in every respect like salsify. The genus is a member of the family Compositae, and closely allied to *Tragopogon,* to which salsify belongs.

SCOT, MICHAEL (? 1175–*c.* 1232), Scottish translator, mathematician and astrologer. He studied at Oxford and Paris. and after being ordained, held various benefices in Italy, but refused the appointment of archbishop of Cashel in Ireland. Having acquired a knowledge of Arabic at Toledo, he became one of the scholars of the court of Frederick II, and at the instigation of the emperor superintended (along with Hermannus Alemannus) a fresh translation of Aristotle and the Arabian commentaries from Arabic into Latin. The chief of these were the *De Animalibus,* the *De anima,* the *De coelo,* and probably the *Physics* and the *Metaphysics,* and also the *De Sphaera* of Al Bitrogi. Scot's own books, dealing almost exclusively with astrology, alchemy and the occult sciences generally, are mainly responsible for the development of the Michael Scot legend. Chief among these are *Super auctorem spherae,* printed at Bologna in 1495 and at Venice in 1631; *De sole et luna,* printed at Strassburg in 1622 in the *Theatrum chimicum,* and containing more alchemy than astronomy, the sun and moon being taken as the images of gold and silver; *De chiromantia,* an opuscule often published in the 15th century; *De physiognomia et de hominis procreatione,* of which there were 18 editions between 1477 and 1660.

The *Physiognomia,* which also exists in an Italian translation. and the *Super auctorem spherae* expressly state that they were undertaken at the request of the emperor Frederick. Michael is said to have foretold, after the manner of the ancient oracles, the place of Frederick's death, which took place in 1250.

Around his own death many legends gathered. He was supposed to have foretold that he would end by a blow from a stone of not more than two ounces in weight, and that to protect himself he wore an iron helmet, and that, raising this in church at the elevation of the host. the fatal stone fell on him from the roof. Italian tradition says he died in Italy; other accounts place his death in his native country, and his burial at Holme Cultram in Cumberland or in Melrose abbey. In the notes to Scott's Lay of *the Last Minstrel,* Scott recounts the exploits attributed by popular belief to the magician. "In the south of Scotland any work of great labour and antiquity is ascribed either to the agency of Auld Michael, of Sir William Wallace or the devil." Other powers and exploits are narrated in Folengo's Macaronic poem of *Merlin Coccaius* (1595). Michael's reputation as a magician was early established. He appears in the *Inferno* of Dante (canto xx, 115–117) among the magicians and soothsayers. He is represented in the same character by Boccaccio.

SCOT AND LOT, a phrase common in the records of English medieval boroughs, applied to those householders who were assessed to any payment made by the borough for local or national purposes. They were usually members of a guild merchant.

SCOTER (*Oidemia nigra*), a diving duck. also known as the black duck from the male being. save for a stripe of orange down the bill, wholly of that colour. Of all ducks the scoter has the most marine habits, keeping to the sea in all weathers, and coming to land only to breed. A second species, the velvet scoter, *O. fusca,* of larger size. with a white spot under each eye and a white bar on each wing, is less abundant. It has its American counterpart, *O. americana,* and a third, the surf-duck, *O. perspicillata,* with a white patch on the crown and another on the nape, and a curiously parti-coloured bill, is not uncommon in North American waters. All the species have their true home in arctic or subarctic countries. but the scoter itself breeds occasionally in Scotland. The nest is on the ground and contains five to eight creamy eggs. The females are soot coloured above and brownish white beneath. The flesh of all these birds has an exceedingly strong taste. and ranked as fish in ecclesiastical dietary.

SCOTLAND, the most northern of the three countries that constitute Great Britain. Scotland includes the Outer and Inner Hebrides and other islands off the west coast, and the Orkney and Shetland islands off the north coast. With England lying to the south, it is bounded on the north and west by the Atlantic ocean and on the east by the North sea. It is separated from England by the Solway firth, the Sark, Scotsdyke (an old embankment connecting the Sark with the Esk), the Esk (for 1 mi.), the Liddel, the Kershope, the Cheviot hills, the Tweed and a small area known as the "liberties" of Berwick. The greatest length, from Cape Wrath in Sutherland to the Mull of Galloway, is 274 mi., and the greatest breadth, from Buchan Ness to Applecross in the shire of Ross and Cromarty, 154 mi.; but from Bonar Bridge at the head of Dornoch firth to the head of Loch Broom it is only 26 mi. wide, and 30 mi. from Grangemouth on the Forth to Bowling on the Clyde.

The coast line of Scotland is estimated at 2,300 mi., the arms of the sea being so numerous and in several cases penetrating so far inland that few places are beyond 40 mi. from salt water. The area is 29,795 sq.mi.

The name Scotland (the ancient Caledonia—a name still poetically used) originated in the 11th century, when (from the tribe of Scots) part of it was called Scotia (a name previously applied to nhat is now Ireland) ; and the name of Scotland became established in the 12th and 13th centuries.

PHYSICAL GEOGRAPHY

Physically, Scotland is divided into three structural regions—the Highlands (subdivided by Glen More into the northwestern and southeastern Highlands); the central lowlands (a tract of southwesterly to northeasterly trend, between a line drawn roughly from Girvan to Dunbar and a line drawn from Dumbarton to Stonehaven); and the southern uplands. To these. geographers add a fourth division, to be regarded as at least a subregion of the Highlands, viz., the lower eastern slopes of that region bordering the North sea, from Stonehaven and Aberdeen in the south to the high plain of Caithness in the north. It may be termed the northeastern region.

The Highlands. — Nearly all this region is high ground, deeply trenched with valleys and sea lochs. The Highland hills stand in a succession of more or less parallel confluent ridges, having in the main a trend from northeast to southwest. These ridges are separated by longitudinal and furrowed by transverse valleys. The longitudinal valleys, which run in the same general direction as the ridges, have had their trend defined by geological structure, such as a line of dislocation (the Great Glen), or the plications of the rocks (Lochs Ericht, Tay and Awe, and most of the sea lochs of Argyllshire). The transverse valleys run northwest or southeast and are for the most part independent of geological structure. The valley of the Garry and Tay crosses the strike of all the Highland rocks, traverses the great fault on the Highland border, and finally breaks through the chain of the Sidlaw hills at Perth. River-gorges are characteristic features in many of the valleys. In the Old Red Sandstone they are particularly prominent where that formation has lain in the way of the streams sweeping down from the Highlands. In the basin of the Moray firth some fine examples may be seen on the Nairn and Findhorn, while on the west side of the Cromarty firth some of the small streams descending from the high grounds of the east of the shire of Ross and Cromarty have cut out defiles in the conglomerates, remarkable for their depth and narrowness. Toward the south margin of the Highlands instances of true canyons in the Old Red Sandstone are to be seen where the Isla and North Esk enter that formation.

While many of the Highland mountains, viewed from near at hand, tower above the surrounding country, and are often of noble form, from a distance they are seen not to vary much from a general uniformity of height. A few exceptions occur along the western seaboard of Sutherland, in Skye, and elsewhere. but their structure explains the reason of their prominence. Regarded broadly, the Highland mountains are monuments of erosion. the relics of an old plateau, the surface and former slopes of which are shown approximately by the summits of the existing masses and the directions of the chief waterflows. The surface is rugged. The rocks project in bosses and crags, which roughen the sides and crests of the ridges. The shape and colour of these roughnesses depend on the nature of the underlying rock. Where it is hard and jointed. weathering into large quadrangular blocks, the hills are distinguished by the gnarled bossy character of their declivities, as may be seen in Ben Ledi and the heights to the northeast of it. Where. on the other hand, the rock decays into smaller debris, the hills assume smoother contours, as in the slate hills running from the Kyles of Bute to Loch Lomond.

The process by which the ancient plateau has been trenched into valleys and confluent ridges is best displayed among the higher mountains. where erosion proceeds at an accelerated pace. The long screes or talus slopes at the foot of every crag and cliff bear witness to the continual waste. The headwaters of a river cut into the slopes of the parent hill. Each valley is consequently lengthened at the expense of the mountain from which it descends. Where a number of small torrents converge in a steep mountain recess, they cut out a crescent-shaped hollow or half-cauldron. which in the Scottish Highlands is known as a corrie. Usually the upper part of a corrie is formed by a crescent of naked rock, from which long trails of debris descend to the bottom of the hollow. Every distinct variety of rock has its own type of corrie, the peculiarities being marked both in the details of the upper cliffs and crags, and in the amount, form and colour of the screes. The Scottish corries have been occupied by glaciers. Hence their bottoms are generally ice-worn or strewn over with moraine stuff. Often a small tarn fills up the bottom ponded back by a moraine. It is in such localities that we can best observe the evidences of the glaciers that once overspread the country. Among these high grounds also the gradual narrowing of ridges into sharp, narrow, knife-edged crests and the lowering of these into cols or passes can be well seen. The stages in this demolition are clearest where the underlying rock is of granite or similarly tough material, which at the same time is apt to be split and splintered by means of its numerous transverse joints. The granite mountains of Arran furnish excellent illustrations.

Where a rock yields to weather with considerable uniformity in all directions it is likely to assume conical forms in the progress of denudation. Somelimes this uniformity is attained by a general disintegration of the rock into fine debris, which rolls down the slopes in long screes. In other cases it is secured by the intersection of joints. whereby a rock, in itself hard and durable, is divided into small angular blocks, which are separated by weathering and slide down the declivities. In many instances the beginning of the formation of a cone may be detected on ridges which have been deeply trenched by valleys. The mountain Schiehallion (3.547 ft.) is an instance of a cone not yet freed from its parent ridge. A further stage in denudation results in isolated groups of cones completely separated from the rest of the rocks among which they once lay buried. Such groups may be carved out of a continuous band of rock extending into the regions beyond. The Paps of Jura, for instance, rise out of a long belt of quartzite which stretches through the islands of Islay, Jura and Scarba. In many cases, however, the groups point to the existence of some boss of rock of greater durability than those in the immediate neighbourhood, as in the Coolins (Cuchullins or Cuillins) and Red hills of Skye and the group of granite cones of Ben Loyal, Sutherland. The most impressive form of solitary cone is that wherein, after vast denudation, a thick overlying formation has been reduced to a single outlier, such as Morven in Caithness, the two Bens Griam in Sutherland. and the pyramids of red sandstone on the western margin of the shires of Sutherland and Ross and Cromarty. While in Scotland the dislocation of rocks has generally prevented the formation of continuous escarpments, there are instances of these in the wide basalt plateaus of the Inner Hebrides. where lava has been poured out in nearly horizontal sheets, with occasional layers of tuff or other softer rock between them.

Platforms' of erosion, successively established by the wearing down of the land to sea level, occur both in the Highlands and among the southern uplands The flat-topped moorlands in the eastern Grampians reach heights of 3,000 to 4.000 ft. above the sea. The summits of Lochnagar and Ben Macdhui may be taken as examples. These mountains lie within granite areas; but not less striking examples may be found among the schists. That these high plateaus are planes of erosion is shown by their independence of geological structure. the upturned edges of the vertical and contorted schists having been shorn off and the granite wasted and levelled along its exposed surface. An example of the similar destruction of a much younger platform is to be found in the terraced plateaus of Skye, Eigg, Canna. Muck, Mull and Morven, which are portions of what was probably originally a continuous plain of basalt. Though dating back only to older Tertiary time, this plain has been so deeply trenched by denudation that it has been reduced to scattered fragments.

The Highlands are separated into two disconnected and in some respects contrasted divisions by the depression of the Great glen, extending from Loch Linnhe to Inverness. In the northwestern section the highest ground is found along the Atlantic coast. mounting steeply from the sea to an average height of 2.000 to 3.000 ft. The watershed consequently keeps close to the western seaboard. in some places not above $1\frac{1}{2}$ mi. from it. From these hills, which catch the first downpour of the rains from the ocean, the ground falls eastnard. Numerous eminences, however, prolong the mountainous features to the North sea and southeastward to Glen More. The difference of the general level on the two sides of the waterparting is reflected in the length of their streams. On the west the drainage empties itself into the Atlantic after floaing only a very fen miles; on the east it has to run 30 or 40 mi. At the head of Loch Nevis the western stream is but 3 mi. long, while the eastern has a courie of some 18 mi. to the Great glen. Throughout the northnestern region uniformity of features characterizes the scenery, betokening, even at a distance, the general monotony of structure. But the sameness is relieved along the western coast of the shires of Sutherland and Ross and Cromarty by groups of cones and stacks, and farther south by the terraced plateaus and abrupt conical hills of Skye. Rum and Mull.

The southeastern region of the Highlands, having a more diversified geological structure, offers greater variety of scenery. Most of the valleys, lakes and sea lochs run in a southwesterly and northeasterly direction, a feature strikingly exhibited in west Argyllshire. But there are also several important transverse valleys, that of the Garry and Tay, already noticed, being the most conspicuous example. The watershed, too, is somewhat different. It first strikes eastward round the head of Loch Laggan and then swings southward: pursuing a sinuous course till it leaves the Highlands on the east side of Loch Lomond. The streams flowing westward, however, are still short, while those running to the northeast, east and southeast have long courses and drain wide areas. There is a marked contrast between the configuration of the northeastern district, and the other parts of this region. In that area the Grampians rise to level or gently rounded summits, often more than 3,000 ft., and in a few places exceeding 4.000 ft. in height, and bounded by steep declivities and sometimes by precipices. Farther southwest, in the shires of Perth, Inverness and Argyll, they give place to the more typical hummocky crested ridges of Highland scenery which, in Ben Nevis and Aonach Beg, reach heights of over 4,000 ft. Geological structure alone does not account for this contrast, and one reason may lie in the heavier rainfall, and consequently stronger erosion. to which the western mountains! facing the Atlantic ocean. have been exposed. Long narrow strips of flat land occur in the more important valleys. Most of the straths and glens have a floor of detritus which, spread out between the bases of the boundary hills, has been levelled into meadow land by the rivers and provides almost the sole arable ground in each district. It is appropriate here to notice certain terms common throughout Scottish topography in application to types of valleys and low-lying land. for examples of most of them are found in the Highlands or on their borders.

Straths are broad expanses of low ground between hills, usually traversed by one main stream and its tributaries; *e.g.,* Strath Tay, Strath Spey, Strath Conon. This name, however. has also been applied to wide tracts of 10x1-land which embrace portions of several valleys, but are defined by lines of heights on each side; the best example is afforded by Strathmore — the "Great Strath" —between the southern margin of the Highlands and the line of the Sidlaw hills. This long wide depression, though it looks like one great valley, includes portions of the valleys of the Tay, Isla, North Esk and South Esk. all of which cross it. Elsen-here in central Scotland such a wide depression is known as a *howe,* as in the Howe of Fife between the Ochil and Lomond hills. A *glen* is a narrower and steeper-sided valley than a strath. though the names have not always been applied with discrimination. Most of the Highland valleys are true glens, Glencoe being the best known example. The hills rise steeply on each side, sometimes in grassy slopes. sometimes in rocky bosses and precipitous cliffs, while the bottom is occupied by a lake. In the south of Scotland the larger streams flow in wide open valleys called *dales,* as in Clydesdale, Tweeddale, Teviotdale, Liddesdale, Eskdale and Nithsdale.

The strips of alluvial land bordering a river are known as *haughs,* and where, along estuaries, they expand into wide plains they are termed *carses.* The carses oi the Forth extend seaward as far as Bo'ness and consist chiefly of raised beaches. The Carse of Gowrie is the strip of low ground intervening between the Firth of Tay and the Sidlaw hills. Brae signifies the steep bank of a river, and so any slope or hillside.

Scottish lochs (or lakes) are sometimes classified into four groups — glen lochs, rock tarns, moraine tarns, and lochs of the lowlands, of which the first and most important are practically confined to the Highlands and the second and third are far more numerous there than elsewhere. The small rock tarns, lying in rock basins on the flanks of mountains, or the summit of ridges or rocky plateaus, are by far the commonest, and especially so in the northwest. They almost invariably lie in strongly ice-worn platforms, and are held to occupy hollows produced by the gouging action of the ice-sheets in glacial times. Moraine tarns — small sheets of water dammed back by moraines left by retreating glaciers — are also numerous in the Highlands, nestling in the bottoms of corries. In the southwest, where the glaciers continued longest to reach sea level, lakes retained by moraine barriers are seldom found above the sea. More important, if less numerous than either of these categories, are the larger glen lochs, which are associated with the finest inland scenery in the Highlands. These occupy depressions in the glens, not due to local heaping up of detritus, but true rock basins, often of great depth. It is commonly but not invariably held that these depressions were formed by the erosive action of ice! since glaciers occupied the glens where they occur and wore down the rocks along the sides and bottom; but it is a point of difficulty in this theory whether ice could have eroded the deepest of the hollows.

The western Highland coast is intersected throughout by long narron- sea lochs or fjords. The mainland slopes steeply into the sea and is fronted by chains and groups of islands. These fjords are submerged land valleys, for the whole western coast has subsided to a considerable depth beneath its former level. The Scottish sea lochs must be considered in connection with those of western Ireland and Norway. The whole of this northwestern coast line of Europe bears witness to recent submergence. On this view the Outer and Inner Hebrides were formerly one with themselves and the mainland, and the western isles therefore are truly grouped with the Highland province of Scotland. Nearly the whole coast line is rocky. On the west the coast is mostly either steep rocky declivity or a sea wall, though strips of lower ground are found in the bays. The cliffs vary in character according to the nature of the rock. At Cape Wrath, precipices 300 ft. high have been cut out of the Archean gneiss. The varying texture of this rock, its irregular foliation and jointing. and its ramifying veins of pegmatite give it very unequal powers of resistance. In some places it projects in irregular bastions and buttresses, in others it retires into deep recesses and tunnels, but shows everywhere a characteristic ruggedness. In striking contrast to these precipices are those of the Cambrian red sandstone a few miles to the east. Vast vertical walls of rock rise to a height of 600 ft., cut by their perpendicular joints into quadrangular piers and projections, some of which stand out alone as islets in front of the main cliff.

The population of the Highlands is naturally scattered, since great tracts of mountain and moorland are uninhabitable. The few small towns and larger villages are for the most part such as have grown in modern times as touring centres and places of summer residence along the west coast and the railways, in particular the line between Perth and Inverness. Settlements remote from these influences are commonly small, and some on the western seaboard share with Norwegian fjord-side settlements the characteristic of having their chief lines of access by water. The Highlands are not rich in minerals; only a few workings, such as that of the iron ore of Raasay, near Skye. are encountered; north of Fife coal is virtually nonexistent, except for the pit at Brora in Sutherland. The development of hydroelectric power, especially since the creation in 1943 of the north of Scotland hydroelectric hoard, gives promise of considerable industrial activity. Otherwise, homestead industry, such as the manufacture of Harris tweed in the Outer Hebrides, can maintain itself (apart from local consumption) only by the special excellence of its products. It thus follows that the Highland population is principally agricultural and concentrated upon the limited cultivable areas, the resources of which it tends easily to outgrow, so that the Highlands have sent and still send abroad many emigrants. Only a few alluvial basins — up to an elevation of 1,200 ft. in Banffshire, but usually much lower—the levels of raised beaches, and narrow isolated coastal strips offer fair agricultural land and a more or less complete subsistence to the crofters; those on the coastlands may add to their means of livelihood by fishing. while others may take service as gamekeepers on the large sporting estates which occupy a high proportion of the total area, or in the forestry reserves.

The Northeastern Region. — This division embraces the considerable low-lying areas in eastern Aberdeenshire and the northern parts of Banff, Moray and Nairn, together with the level strip of land bordering both sides of Moray firth. Farther north. the Highlands of Sutherland sink close to the coast, but the narrow coastal belt there broadens northward again in Caithness. which does not strictly belong to the Highlands. In the southeastern part of the region (east and southeast of Moray firth) the principal rivers—Spey and Dee. and, within the angle formed by these, the Don, Wthan. Deveron and others — drain long valleys separated by extended spurs of the Highland mountains. The hills sink to a fairly wide foreland, sloping gently to the sea, or broken off in low cliffs. On this part of the coast there are neither islands nor deep inlets, though plenty of small bays offer shelter for shipping, especiaily fishing vessels. Northward, the coast is deeply indented by the firths of Moray, Cromarty and Dornoch, and a further series of fine rivers, hardly less famous among salmon and trout fishermen than those just mentioned, enter the sea from the mountains to the west. The chief of these rivers are the Findhorn, Beauly, Conon, Shin and Helmsdale. The peninsulas between the firths reach no great elevation — an extreme height of 800 ft. is found in the Black Isle south of Cromarty firth. The coastal lowland of Sutherland, as already indicated, is very narrow, but Caithness is a wide moor, terminating almost everywhere seaward in a range of precipices of Old Red sandstone.

The population of this region is, on the whole, closer on the coastal lands than in the interior; the largest towns, such as Aberdeen, Peterhead, Fraserburgh, Banff. Inverness and Wick are seaports. In Sutherland population is almost confined to the raised beaches of the narrow coastal belt. On the other hand a fairly dense rural population covers most of the area between the lower Dee and the Deveron and extends far up the valley of the Spey. The region is not devoid of fertile lands! although their preparation for tilling has, in the past, necessitated in some parts immense labour in clearing the glacial boulders with which they were bestrewn. A high standard of farming is reached in the lower parts of the Dee and Don basins, the Laigh of Moray, and other localities. Oats and turnips, with some barley, are main crops, and the lower lands of the eastern division are famous for cattle. On the higher grounds sheep are more prominent. Granite is quarried at several points in the same division and granite polishing is a characteristic industry at Aberdeen. Pure water, favourable for malting, has helped in the establishment of the distilling industry. The fisheries centre mainly on Xberdeen, which is-also the principal port for the export of herrings; the pelagic fisheries are carried on mostly from more northerly ports — Peterhead, Fraserburgh and Wick (as well as the Orkney and Shetland Islands).

The Central Lowlands. — These constitute a broad depression with southwesterly to northeasterly trend lying between the Highland line that runs from the head of the Firth of Clyde to Stonehaven and the pastoral uplands that stretch from Girvan to Dunbar. They may be regarded as a long trough of younger rocks let down by parallel dislocations between the older masses to the south and north. The depression as such, however, is of great geological antiquity. Long dislocations have sharply defined its northern and southern margins. By other fractures and unequal movements of upheaval or depression portions of the older rocks have been brought up within the bounds of the younger, and areas of the younger have been enclosed by the older. On the whole, these disturbances have followed the prevalent northeasterly trend, and hence a tendency may be observed among the main ridges and valleys to run in that direction. The chains of the Ochil, Sidlaw, Pentland, Renfrew, Campsie and Fintry hills, and the valleys of the Strathmore, Firth of Tay, and the basin of Midlothian are examples. But the dominant cause in the determination of the topographical prominences and depressions of the district has been the relative hardness and softness of the rocks. Almost all the eminences in the lowlands consist of hard igneous rocks, forming not only chains of hills such as those just mentioned and others in Ayrshire and Lanarkshire, but isolated crags and hills like those on which stand the castles of Edinburgh and Stirling, and others conspicuous in Fife and the Lothians.

Of the three chief valleys in the central lowlands, two, those of the Tay and the Forth. descend from the Highlands. and one, that of the Clyde, from the southern uplands. Though on the whole transverse. these depressions furnish another notable example of that independence of geological structure already referred to. The gorge in which the famous Falls of Clyde are situated is the best example of a river gorge in the lowlands. Lochs are not many. Occasional rock tarns are found in the hills. The larger Iochs of the lowlands lie in hollows of the glacial detritus, which is strewn thickly over the lower grounds. As these hollows were caused by original irregular deposition rather than by erosion, they have no intimate relation to the present drainage-lines. The lakes vary in size from pools to sheets of water several square miles in area. As a rule they are shallow in proportion to their extent and surface. They were once more numerous than they are now, for some have disappeared through natural causes and others have been drained. The largest sheets of fresh water in the lowlands are lakes of the plains.

The fact that two-thirds of the population of Scotland live in the central lowlands on one-tenth of the total area of the country is evidence of the pre-eminent industrial position of this region. Among the geographical reasons for that pre-eminence we find, first, ease of communication, both internal and external. The Firth of Clyde on the west, the Firths of Forth and Tay on the east, deeply indent the coasts and offer access for shipping directly or near to the chief industrial centres. Secondly, the Carboniferous rocks of the lowlands carry important coal fields, of which, with the working out of the once rich Lanarkshire field, the most productive are those in Ayrshire, about the head of the Firth of Forth. in the Lothians and in Fife. Iron is allied with coal, notably in the Ayrshire and Lanarkshire fields. Oil shale is worked in Midlothian and West Lothian. but its importance has declined; lead is worked in Lanarkshire. Upon the Lanarkshire coal field, the city of Glasgow and its neighbouring industrial towns, there centre a variety of great manufacturing industries—shipbuilding and engineering, cotton, woollen and linen manufactures, brewing and distilling, chemical, pottery and glass manufactures, and many others. Elsewhere certain great industries are definitely localized. such as the jute manufacture and jam and marmalade making at Dundee; the woollen industry in Stirlingshire and Clackmannanshire. linen manufacture at and about Dunfermline, Arbroath and Montrose, that of linoleum and oilcloth at Kirkcaldy. that of paper in places neighbouring to Edinburgh, and the dyeing industry at Perth. All the textile industries, the paper mills, and the distilleries owe their establishment in part to ample supplies of pure mater. Rich agricultural lands, albeit restricted in area: lie close to the manufacturing districts, especially in the east, in Perthshire, Angus.' Fife and the Lothians; barley, a high yield of wheat on a small acreage, and potatoes are crops especially noted.

The Southern Uplands. — These extend from the north channel in the southwest to St. Abb's Head in the northeast, and form a well-defined belt of hilly ground, and though much less elevated (their highest point is 2,764 ft. above the sea) than the Highlands, rise with scarcely less abruptness above the lower tracts that bound them. Their northwestern margin for the most part springs boldly above the fields and moorlands of the central plain, and its boundary for long distances continues remarkably straight. On the south and southeast their limits in general are less prominently defined but are better seen west and southwest of the Nith, from which they extend to the sea and Loch Ryan, terminating in the extreme southwest in a plateau of which the loftiest point is little over 1,000 ft. above the sea. The Cheviots do not properly belong to the uplands, from which they are separated by Liddesdale and other hollows, and on which they abut abruptly. But though geologically the one set of mountains must be separated from the other, geographically it is convenient to include within the southern uplands the whole area between the central plain and

[1]By a resolution of the county council in May 1928, the county reverted to its older historic name of Angus in place of Forfarshire. Other instances of shire names derived from the county town giving place to the older name are the three Lothians—East, West and Midlothian—for Haddingtonshire, Linlithgowshire and Edinburghshire, and Moray for Elginshire.

the border. A survey of the uplands, therefore, presents in succession from southwest to northeast the Kirkcudbrightshire and Ayrshire mountain moors, the Lowthers, the Moffat hills, the Moorfoots and the Lammermuirs. Distinguished by the smoothness of their surface, they may be regarded as a rolling moorland, traversed by many valleys conducting the drainage to the sea. This character is well observed from the heights of Tweedsmuir. Wide, mossy moors, 2,000 ft. or more above the sea, and sometimes level as a racecourse, spread out on all sides. Their continuity, however, is interrupted by numerous valleys separating them into detached flat-topped hills, seldom marked by precipices of naked rock. Where the rock projects it more usually appears in low crags and knolls, from which long trails of gray or purple debris descend till they are lost among the grass. These smooth green hills form excellent pasture land, while the alluvial flats in the valleys, and even some of the lower slopes, are fitted for grain and green crops. Only in the higher tracts are there rugged features recalling the character of Highland scenery. In the heights of Hart Fell (2,651 ft.) and White Coomb (2,695 ft.), whence the Clyde, Tweed, Annan and Moffat Water descend, the high moorlands have been scarped into gloomy corries, with crags and talus slopes, which form a series of landscapes all the more striking from the cuntrast with everything around them. In Galloway, also, the highest portions of the uplands have acquired a ruggedness and wildness more like those of the Highlands than any other district in the south of Scotland. In that region the Silurian rocks have been invaded by large bosses of granite, and have undergone a variable amount of metamorphism which has, in some places, altered them into hard crystalline schists. These various rocky masses have yielded unequally to disintegration; the harder portions project in rocky knolls, crags and cliffs, while the softer parts have been worn down into more flowing outlines. The highest summit in the south of Scotland—Merrick (2,764 ft.)—consists of Silurian strata much altered by proximity to the granite, while the rest of the more prominent heights [all in Kirkcudbrightshire) —Rhinns of Kells (2,668 ft.), Cairnsmore of Carsphairn (2,612 ft.), and Cairnsmore of Fleet (2,331 ft.)—are forined of granite.

The watershed of the southern uplands runs from the mouth of Loch Ryan in a sinuous northeasterly direction, keeping near the northern limit of the region till it reaches the basin of the Nith, where it quits the uplands, descends into the lowlands of Ayrshire, and, after circling round the headwaters of the Nith, strikes southeastward across half the breadth of the uplands, then sweeps north and eastward between the basins of the Clyde, Tweed and Annan, and then through the moors that surround the sources of the Ettrick, Teviot and Jed, into the Cheviot hills. Here, again, the longest slope is on the east side, where the Tweed hears the whole drainage of that side into the sea. Although the rocks throughout the southern uplands have a persistent northeasterly and southwesterly strike, and though this trend is apparent in the bands of more rugged hills that mark the outcrop of hard grits and graywackes, nevertheless geological structure has been much less effective in determining the lines of ridge and valley than in the Highlands. On the southern side of the watershed, in Dumfriesshire and Galloway, the vaileys run generally transversely from northwest to southeast. But in the eastern half of the uplands the valleys do not appear to have any relation to the geological structure of the ground underneath.

In the southern uplands, owing to the greater softness and uniformity of texture of the rocks, as compared with those of the Highlands, rocli tarns are comparatively infrequent, except in Galloway, where the protrusion of granite and its associated metamorphism have reproduced Highland conditions of rock structure. The best known and one of the most picturesque of moraine-dammed lochs is the wild and lonely Loch Skene, lying in a recess of White Coomb at the head of Moffat Water. Others are sprinkled over the higher parts of the valleys in Galloway.

On the east the southern uplands plunge abruptly into the sea near St. Abb's Head in a noble range of precipices 300 to joo ft. in height, and on the west terminate in a long broken line of sea wall, which begins at the mouth of Loch Ryan, extends to the Mull of Galloway and reappears again in the southern headlands of Wigtown and Kirkcudbright. Southward they sink to the narrow lowland bordering Solway firth.

On the grassy hills of the uplands, from end to end, sheep farming is naturally an outstanding occupation, and with it is associated the woollen industry centred in the chief inland towns of the Tweed basin. In the west (Galloway, Ayrshire) dairy farming is highly developed for the supply of the neighbouring populous centres in the lowlands. Into the western dales, too, some of the industries of the lowlands extend, with some coal mining in Nithsdale, quarrying of freestone, etc., while the granite of Creetown and the neighbourhood is famous. But, as a whole, the human, like the physical, geography of the southern uplands, is clearly differentiated from that of the Highlands and the lowlands; it approaches more nearly in character to that of the northeastern region of England. (O. J. R. H.; X.)

GEOLOGY

Scotland lies on the course of a pre-Devonian: southwestwardly trending mountain chain, stretching from Scandinavia to Ireland and called Caledonian by Eduard Suess. The front of this chain is situated in the northwest Highlands. Its latest manifestation is the corrugation of Ordovician and Silurian in the southern uplands, where Charles Lapworth demonstrated the true worth of graptolites.

Pre-Devonian of the Northwest Highlands and Islands.—The oldest Scottish rocks, grouped as Lewisian complex, outcrop in Lewis and on the adjacent mainland coast. Some claim as earliest members certain metamorphic sediments, including magnesian marbles and graphitic schists. With these occur much more abundant igneous gneisses (acid, intermediate and basic). Locally, late dikes of the complex have suffered but little from metamorphism, though elsewhere transformed into hornblende schist. A great development of "flinty" crush-rock, a product of frictional fusion, follows an east-southeastwardly inclined shear zone along the east coast of the Outer Hebrides.

Torridonian succeeds Lewisian with complete unconformity. From Islay to Skye, the formation starts with Lower Torridonian basal conglomerates, epidotic grits, gray sandstones, flags and gray and black shales (7,000 ft.). Farther north, Middle Torridonian arkose (6,000–8,000 ft.), with local breccias, rests among and covers over "fossil hills" of Lewisian gneiss, which are sometimes more than 2,000 ft. in individual height. Upper Torridonian sandstones, flags and shales attain 4,500 ft.

Durness Quartzite and **Limestone.**—Durness sediments, Lower Cambrian extending into Lower Ordovician, are of American facies in lithology and fauna: basal quartzite, 320 ft.; quartzite with vertical worm "pipes," 270 it.; dolomitic shales, mudstones and dolomites, with *Olenellus*, etc., 50 ft.; grit, with *Salterella* and also *Olenellus*, 30 ft.; limestones and dolomites, some fossilerous, 1,500 it. Plutonic (possibly early Devonian) intrusions of alkalisyenite, borolanite, etc., accompanied by sills, cut these sediments. Contact effects include dedolomitization.

The sediments and intrusions pass east-southeastward in disturbed fashion under the Moine thrust of the Caledonian chain! which is overlain by crystalline schists and traceable from Durness to Skye. Near Durness, a thrust-outlier (Klippe) of the Moine Thrust-mass (nappe) is down-faulted 10 mi. in advance of the main outcrop. In Assynt and Glencoul, subsidiary thrusts carry 1,joo ft. slices of Lewisian for miles over Cambrian. Spectacular inversion occurs at Loch Alsh. Isoclinal packing, *Schuppenstruktur*, mylonitization, etc., are diagrammatically exposed at many localities.

Pre-Devonian of the Highlands Southeast of Moine Thrust.— Sedimentary quartzo-feldspathic and micaceous schists are prevalent northwest of the Caledonian canal, and are grouped together as Moine schists. Several minor outcrops of Lewisian igneous and sedimentary types are by some authors interpreted as Lewisian inliers interiolded with unconformable Moines. The Inchhae porphyritic granite, now gneissose, was intruded into the Moines before these had suffered regional metamorphism; and adjacent indurated hornfeis retains minutiae of sedimentary structure, such as grains, ripple marks and sun cracks. Garnets are widely developed in the Moine schists, and some distance east of the Moine thrust granitic injection is common with associated sillimanite. At Tarskavaig in Skye there is a thrust mass under the Moine thrust. the rocks of which are variously interpreted as Moines or Torridonian. Some think all Moines are metamorphosed Torridonian; others regard Moine metamorphism as pre-Torridonian.

Moines cross the Caledonian canal: or Great Glen fault: but half of the Highlands to the southeast consists of undated Dalradian schists. The fault, according to good but inconclusive evidence, is a tear fault with horizontal displacement of 65 mi. In the Dalradian, quartzites. limestones and graphitic schists are characteristic members; the Schichallion boulder-bed may be glacial; pillow lavas occur at Loch Awe; basic intrusions are widespread. Current or graded bedding, both in Dalradian and Moine sediments, often settles age relations. The Dalradians overlie Moines, pitching off them toward Loch Awe and Banffshire. Large-scale recumbent folds with fold faults (slides), the whole refolded, are typically shown at Ballachulish and elsewhere.

Zonal mapping of regional metamorphism was first carried out in the Dalradian belt. The grade, varying from roofing slate to sillimanite-gneiss, is low at Loch Awe. in Banffshire and along the southeastern Highland border. In the sillimanite zone granitic permeation is characteristic.

Middle Cambrian limestone (near Callander) and Upper Cambrian to Ordovician pillow lavas, radiolarian cherts and serpentine with fossiliferous shales outcrop discontinuously along the Highland Border fault. At Stonehaven they are unconformably overlain by Downtonian sandstones with mudstones, tuffs and conglomerates (2,760 ft.), that yield fish and *Dictyocaris*.

Silurian of **Lesmahagow** and **Pentland** Anticlines in the Midland **Valley.**—Lesmahagow exposures of Silurian show: (?) Wenlock graywacke and shale. 1,300 ft.; Ludlow mudstone, graywacke and shale. 1.480 ft.; Downtonian yellow. red and chocolate sandstone with a quartzite conglomerate and some mudstone. 2,700 ft. The Wenlock-Ludlow rocks have yielded many brachiopods and molluscs, especially in the Pentlands; also scorpion, phyllocarids, eurypterids and fish. The three last appear again in the Downtonian.

Ordovician and Silurian of the Southern Uplands.—Closely packed isoclinal folding and rapid cross-strike change of facies and thickness are characteristic. The Ordovician commences with Arenig pillow lavas, continuing into the Llandeilo and capped by Llandeilo radiolarian cherts (70 ft.)—the term Llandeilo is used in Lapworth's sense. Near Girvan 1.500 ft. of Arenig volcanic rocks are associated with serpentine, gabbro and granite. the whole exposed to erosion before deposition of conglomeratic Cpper Llandeilo (830 ft., including 60 ft. interbedded fossiliferous Stinchar limestone). Southeast of Stinchar valley. Cpper Llandeilo becomes conformable to the volcanic series. and consists of mudstones and grits (joo ft.) and conglomerate (500 ft.). Farther southeast it passes to grit and graywacke (1,000 ft.) and then near Moffat to 20 ft. of graptolite shale (Glenkiln). The Caradoc (including Ashgillian) at Girvan is mostly mudstones, grits. flags and shales (2,800 ft.) with interbedded shelly and graptolitic faunas. Near Moffat this reduces to 100 ft. of graptolite shale and barren mudstone (Hart Fell). Acid lavas occur at Wrae in Tweeddale.

A general palaeontological break introduces the Silurian. although without upheaval at Moffat. The Llandovery at Girvan consists of conglomerates, grits. flags, shales and thin limestones (1,050 ft.) with interbedded shelly and graptolitic faunas. Near Moffat there are only 100 ft. of graptolite shale (Birkhill). The Tarannon, hoxvever, both at Girvan (2,100 ft.) and Moffat (3,000–4,000 ft.). consists of grits, flags and shales with occasional graptolitic intercalations. Wenlock is doubtfully represented near Girvan by conglomerates, grits. flags and shales (joo ft.), with minor graptolitic and shelly layers. Near the English Borders Wenlock conglomerates, grits, graywackes, shales and mudstones (1,000 to 1.500 it.) contain several graptolitic bands with occasional eurypterids, Shelly layers also occur. In the same district Ludlow mudstones with limestone-nodules and grits (500–7jo ft.) yield shells.

Ordovician and Silurian conglomerates usually contain material derived from the Arenig lavas. Quartzite appears as pebbles in the Caradoc, and micaschist in the Llandovery. Undated post-Silurian mineral veins occur at Leadhills.

Devonian.— The Scottish Devonian is wholly continental Old Red sandstone, and except at Stonehaven and Lesmahagow follows older formations with striking unconformity. Three divisions are recognized with distinct faunas and floras. Fish have furnished the majority of determinable fossils. The Lower Old Red Sandstone is most fully preserved in the midland valley (19.000 ft., including lavas. Kincardineshire). Dull purplish brown sandstone is widespread, covered in Strathmore by red sandstones and marls. Conglomerates attain great prominence towards the Highlands and southern uplands. Volcanic rocks (basalts. andesites, rhyolites) occupy a roughly central position in the 10x1-land sequence (6,500 ft. in Ochils. well exposed also Pentlands to Ayrshire). In the Highlands (Oban, Glencoe. Ben Nevis) and also at Cheviot, lavas greatly exceed sediment. Glencoe and Ben Nevis are famous for cauldron subsidences. At both localities granites (or granodiorites) with northeastern dike swarms are later than the lavas. Granites cutting Lower Old Red Sandstone also occur at Distinkhorn (Ayrshire) and Cheviot. Others penetrate folded Silurian (southern uplands). Many undated Highland granites are probably of Lower Old Red age; but granite pebbles are well known in Lower Old Red Sandstone conglomerates (Glencoe, Stonehaven).

Middle Old Red Sandstone is widely developed in northeast Scotland (18,000 ft. in Caithness), extending to Orkney and the Moray firth. It largely consists of flags, often bituminous, calcareous, ripple marked and sun cracked. The Rhynie chert with wonderfully preserved plants is generally referred to this formation.

Upper Old Red Sandstone (some thousands of feet thick) is found in the midland valley and northeast Scotland, everywhere, except perhaps in Shetland. unconformable to its predecessors. Red sandstones with some wind-rounded grains are common in its earlier parts; while paler sandstones with cornstones occur toward the conformable base of the Carboniferous.

Carboniferous.— The Scottish Carhoniferous. a marine, estuarine and terrestrial accumulation; is typically developed in the midland valley and along the English border. The two areas of deposition were always connected across the east end of the southern uplands. Farther west (Sanquhar) Upper Carboniferous rests on Silurian. In the Highlands. Carboniferous is scarcely known (Campbeltown. Bridge of Awe. Morven). In the midland valley and on the borders it follows Upper Old Red Sandstone conformably. but with a palaeontological break. Subdivisions in Edinburgh district are: Calciferous Sandstone series, including Cementstone group (1,000 ft.) and Oil Shale group (3,000 ft.); Scottish Carboniferous Limestone series. including Lon-er Limestone group (700 ft.), Limestone (or Edge! Coal group (1,050 ft.). and Upper Limestone group (1,0jo ft.); Millstone Grit (800 ft.); Productive Coal Measures (1,500 ft.); Barren Red Coal Measures (in Ayrshire. 1.joo ft.). Palaeontologically, the sequence is important for abundant Lower Carhoniferous land plants and estuarine fishes. These are completely replaced by Upper Carboniferous forms one-third way up the Millstone Grit. Spreading deltas may have accelerated migration.

Economically. the oil shale and the two coal-bearing groups (with ironstones) are valuable. Marine limestones are scarcely represented except in the Lower and Upper Limestone groups (near Edinburgh, eight beds reach the quite exceptional total of 230 ft.). A well-known 40-ft. fresh-water limestone (Burdiehouse) occurs in the Oil Shale group.

Rapid variations of group thicknesses are characteristic, as on the two sides of the Kerse Loch fault near Patna in Xyrs'nire. Change of facies is exemplified by restriction of workable oil shale to West Lothian and its borders. Vulcanicity is common till the close of the Rlillstone Grit. Special activity reigned abour the end of the Cementstone group (Clyde plateau, Arthur's Seat, Garleton hills). Products include essexitic basalts, mugearites, trachytes and phonolites. Contemporaneous weathering of Millstone Grit basalts has given valuable bauxitic clay (Ayrshire).

New Red Sandstone.— The Scottish New Red deposits are of continental facies. From Trias on the Solway a train of Permian outcrops reaches intermittently across the southern uplands and midland valley to Arran. In Ayrshire the Permian succession consists of lavas and tuffs (basalt and nepheline-basalt. 500 ft.) overlain by brick-red desert sandstone (1.500 ft.). The volcanic period was one of faulting, and was further marked by ash-necks (also prominent in East Fife) and doleritic intrusions—some (essexitic) carry nepheline. others quartz. It also corresponds roughly with the "Permo-Carboniferous" intrusion period responsible for many quartz-dolerite sills and east to west dikes between Stirling and Northumberland. In Xrran. 2.000 ft. of Permian. mostly brick-red desert sandstone and breccia. underlies 1.000 ft. of Trias, interbedded sandstone and marl with occasional nodular limestone. A mass fallen into a Tertiary volcanic neck includes *Pteria contorta* shales (Rhaetic).

The base of the Mesozoics from Mull northward consists of Trias conglomerates and sandstones with concretionary cornstones. Red colouration is often subordinate. In western Mull 200 ft. of these rocks underlie 40 ft. Rhaetic with *Pteria contorta*. Elsewhere Rhaetic is only doubtfully distinguishable.

In Elgin two outliers of New Red Sandstone have yielded remarkable reptilian faunas. One of these outliers is of marked desert character and is perhaps Permian; the other is certainly Trias.

Jurassic.—Low-lying outcrops of Jurassic, conformable to Trias. are preserved on the west and east coasts of the Highlands. On the west, where a cover of Tertiary lavas has furnished additional protection, the type area. richly fossiliferous. is Skye and Raasay: Lower Lias (Broadford Beds, with prominent *Gryphaea* limestones. 340 ft.; Pabba Shales. 700 it.); Middle Lias (Scalpa Sandstone, 240 ft.); Upper Lias (shales. 80 it.: thinner with 8 ft. ironstone in Raasay): Inferior Oolite (mainly sandstone. 780 ft.): Bathonian Great Estuarine series (hituminous shales with thin shelly limestones. 600 ft.); Cornbrash (limestone with comminuted shells, only in Raasay. 20 ft.); Callovian. restricted (sandstone remnant in Skye); Oxfordian (shales. 120 ft. in Skye); Corallian (calcareous grits and shales, 140 ft. in Skye); Kimmeridgian (shales, 40 ft. in Skye).

At Brora on the east coast are found: Lower Lias (shales with thin coals. 80 ft.); faulted against Great Estuarine series (over 80 ft. shale, sandstone etc.. with 3 it. Brora coal at top'): Callovian. restricted (marine limestone, j ft.); Lower Oxfordian (shales. 275 ft.): Upper Oxfordian (gritty sandstone. 170 ft.); Corallian (limestones. 20 ft.; sandstone and shales 200 ft.): Kimmeridgian (shales and boulder-beds. 1,500 ft.). The boulders of the boulder-beds consist of Old Red Sandstone. Many are big: one measures 150 × 90 × 30 ft. They have fallen from a moving submarine fault scarp and are mixed with corals and shells. The throw of the fault exceeds 2.000 ft. In Skye another 2.000 ft. post-Corallian fault can be shown to have been planed down by erosion before Upper Cretaceous times. Also. in Mull and on the Moray firth the Great Glen fault seems to have stirred in Kimmeridgian times.

Cretaceous.— Transgressive Upper Cretaceous is known *in situ* (Skye. Scalpa. Raasay. Eigg. ?\lull. Morven). as a block in a Tertiary vent (Arran), and as remanié flints (Xberdeenshire). The Morven succession is: Cenomanian Greensand (45 ft.); White Sandstone (35 ft.); Silicified Chalk with *Belemnitella mucronata* (5 it.). The White Sandstone consists of desert sand blown on to the Scottish shore of the Franco-Britto-Russian Chalk sea. Desert conditions presumably reduced river polution to a minimum. In Morven. Cretaceous is still preserved 1.600 ft. above sea level.

Tertiary.— The Cretaceous Chalk was upraised. weathered and silicified and its crannies filled with desert sand (Mull). Subsequent conglomerate, lateritically weathered ash and leaf beds among lavas bespeak a change to moist climate and volcanic eruptions. Botanical research suggests dates ranging from Oligocene to Miocene. Subaerial basalt lavas characterize Skye. Eigg, Mull and Morven. Exceptionally these lavas are columnar (Staffa). The basalt succession in Mull is: olivine-rich flows, 3.000 ft.; olivine-poor, 3.000 ft. The Sgur of Eigg pitchstone seems to he an acid lava that filled a valley, the sides of which, consisting of basalt, have since been eroded away. Great plutonic centres occur at St. Kilda, Skye. Rum, Mull, Ardnamurchan and Arran. Some think that most of the lavas. still preserved, were fed from these centres. A Kilauean sink. repeatedly renewed in central Mull. mas often occupied by a crater lake: and lavas flowing into it developed pillow structure. T'ent-agglomerates are abundant in Skye. Mull. Ardnamurchan and Xrran.

The Skye plutonic centre is well known for its gabbro to granophyre succession: Rum for its peridotites; Mull and Ardnamurchan for their ring-dikes—in Mull the plutonic succession is very complex and begins with granophyre. in Ardnamurchnn it is essentially gabbroidal; Arran is specially noteworthy for the doming of its granite's roof. Peripheral upheaval is also conspicuous in Rum. and peripheral folding in Mull and Skye. Cone-sheet complexes are extensively developed in Skye, Mull and Ardnamurchan. The Skye, Rum. Mull and Arran centres have crowded dike-swarms. The general dike direction is northn-est. Some believe that most of the Hebridean lavas were fed from dikes (fissure eruptions). It is certain, however. that the great centres were established before the dike-swarms. since they locate the latter. It is also certain that most of the dikes are later than any lavas spared by erosion.

West Highland scenery has been shaped entirely since the Tertiary eruptions. The magnificent mountain and valley forms of Skye are cut in Tertiary plutonics.

Possible Pliocene gravel occurs near Turriff, Fyvie and in central Ruchan. all in Aberdeenshire.

Pleistocene and Recent.— During the Glacial period. Scotland functioned as a complex centre of dispersal within the great North European ice sheet. Scandinavian currents were almost excluded except in Shetland, while Scottish currents freely invaded England. Some districts were crossed by ice that traversed the sea bed bringing in shells and. in Caithness, Mesozoic erratics. Glacial erosion is often pronounced. Crag and tail is developed to perfection in Edinburgh and elsewhere. Rock basins are numerous in the Highlands, with Loch Coruisk as a diagrammatic example. Characteristic deposits are: West Highlands, hummocky moraines: East Highlands. fluvio-glacial gravel: Lowlands, boulder clay, either flat or in drumlins, and gravel kames. In Glen Koy glacially dammed lakes are recorded by conspicuous strand-lines; and throughout most of eastern Scotland glacially diverted rivers can he traced by channels now left dry.

Raised beaches up to about 100 ft. occur round Scotland. but not in the Outer Hebrides. Orkneys and Shetlands. The higher beaches are late Glacial and are locally interfered with by glacial readvance (Loch Lomond and Mull). The best-marked beach, often about 30 ft.. has a temperate fauna. It rests in places on a peat or forest bed that continues below sea level. Traces of early man are found in this raised beach. (E. B. B.)

FLORA AND FAUNA

Flora.— The flora of Scotland is much affected by the varied climate to be found in so small a country, by the varied geology and physiography and by the activities of man. The Atlantic climate of the west coast and islands is warm and wet and the rocks are mainly poor and acidic. X general covering of peat with comparatively little glacial drift beneath it grows a sour herbage of sedges (*Carex* and *Eriophorum*) with some heather (*Erica* and *Calluna*) and such northern shrubs as bearberry (*Arctostaphylos*), crowberry (*Empetrum*) and blueberry (*Vaccinium*). An exception is a narrow strip along the west coast of the Hebrides and some of the mainland. where shell sand of high basic content has been washed up by the ocean and blown inland; behind the marram-covered dunes is a flatter expanse of sandy soil with a stable grassland of *Agrostis-Festuca-Trifolium* type, with many calcicolous flowers. Tree growth is sparse or nonexistent on the western coasts where winds are excessive in frequency and strength, but where there is shelter birch woods grow readily, with rowan and willow interspersed. Vestigeal oak and pine may also be found along the fjordlike sea lochs of the mainland. The tree line is low in Scotland, rising from 500 ft. near the west coast to around 2 000 ft. in central Scotland. The west Highlands and islands show vestiges of a Lusitanian flora, for example, pale buttermort (*Pinguicula lusitanica*), dwarf cicendia (C. *pusilla*), and the moss *Myurium hebridorum*.

Glacial drift is commoner across the Grampian hills, toward the east, and in the southern uplands, so heather is much commoner on the still acidic moors, and may attain to an almost unbroken stand. These heather moors are an example of arrested succession, for if left to themselves they nould gradually become woodland of birch and Scots pine, with oak in the better situations. Mankind has left very little pristine oak and pine forest in Scotland, and such stretches as remain are the subjects of earnest efforts towards conservation. The moors are grazed by sheep and are burnt periodically. This form of husbandry keeps the heather young and prevents regeneration of forest, but a consequence in the west is the serious spread of the bracken fern *(Pteris)*. Sheep and burning on heather moors favour the density of red grouse (*Lagopus scoticus*), a valued object of sport. The upper 1,000 ft. of the hills of the Highlands, rising to over 4 000 ft., may be said to carry a more or less pristine flora of boreal mountain grassland with many saxifrages and such miniature shrubs as *Loiseluria* and dwarf willow. Areas of serpulite grit, including Ben Lawers (3,984 ft.) have a rich alpine flora. Some of the eastern hills of the southern uplands carry a grassy flora which under sheep and burning is moving towards a predominance of moor mat (*Nardus*).

In both the Highlands and the southern uplands a good deal of land is now being afforested, mostly nith exotic conifers. Scotland, early isolated from Europe, has but three species. Scots pine. juniper and uncommonly the yew. Larch was introduced about 1725 and since then Norway spruce and many west coast species from North America.

The eastern side of Scotland is highly farmed, much land being on the Old Red Sandstone; natural grassland and untouched places are few. the sea cliffs and some estuarine situations being the only sites which may be said to carry a natural flora. The central plain is in the same case, but there are a few bogs here which hold distinctive plants such as the ericaceous shrubs, *Andromeda polyfolia* and *Ledum groenlandicum*. It is still not unusual to find plants new to Scotland which are common in the subarctic.

Fauna. — The fauna of Scotland is an enviable one for so small a country. The largest wild mammal is the Atlantic gray seal *(Halichoerus)*, which is more numerous off Scottish coasts than anywhere else. The island of North Rona, less than half a square mile in extent, lying nearly 50 mi. N.W. of Cape Wrath, has a stock of some thousands at the autumn breeding season. The common seal (*Phocus*) is fairly generally distributed and locally numerous. The red deer is truly wild in Scotland, one-eighth of the whole country being scheduled as deer forest, and the species ranges over another 1,000,000 ac. of sheep ground. The total number may be between 75,000–100,000. Roe deer are found wherever there are woods or scrub. Feral goats (goats that have gone wild) occur in many deer forests and on a few small islands. Foxes and badgers are common in Scotland. Both species prey extensively on the rabbit, an introduced animal. and. as far as the northern Highlands are concerned, introduced as late as 1845. The wildcat has increased and widened its range in the first half of the 20th century. Otters are common on the river systems. and on small islands they may live wholly on sea fish. The polecat is extremely rare and for some time was considered extinct. Pine martens are probably more numerous than at the turn of the century and may be expected to increase with reafforestation. Nevertheless. there are more pine martens in treeless northnest Sutherland than elsewhere in Scotland. The mountain hare is distinctly cyclic in population and is a pest on hill sheep ground in peak years. The brown hare occurs where there is true soil and agricultural husbandry. not on the hills and peat moors.

The early isolation of various island groups has led to the evolution of distinct types of some animals, notably the voles Differentiation has gone far enough for sub-specific rank to be accorded. Thus, there are the Orkney, Raasay and Mull subspecies of field or bank voles. The same phenomenon is evident in some birds. There are St. Kilda, Hebridean and Shetland wrens and Hebridean starlings and thrushes. The Island of Soay in the St. Kilda group holds a pure stock of a primitive, brown, short-tailed sheep of Moufflon type. The original animals are thought to have been placed there by Norsemen 1,000 or more years ago.

Scotland lost the brown bear in the 9th century, the elk and the reindeer in the 12th. and the beaver in the 16th. These animals could not subsist adequately in Scotland now for the vegetation has so greatly changed. The last wolf was killed in Inverness-shire in 1743.

The bird life of Scotland is rich. though many species found farther south do not occur. Its chief glories are the numerous seabird cliffs thickly populated by auks, fulmars and gannets; the existence of more than 100 pairs of golden eagles; the breeding colonies of the night-flying Leach's fork-tailed petrel on four small. remote islets; and the sight and sounds of green-shanks and black-throated divers in the deer-forest country. Graylag geese still breed in the Hebrides. and certain places are focal points in the wintering of other northern geese.

Most Scottish rivers are run by salmon and sea trout, and many lochs hold distinct races of char. Pike are in many river systems by accident or design, but the muddy-water fish common to English rivers are for the most part absent from Scotland.

Biological exploration of the invertebrate life of Scotland is far from complete and the life histories of many insects already known have not been determined. Summer visitors to the west Highlands appear intensely aware of a tiny dipterous fly known as the midge (*Culicoides*). (F. F. DG.)

HISTORY

The kingdom of Scotland is best dated from the early years of the 11th century when four tribal kingdoms — Scots, Picts, British and Angles, two of which, Scots and Picts, had been united in 843, were amalgamated. The Scots were an Irish tribe who settled, about the beginning of the 6th century. in the district of Dalriada known later as Argyll. The Angles, in the second half of the same century, colonized what became the Lothians'and the counties of Berwick, Selkirk, Peebles and Roxburgh. The British, who occupied the country between the Solway firth and the Firth of Clyde, were akin to the Welsh. The identification of the Picts and Caledonians whom the Romans found in the country in the first centuries of the Christian era has been for generations a subject of controversy. For Scotland in Roman days *see* CALEDONIA, also BRITAIN.

Christian Scotland. — Scottish history has been said to begin with the mission of St. Columba in 563. Columba was an Irishman of noble birth who became a monk and a priest and settled in Iona to undertake the conversion of the portions of North Britain which were still heathen. Iona belonged to the small kingdom of Dalriada, which had. comparatively recently, been founded by the race to which Columba belonged, and its ruler was his kinsman. The Scots had come from Ireland, a Christian land, and had brought their religion with them. and Christianity had persisted from Roman times. or had been revived, in Strathclyde. In the beginning of the 5th century. St. Ninian had preached in Strathclyde and Galloway and had sent his disciples to convert Pictland, and it is very possible that many of the religious foundations in the northeast of Scotland. generally ascribed to St. Columba, really date from an older missionary effort.[1] Some years before St. Columba landed in Iona, a great Christian teacher, known as St. Rentigern or St. Mungo, mas labouring in Strathclyde, and to his mission is traced the foundation of the future city of Glasgow. St. Columba. therefore, cannot be said to have converted Scotland, but he laboured as a missionary in Pictland and he made Iona the centre of Scottish Christianity. In the century succeeding his death in 597 one of the most important contributions made by Scotland to the history of Great Britain was the direct result of his work — the reconversion of the north of England to Christianity. A pagan reaction in the second quarter of the 7th century

[1] W. D. Simpson, *The Historical St. Columba* (1927).

had dethroned the Christian king, Edwin of Northumbria, who ruled from the Humber to the Forth. When his nephew Oswald, who in exile had been educated at Iona, obtained the kingdom of Northumbria by his victory at Hexham in 633 he brought Scottish missionaries to rebuild the shattered fabric of Christianity. The influence of Scotland upon English Christianity was, however, short-lived. There were some differences of method, organization and ritual between the Irish church and the Roman church. Oswald's successor. Oswy, declared in favour of Roman custom, and the Scottish missionaries abandoned Northumbria after the Synod of Whitby (663 or 664).

Picts, Scots and Norse.—The kingdom of Northumbria had by this date reached the height of its greatness and its rulers were ambitious of conquering the north of the island. In 68j a great Northumbrian army invaded Pictland but was defeated at the battle of Nechtansmere. fought near Dunnichen in Forfarshire. This defeat brought the end of Northumbrian supremacy in England; the centre of English power shifted southward and the menace of an English conquest was removed. North Britain was to be left, for some centuries. to work out its own destiny. The Picts became supreme in the north and gained control over both the Scots of Dalriada and the British of Strathclyde. Then the Picts mere weakened by the attacks of the Norsemen, who first attacked the coasts in the end of the 8th century and about 83j began to make permanent settlements. Dalriada threw off Pictish control and in 843. when the Norsemen were attacking Pictland, Kenneth MacAlpin, king of the Scots, established a claim by the Celtic law of tanistry to the Pictish throne.

The union of Picts and Scots was folloned by an attempt to snatch the Lothians from Northumbria, then devastated by the Danish invasions; but the effort was unsuccessful, and Kenneth's successors were themselves engaged in struggles with the Norsemen, who occupied the Hebrides and the Orkney and Shetland Islands and made settlements along the western and northern coasts and on the east coast as far south as the Moray firth. They also attacked the kingdom of Strathclyde and founded colonies between the Esk and Dee rivers. The islands became definitely Scandinavian. as also did a large part of Caithness. During the long conflict with the Norsemen, the Scots sometimes allied themselves with the English against the common enemy from the time that Constantine III took Edward the elder to "father and lord" *c.* 920. and these alliances constituted, long afterward. a ground of the English claim to the overlordship of Scotland; but there were other occasions upon which the Scots joined the Norsemen against the English.

The most important alliance between the Scots and the Norse was made in 937 when the Scottish king. Constantine III was among those defeated by Athelstan of England at Brunanburh (perhaps Burnswark on the Solway). Constantine's object was the realization of a persistent ambition which is, perhaps, the most remarkable feature of Scottish history in the two centuries following the union of the Picts and Scots—the severance of the Lothians from the kingdom of Northumbria. These attempts continued throughout the 10th century, the decisive event being perhaps the grant of Lothian by Edgar to Kenneth II, but not till Malcolm II completely defeated the Northumbrians at the battle of Carham, near Coldstream (c. 1016 or 1018?), was the area between Forth and Tweed secured for the Scottish kingdom. Malcolm was followed in 1034 by his grandson, Duncan, who had already succeeded by inheritance to the throne of Strathclyde, and thus Scots, Picts, Angles and British were all included within the kingdom which came to be known as Scotland. The Norsemen still held the islands; the Hebrides were not recovered till after the middle of the 13th century, and the Orkneys and Shetlands not till the middle of the 15th century, when they passed from Denmark to Scotland through the marriage of the Danish princess Margaret to James III.

ANGLICIZATION AND FEUDALIZATION

Macbeth and Malcolm 111.—Duncan, the Duncan of Shakespeare's Macbeth, the first ruler of the historical kingdom of Scotland. did not experience the "plenteous joys" which brought tears into his eyes in the play. He met with defeats both from the Northumbrians and from the Norsemen, and in 1040 he was slain in a civil war by his own general, Macbeth, who had a claim to the succession, both in his own right, and as the representative of his wife and stepson. Macbeth, whose accession also represented a reaction of the north against a dynasty now associated with the south, was almost certainly in alliance with the Norwegian earl of Caithness and Sutherland, a cousin of Duncan, named Thorfinn. While Thorfinn lived, attempts to dethrone Macbeth, who proved himself an efficient ruler, were unsuccessful, at all events in Pictland, though Strathclyde and the Lothians may have acknowledged Malcolm Canmore the son of Duncan. After Thorfinn's death Malcolm defeated and slew Macbeth at Lumphanan in Aberdeenshire (1057). The kingdom of which Malcolm III took possession was a Celtic kingdom. though one of its provinces was peopled by Angles. Local and tribal custom prevailed alike in Scotland proper (the district north of the Forth and Clyde) and in Galloway; the speech was Celtic; the court and the administrative system, so far as the latter can be said to have existed, were Celtic. The church still retained, to a large extent, the structure and customs of Irish Christianity, although in the beginning of the 8th century a powerful Pictish monarch had ordered his people to keep the Roman date for Easter (one of the points disputed at the Synod of Whitby) and this rule had afterward been followed in Dalriada and probably in Strathclyde. The Celtic church did not repudiate papal authority, but there was no opportunity for the exercise of papal jurisdiction. Diocesan organization did not exist. There was only one bishop of the Scots; his see was St. Andrews and he could enjoy little influence outside-his own neighbourhood. Such organization as the Columban church had originally possessed was based upon powers claimed by the abbots of the monasteries, but the abuse of appointing lay abbots had destroyed the early monasticism, and a later order of monks, the Culdees, which had developed in the 9th century, had no administrative authority.

Queen Margaret.—The disorganized state of the Scottish church, and some peculiar customs which marked its ritual, shocked the conscience of Malcolm's wife, an English princess, Margaret, who, after the Norman Conquest, sought refuge in Scotland along with her brother, Edgar the Atheling. After their marriage in 1070 English influence increased in Scotland, and southern places such as Edinburgh and Dunfermline became the chief residences of the court. For the rest of his reign Malcolm was involved in frequent fighting against William the Conqueror and his sons. Margaret was a woman of saintly life—she was canonized a century and a half after her death—and her own desire was to be a nun. She would have been the glory of a cloister, but she accepted her mission to redeem an ignorant and almost schismatic nation. She was not destined to fulfil that mission herself, but its accomplishment was, nonetheless, her work. There were many difficulties in her way. She could not introduce a diocesan system until there was a vacancy in the one Scottish bishopric and none occurred in her lifetime. She could not reform the monastic system and bring it into line with European monasticism because Malcolm, though amenable in many ways to his wife's influence, refused to surrender the gains which he and other laymen, the great men of the land, enjoyed from the secularization of monastic revenues. She did succeed in changing some Scottish customs. She brought English clergy to convince the Scots of the error of their ways (Malcolm, who had been in exile in England, acting as interpreter); she restored the monastery of Iona which had been destroyed by the Northmen; and she encouraged the Culdees as the nearest approach to the religious life which she admired. Her most important personal achievements were the introduction of an English-speaking court and of English-speaking clergy, and the education of her children in English ways and traditions. She bore six sons to Malcolm, but he was not allowed to give any one of them his own name, or the name of any of his predecessors; four of them were named after Saxon kings of England.

Anglicization of Church and Administration.—Margaret's three sons, who successively came to the throne, had all had some personal experience of English life. Malcolm III and his son Edward were killed in 1093 in one of the raids on the north of England from which his pious wife vainly tried to restrain him. After his death there was a Celtic reaction against the anglicizing influences introduced by Margaret (who was herself dying when her son Edgar brought her the news of the deaths of his father and brother). The English who had followed the queen to Scotland were driven out. and Edgar and his brothers. Alexander and David. took refuge in England. It was with English help that Edgar regained his throne in 1097; he died ten years later and was succeeded by Alexander. and he in turn by David (1124–53). The three brothers were all their mother's sons, and they continued her work. All three were pious and all three were English in tastes and sympathies. and were bent upon converting Celtic Scotland into a feudal kingdom of the Anglo-Norman type. Piety and policy both pointed in one direction: the church was to be one of the most powerful instruments of anglicization. Edgar abandoned Malcolm's palace at Dunfermline and held an English court at Edinburgh. Alexander suppressed a Celtic rebellion in Moray and Mearns so efficiently that he earned the description "the Fierce." and he followed up his victory by founding a house of Augustine canons at Scone (the coronation place of the Pictish kings and their Scottish successors) and filling it with English monks. The anglicization of the country, outside the western and northern Highlands, was to a considerable extent the result of ecclesiastical influences. Alexander I and David I planted English monasteries in many districts of Scotland, south of the Moray firth. and endowed them so liberally that David acquired a popular reputation for sanctity.

The plantation of monasteries was accompanied by a diocesan organization of the church. This was essential for efficient ecclesiastical administration and for the exercise of papal supremacy, but it was also useful as a means of furthering royal policy. The new bishops were English. their sees were richly endowed with lands, and their religious authority was enhanced by their position as territorial magnates. Diocesan organization was delayed by claims asserted by the sees of Canterbury and York to possess superiority over the church in Scotland. Two Englishmen in succession. Turgot. the chaplain and biographer of Queen Margaret, and Eadmer, the ecclesiastical historian. were elected to the see of St. Andrews. but Turgot acknowledged the superiority of York and Eadmer that of Canterbury, and neither was allowed to reside in Scotland. Alexander I would not tolerate pretensions which, apart from introducing complications into the relations between church and state. were likely to compromise the independence of the Scottish crown. Ultimately, on Eadmer's death in 1124, Robert. the English prior of the new monastery at Scone, was consecrated to the see of St. Andrews by the archbishop of York, without prejudice either to the claims of York or to the freedom of the church in Scotland. Under David I the process of organization went on rapidly. and all the mediaeval Scottish dioceses except Argyll had been founded by the end of his reign.

David I was more familiar with English ways than any of his brothers. His sister was married to Henry I and he spent some years of his youth at the English court, made friends with Anglo-Norman barons and married the widow of one of them. He changed his system of land tenure in Scotland by making to his English friends grants of land. on the model of the charters granted by the Anglo-Norman kings of England. The first of the Scottish Bruces, for example, received by charter a grant of over 200.000 ac. in Xnnandale. and the progenitor of the house of Stewart crime to Scotland as the king's steward and the recipient of charters conveying great tracts of land in Ayrshire and Renfrewshire. There was no dispossession of the existing landowners: they were to hold their rights, in future, from the new lord instead of directly from the crown. Such charters were granted not only to newcomers. but also to great landlords who had hitherto held their lands by tribal custom and were glad to receive written guarantees of their possessions and privileges. Gradually the whole of the land. outside the Highlands. came to be held under feudal law, and the landowners, whether Anglo-Normans or representatives of the old Scottish families (who intermarried with David's new nobility), were. like the monks and the bishops, inevitably instruments of the royal policy of anglicization. The civil! as well as the ecclesiastical, organization was gradually remodelled in accordance with English (and European) institutions, and under David and his successors great officers of the household (whose functions were analogous to the duties of later administrative departments) came into existence. The English office of sheriff was borrowed for purposes of local government, and the old tribal laws of the component parts of the kingdom were replaced by adaptations of English legislative measures. To the influences of an English court, an English church. and an English system of law and land-tenure were added the effects of English trade. Commerce was mostly with England and from England was adopted the institution of the burgh. The early Scottish burgh charters were all founded on English models and colonies of English (and Flemish) merchants settled in Scottish towns. These processes. initiated under the sons of Queen Margaret, had a continuous development until the outbreak of the War of Independence. A series of Celtic revolts against the anglicizing policy of the crown occurred in the course of the 12th century and in the beginning of the 13th. but they were all suppressed (sometimes with English help) and before the death of Alexander III in 1286 the organization of Lowland Scotland. from the Moray firth to Tweed and Solway, was definitely English, and the English tongue was spoken in a large portion of the area.

Relations with **England.**—While this process of anglicization was in progress, political relations with England were not, for many years. entirely friendly. The border line between the two countries had not been definitely ascertained. As the rulers of Strathclyde, the Scottish kings had some claim to Cumberland and Westmorland, and they cherished an ambition of annexing portions of the old Northumbrian kingdom beyond the Tweed. The raids of Malcolm III (Canmore) had led William I to found Newcastle-upon-Tyne in 1080 and William II to fortify Carlisle in 1092, and the boundary line might be regarded as stretching from the Tyne to the Solway, although the English did not admit Scottish claims between Tweed and Tyne. Matilda, the wife of David I, as daughter of Waltheof. brought him the earldom of Huntingdon and 'some claim to that of Northumbria. Henry I recognized his brother-in-law's claim to the former, but refused to acknowledge that Northumbria had passed to Matilda from her grandfather. Earl Siward. When the English throne was disputed between Stephen and the empress Matilda, David invaded England in support of the empress. who was his niece. His real purpose was to take possession of Northumberland and he succeeded in effecting it in spite of his defeat at the battle of the Standard, fought near Northallerton in Xug. 1138. Stephen, whose wife was also a niece of David. granted Northumberland as an English fief to Prince Henry, the heir to the Scottish throne. The gift did not secure David's loyalty, for when the future Henry II made his first, and unsuccessful. attempt to gain the English throne in 1149. David aided him and was promised the whole area north of the Tyne. This promise was repudiated by Henry II on his accession in 1154. David had died in 1153, his son had predeceased him, and his young grandson, Malcolm IV (1153–65), had to surrender David's territorial gains. so that in 1157 the boundary of the kingdoms became fixed at Tyne and Solway.

The ambition of annexing Northumbria continued to guide Scottish policy, and William the Lion (1165–1214), the brother and successor of Malcolm IV, hoped to attain it by joining the English rebels against Henry II in 1173–74. His capture near Alnwick in July 1174 not only put an end to such expectations but resulted in the temporary loss of Scottish independence. The 10th-century alliances against the Danes were by this time interpreted in England as having involved a feudal subjection of Scotland to England and, since the time of William the Conqueror, the Scottish kings had held English fiefs and had done homage for them. The precise nature of this homage had not been defined and the meaning of the ceremony had been left deliberately ambiguous. What the Scottish kings gave as homage for English lands. English kings could receive as homage for the crown of Scotland. Henry released William only after forcing him to consent to the treaty of Falaise (1174) by which he did homage avowedly for the Scottish crown. The treaty was cancelled 15 years later by an agreement between William and Richard I, who sold the rights extorted by his father, receiving in return a sum of 10,000 marks required for the third crusade. The bargain merely annulled the treaty of Falaise and left the question of homage precisely where it had been in 1174. One ancient controversy was, however, settled immediately after the agreement was made. The treaty of Falaise had also admitted the subordination of the Scottish to the English church, but its provisions did not come into operation because of the rival claims of Canterbury and York. In 1192, after the close of a controversy between William the Lion and the papacy. Pope Celestine III issued a Bull declaring the Scottish church to be the special daughter of the Holy See, "with mediation of none." The church in Scotland was still denied the privilege of a metropolitan see, although in 1225 Honorius III granted the clergy permission to hold regular provincial councils under the presidency of an elected "conservator of the privileges of the Scottish church." It was not till 1472 that St. Xndrews was given metropolitan jurisdiction in Scotland; 20 years later a province was detached and placed under the newly founded archbishopric of Glasgow.

The Golden **Age.**—William the Lion (the ascription of that title to him is an unsolved problem) continued to hope for the restoration of Northumberland. He offered to purchase it in 1194, but refused to accept it when Richard I proposed to exclude from the bargain the right of holding fortified castles; and he made further unavailing efforts, including an admission of the right of King John to choose a wife for his son Alexander, the heir to the Scottish throne? as well as to the possessions of the Scottish royal house in England and to their Northumbrian claims—a dangerous expedient in view of English pretensions to overlordship. Alexander II (1214–49) tried to seize Northumberland during the struggle which followed the grant of Magna Carta; but in 1236, by the treaty of York, he resigned his claims to the earldom of Northumbria and also his possessions in Huntingdon in return for a grant of lands in the north of England. His reign witnessed the last of the Celtic revolts against the policy of anglicization, and in his later years Scotland entered upon a period of consolidation and prosperity which continued throughout the reign of his son. Alexander III (1249–86). The recovery of the Western Isles, which had been under Norse rule, was achieved by Alexander III after the battle of Largs (1263), in which the Norwegians were defeated. In 1266 Eric of Norway surrendered the Hebrides in return for a money payment. There was continuous peace with England. Alexander was the nephew and also the son-in-law of Henry III, and his relations both with him and with his brother-in-law, Edward I, were on the whole friendly. The borders, about to be the scene of almost incessant fighting for two and a half centuries, were quiet and peaceful. Later tradition did not err in regarding the reign of the last of the old line of Scottish kings as a golden age. His death closed the period of anglicization and in the later middle ages Scotland drew its inspiration rather from France than from England.

THE WAR OF INDEPENDENCE

The Succession Problem.— Alexander III was killed by a fall from his horse in March 1286. His two sons and his daughter had predeceased him and his only living descendant was his daughter's infant child Margaret. daughter of Eric of Norway. Her age, her sex and her nationality would have combined to prevent the succession of the little Maid of Norway, if there had been any adult male claimant nearly related to the late king. But Alexander left neither brother, nephew nor cousin, and there was no living legitimate descendant of any Scottish monarch later than David I. Of the three grandsons of David, two, Malcolm and William, had succeeded to the throne. The third, David, who had been given the English earldom of Huntingdon, had left a son and three daughters. The son had died without issue; the eldest daughter had married an Anglo-Scottish baron. and her grandson John Balliol (through her daughter. Devorguilla, the foundress of Balliol college at Oxford) was, by the theory of primogeniture, the direct heir to the crown. But the rule of succession by primogeniture was not yet firmly established, and the claim of Balliol was disputed by Robert Bruce, the son of the second daughter of David of Huntingdon. Bruce argued that a grandson. being closer in descent to the grandfather from whom the claim was derived, was his true representative, rather than a great-grandson who was separated from him by an additional generation. Years before, when Alexander II was childless, Bruce had been recognized as heir presumptive, and the birth of Alexander III had deprived him of a chance which in 1286 he held to have recurred. The Scots were thus faced by a choice between the minority of a baby girl who was the daughter of a foreign sovereign, and a civil war between two Scottish claimants. The nobles decided that the former was the lesser of the two evils, and the Great Council of Scottish tenants-in-chief, clerical and lay, appointed guardians to conduct the government in the name of Margaret of Norway.

English Intervention.— At first, it seemed as if the choice were to involve the country in both evils: for the Bruce party began to raise a rebellion, but Edward I of England, a great-uncle of the baby queen. intervened to secure her throne. This intervention was welcome in Scotland; in the late king's minority, his father-in-law. Henry III, had taken part in Scottish politics, describing himself as principal counsellor to the king of Scots rather than claiming overlordship. Edward I now made no pretension to the right and duty of an overlord to act as guardian during a minority. The long continuance of peace with England, and the two centuries' tradition of the adoption of English speech. manners and institutions, made it natural for him to offer. and for the Scots to accept, a guarantee of the succession of the little Maid. Edward, in fact, devised the statesmanlike scheme of a union of the two crowns by the marriage of the heiress of Scotland to his son Edward (afterward Edward II). English, Scottish and Norwegian commissioners met to discuss the question, and in the summer of 1290 the treaty of Birgham-on-Tweed defined the conditions of the marriage. In proposing his scheme, and in the terms of the treaty. Edward showed every consideration for Scottish feelings, and it was provided that after the marriage, and even after the succession of a son of the marriage to both crowns, the two kingdoms should remain separate organizations. Doubtless Edward hoped that a union of the kingdoms would follow a union of the crowns, but he was content to lay the foundations of that union. Further, it was agreed in the treaty that, should there be no heir of the marriage, the crown of Scotland was to revert to the proper heirs and the kingdom of Scotland was to be "free in itself, without subjection, as it hath hitherto been." Any rights, pertaining to the crown of England were reserved, but these rights were neither asserted nor defined.

The agreement promised a peaceful future for both countries, as far as their relations with each other mere concerned, hut within two months the Maid of Norway died on her way to Scotland (Sept. 1290). Civil war between the Bruces and the Balliols was inevitable. and each party wished to secure Edward's support. During the minority of Alexander III the Bruce family had supported the policy of Henry III in Scotland. and Robert Bruce, the claimant, was. like Balliol. an English landowner, had held high official positions in England. and had fought with Edward during the Barons' Wars. There are indications that he would have acknowledged English overlordship in return for Edward's support, but such a bargain would not have fulfilled the purpose which Edward had begun to cherish—the reduction of Scotland to the position of a vassal kingdom of England. A compact with the Bruces would only have resulted in placing behind Balliol all who upheld Scottish claims to independence, and Edward was determined to obtain an acknowledgment of his paramount authority from all the 12 competitors—there were rivals to Balliol and Bruce, but with clearly inferior pretensions. After collecting evidence from monastic chronicles about the history of the overlordship controversy, Edward asked the Scottish nobles to meet him at Norham-on-Tweed in May 1291. There he at once announced his intention of establishing his claim to be the feudal overlord of the kingdom of Scotland, and he gave the Scottish magnates some days to consider their attitude. Meanwhile, a great English army was assembling on the opposite bank of the Tweed. Edward's claim was not entirely repugnant to an assembly consisting largely of Anglo-Norman barons, some of whom held lands in England as well as in Scotland, and, after a protest had been entered in the name of the "community" of Scotland the English overlordship was admitted and the admission was duly recorded. The lord paramount then ordered an enquiry into the claims of the various competitors. who were reminded that any symptoms of recalcitrance would be followed by a declaration that the kingdom, owing to failure of heirs. had reverted to the overlord. Edward then made a progress as far north as Perth, through the kingdom of his (as yet unidentified) vassal.

Balliol's Revolt.—In Nov. 1292 Edward, after a judicial investigation, gave his decision in favour of John Balliol, thus defining the right of succession in accordance with the later rules of primogeniture. Within three years the vassal king mas in revolt against his overlord. who had subjected him to ignominious treatment. Whether Edward deliberately intended to produce this result is uncertain. Balliol's character and disposition suggested that he would submit to almost any humiliation rather than face Edward's wrath and, if the English king did contemplate a conquest of Scotland, he cannot have wished to undertake it in 1295, when he had on his hands a Welsh rebellion, a French war and serious domestic quarrels. Edward, in insisting on the letter of a feudal suzerain's right, showed no appreciation of incipient Scottish nationality. The remark attributed to him when news was brought of Balliol's alliance with France, "Has the fool done this folly?" indicates that he was surprised by the audacity of his vassal. Balliol, indeed, seems to have been compelled by Scottish opinion to take action. Edward at once assembled a powerful army to give effect to a new claim—that Scotland, as the fief of a disobedient vassal, had passed by forfeiture into the direct possession of the feudal superior. The strength of Scottish feeling is illustrated by the stubborn resistance offered by the Anglian population of the prosperous mercantile town of Berwick-upon-Tweed, where English rule might have been expected to be more welcome than in any other part of Scotland. Edward took vengeance by a merciless massacre (the first act of warfare for nearly a century) and gave a precedent for a cruel and relentless struggle. At first it seemed as if the conquest mere to be a very simple process. Scotland mas divided—the Bruces denied support to Balliol—and Edward, easily defeating a Scottish army at Dunbar (April 1296), made a triumphal march through Scotland. The annexation of the country and its loss of the status even of a vassal kingdom was emphasized by the destruction of the Great Seal and by the removal to London of the national records and of the "Stone of Destiny" upon which the Scottish kings were crowned. In October Edward returned home, leaving Scotland under a military occupation.

William **Wallace.**—English soldiers and officials were far from tactful; but the explanation of the revolt that followed is not to be found in garrison outrages. The lay magnates who had accepted the English overlordship were largely of Anglo-Norman blood; the smaller landowners and the lower classes of the population nourished a stronger dislike to English rule than did their natural leaders who had deserted the cause of independence. They found at once a nen. leader in Sir William Wallace, a younger son of a Renfrewshire landowner, and it was soon proved that only leadership was wanted to enlist an army of soldiers drawn from all parts of Scotland. including the Highlands. On Sept. 11, 1297, Wallace, as commander of "the army of the commons of Scotland." routed the English army of occupation at Stirling bridge, and for a year he ruled Scotland in the capacity of guardian for John Balliol. Meanwhile. Edmard I, relieved both of foreign and of domestic anxieties, prepared to lead an army to Scotland in person. At Falkirk, on July 22, 1298, he defeated Wallace, who escaped but resigned his office of guardian. The victory did not, hon-ever, restore the English to the position they had held in 1296. The spirit of resistance. thoroughly awakened. was not dismayed by defeat. New guardians were appointed, including Robert Bruce, the future Robert I and grandson of the competitor, and Edward, summoned to London by fresh domestic complications, had to leave Scotland unconquered. It was not till the autumn of 1303 that he was able to undertake operations on a scale adequate for his purpose. He brought a great army to Scotland in September, traversed the country. met with little resistance, and spent the winter in Scotland. In the summer of 1304, having captured Stirling castle, he again left behind him what he believed to be a conquered country. In 1305 Wallace was captured, and in August the noblest of Scottish patriots was put to the cruel death prescribed by English law for a traitor.

Robert Bruce.—Six months later, Robert Bruce and John ("the Red") Comyn. both of them ex-guardians of Scotland, met secretly in the Greyfriars church at Dumfries. Comyn was a nephew by marriage of Balliol and was regarded as the representative of the Balliol claims. A meeting of the only two possible candidates for the Scottish throne must have been held for the purpose of adjusting their claims with a view to further resistance. The result of the conference was to make resistance inevitable and immediate. There was a quarrel, and Bruce stabbed Comyn; his followers dispatched the wounded man. It was impossible for Bruce to conceal his real aims from Edward, and! though he had made no preparations for resistance, he was crowned in March 1306 at Scone. His chances of success seemed slight. for the kindred and friends of the great families of Balliol and Comyn were violently hostile to him; and the clergy, who had hitherto supported the cause of independence, were likely to be alienated by a crime which combined murder with sacrilege. A defeat at Methven. near Perth. in June, might well have put an end to the rising, and Bruce's failure in the battlefield was followed by other misfortunes. He spent the winter of 1306–07 as a fugitive—his adventures are described in Barbour's *Bruce* and in Sir Walter Scott's Lord *of the Isles* and *Tales of a Grandfather*. But Bruce was to prove himself a great national leader, the determination of the Scots to regain their independence had been strengthened by the death of Wallace, and even the clergy did not desert the new monarch in spite of a papal excommunication. In the spring Bruce appeared on his own lands in Ayrshire, and in May he won a victory at Loudoun hill in the same county. Then an event happened which changed the whole situation. Edward I had spent the winter at Lanercost abbey in the north of England, and had moved to Carlisle, where in March he sentenced to death two of Bruce's brothers who had fallen into his hands. On hearing the news of Loudoun hill he resolved to lead his army to Scotland in person, but he died at Burgh-on-Sands on July 7 and his successor abandoned the campaign.

Edward II probably had adequate reasons for returning to London, but he missed a great opportunity in Scotland. One of his father's difficulties had been that Scottish barons and bishops were ready to take. and just as ready to break, oaths of allegiance to the sovereign of England. He could not rely upon the unfailing support of any Scottish family or faction. The murder of Comyn had accomplished what all the first Edward's oaths had failed to achieve—the creation of an English party in Scotland which could be trusted unswervingly to maintain English interests. There was an irreconcilable blood-feud between Ring Robert and the friends and adherents of the murdered Comyn. Edward II left this party without support and without any definite plan of campaign, and between 1307 and 1310 King Robert crushed its members individually. A futile and half-hearted invasion led by Edward in 1310 did nothing to retrieve the balance and for the next four years Bruce, with the help of his brother Edward and of the "Black" Douglas. not only expelled English garrisons from Scottish castles but was able to inflict great damage by raids upon the northern counties of England. At last, in 1314, Edward II made a serious effort to recover his father's conquest and suffered at Bannockburn (June 24) the greatest disaster which an English army had ever sustained. The fight was not of Bruce's seeking; he had avoided a general action in 1310 in accordance with the usual Scottish policy of guerrilla warfare. A pitched battle was too great a risk in view of the comparative resources of the two countries, and it mas an imprudent challenge accepted by Edward Bruce from the English governor of Stirling castle in the summer of 1313 that led to what proved to be the only successful battle on a great scale ever won by the Scots over the English. But Bannockburn was won, and it was sufficient for the vindication of Scottish independence. The English stubbornly declined to admit the accomplished fact. For many years Bruce carried terror into the northern counties and he also dealt a serious blow to English dominion in Ireland. It was not till after the deposition and murder of Edward II that the regents for his son, Edward III. agreed to the treaty negotiated at Edinburgh and ratified at Northampton (1328) by which England acknowledged the independence of the kingdom of Scotland.

Revival of the Conflict.—In the following year King Robert died, leaving as his heir a son, David I1 (1329–71), who, though only a child of five. had already been married, in accordance with a provision of the treaty of Northampton. to Joanna, a daughter of Edward II. In 1330 Edward III threw off the yoke of his mother and her paramour, Mortimer, who had deposed his father, and a new phase of the War of Independence began. It was then that the most disastrous effects of the murder of Comyn began to operate. Bruce had vanquished the Scottish opponents whose bitter enmity that deed had provoked. but they had resolutely refused to acknowledge his sovereignty or, in the mediaeval phrase, to "come into his peace." Their estates had been forfeited and they had taken refuge in England. Thus. when England had again a strong king and Scotland a weak one, there was at the English court a body of "disinherited." as they were called, who urged the young Edward to wipe out the shame of Bannockburn and Mortimer's treaty of peace. Though not included in the terms of the treaty some promise to restore the disinherited seems to have been made, but the Scottish regent. Randolph, earl of Moray, a nephew of King Robert. felt that it was not safe to take this step while the king was a child and to antagonize the new possessors. It was an ominous circumstance that the new English king had invited from France Edward Balliol, the heir of John Balliol. who was known to be contemplating an attempt to regain his father's vassal throne. In the summer of 1332, while England and Scotland were officially at peace, Edward III connived at Balliol's leading an army of the disinherited for the recovery of Scotland. The earl of Mar, uho had just succeeded to the regency on Randolph's death, was defeated by Balliol at Dupplin moor (Aug. 1a. 1332), and in September Balliol was crowned at Scone as Edward I of Scotland. The English king then openly espoused Balliol's cause and, abandoning his grandfather's final policy of complete annexation, reverted to the earlier project of a vassal kingdom

Before Edward III could come to Balliol's assistance his vassal had been ignominiously driven out of Scotland, but he led a large army to the siege of Berwick-upon-Tweed, which had been recovered by Bruce in 1318. The Scots suffered a crushing defeat at Halidon hill, near Berwick (July 19. 1333), and the town fell into English hands. Edward then modified his consent to the revival of the vassal kingdom by extorting from Balliol a cession of most of the southeast of Scotland (including the counties of Linlithgow, Edinburgh. Haddington, Berwick, Selkirk, Peebles and Roxburgh). This district passed under the administration of English officials, but Balliol. in spite of successive invasions of Scotland by his overlord in the years 1334–37, never established himself as king. Then there occurred another change in the political situation, involving effects similar to those which had followed the death of Edward I, 30 years earlier. In the autumn of 1337 Edward III, partly because of Philip VI's support of the Scots, entered on the long war with France, and he at once lost interest in Edward Balliol's feeble pretensions and even in the defence of the ceded territory. The Scottish regents were left, as Robert Bruce had been left, to suppress Scottish traitors and expel English garrisons, until, by 1341, Perth, Stirling and Edinburgh were in Scottish hands. the English had been driven out of a large area in southern Scotland. and the young David II was brought back from France, whither he and his English queen had been sent for safety in 1334.

The Franco-Scottish Alliance.—The diversion of English ambition from Scotland to France really marked the close of the War of Independence, but it also inaugurated a new series of hostile relations between England and Scotland. Although John Balliol had made his original defiance of Edward I in the assurance of support from Philip IV of France, the help given by the French in the earlier stage of the struggle for independence had been negligible. In 1298 Philip had agreed to a truce, and again in 1303, the darkest hour in Scottish history, he had concluded a permanent peace with England. When the struggle began again, however, the French under Philip VI had given refuge to the young David II and French support of Scotland was one of the reasons for the English attack upon France. When that attack began in earnest in 1346 Edward III offered to restore the portions of Scotland which were still in English hands on condition of Scottish neutrality in the Anglo-French war. The Scots made a decision which on several later occasions they declined to revoke. The explanation of their persistent adherence to a Franco-Scottish alliance lies in their conviction that no peace with England could possibly be permanent. If the English became the masters of France, they were not likely long to acquiesce in the existence of a small independent kingdom on their northern borders. If they failed to establish English dominion in France they we e equally sure to seek such compensation as a conquest of Scotland would afford, and the Scots, if they deserted France in its hour of need, could expect no help in their own. The Franco-Scottish alliance as a factor in European history. began in 1346, when the Scots, invading the north of England in the interests of France. were defeated with colossal losses and David I1 himself captured at the battle of Neville's Cross, fought near Durham on Oct. 17, about two months after Crécy. The English at once reoccupied a large area of southern Scotland and thus provided an unanswerable reason for the maintenance of Franco-Scottish friendship. While England held portions of France and of Scotland, an alliance of the two victims was inevitable. There was, indeed, no other bond of union between French and Scots, and the political alliance was by no means always a happy or cordial arrangement, although France took, in the development of Scottish civilization, the place which had been held by England before the War of Independence, and profoundly influenced Scottish law and institutions as well as manners and customs.

The Ransom of David 11.—Scottish intervention in the Anglo-French war proved to be rather irritating than actually dangerous to England, and Edward III made a remarkable attempt to get rid of the complications which it involved. His prisoner. David II, was childless and extravagant; he hated his heir, Robert the Steward, the son of his half-sister and his own senior by some years. David was released in 1357 and the Scots undertook to pay a heavy ransom in instalments spread over many years. The Scottish crown was thus impoverished and David, who had been kindly treated in London and had made many friends in England. listened to a suggestion of the English king that the ransom should be commuted for an acknowledgment of an English prince as the heir to the throne of Scotland. The son of Robert Bruce actually made this proposal to the Scottish parliament, which contemptuously repudiated it. The long-continued negotiations for the ransom of David II accelerated an important development in the parliamentary constitution of Scotland. Whatever it may have derived from the Celtic heritage of the kingdom, the great council of the land had been organized by the descendants of Malcolm Canmore upon an English model. It was both the supreme court of law and an advisory council of the sovereign, and it was composed of the tenants-in-chief, clerical and lay. To these two estates of the realm. the clergy and the barons, was added in the 14th century a third estate, consisting of representatives of the royal burghs. Burghs had first been summoned to attend the king in parliament when Robert I's financial needs were urgent, in 1326, and they were called again to assist the return from France of David II in 1341. Their help was now required in greater measure for the payment of the ransom, and it was therefore necessary to secure their concurrence in the decisions taken by parliament. The presence of burgess representatives in parliament or in the less formal meetings of the estates known as general councils was thus continuous from 1357. It cannot be shown to have exercised any notable influence upon either the authority or the policy of the crown, but its influence may be traced in a long series of legislative measures dealing with trade, commerce and police.

THE CONFLICT BETWEEN THE CROWN AND THE BARONS

The Early Stewart Kings.—The War of Independence and the subsequent warfaré with England deeply affected the relations between the crown and the great baronial families. The distribution of the estate of the disinherited among Bruce's supporters was one of the causes of the dangerous greatness of the house of Douglas and of other Scottish families. and in the course of the English wars the crown was frequently weakened by the premature deaths of monarchs and by the recurrence of minorities. The initial weakness of the crown after the death of Robert I was, however, due not to such accidents but to the personality of his first three successors. David II was a futiie ruler and a worthless man, and the determination of the Scots to maintain their independence receives additional proof from the circumstance that his reign did not witness its loss. When he died in 1371 the nephew who succeeded him, Robert II (1371–90), the first monarch of the house of Stewart. was jj years of age and already worn out by a strenuous public life. His reign was largely spent in conflict with England, but he took no part in the warfare. Scotland had been included in truces between England and France. and when the Anglo-French struggle entered on a new phase in 1377 the Scots renewed their efiorts to expel the English from the occupied country in the south. Their success provoked invasions by John of Gaunt 'and by Richard II, which resulted solely in devastations of Scottish soil. The best remembered incident was the battle of Otterburn (1388), a chivalrous and romantic episode, but negligible as a military event. The next king. Robert III (1390–1406), was a lame old man who with some reason described himself as "the worst of kings and the most wretched of men." His legitimacy was doubtful, his parents having only been married with papal dispensation 10 years after his birth, and he made no effort to repress the disorders which were rampant in the country. During the early years of his reign the government was in the hands of his younger brother, the earl of Fife. whom he created duke of Albany. but in 1399 his eldest son, the duke of Rothesay. ousted his uncle from the regency. There was a bitter feud between Rothesay and Xlbany and in 1401 Xlbany recovered power. In the following year Rothesay died mysteriously at Falkland (the story is told in Sir Walter Scott's Fair *Maid of Perth*), and rumour. which has crystallized into tradition. ascribed his death to Albany. The old king was alarmed by the fate of his heir and early in 1406 he sent his remaining son, Prince James, to be educated in France. The boy was captured by the English at sea and Robert III died when the news reached him. The reign of James I nominally covers the years 1406–37, but he was a prisoner in England until 1424, and during this period Scotland was governed by Xlbany until his death in 1420 and thereafter by his son. Murdoch, 2nd duke. The regency of the elder Albany witnessed the foundation of the first Scottish university (St. Andrews, 1411a)—partly an endeavour to repress the Lollard heresy which had reached Scotland—and the battle of Harlaw, mhich has frequently been misinterpreted as a decisive struggle between Celt and Saxon in Scotland. It was. in fact, a fiercely fought skirmish between Donald of the Isles. a grandson of Robert II, who claimed the earldom of Ross in right of his wife. a member of a lowland family, and the burghers of Aberdeen, reinforced by the earl of Mar and other Aberdeenshire lairds. Donald. having defeated the Mackays and the Frasers (Highlanders who opposed his claim), n-as inarching to plunder the town of Aberdeen. Like other disaffected Scottish barons. he had made an alliance with England, and Harlaw was an episode in Anglo-Scottish warfare. Xlbany made considerable progress in the recovery of southern Scotland from the English. and he also encouraged the recruitment of Scottish soldiers for the struggle in France. In the year after his death the Scots rendered their most distinguished service to the French in helping to win the victory of Baugé (1421), the first French success since the invasion of France by Henry V of England.

The first two Stewart kings had been feeble rulers and though the elder Albany was a strong man his position, and possibly his personal ambitions. prevented him from suppressing the feudal anarchy which threatened the monarchy and paralysed the central administration. while his son was weak and easygoing. James I, who was released on payment of a ransom in 1424, was fearless and determined and he resolved to establish order and good government—in his own words, to "make the key keep the castle and the bracken bush the cow." He was merciless in his treatment of the great barons and he roused many enemies. He tried to find support for his reforms by making bicameral the general council or parliament, as he had seen the English parliament to be, and by introducing representatives of the shires; but the statute passed in 1428 for this purpose was inoperative. Nonetheless, the parliaments of the reign passed a long series of beneficent legislative measures; the king's difficulty lay in enforcing them. In 1437 he fell a victim to a conspiracy organized by his uncle. the earl of Athol, who, as the indisputably legitimate son of Robert II's second marriage, claimed to be the rightful king. His son and successor James I1 (1437–60) was a child of six and the advance made by the central government during the personal rule of James I was lost in the intrigues and factions of a minority. When James II began his personal rule the great house of Douglas, in spite of sustaining a severe blow by the murder of its young chief in the course of the royal minority, was a grave danger to the supremacy of the crown. James found a pretext for invading the Douglas dominions while the 8th earl of Douglas was on a pilgrimage to Rome. and Douglas, on his return, made a league with his three brothers. Archibald. earl of Moray. Hugh. earl of Ormond, and John: lord of Balveny, and with a great northern magnate, the earl of Cramford. The king heard of the league and sent for Douglas to Stirling castle, giving him a safe-conduct. The earl refused to break the bond into which he had entered and James. losing his temper, stabbed him fatally (Feb. 1452). An obedient parliament found that the earl was "guilty of his own death by resisting the king's gentle persuasions to aid him against rebellious subjects." but the murder was necessarily the signal for a final conflict between the crown and the house of Douglas. James defeated the Douglases on the battlefield at Arkinholm, near Dumfries, and captured their strongholds; and the 9th earl fled to England to reappear in Scotland in the next reign.

Recovery of Southern Scotland.—The Douglases had been involved in many intrigues with England, but they had played a notable part in the recovery of southern Scotland and by the year 1460 this task had been completed except for the town of Berwick-on-Tweed and the castle of Roxburgh; the town of Roxburgh, once one of the leading Scottish burghs, had been entirely destroyed in the course of more than 160 years of almost continuous warfare. The outbreak of the Wars of the Roses in England afforded a suitable opportunity for the recovery of the castle and James besieged it in the summer of 1460. He himself. interested in the growing use of artillery. was watching the operations of his gunners when he was hit and killed by "a piece of mis-framed gun that brak in the shooting." and Scotland was again plunged into the woes of a minority. Roxburgh castle mas taken a few days after the king's death, and with the expulsion of the English from Scotland the real reason for the Franco-Scottish alliance had come to an end. While the English held large portions of France and of Scotland alike, an alliance of their two enemies was inevitable. and James I had repeated the Scottish refusal of English offers of friendship on condition of Scottish neutrality in the French war. The Scots had rendered greater military assistance to the French than they had received from them. but it mas the French who bore the brunt of the conflict against the common enemy. and in negotiations with the English they never failed to protect Scottish interests. By 1460 the alliance had served the purpose for which it was formed; the English held only Calais in France and Berwick in Scotland. During the minority of James III (1460–88) the Scots took advantage of the civil war in England to obtain the cession of Bern-ick-on-Tweed from

Margaret of Anjou, the wife of Henry VI, giving in return some help to the Lsncastrian cause. Edward IV retaliated by an intrigue with John. Lord of the Isles, and the exiled Douglas but the Scots recognized the accomplished fact of Yorkist supremacy in England and a truce for 15 years was made in 1464.

James **III** and **IV.**—During the first years of the minority of James III, Scotland was ruled by a statesman. Bishop Kennedy of St. Andrews, and though there were troubles after his death, the young king, when he assumed the government in 1469, began his reign in fortunate conditions. There was peace with England; his father had destroyed the perilous greatness of the Douglases; his marriage with Margaret of Denmark led to the acquisition of the Orkney and Shetland Islands, which had been Scandinavian for centuries; and the prestige of the kingdom was enhanced by the creation of the metropolitan see of St. Andrews in 1472. Four years later the lord of the isles was reduced to submission by an army led by some of the great barons whose ambitions had hitherto been dangerous to the crown. Yet James 111 was one of the most unfortunate of the Stewart kings. His nobles complained that he "delighted mair in music and policy of building than in the government of his realm," and they preferred his brother, the duke of Albany. The brothers quarrelled, Albany fled to France, and James was sufficiently unwise to break the truce with England. The 9th earl of Douglas was still in receipt of an English pension and with Douglas as an intermediary Edward IV made a treaty with Albany for his establishment on the Scottish throne as an English vassal, and for the restoration of the house of Douglas. Albany, calling himself Alexander, king of Scots, led an army to the borders. accompanied by Kichard, duke of Gloucester (afterward Richard III). Gloucester retook the town and castle of Berwick-on-Tweed, which thus passed finally out of Scottish hands (1482), and Albany invaded Scotland. The army which James led to meet him brought about a revolution; the nobles, under the leadership of the earl of Angus, the head of the Red Douglases who had risen on the ruins of the older or Black Douglases, seized and hanged the musicians and architects who were the king's friends. and made an agreement with Albany. The amusing story of how Angus gained his nickname. Archibald-Bell-the Cat, is told in Scott's *Tales* of *a Grandfather*. In the following year Albany was again an exile in England, and in 1484 he and Douglas again invaded Scotland with small English force, but mere defeated. Albany escaped to France, where he was killed in a tournament in 1485, and the 9th and last earl of Douglas died a prisoner in the monastery of Lindores.

Four years later James III was killed in a civil conflict. The faction of the nobility which conspired against him and defeated him at Sauchieburn near Stirling (June 1488) had seized the person of his son and heir, the prince of Scotland, and brought him to the field against his father. This circumstance indicates the permanent character of the change in Scottish politics brought about by the victory of James II over the Douglases. Neither of the two rebellions against James 111 was directed against the dynasty, and each of them was the result of widespread political opposition to the king's conduct of public affairs, and not of secret conspiracies inspired by jealousy of the house of Stewart. It is also significant that. in 1488, the rebels defended their action on political grounds; rebellion for the first time admittedly required an excuse capable of being stated openly. The revolution was followed by indications of a tendency toward constitutional government and an assertion of parliamentary authority, but this tendency did not survive the assumption of power by James IV (1488–1513) in person. He was an able and strenuous ruler, and he soon acquired complete control over the traditionally amenable Scottish parliament. He humbled rebellious barons who, either as partisans of the late king, or for other reasons, resisted him, and he annexed to the crown the title of lord of the isles and by personal visits established royal authority in the Hebrides.

(R. S. R.; E. W. M. B.–M.)

SCOTLAND, ENGLAND AND FRANCE

James **IV's** Foreign Policy. — For some time James IV seemed to be content to follow the traditional policy of the French alliance. He built a great navy, encouraged his captains to challenge the English seamen. and for a short period (1495–97) gave half-hearted support to Perkin Warbeck's pretensions to the English throne. But, anxious to make Scotland count in European politics, he heeded, at least intermittently, those older counsellors who advised him against automatically committing the realm to the support of France and the enmity of England. Failing to find a Spanish bride, he eventually accepted Henry VII's offer of the hand of his elder daughter Margaret. This marriage, celebrated by the poet William Dunbar as the union of the thistle and the rose (1503), was a triumph for the statesmen who argued that Scotland need not be on perpetually hostile terms with its great neighbour, and it brought the northern country a brief spell of commercial prosperity. Among those who appreciated its benefits was the famous scholar. John Major, who a little later was to urge, in his *Historia Majoris Britanniae* (1521), the expediency of royal intermarriages with a view to the ultimate union, on a peaceful basis, of Scotland and England.

Another century was to pass before this happy consummation became a reality. Meanwhile, Anglo-Scottish relations deteriorated soon after the aggressive Henry VIII succeeded his more cautious father (1509). and the formation of the Holy League (including England) against France determined the headstrong Scottish monarch to adhere to the old custom of helping France in its hour of need. Disregarding the temperate views of Bishop Elphinstone and others like him, James crossed the border with a strong army and was defeated and killed at the battle of Flodden (Sept. 1513), leaving his crown to an 18-month old infant and his kingdom to the hazards of another minority.

James V and the French Alliance. — The marriage of the queen-mother, Margaret Tudor, to the earl of Angus (1514) debarred her from the regency and this was entrusted instead to Alexander, duke of Albany, son of James III's treacherous brother, and by birth and education a Frenchman. Albany's tenure of office (1515–24) was marked by indecisive warfare with England and by quarrels between Margaret and her second husband. The regency was terminated in 1524, when the young king was declared to be old enough to govern the realm, but for four years the real power lay with Angus, who, though estranged from his wife (the marriage being annulled in 1527), did his best to further the interests of England, until in 1528 James escaped from the control of his hated stepfather.

James V (1513–42) was in some ways a capable as well as a popular ruler, but the circumstances of his age proved too much for him in the end. Henry VIII, after his breach with Rome, urged his nephew to follow his example, and his overtures brought James face to face with the same dilemma as had beset his father. Largely dependent on clerical aid and advice, unsympathetic to the doctrines of the reformers and unwilling to suppress the monasteries, the king chose to adhere to the traditional policy of the Franco-Scottish alliance. He made two French marriages, first to Madeleine, daughter of Francis I, and then, after her death (1537), to Mary of Guise. His refusal to meet the English king at length induced Henry to revive the claim of homage and to invade Scotland. James by his very success in restoring order had lost the favour of many of his nobles and barons, especially in the borders and the Western Isles (Hebrides), and they refused to support what they called a French war. It was therefore Cardinal Beaton and the clergy who furnished the army that was routed at the battle of Solway Moss (Nov. 1542); the king, broken in health and spirit, died at Falkland on Dec. 14, a week after the birth, at Linlithgow, of his daughter and only surviving legitimate child, Mary, queen of Scots.

The early years of the reign of Queen Mary (1542–67) gave Henry VIII an opportunity to wean Scotland from the old church and the old alliance. for the new regent, the earl of Arran (who was heir-presumptive to the throne), was hostile to Beaton and inclined to favour the doctrines of the Reformation. In July 1543 a marriage was arranged between Henry's heir (afterward Edward VI) and the infant Scottish queen, but the English king then overplayed his hand by making unacceptable conditions. Beaton and Arran were reconciled and the marriage treaty was repudiated (Dec. 1543). Henry's ill-advised retort was to send the earl of Hertford (afterward the protector Somerset) to conduct savage campaigns of reprisal in southern Scotland (1544 and 1545); and, in turn, this "rough wooing" threw the Scots into the arms of the French. The assassination of Beaton (May 1546) in revenge for the martyrdom of George Wishart did not alter the course of Scottish diplomacy, nor did the death of Henry VIII and Somerset's victory at Pinkie (Sept. 1547) in the last battle fought between the national armies of Scotland and England. Arran opened negotiations for the marriage of the girl queen to the heir to the French throne, and in Aug. 1548 (with this ultimate aim in view) Mary was sent to France.

The French helped the Scots to recover their territory and included them in the peace made with England in 1550. Thereafter the French soldiers remained in Scotland and incurred general odium. Arran (who was given the title of duke of Chatelherault as a solatium) resigned the regency in 1554 in favour of Mary of Guise, whose policy was to make Scotland a province of France—a Frenchman even shared the chancellorship with the earl of Huntly. The marriage of Queen Mary to the dauphin (April 1558) injured rather than assisted the French alliance, for it was suspected (and it is now known) that Henry II of France had induced the young queen to recognize his own and his heirs' quite fictitious claim to succeed her, in the event of her decease without issue, in Scotland. The event had shown the French cause, viewed at close range, to be as unpopular as the English.

Social and Economic Conditions.—Despite royal minorities, baronial turbulence and foreign entanglements, Scotland, toward the close of the middle ages. made some progress in the arts of peace. Episcopal initiative, royal patronage and papal good will made possible the foundation of the universities of St. Andrews (1412), Glasgow (1451) and Aberdeen (1495), and an education act of 1496 enjoined barons and freeholders to put their eldest sons and heirs to grammar school and to "the schools of art and law." The printing press was introduced and the Royal College of Surgeons was established during the reign of James IV: at this time Scottish letters reached their pre-Reformation height with the poetry of William Dunbar (*c.* 1460–1520), and a little later the new learning came to Scotland in the work of John Major (1469–1550) and Hector Boece (*c.* 1465–1536).

Trade and industry were the subjects of a large number of parliamentary enactments. Commerce was in the hands of the merchants of the guild in the greater royal burghs (of which there were about 45 by the middle of the 16th century), and the trade routes ran to the Baltic ports, the Netherlands. France. England and Ireland. From Leith, Kirkcaldy. Perth, Dundee. Montrose, Aberdeen, Inverness and Ayr. cargoes of wool, woolfells. skins and hides. salmon and herring. moved outward. and to them, in return. were shipped iron, timber, salt, tar, flax and hemp, wines and spices. fine cloths and articles oi fashion and luxury. Goods and services were supplied locally by the craftsmen of the royal burghs and of the lesser "burghs of barony," of which about 100 were erected by charter between 1450 and 1560. The towns were not large. Edinburgh may have had 20 000 inhabitants, and the others far fewer—Glasgow perhaps 4 500, Stirling not more than 2,000. Arbroath only 1,000, although these three were among the 20 largest burghs. All but a small fraction of the total population (estimated at about 750,000) were engaged in the basic and changeless tasks of subsistence farming—groning, in open fields. oats (the food crop). "bere" or rough barley (the drink crop), a little wheat. rye and flax, raising a few cattle for beef or as plowing oxen, and. in the border country, keeping large flocks of sheep for the sake of their fleeces.

THE REFORMATION IN SCOTLAND

Diplomatic and Religious Revolution.—The popular revolt against a church which had largely fallen from spiritual grace, which gave rich livings to a few men mostly driven by secular ambitions and which starved the parishes for the upkeep of the cathedrals. larger abbeys and collegiate churches, may be dated from the burning in 1528 of Patrick Hamilton, abbot of Ferne. As elsewhere, there was some mixture of motives; nobles and lairds envied the church its relatively great wealth, and English gold forwarded the Protestant cause. But the dissemination of the Bible "in the vulgar tongue," especially from 1543, the example of George Wishart (1546), and the admonitions of John Knox, gave Scottish Protestantism a popular appeal, and the movement received form and shape when its leaders leagued together as "the Lords of the Congregation" and signed the first National Covenant (1557).

When the Roman Catholic Mary Tudor died and was succeeded by her half-sister Elizabeth (Nov. 1558), English help for the Scottish Reformers became a possibility; it became a certainty in the following year, when the husband of Queen Mary (now claiming to be rightful queen of England as well as Scotland) succeeded in France as Francis II. The Franco-Catholic menace was too real and pressing to be overlooked by Elizabeth, who promised, and sent, military and naval assistance by the treaty of Berwick (Feb. 1560). The diplomatic revolution was sealed by the treaty of Edinburgh (July 1560), which provided for the departure of the French troops (Mary of Guise having died in June) and which marked the end of the "auld alliance." The religious revolution was effected in August, when a parliament, irregularly summoned but broadly representative of the nation, abolished papal authority and forbade the celebration of mass. When, therefore, Mary, widowed at the age of 18. returned to Scotland, she came to govern a state nhich had, in a few fateful months, broken away from the land which she loved and the faith which she professed (Aug. 1561).

Mary, and **the** Early Policy of James **VI.**—The saga of Mary's life in Scotland (1561–68) provides the romantic high light of Scottish history—her conflicts with Knox and her inability to secure toleration for her co-religionists; her marriage schemes and her hopes of succeeding Elizabeth on the English throne; her choice of her cousin Henry, Lord Darnley (who stood next to herself in the English succession) as her second husband (July 1565), in defiance of her half-brother. the earl of Moray, whom she forced to flee; the murder of her secretary, David Rizzio (March 1566), and the birth of her son. James, in the following June; her constant quarrels with her worthless husband and the strong suspicion that she was privy to his assassination (Feb. 1567) (*see* CASKET LETTERS); her fatal selection, as her third husband, of the earl of Bothwell. known to be a principal actor in the crime (May 156;) ; her defeat and surrender at Carberry hill (June) ; her abdication in favour of her son as king and of Moray as regent. and her imprisonment in Lochleven castle; her escape within a year. her final defeat at Langside, and her flight to England (May 1568), to suffer confinement that was to end only with her execution (Feb. 1587).

The historical rather than the biographical interest of the reign concerns the rise of the Protestant church of Scotland. Knox's *Confession of Faith* was adopted in 1560 and his *Book of Common Order* in 1564, but the nobles, greedy to seize and secularize the church lands, refused to sanction the *First Book of Discipline* (1560), in which he proposed an adequate endowment of the kirk and laid down its responsibility for the education of the laity and the relief of the disabled poor, as well as the cure of souls; of special importance was his insistence on the establishment of a school in every parish. Ecclesiastical organization depended in the localities on the kirk sessions, which began to be set up as early as 1559, and at the centre on the general assembly, which first met in Dec. 1560; provision was made in 1563 for payment, from "thirds of benefices," of ministerial stipends. The Protestant revolution, furthered by Mary's failure in diplomacy and politics. was sanctioned by parliament in Dec. 156;.

hlary's departure left a "queen's party" to trouble the four suocessive regents for the young James VI (1567–1625) (who was also to become King James I of England in 1603)—Moray (1567–70), Lennox (1570–71), Mar (1571–72) and Morton (1572–78)—and not until Edinburgh castle was captured in 1573 did the resistance of Mary's adherents cease. The presbyterian system of graded church courts—general assembly. provincial synod presbytery and kirk session—became the characteristic feature of

Scottish Protestantism by 1581; the main advocate of this fully developed organization was Andrew Melville, who denounced even a modified episcopacy, insisted upon the essential parity of ministers, and maintained that ecclesiastical authority, the power of the keys, was different from, and independent of, the civil authority, the power of the sword. These claims were bound to lead to a struggle between church and state; they caused friction with Morton, and they aroused the undying hostility of King James when (in 1581) he assumed the government.

James's leading ambition was to succeed Elizabeth on the English throne; to this end his policy was steadily directed and from it nothing could deflect him — neither pity and anger over his mother's death, nor diplomatic flirtation with Spain, nor concessions to the Scottish Catholics. His secondary aim, not unconnected with the other, was to make the Church of Scotland episcopal in government, as was that of England. After being kidnapped in the raid of Ruthven (Aug. 1582) and held a prisoner by the extreme Protestants for ten months, he escaped and induced parliament to pass the Black acts, asserting the royal supremacy and the king's right to appoint bishops (1584). Presbyterian recovery came in 1592 with the "Golden act," which partially repealed the earlier statute and confirmed the status of the church courts. The ministers in turn pushed their claims too hard, and from the end of 1596 James was in command of the situation; he obtained the approval of the general assembly for his proposal to create titular bishops with seats in parliament. Meanwhile, as early as 1585 he had made a league with England, and his constant care not to offend Elizabeth or her chief ministers brought its reward in March 1603, with his accession to the English throne.

Constitutional Progress. — The 16th century saw the introduction of several improvements in the machinery of government. The full parliament or the less formal assembly, which had previously been called a general council and was now styled a convention of estates, met fairly frequently; king, queen, regent or even a faction in temporary possession of the power of the state consulted it upon all matters of high policy — legislation and taxation, justice and the legalization of a *coup* d'dtat. The three estates — prelates, nobles and burgesses of the royal burghs — attended, though sometimes in small numbers and always prepared to entrust their authority to the committee of the lords of the articles (the articles being the agenda for the meeting). The extant records, which are scanty, suggest that by 1525 this committee was chosen by the device of cross election, whereby the nobles chose the prelates and the prelates chose the nobles; whether (as was later the case) those two estates together elected the burgess members does not appear. The lesser barons, whom James I had tried to bring in, mostly refrained from attendance, but they did turn up in large numbers at the Reformation parliament (Xug. 1560); and James VI in 1587 carried out his ancestor's wishes in this matter by authorizing their representatives (two for each shire, save Clackmannan and Kinross, which were allowed one each) to sit and vote in parliament.

The financial theory was that the king, who was a large landowner, "should live of his own," without troubling the poor lieges, but parliament from time to time voted a tax or "stent" for a stated purpose; in that case the practice was that the clergy paid one-half, the nobles one-third and the burghs one-sixth. The judicial system was much strengthened in 1532 when, from moneys granted by the papacy to the crown, the college of justice or court of session was established. This court was composed of a president and 14 other lords, and it was supreme in civil justice. The other important constitutional development of the century concerns the growth, out of informal or ad *hoc* meetings, of an assembly representative of all the royal burghs and dealing with municipal and commercial affairs — theconvention of royal burghs (1552).

THE UNION OF THE CROWNS

Enhancement **of** Royal Power. — The resources and prestige of the English crown gave King James greater authority in Scotland than any of his predecessors had enjoyed. No longer was it possible for disaffected nobles to conspire with, and accept bribes from, a foreign monarch beyond the Tweed; instead the magnates of the realm now found it profitable to stand well with James VI and I. His chosen instrument of executive government was the privy council, and he contrived to ensure, by manipulating the customary cross elections, that the councillors should also control the lords of the articles, and, through them, parliament itself. In the field of local administration he endeavoured, though with little success, to transplant Tudor efficiency to his northern kingdom through the institution of justices of the peace (1609). His pacification of the borders (now "the middle shires") by means of patrols of mounted police under an Anglo-Scottish commission was more effective (1605). By the Statutes of Icolmkill (1609), many of the chiefs in the Western Isles were induced to profess the Protestant faith, to become responsible for the good order of their estates, and to undertake to give their sons a lowland education. The earl of Orkney was beheaded in 1615 and his earldom annexed to the crown. The plantation of Ulster was begun in 1610 and an ambitious scheme for settling Acadia, or Nova Scotia, was launched in 1621; but the French saw to it that the plan miscarried, so that it led only to the granting of Nova Scotia baronetcies.

Convinced that episcopacy agreed best with monarchy, James achieved his greatest triumph in the church. His adroit and tortuous manoeuvrings finally gave him complete control of the general assembly. Parliament reaffirmed the royal supremacy in ample terms in 1606, the general assembly approved an episcopal constitution in 1610, bishops with Anglican consecratian were appointed in the same year, and all was ratified by a statute of 1612. An episcopal superstructure had been imposed on a presbyterian foundation, and James was wise enough not to press the innovations in ritual known as the Five Articles of Perth (1618).

James, king of Great Britain (by royal prerogative), was the first to use the "Union Jack" and to secure the recognition of mutual rights of citizenship: but English mercantile jealousy frustrated his plans for a closer union (1607).

Charles I and the Covenants. — Charles I (1625–49), having alienated his natural supporters, the nobles, by providing for the maintenance of the ministry out of ecclesiastical lands and teinds or tithes (1625–33), imperilled the Jacobean compromise by seeking to make the government and worship of the church uniform with those of the Church of England. His book of canons (1635) and a new prayer book (1637) impressed the Scots as being popish, and resistance came into the open at the St. Giles riot in Edinburgh (July 1637). The National Covenant, protesting against the recent innovations, was drawn up and signed with enthusiasm in 1638 and in December of that year the Glasgow general assembly abolished episcopacy. The Covenanters (*q.v.*), with the good will of Charles's English opponents, invaded northern England in the Bishops' wars (1639–41). The king attempted to win over his Scottish critics by concessions (1641) and after this policy had failed he was obliged to summon the Long Parliament to get rid of the Scottish army, by payment or by fighting. England's Civil War was no affair of the Scots (whose grievances had been settled), but parliament's need of help induced the Covenanters to offer their aid against the royalists on the basis not of a civil league but of a pact for religious uniformity on the presbyterian model. In accordance with the Solemn League and Covenant (1643), the Scots did help in the parliamentary victory of Marston Moor (July 1644). Organized royalist opposition was ended in England by the battle of Naseby (June 1645) and in Scotland by the defeat at Philiphaugh of the marquis of Montrose, who had turned in disgust from the covenanting extremists (Sept. 164;). In May 1646 Charles surrendered to the Scots, who were still hoping that the king, a devout Anglican, would accept reconciliation on the basis of the Solemn League and Covenant.

Cromwell.—Amid the tangled manoeuvres and negotiations that followed Charles I's admission of defeat, the salient fact was that Cromwell's army was stronger than Scots and parliament, royalists and Covenanters, or any combination of them. In accordance with the Engagement, a design to restore the king, the duke of Hamilton led a force of Scottish invaders to their doom at Preston (Aug. 1648). After the execution of Charles I in Jan.

1649, another royalist reaction, this time on behalf of the ludicrous figure of the covenanted Charles II, was crushed, first at Dunbar (Sept. 3, 1650) and finally, on the first anniversary of that battle, at Worcester. All Scotland lay at Cromwell's feet.

In some ways the protector was surprisingly gentle toward the conquered country. Impartial law was enforced sound order was maintained, and trade with England and its plantations was opened to the Scots merchants. The general assembly mas forbidden to meet but the lower courts were undisturbed. Scotland was admitted into the commonwealth by what had the appearance of a voluntary union and was given representation in the united parliament under the terms of the various paper constitutions of the time. But material benefits and legal rights did not reconcile the Scots to alien administration. Toleration of the Independents, on which Cromwell insisted, was in their eyes hateful and wicked. Commerce was injured by the protector's Dutch wars, and maritime danger and loss intensified economic dislocation; this in turn, in conjunction with the growing trend toward larger seagoing ships, led to the concentration of trade in such ports as Leith, Bo'ness, Dundee, Aberdeen and Glasgow, and the degradation of the lesser coastal burghs into fishing villages. Thus even financial prosperity eluded the Scots and the taxation that was levied to help to defray the huge expenses of the military establishment rendered the Cromwellian union—tied as it was both to the sanction of the sword and to religious laxity—trebly unpopular. Though the country took no initiative in bringing about the Restoration (1660), that event was almost universally welcome.

RESTORATION AND REVOLUTION

The Second Episcopacy.—The Presbyterians looked to their covenanted king to respect and favour their legally established church, but Charles's ideas were quite different. His way with men whom he regarded as disloyal sectaries was short and brutal. An obedient parliament in March 1661 passed the Act Rescissory, which at a blow repealed all legislation enacted since 1633 and automatically reinstated episcopacy as the lawful government of the church. Persecution of dissenters began soon after and became the keynote of the reign. Bishops were appointed and given the duty of supervising the lower courts of the church. Lay patronage of livings was restored, all office-bearers had to renounce the covenants, fines were imposed for nonattendance at parish churches, the clergy were ordered to send in lists of absentees, and soldiers were quartered in disaffected areas, especially in the southwest. The people rallied round their ejected ministers, secret conventicles were held, and further repression was attempted: this in turn led to the bearing of arms at field meetings and eventually to open rebellion.

The first rising came late in 1666, when the western insurgents marched upon Edinburgh but were easily defeated at Rullion Green, in the Pentland hills. The earl (later the duke) of Lauderdale came into power as royal commissioner and he was the virtual ruler of Scotland, in Charles's name, until 1679 His policy alternated between phases of mildness and conciliation and bouts of savage persecution; its outcome was another armed rebellion. On June 1, 1679, the Covenanters had a victory over James Graham of Claverhouse (later Viscount Dundee) at Drumclog in Lanarkshire, but three ueeks afterward their small force was crushed by James, duke of Monmouth, at Bothwell Bridge. The king's brother and successor, the duke of York, governed Scotland from 1680, a period which was marked by the widespread use of the boot and the thumbscrew and was long remembered as the "killing time." The closing years of Charles's reign saw the southwest seething with sullen resentment or open defiance of the government.

When the Roman Catholic duke of Tork succeeded as James VII (1685–88), the earl of Argyll, in conjunction with Monmouth in England, headed yet another western rebellion, but the government easily suppressed it, and captured and executed its leader. A fanatically loyal and submissive parliament imposed the death sentence for mere attendance at a conventicle, but even it baulked at toleration for Roman Catholics, on which the king had set his heart (1686). Falling back on the royal prerogative James issued a Declaration of Indulgence (1687), which ended persecution but, because of the popular antipathy to popery, earned him little gratitude from his now thoroughly alarmed subjects. His appointment of Roman Catholics to high office in the central government and his arbitrary nomination of others to burgh magistracies and town councils (1687–88) made the vast majority of the people ready to welcome the Revolution, but no overt action was taken until news came from England of the king's flight and the landing of William of Orange. Then Holyrood, given over to the papists, was sacked, and the episcopal clergy in the south and southwest were "rabbled."

The Revolution.—A convention of estates, summoned by the prince of Orange in April 1689, declared that James had forfeited the crown, and settled it on William and Mary, their issue: and then Princess Anne. The Claim of Right also stated that episcopacy was an insupportable grievance and ought to be abolished, and this avowal of the policy and intention of the convention (which was converted into a parliament in June) inevitably made the Scottish Episcopalians, now and for two generations, a Jacobite party. Edinburgh castle held out for King James until June 13, and Viscount Dundee, his chief Scottish champion, was killed in the hour of victory at Killiecrankie (July 27). His death ended any danger of a Jacobite restoration. Presbytery was re-established in 1690, and later that year the general assembly met, for the first time since 1653. The revolution was complete in church and state.

The *Massacre* of *Glencoe*.—The new regime was disliked in the Highlands and some of the chiefs were slow to take the oaths of allegiance to the king and queen; one of them, Alexander Macdonald of Glencoe, was late in doing so and the government resolved to punish him and his men as technical traitors. Sir John Dalrymple, master of Stair, probably had in mind such a precedent as the issue of "letters of fire and sword." in James VI's reign, against the Macgregors; that clan had, as a result, been expelled from their lands and dispersed. In the case of the Macdonalds, however, the punishment (entrusted to Captain Campbell of Glenlyon) involved the slaughter, in circumstances of peculiarly revolting treachery, of nearly 40 persons, though the majority of the clansmen and their families escaped to the hills (Feb. 12, 1692). Apart from Jacobite propaganda, much sympathy was felt for the Macdonalds and antipathy toward the government, and William was criticized for visiting Dalrymple, the responsible official, with the belated and light punishment of dismissal from office in 1695.

Economic Enterprise.—The greatest change brought by the 17th century to the Scottish economy was the nine years' experiment in free trade under the Cromwellian regime, but Scotland, as we have seen, was unable to take full advantage of the opportunities of the time. Both before and after the protectorate, prosperity eluded the nation, mainly because both industry and commerce were still subject to restrictive practices of the kind associated with feudal privilege. Efforts were made to break out into new lines. The crown granted many monopolies to encourage individuals or partnerships to set up new industries, *e.g.*, linen weaving, glass blowing, soapmaking and leather tanning. Other attempts were made to maintain and expand the traditional rural and semirural occupations, such as the trade in black cattle, the knitting of stockings, the weaving of coarse plaiding, coal mining, and the export of cured salmon and herring; a fishery society on a grand scale was promoted by Charles I (1632) and also by Charles II (1661), but in each case the result was total failure. Some success, however, attended the numerous joint stock companies which were set up by parliament or privy council, especially after 1661; the New Mills manufactory of fine cloth, established in East Lothian, was typical of these (1681–1713).

For the most part the burghs looked askance at these ventures; as early as 1633 they got parliamentary confirmation, in the amplest form, of their exclusive trading rights and, while these were seriously modified by a statute of 1672, they recovered much of the lost ground in 1681 and 1690. Between 1660 and 1707 a large number both of burghs of barony (with local markets and crafts) and of nonburghal weekly markets and annual fairs were set up in favour of nobles and lairds. The alarmed merchants of the royal burghs tried, by the "communication of trade" (1693), to induce the greater of the "unfree" burghs to share the right of foreign trade in return for an undertaking to pay 10% of the burghal tax; but the scheme never worked well.

The Darien Disaster.—The revolution further stimulated the nation in its hankering for economic adventure and material advance. This spirit found expression in a statute passed in 1695 (the year in which the Bank of Scotland was set up). which provided for the formation of an overseas trading company. The English parliament, from mere jealousy, forced the withdra al of the promised English capital; the Scots thereupon raised the money themselves and proceeded with the foolhardy project of colonizing the isthmus of Darien (Panama), on territory claimed by Spain. It was a delicate moment in European diplomacy. and the 1,200 emigrants and traders sent out in 1698 encountered, in addition to an intolerable climate, Spanish hostility and English aloofness; two further expeditions joined in the hopeless struggle against disease, famine and Spanish attacks, and the remnants of Scotland's greatest colonial adventure withdrew in March 1700, after suffering a loss of life and treasure of crippling dimensions.

UNION OF THE PARLIAMENTS

Constitutional Developments.—In Scotland it was Dutch William and the jealous English parliament who incurred the odium of the Darien disaster, but in truth the disaster was a bitter and tragic lesson in the realities of the constitutional dilemma and in the unworkability of the regal union. Before 1689 it was only on rare occasions—at the Reformation crisis (1560) and during "the Troubles" (1638–51)—that parliament had directed national policy; at other times its powers were entrusted to the lords of the articles, a small and manageable business committee drawn from each estate and having a membership resembling too closely that of the privy council. The 17th-century sovereigns of the house of Stewart had to allow their English parliament a great and growing share in the shaping of national policy, but they were able to keep-the Scottish parliament, as it had generally been, little more than a dignified court of registration; as long as the real power lay between the crown and the English ministers, the union of 1603 was practicable. It was disappointing that, in succession, negotiations for a commercial treaty (166;) and for a closer union (1670) broke down, but no acute constitutional problem was posed by these failures.

The reforms of 1689–90 transformed the situation. The lords of the articles were abolished and parliament obtained the right of initiating legislation. Proceedings were minuted, rules of debate were adopted, votes were free and effective, and casual vacancies were supplied by new elections. An act of 1690 modified shire representation to accord better with the distribution of wealth and population: the 11 largest shires got 4 members each, 4 others got 3 each. 16 were left with 2 apiece. Clackmannan and Kinross with 1 each. The 90 "barons" or lairds now formed the largest estate. There were 67 burgesses from 66 royal burghs (including 2 from Edinburgh), and by 1700 some 60–70 of the 140-odd peers were accustomed to attend the sittings in Parliament house. For the last 17 years of its life (1690–1707) the Scottish parliament acted vigorously and effectively in domestic affairs and tried also to control foreign policy; and the existence of two sovereign legislatures under one crown made the continuance of a mere regal union impossible.

In 1689 and again in 1702–03 projects for a closer union miscarried, and in 1703-04 international tension provoked a dangerous legislative warfare between the two parliaments. On both sides of the border, however, statesmen were beginning to realize, with much reluctance, that an incorporating union offered the only mutually acceptable solution to a problem suddenly become urgent. Scotland's need was for economic security and material assistance. England's for political safeguards against French attacks and a possible Jacobite restoration, for which Scotland might serve as a conveniently open backdoor. England's bargaining card was freedom of trade; Scotland's. acquiescence in the Hanoverian succession. Both points were quickly accepted by the commissioners appointed by Queen Anne to discuss union and within three months they had agreed on a detailed treaty (April–July 1706).

The two kingdoms were to be united, the Protestant succession was adopted, and trade was to be free and equal throughout Great Britain and its dominions. Subject to certain temporary concessions, taxation. direct and indirect, would also be uniform. and England, with calculated generosity, compensated Scotland for undertaking to share responsibility for England's national debt by payment of an equivalent of £398,085 10*s*. Scots law and the law courts, and the whole fabric of feudal privilege, were to be preserved. In the united parliament the northern country, because of its relative poverty, was given the inadequate representation of 45 commoners and 16 lords. By separate statutes annexed to the treaty the Presbyterian Church of Scotland and the Episcopal Church of England were secured against change or disturbance, and the Scottish parliament allocated its quota of the 45 commons seats—30 to the shires and 15 to the burghs.

With only minor amendments the Scottish parliament passed the treaty by 110 votes to 69 in Jan. 1707, and the English ministers had no difficulty in either house. Jacobite assertions that the treaty was carried by bribery in Scotland have been shown to be without substance. The royal assent was given on March 6 and the union went into effect on May 1, 1707.

The Jacobite Risings.—The Revolution settlement, the Hanoverian dynasty and the union of 1707 were alike detested in the Highlands. where Jacobite, Roman Catholic and Episcopal sentiments were cherished. Within 40 years of the passing of the treaty four attempts were made in favour of the exiled Stewarts. Two of these which need not be considered were a French invasion which misfired completely (1708) and a west Highland rising, aided by Spain, which was nipped in the bud at Glenshiel (1719). But the 1715 and the 1745 rebellions were formidable affairs.

In the summer of 1715 the earl of Mar, an embittered and unstable ex-unionist, raised the Jacobite clans and the Episcopal northeast for "James III and VIII" (the Old Pretender). **A** hesitant leader, Mar advanced only to Perth and wasted much time before challenging Argyll's numerically inferior force; the result was the drawn battle of Sheriffmuir (*q.v.*), and at the same time the hopes of a southern rising melted away at Preston (Nov. 1715). James arrived too late to do anything but lead the flight of his chief supporters to France.

The outlook in 1745 seemed hopeless, for another French invasion, planned for the previous year, had miscarried and little help could be expected from that quarter. The number of Highlanders prepared to turn out was smaller than in 1715, and the lowlands were apathetic or hostile; but the charm and daring of the young prince. Charles Edward, and the absence of the government troops (who were fighting on the continent) produced a more dangerous rising. Within a few weeks Charles was master of Scotland and victor of Prestonpans (Sept. 21); though utterly disappointed as regards an English rising, he marched south as far as Derby (Dec. 4), and won another battle (Falkirk, Jan. 17, 1746) before retreating to the Highlands. The end came on April 16, when the duke of Cumberland crushed the Jacobite army at Culloden, near Inverness. About 80 of the rebels were executed, many more were driven into exile, and the Highland dress was proscribed until 1782, while the Episcopalian clergy were heavily penalized; but the government, through the commissioners for the annexed estates, did their best to foster education, farming, linen spinning and other crafts from the Highland rents that fell into their hands (1752–84).

Government and Administration.—Scotland's share in the united parliament of 16 representative peers, 30 "barons" or shire members, and 15 burgesses fell short of its deserts. and the position worsened for each of the three groups who had some say in the legislative process. Between 1711 and 1782 Scottish peers who were created peers of Great Britain were. by a ruling of the house of lords. denied a seat as such in the upper chamber; this was resented by many Scots and widely regarded as a major breach of the union. The numbers of shire voters were inflated, in the interests of certain large landowners, by the collusive transfer of the superiority, without the actual possession, of an estate of the qualifying value (£400 per annum); the fictitious votes of these "parchment barons" went far to make many county elections farcical. Burgh representation was limited. in accordance with the feudal structure of society and the Scottish parliament's rigid insistence on traditional privilege, to the 66 royal burghs. Of these, Edinburgh got its own member, but the others were split into districts of four or five neighbouring burghs, without regard to their relative importance, so that Glasgow shared a member with the three small towns of Dumbarton, Renfrew and Rutherglen, and five small fishing villages in Fife got the right that was denied to flourishing places like Paisley, Leith and Greenock.

Parliament in these circumstances could not serve as a focus of the national life, which sought other channels in farming, trade and industry, in education. literature and the arts, and in the disputes and schisms which rent the church. Politics engaged the interest of a tiny minority of the people—a handful of ambitious nobles and lairds, and the legal families of Edinburgh and the Lothians, who formed almost a hereditary caste. The purchase of municipal votes, the claims of kinship in shire elections, the unofficial appointment of an outstanding politician as "manager" for Scotland, and the open use of state patronage to reward loyal support were routine practices. and they explain the general apathy of the nation toward the proceedings at Westminster.

Apart altogether from parliament. there were defects and anomalies in the methods of administering Scotland between 1707 and 1832. The Scottish privy council, the old agency of central executive government, was abolished in 1708 and this measure was denounced by some as a breach of the treaty. From 1709 until 1746 a third secretary of state, with Scotland as his province, was sometimes appointed, but throughout most of the century the English ministers in London relied on a Scottish manager to keep Scotland quiet and amenable. The severe English treason law was extended to Scotland in 1709 as a means of combating the Jacobite threat. That there was no exaggerated sense of respect for the law of the land is clear from the continued prevalence of smuggling and from the Shawfield riot in Glasgow (1725) and the Porteous riot in Edinburgh (1736), each of which was in some sense a popular demonstration against state regulation of trade. The greatest and most far-reaching legal reform of the century was the abolition, from 1748. of heritable jurisdictions—the private rights of justice which were a basic element of the feudal order of society. Thereafter the royal, or public, courts of law improved their standing, while a money economy took the place of the old personal relationships.

In the localities an attempt was made to strengthen the justices of the peace (1708); but neither they nor the commissioners of supply—the great landowners who controlled county finance—were efficient instruments of government. The baronies gradually wilted and lost their powers under the act of 1747 which dealt with heritable jurisdictions. The town councils of the burghs were narrow, self-elective oligarchies; their besetting sin (as portrayed vividly in John Galt's The *Provost*, 1822) was their negligent or corrupt alienation of valuable common lands. The most successful agent of local administration was the kirk session, and it was also the body that was most responsive to the pressure of public opinion. It maintained the parish school, it relieved (with pittances it is true) the aged and impotent needy, it succoured the victims of fire, flood and famine, and it endeavoured to make the parishioners a moral and law-abiding community.

The Rise of the Whigs.—The most capable, and the most notorious, of the Scottish managers was Henry Dundas, who was the trusted lieutenant of the younger Pitt and later became Viscount Melville. During the greater part of the period 1775–1804 he was the virtual ruler of Scotland; his administration was so autocratic, his control of elections so nearly complete. that he was styled "King Harry the Ninth." From the 1780s advanced politicians were advocating the reform of both parliament and the burghs. but the government set its face against the agitation. The outbreak of the French Revolution (1789) at first evoked much sympathy in Scotland. and the Society of the Friends of the People demanded universal suffrage and annual parliaments. As the violence of the revolutionaries developed, the government came to regard the reform movement as seditious; the outbreak of war with France and the inception of the Reign of Terror in that country (1793) impelled the panic-stricken ministers and judges to repression and persecution. Whig protests against "the Dundas despotism" were unavailing and after grossly unfair trials Thomas Muir was sentenced to transportation for 14 years and Thomas Fyshe Palmer for 7 years. Fears of a French invasion led to the enrolment of volunteers in 1794 and of a militia in 1797, but the sullen masses now suspected a design to lure them into foreign service; there was a riot at Tranent in which 11 persons were killed, and four further sentences of 14 years' transportation were imposed. Deposed in 1796 from the deanship of the faculty of advocates because of his political sympathies. Henry Erskine assumed the leadership of the Whig party. The foundation of the *Edinburgh Review* (1802) gave the reformers a journal of standing in which to attack the Tory government. Viscount Melville was impeached in 1805 for peculation; though he was acquitted in the following year, his power was shaken. Nevertheless, his party remained in office, with the exception of a brief interlude in the years 1806–07, until 1830, and stubbornly resisted the ever growing demands for reform.

Social and Economic Life.—The population of Scotland in 1707 has been estimated at about 1,100,000, of which total the towns held less than a quarter. Edinburgh, with some 40.000 inhabitants living in great congestion in its lofty and picturesque tenements, the whole dominated by the massive pile of its ancient castle, was much the largest, as well as the gayest and most colourful, of the towns. Glasgow, the second city, housing 12,500 people, won the admiration of visitors for its broad streets, handsome churches and fresh country air; while favourable comment was sometimes made also on Dundee. Aberdeen and Perth, each with 5,000–8,000 inhabitants. The remaining towns, numbering about 200, depended on local markets, a little coastwise trade and a few petty craftsmen; many burgesses were in fact small crofters living in a village community, and their mean hovels and the ubiquitous heaps of street garbage proclaimed their primitive mode of life.

In the countryside what attracted the eye and evoked the adverse criticism of the traveller was the absence of enclosures, the lack of trees, the open fields, the bad roads and the poor inns. Men moved about only when journeys were unavoidable, and then stayed overnight with friends or relatives in private houses. Nobles and lairds fared tolerably well, the land yielded beef and mutton, ground game, pigeons and game birds, the rivers and seas held salmon, herring, white fish and shellfish; oatmeal was the staple foodstuff, home-brewed ale or claret the customary drink, and the country had a good culinary tradition in rich soups and savoury sweets. The diet of the farmers and tenants showed far less variety and indeed tended toward monotony. Housing was bare and simple, even for the wealthy, and homespun woollens were worn almost universally. If, however, life was harsh and severe, the hardships were suffered in common by a society that was well-knit and had no barriers between the classes: social snobbery was nearly unknown and the laird and his man conversed as equals.

During the 18th century the Scottish economy underwent radical changes. From 1723, when the Society of Improvers in the Knowledge of Agriculture in Scotland was set up, farming techniques were revolutionized in all the better districts; enclosures, crop rotation, fallowing, manuring, drilling, the planting of trees and the growing of winter feed for cattle marked the improved estates. The board of trustees for manufactures (1727) fostered the spinning and weaving of linen. New developments were facilitated by the establishment of stable but enterprising banks, particularly the Royal Bank of Scotland (1727) and the British Linen company (1746). Glasgow's tobacco trade with Virginia and Carolina brought fabulous wealth to its merchant princes. until the outbreak of the American Revolution (1775) put an end to the artificial monopoly. The foundation of the Carron ironworks (1759) and the opening, especially in the last two decades of the century, of new coal pits in the west foretold the transformation of the country that was to come after 1800. A brand new industry appeared in 1779, when the first cotton mill was built at Rothesay, and took firm root with the opening of the New Lanark mill in 1786; by 1800. heavily concentrated in Lanarkshire and Renfrewshire, cotton was Scotland's premier industry. By this time, too, there were 2,000 seagoing ships, instead of the 100 of 1707.

Social changes accompanied the various "improvements." The population grew to 1,608,000 in 1801. when Edinburgh and Glasgow each had about 80,000 inhabitants, and many other towns were likewise attracting new settlers from the country. From about 1750 Edinburgh entered on its gayest. most cultured and most fashionable period; with its newspapers and assemblies, its societies, clubs and coffeehouses. its distinguished university and medical school, it was a brilliant and cosmopolitan city, which, from 1772, carried out in the gracious squares, streets and terraces of the New Town Scotland's most successful town planning of all time. In a modest way other towns strove for elegance and sophistication, while the lairds, benefiting from enhanced rent-rolls. built larger and more comfortable homes, often in the new Palladian style. It is, however, clear—and it was deplored by the ministers—that by 1800 the addiction to heavy drinking was spreading to all classes.

THE REFORM ERA

Parliamentary and Administrative Reform.—Scotland had its share of the postwar discontents of the years 1815–20, and political rioting. which was dubbed the "Radical war;" broke out in 1819–20; the outburst was closely related to agrarian distress and industrial unemployment. In the reign of George IV (whose visit to Edinburgh in 1822 brought a ruling monarch to Scotland for the first time since the reign of Charles 11), the demand for reform gained momentum and the Whigs were returned to power in 1830. The necessity for reform is apparent from the fact that in all Scotland the shire voters fell short of 3.000. while the burgh franchise, confined to magistrates and councillors, extended at most to 1,200 persons. In 1832 came the first instalment of the needed change; the act of that year gave Scotland eight more members, all the additional seats going to the cities and the larger industrial towns. The vote was entrusted to the £10 householder in the burghs and to the £10 proprietors and £50 occupiers in the shires.

Further changes, both in the franchise and in the distribution of seats, were made in Scotland. as in England, by the Reform acts of 1867–68 and 1884–85. In two stages adult male suffrage was conveyed to town and country, while Scotland's quota of seats was again raised, to 60 and eventually to 72. By 1885 Glasgow had seven members. Edinburgh four: Aberdeen and Dundee two each, and Lanarkshire formed six divisions; the arrangements followed the population figures closely and for the first time in the history of the united parliament Scotland had no grievance over its representation at Westminster. In 1872, also, the Secret Ballot act safeguarded the voter against any form of intimidation.

The long and unsavoury tradition of an unofficial manager was abandoned by the Tory government in 1827 and from then until 1885 Scottish administration was controlled by the home secretary, advised by the lord advocate; statutory boards were set up in Edinburgh to supervise poor relief (1845), lunacy (1857), prisons (1877) and fisheries (1882), while an education department, nominally a committee of the privy council, came into being in 1872. These arrangements were both untidy and inefficient, but it was only after considerable agitation that, in 1885, a Scottish secretaryship, of cabinet rank, was conceded. The statutory boards retained a substantial measure of independence, but the secretary's staff, known as the Scottish office, came to be recognized as the chief central agency. The board of supervision (responsible for poor law administration) was transformed in 1894 into the local government board.

Burgh reform was enacted for Scotland in 1833, two years before a similar change was made in England; the councils of the 66 royal burghs and 13 parliamentary burghs (as defined in 1832) were to be elected by the £10 householders. Legislation of 1833 and 1847 allowed the older burghs to adopt a "police" system, including new and growing duties in the sphere of the social services; and acts of 18jo and 1862 permitted "populous places" to become "police burghs." The kirk sessions (greatly weakened by the Disruption of 1843) lost their powers in poor relief to parochial boards (1845) and in education to school boards (1872). County police forces. under the commissioners of supply, were made permissive in 1839 and compulsory in 1857. Other acts dealt with the registration of births. deaths and marriages (1854), public health and water supply (1867) and county roads (1878), but the biggest change came in 1889 with the establishment of elected county councils, administering police. roads, health services and many other branches. The local government reforms of the century were completed with a measure consolidating municipal legislation (1892) and another which committed all parochial duties, save in education, to popularly elected parish councils (1894).

Liberal Ascendancy.—In the general election of 1832 Scotland returned to the reformed parliament 41 Whigs (or Liberals) and 12 Tories (or Conservatives). This was an omen, for until 1900 the Liberals won every general election in Scotland, usually by a substantial margin; there were in 1885 more Scottish burgh seats with unbroken records of Liberal representation since 1832 than without. This experience contrasts sharply with that of England, which was accustomed in Victorian times to a fairly regular saing of the pendulum. The Tory candidates appealed mainly to the landowners and the farmers, whose numbers and influence were steadily declining, while, on their left, the Liberals had little to fear from Chartist or socialist rivalry. The powerful support of Presbyterian dissent. the manufacturing interest, the urban middle class and large sections of workers was aligned behind the Liberals, who also enjoyed the backing of the two leading newspapers—the *Glasgow Herald* and the *Scotsman*. They were thus able to give the British parliament something like a constant bias toward progressive ideas and to advance effectively their cherished causes of free trade (1846), temperance legislation (1853), public education (Scottish act 1872), adult male suffrage (1884), the reform of Scottish administration (1885) and responsible local government (1889 and 1894).

The near-monopoly of Scottish representation held by the Liberals was ended by Gladstone's decision to grant Irish Home Rule (April 1886), which led to the defection of the Liberal Unionists and to the loss of influential press support. In alliance, and ultimately in amalgamation, the Conservatives and Unionists, as champions of the new patriotism and empire loyalty, commanded a volume of support in Scotland that was comparable to that of their opponents. Thus in 1885, before the split, the Liberals had won 62 of the 72 seats, but in 1900 38 Conservatives were returned and only 34 Liberals; Glasgow. which had been represented in 1885 by seven Liberals, elected seven Unionists in 1900. Two generations of Liberal dominance were ended.

The Industrial Age.—In the course of the 19th century the Scottish economy underwent profound changes. Agriculture, protected by the corn laws from 1815 to 1846, and thereafter exposed to the full blast of world-wide competition, tended to become localized and specialized; the arable area shrank, the farming population decreased. Highland crofts and even sheep farms became uneconomic, but Scotland was famed for the wheat of the Lothians and the east country seed potatoes, for Ayrshire dairy products, Clydesdale horses and fruit, and Aberdeen-Angus cattle. Mechanization was applied in turn to the basic processes of the spinning and weaving of cottons, woollens and linens. The hand-loom weaver was squeezed out of the labour market, though for a long period (1820–70) the Paisley shawl makers fought gallantly to maintain their skilled craft. Banks became larger and fewer; there were ten by 1900 (and only six by 1954), most of them with numerous branches throughout the country.

The most spectacular advances were, however, made by the metallurgical industries, which became closely integrated and interdependent and, as heavy industry. dominated the economic life of the country. At its base, coal mining was the primary concern of large numbers (over 100,000 by 1900) in the central lowland belt, stretching from Ayrshire to Midlothian and west Fife. Ironworks, profiting irom David Mushet's discovery of the properties of blackband ironstone (1801) and from James Beaumont Neilson's invention of the hot-blast furnace (1828), were concentrated in north Lanarkshire. Henry Bell's successful steamship, the "Comet" (1812), inspired the establishment of many shipyards. especially on the Clyde. but 'also on the Forth. Tay and Dee. So, too. from the modest beginning of the short Monkland-Kirkintilloch line (1826), a network of railways was spread over the entire country, control ultimately going to five main-line companies. Throughout the century marine and general engineering expanded steadily, and from the 1880s steel-making was carried on intensively in the Motherwell area. By 1900 heavy industry was the life-blood of the nation, though other activities. particularly seaborne commerce and a wide variety of small local businesses, shared in the general prosperity.

The second phase of the Industrial Revolution wrought enormous. and often adverse, changes in the structure of society and in living conditions. The total population increased during the 19th century from 1.608.000 to 4,472,000; even more remarkable was the geographical redistribution of the inhabitants. While one after another the Highland counties passed their peak and began to experience depopulation. and while the numbers in the prosperous farming areas remained fairly stable. the figures for the central lowlands increased sharply every decade. The counties of Ayr, Renfrew. Dumbarton, Lanark. Stirling. West Lothian and Midlothian, with 522.000 inhabitants in 1801, had no fewer than 2,673,000 in 1901: that is, nearly 60% of the total population lived in an area equal to 11% of the whole. Glasgow and Edinburgh, including their suburbs. had 762,000 and 317,000 persons respectively; and great advances were shown, not only by such old towns as Dundee. Aberdeen, Paisley. Leith and Greenock. but also by new, or almost new, concentrations: like Airdrie. Coatbridge, Wishaw, Motherwell. Clydebank and Cowdenbeath. From the 1840s, many thousands of Irish immigrants and their descendants went to swell these totals; it is estimated that in some towns they numbered as many as a quarter of the inhabitants.

While life was pleasant and exciting for the well-to-do, the years 1800–50 meant for the toiling masses crowded in filth and degradation in city slum and mining village inescapable squalor, insecurity and poverty, congestion, disease and death. Typhus fever took a steady toll of the poor. and cholera, in its three major visitations (1832. 1848 and 1854). killed many thousands. The marvels of the age. railway and steamship travel, piped water. gas lighting, did not reach the wage earner. Poor relief was chaotic and inadequate. juvenile delinquency all too prevalent, intemperance the almost universal response to the discontents of the working class. The hasty and unplanned industrialization of the country involved happiness for the few and social deterioration for the many.

Rise of the Social Services.—In the first half of the century private charity did something to alleviate distress by may of soup kitchens, the distribution of clothing and food at times of grave unemployment and the provision of medicines through dispensaries for the poor. Savings banks. mechanics' institutes: friendly societies, trade unions, temperance societies (from 1829) and "ragged" or industrial schools (from 1841) were among the various kinds of collective action taken to combat the ills of society. From 1800, and more especially from 1833. the civic authorities were being entrusted with wider "police" powers which included street cleaning, lighting and water supply. The amendments of the poor law in 1845 encouraged the relief from the parochial rates of the aged and orphans, the impotent and the indigent.

In the main: however, it was only after 1850 that strenuous, and ultimately successful, endeavours were made by the central and local government to ameliorate the conditions of the poorer inhabitants. The cause of temperance was advanced by the Forbes-Mackenzie act (1853). which set up strict control of the liquor trade. Where the need was most acute, a clean and adequate supply of water was provided for Glasgow through the Loch Katrine scheme (1859). Medical officers of health were appointed at Edinburgh (1862) and Glasgow (1863), and soon after special fever hospitals were established. Slum clearance on a large scale was begun at Glasgow in 1866 and at Edinburgh in 1867. Gas lighting was municipalized at Glasgow in 1869 and at other towns not long afterward: electricity and the tramways (horse-drawn from the 1870s, electrified from about 1900) followed in the 1890s. The provision of public parks. municipal washhouses and baths, model lodginghouses and public libraries brought new amenities to the ordinary town dweller, and co-operative societies offered him cheap groceries. Some measure of the general improvement wrought by the social services is afforded by the fact that the death-rate fell from 22 to 17 per 1,000 in 40 years (1860–1900).

THE TWENTIETH CENTURY

Party Politics 1900–1955.—The Scottish electors, by a narrow margin, had supported the Unionist government in 1900, but by 1905 they reverted to their traditional allegiance; in that year they returned 58 Liberals, 12 Conservatives and Unionists, and 2 members of the Labour party. The nation generally favoured the radical policies of the Liberal administrations during the years 1905–14, as instanced by the introduction of old age pensions (1908), house of lords reform (1911). national insurance (1912) and the very controversial Irish Home Rule bills of 1912 and later years; and the two general elections of 1910 made little change in the relative strength of the parties.

World War I.—From Aug. 1914 until Nov. 1918 all energies were bent to the single object of winning the war. In that struggle some 74,000 Scotsmen were killed and a much larger number suffered from wounds, sickness and exposure. The long agony of trench warfare added many heroic pages to the regimental histories, while at home it was a time of feverish industrial activity, of civilian privations, but also, fortunately, of little direct war damage. Party politics were mostly laid aside under a coalition government, though the Clyde Workers' committee advocated extreme socialism and prepared the way for what came later to be known as Red Clydeside.

Between the Wars.—In the "coupon election" of Dec. 1918 (in which, for the first time, all women over 30 could vote), Scotland returned 60 supporters of the Lloyd George administration that had been in office for the latter part of the war, and only 14 opponents. Government by coalition continued until 1922, when party politics were resumed. The most striking feature of the years 1922–31, in Scotland to a far greater degree than in England. was the advance of the Labour party, who won 30 of the 74 Scottish seats in 1922, 35 in 1923, and 38 in 1929; concurrently, the Conservatives made marked gains from the once great Liberal party, who held only 9 Scottish constituencies in 1924 and 14 in 1929. From about 1927 industrial depression and the example of Ireland led to a revival of the demand for Scottish Home Rule, which had been mildly advocated by the Liberals for a generation before World War I; and the Scottish Nationalist party was founded in 1927 to press for complete self-government.

The acute financial crisis of 1931 precipitated the formation of a broad-based national government and the subsequent rout of the Labour opposition. which was reduced in Scotland to seven members. From 1931 the political scene was dominated by the great depression and the measures taken to promote economic recovery, until, from 1936, this major issue was overshadowed by the even greater menace of the approach of war. In Nov. 1935 the national government, now predominantly Conservative in composition and policy, was returned to power with a reduced but still substantial majority (over 240 in the whole country) and won 46 Scottish seats; the 28 others comprised 20 official Labour seats. 4 Independent Labour, 1 Communist and only 3 Liberals.

World War *II* and After.—For nearly six years (1939–45) military, naval and air operations occupied men's thoughts to the exclusion of politics in the narrow sense; though casualties were fortunately fewer (34,000 in the services and 6,000 civilians) than in World War I, and air-borne destruction was lighter than might have been expected. it was again a period of anxiety and danger, of privation and all-pervading "austerity." In May 1940 a national coalition government was formed under the leadership of Winston Churchill. A party truce was agreed and observed for the duration of the war. but toward its end political restiveness declared itself through the election of Sir John Boyd Orr as an

Independent member for the Scottish universities and of Robert McIntyre as a Scottish Nationalist at Motherwell (both in April 1945). In domestic affairs the greatest event of the time was the Beveridge report, outlining a comprehensive plan of social security and a national health service (Dec 1942).

The most remarkable trend of the postwar years was the emergence, to something very like parity. of the Conservative and Labour parties, with the Liberals being squeezed out of existence as a middle group. Labour may be said to have non Scotland by very narrow margins in 1945 and again in 1950, but the returns in 1951 showed the two major parties exactly balanced. nith 35 seats each. while Orkney and Shetland returned Scotland's solitary Liberal member. With one net gain (Central Ayrshire) in 19jj, the Conservatives (including associated parties) could in turn claim to have achieved a slender victory at the polls

Although Scotland had attained (through the Scottish Grand committee) a limited share of legislative devolution and (through the Scottish departments located in Edinburgh) a substantial measure of administrative devolution, agitation continued for a separate Scottish parliament to deal with Scottish affairs. Before 1949 the nationalist movement, while it had attracted much attention and inspired widespread discussion. had achieved by direct political action only one short-lived parliamentary victory and a few gains in local and other elections. In 1949, however, the Scottish covenant nas launched, in an efiort to ain all-party support for a Scottish parliament. Within two years the sponsors of the covenant claimed over 2,000,000 signatures

Economic and Social Development. — The basis of the Scottish economy — excessive and even unhealthy reliance on heavy industry — remained unaltered down to 1914; a large flow of orders for the building of both naval tonnage and merchant vessels kept the shipyards busy and gave an illusion of continuing prosperity. The stimulus of wartime needs in the years 1914–18, for repairs and new ships. for armaments and service clothing, and for home-grown food, meant temporary boom conditions for many of the metallurgical and textile concerns and for farming in general, but such developments as the enforced abandonment of foreign markets (*e.g.*, for coal shipments and textile goods) mere the worst possible augury for Scotland's future. These lessons were brought home painfully during the 1920s, when short spells of profitable enterprise, as in the replacement of lost merchant ships. alternated with long bouts of trade stagnation or depression. The background was supplied by industrial disputes (most notably the prolonged coal stoppage of 1921 and the nine-day general strike of 1926), mounting figures of unemployment and the fierce competition offered in a shrinking world market by such foreign rivals as Indian jute, Polish coal, Czechoslovakian linens and German ships.

The great depression. which began with the financial crisis of 1931, affected Scotland. with its insufficiently varied economy. with peculiar severity. Wheat sold for 24*s*. 8d. a quarter, instead of (as during the war) 70*s*.; at one time in 1931 only one of Scotland's 77 furnaces was in blast; Clyde shipbuilding output. which had stood at 750,000 tons in 1913, sank to 56,000 in 1933; and the unemployed total rose to 407.000 in 1933, or over 30% of the insured workers. Scotland's plight had indeed never been worse.

The country climbed slowly from the depths of the great depression: its recovery was assisted by the adoption of full protection (1932); the designation of central Scotland, as of other areas, as a distressed (later a special. and finally a development) area (1934): the establishment of the Herring Industry board in 1935 (followed in 1951 by that of the White Fish authority); the institution of industrial estates. with factories for renting. starting at Hillington in 1937; and the rearmament orders that flowed in during the years before the outbreak of World War II. That great conflict did less damage to the economy than did World War I; from it. indeed, some positive gains accrued, including steady and assured support for agriculture, and the fruitful work of the north of Scotland hydroelectric board (1943). Under the Labour governments of 1945–51, coal mines, railways and certain sectors of road transport were nationalized, and the welfare state meant high wages and full employment; while strenuous efforts were made, by private as by public enterprise, to introduce new, light, consumer industries. The improvement and diversification of the country's economy were also the aims of the forestry commission. the Scottish council (development and industry), the Scottish tourist board and the crofters' commission, nhile the planning of three New Towns, at East Kilbride. Lanarkshire. Glenrothes. Fife, and Cumbernauld, Dunbartonshire, was another move in the same direction.

Gron th of the population continued in the 20th century (see belon). though at a slower pace than formerly, from 4,472,000 in 1901 to 5,096,000 in 1951. This increase is more than accounted for by the gron th of the eight central counties, stretching from Ayr to Midlothian and Fife (from 2,892 000 to 3,573,000); and by 1951 no less than 82.9% of the inhabitants dnelt in towns of over 1,000 people In the arable farming areas of the east. as well as the crofting Highlands and the dairying southwest, rural parishes were everynhere declining in the face of urban growth.

State policy was directed toward the much-needed improvement of Scottish housing. After 1945 the annual output of building rose to reach a peak of aver 39,500 in 1953, most of these being local-authority houses for renting (see *Housing* below). As a result the numbers living in houses of one or two rooms (which were generally of low standard) fell from 49.6% of the population in 1911 to 29.7% in 1951. Much slum clearance remained to be done; e g., over three-fourths of the inhabitants of tao of Glasgon's wards still lived in one or two rooms. Yet the general death rate dropped from 1j per 1,000 in 1900 to 12 in 1952, while infant mortality which had never been below 100 per 1,000 until 1916, stood at 29 in 1956.

Noteworthy, too, are the social changes which cannot be measured statistically The masses. with increased leisure and higher real wages, made greater use of the agencies of instruction, enlightenment and entertainment such as libraries, museums and art galleries, daily nenspapers and evening classes, rural institutes, clubs and societies. the cinema (from the 1900s), the radio and dance hall (from the 1920s) and television (from 1952). The increased mobility of all ranks by motorbus and car, by bicycle and afoot, brought the countryside back to the city dweller and contributed to the general improvement of the health of the nation.

(G. S. P.)

POPULATION

At the census taken in 1961 the population of Scotland was 5,178,490 (females 2,694,320). This was an increase of 1.6% on the number enumerated at the previous census of 1951 and continued the series of intercensal increases recorded at every census except 1931, when a decrease of 0.8% on the 1921 figures was recorded. Since the mid-19th century the population has approximately doubled. At the 1841 census the total population enumerated was 2,620,184, which represented an increase of more than 1,000,000 on the total at the first official census in 1801. At the end of the 15th century it is estimated that the population did not exceed 500,000 — Edinburgh having about 20,000 inhabitants, Perth about 9,000, and Aberdeen, Dundee and St. Andrews about 4,000 each.

Since the middle of the 19th century there has been a net emigration from Scotland to other countries of about 1,870,000, of whom about 1,400,000 have emigrated since 1900. In 1921–30 emigration was over 390,000, or about 8% of the population at the beginning of the decade. Because the age groups affected were in the lower range, the consequential loss was greater than the total suggests. The 1920s were years of considerable unemployment but in the next decade and during World War II the outward flow of migration mas checked, and in the years 1931–51 the net loss was about 240,000, mainly to England. After 1951 it averaged about 24,000 a year.

There has also been an appreciable inflow of population. At the 1931 census 346,050 of the population (7.14%) were born outside Scotland. In 1951 the number was 400,537 (7.86%), of whom 231,794 were born in England and Wales, 43,354 in Northern Ireland and 45,126 in the Republic of Ireland.

If the population were evenly distributed throughout Scotland it would have amounted in 1961 to 174 per square mile. Actually,

by far the largest part of the country had a population density of less than one person per square mile, the maximum degree of concentration being found in the highly industrial area lying approximately between the upper reaches of the Firth of Clyde and the Firth of Forth. A secondary but much smaller concentration is found along the southwestern and the eastern coasts. During the period 1951-61 there was a slight loss of population in most of the northern and border counties. and a more than compensating gain in the central industrial area. The population in the different counties is shown in Table I.

TABLE I.—Area and Population of Civil Counties in Scotland
(1951 census)

Civil counties		Area (sq. mi.)	Population
1. Northern:	Zetland (Shetland)	551	17,809
	Orkney	376	18,743
	Caithness	686	27,345
	Sutherland	2,028	13,442
2. Northwestern:	Ross and Cromarty	3,089	57,607
	Inverness	4,211	83,425
3. Northeastern:	Nairn	163	8,421
	Moray	476	49,156
	Banff	630	46,400
	Aberdeen	1,971	298,503
	Kincardine	382	48,810
4. East Midland:	Angus	874	278,370
	Perth	2,493	127,018
	Fife	504	320,541
	Kinross	82	6,704
	Clackmannan	55	41,391
5. West Midland:	Stirling	451	194,858
	Dunbarton	241	184,546
	Argyll	3,110	59,315
	Rute	218	15,129
6. Southwestern:	Renfrew	225	338,815
	Ayr	1,132	342,855
	Lanark	898	1,626,317
7. Southeastern:	W. Lothian	120	92,764
	Midlothian	366	580,332
	E. Lothian	267	52,653
	Berwick	457	22,441
	Peehles	347	14,117
	Selkirk	268	21,055
8. Southern:	Roxburgh	665	43,171
	Dumfries	1,075	88,423
	Kirkcudbright	897	28,877
	Wigtown	487	29,107

During the period 1951-61 speakers of Gaelic declined by 19,939 to 75.508, of whom 1.079 spoke no English. The two principal Gaelic-speaking counties were Ross and Cromarty and Inverness. In 26 counties less than 1% of the population spoke Gaelic. There had been comparatively little diminution since 1891 in the number of children aged three and four years speaking Gaelic but not English. which would indicate that the language was still largely in use in the homes of the people. The percentage speaking only Gaelic began to fall after the beginning of school life, and continued low through middle age, rising again with those aged 60 and over.

Births during 1931–50 totaled 1.849,272, an annual average of 92.464. In 1955 there were 92,539 births. equal to a rate of 18 per 1.000 of the population. Births per 1,000 married women aged 16-44 in 1955 were 134.2. The average size of the families of women aged 4j-jo at the time of the 1951 census was 2.52. The corresponding figure for 1911 was 5.08.

The average annual death rate for Scotland in 1931–50 was 13.2 per 1,000. This rate had progressively diminished since 1861–70, when the registered rate reached 22.1. Deaths from all causes in 195j numbered 61.645. representing a death rate of 12 per 1.000.

The average annual marriage rate in 1931–50 was 8 1 per 1.000 of the population. The comparable figure in the period 1921–30 was 6 9 During and immediately after World War II the rate rose considerably. reaching 9.4 in 1945. In 19jj there were 43,212 marriages registered. which represented a rate of 8 4 per 1.000. The rate was higher in the central industrial area than in the north or south. The Marriage (Scotland) act, 1939, operating from July 1, 1940, abolished irregular marriages by declaration. including what was often known as the "Gretna Green marriage" and "marriage before the sheriff." It instituted a new form of civil marriage. to be contracted after publication of notice in the office and presence of registrars authorized for the purpose. In 1955 there nere 8.333 such civil marriages.

The populations of the largest towns (1961 census) were: Glasgow 1,054,913, Edinburgh 468,378, Aberdeen 185.379, Dundee 182,959, Paisley 95,753, Greenock 74,578, Motherwell and Wishaw 72,799, Coatbridge 53,946, Kirkcaldy 52,371.

SOCIAL CONDITIONS

Religion. — The Church of Scotland (Presbyterian) is the most influential and powerful religious body in Scotland (see SCOTLAND, CHURCH OF and FREE CHURCH OF SCOTLAND). Its system of government is based on the right of congregations to choose their own ministers. The administration of each parish is in the hands of a kirk session, comprising the minister and ruling elders, nominated by the congregation; groups of parishes constitute presbyteries; and these latter are grouped in synods. The presbyteries send clerical and lay representatives to the general assembly of the church. held annually in Edinburgh. The number of communicants in the Church of Scotland at the end of 1954 was 1,292,127. The Roman Catholic population in Scotland is estimated to be more than 760,000. It is located mainly in Glasgow and the neighbouring towns, where many Irish immigrants have settled, but there remain a number of Roman Catholic communities in the isolated parts of the Highlands and in the Hebrides which were unaffected by the Reformation. The Episcopal Church in Scotland had 56 528 communicants in 1955 Other religious groups include the Baptists, the Methodists. the Congregationalists and the Unitarians, while there is also a Jenish community of about 15,000 mainly concentrated in Glasgow.

Education. — History. — Schools were founded in Scotland during the middle ages under the patronage of the church and latterly also of the burghs, but it was only after the Reformation that the ideal of a comprehensive system of education was formulated. The First Book of *Discipline* (1560), drawn up by the leaders of the Reformed Church. included a scheme which provided that every town was to have a school and every parish a schoolmaster, and that the children of all, whether rich or poor. were to receive education according to their capacity. The Reformed Church lacked the resources needed to carry out this scheme, but the ideal behind it was never lost sight of. and in 1696 the Scots parliament enacted that it should be the duty of the heritors (landowners) of every parish to provide a "commodious house for a school" and the salary of a teacher.

From 1834 Scotland received parliamentary grants for education, and government inspection of schools followed. The supervision of the schools had long remained with the church, but the Education (Scotland) act of 1872 transferred the organization and administration of education to popularly elected school boards, and made education compulsory betneen the ages of 5 and 13. The school leaving age was raised to 14 in 1901 and to 15 in 1947. The Roman Catholic Church and the Scottish Episcopal Church retained their voluntary schools until the passage of the Education (Scotland) act 1918, which substituted for the school boards 33 county and 5 urban ad *hoc* education authorities and provided for the transfer to them of church schools subject to conditions designed to preserve their denominational character. The Local Government (Scotland) act, 1929. eliminated the separate education authorities and committed the local administration of education to the county councils and the tonn councils of the four cities (Edinburgh. Glasgon. Xberdeen and Dundee). The Education (Scotland) act. 1945, contained fewer important innovations than the English act of 1944, as some of the major changes effected by the English measure had already been carried out in Scotland. The Education (Scotland) act, 1946. which consolidated earlier Scottish educational legislation, conferred on the secretary of state for Scotland various poners and duties. including the distribution of grants, nhich are exercised through the Scottish education department and laid on the 35 education authorities the duty of making adequate provision for educational needs.

Types of *Schools*.—There are three main classes of schools in Scotland, all subject to inspection; public schools. managed by education authorities; grant-aided schools, conducted by bodies of voluntary managers nho receive grants from the secretary of state, and independent or private schools, nhich receive no assistance from public funds but are required to be registered In the year ending July 31, 1957, there were 3,234 public schools, with over 842,000 pupils, 31 grant-aided schools with over 15,000 pupils, and approximately 160 independent schools attended by about 22,000 pupils. Over a quarter of the public schools are one-teacher schools. while those with not more than three teachers amount to almost half the total. Of the public and grant-aided schools, 787 provide secondary education. and of these 203 provide a full secondary course extending to at least five years. Primary and secondary education is available free in public schools. The functions of education authorities include the medical inspection of school children, the provision of milk and midday meals, the convevance of children living at a distance from school and the award ofbursaries covering both school and postschool studies.

The primary school is attended by children from 5 to about 12 years of age. The Schools (Scotland) code prescribes only the broad general lines which the curriculum should follow, the actual framing of detailed courses being left to the school authorities, subject to the approval of her majesty's inspector. Pupils are allocated, generally between the ages of $11\frac{1}{2}$ and $12\frac{1}{2}$, to the various types of secondary course according to their fitness to profit from them, assessed on teachers' estimates of attainment, intelligence tests and attainment tests. Regard is also paid to the wishes of the parents. Secondary schools are of two main types. those providing courses extending to three years (junior secondary schools) and those providing courses of five or six years (senior secondary schools). In each type of school the courses are intended to provide a general education. but they are differentiated to suit the varying needs and abilities of the pupils, and include academic, commercial, technical, domestic and rural courses. There are a number of comprehensive or omnibus schools in which all types of courses. both junior secondary and senior secondary. are provided. Modified courses are also provided for pupils of limited ability. Most schools are attended by both boys and girls. The courses in senior secondary schools normally extend to five or six years and lead to presentation for the Scottish leaving certificate, which is awarded and issued by the Scottish education department. A student securing the requisite number of passes obtains exemption from the entrance examinations of Scottish and some other universities and also admission to or exemption from the examinations of a number of other professional and examining bodies. Special schools are provided by education authorities for children with physical or mental handicaps.

There are 21 approved schools in Scotland to which the courts under the Children and Young Persons (Scotland) act, 1937, may send children under the age of 17 who need care and training. All but one of these schools are under voluntary management.

Further Education.—The great majority of young people enter employment direct from school, most of them at the age of 15. Since 1942, those who wish to enter certain industries have in many parts of the country been given the opportunity of attending full-time prevocational courses. Once they are in employment, young people may supplement practical experience by attending evening classes or part-time day-release classes. Apprenticeship training schemes are in operation in various industries. Advanced instruction in various technical and commercial subjects, in the arts and in domestic science is provided in the colleges, known as central institutions. which are under the management of independent bodies of governors and function to a considerable extent on a regional basis. Three agricultural colleges are under the general administration of the department of agriculture and the remaining 13, which include the Royal College of Science and Technology in Glasgow and the Heriot Watt college in Edinburgh. are under that of the Scottish education department. Many of the central institutions award diplomas or certificates. Others present students for national diplomas, or for certificates awarded after three and five year courses of part-time classes. For certain courses, some of the central institutions are affiliated to local universities and prepare students for degrees.

The number of students attending cultural and recreational classes for adults in 1957 was about 95,000. Through the generosity of the 11th marquess of Lothian, Newbattle Abbey college was opened as a residential college of adult education under a representative governing body in 1937. Facilities for leisure-time occupation for young people over school age are provided largely by voluntary associations and the churches with assistance from education authorities. who also make some direct provision.

All teachers in public and grant-aided schools in Scotland are expected to hold one of the certificates issued by the secretary of state on successful completion of a course of professional training. Courses of training last from one to three years according to the nature of the certificate and the degree or other qualification already held. The total number of certificated teachers employed at Oct. 7, 1957, in educational establishments of all kinds was 36,109.

TABLE 11.—Attendance at Scottish Educational Establishments,

Sessions	1938–39	1956–57
Nursery schools and classes		4,461
Primary schools and departments		603,427
Secondary schools and departments	179,930	240,188
Special schools and classes		
Approved schools	1,596	1,264
Central institutions (day and evening classes)	21,281	29,170
Further education centres (day and evening classes)	172,518	216,714

Universities.—There are four universities in Scotland: St. Andrews (founded 1411), Glasgow (1451), Aberdeen (1494) and Edinburgh (1583). By the Universities (Scotland) act, 1858. as modified by the Universities (Scotland) act, 1889, the government of the universities as regards things academic is entrusted to the senate and as regards finance and general administration to the university court. Within this framework, the University of St. Andrews, under the Cniversity of St. Andrews act, 1953, enjoys a constitution differing in some respects from those of the other universities because its teaching activities are divided between Dundee and St. Andrews. The local ton-n councils, including Dundee in the case of St. Andrews university, are represented on university courts. Although the universities receive parliamentary grants, they are autonomous institutions, with their own endowments.

The titular head of each university is the chancellor, elected for life by the general council. The office of vice-chancellor is usually held by the principal of the university, who is appointed in the case of the universities of St. Andrews, Glasgow and Aberdeen by the crown, and in Edinburgh by a body of curators of patronage. The principal is also president of the university senate, and the rector, elected triennially by the matriculated students, is the president of the university court. The court is the supreme authority in regard to finance and the regulation of the duties of professors and lecturers. The university senate consists of the principal, all the professors, and readers and lecturers specially elected, its main responsibility being the teaching and discipline of the university. The general council, comprising the chancellor, the members of the university court, professors, lecturers and readers, and all graduates. meets twice a year to consider proposals for alteration or improvement in the arrangements of the university. The domestic affairs of each faculty in the university are administered by a dean. The faculties consist of arts, science, divinity, law and medicine.

In 1901 Andrew Carnegie founded the Carnegie Trust for the Universities of Scotland. the annual income of which (about £120,000) is devoted partly to the payment of students' fees and partly to assist the universities in their development projects and in fostering research. This gift, together with bursaries provided by education authorities, has helped to make it possible for anyone to attend the university who is able to obtain the necessary qualifications for admission.

The Royal College of Surgeons, the Royal College of Physicians of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgom jointly confer registerabie medical qualifications.

The Arts.—Since the end of the 19th century Scottish contributions to the arts have been mainly in the fields of painting and writing. The scene dominated by William MacTaggart and the painters of the Glasgow school until the outbreak of World War I was later occupied by S. J. Peploe (1871–1935). His chief contemporaries were Leslie Hunter (1879-1931) and F. C. B. Cadell (1883-1937) and the influence of the group can be seen in the work of W. G. Gillies. MacLauchlan Milne and William MacTaggart, grandson of the landscape painter. The work of the painters and sculptors is seen at the annual exhibitions of the Royal Scottish academy in Edinburgh and the Royal Institute of the Fine Arts in Glasgow. Other annual exhibitions are those of the Society of Scottish Artists, which specially encourages experimental work, and the Royal Scottish Society of Painters in Water Colours. In architecture the functionalism of Charles Rennie Mackintosh (1869-1928) has had a wide influence, even more abroad than in Scotland. For the work of such earlier Scottish painters as Allan Ramsay and Sir Henry Raeburn see their biographies.

For Scotland's main contribution to literature see SCOTTISH LITERATURE. It should be noted, however, that the revival of interest in drama has been a marked feature of the 20th century and the work of James Bridie (O. H. Mavor) (1888-1951) has had a stimulating effect. It was largely due to his inspiration that the Glasgow Citizens' theatre was founded. There are now thriving repertory theatres also in Dundee. Perth and Edinburgh. The Scottish Drama association has successfully formed many small amateur groups throughout the country.

In 1947 the Edinburgh International Festival of Music and Drama was founded. With its complementary art exhibitions. film festival and military tattoo. it is held annually for three weeks in late August and early September and has established itself as a notable event in the British calendar.

Cultural Institutions.— Library services are operated both by tonn councils which have adopted the Public Libraries (Scotland) acts, 1887 to 1955, and by county councils under the Education (Scotland) act. 1946. The development of libraries in Scotland has been greatly stimulated both by the liberality of Andre\\ Carnegie during his lifetime and also by the support of the Carnegie United Kingdom trust. which is responsible for the establishment of the Scottish Central Library for Students.

The Library of the Faculty of Advocates in Edinburgh. which had been founded in the 1680s and had enjoyed since 1709 the privilege of deposit under the Copyright act of that year, became the National Library of Scotland in 1925, when its great collections of books and manuscripts, other than those concerned aith lan. were offered to the nation. The library contains the largest collection of Scottish books and manuscripts in the world and. nith a leaning to the humanities rather than natural sciences, it maintains collections representative of the western norld and especially of France. Spain and the United States.

The Royal Scottish museum established in Edinburgh in 1854, is financed by the government and is under the administration of the Scottish education department. There are four departments: art. archaeology and ethnology; natural history; geology; and technology. It provides a world-wide review of the natural and applied sciences and of man's handicrafts, exclusive of pictorial art and modern sculpture. It lays considerable emphasis, however on the Scottish fauna and upon Scottish achievements in the realm of industry and technology. The National Gallery of Scotland, opened in 1859, and the Scottish National Portrait gallery, opened in 1889 (both in Edinburgh) are financed by the treasury and a number of private endowments and are controlled by a board of trustees responsible to the secretary of state. The National Gallery of Scotland contains a collection of European paintings from the 14th to the early 20th century which includes such masterpieces as Velasquez "An Old Woman Cooking Eggs,· \ermeer's "Christ in the House of Martha and Mary," Rembrandt's "Hendricke Stoffels in Bed." Watteau's "Fête Vénitiennes" and Constable's "The Vale of Dedham." Scottish painting is represented more thoroughly. uith particular emphasis on Ramsay, Raeburn and Wilkie, and on moderns such as Peploe, Hunter and Cadell.

The National Museum of Antiquities of Scotland (Edinburgh) has one of the most important prehistoric collections in Britain; a notable Roman section including the Traprain treasure: rare relics of the Celtic church and other dark age and Viking metalwork, with a large series of sculptured monuments. Relatively less of consequence has survived from medieval Scotland. The museum has the best collection of Scottish coins and of 17th- and 18th-century Scottish weapons and accessories, and considerable domestic and "folk-life" sections.

The National Trust for Scotland was founded in 1931 to promote the preservation of lands and buildings of beauty or historic interest. Among the properties the trust has acquired are such scenes of beauty and grandeur as Glencoe and Rintail, such monuments of the past as Bannockburn and Culloden, and the birthplaces of such national figures as Thomas Carlyle (at Ecclefechan), J. M. Barrie (at Kirriemuir) and Hugh Miller (at Cromarty). The trust has restored old buildings to use, as in the old burgh of Culross in Fife, and also holds several castles and family mansions. such as Crathes castle and Falkland palace, on terms which, while securing access to the public. enable the family to remain in residence, thus perpetuating a living historic association.

GOVERNMENT

Central Government.— Since the union of the Scottish and English parliaments in 1707, Scotland has been represented in the house of lords and the house of commons. The provision of the Treaty of Union whereby the holders of Scottish peerages created before 1707 are represented by 16 of their number elected at the beginning of each parliament still stands but there is a much greater number of Scotsmen in the house of lords uho hold peerages of Great Britain or the United Kingdom created since then. In the house of commons, by the Treaty of Union. Scotland was given 45 members. This number has been increased at different times since the Reform bill of 1832. By the Representation of the People act, 1948, Scotland was divided into 71 constituencies, each of which returns one member to the house of commons.

In the house of commons it is the practice for bills which apply exclusively to Scotland. and occasionally the Scottish part of a bill applying to Great Britain, to be referred for consideration to the Standing Committee on Scottish Bills.

On the union of the English and Scottish parliaments the ministers who had previously been responsible for Scottish administration for the most part ceased to exist. The law officers, known as the lord advocate and the solicitor general for Scotland. continued to discharge their legal functions and soon after the union of 1707 an additional secretary of state was appointed for Scottish affairs. But the appointment was by no means continuous and between 1 jog and 1746 the office was vacant during 20 years. The additional secretaryship came to an end altogether in 1746. For a period thereafter Scottish business fell to the department of the northern secretary of state; and in 1782 the home secretary was made responsible for Scottish affairs. the lord advocate, chief law officer of the crown in Scotland, acting as his adviser. This arrangement was increasingly resented in Scotland and in 1885 the new office of secretary for Scotland was created. To the holder of this office were transferred functions relating to Scotland previously assigned to the home secretary, the privy council. the treasury and the local government board. The headquarters of the secretary for Scotland, the Scottish office. were in London. In 1926 the office of secretary for Scotland was abolished and the functions of its holder transferred to a principal secretary of state. The Scottish ministers. in addition to the secretary of state who is a member of the cabinet, include the lord advocate. the solicitor general. a minister of state and three parliamentary undersecretaries.

During the 19th century and the early years of the 20th century a number of boards were established in Edinburgh to deal with various aspects of Scottish administration. All of these boards mere in varying degrees subject to the control of the secretary for Scotland. In 1928 three of the most important of them were replaced by departments of the standard civil service pattern. each directly answerable to the secretary of state. In 1935 a division of the Scottish office (*i.e.*, the secretary of state's office in London) was opened in Edinburgh. Then in 1939, by the Reorganization of Offices (Scotland) act. the functions of the Scottish departments and boards were transferred, with minor exceptions, to the secretary of state, who set up four administrative departments in St. Andrew's house, Edinburgh. These four main departments are the department of agriculture for Scotland, the Scottish education department, the department of health for Scotland and the Scottish home department. In the spheres of foreign and commonwealth affairs, trade, industry, employment, supply, transport (with the exception of roads. which became the responsibility of the secretary of state for Scotland in 1956) and defense, in which the life of Scotland is closely interlinked with that of England and Wales, the responsibility for administration is vested in departments of ministers whose functions extend throughout Great Britain. The secretary of state takes a general interest, however, in all administration affecting Scotland and ensures that, even in matters for which he is not directly responsible, the interests of Scotland are safeguarded.

Local Government. — Scottish local government has its antecedents in the burghs, shires and parishes of medieval Scotland. The burghs were primarily settlements of merchants and craftsmen, often with special privileges and property granted to them by charter from the crown or from territorial magnates for the fostering of trade. The shire was the area over which the sheriff, as the royal representative, had jurisdiction for the preservation of law and order. The parish nas centred on the church and concerned itself from early times with the relief of the poor and with education. In the 19th century, the industrial revolution and the attendant huge increase in population in central Scotland brought new and pressing problems of local government and at the same time a demand for more democratic control of local government units. Throughout that century there was a twofold movement: to set up town councils for the new communities which had come into being; and to reform the constitutions of town councils of the old royal and parliamentary burghs. Elected county councils were set up in 1889 and were given powers chiefly in relation to roads, police and public health; elected parish councils were set up in 1894 but were abolished in 1929.

The local government system in Scotland as it exists today mas established by the Local Government (Scotland) act, 1929, but is now based for the most part on a consolidating act of 1947. The country is divided into 33 counties, two pairs of which—Perth and Kinross, and Moray and Nairn — are combined for certain purposes; there are also large and small burghs and four counties of cities (Edinburgh. Glasgow. Dundee and Aberdeen); the part of the county outside the burghs is known as the "landward area" and is divided into districts. Local government is by town councils, county councils and district councils. The powers of town councils vary according to the degree of importance of the burgh. In the counties of cities the town council performs all local authority functions; in the 20 large burghs the town council performs almost all functions except education. valuation for rating and, in some cases. police; in the 173 small burghs the town council performs some (*e.g.*, housing, water supply and cleansing). but another large group (including education, police, classified roads and health services) is performed by the county council. In the landward area of the county the county council exercises all local authority functions except certain minor ones mostly concerned with amenity which are entrusted to district councils. District councils may also exercise powers delegated to them by the county council.

Town council elections in burghs are held annually to replace the third of the council who have been longest in office. The whole of each county council is elected once in every three years. The district council is elected along with the county council.

The cost of the services provided by the local authorities in Scotland is met principally from rates and government grants, and, to meet expenditure of a capital nature, by the raising of loans. Rates are levied on the owners and occupiers of lands and heritages on their ratable value. as shown in the valuation roll; properties are revalued every five years under the Valuation and Rating (Scotland) act, 1956, but the roll is made up yearly to show gross annual, net annual and ratable values. There are two main kinds of government grants. Grants are paid toward the cost of specific services (such as education, housing, roads, child care, police, fire services and civil defense) and are normally a given percentage of approved expenditure. The other type of grant is the exchequer equalization grant which is given toward the general expenditure of local authorities; the effect of this is to bring the financial resources of local authorities up to a certain national average. Other sources of local authority income include rents of local authority houses; fees, fines and miscellaneous charges; and profits from trading undertakings such as transport services, markets and slaughterhouses.

A feature of burgh finance peculiar to Scotland is the "common good." which originally formed the main revenue of burghs and normally consisted largely of property granted in the foundation charter or subsequent gifts. The purposes for which the income from the "common good" can be used include, generally speaking, anything which furthers the general good of the inhabitants or the dignity of the burgh, and thus it can be used for purposes for which there is no authority to levy a rate. Not all burghs have a "common good" and in 1947 local authorities in general were given power to set up "fee funds" from certain fees and commissions, which may be used for any purpose for which the "common good" may be used.

Law and Administration. — By the Act of Union of 1707 the legal system then existing in Scotland was preserved and the civil and criminal jurisdiction of the Scottish courts has remained separate and distinct from that of England. The supreme civil court is the court of session, which is composed of 15 judges and sits in the old Parliament house in Edinburgh It is divided into an outer house consisting of seven judges, and an inner house consisting of two divisions of four judges. Each division sits as a court of appeal — the first presided over by the lord president and the second by the lord justice-clerk — to hear appeals from the outer house or the sheriff court (see belou). A right of appeal from the decision of the court of session normally lies to the house of lords. The supreme criminal court of Scotland is the high court of justiciary, of which the judges are the same as those of the court of session. It sits not only in Edinburgh but also on circuit in certain cities and burghs. Trials before the high court are always trials by jury, the Scottish jury consisting of 15 persons. The verdict may be returned by a majority and may in cases of reasonable doubt be one of "not proven." Since 1926 the high court, sitting as a court of criminal appeal, has been empowered to hear appeals in certain cases tried by jury in either the high court or the sheriff court. There is no appeal in criminal cases to the house of lords. Scotland is divided for local judicial purposes into 12 sheriffdoms, for each of which the crown appoints a sheriff and a number of sheriffs substitute. The sheriffs of Lanarkshire and of the Lothians and Peebles and the sheriffs substitute throughout Scotland are whole-time resident judges presiding over the sheriff courts, a Scottish institution of great antiquity. The other ten sheriffs are part-time officers, chosen from among leaders of the Scottish bar, whose functions are normally limited to hearing occasional appeals from their sheriffs substitute and to performing certain administrative duties. The sheriff court has a civil jurisdiction virtually concurrent with that of the court of session (except that it cannot deal with divorce) and it also has a wide jurisdiction in criminal cases. Minor criminal offenses may be tried in the burgh police court presided over by magistrates appointed (except in the case of one stipendiary in Glasgow) by the town council from among their own number, or in counties before justices of the peace appointed by the secretary of state for Scotland on the recommendation of local advisory committees.

Responsibility for the institution of criminal proceedings in the high court and the sheriff court rests with the lord advocate, who is assisted in the discharge of this function by the solicitor general, four advocates depute and procurators fiscal stationed throughout Scotland. The crown office in Edinburgh, of which the permanent head is the crown agent, is the central department concerned with this work. Prosecutions in the burgh and justice of the peace courts are instituted by prosecutors specially appointed by the town council or the justices. (*See* also SCOTS LAW.)

Liquor Licensing System. — The sale and supply of excisable (*i.e.*, alcoholic) liquor is regulated by statute. For each county and each burgh with a population exceeding 7,000 (and for a few smaller burghs) there is a licensing court which in a county is composed of an equal number of county councilors and justices of the peace. and in a burgh is composed of the magistrates. Licensing courts of appeal consider appeals against decisions of the licensing courts. In addition to fixing (within a statutory maximum) the hours during which liquor may be sold the licensing court grants certificates, valid for one year at a time, to keep licensed premises. There are three forms of certificate—for hotels, public houses and grocers. Clubs do not require a certificate from a licensing court. but must be registered by a sheriff after inquiry and consideration of any local objections. On Sundays public houses and grocers may not sell liquor; but hotels may supply residents and travelers.

Under the Temperance (Scotland) act. 1913, a local authority must, if required, hold a poll in the parish, burgh or ward concerned to decide (1) whether there should be no change in the power of the licensing court to grant certificates; (2) whether the number of certificates should be reduced by 25%; or (3) whether no certificates should be granted. except for the sale of liquor with meals. Between 1920 and 1929 there were 1,079 polls; between 1929 and 1957 only 25. In 1957 there were 17 areas with a limited number of certificates and 22 with none.

Police, Prisons and Borstal Institutions.— Before 185;. the provision of police forces in Scotland was governed by adoptive acts. In that year, however, the Police (Scotland) act made the establishment of efficient police forces in every county compulsory. In burghs, most of which already maintained police forces, the establishment of police forces was made compulsory in 1892. The Local Government (Scotland) act. 1929, transferred to county councils responsibility for policing all burghs other than large burghs (*i.e.,* burghs with a population of 20.000 or more) then having their own force. and limited to burghs with a population of 50,000 the right to establish their own forces in future. The Police (Scotland) act (1946) empouered any two or more police authorities to amalgamate their police forces and administer them by a joint committee; and also empowered the secretary of state to amalgamate police forces compulsorily if he considered this to be in the interests of police efficiency. The law relating to police administration was consolidated by the Police (Scotland) act. 1956. There were 33 police forces in Scotland in 1956, with strengths ranging from 16 to 2,590; the total establishment was 8.843.

Under the Prisons (Scotland) act. 1877. the administration of prisons in Scotland was transferred from the local authorities to the state. and prison commissioners for Scotland were established. The administration passed in 1929 to the prisons department for Scotland and in 1939 to the Scottish home department. The acts governing the administration of prisons and Borstal institutions were consolidated under the Prisons (Scotland) act, 1952. There are eight prisons, two of which have sections set aside for the detention of Borstal inmates, and four separate Borstal institutions. one of which has a small prison section attached. The average number in custody in 1957 was 2,435, of whom 1,935 were prisoners. 84 criminal lunatics and 416 Borstal inmates.

Social Services.——Formerly the relief of destitution mas dealt with under the poor law which in Scotland goes back to 1424. The act of a Scots parliament in that year and other early acts, however, were largely concerned merely with restricting begging to those nho could not win their living otherwise. But eventually there mas developed a system of relief based on the parish and administered largely by church authorities. The law was consolidated in the Poor Law (Scotland) act of 1845 which remained on the statute book for a century. Relief (or public assistance) was mainly "outdoor" (*i.e.,* the recipients remained at home) and was paid in cash. The authorities administering the law had also a duty to provide medical relief where necessary. "Indoor" relief was provided in poorhouses, nhen a poor person required institutional or hospital care. The emphasis in Scotland was on outdoor rather than indoor relief. In 1930 the administration of the Scottish poor law was transferred from some 87j parish councils to 55 large authorities made up of 31 county councils and 24 town councils of large burghs. Central supervision was exercised, in terms of the act of 1845, by a board of supervision nhose duties eventually fell to the department of health for Scotland.

The breakup of the poor law in Scotland (as in the rest of the United Kingdom) began with the Old Age Pension act of 1908 and ended with the passing of the National Assistance act of 1948. Under the latter act relief of poverty by cash payments is undertaken by the national assistance board. but the former public assistance authorities are required to provide residential accommodation for the aged and infirm who require care and attention. The act also empowers the authorities to provide welfare services for the blind. deaf or dumb, and other handicapped persons.

Under the National Health Service (Scotland) act, 1947, there was set up a comprehensive health service similar to the English one (see SOCIAL SECURITY). The following are the principal parts: a full family doctor service with an associated pharmaceutical service; a general dental service; a supplementary ophthalmic service; all forms of hospital care and treatment, both inpatient and outpatient; specialist opinion and treatment; an ambulance service; and arrangements for prevention. care and aftercare of illness (including care of mothers and young children, school health services and day nurseries. domiciliary midwifery services, health visiting. home nursing and domestic help services, vaccination and immunization. and health education). There are three main agencies for the administration of the health service. The 2j executive councils administer the general practitioner services. Almost half of their members are appointed by the doctors. dentists and chemists in each area, and the remainder by the secretary of state or the local authorities. There are five regional hospital boards responsible generally for hospital, specialist and allied services. with the actual day-to-day management of hospitals entrusted to 83 boards of management. Regional board members are appointed by the secretary of state, and board of management members by the regional boards. County councils and town councils of large burghs, as local health authorities, are responsible for the remaining services which are grant-aided by the state to the extent of 50%. All the services are available to every member of the public without any insurance qualification. Charges to patients were introduced in 1951, 1952 and 1956 covering part of the cost of the general dental service, the pharmaceutical service, the supplementary ophthalmic service, and the supply of certain appliances to hospital outpatients. The remainder of the services are free of charge. Estimated total expenditure to be charged to exchequer funds in 1958–59 was £58,300,000 with £10,500,000 from weekly contributions under the National Health Service Contributions acts, 1957 and 1958, and approximately £2,500,000 met by local authorities from local rates.

Housing.—Although the provision of houses by local authorities began late in the 19th century. up to 1919 practically all the houses in Scotland nere privately owned or built by private owners and let to tenants. The rents of these latter houses were first controlled in 191j and for many of them the rents were still controlled in 1953 at a level fixed in 1920. Building by local authorities began on a serious scale in 1919 when state assistance was introduced. In the next 20 years 337,000 houses were built, about two-thirds by local authorities; conditions nere substantially improved. special government subsidies being provided for slum clearance and the relief of overcrowding, and grants for the reconditioning of rural houses. Over 28.000 houses were built during 1 War 11 In 1943 it was estimated that 500.000 houses were still needed. Between 1945 and 1957 nearly 321,000 permanent houses, mainly of three and four apartments, in addition to 32,000 temporary houses. were built. About 91% of the permanent houses were built by local authorities or the Scottish Special Housing association (a body set up to assist local authorities by building in areas of greatest need). Since World War II government subsidies for housing have been available on a large scale to local authorities, but subsidies for new houses to meet other than special needs were reduced by the Housing and Town Development (Scotland) act. 1957. That act introduced a special subsidy to encourage the provision of overspill houses to meet the needs of congested areas in other districts. a problem of increasing importance. Additional subsidies are payable for houses in remote areas, houses for agricultural workers, multistoried flats. experimental houses and in certain circumstances for houses built in

TABLE III.—Houses Built, 1945–57

Year	Private enterprise	Local authority	Other agencies	Total
1945	141	1,428	—	1,569
1946	499	3,811	—	4,310
1947	1,354	10,773	22	12,149
1948	1,541	19,547	123	21,211
1949	1,102	24,180	565	25,847
1950	782	24,314	715	25,811
1951	1,145	20,997	786	22,928
1952	2,242	27,623	1,082	30,947
1953	2,393	35,992	1,163	39,548
1954	2,608	35,331	914	38,853
1955	3,523	29,278	1,268	34,069
1956	4,576	26,290	1,035	31,901
1957	3,513	28,326	598	32,437
Total	25,419	287,890	8,271	321,580

local materials. Since 1949 subsidies and grants have been available to local authorities and private persons for the improvement and conversion of existing houses. In 1952 and 1953 postwar controls on private building were substantially relaxed and in 1954 were abolished altogether, but the volume of private building has been relatively small since 1919.

The 1951 census showed that 31.5% of Scottish houses had only one or two rooms; 9.3% of the households were living at a density of more than two people per room (14.6% in central Clydeside and 15.6% in Glasgow), and 12.6%, 34.4% and 49% did not have exclusive use of a piped water supply, a water closet and a bath respectively.

After World War II local authorities were encouraged, as a first step in the improvement of housing conditions, to concentrate on the building of additional houses so that each family might have a home of its own, but there has since been increasing emphasis on slum clearance and redevelopment. While the provision of new houses has remained a primary aim of housing policy, the Housing (Repairs and Rents) (Scotland) act. 1954, was introduced with a view to ensuring that the best use was made of the existing stock of houses. The act required local authorities to submit proposals for dealing with unfit houses in their areas; these proposals showed that in the three years 1956–58, local authorities intended to demolish or close about 40.000 unfit houses. With the aim of arresting the deterioration of many privately owned. rent-controlled houses, the act also provided that a two-fifths "repairs increase" in the rent of such houses should be allowed, provided that the house was in or was put into good repair, and that an "expenditure test" on repairs could be satisfied. The Rent act. 1957, in its application to Scotland, raised the amount of this increase to one-half and introduced a new alternative increase of one-quarter for houses in good repair: no "expenditure test" is required for the latter increase. The Rent act also removed from rent control houses with a rateable value in excess of £40; any new tenancy of a house is likewise free from rent control.

ECONOMICS

Agriculture.— Until the latter part of the 18th century progress in Scottish agriculture was restricted by warfare and unrest, insecurity of tenure and feudal practices. The quickening of enterprise then was marked by the introduction of new crops, such as turnips and sown grasses and clover, and new methods of rotation farming and by the enclosure and equipment of land in convenient units. This resurgence did not extend, however, to the Highlands and islands where conditions for the crofters were severe. Wholesale clearances in many districts during the first half of the 19th century compelled many crofters either to emigrate or to move into areas already congested. The Crofters' Holdings (Scotland) act. 1886 and later statutes, conferred a measure of security of tenure and provided for the fixing of fair rents, enlargement of crofts and common grazings, improvement of the breeds of livestock. construction and improvement of roads and piers and the development of home industries.

In Scotland the agricultural depression of the late 19th century was marked by a reversion from tillage to stock farming, by rural depopulation and by the breakup of estates and the growth of owner-occupation. The urge toward progress was evidenced, however. by the introduction early in the 20th century of formalized agricultural education, followed after World War I by the establishment of research organizations. Acts of parliament passed in 1919 and 1934 enabled the department of agriculture to acquire estates and farms for land settlement. Government action to meet the depression also included assistance first given to wheat growers in 1932 and extended in 1937 to growers of barley and oats; a subsidy to beef producers; and facilities under marketing acts to regulate production and the marketing of produce. Minimum and overtime rates of wages were fixed under the Agricultural Wages (Regulation) (Scotland) act. 1937. Rates were not uniform for all districts until 1949 when the Scottish agricultural wages board fixed uniform rates throughout Scotland.

Following the outbreak of World War II a system of guaranteed prices and assured markets for the main agricultural commodities was introduced. A high level of food production was still needed after the mar and expansion programs were launched in 1947 and 1952 to increase further the contribution of home agriculture to the national larder. The Agriculture act. 1947, required the government to review annually, in consultation with representatives of agricultural producers, the industry's economic condition and prospects. Following each annual review, the government fixed guaranteed prices for 12 products—cattle, sheep, pigs, milk, eggs. wheat. barley, oats, rye, potatoes, sugar beet and wool. As a supplement to prices, special grants and subsidies were available for certain classes of livestock and fertilizers and for various agricultural operations; *e.g.*, plowing, cultivation of marginal land. drainage, provision of water supplies, bracken eradication. Capital grants were provided under the Hill Farming act, 1946. and the Livestock Rearing act. 1951, for the improvement of land and facilities in poorer agricultural areas. Originally created to assist in the administration of wartime services, a system of agricultural executive committees was continued after the war under the Agriculture (Scotland) act, 1948. This act embodied in permanent form many wartime provisions, including provisions consolidated in a later act, giving a large measure of security of tenure to tenant farmers.

Special provision for the crofting areas of the Highlands and islands was made in the Crofters (Scotland) act, 1955, which brought about important changes in crofting law designed to open the way for the reorganization of holdings and for greater efficiency in their management. It provided for the setting up of a crofters commission and introduced special schemes of assistance designed to suit crofting conditions.

Over 15,000,000 of Scotland's 19,000,000 ac. are devoted to agriculture. Over 3,000,000 ac. are under arable cultivation. 1,000,000 ac are permanent grass and nearly 11.000,000 are rough grazings. The demand for land for urban purposes is continuous, however, and each year up to 4.000 ac. of cultivated land are needed for new houses, schools, factories, etc. There are about 73,000 individual agricultural holdings of more than one acre. About one-quarter of these are owned by the occupiers. Only about 32,000 of the 73,000 holdings can be regarded as full-time farms; the remainder are smaller units and crofts which normally provide only part-time jobs for their occupiers. Farming falls into three main types: arable cropping with stock rearing and fattening in the east; sheep and cattle raising in the Highlands and in the southern uplands; and dairying in the southwest. Livestock and livestock products are the major part of the agricultural output. The dairy breeds of cattle include the Ayrshire and British Friesian; Aberdeen Angus. Beef Shorthorn, Galloways and the picturesque West Highland or Kyloe breed and their crosses are the

TABLE IV.—Principal Crops in Scotland in 1957 main beef breeds. In Dec. 1957, 92% of all the cattle in Scotland was attested as free from bovine tuberculosis. The predominant sheep breeds are Blackface. South and North Country Cheviots, all hill types. and on lowland farms crosses with these breeds and the Border Leicester. Second crosses with English breeds provide lambs suitable for both grass and winter feeding on lowland farms. Poultry are kept on most farms and are of particular importance in Aberdeenshire and Orkney. Pig production has become more important. In 1957 livestock in Scotland numbered: cattle. 1,779,000 (dairy 790,000, others 989,000); sheep. 7,802,000; pigs. 473,000; poultry, 9,158,000; and horses on agricultural holdings. 26,000. The number of horses dwindles yearly. as farm mechanization increases.

Scotland has achieved renown for progressive work in agricultural research nhich is performed at ten institutes: the Rowett institute (founded 1911) dealing with animal nutrition; the Animal Diseases Research association (1921); the Scottish Society for Research in Plant Breeding (1921); the Hannah Dairy Research institute (1928); the Macaulay Institute for Soil Research (1930); the Animal Breeding Research organization (1945); the National Institute of Agricultural Engineering. Scottish station (1946); the Poultry Research centre (1947); the Scottish Horticultural Research institute (1953); and the Hill Farming Research organization (1954).

Forestry.—In primitive times great forests covered much of Scotland but various factors, including the use of charcoal for iron smelting and the extension of sheep rearing, had greatly reduced these by the end of the 18th century More settled conditions during the 19th century led to a revival of interest among landowners in tree planting and at the beginning of the 20th century it is estimated that Scotland had over 1,000,000 ac. of woodland, although this included a large area of scrub oak and birch. World War I made great inroads on the country's reserves of standing timber and in 1919 the forestry commission mas established to prepare and execute a national forest policy. Before the commission's first young plantations had come to maturity World War II made further great demands on the country's timber reserves and in 1946 the commission embarked on an extensive scheme. the aim of which is to provide in Great Britain 5,000,000 ac. of productive noodlands. It was intended that half of this acreage should be in Scotland. Planting proceeded at a steadily increasing rate. Between 1947 and 1956 the forestry commission planted approximately 262,900 ac., and during the same period private owners were estimated to have planted 69,000 ac. At the end of 195j the area of plantations in Scotland extended to 815,000 ac.. of which 388,000 ac. were privately owned and 427,000 ac. belonged to the forestry commission. The main species planted are the native Scots pine. the Sitka and Norway spruces, the European. Japanese and hybrid larches, the Corsican pine and the Douglas fir. The volume of timber produced in Scotland in 1955 from thinnings and clear fellings in private estates and forestry commission plantations was 18.800.000 cu.ft. The 1,135,000 ac. owned by the forestry commission in 1955 were organized in 204 separate forest units. The number of men directly employed was about 4.600. Afforestation brought new life to dwindling communities; three new villages were formed to house forest workers: Ae in Dumfriesshire, Dalavich in Argyll and one at Glentrool forest on the borders of Wigtownshire and Kirkcudbrightshire.

Under the Forestry act, 1945, responsibility for Britain's forest policy is shared by the secretary of state for Scotland and the minister of agriculture. The forestry commission is in Scotland also guided by a national committee which includes Scottish forest commissioners.

Four national forest parks established in Scotland are: Argyll (58 000 ac.). Glenmore. Inverness-shire (12,500 ac.), Glentrool, Kirkcudbrightshire (129,900 ac.) and the Queen Elizabeth Forest park. Perthshire and Stirlingshire (41.500 ac.).

Fisheries.—Sea fishing is an important item in the Scottish economy, the herring catch being more than half the total for Great Britain and the white fish or demersal catch about one-fifth. The chief kinds of white fish caught are haddock, cod and whiting; lemon soles, halibut, hake and plaice are also valuable catches, though less in quantity. Drift-net fishing is the principal method of catching herring; trawling and seine-net fishing and great lining, in that order. are the principal methods of catching white fish. The chief fishing port is Aberdeen. Other important ports are Leith. Fraserburgh. Peterhead and Lossiemouth on the east coast; Lerwick in Shetland; and Ullapool, Stornoway, Mallaig, Campbeltown, Tarbert and Ayr on the west coasts. In 1957 the total quantity of fish landed in Scotland by British vessels was 5,876,220 cwt. valued at £12,867,593 and shellfish valued at £583,264. The principal kinds are indicated in Table V.

Table V.—Commercial Fishing Catch, 1957

	Amount (cwt.)	Value (£)		Amount (cwt.)	Value (£)
Herring . . .	1,648,700	1,640,300	Whiting . .	725,500	1,410,900
Other pelagic fish .	111,600	94,200	Other demersal fish	822,600	3,093,300
Haddock . .	1,689,000	4,114,100	Lobsters (value only) . . .	—	266,400
Cod . . .	878,700	2,514,800	Other shellfish (value only) .	—	316,800

In addition 109,505 cwt. of fish valued at £259,391 were landed by foreign vessels.

Shipments of fish to overseas markets from Scottish ports included 52,000 barrels of pickle-cured herring. The fishing fleet comprised 138 sail vessels? 2.920 motor vessels! 3 steam liners and 164 steam trawlers. a total of 3.225 vessels. The number of Scottish fishermen was 11,623, of whom 1,489 were crofter fishermen and 1,151 were partially employed in fishing.

Salmon fishing is a valuable industry. In 1957 the total salmon catch was 1.581 tons valued at £855,786, of which 310 tons were taken by rod and line and the remainder by commercial net fisheries. The number of men directly employed in commercial salmon fishing during the season was 1.720.

The secretary of state for Scotland. through the Scottish home department, is responsible for Scottish fisheries. The department employs fishery officers at the principal fishing ports; has a marine laboratory, employing four research vessels, at Aberdeen, and a Fresh-water Fisheries laboratory at Pitlochry; and maintains a fleet of fishery cruisers. The Herring Industry board and the White Fish authority operate throughout the United Kingdom; the former has its chief office in Scotland, and the latter has a committee for Scotland and Northern Ireland with delegated powers.

Mining and Minerals.—Coal is the chief source of the mineral wealth of Scotland. The earliest records appear to be the charters granted, toward the end of the 12th century, to William Oldbridge of Carriden in West Lothian, and in 1291 to the abbot and convent of Dunfermline, but coal was not used for domestic purposes till about the close of the 16th century.

After World War I lack of demand in both the home and overseas markets led to a fall in the output of the Scottish coal fields and there was much unemployment in the mining districts. In 1939, 30,500,000 tons of coal were produced compared with 41,300.000 tons in 1910 and during World War II there was a further decline to 21,400,000 tons (1945). Between 1950 and 1955 the average annual production was about 23.000.000 tons. Since the end of World War II coal has also been won from opencast workings at the rate of betneen 500,000 and 1,000,000 tons a year. At the end of 1955 nearly 84,000 people were employed. Apart from thin seams and the prevaience of water, adverse geological conditions in the form of steep inclinations, fault dislocations and igneous intrusions make coal mining comparatively difficult in Scotland. Nevertheless, much progress has been made in mechanized coal mining, modernization of underground transport and power-operated surface installations. Until 1930 the Lanarkshire field produced nearly one-half the coal mined in Scotland but the workable reserves of coal in this field then began to show signs of becoming exhausted. New reserves, honever, have been opened in Fife, the Lothians, Stirlingshire and Xyrshire, and the first undersea bore for coal ever undertaken by any country was completed in the Firth of Forth in 19j5.

The Coal Industry Nationalization act, 1946, vested the ownership and control of the industry in the National Coal board. In Scotland the board took over all the large collieries, representing about 97.3% of the total production; the remainder, mostly small surface mines. continued under the former owners under licence.

Ores of iron and other metals, apart from lead and zinc, have been virtually exhausted, but appreciable deposits of nonmetalliferous minerals remain. Among the minerals worked are limestone, shell sand, dolomite, high grade silica rock and sand, molding sand, ganister, fire clay, bauxitic clay, serpentine, talc, diatomite and barites. Granite for ornamental, monumental and building stone is worked in Aberdeen and Kirkcudbright, and other building stones are widespread. Slate and flagstone are also worked, as are sands and gravels for building and stone for road construction.

Large areas in Scotland are covered with peat, which is still used in remote districts as a domestic fuel and in central Scotland for horticultural purposes. Considerable progress has been made at Altnabreac Moss, Caithness, with a scheme for using peat as a fuel for gas turbines to generate electricity.

Electricity. — Electricity in Scotland is generated from both steam and water power. The generation and distribution of electricity is in the hands of two public boards responsible to the secretary of state — the North of Scotland Hydroelectric board, established in 1943, which is responsible for the north of Scotland district (covering roughly the area north and west of the Firths of Clyde and Tay), and the South of Scotland Electricity board, which in 1955 took over from the British Electricity authority responsibility for electricity in the south of Scotland.

The electricity generated in the south of Scotland is chiefly from steam, although there are hydroelectric stations on the Falls of Clyde and in Gallomay. At the end of 1957 there were 12 steam stations, with a capacity of 1,252 megawatts (Mw.), and 7 hydroelectric stations, with a capacity of 119 Mw. The total annual output was 5,402,000,000 units (5,098,000,000 from steam and 304,000,000 from hydroelectric stations). Works under construction included a new station at Kincardine-on-Forth, which would eventually have a plant capacity of 760 Mw.

In the north of Scotland district there are steam stations at Aberdeen and Dundee, with a total capacity of 133 Mw. generating 228,000,000 units per annum, and a considerable number of hydroelectric schemes with a total installed capacity of 729 Mw. and an estimated average annual output of over 1,980,000,000 units. The major schemes include Loch Sloy (Dunbartonshire). Pitlochry Breadalbane and Lawers (Perthshire), Glen Affric (Inverness-shire), Glascarnoch, Luichart and Torr Achilty (Ross-shire). Garry and Moriston (Inverness-shire), Shira (Argyll) and Shin (Sutherland). A number of other schemes are under construction or survey and it is estimated that the water power resources of the north of Scotland could produce 10,000,000,000 units of electricity per annum.

Atomic Energy. — The U.K. Atomic Energy authority was building at Dounreay, Caithness, an experimental atomic station, housing a fast breeder reactor for research into the economic production of power from nuclear energy for industrial and domestic uses at Chapelcross. Dumfriesshire, a nuclear factory which would provide a by-product output of electricity by 1958. and at Hunterston, Ayrshire, a nuclear generating station which would have an output capacity of 300 Mw.

Gas. — The production and distribution of gas is the responsibility of the Scottish Gas board. In 1956 there were 154 gasworks in production in Scotland, but the number would decrease as gas supplies were made available from larger works by the construction of linkage mains. During 1955–56, 46,678,000,000 cu.ft. of gas were produced at gasworks and 4,320,000,000 cu.ft. of gas purchased from coke ovens. Coal gas accounted for 80.8% of the total gas made and bought; water gas for 8.7%, other gas for 2.0% and coke oven gas for 8.5%.

Iron and Steel. — All the great iron foundries and engineering works are situated in the central lowlands, in close proximity to the shipbuilding yards and coal fields. Formerly iron ore was obtained locally but the deposits are now exhausted and the Scottish furnaces are fed with ores imported mainly from Sweden. Sierra Leone and French North Africa, and with scrap; as a result of the severe world competition for scrap, the need to use proportionately more pig iron production became apparent and the major Scottish producers in the 1950s had developments under way that would increase substantially their pig iron production. A wide range of finished steel is produced but the heavier products predominate, especially shipbuilding plates and sections. The industry suffered severely during the depression of the early 1930s but has prospered since World War II. Output of crude steel in 1955 was 2,343,900 tons compared with 1,601,400 tons in 1938.

TABLE VI.—*Scottish Steel Production, 1929–55*
(in 000 tons)

1929	1932	1939	1943	1945	1948	1950	1951	1955
1,580	550	1,875	2,031	1,747	2,254	2,426	2,115	2,344

The Iron and Steel act, 1953, repealed the Iron and Steel act, 1949, and provided for the return of iron and steel undertakings to private ownership under the general supervision of the Iron and Steel board. Many of the undertakings located in Scotland were as a result returned to private ownership; the remainder were to be returned when suitable arrangements should be completed.

Shipbuilding and Engineering.--Over one-third of the annual output of new merchant ships in the United Kingdom comes from Scottish shipyards. The industry is heavily concentrated on the Clyde, the principal yards being in and around Glasgow (Govan, Scotstoun, Clydebank. Dalmuir) and at Dumbarton, Port Glasgow and Greenock; on the lower firth there are yards at such ports as Ardrossan, Fairlie and Troon. Leading yards on the east coast are at Leith, Burntisland, Dundee and Aberdeen. The Scottish yards maintain extensive facilities for repairs and conversions and there is a substantial marine engineering industry.

Between World Wars I and II the shipbuilding industry suffered periods of severe depression but from 1945 onward the replacement of war losses and the building of tankers to match the increasing world trade in oil brought full order books. The figures of tonnage completed during recent years (in thousand gross registered tons) are as follows: 1949, 513.4; 1950, 534.4; 1951, joo.9; 1952, 454.7; 1953, 477.7; 1954, 564.8; 1955, 507.1. Shortage of steel influenced production during the postwar years. Over one-third of the tonnage completed since World War II has been for overseas owners. At the end of 1955, there were about 33,400 employed on new building in the main yards and about 7,400 on ship repairs.

There has been an increased development of engineering, particularly in the west of Scotland and in many of the larger towns elsewhere. In addition to marine engineering, locomotive manufacture (Glasgow), the making of textile machinery (Glasgow, Dundee and Arbroath), sugar machinery (Glasgow and Greenock), pumps and electrical engineering (Glasgow. Lanarkshire and Edinburgh), mining machinery (Glasgow and Lanarkshire), boilers and boilerhouse plant (Renfrem, Clydebank and Annan) and constructional engineering (Glasgow and Edinburgh), are all well represented. More recent developments in engineering have included the manufacture of aircraft engines, agricultural machinery and fractional engines. Among the metal manufactures are radio and electronic equipment, metal containers, clocks and watches and office machinery. After World War II there was a rapid expansion in the range of products manufactured.

Oil Refining and Chemicals. — In 1851 a refinery was opened for processing the oil shale mined in West Lothian, and others followed. In 1924 a refinery was started at Grangemouth on the Forth for the treatment of imported crude oil. After World War II this refinery was modernized and expanded, and a pipeline built to bring the crude oil across Scotland from Finnart on Loch Long, where it is discharged from tankers. The refinery is linked with nearby chemical plants to which it supplies the raw material for the manufacture of industrial alcohol and organic chemicals required by the plastic and rayon industries and for drugs, dyestuffs and textile manufacturing. Pharmaceuticals, dyestuffs and soaps are also manufactured at Grangemouth; explosives at Ardeer (Ayrshire coast) and chemicals in the Glasgow area.

Textiles. — It was not until the middle of the 19th century when the industry became concentrated in the border towns of the Tweed valley that tweed manufacture assumed its present importance. A sizable modern industry also developed out of the early cottage industry in the Hebridean islands of Lewis and Harris, now famous for their crofter-woven Harris tweed. and in Shetland. Woolens are also manufactured in the Stirling district, Aberdeenshire and at Elgin, Inverness. Dumfries and Paisley. Fingering and many other kinds of woolen yarns are manufactured at Alloa. Hawick is an important centre for hosiery manufacture, a characteristic border industry. Carpets have been made at Kilmarnock since 1723, and other centres of the industry include Elderslie. Xyr. Glasgow and Stirling. About one-third of the carpets made in the United Kingdom come from Scotland.

The manufacture of linen cloth from flax is an ancient process but the industry has gradually declined. Most of the linen is manufactured in Angus, Perth, Fife, Aberdeen, Renfrew and Midlothian. Dunfermline is the principal seat of the manufacture of table and other finer linens. The jute industry was established in Dundee more than 100 years ago and the city now accounts for about the whole of the United Kingdom production. The linoleum industry, based on jute cloth, is mainly centred in Kirkcaldy; in 1948 Scottish firms accounted for about two-fifths of the United Kingdom output.

Cotton was formerly Scotland's chief manufacturing industry, the first cotton mill having been opened at Rothesay in 1779. Changes in fashion and the development of the industry in Lancashire and on the continent in the mid-19th century led to a gradual regression of the Scottish industry. The counties of Lanark (with Glasgow) and Renfrew are the main centres but it is also found in the counties of Aberdeen, Ayr, Perth and Fife. Sewing thread of both linen and cotton is produced in Paisley. Lace and madras manufacture is located in the towns of the Irvine valley in Ayrshire. Silk weaving is carried on at Dunfermline, Paisley and Glasgow. After World War II a number of jute manufacturers in Dundee produced heavy rayon yarn for the making of carpets.

Whisky, Beer and Miscellaneous Manufactures.— Scotland claims a distinctive manufacture in whisky. Whisky is an export commodity of considerable importance. the chief overseas market being the United States. There are four types of malt whisky: Campbeltown, Islay, Highland and Lowland. Grain whisky is produced in the large towns, to which the matured malt whiskies are sent for blending. Brewing of beer has been carried on from ancient times in Edinburgh, where the monks of Holyrood abbey in the 12th century made a much appreciated ale; beer is also brewed at Alloa and elsewhere but Edinburgh is still the main centre, making four-fifths of the Scottish output.

Paper, stationery and printing are industries in which Scotland has always occupied a foremost position. A paper mill was erected in 167j at Dalry, on the Water of Leith, in which French operatives were employed to give instruction! and Midlothian remains the principal centre in Scotland. Ever since it was established, early in the 16th century, the Edinburgh press has been renowned for the beauty of its typography; printing is also carried on extensively in Glasgow. Among other industries are clothing, furniture and wood manufactures, sugar refining (in Greenock), preserves and confectionery (in Dundee, Glasgow and elsewhere) and rubber manufactures (in Edinburgh, Dumfries and Glasgow).

TABLE VII.—*Changes in Distribution of Output and Manpower, 1935–48*
(Establishments employing over ten)

	4 Net output		Average % persons employed	
	1935	1948	1935	1948
Mining and quarrying	11.9	10.3	14.2	10.4
Bricks, cement, glass, etc.	2.1	2.3	2.2	2.3
Chemicals	4.8	3.7	2.2	2.9
Metal manufacture	7.2	7.7	6.7	6.5
Engineering, shipbuilding	12.7	20.1	13.2	20.5
Vehicles	2.3	4.1	3.0	5.1
Metal eoods	1.3	2.2	1.6	2.3
Precision instruments	0.3	0.5	0.4	0.6
Textiles	12.1	9.5	16.9	11.0
Leather, leather goods etc.	0.6	0.7	0.5	0.5
Clothing	2.0	1.7	3.6	2.9
Food, drink and tobacco	14.6	11.7	9.9	8.4
Wood and cork products	2.1	2.4	2.6	2.6
Paper and printing	7.6	5.4	6.5	5.0
Other manufacturing	2.3	1.9	2.0	1.9
Building and contracting	9.5	11.7	12.0	14.5
Gas, electricity and water	6.6	4.1	2.5	2.6
Total	100.0	100.0	100.0	100.0

Industrial Development.— Table VII shows the changes in the industrial scene that took place between 1935 and 1948. and in particular the increased emphasis on shipbuilding and engineering.

A striking feature of recent industrial development has been the establishment of government-sponsored industrial estates, mainly in the central industrial belt. In 1956 there were 340 firms occupying a total of 15,500,000 sq.ft. of factory space and covering a wide range of light industries.

Employment and Unemployment.— The changes that took place in the distribution of industrial manpower between 193j and 1948 are shown in Table VII; the distribution of manpower in Scotland in 1955 is shown in Table VIII.

TABLE VIII.—*Distribution of Total Manpower in Scotland, June 1955**

H. M. forces	81,000	Building and contracting	170,000
g r i c e forestry, fishing	155,000	Gar, electricity and water	28,000
Mining and quarrying	100,000	Transport and communications	188,000
Manufacturing industries:		Distributive trades	290,000
Metals, engineering, shipbuilding and vehicles	386,000	Professional, finanrial'and miircllaneous services	378,000
Textiles and clothing	160,000	Public administration	115,000
Food, drink and tobacco	111,000	Registered unemployed	47,000
Other manufacturing industries	176,000	Total	2,385,000

*These figures include all persons age 15 and over at work or available for work including employers and self-employed persons.

Between World Wars I and II the trend of unemployment in Scotland was similar to that in Great Britain as a whole (see UNEMPLOYMENT). The actual figures, for representative years, calculated in December, mere: 1921. 238 426; 1926, 202,670; 1931, 359,149; 1936, 265,395. The monthly average for eight years following World War II was: 1948, j6 Soo; 1949, 62,100; 1950, 64,700; 1951, 53,400; 1952, 69,300; 1953, 64,100; 1954, 59,500; 1955, 51,000.

Communications.—*Shipping* and Canals.—The principal ports in Scotland are Glasgow. Greenock and Xrdrossan on the west coast, and Leith, Grangemouth. Dundee. Aberdeen and Methil on the east coast. Glasgow is the largest Scottish port and in 1954 handled imports and exports to the value of £263,000,000; of this sum imports accounted for £105,200,000; exports consisted of produce of the United Kingdom valued at £156,800,000 and imported merchandise worth just under £1,000,000. The next largest totals of imports and exports were handled at Leith (£48,230,000), Grangemouth (£45,040,000) and Dundee (£21,200,000). There is also an extensive coastwise traffic between the Scottish ports and ports in England and Wales and Northern Ireland. Large quantities of merchandise are moved between Scotland and England and Wales by road and rail

There are four navigable canals in Scotland, the Caledonian (*q.v.*), the Crinan, the Forth and Clyde and the Union; all are now onned and operated by the British Transport commission. They do not carry much traffic. A fifth canal, the Monkland, which ran between Glasgow and Calderbank, was abandoned for navigational purposes in 1950 as no traffic had passed over it for a number of years.

Railways —The first railway in Scotland for which an act was obtained was that betneen Kilmarnock and Troon ($9\frac{3}{4}$ mi.), opened in 1812 and worked by horses. By 1840 the length of railway lines that had received parliamentary sanction was $191\frac{1}{4}$ mi. The chief companies were the North British which, formed in 1845, developed a network extending from Berwick to Aberdeen and St. Xndrens to Mallaig and including the Forth and Tay bridges; the Caledonian which, formed in the same year, eventually served much of nest and central Scotland; the Glasgow and South-Western, formed by amalgamation in 1850 and. like the North British and Caledonian, running steamers on the Firth of Clyde; the Highland (1865), with a vertical axis running from Thurso to Stanley and a lateral axis from Keith to Kyle of Lochalsh; and the Great North of Scotland (1846), concentrated in the Aberdeen area. By the Railway act of 1921 the companies were merged into the London, Midland and Scottish and the London and North Eastern Railway companies. By the Transport act of 1947 the undertakings of these companies were vested in the British Transport commission and their lines in Scotland were united to form the Scottish region of British Railways. The

Transport act, 1953, provided for the setting up of a railway authority in Scotland under the general financial control of tne British Transport commission; this authority— the Scottish Area board—was set up in 19jj.

Roads.— It was not until the 18th century that the road system of Scotland had its beginning. Under the turnpike acts roads were built in the Lowlands while in the Highlands military roads were constructed to assist in the suppression of the clans. Gen. G. Wade built three main roads. running north from Stirling and Perth and south from Inverness to Fort Augustus and over the Corrieyairack pass (2.519 ft.) to Dalwhinnie. In 18 years at the beginning of the 19th century Thomas Telford made nearly 1.000 mi. of new roads and built 1,117 bridges, under the authority of the Highland roads and bridges commissioners. In 1878 many of the counties were divided into separately rated districts for roadmaking purposes, but the Local Government (Scotland) act, 1929, reduced the landward authorities to one for each county. After World War I the main roads of Scotland, in common with those of Great Britain, became increasingly a responsibility of the national government. In 1936, the minister of transport became the authority for all trunk roads, of which 1,188 mi. were in Scotland; the trunk road mileage was increased to 1,949 under the Trunk Roads act. 1946. In 1956 there mere. in addition, 4,804 mi. of class I road, 3,917 of class II, 6,312 of Class III and 10,451 of unclassified roads, making a total mileage of 27,433. In 1956 responsibility for highway matters in Scotland were transferred from the minister of transport and civil aviation to the secretary of state for Scotland.

Civil Aviation.— Commercial civil aviation began in Scotland in the early 1930s. The first airmail service was inaugurated between Inverness and Kirkwall via Wick in 1934, and the first continental air service between Aberdeen and Stavanger via Newcastle in 1937. Other aerodromes were developed at Edinburgh, Perth and Wick and by the outbreak of World War II a number of air routes were centred on Renfrew and Xberdeen. Prestmick, established by Scottish Aviation Ltd., was enlarged and developed by the air ministry during World War II and became the terminal of the transatlantic air ierry services. Prestwick airport later came under the control of the ministry of civil aviation as Britain's second international airport. It is used by most of the airlines operating on the North Atlantic routes and has services to several northern European capitals. During 1955, Prestwick airport handled 208,450 passengers. Renfrew, airport ior Glasgow, is the focal point ior Scotland's regional air services and handles trunk route traffic to London, Manchester, Birmingham, Belfast, Dublin, the Channel Islands and Paris: Passengers in 1955 numbered 305,600. The airports at Edinburgh (Turnhouse) and Aberdeen (Dyce) are also connected by trunk route services to points in the south. A special ieature of Scottish civil aviation is the air ambulance service which carries patients in need of urgent hospital treatment from landing strips in remote parts of the country to Renfrew, Aberdeen, Wick or Inverness. Since 1956 arrangements have been made ior helicopters oi the Royal Navy or Royal Air Force to move cases of extreme urgency where other means of transport are not available.

Banking and Insurance.— It was fortunate for Scotland that the monopoly granted to its first bank, the Bank of Scotland, on its foundation in 1695 was not renewed when it expired 20 years later. Freedom to issue notes, which in those days was synonymous with banking, made possible the formation of large banks and the spread of branches throughout the country. As a result, the provision of banking services had been concentrated in the hands of a few relatively large and stable institutions even before 1844, when the Bank Charter act began the process of absorption and amalgamation among the small country banks in England. Bank failures were thus a rarity in Scotland. Scottish bank notes provided a cheap and reliable currency during the years when great improvements in agriculture and the development of industry were taking place; and many of these developments were made possible in a country always desperately short of capital, by the "cash-credit" system which was the hallmark of Scottish banking in the 18th and 19th centuries. Cash credits were granted to people who, though short of capital, could command the support of two acceptable sureties, Allied to an unlimited right of note issue, this system, potentially, was highly inflationary in character, and it is a tribute to the shrewdness of the early bankers that overexpansion followed by crisis was so rare. The saving habits of the Scottish people must also be given due credit and it was in Scotland that the first trustee savings bank was formed, by Henry Duncan of Ruthwell, in 1810.

The Scottish banks' still retain the right of note issue but the Bank Notes (Scotland). act, 1845, obliged them to hold gold coins as cover against notes actually in circulation and, with the withdrawal in the 20th century of gold coin from the country's currency, Bank of England notes became the principal covering requirement. These issues, however, still make it possible to maintain branches in small communities where, without them, the provision of banking services would be too expensive.

The following banks now operate in Scotland: Bank of Scotland (1695); Royal Bank of Scotland (1727); the British Linen bank (1746); the Commercial Bank of Scotland Ltd. (1810); the National Bank of Scotland Ltd. (1825); and the Clydesdale and North of Scotland Bank Ltd. (1838).

The business of fire insurance has been transacted since 1719, in which year a company was established in Edinburgh. At first its operations were confined to the insurance oi buildings and it was not until 1767 that goods were insured. The early part of the 19th century saw the establishment in Scotland of several offices, which were quick to extend their fields of operation. By the opening of branch offices, first in the north of England, then in London and in the course of years overseas, Scottish insurance became international in its character and the companies now operate in almost every part of the civilized globe. In 1955 the premium income of the Scottish insurers was: fire insurance, £43,500,000; accident insurance, £59,600,000; marine insurance, £8,700,000. The service given by Scottish offices also covers every phase of life assurance and annuity business including group assurance and group pension schemes for employees of firms or companies. In 19jj the annual premiums received by Scottish offices in this field amounted to £60,790,000. (D. Me.)

SCOTLAND, CHURCH OF. The purpose of this article is to trace the growth of the Scottish kirk as a whole, defining the views on which it was based and the organization in which they took form. The controversies within the Church of Scotland have not arisen out of matters of faith but out of practical questions of church government and of the relation of church and state. Holding a church theory to which the rulers of the country were for a century strongly opposed, Scotland became the leading exponent of presbyterianism (*see* PRESBYTERIAN); and this note has been the dominant one in its religious history.

Scottish Reformation.— The Scottish Reformation came out of a covenant in which the barons, inspired by John Knox, then abroad, bound themselves in 1557 to oppose the Roman Catholic religion and to promote the cause of the Reformation. When parliament, on Aug. 24, 1560, passed the acts abolishing the papal jurisdiction and the Mass in Scotland, it was able. as Knox had been preparing for this crisis, to sanction a new confession of faith for the Reformed Church. Other documents of the new system were quickly forthcoming. The *First Book of Discipline* set forth the whole of the proposed religious and educational constitution, and this book speaks of "the order of Geneva which is no in use in some of our churches." This order, afterward with some modifications known as John Knox's Liturgy and used in the church down to the reign of Charles I, is a complete directory of worship, with forms of all the services to be held in the church.

The type of religion found in these documents is that of Geneva, the unit being the self-governing congregation and the great aim of the system the pure preaching of the Word; but the *First Book of Discipline* does not set forth any complete scheme of church government. Its arrangements are in part provisional. In addition to the minister, who is its most definite figure and proved to be the most permanent, it recognizes the superintendent, the lay elder and the reader. The superintendent was a parish minister whose added function was to plant churches and place ministers, elders and deacons where required. Whether the superintendents were meant to be permanent in the church is not clear. The lay elder was very much what he is still. The reader was to conduct service when no minister was available, reading the Scriptures and the Common Prayer. A noble scheme of education was sketched for the whole country, but neither this nor the provision made for ministers' stipends was carried out, the revenues of the old church, from which the expenses of both were to be paid, being in the hands of the barons.

The system naturally took time to get into working order. The old clergy, bishops, abbots and priests were still on the ground, and were slow to take service in the new church. In 1574 there were 289 ministers and 715 readers. As the ranks of the clergy slowly filled, questions arose which the Reformation had not settled, and it was natural that the old system with which the country was familiar should creep in again. Presbytery was never much in favour with the crown; and when the crown, so weak at the Reformation, gained strength, encroachments were made on the popular character of the kirk, while the barons also had obvious reasons for not wishing the kirk to be too strong. The first parliament of the regent Moray (1567), while confirming the establishment of the Reformed Church as the only true church of Christ, settling the Protestant succession and doing something to secure the right of stipend to ministers, reintroduced lay patronage, the superintendent being charged to induct the patron's nominee—an infringement of the reformed system against which the church never ceased to protest. Andrew Melville (*q.v.*) came to Scotland at this time, and became the leader of the church in place of Knox. who died in 1572. He brought with him from Geneva, where he had been the colleague of Theodore Beza, a fervent hatred of ecclesiastical tyranny and a clear grasp of the Presbyterian church system. The Scottish Church, hitherto without a definite constitution. soon espoused under his able leadership a logical and thorough presbyterianism, which was expressed in the *Second Book of Discipline*, adopted by the assembly in 1577, and was never afterward set aside by the church when acting freely. It recognizes four kinds of office in the church, and no one can lawfully be placed in any of them except by being called to it by the members. Pastor, bishop and minister are all titles of the same office, that of those who preach the word and administer the sacraments, each to a particular congregation. The doctor is a teacher in school or university; he is an elder and assists in the work of government. Elders are rulers; their function also is spiritual. though practical and disciplinary. The fourth office is that of the deacons, who have to do with matters of property and are not members of church courts. Kirk sessions and presbyteries are not named. but the principles are clearly laid down on which these institutions are to rest.

Presbyterian Principle.— By committing itself to this system the Church of Scotland established between itself and the Church of England a division which became more and more apparent and was the cause of much of its subsequent sufferings. It is no doubt strange that it should have endured so much not for any great Christian principle but for a question of church government. On the other hand, presbyterianism stood in Scottish history for freedom. and for the rights of the middle and lower classes against the crown and the aristocracy; and it might not have been held with such tenacity or proved so incapable of compromise but for the opposition and persecution of the three Stewart kings. The history of the Scottish Church for a century after the date of the *Book of Discipline* is that of a religious struggle between the people and the crown.

For several years after its inception presbyterianism carried all before it. The presbyteries came quickly into existence; that of Edinburgh dates from 1580. In that year it was found that there were 924 parishes in Scotland, but not nearly all supplied with ministers; it was proposed that there should be 50 presbyteries and 400 ministers. A great part of the country, especially in the north and west, had not yet been reached by the Reformation. At this time began the long series of attempts made by James VI in the direction of curbing Presbyterian liberty and of the restoration of episcopacy. For a few years his attitude was different. A Roman Catholic rising threw James into the arms of the kirk; in 1592 the *Second Book* of *Discipline* was legalized and presbytery set up. The church was at the time very powerful, the people generally sympathizing with its system, and its assemblies being attended by many of the nobles and the foremost men. Discipline was strict; the temper of the church was in accordance with the Old rather than the New Testament. On his accession to the throne of England in 1603 James entered on a new set of attempts to assimilate the Scottish Church to that of England. In 1609 two courts of high commission were set up by the royal authority with plenary powers to enforce conformity to the new arrangements. In 1612 the act of 1592 which established presbytery was rescinded, and episcopacy became the legal church system of Scotland.

National Covenant. — In all this it was the position and rights of the clergy that were assailed. The people had been less interfered with; the change of church government involved no change in the conduct of worship. But the Articles of Perth, passed by a packed assembly in 1618, foreshadowed what was soon to be the policy of the crown. During the first years of his reign Charles was occupied in other directions; but when he came to Scotland in 1633 to be crowned William Laud came with him, and though like his father Charles showed himself kind to the clergy in matters of stipend, and adopted measures which caused many schools to be built, he also showed that in the matter of worship the policy of forcing Scotland into uniformity with England was to be carried through with a high hand. A book of canons and constitutions of the church, which appeared in 1635, instead of being a digest of acts of assembly was English in its ideas, dealt with matters of church furniture, exalted the bishops and ignored the kirk session and elders. A liturgy was ordered to be used which had not yet appeared, but which proved to be a version, with somewhat higher doctrine, of the Anglican Common Prayer. The introduction of this service book in St. Giles's church. Edinburgh, in July 1637, occasioned the tumult of which Jenny Geddes will always figure as the heroine. The sentiment was echoed throughout Scotland. Petitions against the service book and the book of canons poured in from every quarter; the committee formed to forward the petition rapidly became a powerful body at the head of a national movement, the action of the crown was temporizing and on Feb. 28. 1638, the National Covenant was signed in the famous scene in Greyfriars church and churchyard. This document recited the covenant, signed by King James and his household in 1580, to uphold presbyterianism and to defend the state against romanism, and then declared a new covenant of nobles, barons, gentlemen, burgesses, ministers and commons to continue in the reformed religion, to defend it and resist all contrary errors and corruptions. The crown was unable either to check the popular movement or to come to any compromise with it, and the Glasgow assembly of 1638. the first free assembly that had met for 30 years, proceeded to make the church what the Covenant required, and effected the "second Scottish Reformation." The assembly contained many influential laymen and was carried on the crest of a great national movement. The Covenant was accepted by parliament in 1639.

The succeeding decennium is the culminating period of Scottish presbyterianism, when it not only was supreme in Scotland but exercised a decisive influence over England. The English parliament sought the alliance of the assembly, while the Independents, though in the event presbytery was as little to their liking as episcopacy, joined in the wish to get rid of the episcopal system. In its period of triumph the presbyterianism of Scotland displayed its character. After the injustice and persecution it had suffered it could scarcely prove moderate or tolerant; it showed a vehement determination to carry out the truth it had vindicated with such enthusiasm, to the full extent and wherever possible. The Covenant, at first a standard of freedom, was immediately converted into a test and made the instrument of oppression and persecution. All policy was to be determined by the Covenant; the king and every official were to be obliged to take it. Those who carried their fanaticism furthest were ready to denounce and to unchurch those who showed any inclination to moderation and political sanity, and the beginnings of schism soon appeared in the ranks of the Covenanters.

In 1643, when the full legal establishment of presbytery had just been consummated, the general assembly, asked by the English parliament to arrange a league to be signed in both countries for the furtherance of reformed religion, agreed, but asked that the league should be a religious one. The result was the Solemn League and Covenant. It did not mention presbyterianism; but the assembly had refused to hear of any recognition of independency; if religion were thoroughly reformed, they considered the result must be presbyterianism in England as in Scotland. In the Westminster Standards also, which were the fruit of the Scottish desire for a religious uniformity, Scotland did not obtain by any means all it desired in its church documents. The Scottish divines in the Westminster assembly were only five in number, while the assembly contained effective parties of Erastians and Independents. The Confession of Faith contains no approval of any system of church government, and when the kirk adopted it in 1647 it gave up its old confession in which the principles at least of true church order are laid down.

In accepting in 1645 the Westminster Directory of Public Worship the kirk tacitly gave up its own liturgy, and committed itself to a bald and uninviting order of worship, in which no forms of prayer were allowed to be used.

Struggle Against Episcopacy. — If the mismanagement of Scottish religious affairs under James and Charles I is a melancholy story, what took place under Charles II is infinitely sadder. From the first Charles showed himself determined to force episcopalianism on Scotland and not too scrupulous in the choice of methods for securing his ends. The attempt was nearly successful. In the greater part of the country little change took place in the religious services. The service book was not read nor kneeling at communion required, and it made no immediate difference to the people that the clergy should be under bishops. The inferior church courts still sat, though not the assembly. At the Restoration it was a question whether the bulk of the population was in favour of presbytery or of episcopacy; but the matter was handled in such a way in the west of Scotland that an extreme Covenanting spirit arose, nourished on intolerable grievances, and the nation as a whole decided against the system which had been promoted by such means.

The Rescissory act of 1661 swept away the legislation of the preceding 20 years, and so disposed of the Presbyterian polity of the church. Episcopacy was restored by a letter from the king on Sept. 5, 1661 (*see* SCOTLAND, EPISCOPAL CHURCH IN). An act requiring all ministers appointed during the period when patronage was abolished to get presentation from their patrons and institution from their bishops was applied in the west of Scotland in such a way that 300 ministers left their manses. Their places were filled with less competent men whom the people did not wish to hear, and so conventicles began to be held. The attempts to suppress these, the harsh measures taken against those who attended them or connived at them or refused to give information against them, the military violence and the judicial severities, the confiscations, imprisonments, tortures, expatriations, all make up a dreadful narrative.

Indulgences were tried, and were successful in bringing back about 100 ministers to their parishes and introducing a new cause of division among the clergy. On the other hand, the Covenanting spirit rose higher and higher among the persecuted till the armed risings took place and the formal rebellion of a handful of desperate men against the ruler of three kingdoms.

When William landed in England in 1688 the scene changed in Scotland. The soldiery was withdrawn from the west, and the people at once showed their feelings by the "rabbling" or ejection of the curates who occupied the manses of the ousted ministers, in which, however, no lives were lost. William would have decided for episcopacy in Scotland, as the great body of the nobles and gentry adhered to it, but only on condition that the Episcopalians agreed to support him and that they had the people with them. Neither of these conditions was fulfilled.

On July 22, 1689, the convention which declared the throne vacant and called William and Mary to fill it declared in its Claim of Right that prelacy and the superiority of any office in the church above ministers had been a great and insupportable grievance to Scotland. Effect was given to this; and in April 1690 the act was passed on which the establishment of the Church of Scotland rests, the Westminster Confession being recognized, the laws in favour of episcopacy repealed, though the Rescissory act remained on the statute book and the assembly appointed to meet. Three years later the formula of subscription, to be signed by all ministers, was fixed.

From this time forward the church, while jealously asserting its spiritual independence, was on the side of the crown against the Jacobites, and became more and more an orderly and useful ally of the state. The difficulties which threatened to arise about the union were skilfully avoided; the Act of Security provided that the Confession of Faith and the Presbyterian government should "continue without any alteration to the people of this land in all succeeding ages," and the first oath taken by Queen Anne at her accession was to preserve it. The Act of Toleration of 1712 allowed Episcopalian dissenters to use the English liturgy. This had not hitherto been done. and the claim of the Episcopalians for this liberty had been the occasion of a bitter controversy. The same parliament restored lay patronage in Scotland, an act against which the church always protested and which was the origin of great troubles.

Patronage Difficulties. — Presbytery, being loyal to the house of Hanover while episcopacy was Jacobite. was now in enjoyment of the royal favour and was treated as a firm ally of the government. But while the church as a whole was more peaceful, more courtly, more inclined to the friendship of the world than at any former time, it contained two well-marked parties. The Moderate party, which maintained its ascendancy till the beginning of the 19th century, sought to make the working of the church in its different parts as orderly and regular as possible. to make the assembly supreme and to enforce on presbyteries respect for its decisions. The Popular party, regarding the church less from the side of the government, had less sympathy with the progressive movements of the age and desired greater strictness in discipline. The main subject of dispute arose at first from the exercise of patronage. Presbyteries in various parts of the country were still disposed to disregard the presentations of lay patrons and to settle the men desired by the people; but legal decisions had shown that if they acted in this way their nominee. while legally minister of the parish, could not claim the stipend. To the risk of such sacrifices the church, led by the Moderate party, refused to expose itself. By the new policy inaugurated by William Robertson (1721–93) the assembly compelled presbyteries to give effect to presentations, and in a long series of disputed settlements the "call." though still held essential to a settlement, was less and less regarded, until it was declared that it was not necessary and that the church courts were bound to induct any qualified presentee. The substitution of the word "concurrence" for "call" about 1764 indicates the subsidiary and ornamental light in which the assent of the parishioners was now to be regarded. It was in the power of the church to give more weight than it did to the feelings of the people; but its working of the patronage system drove large numbers from the Establishment. A melancholy catalogue of forced settlements marks the annals of the church from 1749 to 1780, and wherever an unpopular presentee was settled the people quietly left the Establishment and erected a meeting house

Growth of Dissent. — In 1763 there was a great debate in the assembly on the progress of schism, in which the Popular party laid the whole blame at the door of the Moderates, while the Moderates rejoined that patronage and moderatism had made the church the dignified and powerful institution it had come to be. Nor was a conciliatory attitude taken up toward the seceders. The ministers of the Relief (*see* UNITED PRESBYTERIAN CHURCH) desired to remain connected with the Establishment, but were not suffered to do so. Those ministers who resigned their parishes to accept calls to Relief congregations, in places where forced settlements had taken place, and who might have been and claimed to be recognized as still ministers of the church, were deposed and forbidden to look for any ministerial communion with the clergy of the Establishment. The growth of dissent steadily continued and excited alarm from time to time; and it may be questioned whether the peace of the church was not purchased at too high a price. The Moderate period is justly regarded as in some respects the most brilliant in the history of the church. Its clergy included many distinguished Scotsmen, among them Thomas Reid, George Campbell, Adam Ferguson, John Home, Hugh Blair, William Robertson and John Erskine. The labours of these men were not mainly in theology; in religion the age was one not of advance but of rest; they gained for the church a great and widespread respect and influence.

Revival. — With the close of the 18th century a great change passed over the spirit of the church. The new activity which sprang up everywhere after the French Revolution produced in Scotland a revival of evangelicalism. Moderatism had cultivated the ministers too fast for the people, and the church had become to a large extent more of a dignified ruler than a spiritual mother. About this time the brothers Robert and James Haldane devoted themselves to the work of promoting Evangelical Christianity, James making missionary journeys throughout Scotland and founding Sunday schools; and in 1798 the eccentric preacher Rowland Hill visited Scotland at their request. In the journals of these evangelists dark pictures are drawn of the religious state of the country, though their censorious tone detracts greatly from their value; but there is no doubt that the efforts of the Haldanes brought about or coincided with a quickening of the religious spirit of Scotland. The assembly of 1799 passed an act forbidding the admission to the pulpits of laymen or of ministers of other churches and issued a manifesto on Sunday schools. These acts helped greatly to discredit the Moderate party, of whose spirit they were the outcome. In 1810 the *Christian Instructor* began to appear under the editorship of Andrew Thomson, a churchman of vigorous intellect and noble character. It was an ably written review, in which the theology of the Haldanes asserted itself in a somewhat dogmatic and confident tone against all unsoundness and moderatism. clearly proclaiming that the former things had passed away. The question of pluralities began to be agitated in 1813, and gave rise to a long struggle, in which Thomas Chalmers (*q.v.*) took a notable part, and which terminated in the regulation that a university chair or principalship should not be held along with a parish which was not close to the university seat.

The growth of Evangelical sentiment in the church, along with the example of the great missionary societies founded in the end of the 18th and the beginning of the 19th century, led to the institution of the various missionary schemes. and their history forms the chief part of the history of the church for a number of years. The education scheme. having for its object the planting of schools in destitute Highland districts, came into existence in 1824. The foreign mission committee was formed in 182 j, at the instance of John Inglis (1763–1834), a leader of the Moderate party; and Alexander Duff (*q.v.*) went to India in 1829 as the first missionary of the Church of Scotland. The church extension committee was first appointed in 1828 and in 1834 it was made permanent. It was originally formed to collect information regarding the spiritual wants of the country and to apply to the government to build the churches found to be necessary. As the population of Scotland had doubled since the Reformation and its distribution had been completely altered in many counties while the number of parish churches remained unchanged, and meeting houses had only been erected where seceding congregations required them, the need for new churches was very great. The application to government for aid, however, proved the occasion of a "voluntary controversy" which raged with great fierce-ness for many years and never completely subsided. The union of the Burgher and the Antiburgher bodies in 1820 in the United Secession (see UNITED PRESBYTERIAN CHURCH) added to the influence of the voluntary principle in the country, while the political excitement of the period disposed men's minds to such discussions. The government built 42 churches in the Highlands, providing them with a slender endo ment; and these continued to be known as parliamentary churches. Under Thomas Chalmers, however. the church extension committee struck out a new line of action. The great philanthropist had come to see that the church could only reach the masses of the people effectively by greatly increasing the number of its places of worship and abolishing or minimizing seat rents in the poorer districts. In his powerful defense of establishments against the voluntaries in both Scotland and England, in which his ablest assistants were those who afterward became, along with him. the leaders of the Free Church, he pleaded that an established church to be effective must divide the country territorially into a large number of small parishes, so that every corner of the land and every person, of whatever class, shall actually enjoy the benefits of the parochial machinery. This "territorial principle" the church kept steadily in view ever after. With the view of realizing this idea he appealed to the church to provide funds to build a large number of new churches, and personally carried his appeal throughout the country. By 1840 more than zoo new churches had been built.

The zealous orthodoxy of the church found at this period several occasions to assert itself. John M'Leod Campbell, minister of Row, was deposed by the assembly of 1830 for teaching that assurance is of the essence of faith and that Christ died for all men. He has since been recognized as one of the profoundest Scottish theologians of the 19th century, although his deposition was never removed. The same assembly condemned the doctrine put forth by Edward Irving (*q.v.*), that Christ took upon Him the sinful nature of man and was not impeccable, and Irving was deposed five years later by the presbytery of Annan, when the outburst of supposed miraculous gifts in his church in London had rendered him still more obnoxious to the strict censures of the period (see CATHOLIC APOSTOLIC CHURCH).

The Disruption — and After. — The influence of dissent also acted along with the rapidly rising religious fervour of the age in quickening in the church that sense of a divine mission, and of the right and power to carry out that mission without obstruction from any worldly authority. which belongs to the essential consciousness of the Christian church. An agitation against patronage, the ancient root of evil, and the formation of an antipatronage society, helped in that direction. For the ten years' conflict, which began in 1833 with the passing by the assembly of the Veto act, see the article FREE CHURCH OF SCOTLAND; it is not necessary to dwell further in this place on the consequences of those acts. The assembly of 1843. from which the exodus took place, proceeded to undo the acts of the church during the preceding nine years. The Veto was not repealed but ignored, as having never had the force of law. The assembly addressed a pastoral letter to the people of the country, in which, while declining to "admit that the course taken by the seceders was justified by irresistible necessity," they counselled peace and good will toward them and called for the loyal support of the remaining members of the church. Two acts at once passed through the legislature in answer to the claims put forward by the church. The Scottish Benefices act of Lord Aberdeen, 1843, gave the people power to state objections personal to a presentee and bearing on his fitness for the particular charge to which he was presented, and also authorized the presbytery in dealing with the objections to look to the number and character of the objectors.

The Disruption left the Church of Scotland in a sadly maimed condition. Of 1,203 ministers 451 left it, and among these were many of its foremost men. A third of its membership is computed to have gone with them. In Edinburgh many of its churches were nearly empty. The Gaelic-speaking population of the northern counties completely deserted it. All its missionaries left it but one. It had no gale of popular enthusiasm to carry it fonvard, representing as it did not a newly arisen principle but opposition to a principle which it maintained to be dangerous and exaggerated. For many years it had much obloquy to endure. But it at once set itself to the task of filling up vacancies and recruiting the missionary staff. A lay association was formed, which raised large sums of money for the missionary schemes, so that their income was not allowed seriously to decline. The good works of the church, indeed, were in a few years not only continued but extended.

Agitation on the subject of patronage went on in the assembly from 1857 to 1869, when, by a large majority, patronage as restored by the act of Queen Anne was condemned and a petition sent to parliament for its removal. The request was granted. and the right of electing parish ministers was conferred by the Patronage act, 1874, on the congregation; thus a grievance of old standing, from which all the ecclesiastical troubles of a century and a half had sprung, was removed and the church placed on a thoroughly democratic basis. This act, combined with various efforts made within the church for its improvement, secured for the Scottish Establishment a large measure of popular favour, and in the last half of the 19th century it grew rapidly both in numbers and in influence. This revival was largely the result on the one hand of the improvement of its worship which began with the efforts of Robert Lee (1804–68), minister of Old Greyfriars, Edinburgh, and professor of biblical criticism in Edinburgh university. By introducing into his church a printed book of prayers and also an organ. Lee stirred up vehement controversies in the church courts which resulted in the recognition of the liberty of congregations to improve their worship. The Church Service society, having for its object the study of ancient and modern liturgies with a view to the preparation of forms of prayer for public worship, was founded in 1865; it published eight editions of its Book of *Common* Order, which, though at first regarded with suspicion, was largely used by the clergy. Church music was cultivated and improved in a marked degree; and hymns were introduced to supplement the psalms and paraphrases; in 1898 a committee appointed by the Church of Scotland, the Free Church, the Cnited Presbyterian Church and the Presbyterian Church in Ireland issued The Church Hymnary (rev. ed., 1920).

The Committee on Christian Life and Work was appointed in 1869 to supervise the work of the church, to stimulate evangelistic efforts and to organize the labours of lay agents. It organized young men's guilds and revived the ancient order of deaconesses. The Life and Work committee was later merged in the Committee on Social Service and the organizations instituted by it were transferred in some cases elsewhere. The Young Men's guild was put under the authority of the General Administration committee, as was the Woman's guild. This women's organization had a membership in 1957 of 153,180, with branches numbering 2,2jj.

The order of deaconesses passed under the administrative power of the home board, and its scope was considerably widened. The General Assembly in 1956 approved the appointment of a standing Committee on the Order of Deaconesses and also approved a scheme providing for the training of women with the required qualifications to be commissioned as deaconesses and also to be presented to presbyteries for licence as preachers of the word but without reference to probation for the holy ministry. The church's monthly magazine, Life and *Work*, another project of the original Committee on Christian Life and Work, was put under the care of a special Committee on Publications.

Subscription and **Reunion.**—During the later years of the 19th century the church showed an increased liberality of sentiment and variety of opinion; and for this and other reasons the question of subscription was more or less before the church for many years. The formula adopted by the assembly of 1711 had still to be signed by ministers, and was felt to be much too strict. After debates extending over many years. the assembly of 1889 fell back on the words of the act of parliament of 1693, passed to enable the Episcopalian clergy to join the Establishment, in which the candidate declared the Confession of Faith to be the confession of his faith. owned the doctrine therein contained to be the true doctrine and promised faithfully to adhere to it.

This was accompanied by a Declaratory act in which the church expressed its desire to enlarge rather than curtail the liberty hitherto enjoyed. Ten years later the assembly was again debating the question of subscription. A committee appointed in 1899 to inquire into the powers of the church in the matter reported that the power of the church was merely administrative—it was in its power as cases arose to prosecute or to refrain from prosecuting, but it had no power to modify the Confession in any way. Here the matter might have remained, but that the approach to parliament of the United and the Free Churches after the decision of the house of lords in 1904 (*see* FREE CHURCH OF SCOTLAND; UNITED FREE CHURCH OF SCOTLAND) offered an opportunity for asking parliament to remove a grievance the church itself had no power to deal with. The Scottish Churches bill of 1905 left it to the Church of Scotland to frame a new formula for its ministers and professors. After 1909—when the quarter-centenary of the birth of Calvin brought the assemblies together in a memorial service in St. Giles's and a joint committee on union was appointed—the two bodies moved toward reunion. The leaders of the Church of Scotland twice went to parliament in order to secure acts which might remove the scruples of the other church. The first act (1921) ratified a constitution drawn up by the church declaring its spiritual freedom, with nine articles outlining an acceptable doctrinal basis. The second (in 1925) ratified a financial arrangement between the church and the heritors, relating to the teinds. Finally the general assemblies of the Church of Scotland and the United Free Church, in May 1929, resolved on an incorporating union of the two churches.

The union of 1929 resulted in marked progress in solidarity and in effective administration, particularly in the uniting of charges in areas that were formerly served by two or three churches. The number of such unions totaled 743 in 1957. During the two decades following the union, the church under the leadership of John White accomplished much in the way of church extension, bringing the ordinances of religion to the people in every parish of Scotland through a territorial ministry. The church's continued interest in the social welfare of the people was shown in the work of its Social Service committee, which started homes and hostels for children and young people, as well as homes for the aged, several of them supported by the local presbytery.

Another move toward reunion took place in 1956 when the United Original Secession Synod was reunited with the Church of Scotland, thus harmoniously ending a division which had lasted for 223 years.

SCOTLAND, EPISCOPAL CHURCH IN, a Scottish episcopal church in communion with, but historically distinct from, the Church of England. The 14 historic dioceses (Edinburgh founded by Charles I, the others of pre-Reformation date) are arranged as follows, under seven bishops: Aberdeen and Orkney; Argyll and the Isles; Brechin; Edinburgh; Glasgow and Galloway; Moray, Ross and Caithness; St. Andrews, Dunkeld and Dunblane. The bishops constitute the episcopal synod, the supreme court of appeal, whose president, elected by the members from among themselves, has the style, not the functions, of a metropolitan, being called *Primus*. The legislature is the provincial synod, consisting of the bishops, at whose discretion it is summoned, and a lower chamber of presbyters. The canons have the authority of this synod. The representative church council, including laymen, administers finance. Each diocese has its synod of the clergy. Its dean is appointed by the bishop, and on the voidance of the see summons the clerical and lay electors, at the instance of the *Primus,* to choose a bishop, who is presented to the episcopal synod for confirmation and to the *Primus* for consecration. There are cathedrals at Perth, Inverness, Edinburgh, Cumbrae, Oban, Aberdeen, Dundee and Glasgow. The theological college was founded in 1810, incorporated with Trinity college, Glenalmond, in 1848, and re-established at Edinburgh in 1876.

The bishops of the Episcopal Church are direct successors of the prelates consecrated to Scottish sees at the Restoration. After the Revolution, the Comprehension act of 1695 allowed episcopalian incumbents, on taking the oath of allegiance, to retain their benefices, though excluding them from any share in the government without a further declaration of presbyterian principles. The extruded bishops were slow to organize the episcopalian remnant under a jurisdiction independent of the state, regarding the then arrangements as provisional and looking forward to a reconstituted national kirk under a "legitimate" sovereign. But at length the hopelessness of the Stewart cause and the growth of congregations outside the Establishment forced the bishops to dissociate canonical jurisdiction from royal prerogative and to reconstitute for themselves a territorial episcopate. The act of Queen Anne (1712), which protects the "Episcopal Communion," marks its virtual incorporation as a distinct society. But matters were still complicated by a considerable, though declining, number of episcopalian incumbents holding parish churches. Moreover, the Jacobitism of some of the clergy provoked a state policy of repression in 1715 and 1745, and fostered the growth of new Hanoverian congregations, served by clergy episcopally ordained but amenable to no bishop, who qualified themselves under the act of 1712. These causes reduced the Episcopalians, who included in 1688 a large section of the people, to what was in 1754, save in a few corners of the west and northeast, a minority; but the chief bar to progress was removed by the official recognition of George III on the death of Charles Edward in 1788. Statistics showed 387 churches and mission stations, 338 clergy and 56,658 communicants in 1956.

SCOTLAND YARD was originally an area just off Whitehall, London, and took its name from the palace, dating back to the reign of Edgar (959–975), which stood on the site. Edgar gave King Kenneth of Scotland a piece of ground lying beside the new palace of Westminster for his residence, requiring him to make a yearly visit to London to pay homage for the kingdom of Scotland. The palace built there by Kenneth remained the property of the Scottish kings, where they stayed when visiting London, but in the reign of Henry II, after the rebellion of William of Scotland in 1173–74, it was "resumed into the king of England's hands." Margaret, the widow of James IV of Scotland and sister of Henry VIII of England, appears to have been the last Scottish sovereign to have made use of the palace, living there for a considerable time after the death of her husband in 1513, but by the time Elizabeth I came to the throne it was more or less a neglected ruin.

On the death of Queen Elizabeth in 1603, James VI of Scotland succeeded to the English throne as James I. With the sovereignty of the two countries vested in one and the same person, the purpose of the palace at Scotland Yard became unnecessary and the site, which had come to be known as "Scotland," was divided into two yards, known as Great Scotland Yard and Middle Scotland Yard, and was used for government buildings. These included the official residence of the surveyor of works to the crown, which was at one time occupied by Inigo Jones. Jones's successor, Sir John Denham, died there in 1669. The next surveyor was Sir Christopher Wren, who had offices there and designed a house in Scotland Yard for Sir John Vanbrugh. This house was built from the ruins of buildings in Whitehall which had been destroyed by fire in 1697. John Milton, when appointed secretary for foreign tongues under Oliver Cromwell's Commonwealth in 1649, soon found it convenient to take up official residence at Scotland Yard, where he lived until he moved to Petty France in 1651. Other notable inhabitants of Scotland Yard include Susannah Cibber, the actress sister of Thomas Arne, and Thomas Campbell, the Scottish poet.

Early Police Connections. — The name of Scotland Yard is, however, better known by its association with the metropolitan police force. The first association of police with Scotland Yard appears to have been in 1662, when the first police or improvement commissioners for London and Westminster set up offices there, but these commissioners were more concerned with paving, lighting and cleaning of streets than mith police duties as they are understood today. A further association occurred when Col. Sir Thomas de Veil, the first of the Bow street magistrates, had an office in Scotland Yard, where he acted as an agent for memorials to public departments before moving to Bow street about 1735. But the direct association between Scotland Yard and the metropolitan police started when the force was formed in 1829 by Sir Robert Peel, the home secretary of the time. The newly formed force was to police the area in and immediately around London—with the exception of the City of London, with its area of just more than one square mile, which was not included but which was to form its own police force ten years later—and the headquarters of the metropolitan force were at no. 4, Whitehall place, with a police station at the rear, entered from Scotland Yard itself. Although the proper official address of the headquarters was no. 4, Whitehall place, from the very beginning it was always referred to as Scotland Yard by the press and others. Even officialdom, which started by referring to it either as Whitehall Place or as Scotland Yard in about equal measure, soon dropped the former style of address altogether and Scotland Yard became an expression used throughout the world to denote the headquarters of the metropolitan police force.

At the time of their formation, the metropolitan police were placed under the leadership of two joint commissioners, Richard Mayne (made K.C.B. in 1851) and Col. Charles Rowan (made K.C.B. in 1848), the former "a sensible lawyer" and the latter "a military man conversant with the details of the police system in Ireland." At first the new force met with fierce and bitter opposition from many quarters and was referred to by many uncomplimentary names, including the "raw lobster gang," "Peel's bloody gang" and "the blue devils," but under the wise and able control of Mayne and Rowan they succeeded in overcoming this opposition and by the time of Mayne's death in 1868 (Rowan had retired in 1850) the force had progressed a long way toward establishing the reputation and popularity which it enjoyed thereafter.

Building Development. — As the work and duties of Scotland Yard increased, adjoining premises were taken over and by the early 1880s the headquarters consisted of a number of separate buildings which, apart from the inconvenience, were extremely overcrowded. Important records and papers were crammed into cupboards and piled high on landings, and the provision of a new headquarters had become a pressing necessity. It was generally agreed that the headquarters should be situated in the immediate vicinity of the home office and the seat of government, since the home secretary is directly responsible to parliament for police matters. The only acceptable site was one on reclaimed land made available by the construction of the Thames embankment, which was opened in 1870. On this site of about 70.000 sq.ft., Colonel Mapleson had begun to build a national opera house on a very ambitious scale. The foundation stone was laid in 187j by the duke of Edinburgh and the intended opera house had been partly constructed, between £80,000 and £90,000 having been spent on it, when the scheme fell through for lack of further financial support.

A private offerwas made in 1880 to the deputy surveyor of the police to buy the site as it stood for £25,000, and after very lengthy discussion the site was finally purchased in 1886. Richard Norman Shaw was entrusted with the designing of the building and his design, although adopted, was the subject of much disagreement in official and other circles. By late 1890 the building was completed, faced up to the top of the second floor with 2,500 tons of granite quarried and dressed by the convicts of Dartmoor, and continuing upward in red brick with Portland stone dressings. On May 11, 1941, a high explosive bomb fell on one corner, causing extensive damage and resulting in many tons of masonry and millions of index cards from the registry two floors above to fall into the commissioner's room. No lives were lost and the commissioner was not in his room. Had the building been less substantial far greater damage would have been done.

The move of all the headquarters staff to the new premises took place in Dec. 1890, and the building was officially designated New Scotland Yard. Scotland house (to become known later as New Scotland Yard South), the complementary building occupied by the receiver for the metropolitan police district, to the south of New Scotland Yard and connected by an archway over the road, was added several years later, from Shaw's designs. At the same time the wrought-iron entrance gates mere added. These gates were designed by Thomas Elsley as an exhibition piece and had been exhibited at the New gallery. Shaw found them at Elsley's shop, standing unused, and they were placed in their present position with the addition only of the arms of King Edward VII.

By 1935 the position at New Scotland Yard had once again reached a point where some extension or resiting was very necessary, and it was decided by the commissioners of the office of works to incorporate a new police building in the development scheme for Richmond terrace, Westminster, and a site extending northward from New Scotland Yard was agreed upon. The reproduction of Shaw's design in the new building was found unacceptable on the grounds that it would be difficult to reconcile it mith further developments in the immediate vicinity and that New Scotland Yard itself was considered to be wasteful in planning by modern standards. A building more in relationship with modern ideas was required, and indeed it was even suggested that Shaw's building should be demolished and replaced by buildings with better accommodation and more in harmony with a general development scheme. This suggestion was, however, dropped when questions of finance and the remoteness of such a general scheme were raised. W. Curtis Green was the man selected to design the new extension, which began to take shape, but at the outbreak of World War II in Sept. 1939 the building was still some way from completion. Under increased pressure of war duties, it was found necessary to move some personnel into the unfinished building, and in early 1940 parts were occupied while work was still in progress on the upper part of the structure. By Dec. 1940 the building was ready for complete occupation, but certain parts of it were, as a wartime necessity, used for nonpolice purposes.

The section of the fighting services known as combined operations took up its headquarters in the building in 1940, and occupied part of it until 1945. Admiral of the Fleet Sir Roger Keyes, Vice-Adm. Lord Louis Mountbatten and Maj. Gen. Robert Laycock successively controlled this service from a room on the third floor of the building. It was not until 1945 that the building became completely available for its original purpose. By mid-century it housed the immense telephone switchboard of Scotland Yard, the information room with its emergency 999 service, the forensic science laboratory, the criminal record office, the fingerprint and photography departments and several other branches of the criminal investigation department.

With the completion of the northern extension it became necessary to rename the buildings at the headquarters. At first it was decided to name the new building Richmond house, as the first step in the Richmond terrace development scheme, but on reconsideration it was thought that the title of Scotland Yard had come to have such a special meaning for the metropolitan police that its use should be retained. The new building was accordingly designated New Scotland Yard North, and the official name of Shaw's building was altered to New Scotland Yard Central. Scotland house, the building of the receiver for the metropolitan police district, became officially New Scotland Yard South.

The three buildings on the Thames embankment alone do not, however, constitute what is generally understood by Scotland Yard, although they do form the core of the metropolitan police administration. Apart from the 175 police stations and other police buildings spread throughout the metropolitan police district, there are several other buildings housing departments which are integral parts of the headquarters. but which, mainly for reasons of space, it has been found necessary to house elsewhere. The public carriage office, the police garage and lost property office at Lambeth, the aliens' registration office at Piccadilly place (formerly the well-known Vine street police station) and offices at Walton street, Kensington, and Ramillies place, Westminster, are all working branches of Scotland Yard's headquarters.

Organization.—At its commencement in 1829, the extent of the metropolitan police district controlled from Scotland Yard was approximately 120 sq.mi., with an estimated population of less than 1,500,000 persons; for this area there was a police force of 1,000. Ten years later, in 1839, the area was extended to 699.42 sq.mi., and the strength of the police had been increased to 3,350 for an estimated population of nearly 2,250,000. No further alteration was made to the size of the district until 1947, when, by a readjustment of police boundaries under the Police act of 1946, it was extended to cover 734.88 sq.mi., the strength of the force having by this time increased to 15,610, for a population of 8,391.000.

At the top of the administration of Scotland Yard and in charge of all the police of the metropolis is the commissioner, who is appointed by the crown on the recommendation of the home secretary. In 1953 the holder of this office was Sir John Nott-Bower, who was the first commissioner to have made the police his life career. All the previous 14 commissioners were brought into the police service from outside careers, 10 from the armed services, 3 from civil administrative positions and 1, Sir Richard Mayne, from the legal profession.

Directly under the commissioner, as his right-hand man and deputy, is the deputy commissioner, and below them at headquarters there are six main departments: administration ("A"); traffic ("B"); criminal investigation ("C"); organization ("D"); secretariat ("S"); and the legal department ("L"). The first four of these departments are each headed by an assistant commissioner. Each assistant. like the commissioner and the deputy commissioner, is appointed by the crown on the recommendation of the home secretary. The commissioner, deputy commissioner and assistant commissioners are also justices of the peace for the counties of London, Middlesex, Surrey. Hertfordshire, Essex, Berkshire. Kent and Buckinghamshire, but their functions as justices are limited to executive police matters.

The assistant commissioner at the head of the administration department is responsible for discipline, distribution and other administrative matters in the force and his department includes the women police and mounted branch. Not the least of his important duties is the control of all police arrangements in connection with the many ceremonials in London.

The traffic department deals with all traffic matters, including the very difficult problem of controlling London's traffic, the public carriage office with its licensing and control of cabs and their drivers, and the drivers and conductors of buses, coaches and trolley vehicles in the metropolitan area, police transport, the police motor driving school and the lost property office.

The criminal investigation department deals with all aspects of criminal investigation, including the criminal record office, fingerprint and photography sections. the company fraud squad, the flying squad. special branch, the metropolitan police laboratory and the detective training school.

The organization department is concerned with civil defense. supplies and equipment, first aid. buildings and housing. recruitment and training. police dogs. medical services, communications including the information room, and welfare.

The secretarial department is under the control of the secretary, who is not a police officer but the highest member of the civilian staff of the metropolitan police force. This appointment is made by the home secretary on the recommendation of the commissioner. His special province is the control of the 1,450 civilians employed in the structure of the force. and all its secretarial work, including its vast registry, pay and pensions and the press and information department.

The legal department is headed by a solicitor, whose duty is to advise the commissioner on all legal matters. The solicitor to the metropolitan police district is appointed by the home secretary on the recommendation of the commissioner and is also the prosecuting solicitor to the quarter sessions of London, Middlesex and Surrey (metropolitan area).

In addition to these main departments, a small research and planning branch was established, responsible directly to the commissioner, through the deputy commissioner, for keeping the whole organization under constant review, particularly with regard to the economic and efficient use of manpower and the planning of future developments. (R. M. H.)

SCOTS GREYS, THE ROYAL (2nd Dragoons). This famous corps was raised in Scotland in 1678 and derives its title from the colour of its original coats—stone grey. Its members were also mounted on grey horses for a great number of years and were, with the 1st Royal Dragoons, the last regiment to give up their horses, in Palestine in 1940. As the Scots Dragoons they served under William III in Flanders. In 1702 as the Grey Dragoons they served in the Low Countries. The regiment was at the battle of Blenheim and was also with the victorious army at Oudenarde and Malplaquet.

In 1736 it bore the title of Royal North British Dragoons which it retained until March 1877, when it became the and Dragoons (Royal Scots Greys). At Waterloo Napoleon referred to the Greys as *ces terribles chevaux gris* (those terrible grey horses) because of their fine fighting qualities. Their long roll of battle honours also shows service in the Crimean War, South Africa, 1899–1902, and World Wars I and II, in the latter as an armoured regiment in the western desert, Italy and northwest Europe. They have been called the "household cavalry of Scotland."

SCOTS LAW. At the union of the parliaments of England and Scotland in 1707, the legal systems of the two countries were very dissimilar. Scotland, mainly in the preceding century, had adopted much of the Roman law, as developed and in some senses altered by the jurists of Holland and France, as an important guide. But it is a fallacy to suppose that, as is sometimes said, the law of Scotland is founded on the law of Rome. The Scots only turned to Roman law when there was a gap in their own common or customary law. Certainly, however, there is a considerable infusion of Roman law and not least in the field of nomenclature. English lawyers on the other hand had forgotten or refused to acknowledge the debt owed to Rome both by common law and equity. At the union the law of Scotland had recently been set forth in the *Institutions* of Lord Stair, a masterpiece of lucidity and orderly arrangement. In England the student or practitioner had little to guide him through a maze of precedents and forms of pleading beyond the difficult pages of Coke. But perhaps the most important point of distinction was the fact that Scotland, unlike England. did not separate the administration of equity and law.

What this separation has led to in England in the way of confusion, expense and hardship to litigants may be read in many works, although the separate administration of equity has doubtless contributed to a thorough development of some branches of what may be called generally "law," as for example the law of trusts. But such a conception as, say, the English one of "equitable property" is as completely incomprehensible to a Scottish lawyer as it is to any continental lawyer. The Scottish conception of equity is not, like the English, the conception of a system running parallel to the common law. It is rather: (1) a few fairly simple rules aimed at supplementing the law where to fail to do so would result in hardship: and (2) the relegation of certain remedies to the class of equitable remedies, which the court has a large discretion on equitable grounds to grant or withhold. It may truly be said that the word "equity" in the law of Scotland is never in its meaning removed from the original meaning of the word as it is in England. The Scottish outlook upon this whole topic ranges the Scottish system clearly alongside the continental and not the English system.

It is worthy of note that the tendency since the 1870s is for the English to approach the Scottish model of the administration of law and equity in one court and not vice versa, but there still remains a world of difference.

Historical Development.— The legal history of the centuries following the union shows a considerable measure of assimilation between the two systems, in which for the reasons mentioned below the tendency has been for the English law to affect the other, though there have been many exceptions. It would seem as though assimilation will never be complete. Public opinion in Scotland, even though it be lay opinion, is alive to the great and fundamental differences between the two systems and believes that the Scottish system is that which is best suited to the people of Scotland, as no doubt it is. One main cause of assimilation is that much of the existing law of Scotland depends on statutes applicable to both countries. The house of lords, consisting in its legal aspect until 1876 exclusively of English lawyers acting as the supreme court of appeal from Scotland, had a tendency to apply English law in Scottish appeals, and in some cases seems to have forgotten the distinction between its legislative and its judicial functions. Thus in a case decided in 1790 the house held that the law of stoppage *in transitu* was applicable to Scotland without any evidence that it had ever before been suggested to be the law there. Yet another cause of assimilation is the influence of text writers, some of whom, such as G. J. Bell, have been too much given to treating English law as though it were the law of their own country. The citation, too, of English authorities in court, despite judicial remonstrance, has had considerable effect. Not surprisingly the greatest measure of assimilation has been in the field of mercantile law. In other fields the systems are still widely separated.

Courts of Law.—The scheme of the Scottish courts is completely different from that of the English and once again the greater similarity of the Scottish to the continental pattern is noticeable. The supreme Scottish court (the house of lords, which is not a native court, being for the moment disregarded) is the court of session, instituted by King James V in 1532 largely upon a French model. Despite the interest of its history there is only space here to touch upon its constitution and functions today. The court has two main functions. It has original jurisdiction in a very wide range of cases, which is exclusive in a few matters such as actions affecting status. In its appellate capacity it hears appeals (by reclaiming petition) from the six court of session courts of first instance (called compendiously the outer house), each presided over by a lord ordinary, and also from the sheriff's courts. The appellate court (inner house) sits in two divisions, the first and second prtsided over respectively by the lord president of the court of session and the lord justice clerk. All the judges have the courtesy title of "lord," but are not on that account peers.

While the judges of the court of session are traditionally judges of fact and law, an innovation was made in the early 19th century when the civil jury was introduced, less because it was wanted in Scotland than because the house of lords was weary of the multiplicity of appeals which (since the decision of a jury is not in the ordinary sense appealable) would be drastically reduced by the change. The civil jury has never commended itself to Scottish lawyers and it seems to become less and less popular in England. From the inner house appeal lies in many cases to the house of lords as of right and not, as in England, by leave. How the house of lords, whose position was not dealt with in the treaty of union, came to be the ultimate court of appeal for Scotland is an interesting and rather obscure story which cannot be told here. The right of audience in the court of session is possessed exclusively by members of the faculty of advocates.

The lower civil courts are the sheriff courts. These very ancient courts are to be found distributed by counties throughout Scotland. They are manned by (1) the sheriff principal and (2) the sheriff substitute. The former (who has some administrative as well as judicial functions) is in civil matters an appellate judge only and hears appeals from the sheriff substitutes of his jurisdiction. The latter's absurd title conceals their great importance. For except in divorce and one or two other less important matters their jurisdiction, by a strange arrangement, almost exactly coin. cides with that of the court of session. As a local and comparatively inexpensive court the sheriff court is more popular than the court of session. It will be seen that the sheriff court (which has also a wide criminal jurisdiction) cannot for a moment be compared with the English county court, with its very limited civil jurisdiction and complete lack of criminal powers. The justice court has a limited jurisdiction in small debt actions. The dean of guild court has a quaestorial jurisdiction in questions of building in the towns, the land court in dealing with the relations of landlord and tenant in agricultural districts.

It should be added that the court of session has absorbed the functions of certain ancient courts, the court of exchequer, the admiralty court, the teind (or tithes) court and the commissary court, which dealt with questions of marriage law and executry, while the judges have by statute been given separate duties in a lands valuation court and a registration appeal court.

Land Tenure.—In Scotland as in England the law of land tenure has been greatly complicated by the survival of much of the feudal system. In theory the crown is at common law the ultimate owner of almost all land, which passes from it to others in the first place through a grant. The grantee or "vassal" may make a subaltern grant and so can successive grantees, by what is called subinfeudation, a process forbidden centuries ago in England by the statute *Quia Emptores.* The grantee can also sell his land so as to take himself out of the descending chain and put a purchaser in his place. As in other systems, land can be used to provide security for a loan to the owner of it. This is done by a bond with a disposition of the land in security. Or it may be done by an outright conveyance together with a "back letter" from the lender entitling the owner to recover the land on the loan being repaid. The word mortgage is not used. The consequence of unrestricted subinfeudation has been that the rights of subject superiors—the superior is the person who feus or grants the land —have bulked much more largely in Scotland than in England. A series of statutes, culminating in the Feudal Casualties act, 1914, abolished all payments exigible from the vassal except feu duty, and at mid-20th century it might be said that a feu—the normal tenure in Scotland—was equivalent to an English freehold, subject, in cases where there was a feu duty, to a perpetual rent charge. There is, however, a very important distinction in the system of registration of title, only partially and imperfectly developed in England. In Scotland, since the establishment of the Register of Sasines in 1617, all deeds relating to land may be recorded in that register, and it has for long been established that a purchaser, or a lender on heritable security, is entitled to trust to the register, and is not affected by any conveyance or burden which is not there recorded. This is a state of security not even yet attained in England.

Leases for any period exceeding 21 years, though not unknown, have never been common in Scotland. Legislation, however, has established a system of leasehold in agricultural subjects not exceeding 50 ac., with security of tenure and the right to have the rent fixed judicially by the land court, and in this respect there is no English analogy. In other respects the law of country leases is, in its main aspects, the same in England and Scotland and the Scottish Agricultural Holdings act of 1949 differs only in minor respects from the English act of 1948.

The law of house leases differs markedly from the law of England in a number of ways. For example Scots law demands in most cases that notice of intention to remove be given even if the lease itself provides for termination at a particular date. Failing this the lease will be continued by what is called tacit relocation. Then the landlord is bound to provide premises reasonably fit for the purposes of the let and so to maintain them. Failure to repair may be met by retention of the rent by the tenant. On destruction of the premises both parties are freed from their obligations. Local rates in Scotland are payable partly by the owner of property and partly by the occupier who may, of course, be a tenant. This system has been much criticized.

Rights in Land. — Apart from its theoretical ownership of all Scottish land the crown is an important owner of heritable property; *i.e.,* land and what is built upon or planted in land. Its rights are known as the regalia. Some are *majora* and are inalienable. The minora or lesser rights may be alienated.

The foreshore of the sea may-be alienated but the public rights to anchor boats, embark and disembark and others may not be frustrated. Mention may be made of particular regalia *minora* such as the rights to salmon fishing, to precious metals and to highways. Possession of heritage has some important consequences. Thus a bona fide possessor who unjustifiably takes the produce of the land need not make it good; in contradistinction to the possessor in bad faith, who must pay penal damages. Again a bona fide possessor is entitled to recompense for improvements.

The individual owner of land is entitled in theory to use it as he likes but. as in other countries, there are in Scotland numerous statutory restrictions and disabilities. Among common-law rights, the right of support of land in its natural state by the land of one's neighbours is important. Surface or percolating water may be impounded but water in a stream may not be prevented from descending to lower proprietors. Where the lands of several proprietors adjoin a loch, they have a joint right in it. The right to fish in inland waters and the right to take game are incidents of property. It is open to a proprietor of land to confer upon neighbouring proprietors what is called a servitude: *i.e.,* the right to use the grantor's land in some way (a positive servitude) or the right to restrain the grantor from using his land in some way (a negative servitude). Examples would be, respectively, a right of way given to X over A's land and a right to X of preventing A from building above a certain height on his, A's, land. A public right of way, unlike a servitude, exists for the benefit of the public and not for the benefit of a particular piece of land. A subject of importance in connection with possession of land is the positive prescription. When land is held on a title ex facie valid for 20 years recorded in the register, an unchallengeable title is acquired by prescription. The term prescription has another sense in relation to contract and to rights in movables, as will be seen later.

Husband and Wife: Children. — The enfranchisement of women has placed husband and wife, as in England, upon an almost equal footing in matters of property. Gone are the days when on marriage the wife's whole movable property became her husband's and his assent was needed to any transaction affecting her heritage. In the law of marriage and divorce. too. the two systems have been gradually drawing closer. Thus the celebrated irregular marriage of Scotland has all but disappeared. "Gretna Green" is no more. The Scottish registrar has a new function. Yet in fairness it should be realized that the irregular marriage was as binding as the regular and found a warranty in the canon law. Its abolition. many think, was a misfortune. In the law of divorce, on the other hand, the English law has come closer to the Scots law. In Scotland: divorce was always allowed on the same grounds to each party. Moreover, it was given for four years' desertion as well as for adultery. Today the four years have become three and cruelty, unnatural vice and incurable insanity have. as in England, been added as grounds of divorce. One very important difference between the two systems is that in England "recrimination"; *i.e.,* the answer by a respondent that the petitioner has also committed adultery, is a bar to a divorce unless the court exercise discretion. In Scotland recrimination is no defense and a party himself or herself guilty of adultery is entitled to divorce even if the other party has committed adultery. Cross divorce is the solution. In Scotland a decree of divorce dissolves the marriage at once. In England neither party is free to remarry until six months have expired. In both countries the crown may interest itself in the proceedings as. for example, to discover collusion or, in England, concealment of adultery by the petitioner. In Scotland this intervention is made by the lord advocate. It is rare, probably because the law does not recognize recrimination. There is no queen's proctor. For the matrimonial offenses of adultery and cruelty (including habitual drunkenness) the courts grant, if sought, the lesser remedy of judicial separation. This, if allowed, is normally accompanied by an award of aliment. The property position on divorce is quite different from the English. The guilty spouse is treated as notionally dead and the legal rights exigible on death (see succession. below) are similarly exigible on divorce. This is a capital transaction. There is no award of a periodic alimentary payment.

Children. — Scots law divides minority into two periods: (1) minority proper. from 12 to 21 for girls, 14 to 21 for boys: and (2) pupillarity; up to 12 and 14 respectively. Pupils act by their tutors. normally the father. Minors act with the consent of their curators, normally the father. A pupil can never act for himself. But a minor. if he has no father. need have no curator and can legally treat himself as if he were major. The independence thus allowed to young people is an outstanding feature of the law. But 16 is the lowest age for marriage. Disadvantageous transactions by minors and pupils can be set aside within four years of attaining 21.

Intestate Succession. — In the law of succession the Administration of Estates act. 1923, by establishing a general order of intestate succession in England. has created a fundamental difference between the countries. In Scotland the order of succession in heritable (real) and movable (personal) property remains separate. And Scots law has never admitted absolute freedom of bequest in cases where there is a surviving husband. wife or child. A widow has a legal right. known as *jus relictae*, to one-half of her husband's movable property if there is no surviving child; if there is, to one-third. A widower. by the Married Woman's Property act, 1881, has a similar right in the movable property of his wife (*jus* relicti).

In heritable property a widow has a legal right (terce) to a liferent of one-third; a widower. under certain limitations. has a right of courtesy. which gives him a liferent of the whole of the wife's estate. Children have a legal right to legitim in the movable estate of each parent, one-half if there is no surviving spouse, one-third if there is. All rights may be excluded by antenuptial marriage contract; any particular claim by postnuptial contract between husband and wife, or between parent and child. They cannot, however, be excluded or limited by will, and attempted disregard of this may be successfully challenged in the courts.

Testate **Succession.**—No legacy made orally is valid unless it is of £100 Scots (£8 6s. 8*d.*) or less. This apart. a will must be made by a writing signed and witnessed as a deed (by two witnesses) or by a writing entirely in the testator's handwriting and signed by him. a holograph will. When a testator cannot write. the will may be signed for him by a solicitor, notary, justice or parish minister.

The validity of a will is, in Scots law, not affected by the subsequent marriage of the testator. It may be said that, with considerable differences of detail. the law of wills is not markedly different in the two countries. Undoubtedly, however, the existence in Scotland of "legal rights" to succeed introduces a complication which does not arise in England. (See also WILL.)

Executors and Trustees. — These are persons nominated by the deceased (executors nominate) or appointed by the court (executors dative) who alone are entitled to get in the estate and pay creditors and legatees. Sanction to act is conferred by confirmation; the term probate is a solecism in Scotland. Any other person dealing with the estate is called a *vitious intromitter* and may, unless relieved by the court, incur liability for the debts of the deceased. A special summary process is competent in the case of small estates of a few hundred pounds in value. The heir of an executor does not succeed to his office. The same persons are frequently executors and trustees in estates of any size and especially where life interests have to be carried on. The law of trusts. a subject of great importance, is to be found in its main features in the Trusts (Scotland) act, 1921. It in many respects resembles the law in England but the conception of holdings in trust as a sort of property running parallel to legal property is quite foreign.

A Scottish trust is normally constituted by an act of its creator but it may also arise through implication from circumstances. Writing is not in all cases necessary. Trustees act by a majority. They may assume new trustees and may resign if they provide for the continuance of the trust. A trust may be terminated with the consent of grantor and beneficiaries, but a trust taking effect on its creator's death may not be terminated even with the beneficiaries' consent if its purpose is alimentary; *i.e.,* for the maintenance of the beneficiary. Such a protected trust may be created in favour of a man.

Contract. — In regard to form of contract there are three possibilities: the contract must be in writing (*e.g*, for sale of land); it may be made orally but must be proved by writing (e g., contracts of an unusual nature); or it may be made and proved in any way (*e.g.,* sale of goods). The specialities of the document under seal are unknown, and consideration is unnecessary. Where writing is needed merely by way of proof and none is available, the party desiring to prove the contract may have the other put on oath and called upon to admit the contract. If this fails only part performance can save it. The only drawback to a contract lacking consideration is that it must be proved by writing. It is a peculiarity of Scots law that when a third party, X, is deliberately benefited by a contract between A and B, X has a right to sue A or B if either of them fails to perform the obligation. Where one party has been precluded through some cause beyond his control from performing his obligation, the law of Scotland enforces the return of any advance payment that has been made. (The law of England which refused this had, by mid-20th century, come into line.) There is much in the law of contract in the two countries that is similar. Yet the two are far from being identical. Mention may be made of the negative and short prescriptions, so closely though not exclusively connected with contract. Very shortly, a person who fails to enforce his rights under contract for 20 years is prevented by the long negative prescription from doing so. Shorter periods such as three and six years apply to particular contracts, but these in the usual case merely add the need of writing to the burden of proof, without extinguishing the rights.

A useful conception is that of quasi contract. This means the obligation imposed, not by express agreement, but by force of circumstances. One example is *negotiorum* gestio, which means the obligation to make good expense incurred in intervening to help another in an emergency.

Sale of Goods.--One statute, the Sale of Goods act, 1893. provides a short code of law upon this subject for Scotland and England. There is a background of considerable differences but these were largely reconciled in the act. There remain a few differences, however, of varying importance. Thus the law as to the effect of breach of warranty and condition is different. In English law the remedies of a buyer depend upon whether the seller's failure is concerned with a warranty or a condition. In Scotland the question is whether the seller's failure is in the circumstances a material failure. Again, where the value of goods sold exceeds £10 there must in England be a memorandum in writing; in Scotland oral evidence is in all cases sufficient.

Movable Property. — It is impracticable in a short article even to mention the multifarious aspects of this topic, some of which, however, are referred to under other headings. A few observations upon the origin and use of property are all that can be attempted. Whatever has, never had an owner may be taken and converted into property by occupatio, subject to some restrictive laws. Nondomestic animals are an example, even game, but poached game may be forfeited. Accessio is another mode: whatever is affixed to heritage or grows in it tends to become the property of the owner of the heritage. (Land itself cannot be acquired by occupatio since land in nobody's hands reverts to the crown.) But most property is acquired by transactions such as sale or gift or succession. By other transactions such as liferent, hire, deposit and loan something short of property is acquired, usually possession, which is a concomitant of property. These transactions have their counterpart in heritage, and liferent is of especial importance there. A liferent cannot be created in favour of a person as yet unborn as, for example, by a bachelor in favour of his legitimate grandchild. If this is attempted the person selected becomes the owner.

Liferent confers rights upon the holder so extensive as to render him virtually owner for life. Thus the liferenter is liable for discharge of burdens of all kinds upon the property not in the nature of capital payments; while he is entitled to use the liferented property as he pleases, except that he may not dilapidate it nor dispose of it for a period longer than the duration of his life. One important feature of the Scots law of property is the stress laid upon possession of the subject of a transaction. With exceptions of little importance no security over movables can be created without actual or constructive delivery. Several important differences from English law follow. Thus the bill of sale is unnecessary and unknown and the "floating charge" is incompetent. Security, too, by way of deposit of deeds is out of the question. Gift in Scots law is, in accordance with the same principle, effected only by transfer of the thing given. And before 1893 the property in goods sold only passed on actual delivery.

Delict.—By this word is meant in modern usage a wrong in its civil aspect. The basic rule of Scots law is that whoever injures another in his fortune, his person or his good name either intentionally (delict) or through negligence (quasi delict) is liable to pay such damages as will, so far as practicable, restore the status quo ante. This is known as reparation. Damages are therefore given for injury, pain, damage to property, interference with trade, defamation, wrongful imprisonment and the like. Injury to feelings, as through bereavement, is met by an award of *solatium.* This occurs where near relatives (father, mother, children) or husband and wife are killed. (In England Lord Campbell's act, 1846, is based on the Scots common law, with differences.)

The law of reparation rests upon the existence of culpa or fault and no liability attaches because of mere ownership of an object which causes damage. It is, too, only for the foreseeable results of negligence that damages are given. An important body of case law goes to illustrate the liability of employers for the acts of their servants. In the law of defamation no distinction is drawn between written and spoken words. Utterance to the defamed person himself constitutes publication. It is not necessary in any case to prove special (particular and ascertainable) damage. There is no such thing as criminal libel, and holding up to mere ridicule is not actionable. Whatever the preunion law of Scotland, the crown was in postunion times immune from liability for wrongs done by its servants. In 1947, however, the Crown Proceedings act introduced liability in most cases, thus probably restoring the Scots common law.

Procedure; Diligence; Bankruptcy. — These highly technical conceptions lend themselves in a condensed account to none but the most summary treatment. They all differ greatly from their English counterparts. Civil procedure in the court of session and the sheriff court are similar and only the former is considered here. A summons usually begins the proceedings though petition is also known. All averments of fact must be explicitly answered and each party's legal contentions are contained in numbered pleas in law. Great importance is attached to "relevancy"; *i.e.,* the statements made must if proved import the remedy. Otherwise the case may be dismissed. In civil trial by jury, issues are settled in writing for presentation to the jury. The course of an action is arranged in the procedure roll. It has for centuries been the boast of the Scottish bar that nobody ever lacked their help for want of means.

Diligence is the Scottish equivalent of execution and it takes several forms. Thus, for example, poinding (pronounced "pinding") means taking movables to satisfy the decree of the court. Arrestment involves directing the debtor of the judgment debtor to pay the latter's creditor direct. Adjudication means taking heritage in satisfaction.

Bankruptcy (technically "sequestration") is the state of officially recognized insolvency which follows usually upon unsatisfied diligence. It affects all property of the bankrupt in the British Isles. Various types of arrangements with creditors may avert the disaster. Statutory safeguards prevent abuse by way of fraudulent preference and the like. A bankrupt suffers civil disabilities ceasing on his discharge, which depends upon conduct and satisfactory payments.

Criminal Law.—A crime is a wrong which even if it directly injures an individual is held to be harmful to the community. Pursuant to this view and with the rarest exceptions, prosecution is exclusively a public function carried through by a public prosecutor.

The lord advocate is the head of a system of prosecuting counsel and other officials (procurators fiscal) who prosecute in the high court and the sheriff courts respectively throughout Scotland. Other criminal courts have also public prosecutors. Private prosecution is today virtually unknown although in theory and in the unlikely event of the crown's unjustifiably declining to prosecute, the victim may be given leave to do so. Proof of a guilty intention on the part of the accused, as well as of an overt act, is necessary before a conviction can be obtained save where statute makes an exception or where the court has admitted the vicious principle of vicarious responsibility. Such circumstances, therefore, as youth (no crime under eight), insanity or compulsion will, subject to certain rules, render conviction impossible. The question of the responsibility of the insane is no more satisfactorily settled than elsewhere, but Scots law gives greater exculpatory effect to insanity than English law. The English distinction, in modern times idle and even misleading, between felony and misdemeanour is not made. The field of particular crimes is covered thoroughly as in most systems and no act involving moral delinquency will fail of punishment merely because precedent or a name is lacking.

Nomenclature differs considerably from English nomenclature and the same word (like embezzlement) may point to different offenses. Burglary and housebreaking are not distinguished; manslaughter is culpable homicide; receiving is reset; concealment of pregnancy and not concealment of birth is the crime and so on. The criminality of suicide lacks satisfactory warranty and Hume, the prime authority, shies away from pronouncing even upon attempt. In modern practice the public prosecutor may, but rarely does, prosecute an attempt as a breach of the peace. Almost always such cases, which usually involve insanity, are dealt with administratively after medical examination. It may be said too that the incidence of crime is different north and south of the border and the popular attitude to certain crimes also differs. Thus blackmail is almost unknown. And for many years in the earlier part of the 20th century Scottish juries could scarcely be brought to convict of murder.

Criminal Courts and Procedure.—The high court of justiciary is the ancient supreme criminal court. It consists of the judges of the court of session but in their capacity of lords commissioners of justiciary. Its sittings take place in Edinburgh and on circuit. It tries cases with a jury but has an appellate jurisdiction in summary cases. Since 1926 its judges have had power to entertain appeals against convictions on indictment also. The sheriff court tries both on indictment and summarily. Two years' imprisonment is the maximum. Lower courts are the police courts of the bailies in the towns and justices in the country. There is no coroner. Fatal accident inquiries, however, are held in certain cases and the procurator fiscal investigates every case of suspicious death.

Criminal procedure in Scotland is simple and expeditious, Innocence is presumed and guilt must be proved beyond a reasonable doubt. Proceedings are instituted by the crown officials who decide on form of trial and forum. The police do not prosecute. Juries consist of 15 and may decide by a majority. A verdict of "not proven" is competent and useful. Even in the case of serious crime there is only one public hearing, so that juries can never be prejudiced by the reading of one or two detailed reports of earlier hearings. In the trial itself the last word in every case (subject to the judge's summing up) lies with the accused, never with the prosecution. There is no opening speech on either side.

SCOTT, ALEXANDER (*c.* 1525–*c.* 1585), Scottish poet, one of the "last of the makaris" of the 16th century, a writer of lyrical freshness and technical skill. Nothing is known of his life, though he seems to have been familiar with Edinburgh and Dalkeith, and he is probably the "old Scott" referred to by Alexander Montgomerie, his younger poetic contemporary, in a sonnet dated *c.* 1584. All his extant poems, about 35 in number, are contained in the Bannatyne manuscript (1568 ; in the National Library of Scotland). Since Allan Ramsay printed a selection of his verse in his collection of old Scots poetry, *The Ever Green* (1724), Scott's reputation as a genuine minor lyric poet has been maintained. He left an amusing burlesque, "*The Justing and Debait vp at the Drum betuix William Adamsone and Johine Sym.*" He also wrote a ceremonial and highly alliterative poem, "*Ane New Yeir Gift to the Queen Mary, quhen scho come first Hame, 1562,*" which gives an interesting reflection of early Reformation Scotland. His best work, however, is to be found in his love lyrics; these show a striking range of mood, from the tender to the coarse, and an admirable metrical suppleness and variety.

BIBLIOGRAPHY.—Scott's poems were edited by J. Cranstoun, Scottish Text Society (1896); by A. K. Donald, Early English Text Society (1902); and by A. Scott, Saltire Society (1952). *See* also C. M. Maclean, *Alexander Scott, Montgomerie, and Drummond of Hawthornden as Lyric Poets* (1915). (E. G. M.)

SCOTT, CHARLES PRESTWICH (1846–1932), British editor and journalist, born at Bath, Somersetshire, on Oct. 26, 1846, was the youngest son of Russell Scott. He was educated privately and at Corpus Christi college, Oxford, where he graduated with a first class in 1869. After training under Alexander Russell of *The Scotsman*, he, in 1871, began a long connection with *The Manchester Guardian*, of which his brother-in-law, J. E. Taylor, was proprietor. He himself became editor in 1872, and, after the death of Taylor in 1905, also chief proprietor. He enlisted the services of W. T. Arnold and many of the leading critics of literature, art and music of two generations, so that the paper became one of the foremost journals of the day. Gradually developing from Whiggism to advanced Liberalism, *The Manchester Guardian*, as directed by Scott, was always sober in tone and scrupulous in policy. He retired in 1929.

Always active in local politics, after three unsuccessful contests for the representation of North-East Manchester, Scott was elected Liberal M.P. for the Leigh division of Lancashire in 1895 and sat until 1906.

See J. L. Hammond, *C. P. Scott of the Manchester Guardian* (1934).

SCOTT, CYRIL MEIR (1879–), English musical composer, pianist and author, was born at Oxton, Birkenhead, on Sept. 27, 1879, and studied music at the Hoch conservatorium, Frankfurt am Main. On his return to England, Hans Richter in 1900 produced his orchestral *Heroic Suite* at Liverpool, and an overture to *Pelléas and Mélisande* was shortly afterward played at Frankfurt, but both of these and several of his other early works were afterward withdrawn by the composer as immature. His works include songs, piano and violin compositions, operas, a ballet, choral and chamber music and orchestral works.

Scott wrote verse and an autobiography, My *Years of Indiscretion;* he also wrote *Music: Its Secret Influence Throughout the*

Ages, 5th ed. (1950), and books on mysticism.

SCOTT, DUKINFIELD HENRY (1854–1934), English paleobotanist, the leading authority of his day on the structure of fossil, and especially of Carboniferous, plants, was born in London on Nov. 28, 1854. His early education was by private tutors. In 1876 he graduated from Christ Church, Oxford. He became financially independent when his father died. Soon thereafter, he decided to study botany under Julius von Sachs (*q.v.*) at Wiirzburg where, in 1882, he received his doctorate. He taught at University college, London (1882), and the Royal College of Science (1885) and, in 1892, became honorary keeper of the Jodrell laboratory at Kew. He was elected a fellow of the Royal society in 1894. He left Kew in 1906 and settled at Oakley where he died on Jan. 29, 1934.

Scott's early work was in plant anatomy, but his interests turned to paleobotany when he wrote, with William Crawford Williamson (*q.v.*), three memoirs on the organization of the fossil plants of the carboniferous rocks (1895–96). In 1897 he described the complex cone of *Cheirostrobus.* His paper on *Lepidocarpon* (1901) showed that some Paleozoic lycopods bore "nascent" seeds, and the paper on *Botrychioxylon* (1912) revealed the presence of secondary wood in a Paleozoic fern. In 1904 Scott and F. W. Oliver announced their discovery that the seed *Lagenostoma* belonged to the fernlike *Lyginodendron,* thus bringing to light a new class of seed plants for which the name Pteridospermae was proposed. He wrote *Studies in Fossil Botany* (1900; 3rd ed., 1920–23) and *Extinct Plants and Problems of Evolution* (1924).

See notices in *Ann. of Bot.*, vol. xlix, pp. 823–840 (1935), containing a list of Scott's 154 publications, and in *Nature,* vol. cxxxiii, pp. 317–319 (1934), vol. clxxiv, pp. 992–993 (1954). (J. W. Tr.)

SCOTT, SIR GEORGE GILBERT (1811–1878), English architect of the Gothic revival, whose main work was the restoration of churches and cathedrals, was born in 1811 at Gawcott near Buckingham. Scott was apprenticed to a London architect, filled various staff posts, and designed his first church in 1838. But his real artistic education dates from his study of A. W. N. Pugin's works on medieval architecture. The first result of this new study was his design for the Martyrs' memorial at Oxford, erected in 1840, a clever adaptation of the late 13th-century crosses in honour of Queen Eleanor.

In 1844 Scott won the competition for the new Lutheran church at Hamburg, a noble building with a lofty spire, designed in 14th-century German Gothic. In 1847 he was employed to renovate and refit Ely cathedral, the first of a long series of English cathedrals and abbey churches that passed through his hands. In 1851 he visited and studied the architecture of the chief towns in northern Italy. In 1856 a competition was held for designs for the new government war and foreign offices in London; the work was given to Scott on the condition (insisted on by Lord Palmerston) that he should make a new design, not Gothic, but Classic or Renaissance in style. In 1862–63 he was employed to design and construct the Albert memorial, a costly and elaborate work, in the style of a magnified 13th-century reliquary or ciborium, adorned with many statues and reliefs in bronze and marble. On the partial completion of this he was knighted. In 1873, because of illness caused by overwork, Scott spent some time in Rome and other parts of Italy. The mosaic pavement which he designed for Durham cathedral soon afterward was the result of his study of the 13th-century mosaics in the old basilicas of Rome. He died on March 27, 1878. Scott's volume of *Personal and Professional Recollections* was published in 1879.

SCOTT, SIR GILES GILBERT (1880–1960), British architect, born Nov. 9, 1880, was the son of George Gilbert Scott and grandson of Sir George Gilbert Scott, R.A. Educated at Beaumont college, Old Windsor, he began to practise in London in 1902. His first commission was for the projected cathedral at Liverpool, his designs for which expressed the architect's hope for a revival of Gothic architecture through the true understanding of its spirit and were accepted on the condition that G. F. Bodley, R.A., be associated with him as joint architect in consideration of his youth. In July 1904 the foundation was laid by King Edward and the Lady chapel was completed in 1910. The consecration took place on July 19, 1924, in the presence of King George V and Queen Mary. Designed in Gothic style; it was the first Anglican cathedral built in the northern provinces since the Reformation. The design for the tower was considerably altered in 1924. The exterior is of red sandstone, and its massive bulk dominated the city and the seaway. Later Scott designed many other church buildings including Charterhouse school chapel, the nave of Downside abbey and the Abbey church at Ampleforth.

Scott also was the architect for the new university library and extensions to Clare college, Cambridge. In 1944 he was chosen as architect of the new house of commons chamber, a simplified version of the chamber destroyed in World War II; the building was completed in 1950. He was elected associate of the Royal Academy in 1918, Royal Academy in 1922, and was president of the Architectural association, 1920–21, and of the Royal Institute of British Architecture, 1933–35. He was knighted after the consecration of Liverpool cathedral in 1924 and in 1944 received the Order of Merit. He died in London on Feb. 8, 1960.

SCOTT, JAMES BROWN (1866–1943), U.S. jurist, publicist and educator, one of the leaders in the international peace movement of the 20th century, was born of American parents on June 3, 1866, at Kincardine, Ontario. Graduating from Harvard in 1890 (M.A. 1891), he subsequently studied at Berlin, Paris and Heidelberg, (J.U.D. degree from the last, 1894). Devoting his life to expounding and advocating the application of law and justice between nations through arbitration and judicial settlement, Scott played an important part in establishing at The Hague the Permanent Court of International Justice (1921) and the Academy of International Law (1914). He was one of the founders of the American Institute of International Law (1912), the American Society of International Law and its *Journal* (1906), the first English-language periodical of its kind, of which he was editor in chief. He was author, among other works, of *Cases on International Law,* 2nd ed. (1922), *The Spanish Origin of International Law* (1933) and *Law, the State and the International Community* (1939).

Law school dean (Los Angeles law school [Southern California] and Illinois) and professor (Columbia and Georgetown) from 1896 to 1940, Scott was editor of several casebooks and general editor (1908–15) of the *American Casebook* series begun in 1908 at his suggestion. Solicitor of the U.S. department of state (1906–10) and technical adviser, Scott was counsel to the U.S. agent in the North Atlantic fisheries arbitration and was delegate to numerous international conferences, including the 1907 Hague peace conference, where he urged the establishment of an international arbitral court. He was secretary (1910–40) of the Carnegie Endowment for International Peace and director of its division of international law (1911–40). He died on June 25, 1943, at Annapolis, Md.

SCOTT, ROBERT (1811–1887), English theologian and lexicographer, was born on Jan. 26, 1811, at Bondleigh, Devonshire, and educated at Shrewsbury school and Christ Church, Oxford.

Scott's great achievement was his collaboration with Dean Liddell in the Greek lexicon (1843), of which a new edition, revised by H. S. Jones and R. McKenzie, was published in 1925. He died at Rochester on Dec. 2, 1887.

SCOTT, ROBERT FALCON (1868–1912), British sailor and explorer, was born at Devonport on June 6, 1868. Educated at Stoke Damerel and Stubbington House, Fareham, he passed into H.M.S. "Britannia" in 1880, and in 1882 became a midshipman on the "Boadicea." In 1897 he was promoted first lieutenant, and two years later he was recommended as commander of the National Antarctic Expedition. On taking up his duties in the "Discovery," in 1900, he was promoted commander. During the four years which followed, Scott proved both an intrepid and able leader, and a competent scientific investigator; and on his return in 1904 he was promoted to the rank of captain. For the next six years he served in the navy, commanding successively, the "Victorious," the "Essex," and the "Bulwark," until, in 1909, he announced his intention of organizing another Antarctic expedition, for the purpose of continuing the work of the "Discovery" and of reaching the South Pole.

Backed financially by the British and Dominion Governments, Scott set sail in June 1910 in the "Terra Nova," and in Nov. 1911, began his southern sledge journey. Though delayed by bad weather, Scott and his four companions reached the Pole on Jan. 17, 1912, to find that they had been forestalled by Amundsen. Sickness, insufficiency of food, and the severity of the weather, made travelling very slow on the return journey, and on Feb. 17, Petty Officer Evans broke down under the strain and died. A month later, Oates, who was too ill to travel further, walked out into a blizzard, hoping, by his sacrifice, to save his companions; but the weather prevented all possibilities of advancing, and the remdinder of the party perished on or about March 27, 1912. On Nov. 12, 1912, a search party found Scott's tent, containing the bodies of Scott, Dr. E. A. Wilson and Lieut. H. R. Bowers, as well as Scott's records and diaries, in which was given a full account of the journey and the deaths of Capt. Oates and Petty Officer Edgar Evans. A memorial service was held in St Paul's cathedral, London, on Feb. 14, 1913, and a Mansion House fund was subsequently raised to make provision for the surviving relatives of the lost explorers The rank and precedence of the wife of a K.C.B. were by royal warrant conferred on Captain Scott's widow.

SCOTT, SIR WALTER, BART. (1771–1832), Scottish poet and novelist, was born at Edinburgh on Aug. 15, 1771. He came of an old Border family, and it was his pride in their real or supposed feudal dignity and their rough marauding exploits that first directed him to the study of Border history and poetry, the basis of his fame as a poet and romancer. His father, Walter Scott, a writer to the signet (or attorney) in Edinburgh—the original of the elder Fairford in *Redgauntlet—was* the first of the family to adopt a town life or a learned profession His mother was the daughter of Dr. John Rutherford, a medical professor in the University of Edinburgh, who also traced descent from the chiefs of famous Border clans.

Scott's health in boyhood was uncertain; an attack of fever in infancy had left him permanently lame, and his nature was so lively and excitable that it was considered dangerous to press him and prudent rather to keep him back. He was therefore left very much to himself in the matter of reading, and began at an early age to accumulate the romantic lore of which he afterwards made such splendid use. At ten his collection of chap-books and ballads had reached several volumes, and he was a connoisseur in various readings. Thus he took to the High School, Edinburgh, when he was strong enough to be put in regular attendance, an unusual store of miscellaneous knowledge and an unusually quickened intelligence. Throughout his school days and afterwards when he was apprenticed to his father, attended university classes, read for the bar, took part in academical and professional debating societies, Scott steadily and ardently pursued his own favourite studies. He was still a schoolboy when he mastered French sufficiently well to read through collections of old French romances, and not more than 15 when, attracted by translations to Italian romantic literature, he learnt the language in order to read Dante and Ariosto in the original. In one of the literary parties brought together to lionize Burns, when the peasant poet visited Edinburgh, the boy of 15 was the only member of the company who could tell the source of some lines affixed to a picture that had attracted the poet's attention—a slight but significant evidence both of the width of his reading and of the tenacity of his memory. But he was far from being a cloistered student. absorbed in his books. In spite of his lameness and his serious illnesses in youth, his constitution was naturally robust, his disposition genial, his spirits high: he was always well to the front in the fights and frolics of the High School, and a boon companion in the "high jinks" of the junior bar. At home he had to behave as became a member of a Puritanic, somewhat ascetic, well-ordered Scottish household, but from any tendency to the pedantry of over-culture he was effectually saved by the rougher and manlier spirit of his professional comrades. They were the first mature audience on which he experimented, and it was to this market that he brought the harvest of the vacation rambles which it was his custom to make every autumn for seven years after his call to the bar and before his marriage. His staid father did not much like these escapades, and told him bitterly that he seemed fit for nothing but to be a "gangrel scrape-gut." But, as the companion of "his Liddesdale raids" happily put it, "he was *makin' himsell* a' the time."

His father intended him originally to follow his own business, and he was apprenticed in his 16th year, but he preferred the upper walk of the legal profession, and was admitted a member of the faculty of advocates in 1792. He seems to have read hard at law for four years at least, but almost from the first to have limited his ambition to obtaining some comfortable appointment such as would leave him a good deal of leisure for literary pursuits. In this he was not disappointed. In 1799 he obtained the office of sheriff-depute of Selkirkshire, with a salary of £300 and very light duties. In 1806 he obtained the reversion of the office of clerk of session, which kept him hard at work, his biographer estimates, for at least three or four hours daily during six months out of the twelve, while the court was in session He discharged these duties faithfully for 25 years, during the height of his activity as an author. He did not enter on the emoluments of the office till 1812, but from that time he received from the clerkship and the sheriffdom combined an income of £1,600 a year, being thus enabled to act in his literary undertakings on his often-quoted maxim that "literature should be a staff and not a crutch."

The Poems.—It was as a poet that he was first to make a literary reputation. According to his own account, he was led to adopt the medium of verse by a series of accidents. The story is told by himself at length and with his customary frankness and modesty in the *Essay on Imitations of the Ancient Ballad,* prefixed to the 1830 edition of his *Border Minstrelsy,* and in the 1830 introduction to the *Lay of the Last Minstrel.* The first link in the chain was a lecture by Henry Mackenzie on German literature, delivered in 1788. This apprized Scott that there was a fresh development of romantic literature in German, and while he was in the height of his enthusiasm for the new German romance, Mrs. Barbauld visited Edinburgh, and recited an English translation of Burger's *Lenore.* Scott was moved to attempt such poetry himself, and the impulse was strengthened by his reading Lewis's *Monk* and the ballads in the German manner interspersed through the work. He hastened to procure a copy of Burger, at once executed translations of several of his ballads, published *The Chase,* and *William and Helen,* in a thin quarto in 1796 (his ambition being perhaps quickened by the unfortunate issue of a love affair), and was much encouraged by the applause of his friends. Soon after he composed *Glenfinlas, The Eve of St. John,* and the *Gray Brother,* which were published in Lewis's collection of *Tales of Wonder* (2 vols., 1801). But he soon became convinced that "the practice of ballad-writing was out of fashion," and his study of Goethe's *Götz von Berlichingen,* of which he published a translation in 1799, gave him wider ideas. Why should he not do for ancient Border manners what Goethe had done for the ancient feudalism of the Rhine? He was engaged at the time preparing a collection of the *Minstrelsy of the Scottish Border,* the first instalment of which was published in two volumes in 1802, and was still hesitating about subject and form for a large original work, when chance at last threw in his way both a suitable subject and a suitable metrical vehicle. The countess of Dalkeith, happening to hear the legend of a tricksy hobgoblin named Gilpin Horner, asked Scott to write a ballad about it. He agreed with delight, and the subject grew in his fertile imagination, till incidents enough had gathered round the goblin to furnish a frame ork for his long-designed picture of Border manners. At the same time a friend of his who had met Coleridge in Malta brought home sufficient reminiscences of the still unpublished poem of *Christabel* to convey to Scott that its metre was the very metre of which he had been in search. Scott introduced still greater variety into the four-beat couplet; but it was to *Christabel* that he owed the suggestion, as one line borrowed whole and many imitated rhythms testify.

The *Lay of the Last Minstrel* appeared in Jan. 1805, and at once became widely popular. Its success finally decided that literature was to be the main business of Scott's life, and he proceeded to arrange his affairs accordingly. Since his marriage in 1797 with Charlotte Cbarpentier, daughter of a French refugee, his chief residence had been at Lasswade, about six miles from Edinburgh. But on a hint from the lord-lieutenant that the sheriff must live at least four months in the year within his county, and that he was attending more closely to his duties as quartermaster of a mounted company of volunteers than was consistent with the proper discharge of his duties as sheriff, he had moved his household in 1804 to Ashestiel. When his uncle's bequest fell in, he determined to buy a small property on the banks of the Tweed within the limits of his sheriffdom. There, within sight of Newark castle and Bowhill, he proposed to live like his ancient minstrel, as became the bard of the clan, under the shadow of the great ducal head of the Scotts. But this plan was deranged by an accident. It so happened that an old schoolfellow, James Ballantyne (1772–1833), a printer in Kelso, whom he had already befriended, transplanted to Edinburgh, and furnished with both work and money, applied to him for a further loan. Scott declined to lend, but offered to join him as sleeping-partner. Thus the intended purchase money of Broadmeadows became the capital of a printing concern, of which by degrees the man of letters became the overwrought slave, milch-cow and victim.

When the *Lay* was off his hands, Scott's next literary enterprise was a prose romance—a confirmation of the argument that he did not take to prose after Byron had "*bet* him," as he put it, in verse, but that romance writing was a long-cherished purpose. He began *Waverley*, but a friend to whom he showed the first chapters decided that the work was deficient in interest and unworthy of the author of the *Lay*. Scott accordingly laid *Waverley* aside. We may fairly conjecture that he would not have been so easily diverted had he not been occupied at the time with other heavy publishing enterprises calculated to bring grist to the printing establishment. In 1806 he collected from different publications his *Ballads and Lyrical Pieces*. Between 1806 and 1812, mainly to serve the interests of the firm, he produced his elaborate editions of Dryden (18 vols., 1808), Swift (19 vols., 1818), the Somers Tracts (13 vols., 1809–15), and the *State Papers and Letters of Sir Ralph Sadler* (2 vols., 1809).

Marmion, begun in Nov. 1806 and published in Feb. 1808, was written as a relief to "graver cares," and was even more popular than the *Lay*. Scott's resuscitation of the four-beat measure of the old "gestours" afforded a signal proof of the justness of their instinct in choosing this vehicle for their recitations. The four-beat lines of *Marmion* took possession of the public like a kind of madness, and the critics, except Jeffrey, who may have been offended by the pronounced politics of the poet, were on the whole better pleased than with the *Lay*. Scott was now *facile princeps* among living poets, and touched the highest point of prosperity and happiness. Presently after, he was irritated and tempted by a combination of little circumstances into the great blunder of his life, the establishment of the publishing house of John Ballantyne and Co. A quarrel occurred between Scott's printing firm and Constable, the publisher, who had been the principal feeder of its press. Then the tempter appeared in the shape of Murray, the London publisher, anxious to secure the services of the most popular *littérateur* of the day. The result of negotiations was that Scott set up, in opposition to Constable, the publishing house of John Ballantyne and Co., to be managed by John Ballantyne (d. 1821), James's younger brother. Scott interested himself warmly in starting the *Quarterly Review*, and in return Murray constituted Ballantyne and Co. his Edinburgh agents. Scott's trust in the Ballantynes, and in his own power to supply all their deficiencies, is as strange a piece of infatuation as any that ever formed a theme for romance or tragedy. Their devoted attachment to the architect of their fortunes and proud confidence in his powers helped forward to the catastrophe, for whatever Scott recommended they agreed to, and he was too immersed in multifarious literary work and professional and social engagements to have time for cool examination of the numerous rash speculative ventures into which he launched the firm.

The *Lady of the Lake* (May 1810) was the first great publication by the new house, and next year the *Vision of Don Roderick* followed. The *Lady of the Lake* was received with enthusiasm; it made the Perthshire Highlands fashionable for tourists, and raised the post-horse duty in Scotland; but it did not make up to Ballantyne and Co. for their heavy investments in unsound ventures. The *Edinburgh Annual Register*, meant as a rival to the *Edinburgh Review*, though Scott engaged Southey to write for it and wrote for it largely himself, proved a failure. In a very short time the warehouses of the firm were filled with unsaleable stock, but, so far from understanding the real state of their affairs, Scott considered himself rich enough to make his first purchase of land at Abbotsford. He had hardly settled there in the spring of 1812, and begun his schemes for building and planting and converting a bare moor into a richly wooded *pleasaunce*, when his business troubles began, and he found himself harassed by fears of bankruptcy. The proceeds of *Rokeby* (Jan. 1813) and of other labours of Scott's pen were swallowed up, and bankruptcy was inevitable, when Constable, still eager at any price to secure Scott's services, came to the rescue. With his help three crises were tided over in 1813.

The Novels.—It was in the midst of these embarrassments that Scott opened up the rich new vein of the Waverley novels. He chanced upon the ms. of the opening chapters of *Waverley* which he had written in 1805, and resolved to complete the story. Four weeks in the summer of 1814 sufficed for the work, and *Waverley* was published by Constable without the author's name in July. Many plausible reasons might be given and have been given for Scott's resolution to publish anonymously. The reason given by Lockhart is that he considered the writing of novels beneath the dignity of a grave clerk of the Court of Session. The secret was an open one to all his Edinburgh acquaintances, yet why he kept up the mystification until the disclosure of the year 1827, is easily understood. He enjoyed it, and his formally initiated coadjutors enjoyed it; it relieved him from the annoyances of foolish compliment; and it was not unprofitable—curiosity about "the Great Unknown" keeping alive the interest in his works. Meanwhile he kept on producing in his own name as much work as seemed humanly possible for an official who was to be seen every day at his post and as often in society as the most fashionable of his professional brethren. His treatises on chivalry, romance and the drama, besides an elaborate work in two volumes on Border antiquities, appeared in the same year with *Waverley*, and his edition of Swift in 19 volumes in the same week. In 1813 he published the romantic tale of *The Bridal of Triermain* in three cantos, enlarged from an earlier poem, printed in the *Edinburgh Annual Register* of 1809. The *Lord of the Isles* was published in Jan. 1815; *Guy Mannering*, written in "six weeks about Christmas," in February; and *The Field of Waterloo* in the same year. *Paul's Letters to his Kinsfolk* and *The Antiquary* appeared in 1816; the first series of the *Tales of My Landlord*, edited by "Jedediah Cleishbotham"—*The Black Dwarf* and *Old Mortality*—in the same year; *Harold the Dauntless* in 1817; the two volumes of *The Border Antiquities of England and Scotland* in 1814 and 1817. No wonder that the most positive interpreters of internal evidence were mystified. Scott's fertility is not absolutely unparalleled; Anthony Trollope claimed to have surpassed him in rate as well as total amount of production, having also business duties to attend to. But in speed of production combined with variety and depth of interest and weight and accuracy of historical substance Scott is unrivalled.

The immense strain of this double or quadruple life as sheriff and clerk, hospitable laird, poet, novelist, and miscellaneous man of letters, publisher and printer, though the prosperous excitement sustained him for a time, soon told upon his health. Early in 1817 began a series of attacks of agonizing cramp of the stomach, which recurred at short intervals during more than two years. But his appetite and capacity for work remained unbroken. He made his first attempt at play-writing (The Doom of Devorgoil) as he was recovering from the first attack; before the year was out he had completed Rob Roy, and within six months it was followed by The Heart of *Midlothian*, which filled the four volumes of the second series of Tales of My Landlord, and has remained one of the most popular among his novels. The Bride of *Lammermoor*, the Legend of Montrose, forming the third series by "Jedediah Cleishbotham," and Ivanhoe (1820) were dictated to amanuenses, through fits of suffering so acute that he could not suppress cries of agony.

Throughout those two years of intermittent ill-health, which was at one time so serious that his life was despaired of and he took formal leave of his family, Scott's semi-public life at Abbotsford continued as usual—swarms of visitors coming and going, and the rate of production, on the whole, suffering no outward and visible check, all the world wondering at the novelist's prodigious fertility. The first of the series concerning which there were murmurs of dissatisfaction was The *Monastery* (1820); but its sequel, The Abbot (1820), in which Mary, Queen of Scots, is introduced, was generally hailed as fully sustaining the reputation of "the Great Unknown." Kenilworth (1821), The Pirate (1822), The Fortunes of Nigel (1822), *Peveril* of the Peak (1822), Quentin *Durward* (1823), St. *Ronan's* Well (1824), *Redgauntlet* (1824) followed in quick succession in the course of three years, and it was not till the last two were reached that the cry that the author was writing too fast began to gather volume. St. *Ronan's* Well was very severely criticized and condemned, yet none of Scott's stories is of more absorbing or more brilliantly diversified interest. There must, of course, always be inequalities in a series so prolonged. The author cannot always be equally happy in his choice of subject, situation and character. Naturally also he dealt first with the subjects of which his mind was fullest. But any theory of falling off or exhaustion based upon plausible general considerations has to be qualified so much when brought into contact with the facts that very little confidence can be reposed in its accuracy. The Fortunes of Nigel comes comparatively late in the series and has often been blamed for its looseness of construction, yet some competent critics prefer it to any other of Scott's novels. An attempt might be made to value the novels according to the sources of their materials, according as they are based on personal observation, documentary history or previous imaginative literature. On this principle Ivanhoe and *The* Tales of the Crusaders (1825, containing The Betrothed and The Talisman) might be adjudged inferior as being based necessarily on previous romance. But as a matter of fact Scott's romantic characters are vitalized, clothed with a verisimilitude of life, out of the author's deep, wide and discriminating knowledge of realities, and his observation of actual life was coloured by ideals derived from romance. He did not exhaust his accumulations from one source first and then turn to another, but from first to last drew from all as the needs of the occasion happened to suggest.

During the years 1821–25 he edited Richard Franck's Northern Memoirs (1821), *Chronological* Notes of Scottish Affairs from the Diary of Lord *Fountainhall* (1822), Military Memoirs of the Great Civil War (1822), and The Novelists' Library (10 vols., 1821–24), the prefatory memoirs to which were separately published in 1828.

Financial Ruin.—Towards the close of 1825, after 11 years of brilliant and prosperous labour, encouraged by constant tributes of admiration, homage and affection such as no other literary potentate has ever enjoyed, realizing his dreams of baronial splendour and hospitality on a scale suited to his large literary revenues, Scott suddenly discovered that the foundations of his fortune were unsubstantial. He had imagined himself clear of all embarrassments in 1818, when all the unsaleable stock of John Ballantyne and Co. was bargained off to Constable for Waverley copyrights, and the publishing concern was wound up. Apparently he never informed himself accurately of the new relations of mutual accommodation on which the printing firm then entered with the great but rashly speculative publisher, and drew liberally for his own expenditure against the undeniable profits of his novels without asking any questions, trusting blindly in the solvency of his commercial henchmen. Unfortunately, "lifted off their feet" by the wonderful triumphs of their chief, they thought themselves exempted like himself from the troublesome duty of inspecting ledgers and balancing accounts, till the crash came. From a diary which Scott began a few days before the first rumours of financial difficulty reached him we know how he bore from day to day the rapidly unfolded prospect of unsuspected liabilities. "Thank God," was his first reflection, "I have enough to pay more than 20s. in the pound, taking matters at the worst." But a few weeks revealed the unpleasant truth that, owing to the way in which Ballantyne and Co. were mixed up with Constable and Co., and Constable with Hurst and Robinson, the failure of the London house threw upon him personal responsibility for £130,000.

How Scott's pride rebelled against the dishonour of bankruptcy, how he toiled for the rest of his life to clear off this enormous debt, declining all offers of assistance and asking no consideration from his creditors except time, and how nearly he succeeded, is one of the most familiar chapters in literary history, and would be one of the saddest were it not for the heroism of the enterprise. His wife died soon after the struggle began, and he suffered other painful bereavements; but, though sick at heart, he toiled on indomitably, and, writing for honour, exceeded even his happiest days in industrious speed. If he could have maintained the rate of the first three years, during which he completed Woodstock (1826); *Chronicles* of the Canongate (1827), which included three tales—"The Highland Widow," "The Two Drovers" and "The Surgeon's Daughter"; *The* Fair Maid of Perth (1828, in the second series of Chronicles of the Canongate); Anne of *Geierstein* (1829); the Life of Napoleon (9 vols., 1827); part of his History of Scotland (2 vols., 1829–30, for Lardner's Cabinet Cyclopaedia); the Scottish series of Tales of a Grandfather (four series, 1828–29–30–31), besides several magazine articles, some of them among the most brilliant of his miscellaneous writings, and prefaces and notes to a collected edition of his novels—if he could have continued at this rate he might soon have freed himself from all his encumbrances. The result of his exertions from Jan. 1826 to Jan. 1828 was nearly £40,000 for his creditors. But the terrific labour proved too much even for his endurance. Ugly symptoms began to alarm his family in 1829, and in Feb. 1830 he had his first stroke of paralysis. Still he was undaunted, and not all the persuasions of friends and physicians could induce him to take rest. "During 1830," Lockhart says, "he covered almost as many sheets with his ms. as in 1829," the new introductions to a collected edition of his poetry and the Letters on Demonology and Witchcraft being amongst the labours of the year. He had a slight touch of apoplexy in November and a distinct stroke of paralysis in the following April; but, in spite of these warnings and of other bodily ailments, he had two more novels, Count Robert of Paris and Castle Dangerous (constituting the fourth series of Tales of My Landlord), ready for the press by the autumn of 1831. He would not yield to the solicitations of his friends and consent to try rest and a change of scene, till fortunately, as his mental powers failed, he became possessed of the idea that all his debts were at last paid and that he was once more a free man. In this belief he happily remained till his death. When it was known that his physicians recommended a sea voyage for his health, a Government vessel was put at his disposal, and he cruised about in the Mediterranean and visited places of interest for the greater part of a year before his death. But, when he felt that the end was near, he insisted on being carried across Europe that he might die on his beloved Tweedside at Abbotsford, where he expired on Sept. 21, 1832. He was buried at Dryburgh Abbey.

Scott's wife had died in 1826. His eldest son, Walter, succeeded to the baronetcy which had been conferred on his father in 1820, and the title became extinct on his death in 1847; the elder daughter Charlotte Sophia (d. 1837) was the wife of his biographer, J. G. Lockhart (*q.v.*); and their daughter Charlotte (d. 1858) married J. R. Hope-Scott, and was the mother of Mary Monica, wife of the Hon. J. C. Maxwell, who in 1874 took the additional name of Scott on his marriage with the heiress of

Abbotsford. Mrs. Maxwell-Scott inherited some of the family literary talent! and among other books wrote two volumes about Abbotsford (1893 and 1897).

BIBLIOGRAPHY.—*The Miscellaneous Prose Works of Sir Walter Scott* (6 vols., 1827) were subsequently printed in 30 vols. (1834–71) and in 3 vols. (1841–47). The collected editions of the novels and tales are very numerous. Among them are that known as the "author's favourite edition" (48 vols., 1829–33), for which Scott wrote new preiaces and notes, and the "Border" edition (48 vols., 1892–94), with introductory essays and notes by A. Lang. His *Poetical Works* were printed in 12 vols. (1820); they were edited by J. G. Lockhart (12 vols., 1833–34); by F. T. Palgrave for the "Globe" edition (1866); by W. Minto (2 vols., 1888); by J. Logie Robertson (Oxford complete edition, 1904). Many of the novels have been adapted for the stage, the most famous of these dramatizations being the libretto of Donizetti's *Lucia di Lammermoor* and the *Zvanhoe* of Sir Arthur Sullivan and J. R. Sturgis. His *Minstrelsy of the Scottish Border* (3 vols., 1802–03) was edited (4 vols., 1902) by T. F. Henderson.

The standard life by his son-in-law, J. G. Lockhart, *Memoirs of tlze Life of Sir Walter Scott* (7 vols., 1837–38), was supplemented by the publication (2 vols., 1890) of Scott's *Journal,* covering the years from 1825 to 1832, and of his *Familiar Letters* (2 vols., 1894), both edited by David Douglas. *See* also James Hogg, *Tlze Domestic Manners and Private Life of Sir Walter Scott* (1834), and *R.* P. Gillies, *Recollections of Sir Walter Scott* (1837). Shorter lives are by R. H. Hutton ("English Men of Letters," 1878); G. E. B. Saintsbury ("Famous Scots" Series, 1897); Andrew Lang ("Literary Lives," 1906); G. le Grys Norgate (1906), and J. Buchan (1925). For the Ballantyne controversy *see* also *The Ballantyne Press and its Founders* (1909). *See* also W. Brewer, *Shakespeare's Influence on Sir Walter Scott* (1925); A. Caplan, *The Bibliography of Sir Walter Scott* (1928); W. S. Crockett, The *Religion of Sir Walter Scott* (1929).

SCOTT, WINFIELD (1786–1866), American general, was born near Petersburg (Va.) on June 13, 1786. In 1805 he entered the College of William and Mary where he studied law. In 1807 he removed to Charleston (S.C.), but as war with England seemed imminent he soon left for Washington and offered his services. In 1808 he was commissioned as a captain of artillery, recruited a company in Richmond and Petersburg, and was ordered to New Orleans. In July 1812, as a lieutenant-colonel of artillery, he was sent to the Niagara frontier and fought at Queenston, where he was taken prisoner. He was exchanged in Jan., 1813, became colonel in the following March, was promoted to the rank of brigadier-general in March 1814, and in July received the brevet of major-general. In the battles of Chippewa (July 5, 1814) and Lundy's Lane (July 25) he took a conspicuous part, and was twice wounded in the Lundy's Lane engagement. For his services he was presented with a gold medal by Congress and with a sword by the State of Virginia.

Among the difficult tasks that he was called upon to perform between 1815 and 1861, for the last 20 years of which period he was the commanding general of the United States Army, were: an expedition to the Middle West in 1832, where, after the end of the Black Hawk War, he negotiated treaties of peace with the Sauk, Fox, Winnebago, Sioux, and Menominee Indians; a journey to Charleston to watch the progress of the nullification movement, and to strengthen the garrisons of the forts in the harbour; an expedition in 1836 against the Seminole Indians in Florida; the supervision of the removal in 1838 of the Cherokee Indians from Georgia, North Carolina, Alabama and Tennessee to the reservation set apart for them by treaty west of the Mississippi river; a visit to the Niagara river in 1838 to put an end to the acts by Canadian insurgents in violation of American neutrality; a similar mission to Maine in 1839 to restore tranquillity between the citizens of Maine and New Brunswick, who were disputing the possession of land along the Aroostook river; and a journey to the north-west in 1859 to adjust a dispute between American and British officers concerning the joint occupation of San Juan island in Puget sound.

His greatest achievement was the brilliant Mexican campaign of 1847. As the senior officer of the army, he was placed in command of the invading expedition, and after capturing Vera Cruz (March 29, 1847), and winning victories at Cerro Gordo (April 18), Contreras-Churubusco (Aug. 19–2 j), Molino del Rey (Sept. 8), and Chapultepec (Sept. 13), he crowned his campaign by the capture, on Sept. 14, of the Mexican capital. In March 1848 he received a vote of thanks from Congress, which ordered a gold medal to be struck in commemoration of his services. His nomination for the presidency by the Whigs had been suggested in 1839 and in 1848, and in 1852 he received it; but the Whigs, divided on the slavery question, gave only half-hearted support to their compromise platform; and Scott made several unfortunate extemporaneous addresses. He received the electoral votes of only Kentucky, Virginia, Massachusetts and Vermont. This defeat, however, detracted nothing from his popularity, and in 1852 the brevet rank of lieutenant-general was created specially for him. At the outbreak of the Civil War, though a Virginian, he remained at the head of the United States armies and directed operations from Washington until Nov. 1861. He then visited Europe for a short time, and after returning wrote his *Memoirs,* published in 1864. He died at West Point (N.Y) on May 29, 1866.

Mansfield, *Life and Mzlztary Services of General Scott* (1862); and Marcus J. Wright, *General Scott* (1894), in the "Great Commanders" series.

SCOTTISH LITERATURE. The term Scottish literature cannot be defined with complete satisfaction. It must include writing in Gaelic, which is so important as to merit separate treatment (*see* below); writing in Scots (*i e.,* Lowland Scots or Lallans); writing in standard English; and writing in every possible degree of commingling of English and Scots. There is a strong tendency for the nationality of the Scottish writer to make itself felt, even when he is not using his own language. To this the English prose of Thomas Carlyle is a witness. as is also the Latin verse of George Buchanan; and even where the writer is not of fully Scottish blood it will sometimes be found that Scottish characteristics assert themselves. as they evidently did in Byron. Although, therefore, work done in Scots must claim most of our attention, especially in the period before 1600. works that are wholly or partly in English will also on occasion require to be considered.

IN SCOTS AND ENGLISH

Mediaeval Period.—Apart from poems of doubtful provenance and authorship (*e.g.,* the 13th-century romance *Sir Tristrem* with which Thomas the Rhymer's name is linked) and a few fragments quoted by later writers (such as the well-known "Quhen Alysandyr owre kyng wes dede" included by Andrew of Wyntoun in his *Cronykil*), the earliest extant literature belongs to the second half of the 14th century. No doubt a good deal of literature before this date has been lost, as neither John Barbour's *Brus* (1376) nor *The Pistill of Susan* (*c.* 1360; ascribed to Huchown of the Awle Ryale, but *see* HUCHOWN) can be called fumbling or primitive in technique. It is clear that these poems represent two distinct traditions, the former being in octosyllabic rhyming couplets, its affinities with the French *chanson de geste,* and the latter having that nonsyllabic alliterative rhyming stanza with concluding "bob" and "wheel" which apparently reached Scotland through the Middle English alliterative writers of the north and northnest and which became a very characteristic Scottish poetic form. To the first of these traditions belong Andrew of Wyntoun's *Orygynale Cronykil* (c. 1420); and *The Buik of Alexander* and *Legends of the Saznts,* which belong to Barbour's time and region if not to Barbour. The second tradition developed romance and fantasy rather than history, and includes the poem (sometimes ascribed to Huchown) *The Awntyrs off Arthure at the Terne Wathelyne;* Richard Holland's *Buke* of *the Howlat* (c. 1450); the anonymous *Golagros and Gawane* (c. 1470); *Rauf Coilȝear* (*c.* 1480); and shorter pieces like *Tlze Gyre-Carling,* William Dunbar's *Kynd Kzttok* (if it is by Dunbar), and Robert Henryson's *Sum Practysis of Medecyne.* The rather dry, economical, unadventurous style of John Barbour. suited though it was to his own patriotic narrative, had little influence on later Scottish poetry; the *Brus,* national epic in category if not in value, is an isolated poem. The more flamboyant alliterative tradition, however, which in Scotland was readily employed not only for serious romance narratives like *Tlze Awntyrs off Arthure* but also for delightful "dremys and drevillings" such as the *Buke of tlze Howlat* and for the wild ribaldry of *Tlze Gyre-Curling* or *Sum Practysis,* proved more congenial and had a lasting effect, well beyond the mediaeval period. Satire and fantasy, always strong elements in Scottish poetry, were well served by "thir mokking meteris and mad matere." The alliterative style was also valuable in forging a link between popular and sophisticated verse, which in Scotland was not broken to the same extent as it was in England after William Langland's "rum ram ruf" gave way to Geoffrey Chaucer's decasyllabics.

The **Makaris.**—The great period of the makaris, or the Scottish Chaucerians as they have been inadequately but inescapably labelled, may be taken to be *c.* 1425–1550. It includes the four chief pre-union poets, Robert Henryson (1425?–1500?), William Dunbar (1460?–1520?), Gavin Douglas (1474/5–1522) and Sir David Lyndsay (1490?–1555); and to them must be added the author of *The Kingis Quair* (probably James *I)* and the author of *Schir William Wallace* (traditionally Henry the Minstrel). Scottish poetry has never been so confident. so dexterous, or so varied as it was in the century that produced Henryson's *Testament of Cresseid,* Dunbar's *Tua Mariit Wemen and the Wedo,* Douglas' *Eneados,* and Lyndsay's *Satyre of the Thrie Estaitis.* The rough, swarming, precarious culture which nourished this remarkable literature has often the appearance of a rejuvenated mediaevalism rather than of a premature Renaissance. A fable by Henryson closes with its "moralitas"; Dunbar and Douglas continue and develop the conventional and centuries-old dream-allegory; Lyndsay is a reformer who remains within the church. What was not mediaeval, however—and it is an important element if we are to speak of rejuvenation—was the keen linguistic consciousness, the desire to expand and enrich the vernacular resources by all available means, which followed the political self-determination of Scotland in the 14th century and accompanied the Scottish writer's literary pride in the century after. The elaborate "aureate" style in which the makaris often indulged has been criticized as artificial, and naturally it has its excesses, like those of Polwart who lauds James VI for the "prudent hie precellence" of his "princelie presence superexcellent"; but such excesses, which have their parallel in Elizabethan England, were a necessary stage in the development of a full literary medium. The term "aureate" itself tells only half the story; Dunbar's *Goldyn Targe* cannot be called typical either of him or of his century's poetry. When Gavin Douglas, justifying his borrowings from other tongues in his translation of Virgil, spoke of his desire for "fouth of langage," he was revealing a very Scottish preference. Fouth—copiousness—demanded the encouragement of anti-aureate and popular elements as well as the aureate and the classical; of alliterative as well as Chaucerian tradition. Douglas' powerfully atmospheric descriptions of scenery and weather are almost bursting with words, but the etymological and idiomatic texture is far too rich for the restrictive implications of "aureate diction" to hold any meaning. This is even more true of works like *The Cursing of Schir John Rowll* and *The Flyting of Dunbar and Kennedie,* where commination and *estrif* induce the most uninhibited fouthiness of effect. (For the continuity of this quality, see also *The Complaynt of Scotlande; Polemo-Middinia;* Sir Thomas Urquhart *passim;* Hugh MacDiarmid's *Scots Unbound.*)

Chaucer was to the makaris the eagerly acknowledged "rose of rethoris all," and there is no doubt that they gained from him an ideal of poetic utterance, a rhetoric or a diction, and metrical forms like the decasyllabic couplet used in *Schir William Wallace* and the Troilus stanza used in *The Kingis Quair,* which taken together go far toward confirming the term Scottish Chaucerians. The highly developed uncouthness of Scottish poetry was fascinated by Chaucer's subtleties, just as its love of the incongruous almost succumbed to Chaucer's good sense and order. Nevertheless, it was only one influence among many. Both Chaucer and Dunbar were closely connected with the court circles of their day, and they addressed a courtly and educated audience; yet Dunbar refers with relish to the farcical anonymous fantasies like *Colkelbie Sow* which enjoyed widespread popularity beyond the court. and the grave Gavin Douglas shows his familiarity with *Rauf Coilȝear.* Lyndsay goes further toward meeting "John the Commounweill" halfway, and openly declares in his *Dzalog* "Quharefore to colȝearis, cairtaris, and to cukis, /To Jok and Thome my rhyme sall be direckit." If the two extremely popular poems of Jock and Tom's festival merrymaking, *Christis Kirk on the Green* and *Peblis to the Play,* did in fact originate from James I or James V, as variously surmised, it would be another remarkable instance of this social give-and-take, perhaps not unexpected in a small country that had been only partly and haphazardly feudalized. "A man's a man for a' that" is a recurring statement in Scottish literature, representing a point of rest between outspoken social criticism on the one hand (Henryson, Lyndsay, Burns, MacDiarmid), and all the degenerations of the couthy and the pawky on the other hand *(Whistle-Binkie* and Kailyard, for which *see* below). Apart, therefore, from questions of verse technique, we must supplement the Chaucerian influence by two additions: the vehement, practical, propagandist social satire of a Lyndsay, and (perhaps as a counterpoise) the extravagant daftness of a *Lichtounis Dreme,* with its impractical but equally Scottish occupation of "rostand straberries at ane fyre of snaw."

The golden period of the makaris had something of a Silver Age aftermath in the accomplished but limited love poetry of Alexander Scott, Alexander Montgomerie and William Fowler; the Italian translations and moral reflections of John Stewart of Baldynnis; the impressive plainness and sincerity of Sir Richard Maitland; and single outstanding lyrics from Alexander Hume and Mark Alexander Boyd. Here may also be mentioned the only surviving vernacular drama apart from Lyndsay's *Satyre*—the anonymous *Philotus (c.* 1600), a complicated romantic comedy, coarse in details but vigorously written and certainly amusing.

The 17th Century.—With the union of the crowns in 1603 and the transference of the court to London. Scottish writing became increasingly anglicized; nor was much of it, in this century, of the first quality. Although James VI himself showed that he was capable of turning out a lyric in Scots, the new poets wrote almost exclusively in English. The best of these, William Drummond (1585–1649), was as "well-languaged" as Samuel Daniel, but his lyrics lack intensity and force, and one would gladly attribute the quite un-English *Polemo-Middinia* to him, if only for its bold macaronic gusto., The lyrics of Sir Robert Aytoun and James Graham, marquess of Montrose, are graceful without being distinguished. The sententious and indefatigable Sir William Alexander accomplished nothing that Fulke Greville and George Chapman had not done better. Vernacular poetry, neglected on the literary level, was kept alive in popular songs and ballads, and such literary verse as does guard the thin continuity of tradition between the makaris and Allan Ramsay is equally popular in character, with leanings toward the rustic, the homely and the humorous *(see,* for example, Robert Sempill's *Life and Death of Habbie Simson, the Piper of Kilbarchan).* Whether grim and tragic as in the older ballads, or amusing as in *Habbie Simson,* this tradition mas of the heart rather than of the head, and indeed the absence of an intellectual and critical quality has been a besetting weakness in subsequent Scots verse. The divorce of intellect and feeling was a natural result of the loss of Scots as a complete communicative instrument in the 17th century.

At this point it will be convenient to deal with the somewhat unspectacular history of Scottish prose. which covers (in its extant examples) the approximate period 1450–1630. The earliest work, dated 1456. is Sir Gilbert Hay's *Buke of Armys, Buke of the Order of Knichthede* and *Buke of the Governaunce of Princes;* but these are translations. The first original literary prose appears in the theological tract writing of John of Ireland (*c.* 1490). The prose of these works, written in "the commoune langage of this cuntre," has not yet developed a great variety or flexibility of construction. Early in the 16th century there was an attempt at a more plain, less latinized prose in Murdoch Nisbet's version of the New Testament, but the language is too southern to be quite successfully idiomatic. Some English influence is seen also in the historical writings of John Bellenden. John Lesley and Robert Lindesay of Pitscottie; and to a greater extent in works like John Knox's *History of the Rejormation.* These four writers, however, had a good command of narrative, and Pitscottie and Knox had also the gift of style, which has made passages like Pitscottie's account of the Linlithgow apparition and Knox's interviews with Mary Queen of Scots justly famous. Almost as vivid as Knox's writing is the autobiographical *Historie of the Lyff of James Melvill,* which covers the second half of the century. Standing by itself is the remarkable anonymous *Complaynt of Scotlande* (1548–49), interesting not only as the work of an earnest and well-read Scottish patriot but also as the first work of a Scottish experimenter in prose style, ranging from the most aureate "oncoutht exquisite termis" to the most common and onomatopoeic "domestic Scottis langage." The necessity of reaching an English audience is seen in the writings of James VI: the manuscript of his *Basilikon Doron* (1598) is in Scots, but when published it had been translated into English. William Drummond's *Cypresse Grove* (1623) is in careful, grave, mannered English; and not much Scots prose occurs after that date. A general justification for this turning to English may well be seen in the lucid and forceful 18th-century prose of David Hume, Adam Smith, James Boswell and Tobias Smollett; though on the debit side must be placed the extreme difficulty of all attempts to revive vernacular prose, in a tradition which was so drastically severed. One particular justification is Sir Thomas Urquhart. "the free'st spoke Scot of any," whose translation of Rabelais (1653) and extraordinary original works show a polymathic gorgeousness that would have cracked the moulds of Scots as it did those of English.

The 18th Century. — While Scottish prose writers were preparing to challenge English on its own terms, and while the union of 1707 was suggesting an even closer cultural binding of the two countries than had been possible a century before, a contrary impulse was making itself felt in poetry. Almost in the year of the union appeared James Watson's first *Choice Collection of Comic and Serious Scots Poems* (1706), which contained (among English pieces) vernacular poetry from *Christis Kirk on the Green* and *The Cherry and the Slae* to recent verse like *Habbie Simson* and *The Blythsome Bridal.* This was followed by Allan Ramsay's *Ever Green* (1724) and *Tea-Table Miscellany* (1724 ff.), and by the later collections of David Herd, John Pinkerton, and James Johnson. These anthologies testify to a new national consciousness which began with a deliberate invocation of past achievements and eventually produced original work in the tradition of these achievements. As political identity was lost, cultural differences were increasingly recognized as significant. Educated speech was slowly but surely following written prose into anglicization. In poetry, the heart of the language was still felt to beat, however faintly; as it was also in common speech and in the old songs and ballads which were now being reprinted. Ramsay's own poetry, like that of Robert Fergusson and Robert Burns after him, flourished on a union of these elements: the racy vigour of Scots speech, the musical lilt of the songs, and the poetic forms and techniques, such as the Habbie Simson stanza, the humorous elegy, and the verse epistle, with which recent poets like the Sempills and William Hamilton of Gilbertfield had helped to solder the vernacular tradition. This new poetry lacked the range and also the intellectual power of the makaris' verse. Nevertheless, its own qualities were notable and infinitely attractive: in the love song, with moods from *Duncan Gray* to *O, wert thou in the cauld blast;* in the voice that is given to the joy and pathos of "randie gangrel bodies" in *The Jolly Beggars;* in the unembittered descriptive tartness of Fergusson's *Auld Reekie* and *Butterfly.* Burns excelled both in satires and in love lyrics; in the former he carried on where Dunbar left off, and in the latter he crystallized the floating anonymous songs in forms that mere at once popular and authoritative. Many traditions meet in Burns and his poetry reaffirms, perfects and consolidates existing poetic modes and themes in a way which even in his own lifetime made it apparent that he was going to be a national bard. If any poet had deserved the epithet life-giving it is Burns, and yet by one of the ironies of literary history he proved to be a liberator for the poetry of England, but not for the poetry of his own country.

Among the minor poets of the period, some of the best were women. Lady Grizel Baillie. Jane Elliot. Lady Anne Lindsay and Lady Nairne. Of writers in English, James Thomson in his *Seasons* shares with Gavin Douglas the ability to make winter more impressive than summer, and produces some heavily drawn pictures of "Caledonia, in romantic view." Robert Blair's *Grave* shows a grim churchyard relish that does not lack Scottish analogues. William Falconer's *Shipwreck,* admired by Burns, deserves mention; and James Beattie's *Minstrel* has some historical importance as an early Romantic poem. Here must also be noted three popular and influential works of the time: John Home's tragedy, *Douglas,* Scottish in theme but not in language; the cloudy grandeurs of James Macpherson's Ossianic fragments, which presented Europe with a vision of the noble Gael; and that "bosom favorite" of the young Burns, Henry Mackenzie's tear-strewn *Man of Feeling.*

The 19th Century. — The *Man of Feeling* appeared in 1771, and in that year was born Sir Walter Scott (1771–1832), who was destined to turn prose in a very different direction. The re-emergence of a vernacular prose, mainly within the novel and the short story, is one of the distinguishing features of this period. The writers may be divided into two groups: those who restricted Scots to dialogue and used English for the narrative, and those who employed a form of Scots, or at least a scotticized English, throughout. The former included Scott himself, Susan Ferrier, James Hogg, George Macdonald, Mrs. Margaret Oliphant, William Black and R. L. Stevenson; in the second and smaller group are John Galt, David Moir. and (in the following century) Lewis Grassic Gibbon. A book like William Alexander's *Johnnie Gibb of Gushetneuk* contains so much dialogue as practically to belong to the scotticizers; it is. however, of interest mainly to philologists. The advantage of the method used by Galt in his *Annals of the Parish* (1821), of casting the book as the reminiscences of a Scots-speaking person, was that it secured a homogeneous tone, and the exact but not exaggerated Scots idiom is admirable. Scott, on the other hand, has the wider range that comes from contrast between English and Scots (as, most obviously, when we come to Wandering Willie's Tale in *Redgauntlet),* but the faults of his own English writing. and the restriction of his brilliant Scots dialogue to minor characters, sometimes make the result patchy and unsatisfactory, even if the great sweep of the story carries the reader through. It may certainly be argued that the most Scottish of Scott's stories—*The Bride of Lammermoor,* for instance — are among his best.

A novel that begins "Come oot o' the gutter, ye nickum!" (George Macdonald's *Sir Gibbie,* 1879) is evidently of another type, and it may in fact be claimed as one of the many forerunners of the phenomenon of Kailyard which appeared toward the end of the century in the works of Ian Maclaren (John Watson, 1850–1907), S. R. Crockett (1860–1914) and James Barrie, (1860–1937). (At the same time Fiona Macleod (William Sharp, 1855–1905) in his Celtic stories was creating the "Kailyard of the Gael.") The sentimental viewpoint that vitiates *Beside the Bonnie Brier Bush* and weakens *A Window in Thrums,* the cosy hypocrisies, the idealization of village and humble life, were pitilessly exposed when George Douglas Brown's *House with the Green Shutters* was published in 1901. Brown's brutal tale, nevertheless, had its own exaggerations, those needed for its theme of tragic melodrama, and it had no more than a temporary effect in "sticking the Kailyarders like pigs," as one critic hoped. There is something in Kailyard which is still very acceptable to the Scottish popular temperament.

The history of poetry in this period is very nearly a blank. Two poems of the supernatural keep up an ancient Scottish tradition: James Hogg's *Kilmeny* and William Bell Scott's *Witch's Ballad;* there are some good vernacular lyrics by Scott, Allan Cunningham and George Macdonald; but for the most part, the century after Burns saw merely the proliferation of the maudlin and the jocose in well-worn verse forms, the distortion and coarsening of Burns's gaiety and pathos, and the popularizing of everything in him that was less than first-rate. The widely read mid-century anthologies of verse called *Whistle-Binkie: A Collection of Songs for the Social Circle* mere the poetic equivalent of Kailyard, and their popularity is a comment on the poetic taste of the age. Indeed, during the latter half of the century more interesting poetry was being written in English, by James Thomson ("B.V."), Alexander Smith and John Davidson. What we feel to be lacking in Kailyard and *Whistle-Binkie*—the impact of the contemporary world, of science, of industrialization, of the city, even (one must add) of ideas—gives strength and power to Smith's *Glasgow* (1857), to Thomson's *City of Dreadful Night* (1874) and to Davidson's *Testaments* (1901–08).

The 20th Century.—Prose fiction has developed, with minor variations, mainly within the Scott-Stevenson tradition. The "descriptions of the physical" that Stevenson prided himself on (though it was by no means his only gift), and the reliance on action rather than on psychological subtleties which we find in Scott, are continued in varying degrees in John Buchan, Neil Munro, Neil Gunn and R. B. Cunninghame Graham, the last-named having shown in his *Scottish Stories* a nice use of Scots and a fine command of the macabre. More original are the picaresque, witty and often fantastic narratives of Eric Linklater; the passionately written *Scots Quair* of Lewis Grassic Gibbon. with a remarkable stylistic attempt to sink Scots idiom and vocabulary into the body of a richly descriptive English; and the experiment of a Joycean (and Urquhartesque) punning Scots in S. G. Smith's ribald *Carotid Cornucopius*.

Drama, which had revived to some extent at the hands of Barrie, discovered a more distinctively native voice in James Bridie (O. H. Mavor. 1888–1951); his entertaining and surprising plays, on an unusually wide variety of themes, combine the humorous, the ethical and the supernatural in a very Scottish manner. Plays written entirely in Scots are now frequent and popular on the Scottish stage.

It is to poetry, however, that the term revival is more properly applied. The first steps toward a Scots verse that would more closely represent real experience were made by Stevenson (in *Underwoods*, 1887), Marion Angus, Charles Murray, Violet Jacob, Pittendrigh Macgillivray, Helen Cruickshank and Alexander Gray. In the second decade of the 20th century the explosive personality of Hugh MacDiarmid (Christopher Murray Grieve, 1892–) made itself felt, as the centre and motive force of what has been variously called the Scottish Renaissance movement. the Lallans revival and Synthetic or Plastic Scots. This movement, by re-expanding the Scots vocabulary after its post-Burns stagnation, complacency and "hameliness," aims to restore the intellectual prestige of Scots and to create a medium that would be capable of dealing with the objects and ideas of the modern world as well as with the perennial sources of lyricism. MacDiarmid himself has written the best lyrics since Burns; his sesquipedalian, polyglot, encyclopaedic, polemical, metaphysical verse has not aroused the same enthusiasm, but is interesting and significant. Other members of the movement have included the learned Douglas Young, the love poet S. G. Smith and the wry observer William Soutar (1898–1943). Of poets using English, Edwin Muir with his meditative myth-haunted verse has been the most distinguished; Andrew Young has been noted for his sinewy nature poems; and W. S. Graham, of a younger generation, has shown a craftsman possessed of great verbal energy. The problem of English or Scots is one that has still to be worked out, and its difficulties are a part of the whole cultural situation. The Scottish sense of separateness is too real to be swamped, but English is dominant in prose writing and in educated speech, and the Scottish poet of the 20th century has been therefore like a shaman who must try out many disguises until he finds the one in which he can best prophesy and persuade.

(E. G. M.)

IN GAELIC

The early history of Scottish Gaelic literature, like that of the language, cannot be adequately considered in isolation from the literature and language of Irish Gaelic. Kenneth Jackson demonstrated in his Sir John Rhys memorial lecture (1951) that Scottish and Irish Gaelic were identical until the 10th century, that they proceeded to diverge during the centuries from the 10th to the 13th, but that the language which he conveniently calls Common Gaelic survived as a living tongue until the 13th century. The conservatism of the literary classes ensured that there was a common corpus of literature even after the spoken languages diverged. Thus a distinct Scottish Gaelic period in literature can hardly be said to begin much before the 15th century. The Scottish parliament had made an enactment against the bards in the year 1457, when it was decided to take an inquisition of all "sornares, bairdes, maister-full beggers or feinziet fuiles." This enactment, and some subsequent ones, were no doubt directed against the strolling bards, but the volume of governmental disapproval of the bards and of the Gaelic language and way of life grew, and the policy of centralization, and the gradual de-Gaelicization of the titled and moneyed classes eventually deprived the Gaelic poets of their patrons, bringing both loss and gain to Gaelic poetry. But before looking at the literature of the modern Scottish Gaelic period we must take a glance at what lies behind it.

Earliest Manuscript Remains.—The earliest document containing Gaelic matter which Scotland can claim is the *Book of Deer*, now preserved in the Cambridge university library. This manuscript contains portions of the Gospels in Latin, written in an Irish hand, with illuminations. Inserted in the margins and blank spaces are later notes and memoranda partly in Latin, partly in Gaelic. The six Gaelic entries appear to have been made between 1131 and 1153, although some of them may be copies of earlier, perhaps traditionally preserved, grants of land and other privileges made from time to time to the monastery of Deer, Aberdeenshire. The scribes appear to have been trained, but somewhat imperfectly, in the Common Gaelic tradition of the period.

Another strangely isolated survivor is the Islay charter of 1408. This charter, written in Gaelic, was granted by Donald, lord of the isles, to Brian Vicar Mackay of Islay. It is witnessed and very probably written by Fercos MacBetha, who was one of the famous family of hereditary physicians of that surname.

These MacBeths, Beatons or Bethunes had in their possession a number of important medical manuscripts, some of which are now in the collection of Gaelic manuscripts in the National library of Scotland. The O'Conachers, or McConachers, of Lorn were also hereditary physicians whose manuscripts are in part preserved. These manuscripts translate and paraphrase the works of such men as Bernard Gordon, Galen, Avicenna and Hippocrates, while in their extra-medical digressions they show an acquaintance with the works of Aristotle. Socrates, St. Thomas Aquinas and others. Such various subjects as metaphysics, astronomy and astrology, theology and music are treated. In medical matters the scribes sometimes give their own observations. These manuscripts date mainly from the 15th, 16th and 17th centuries.

There are many other manuscripts, belonging to the common Scots-Irish tradition, which contain versions of heroic tales and sagas, poetry, ecclesiastical writings and miscellaneous matter. One such, the Glenmasan manuscript (no. liii in the National library collection) was probably written about 1500, but may derive from a 13th century original. This contains the famous story of Deirdre and the sons of Uisneach. A part of the manuscript containing the story of *Mesca Ulad* dates from the year 1538. There is also a version of the most famous of Irish epics, the *Táin Bó Cúailnge* (ms. xxxii), and a Gaelic version of Lucan's *Pharsalia* (ms. xlvi), besides poetry written by Irish and Scottish bards.

But from the purely Scottish Gaelic point of view, the most important of the manuscripts from this period is the *Book of the Dean of Lismore*, an anthology of verse compiled by Sir James Macgregor, dean of Lismore in Argyllshire, and by his brother Duncan, between 1512 and 1526. These poems fall into three main groups, (1) poems by Scottish authors, (2) poems by Irish authors and (3) Ossianic ballads. The Irish poems belong mainly to the period 1200–1500. There are 29 poems in the third group. of which 4 belong to the Cú Chulainn cycle rather than the Ossianic one—in all. 2,672 lines. These poems are attributed to various authors, *e.g.* Oisein. Ferghus File, Caoilte Mac Ronain and Conall Ceárnach.

The poems by Scottish authors are interesting historically, linguistically and poetically. Linguistically, the poems have a considerable potential interest. They are written in a semiphonetic spelling. partly based on the spelling of contemporary Scots, and thus provide some evidence as to the pronunciation of the Perthshire dialect of Gaelic in the dean's time. Peculiarly Scottish features of pronunciation, morphology and grammar can be detected in it.

Furthermore, the poems give valuable evidence concerning aspects of the society of their times. As to date of composition, they range from *c.* 1310 to *c.* 1519. Many of them have a Perthshire setting, or are composed to a Macgregor chief, but there are also, for example, poems to MacDougall of Dunollie. Macleod of Lenis, MacNeill of Gigha, and others. The bard who is best represented is Fionnlagh Ruadh, bard to John, chief of Clan Gregor (d. 1519). There are also three poems by Giolla Coluim mac an Ollaimh, who was probably a poet at the court of the lords of the isles. He laments the misfortune which had befallen this proud family in the late 15th century. Other poets who may be briefly mentioned here are the dean of Knoydart (late 15th century). Duncan Campbell, the Good Knight of Glenorchy, who died at Flodden, Giolla Criost Brúilingeach, and two women, Aithbhreac Inghean Coirceadail (mid-15th century) and Isabella, countess of Argyll (probably the wife of the first earl). These last two are satisfying poetically, as is also the work of Giolla Coluim and of Giolla Criost.

The 16th and 17th Centuries. — Very little Gaelic poetry from the 16th century has survived, and most of what there is survived in oral tradition until the mid-18th century before it was written down. We can point to a few poems like An Duanag *Ullamh*, composed in honour of Archibald, fourth earl of Argyll, c. 1556, the lovely lament *Griogal* Cridhe, composed *c.* 1570; *Oran na Comhachaig*, in part no doubt composed in the second half of the 16th century; some poems by Sir John Stewart of Appin; and some by Niall Mór MacVuirich. It is beyond doubt that the poetry recorded in the Book of the Dean of Lismore was not an isolated outburst, but that poetry is an integral part of the society of the time. Much must have been lost, both of the work of the professional bards and of the popular songs. Songs in the rowing and waulking measures survive, again orally, from the earliest years of the 17th century, and we must conclude that these forms have a previous history in the 16th century, although we can see it only through a glass darkly.

In the year 1567 the first book to be printed in Gaelic in Scotland appeared. Bishop John Carswell's *Foirm na Nurrnuidheadh*, a translation of John Knox's Liturgy. Carswell is modest about his ability to write Gaelic, but in fact his prose is written in classical Common Gaelic, and resembles that of the 17th-century Irishman Geoffrey Keating. His prefatory epistle makes lively and pleasant reading.

The 17th century in Gaelic Scotland is a period of great interest. The political, ecclesiastical and social structures of Scotland were gradually changing, and so was the relationship betneen the central government and the Gaelic area. Enough survives of the Gaelic poetry of the period to show that there was a large number of poets of great talent. It is probably not a coincidence that the 17th century is also the great age of the waulking songs and of ceòl mór, or the classical music of the bagpipes. There seems to have been a diffusion of artistic talent such as is scarcely matched in any other period in Scottish Gaelic history. Some of the poetry and prose of the time is contained in three 17th-century manuscripts. The first two of these are the Black and the Red Books of Clanranald, written by members (e g., Cathal and Niall) of the MacVuirich family, hereditary bards to Macdonald of Clanranald. They were probably written for the most part in the 17th century, but they contain poems by earlier representatives of this family of bards. Much of the two manuscripts is taken up with genealogical matter. and with an account of the Montrose wars and of the achievements of Alasdair Macdonald (Mac Cholla Chiotaich). From 18th-century accounts we know that the MacVuirich family had compiled other manuscripts, most of which were carelessly destroyed, although ms xlviii in the National library of Scotland is apparently a MacVuirich poetry manuscript.

The other important 17th-century Gaelic document is the *Fernaig MS.*, compiled by Duncan Macrae of Inverinate between 1688 and 1693. This contains about 4,200 lines of verse, which is mostly political and religious. The poets represented belong to the 16th and 17th centuries, although little of the work of the major 17th-century poets is given. The compiler had Jacobite and Episcopalian leanings, which are reflected in his anthology.

The two best-known poets of the 17th century are Mary Macleod and Iain Lom. The former, known as Màiri Nighean Alasdair Ruaidh (c. 1615–*c.* 1706), was closely associated with the households of the Macleods of Harris and Dunvegan. She seems to have been a member of the household of Rory Mór Macleod, who died in 1626, and to have acted as nurse to successive generations of Macleod chiefs. Those for whom she had the greatest affection were probably Sir Norman Macleod of Bernera and Iain Breac Macleod of Dunvegan. Her earliest poem of certain date is the elegy for Roderick Mackenzie of Applecross. (d. 1646), and one of her latest is the elegy for Sir Norman Macleod of Bernera (d. 1705). Her poems show deep personal emotion. Her imagery, though restricted in range, is sincere and telling, and her style is fresh and natural. She inherits much of the imagery of the bardic poets. but places it in a new setting, and her metres are the comparatively new strophic ones rather than the strict syllabic metres of the classical bards.

John Macdonald, known as Iain Lom, (c. 1620–*c.* 1710), was related to the chiefs of the Keppoch Macdonalds, and he took an active interest and an active part in the events of his time. His life spanned an eventful period in Highland history, and his poetry is full of comment on these events. He composed poems about the battles of Inverlochy (1645), Auldearn (1646) and Killiecrankie (1689), a lament for Montrose (1650). a poem on the restoration of Charles II (1660), several poems dealing with the Keppoch murder of 1663, an elegy for Sir James Macdonald of Sleat (1678), a song to William and Mary (1688), and a song bitterly opposing the union of the parliaments in 1707. He is a royalist and a fervent Macdonald panegyrist. As a Macdonald he lashes the Campbells; as a Roman Catholic he does the Presbyterians less than justice. But the breadth of his interest in national affairs is notable His versification is less melodious than Mary Macleod's, and he has none of her tenderness and nostalgia. But he has that compression and concentration of expression which so much later Gaelic poetry lacks. This may derive in part from the style of the classical bards, as the directness of his utterance may from the popular or folk poetry. He can achieve more at times by understatement than the 18th-century poets can by a plethora of epithets.

We can do little more than mention some of the other 17th-century poets of whose works interesting fragments have survived. Donnchadh MacRuaraidh was-bard to Biacdonald of Sleat, and his best-known poem consists of four calm resigned verses composed on the day of his death (c. 1630). The work of Alasdair Mackenzie and of Murdoch Mackenzie, both of Achilty, is represented in the Fernaig MS. Alasdair is the *laudator temporis acti;* Murdoch sometimes shows a lively interest in action and movement, as in his An *Làir* Dhonn. Roderick Morrison, usually known as An Clarsair Dall (the Blind Harper), was born in Lewis and became harper to Iain Breac Macleod of Dunvegan. Little of his work survives, but the strong texture and poetic intensity of his *Oran Mór MhicLeòid* and his *Creach* na Ciadain are remarkable. Dorothy Brown and Silis na Ceapaich are women poets of great talent, and nith them may be grouped other women, Mairearad Nì Lachainn and Catriona Nic Ghilleathain. Dorothy Brown's poem on Alasdair Mac Colla and Silis na Ceapaich's laments for Lachlan MacKinnon and for Alasdair of Glengarry (d. 1721) are moving and artistic utterances. Eachann Bacach Maclean would be honoured for the one poem A' Chnd *Shamhna* (1648), even did no more of his work survive.

Four other poets mark, in various ways, the transition from the poetry of the 17th century to that of the 18th. These are Lachlan MacKinnon (Lachlann Mac Theàrlaich Oig), John Mackay (Am Piobaire Dall), John Macdonald (Iain Dubh Mac Iain 'Ic Ailein), and John Maclean (Iain Mac Ailein). All four were born c. 16jj–6;. Much of their work lacks the economy of the best 17th-century poetry, and also its richness of imagery. It is a much less ornate, a more obvious poetry. John Macdonald's *Oran nam Fineachan* is not the worst in a series of tedious jingles which we can label clan verses, and which were popular with 18th-century poets. John Maclean shows a great interest in early Gaelic legend, and he composes amusing verses in a mock-heroic strain. He also uses a mixture of verse and prose, as in his *Crosanachd Fhir nan*

Druimnean. John Mackay's *Coire an Easa* is significant in the development of Gaelic nature poetry.

Finally, bardic poetry continued to be composed into the 18th century by two members of the MacVuirich family, Niall and Domhnall.

The 18th Century.—The 18th century in Gaelic poetry has eclipsed the 17th partly on account of the brilliance of some individual achievements, and partly because it is from the viewpoint of the 18th century that we often begin our retrospect of earlier Gaelic poetry. No secular poetry in Gaelic was printed before 1751, and the great bulk of earlier verse was recovered from oral tradition subsequent to that date. The interest in that verse was part of the more general antiquarian revival.

Much of the inspiration of Gaelic printing in the 18th century can be traced to Alexander Macdonald, or Alasdair Mac Mhaighstir Alasdair (*c.* 1700–*c.* 1770), who published a Gaelic vocabulary in 1741 and the first book of secular poetry, his *Aiseiridh na Sean Chdnoin Albannaich* (Resurrection of the Ancient Scottish Tongue), in 1751. On both political and literary issues he showed virtues of independence and leadership which mark him out as a man apart among Gaelic poets of the 18th century. During the '45 rising he was granted a captain's commission by Prince Charlie, and he seems to have regarded the rising as a crusade for the Highlands, or even for the Gaelic way of life. He rallied his fellow-Highlanders to the prince's cause with such poems as *Brosnachadh nam Fineachan Gaidhealach* and *Hi ri rì tha e tighinn,* a song of welcome to the prince.

His poetical range was wide. His songs on the seasons must have been composed near the same time as James Thomson's *Seasons.* Another notable nature poem is his *Allt an t-Siùcair.* His *Urnuigh do'n Cheblraidh* contains an adult statement of the aims of his art. His masterpiece and longest poem, the *Birlinn of Clanranald,* is an extravaganza which is ostensibly a description of a voyage from South Uist to Carrickfergus. A fine poem in a quite different mood is the love poem *Moladh Mbraig.* He also composed drinking songs and bitter satires. He has a rich vocabulary and a strong sense of technique.

Duncan Macintyre, or Donnchadh Bin (1724–1812) was influenced in various ways by Macdonald. He published his poems in 1768, and we can see signs of influence in the subject matter and the metres, and sometimes in the phraseology of certain poems. But his individuality is not lost. The two men were profoundly different in nature and in training. Macdonald had received a formal education; Macintyre could neither read nor write. Macdonald was ambitious, independent and restless; Macintyre had none of these uncomfortable qualities. Macintyre fought on the Hanoverians' side at the battle of Falkirk, and later sang the praises of George III in *Oran do'n Rlgh.* He composed other soldiering songs, and various other set pietes on the clans, the bagpipes, and on the Gaelic language, but his true subjects are wild life and wild nature—the haunts and the habits of the red deer. He had been a forester on the Perthshire-Argyllshire borders in his early manhood, and this is the setting for his greatest poems, *Moladh Beinn Dóbhrain* (Praise of Ben Dorain) and *Coire Cheathaich* (The Misty Corrie). These poems are remarkable for their emotional closeness to nature, their minute and objective detail and their personal and lyrical quality. His most famous love song is *Màiri Bhàn Og,* addressed to his wife. Donnchadh Bin is the best-loved of the Gaelic poets.

There were several other poets of note in the 18th century. John MacCodrum (*c.* 1700–79) was appointed bard to Sir James Macdonald of Sleat in 1763, and his elegy for Sir James is probably the best of his poems. He had a good memory for genealogy and for poetry, and was a known wit. He composed much humorous and satirical poetry. Rob Donn Mackay (*c.* 1714–78) was the bard of the Reay country, and used his gifts of observation and satire in commenting on the life of his district. Characters such as the miserly brothers of Rispond have a quality of universality. There is much social satire in his verse, and some delicate feeling for nature, as in *Cead Fhir Bhìoguis do'n Fhrìth.* William Ross (*c.* 1762–90) is the romantic poet of the group. His poetry is emotional, subjective and at times sentimental. He had an unhappy love affair which occasioned several of his best poems, such as *Feasgar Luain* and *Oran Eile.* Another well-known poem is *An Suaithaeas Bàn,* composed on hearing of the death of Prince Charles Edward in 1788. David MacKellar published his *Hymn on the Creation* in 1752, but the greatest composer of Gaelic religious verse in the 18th century was Dugald Buchanan (1716–68) whose poems were published in 1767. His poems, the *Day oj Judgement* and *The Skull* are impressive and sombre, and show considerable imaginative power. Buchanan assisted Stewart of Killin in preparing his Gaelic translation of the New Testament (1767). Ewen Maclachlan (1773–1822) was librarian of King's college, Aberdeen. He transcribed many Gaelic manuscripts, including the *Book of the Dean of Lismore,* translated more than seven books of Homer's *Iliad* into Gaelic verse, and wrote Gaelic poems on the seasons.

Collections of Gaelic Poetry.—From the middle of the 18th century onward a number of important collections of Gaelic poetry were made. One of the earliest was the Rev. Alexander Pope's, made *c.* 1739. Jerome Stone had collected Ossianic ballads and other verse before 1756, and Archibald Fletcher's Ossianic ballads were memorized by him about this time, although written down later. The Rev. James Maclagan continued to collect material throughout the second half of the century, and his manuscripts rest in Glasgow University library. The Rev. Donald MacNicol's collection also belongs to this period. Dr. Hector Maclean of Mull's manuscript dates from about 1768. In 1776 Ranald Macdonald's *Eigg Collection* was published, and in 1886 Gillies', based on Maclagan's. James Macpherson's notable enterprises, the publication of his *Fragments of Ancient Poetry* in 1760, his *Fingal* in 1762, and his *Temora* in 1763, stem from this new collecting zeal, and in turn reinforce it. Macpherson's work is partly based on genuine Gaelic ballad sources, which can be elucidated, and is partly constructed from borrowed English and Irish sources, and from his own imagination. But it is probable that we owe to Macpherson the collection and in some cases the preservation of valuable oral and manuscript material, as for example the dean of Lismore's manuscript. The Rev. Patrick Macdonald's *Gaelic Vocal Airs* was published in 1781. Important collections of the early 19th century were those of A. and D. Stewart (1804), Patrick Turner (1809), and Alexander Campbell's *Albyn's Anthology* (1816–18). The movement continues with John MacKenzie's *Beauties of Gaelic Poetry* (1841), Donald Macpherson's *An Duanaire* (1868), and the work of the two giants among 19th-century collectors, John Francis Campbell of Islay and Alexander Carmichael. Campbell's four volumes of *Popular Tales of the West Highlands* were published in 1860 and 1862, and his *Leabhar na Féinne,* a great collection of Ossianic ballads, in 1872. The first instalment of Carmichael's great work, *Carmina Gadelica,* was published in two volumes in 1900, and three further volumes have followed. Alexander Cameron's *Reliquiae Celticae* (1892–94) made available in print much valuable manuscript material, such as the *Fernaig* manuscript, parts of the *Books of Clanranald,* and some of the Edinburgh manuscripts, together with Ossianic and other material from various manuscript collections. A collection of Gaelic proverbs had been published by Donald Macintosh in 1785, and this was supplemented and enlarged by Alexander Nicolson in 1881. A new edition, edited by Calum Macinnes, appeared in 1952. Frances Tolmie's fine collection of Gaelic folk songs was published in 1911. Beginning in 1872, we have the valuable series of *Transactions of the Gaelic Society of Inverness,* which has published much material from manuscript and oral sources. The periodical, *Scottish Gaelic Studies,* was launched in 1926.

19th and 20th Centuries.—A fair volume of periodical literature was published in the 19th century and after. For a brief account of this, see the Rev. Donald Maclean's *The Literature of the Scottish Gael. An Gaidheal* is the lineal descendant of some of these periodicals. It has been joined in a scanty field by *a* quarterly, *Gairm.*

These periodicals contain the main volume that we have of Gaelic prose. In addition there is a quantity of translation of religious works. A translation of Calvin's Catechism is said to have been issued in 1631. Fifty of the psalms, together with the

Shorter Catechism, appeared in 1659. Kirke's Psalter in 1684. and the Synod of Argyll's in 1694. Kirke's Irish version of the Bible in Roman type appeared in 1690. James Stewart's Gaelic edition of the New Testament was published in 1767, and John Stewart of Luss and John Smith of Campbeltown published a translation of the Old Testament (1783–1801). The complete Gaelic Bible was issued in 1807, and the first standard revision was that of 1826. Meantime many other religious translations were appearing, of works by Richard Baxter, Thomas Boston. John Bunyan, Philip Doddridge and others, and later volumes of original sermons appeared.

Some notable original prose contributions are Lachlan Maclean's *Adam and Eve* (1837). the writings of the Rev. Norman Macleod or *Caraid nan Gaidheal* (1867), Donald Mackechnie's *Am Fear Ciùil* (1904), and Angus Robertson's *An t-Ogha Mor* (1913).

There was a dearth of vital poetry in the 19th century, when much verse arising out of induced moods was composed. But there are partial exceptions, in some of the work of John Maclachlan of Rahoy (1804–74), Evan Maccoll (1808–98), Neil Macleod (1843–1913), and Mary Macpherson (1821–98). John Morison (1790–1852), the poet-blacksmith of Rodel. composed some elevated and imaginative religious poetry. William Livingstone (1808–70) is full of rebellion and resentment, and he tried, without much success, to clothe Scoto-Norse history in poetic and dramatic dress. Angus Robertson's *Cnoc an Fhradhairc* (1940) is a hard poem to read, but it is rewarding in parts. In recent years a new movement to free Gaelic poetry from oppressive traditional shackles has been inaugurated by Somhairle MacGilleathain's *Dàin do Eimhir* (1943), George Campbell Hay's *Fuaran Sléibh* (1947) and *O na Ceithzr Airdean* (1952), and Ruaraidh MacThómais' *An Dealbh Briste* (1951). In a style partly traditional and partly new is James Thomson's *Fasgnadh* (1953).

Little of permanent value has been done in the drama. The art of the short story has been cultivated spasmodically in periodicals and in Gaelic radio programs. No fully adult Gaelic novel has appeared. The art of essay writing, however. has been pursued with distinction by writers such as the Rev. Donald Lamont and others. (D. S. T.)

SCOUT, a soldier whose duty it is to obtain information of the enemy's movements or capabilities. He is usually a regular member of the armed forces, not a spy, and is treated as a prisoner of war if captured; but some scouts are irregulars or auxiliaries. Men are usually chosen for duty as scouts because they have special aptitudes such as knowledge of the terrain or ability to speak the language of the country. Scouts normally go out alone or in small groups ahead of the main body of troops and serve as the "eyes and ears" of the main force. During the Indian wars of the United States. the best scouts were white fur traders and friendly Indians who could find their way across the plains, track the enemy through the forest and warn of ambushes. One of the most famous was Christopher ("Kit") Carson (*q.v.*). Native scouts served a similar purpose in the Pacific island campaigns of World War II and were indispensable in jungle operations.

For boy scouting, *see* BOY SCOUTS; for girl scouting, GIRL SCOUTS and GIRL GUIDES. (LN. MS.)

SCRANTON, a city of northeastern Pennsylvania. U.S., the county seat of Lackawanna county. is 134 mi. W.N.W. of New York city and 110 mi. N.N.W. of Philadelphia. It is situated in the Lackawanna river valley on the western fringes of the Pocono mountains at an elevation of 752 to 1,770 ft. above sea level. Pop. (1960) city 111,443; standard metropolitan statistical area (Lackawanna county) 234.531. For comparative population figures *see* table in PENNSYLVANIA: *Population.*

Permanent settlement of the valley dates from 1788 when it was known as Slocum Hollow. In the next few years a gristmill, a sawmill and a charcoal furnace were built along the Lackawanna (Indian for "stream that forks"). but there was little development except for names: the village was called Slocum Hollow, Unionville, Harrison and Scrantonia before becoming Scranton in honour of the New Jersey family which established the Lackawanna Iron and Coal company there in 1840. George W. Scranton (1811–61) and his brother, Selden, bought a large tract (most of the present downtown business section) for $8,000 and began to smelt iron from local ores, using an anthracite hot-blast process. Persistent efforts by the two Scranton brothers and timely financial aid by their cousin, Joseph Hand Scranton, made the venture a success. By 1850 a rolling mill, a nail factory and a steel-rail works were in operation and transportation facilities had been provided. Scranton was incorporated as a borough in 1853 and chartered as a city in 1866.

Even before the iron ore was exhausted, the iron industry was overshadowed by the anthracite industry which has had a profound impact on the history of Scranton. The ethnic diversity of the area and the rapid population growth stemmed from the need for labour for the mines and allied industries. The first wave of immigration brought skilled English, Welsh and German miners but they were soon followed by the Irish: Austro-Hungarians, Poles! Russians and Italians. The wives of these immigrants provided a labour force that made possible the development of silk, apparel and other industries; Scranton has long been noted for its production of Nottingham lace.

Like the other cities of the anthracite coal region in northeastern Pennsylvania, Scranton has been forced to readjust its economy to the decline in the anthracite industry. Coal production valued at $196,908,000, or two-thirds of the combined total of mining and manufacturing in 1948, dwindled to approximately one-fourth of the total value a decade later. During the same period the percentage of workers employed in producing anthracite dropped from 33% to 14%, creating chronic unemployment of 15% to 20% of the total labour force. The "Scranton Plan" was developed to provide more jobs through industrial expansion. In 15 years after World War II over *30* plants and 3.000.000 sq.ft. of new floor space were made possible by the combination of community contributions, private fiiiancial and state aid. These new plants were either leased or sold to industries moving into the area, and the net income was reinvested in more plants. Textile, apparel, electronics and metal products manufacturers are the leading employers.

The economic readjustment brought on by the end of the war and the decline in the anthracite industry was also eased by Scranton's natural position as the centre of a large retail, wholesale and jobbing trade. Railroads. bus lines and airlines (at the Scranton-Wilkes-Barre airport. 6 mi. S. of the city) provide communication with all urban centres in the eastern United States. Three federal highways, and the northeastern extension of the Pennsylvania turnpike and the Pan-Canada international highway system provide the road transportation network of the area.

Educational facilities include the University of Scranton. established in 1888; Marymood, established in 1915; Lackawanna Junior college, organized as the Scranton Business college in 1894, becoming a junior college in 1959; a campus of the Pennsylvania State university commonwealth campus system (of two-year colleges). opened in 1921; the state school for the deaf; and the International Correspondence school, largest institution of its kind in the world. The public library has branches throughout the city and there is a county historical society.

The fine arts form a prominent part of the city's cultural life with a ballet guild, a philharmonic orchestra and an art league. The Everhart Museum of Natural History, Science and Art, located in Nay Aug Park, provides a focus for the appreciation of the fine arts. The park also contains zoological and horticultural gardens and a model mine open to the public. The Pocono mountains provide recreational opportunities as do the many mountain lakes and state parks within the area. (R. D. WI.)

SCRAP METAL. Used metals may be as important as ores as a source of metals and alloys for industrial use. The relative importance of scrap metal increases as the supply of metal in use accumulates and the supply of ores diminishes or the average grade declines. Scrap metals are particularly important in the production of steel, copper. lead, aluminum and zinc. Smaller amounts of tin. nickel, magnesium and precious metals are also recovered from scrap.

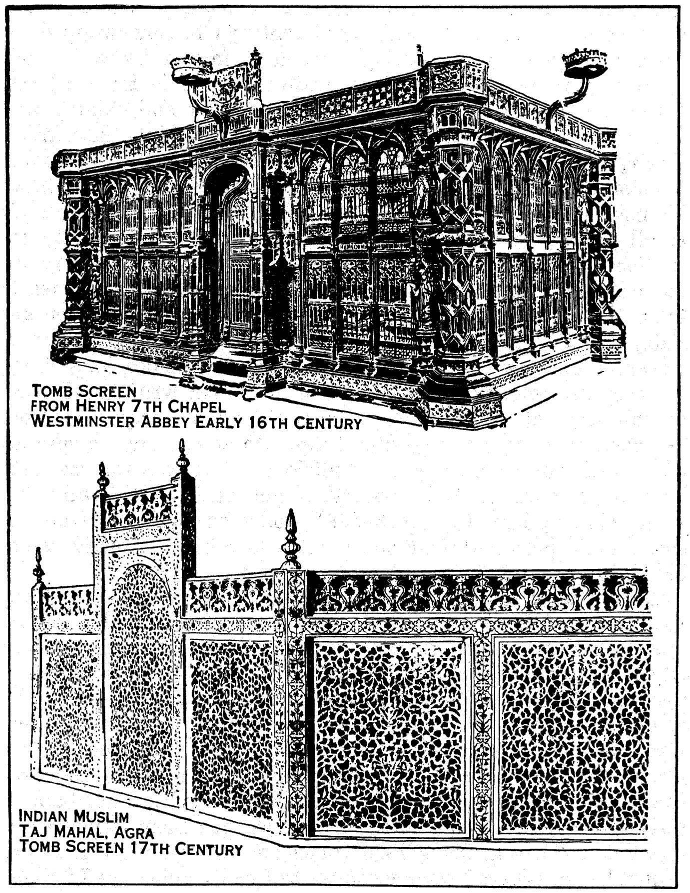
There are two distinct kinds of metal scrap: "old scrap" is metal that has been discarded after use and is returned to the metallurgical industry for reprocessing; "new scrap" is metal from manufacturing operations that has not been used in an end product and is therefore still in the process of manufacture. Metals produced from scrap usually are known as secondary metals as distinguished from primary metals, which are produced directly from ores. No such distinction is made for steel and precious metals. Steel is produced from a combination of scrap iron, pig iron and iron ores. Old scrap is gathered from widely scattered sources by scrap-metal or junk dealers and sold to secondary smelters. New scrap is concentrated in industrial areas and is usually purchased directly by secondary smelters. Many of the larger metal producers who produce secondary as well as primary metals buy back the new scrap from manufacturers to whom they sell primary metal.

Scrap usually is processed by sorting: blending and remelting to produce alloys similar to or more complex than those from which the scrap was derived. Old scrap in particular ordinarily is contaminated with foreign materials. Organic materials such as wood, plastic, paint or fabric can be burned off. Metallic impurities that are beneficial or inert usually are retained in the secondary ingot. Undesirable metallic impurities are diluted to tolerable proportions by the addition of pure metal or are removed by refining, *e.g.,* zinc is readily removed by distillation; lead can be refined by melting with a suitable flux. The price differential between scrap and refined metal permits only simple refining methods to be used. (H. W. S. C.)

SCREAMER *(Palamedea* ***cornuta*)**, a bird inhabiting Guiana and the Amazon valley. About the size of a turkey, it is remarkable for the slender "horn" more than gin. long, on its crown, the two sharp spurs on each wing, and its long toes. Its plumage is mainly greyish-black above with some white and reddish-brown, while the lower parts are white. Related to this bird is *Chauna chavaria,* the "Crested Screamer," a name first bestowed on the Seriema (*q.v.*). This bird inhabits the lagoons and swamps of Paraguay and Southern Brazil, where it is called "Chajá" and is smaller than the preceding, wanting its "horn," but having a crest of feathers; the plumage is mainly grey. Its nest is of dry rushes, having its foundation in the water, and contains six eggs, which are white tinged with buff. The young are covered with yellowish-brown down A singular habit of this bird is that of soaring in circles at an immense altitude in flocks uttering at intervals their far-reaching and melodious cry. They also sing on the ground *(see* W. H. Hudson, *Naturalist in La Plata,* who also records hearing over a hundred thousand burst into song together). The young are often reared by the people to defend their poultry, a duty which is faithfully and, owing to its spurs, successfully discharged. Another curious property of this bird is a layer of air-cells between the skin and the muscles, so that on the body being pressed a crackling is heard. In Central America the darker *C. derbiana* occurs. It is a smaller bird than the others, with slate-gray plumage and white throat.

The *Palamedeidae* are by many authors placed in a distinct order, *Palamedeiformes,* near the *Anseres.* *(See* BIRD.)

SCREEN, in architecture, any one of various types of subdivisions between adjacent portions of the same open space. Thus the colonnades under the great arches in the tepidaria of certain Roman baths formed screens, mainly decorative, between the central space and alcoves or recesses at the ends and sides.



TOMB SCREEN FROM HENRY 7TH CHAPEL WESTMINSTER ABBEY EARLY 16TH CENTURY

INDIAN MUSLIM TAJ MAHAL, AGRA TOMB SCREEN 17TH CENTURY

The term is especially used in ecclesiastical architecture for the railings, barriers or other dividing elements between chapels and the aisle or nave or around the choir. Chapel screens were usually open and consisted of an arcade of tracery or of a metal grille. Choir screens, on the other hand, were, in north and west Europe, largely solid, although relatively small in height, so that the services held behind them could be heard by those in the nave although the clergy and choir remained unseen. Of choir screens of this type, those of the cathedrals of Amiens and Chartres, both of the 15th century, are especially rich; in England, that of York (1475–1505), Canterbury (15th century) and Exeter (first half 14th century) are noteworthy. In Italy the tradition of the early Christian bemas, ambones and low chancel railings dictated an entirely different type of screen; the chancel front of S. Miniato, near Florence, with its elaborately inlaid marble parapet of the late 11th and early 12th century is typical. With the coming of the Renaissance even this amount of separation was abandoned and in the great Renaissance churches of Italy the use of the screen as a separation for the choir disappears. In Spain the high development of ironwork led to the extensive use of that material for both choir and chapel screens. This iron screen work, termed *rejeria* (*q.v.*), constitutes one of the most glorious adornments of the Spanish churches. See JUBE; STALL. (T. F. H.)

SCREENS OF CHINA AND JAPAN

Because of their fragile nature, no screens of great antiquity have survived, but references to them are not wanting in ancient literature. Folding screens were known in China as early as the 2nd century B.C., at which period glass or mica panellings for them are noted as of much value, their transparent nature affording both enjoyment of an outdoor view and shelter from the elements. Then, in the century preceding the Christian era, screens carved and inlaid with jade and other precious materials seem to have been produced. Already in this early period the art of painting screens was practised, for it is recorded that "Figures of Exemplary Women," illustrating the good or evil effects from right or wrong-doing were depicted on a screen. The Chinese artist Ts'ao Pu-hsing (3rd century) having dropped ink upon a screen while painting, turned it into a fly which Sun Ch'üan (A.D. 181–252) tried to brush away. Shih Hu (3rd century) made a folding screen covered with silk and painted with hermits, birds and animals, to which he added a long inscription. Chang Mo (4th century) depicted on screens the Buddhist saint, Vimalakirti, and a scene entitled "Beating Newly-woven Silk." In passing, mention may be made of a 14-fold screen in the scroll attributed to Ku K'ai-chih (4th century), owned by the British Museum, confirming the accuracy of contemporary accounts that screens consisted of numerous leaves, sometimes as many as 40. In the 5th century, Lu T'an-wei painted a lion and Fang Huai-chên the "Paragons of Filial Piety." Landscapes were not unknown in these early centuries as themes for screens, for they are referred to in old poems and other writings. Screens of tapestry, of embroidery, of crystal and of lacquer are also recorded in contemporary literature. Moreover, fine calligraphy inscribing moral teachings or auspicious sentiments was executed on screens from the 5th century, if not earlier. It is said that Fang Hsiiang-ling (A.D. 578–648) collected precepts from all sources and inscribed them on screens which he distributed among his children as reminders of proper conduct.

The T'ang Period.—In the luxurious days of the T'ang dynasty (618–907), screens were in constant demand to adorn palaces and mansions. Those which were bedecked with gold and silver, pearl and tortoise shell, or those of fine textiles woven or dyed, bearing characteristic patterns, must have imparted great splendour to the habitations of rulers and princes. Horses sent from foreign tribes to the imperial stables furnished themes for screens, and a fabulous animal called' *mo* which is supposed to eat bad dreams was deemed an appropriate subject for boudoir screens. Then, too, such noted painters as Pien Luan (who treated flowers and birds), Chang Tsao (pines and rocks), and Chou Fang (court beauties), and such accomplished calligraphers as Li Yang-ping and Chang Hsü all decorated screens. Some emperors had about them screens setting forth worthy and moral deeds performed by men of the past, in order that they themselves, as well as their subjects, might derive benefit from these constant reminders.

But for actual examples of T'ang art on screens we have to turn to Japan where, in the Imperial repository called the Shōsōin, at Nara, are still preserved relics of the art of that golden epoch. This treasure-house contains principally the personal selongings of the Emperor Shōmu, which were given to the Great Buddha of the Tōdaiji by the Empress Kōmyō, in 756. The list of donations mentions, among other objects, 100 screens, to which several more were added, at three different times, between the years 756 and 758. Among this large number of screens were examples of Chinese, Korean or Japanese origin which included paintings of landscapes, palaces, figures and flowers; others of batik and of block-resist dyeing, figuring birds, animals and flowers; and, in addition, some screens on which Chinese ideographs formed the chief decoration. Of these 100 odd screens but few remain at present, in whole or in part, among them no painted screens. Nevertheless, the pictorial accomplishments of the 8th century may still be seen in this collection in a six-fold screen, in each leaf of which is shown a figure of a woman standing under a tree. The subject was originally worked in birds' feathers which have disappeared, leaving only the preliminary drawings. Despite the sketchy nature of the drawings of the figures, trees and rocks, one may detect the mature brush-strokes, the importance of which is so much emphasized in the art of painting in the Far East. The screen is probably Japanese, yet its conception and execution are based upon contemporary Chinese patterns. There are also two six-fold screens in this imperial collection, the chief decorative features of which are Chinese inscriptions in large characters. One contains a precept for a ruler, consisting of 48 Chinese ideographs, each written twice, once in the *chuan* ("seal") style and once in the *hsing* ("running") style. The backgrounds of this screen are of silk dyed in green and red-alternating in the six panels—bearing designs of conventionalized clouds, birds, animals, trees, plants and rocks, all in white reserve. The screen is very likely Chinese, one of many gifts sent to the Japanese court from China, although it is said that at one time there was discovered upon it a Japanese date corresponding to the year 751—a fact lacking substantiation. In the Orient, to use writing on a large scale for a decorative scheme is no less frequent than to employ a picture for the purpose. Indeed, good calligraphy (*q.v.*) is considered an art of as great importance as good painting, both being the result of brush-work and both presenting images of mental conception.

An example of the pictorial art of the T'ang as it is reflected in the art of Japan may be seen in a screen which is preserved in the Buddhist monastery of Tōji in Kyoto. It treats a landscape in pclychrome: among trees surrounded by hills and water is a rustic abode within which sits a hermit who is being visited by nobles with their servants. According to an old tradition, the screen was one of the treasures brought back by Kōbō Daishi from China in 806. However, some authorities now regard the painting as a Japanese production of the 11th century, based upon a T'ang original. For, despite its Chinese design, in it are discernible certain technical peculiarities of the early Yamato-é (literally "Japanese picture") style which was developed during the Fujiwara period (900–1189) and is characterized by over-refinement of drawings. Such a landscape screen was used in the baptismal rituals of esoteric Buddhism which required a pictorial representation of a mountain scene in lieu of the natural setting in which the religious service took place in old India No screens of a secular nature dating from the Fujiwara period are now extant, but literary sources disclose the thousands of screens painted for the use of the Japanese court and for the mansions of nobles. As in the preceding epoch, the need for screens was pressing, because of the peculiar style of the architecture of those days—wide openings on the sides of a building which were closed by wooden doors at night but which during the day needed screening arrangements. Regular and occasional State functions also required special screens appropriate to the events. That a large number of screens was produced may be gathered

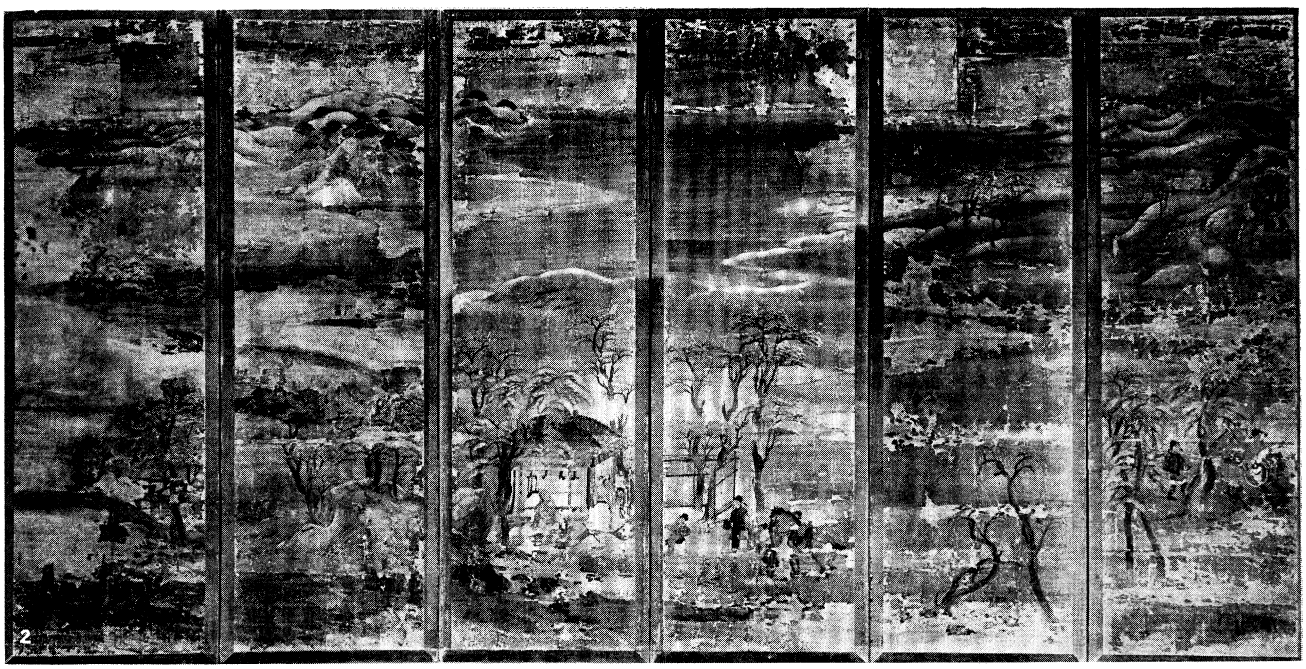
Below: Spider-monkeys, by Hasegawa Tōhaku (died 1610), painted in monochrome on paper. It is one of a pair of six-fold Japanese screens in the Bigelow collection



BY COURTESY OF (1) THE DIRECTOR OF THE IMPERIAL HOUSEHOLD MUSEUM. JAPAN (2) (SHIMBI SHOIN, LTD.) FROM "THE MASTERPIECES SELECTED FROM THE FINE ARTS OF THE EAR

A CHINESE AND A JAPANESE SCREEN IN THE T'ANG STYLE

1. Chinese screen of the eighth century painted with a precept in 48 ideographs. each character written both in the "seal" and in the "model" style. The panels, which are joined with cords, are coloured alternately red and green, with designs of clouds and other conventionalized forms in white. From the Imperial Collection in the Shosoin, Nara, Japan

2. Japanese landscape screen of the 11th century, probably after a T'ang original, depicts the visitation of a noble and his servants to a hermit's house set in a landscape of trees, hills and water. The over refinement of the drawings is characteristic of the "Japanese picture" style of the Fujiwara period (900–1189). From the Buddhist monastery of Toji at Kyoto

from the record that Yoshichika (11th century) painted zoo screens on Lord Yoshimichi's order. A story is told about Hirotaka (10th century) who delineated a scene of hell containing a demon who proved so lifelike as to convince the artist that the call to the unknown region was immediate. The subjects, some Chinese and some Japanese, mentioned in this period are varied and numerous: landscapes of the four seasons, monthly observances, trees and plants, falconry, picnics, polo-playing, the paragons of noble deeds, the descent of the Amitābha, the ten Buddhist regions, etc. In Japan, during the Kamakura period (1190–1336), in making screens they followed the preceding Fujiwara in the main, both pictorially and technically.

The Sung Period.—In China itself in the Sung period (960–1279), the practice among prominent masters of painting and inscribing screens was not abandoned. On the contrary, painters like Tuan Yüan, Yen Hsiao, Wên T'ung and Hsü Tao-ning are known to have thus expressed their art; and noted calligraphers applied their brushes after the time-honoured custom. The most significant branch of the art of the Sung period was the so-called Idealistic school of painting which was closely followed by the artists of the Yüan (1279–1368) and Ming (1368–1644) dynasties. Painters of this school attempted to express in their works certain noble thoughts and ideals. A landscape-painting, for example, was an essay which suggested the sublimity of nature and invited the beholder to identify himself with it. The inherent love of nature of the orientals, coupled with the teaching of *Ch'an* (in Japanese, Zen), produced artists who showed remarkable aptitude for depicting natural phenomena. *Ch'an* means "abstract meditation," the chief aim of its followers being to seek to separate the real from the unreal by divesting themselves of earthly thoughts and desires and by communing directly with nature. Inspired by this teaching, the artists developed marked individuality and their paintings were characterized by purity and suggestiveness. For their themes, the painters of the Idealistic school chose, beside landscapes, birds, animals and even withered trees and rocks, all of which ordinarily were treated in monochrome with China ink. Unfortunately there exists no example of the typical art of the Sung as applied on screens, nor are there any screens dating from the subsequent Yüan and Ming dynasties, in both of which it is recorded that painted and inscribed screens were produced. It is possible, however, that some of the paintings coming from these periods, now mounted as single hangings, were once panels of folding screens.

The Ashikaga Period.—Again turning to Japan, one can see an echo of the Chinese art of these three dynasties in paintings by Japanese artists of the Ashikaga period (1337–1573). Sōtan, Nōami, Sesshū, Masanobu and Motonobu are outstanding figures who painted in ink on screens after the Chinese idealists. A screen by Sōtan, who died in 1464, may be taken as a typical specimen of this style. The vigour of the brush, the subtle quality of the ink, the well-carried-out atmospheric perspective—all tell of the master hand which portrays the spirit of majestic nature. This screen is one of a pair which together show landscapes of the four seasons treated as one composition and consequently forming one composite whole. Beside the "Twelve Monthly Observances" and "Landscapes of the Four Seasons," such themes as "Flowers of the Four Seasons," "Farmers of the Four Seasons," "Lives of the 24 Paragons of Filial Piety," the "Eight Taoist Immortals," etc., frequently occur as single designs. The Idealistic school of painting was carried through the next period, the Momoyama (1574–1602), by artists of the Kano, the Unkoku and the Soga schools. In a screen by Tōhaku (1539–1610) we see a remarkable monochrome; the varied shades of China ink being so used as to suggest the presence of colours, yet with no disturbing element of pigments and no sense of monotony.

A new type of screen introduced some time in the 14th century from Korea contributed much toward revolutionizing the general scheme of composition. Heretofore, a folding screen had consisted of *a* group of separate panels, each with brocaded borders, tied together by means of cords passing through holes pierced at the vertical edges of the panels. In the Korean type the leaves were joined by paper hinges which were built into the body of the screen before the silk or paper for painting was pasted, a brocade border extending over the composite whole.

Whereas in the former style the continuance of the design was interfered with by the frame and the brocade borders of each panel, in the latter style the tightly joined leaves made one surface for painting a picture.

Screens characteristic of the Momoyama period, the inherent love of the Japanese for simplicity notwithstanding, are more decorative in type, with backgrounds of gold leaf upon which appear bold designs in solid pigments on a massive scale. Eitoku (1545–90), who was the chief exponent of the style, is said to have supplied 100 pairs of screens for the Momoyama palace of the Taikō. He painted in two styles, ink and polychrome; the polychrome screens are very effective; for example, one of a pair in which are shown foreigners bringing tribute to the Chinese emperor, Tai-tsung, of the T'ang dynasty; the subject—"Barbarians Presenting Tribute"—being symbolic of the peace and prosperity of the country. The popular pictorial motives on Screens at this time were "The Dragon and the Tiger," "Lions," "Old Pine Trees" (respectively symbolizing the conflict between spirit and matter, nobility and power, longevity and fidelity).

The Tokugawa Period.—In Japan during the Tokugawa period (1603–1868), a new movement in decorative painting was developed by Sōtatsu (1576–1643) who preserved the vigorous and broad brush-work practised by the masters in monochrome, but in place of ink used pigments on a gold ground. Even as he adopted the coloring of the old Yamato-é, so he took many themes from old sources, such as the romances of Genji and Isé, the wars of the Hogen and Heiji Eras, the wind and thunder gods. He was also a genius in the impressionistic treatment of flowers and waterscapes on screens. Following Sōtatsu's style, Kōrin (1657–1716) further enlarged upon decorativeness by introducing more brilliant colours and more daring composition. In the twofold screen depicting violent waves is apparent this artist's largeness of conception and power of technique. In the Tokugawa days, artists in all schools—the Kano, the Tosa, the Genre, the Literary, the Realistic—exerted their artistic efforts on screens. In principle. the pictorial scheme for screens by these painters of varied styles had changed little from that of the preceding Ashikaga and Momoyama periods and it is still continued to-day. A bold design is treated in dissymmetry. yet is well balanced and effective; at the same time it hears a certain moral. historical. legendary or auspicious significance. The subjects treated were many and varied. including those which have already been referred to and also such themes as the "Eight Views of Hsiao Hsing." the "Ten Snow-Incidents." the ".A-fang Pleasance:.' the "Four Gray-beards of the Shan Mountain." the "Seven Sages of the Bamboo Grove.': the "Four Accomplishments." "Floating Fans." "Phoenixes." etc. Generally Japanese screens are six-fold. about 6 ft. in height and 12 ft. in width when stretched. and they are usually executed in pairs. Among the smaller type we may count "pillow" screens with brightly coloured pictures. which are placed about beds, and low. two-fold screens with simple decoration, or none at all, which are used in connection with the tea ceremony (*q.v.*).

The Ch'ing Dynasty.—During the Ch'ing dynasty (1644–1911) in China. painting on screens was practised. as indicated by the presence of occasional examples dating from the last few centuries. But it is in screens of applied art that the period excels. It has already been said that the application of the minor arts to screens began in ancient China. The best known among such screens of recent centuries are the so-called "Coromandel screens" which are made of wooden panels finished with a coat of lacquer, through which designs—landscapes, figures. flowers. auspicious emblems, etc.—are incised and filled with various thick, opaque water-colours; a technique known from the Ming dynasty. A large portion, however. of the existing specimens are of the 17th to 19th centuries. "Coromandel" has no bearing upon their provenance. but indicates that these screens of Chinese origin were shipped to European countries from the coast of Coromandel. Other screens in the category of lacquer are those with lacquered panels (sometimes coated with white oil paint) decorated in gold lacquer; and those of red carved lacquer Screens of carved teakwood construction set with jade and porcelain plaques, or panelled with silks, tapestries or embroideries, are occasionally seen.

(See also JAPANESE PAINTING AND PRINTS; CHINESE PAINTING; EMBROIDERY; FLOWER PAINTING; TEXTILES.)

Furniture. — As an article of furniture, the screen is an ornamental frame, usually of wood, but sometimes of metal, for protection from observation, draught or the heat of a fire. Screens are made of all shapes and sizes, and may consist of leather, paper or textile materials fastened to the framework; they may have several leaves or only one — thus a fourfold screen has four leaves. Fire screens are usually small, with a single leaf — indeed in the Georgian period of English furniture they often took the form of a circular, oval, heart-shaped or oblong piece of framed embroidery fixed to a wooden pole or upright, upon which they could be raised or lowered. This variety, which was called a pole-screen, was more effective as an ornament than as a protection. The hand screen was light and portable, as the name implies. At one time fire screens were often of glass set in metal frames; later they were of metal mesh.

The larger type screen, with several leaves, is of uncertain origin, but probably first came into use toward the end of the 16th century. The earlier examples were of stamped or painted Spanish leather or of some rich stuff such as tapestry; at a later date lacquer was extensively used. They were tall enough to conceal the person sitting behind them, and were frequently exceedingly handsome and stately. (K. T.)

SCREW, a cylindrical or conical member uith a helical groove and ridge on it. (For the screws used to propel ships and airplanes, see SHIPBUILDING.) The helix is found in a wide variety of applications, such as screw pumps (the first by Archimedes)

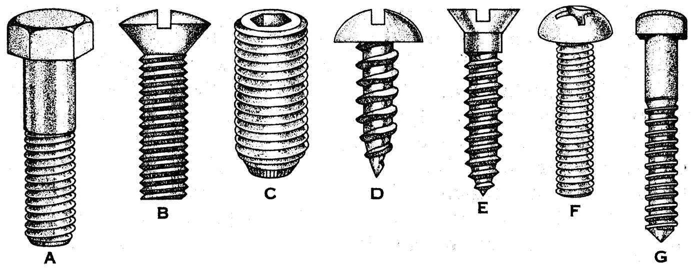


FIG. 1. — SCREWS AND SCREW HEADS: (A) CAP SCREW. (B) MACHINE SCREW WITH OVAL HEAD. (C) SET SCREW WITH HOLLOW HEAD. (D) SELF-TAPPING SCREW. (E) FLAT-HEAD WOOD SCREW. (F) PHILLIPS HEAD SCREW. (G) LAG SCREW

and boring tools for metal, wood, soil, etc. In particular, a screw (without modifying adjective) is a threaded fastening device, without a nut; common examples are the cap screw, machine screw, set screw, wood screw, and lag screw, (fig. 1). The cap screw is machine finished all over and made in sizes of about $\frac{3}{8}$ in. and larger; it generally has a hexagonal head, but may also be made with a hollow head such as shown on the set screw in fig. 1(C).

Machine screws also are usually finished all over but are made in the smaller sizes — up to $\frac{3}{8}$ in. in diameter; various types of heads, nearly always slotted for a screw driver. are used, and patented heads, an example of which is the Phillips head (fig. 1[F]), are common. Set screws are used to prevent relative motion between two parts which tend to slide over one another, as in fastening a small pulley to a shaft; they are obtainable with several different types of heads and points. Self-tapping screws, fig. 1(D), are hardened screws designed to tap their own threads as they are turned into the hole; they are used to join thin sheets of metal, plastics, die castings, etc. Some types are applied with a screw driver, some with a hammer, and they are frequently made with a Phillips head. Wood screws are made in various diameters and lengths; in using the larger sizes, a hole is drilled first in order to avoid splitting the wood and to make the turning easier. A lag screw is a large wood screw, often used to fasten machinery and other heavy objects to wood. It usually has a square or hexagonal head so that it can be turned by a wrench.

Screw Threads. — A thread on the outside of a cylinder is an external or male thread; cut on the inside of a hole, as in a nut, it is an internal or female thread. The purpose in using threaded members may be: (1) to join two or more parts together; (2) to transmit power or force; (3j to obtain a mechanical advantage, that is, a large force from a small one; or (4) to transmit motion either rotary to linear or linear to rotary.

Until about 1841, each manufacturer using threaded fastenings designed the threads for his own convenience. Failure of a screw or bolt resulted in delay, inconvenience and expense because of the difficulty in obtaining a replacement which fitted. Now, however, there is international agreement on some degree of standardization of the form of thread, and general recognition of the desirability of international interchangeability. By interchangeability is meant, for example. that when a large number of bolts and nuts are made to a certain size,and standard, any one of the nuts fits properly on any one of the bolts. In the unified standard of the U.S., fig. 2, which is in accord with an international agreement adopted by English-speaking countries, there are several classes of fits possible. Class 1 is the loosest and cheapest, having the largest tolerances and allowances. Class 2 is about the average fit obtained by ordinary production methods, and is therefore the most common. Class 3 is the closest and most expensive, and would not be used without reason; the specified allowance between bolt and nut is zero. Intermediate classes of fits may be obtained by, for instance, using a class **3** nut with a class 2 bolt.

The largest diameter of a screw thread *(e.g.,* the outside diameter of an external thread) is called the major diameter; the smallest diameter *(e.g.,* the root diameter of an external thread) is called the minor diameter. The top of the external thread is known as the crest, while the crest of an internal thread mates with the root of an external thread.

One fastening thread sometimes used is in the form of a sharp V (fig. 2[A]), but this has disadvantages: the sharp crests are weak and small pieces often break off and the sharp root shape results in a high stress concentration that can lead to failure of the bolt.

Trying to overcome these disadvantages, Sir Joseph Whitworth in 1841 proposed a fastening thread with rounded crests and roots. With an angle between the sides of the thread of 55°, this was the basis of the British standard. In 1864, William Sellers proposed a thread with flat crests and roots and a 60° thread angle (fig. 2[B]), and this later became the U.S. standard and the metric standard.

There are several standard series of fastening threads. The coarse-thread series, with the fewest threads per inch for a particular size, is recommended for general use. The fine-thread series, which has more (and therefore finer) threads per inch, was developed for use in the automotive industry where strength

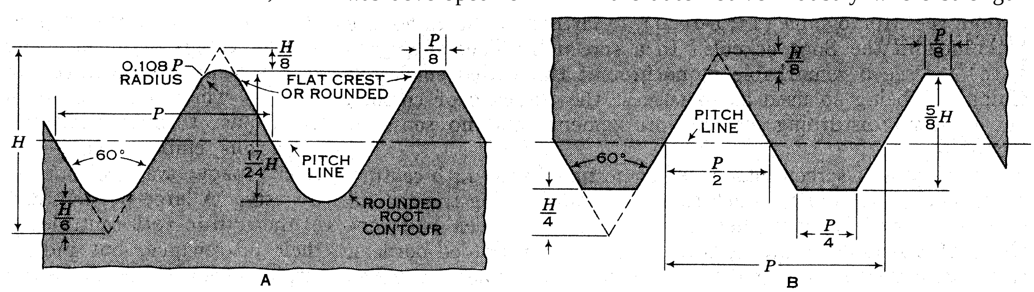

FIG. 2 — PROPORTIONATE DIMENSIONS FOR SCREW THREADS. (A) BRITISH STANDARD. AND (B) U.S. STANDARD. $H = 0.866P$, WHERE P REPRESENTS PITCH

and vibration resistance are important, and where the internal threads are in steel (not cast iron or other brittle material). The extra-fine-thread series of the American standard came about largely in response to the needs of the aeronautical industry. This thread has the maximum root diameter and strength; it is suitable for thinner walls; it is more resistant to loosening from vibration. Fastening screws with these threads are likely to be made of a heat-treated alloy for maximum capacity.

Threads for Transmitting Power.—One of the three forms of threads shown in fig. 3 is usually used for transmitting power or motion. Since the square thread must be cut on a lathe and the Acme thread may be cut with dies, the square thread is more expensive to produce. Not only is the Acme thread less expensive, but it permits use of a split nut with shims between the halves so that wear may be compensated for by removing shims. Ball bearing screws (fig. 4) are used where it is advantageous to have a relatively low input effort and where arrangements with zero backlash are desirable. A worm driving a worm gear may be classified as a screw. often with a thread shape similar to the Acme thread of fig. 3.

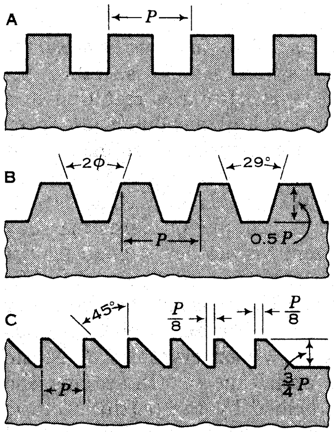

FIG. 3.— POWER SCREW THREADS. (A) SQUARE THREAD. (B) ACME THREAD AND (C) BUTTRESS THREAD. *P*, PITCH; φ, PRESSURE ANGLE AND 2φ, THREAD ANGLE

The pitch P of a thread is the distance between corresponding points on adjacent thread profiles —in inches in some countries, millimeters in countries using the metric system. The number of threads per inch (or per millimeter) is the reciprocal of the pitch. The lead of a thread is the axial distance that the helix advances in one turn, or that a nut will move axially in making one turn. In a single-threaded screw, the lead is equal to the pitch; if two threads run parallel, the lead is twice the pitch (fig. 5). When high mechanical advantage is the prime requisite, a single-threaded screw is best. When high efficiency is essential, as in some worm drives, a large lead (*i.e.,* multiple threads) is necessary. An exception is the ball-bearing screw, which is said to have an efficiency of about 90% at very small leads. However, the efficiency of a screw-and-nut combination depends not upon the magnitude of the lead but upon the slope of the thread at the pitch helix, which is the tangent of the lead angle. The lead angle λ is the angle between a plane perpendicular to the axis of the screw and a line tangent to the pitch helix The pitch helix has somewhat different definitions in different applications, but it is approximately at the mean diameter of the thread. The efficiency also depends upon the thread angle, the degree of lubrication, rubbing speed, materials, alignment and workmanship in general. Some of these factors are accounted for by the coefficient of friction.

A value of the coefficient of friction equal to 0.05 is easily obtained in well lubricated worm drives; a value 0.15 corresponds to a situation at slow rubbing speed with the surfaces merely damp with lubricant.

FIG. 4.—BALL BEARING SCREW; BALLS ROLLING ON EXTERNAL AND INTERNAL THREADS COMPLETE THEIR CIRCUIT THROUGH TUBES AT TOP

Methods of Cutting Screw **Threads.**—The methods of cutting external threads may be described in six categories: turning, die threading, chasing, milling, rolling and grinding.

Turning, a process still used occasionally, employs a single-point cutting tool of the same shape as the space between threads. The member to be threaded (that is, the work) is mounted in a lathe. The change gears on the lathe are arranged so that the work and the lead screw of the lathe turn with the proper relative speed to give the desired number of threads per inch on the work. If the work and lead screw turn at the same angular speed, the number of threads per inch on the work is the same as that on the lead screw; fewer threads are cut if the work turns slower than the lead screw, more if the work turns faster.

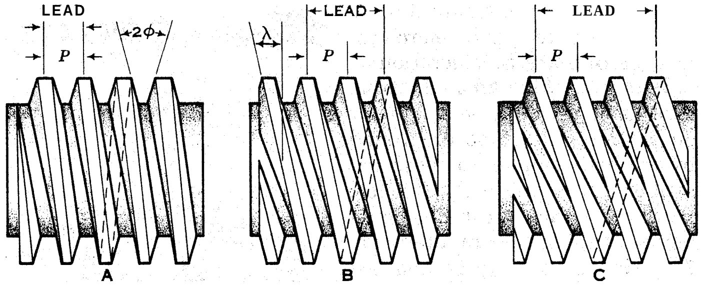

FIG. 5.— DIAGRAM SHOWING RELATION OF PITCH TO LEAD. φ, PRESSURE ANGLE: 2φ, THREAD ANGLE AND λ, LEAD ANGLE

Dies for cutting threads are made with internal cutting edges of the proper shape, size, and pitch (fig. 6[A]). Manual operation of thread dies is common for cutting small pipe threads on the job, but the dies are also used in machines, including automatic thread-cutting machines. On small threads and at slow speed. the die can be depended on to follow its own helical path with reasonable accuracy. On large threads and at high-production speeds the relationship between die and work must be positively maintained.

For machine cutting of threads. the rate of production is improved if the die automatically opens, allowing the work to be directly withdrawn (not unscrewed).

Chasing is the same in principle as die threading. The difference is in the configuration of the cutting edges. In one type, the cutting edges are on small cylindrical tools, as in fig. 6(B); in another type the cutting edges are on flat pieces mounted with the tops of the cutting edges tangent to the root of the threads being cut.

FIG 7—(A) THREAD-CUTTING DIE; (B) CIRCULAR THREAD CHASERS ON REVOLVING HEAD

Milling of threads is done on a standard milling machine, or one especially built for this work, using a milling cutter with a profile the same as the space between threads. In one type of machine, the cutters rotate on their axes and revolve about the work. Milling is especially useful in producing large, accurate threads.

Rolling produces threads by rolling the work between flat or cylindrical dies. Because the rate of production is high, the process was first used to manufacture cheap stove bolts, but it has been improved until bolts and screws of superior quality can be produced in this manner. The die has hardened parallel ridges whose profile is the same as the desired thread profile and whose slope produces the correct lead of the screw. The shank to be threaded has a diameter approximately equal to the pitch diameter. As the blank is rolled between the dies under great pressure, it is indented and metal flows to the root of the die grooves (forming the crest of the thread). The cold working of steel during this process improves its strength, and the resulting surface finish is excellent.

The accuracy that may be obtained depends upon the accuracy of the dies and of the machine. When cylindrical dies are used, there are three of them. and of course the forces exerted by the rollers must be sufficient to cause the metal of the work to flow completely into the valleys of the roller threads.

Grinding can also be used to make threads by gri'nding with a wheel whose form matches the space between the threads. Grinding usually is used as a finishing operation,, especially after heat treatment, for producing threads in hardened steel, and where cost is not a primary consideration.

Internal Threads.—Internal threads may be cut on a lathe or on a milling machine or ground by methods similar to those described for external threads. However, the most common method is by means of a tap (fig. 7). Hand taps may be adapted to low-speed machine work. The taper tap is used first and it is the only one needed for a through hole.

FIG. 7.—TAPS: (ABOVE) HAND TAPS FOR CUTTING INTERNAL THREADS AND (BELOW) COLLAPSING TAP

If it is desired to have good threads all the way to the bottom of a blind hole, the taper tap is followed by the plug tap and then by the bottoming tap. There are different kinds of collapsible taps suitable for high production: after they have completed the tapping, they automatically collapse and withdraw quickly. (V. M. F.)

SCREW DRIVER, the tool which drives screws, must be made of good steel and suitably tempered so it will not snap off through being too hard, or twist or bend through being too soft.

The chief interest in 'this connection in manufacturing processes and repairs attaches to the mechanically operated screw drivers which vastly speed up the rate of removing or inserting screws. Some are driven by a flexible shaft actuated from a cord and pulley, the shaft being maneuvered about anyhow to suit the situation of the screws. Or a pneumatic or electric drill is fitted with the blade, and held in the hands anywhere required. Some small articles demanding the use of numerous screws are placed under a fixed screwdriving machine, the spindle of which carries the driver blade, pressed down by a lever. In woodworking, screwdriving machines are largely used in mass production For hand use only the ratchet and the spiral types are very convenient.

SCREW PINE, the popular name for plants of the genus Pandanus, which are shrubs or trees of peculiar habit, having a main stem and a few branches at the ends of which is a tuft of long, stiff, narrow leaves closely arranged in three strongly twisted lines. The stem forms stout roots some distance above the ground: they grow obliquely downward to the soil and, because of the decay of the lower part of the stem, the plant is often supported merely by these strong proplike roots. The ripe fruits are borne in very large spherical or cylindrical heads. which are often extremely hard. The genus is the principal one of the family Pandanaceae, a small family of monocotyledons, which is widely distributed through the tropics of the old world, especially in the islands of the Malay archipelago and of the Indian and Pacific oceans.

SCREWWORM, the larva of Cochliomyia americana of the family Calliphoridae of the order Diptera (*q.v.*); so-called because of its tapering body bearing rings of spines resulting in a screwlike appearance. The larvae develop in wounds of sheep and other animals and may cause severe myiasis, which may result in death. See BLOWFLY. (C.H. CN.)

SCRIABIN, ALEXANDER MICHOLAEVICH (1871–1915), Russian composer, was born at Moscow on Christmas day 1871 (O.S.). His father was a lawyer; his mother, a good pianist and pupil of Leschetizsky, died when he was one year old. His schooling was received in the Moscow Cadet corps, but he never showed any liking for the military career for which he was intended, and at 18 entered the Moscow Conservatoire of Music where he was a pupil of Safonov and Taneev. On leaving the conservatoire Scriabin was greatly helped by the patriotic music publisher Belaiev, who brought out his earlier works and arranged a European piano recital tour for him. At 20 he returned to Moscow and joined the conservatoire staff. Later he again travelled, this time for six years, visiting the United States among other countries In 1914 Scriabin visited England. giving two piano recitals, playing his own concerto and appearing as pianist in his Prometheus. He was then suffering from a tumour of the lip, from which, soon after his return, he died, April 27, 191j. As a composer, Scriabin represents what may be called the classical-romantic school carried forward to its most advanced point. The form of his sonata and symphony movements he derives from Mozart, through Beethoven; however bewildering these may at first sound, they will be found, on further hearing, to be laid out on essentially the Mozart-Beethoven lines. In his pianistic idiom and general pianistic qualities of style, Scriabin derives largely from Chopin, of whose work he was a great admirer. All this then indicates a conservative side to his composition, but he was more radical in his harmonies, and it was, probably, largely the novelty of these that retarded appreciation of his later works. It is said that Scriabin gradually evolved a synthetic scale of upper partials or "mystic" chord of superposed 4ths. (C,D,E,F#,A,B♭, or as a chord, C,F#,B♭,E,A,D). One's actual impression, however, of his harmony is of an almost ceaseless chromaticism and of an almost unbroken use of the dominant chord with the flat 7th, 9th, 13th, sharpened 4th, and most frequent of all, the sharpened 5th (or flattened 6th). It is seldom one recognizes his chord of superposed 4ths as such, excepting at times the characteristic two perfect 4ths at the top. In his later work he makes still further harmonic excursions, notably with sharp 7ths or flat 2nds. The hint of this new harmonic scheme may be seen in the earliest compositions, and its development was fairly regular and consistent, until it came to dominate his later output. In his later works he discards entirely the old key signatures. In his orchestration Scriabin calls for a large force, and uses it very freely: his scores are exceedingly contrapuntal in texture, the various instruments moving very independently and weaving together their respective themes: muted brass plays a large part in his orchestral colour scheme. In the first symphony a chorus is used in the finale; the Poem of Fire also uses a chorus, but in an orchestral way, no words being supplied. For the last-named work the composer also wrote an optional part for a "Tastiera per luce," or keyboard of light, the intention being that varying colours should play upon a screen as the work was being performed. The composer was greatly interested in theories as to a correspondence between the musical scale and the scale of colours. In his great Mystery (left unfinished at his death) music, dance, speech, perfume and colour were to be combined; this work was to be rather a work of ritual than of art, and was to express its author's idealistic mysticism through the medium of 2,000 participants.

It is usual to look upon Scriabin's musical work as largely the expression of theosophical views, and undoubtedly much of his inspiration was drawn from the works of Blavatsky and others. He was not, however, a close reader or a careful thinker. Seizing the main idea of a book or a creed, he would neglect the details, and then his imagination would quickly develop a huge scheme of thought having little relation to what he had read. The titles of many of his works and of their separate parts, and the marks of expression affixed to particular passages, indicate plainly the existence of a spiritual "programme." The emancipation of the human soul through ceaseless striving, and its achievement of self-expression, may be said, very roughly, to represent the general sense of the spiritual basis of Scriabin's musical works.

The works of Scriabin have been variously classed into periods. A logical classification is into four periods as follows: 1st period, with a strong Chopin influence; the dividing line between this and the 2nd period runs through the first symphony, and the 2nd period shows some Wagner and Liszt influences; the dividing line between this and the 3rd period runs through the fifth sonata, and a 4th period begins with the Poem of Fire.

Among Scriabin's principal works are the following. For orchestra: Reverie, op. 24; first symphony, op. 26; second symphony, op. 29; third symphony (or *Divine* Poem), op. 43; fourth symphony (or Poem of Ecstasy), op. 54; Prometheus (or "Poem of Fire"), op. 60. For piano: ten sonatas, together with a very large number of preludes, Ctudes, impromptus, mazurkas, poems, etc., including the great Vers la *Flamme* poem and the much-discussed last work, the Five Preludes (op. 74). For piano and orchestra: Concerto, op. 20. No songs or chamber music are included in Scriabin's output. (P. A. S.)

SCRIBE, AUGUSTIN EUGÈNE (1791–1861), French playwright, an outstanding dramatic craftsman who dominated the Parisian stage for some 30 years, was born in Paris, Dec. 24, 1791. He chose as his medium the vaudeville, a popular form of satirical comedy with rhymed and sung couplets. which he soon began to transform by replacing its conventional characters with characters observed from contemporary society (*Une Nuit* de la garde *nationale,* 1815) and by introducing elements of the comedy of manners, as in Le Charlatanisme (1825). His first real comedy was Le Mariage *d'argent* (1827), but though without sung couplets. this play retained the dramatic structure of the vaudeville. Scribe maintained that his sole aim was to amuse; addressing the Acad-Cmie Française, to which he was elected in 1836, he denied that the theatre's purpose was to depict society.

He had a facile pen: working alone or with collaborators, he wrote over 400 theatrical works, including a ballet—Manon (1830)—and opera libretti: Fra *Diavolo* (1830), Robert le diable (1831), Les Huguenots (1836) and Le Juif errant (1852). His best-known plays are Le Verre d'eau (1840), Bertrand et *Raton* (1833) and Adrienne Lecouvreur (1849). His plays, which appealed to middle-class tastes and prejudices, brought Scribe a fortune.

Scribe died in Paris, Feb. 20, 1861.

SCRIBES, a group of Jewish scholars frequently mentioned in the Gospels, often together with the Pharisees (*q.v.*) and sometimes together with the high priests. The word "scribe" is used in the English versions of the New Testament to translate the Greek word grammateus (plural, grammateis), which in turn was used to render the Hebrew word *sopher* (plural, sopherim) or sofer. In early biblical Hebrew *sopher* usually designated an important court official, but during the first two-thirds of the period of the second commonwealth (from about 400 B.C. to A.D. 1), when Judaea was successively a province of the Persian, Macedonian and Roman empires, *sopher* meant an interpreter of scripture. It was in this capacity that Ezra (about 400 B.C.) was called a scribe. In the early part of the 2nd century B.C. Jesus ben Sirach, the head of a school of wisdom in Jerusalem, celebrated the intellectual and moral pre-eminence of the *sopherim* or scribes (Ecclus. xxxviii, 24–xxxix, 11). During the last three centuries before the beginning of the Christian era the *sopherim* were the professional interpreters and teachers of biblical law and ethics. Since the Jewish community enjoyed cultural autonomy under foreign rule, it was permitted to govern itself by its own constitution (called *politeia* in the ancient Greek sources), namely the Pentateuch. However, the Mosaic laws required interpretation and expansion to meet the needs of this later age and the work of interpretation was undertaken by the sopherim. The two leading religious-political parties, the Pharisees and Sadducees, both had their professional scholars or scribes, but as the Pharisees enjoyed greater influence among the Jews as a whole, it was the Pharisaic scribes whose interpretation of the law was considered authoritative by later rabbinic scholars. It is the Pharisaic scribes who are meant in most of the Gospel references to grammateis. It should be noted also that the Gospels treat this word as synonymous with nomikoi, "jurists" and *nomodidaskaloi,* "teachers of the law" (*i.e.,* biblical law). The chief Jewish legislative and judicial body meeting in Jerusalem from about 200 B.C. to A.D. 70, known as the great Sanhedrin (*q.v.*), was made up of scribes of the Pharisaic party as well as the scribes and priests of the Sadducaean party. Which party was in the majority throughout this period is not known, but sources indicate that on certain matters the opinions of the Pharisaic scribes prevailed. However, there was a difference in the usage of the word "scribes" between the Jewish and Christian writings of the first two centuries A.D. The rabbinic sources of this period apply the word "scribes" (sopherzm) to the biblical interpreters and jurists of the period between Ezra and their own time, while the Pharisaic scholars or rabbis of their own period are generally called sages (hakamim), though they performed the same functions as the *sopherim.* The latter term was usually applied in the Hebrew writings of the first two centuries A.D. to less eminent persons, such as writers of legal documents, copyists, notaries and teachers of elementary schools. When the Gospels speak of scribes (*grammateis*) as contemporaries of Jesus, they mean the jurists and teachers who had earlier been called *sopherim* but were now generally called *hakamim.*

The chief functions of the scribes throughout the greater part of the period of the second commonwealth were: (1) to interpret the biblical law and to provide new legislation by the construction of the written text or on the basis of the tradition of the elders (*i.e.,* the oral law); (2) to give instruction in all fields of knowledge relevant to the study of Scripture; (3) to act as legal advisers to judges and those who administered the law.

SCRIPPS, EDWARD WYLLIS (1854–1926), U.S. newspaper publisher, who inaugurated the newspaper "chain" in the U.S., was born on a farm near Rushville, Ill., June 18, 1854. Educated in the district school and a private one conducted by his half sister Ellen, Scripps in 1872 joined the staff of the Detroit Tribune, then partly owned and managed by his half brother, James Edmund Scripps, who in 1873 started the Detroit Evening News, on which Edward was a reporter and finally city editor. He left his job in 1877 to tour Europe with his half brother George, and on his return began the *Cleveland Penny* Press in 1878. Buying or establishing papers, first in the midwest and later on the west coast, Scripps before his death expanded his chain to 34 newspapers in 15 states. (See NEWSPAPER: United States: "Chains" and Consolidations.)

His papers were low-priced (originally penny papers), written for the "95 per cent," *i.e.,* the common people, politically independent, liberal and prolabour.

In 1897, with George and Milton Alexander McRae, who were partners in the chain, he organized the Scripps-McRae Press association, ultimately combined with another independent service as the United Press. He also organized the Newspaper Enterprise association, the first newspaper syndicate created to serve a chain of newspapers.

In 1922 he transferred his interests to his son Robert. Scripps died on board his yacht in Monrovia bay, Liberia, on March 12, 1926.

SCROFULA, the general name formerly given to tuberculosis (*q.v.*), "scrofulous," "strumous" and "tuberculous" being nearly interchangeable. The particular characteristics associated with "scrofula" have, therefore, varied at different periods when the real nature of the disease was misunderstood; but essentially what was meant was tuberculosis of the bones and lymphatic glands, especially in children, and it is in this sense that the word survives. The old English popular name was "king's evil," so called from the belief that the sovereign's touch could effect a cure. This superstition can be traced back to the time of Edward the Confessor in England, and to a much earlier period in France. Samuel Johnson was touched by Queen Anne in 1712.

See also KING'S EVIL.

SCROGGS, SIR WILLIAM (*c.* 1623–1683), lord chief justice of England, was the son of a butcher of sufficient means to give his son a university education. Scroggs went to Oriel college, and later to Pembroke college, Oxford. There is some evidence that he fought on the royalist side during the Great Rebellion. He was called to the bar in 1653, was appointed a judge of the common pleas in 1676, and two years later was promoted to be lord chief justice. As lord chief justice Scroggs presided at the trial of the persons denounced by Titus Oates for complicity in the "popish plot," and he treated these prisoners with characteristic violence and brutality, overwhelming them with indecent sarcasm and abuse while on their trial, and taunting them with savage mockery when sentencing them to death. He may at first have been a sincere believer in the existence of a plot; at all events he did nothing to test the credibility of such perjured witnesses as Oates, Bedloe, and Dangerfield. At the trial in Feb. 1679 of the prisoners accused of the murder of Sir Edmund Godfrey he gave a characteristic exhibition of his methods, including a tirade against the Roman Catholic religion. But Oates' next move, accusing the queen's physician, Wakeman, seemed to be going too far, and in the succeeding trials Scroggs impugned the testimony of Bedloe and Oates, thereby incurring great unpopularity in the country. Oates and Bedloe now arraigned him (1680) before the privy council for misconduct of the Wakeman case, but he was acquitted. The same year he discharged the grand jury to save the duke of York from trial as a popish recusant. In Jan. 1681 he was impeached; dissolution saved him, but he was removed from the bench. He died on Oct. 25, 1683.

Scroggs was perhaps the worst of the judges who disgraced the English bench at a period when it had sunk to the lowest degradation; and although his infamy is less notorious than that of Jeffreys, his character exhibited fewer redeeming features. Scroggs was the author of *Practice of Courts-Leet and Courts-Baron* (1701), and edited reports of the state trials over which he presided. He was the subject of many contemporary satires.

See W. Cobbett, *Complete Collection of State Trials*, vol. i.–x. of *State Trials*, 33 vol. (1809); Roger North, *Life of Lord Guilford, etc.*, ed. by A. Jessopp, 3 vol. (1890), and *Examen* (1740); Narcissus Luttrell, *A Brief Relation of State Affairs, 1678–1714*, 6 vol. (1857); Anthony & Wood, *Athenae Oxonienses*, ed. by P. Bliss, 4 vol. (1849–57); Edward Foss, *The Judges of England*, 9 vol. (1848–64); Sir J. F. Stephen, *History of the Criminal Law of England*, 3 vol. (1883); Henry B. Irving, *Life of Judge Jeffreys* (1898).

SCROPE (skrōōp), an old English family of Norman origin. Sir William le Scrope, of Bolton, in Wensleydale, Yorkshire, had two sons, HENRY (d. 1336) and GEOFFREY (d. 1340), both of whom were in succession chief justice of the king's bench and prominent supporters of the court in the reign of Edward II. Henry was father of RICHARD LE SCROPE, 1st Baron Scrope of Bolton (*c.* 1327–1403), chancellor of England, an active adherent of John of Gaunt. Having been knight of the shire of Yorkshire in the parliament of 1364, he was summoned to the upper house as a baron by writ in 1371, when he was made treasurer and keeper of the great seal. In 1378 Lord Scrope became chancellor; he attempted to curb the extravagance of Richard II., and was dismissed in 1382.

His eldest son WILLIAM (*c.* 1350–1399) was created earl of Wiltshire in 1397 by Richard II., and he bought the sovereignty of the Isle of Man from the earl of Salisbury. In 1398 he became treasurer of England. His execution at Bristol was one of the first acts of Henry IV., and the irregular sentence of an improvised court was confirmed by that monarch's first parliament. Wiltshire's father, Lord Scrope, and his other sons were not included in the attainder, but received full pardon from Henry. Scrope, who was the builder of Bolton Castle, his principal residence, died in 1403. He was succeeded in the barony by his second son, Roger, whose descendants held it till 1630. On the death of EMMANUEL SCROPE, 11th baron (1584–1630), who was created earl of Sunderland in 1627, the earldom became extinct.

SIR GEOFFREY LE SCROPE (d. 1340), chief justice of the king's bench as mentioned above, uncle of the first Baron Scrope of Bolton, had a son Henry (1315–1391), who in 1350 was summoned to parliament by writ as Baron Scrope, the designation "of Masham" being added in the time of his grandson to distinguish the title from that held by the elder branch. HENRY LE SCROPE, 3rd Baron Scrope of Masham (*c.* 1376–1415), was a favourite of Henry V., by whom he was made treasurer in 1410 and employed on diplomatic missions abroad. But in 1415 he was concerned in a conspiracy to dethrone Henry and was executed at Southampton, when his title was forfeited. It was, however, restored to his brother John in 1455; and it fell into abeyance on the death, in 1517, of Geoffrey, 11th Baron Scrope of Masham, without male heirs.

See Sir N. H Nicolas, *The Scrope and Crosvenor Controversy* (2 vol., 1832), containing much detailed information about the various branches of the Scrope family; J. H. Wylie, *History of England under Henry IV.* (4 vol., 1884–98); Edward Foss, *The Judges of England* (9 vol, 1848–64); G P. Scrope, *History of the Manor and Ancient Barony of Castle Combe, Wilts* (1852); G. E. C., *Complete Peerage*, vol. vii (1896).

SCROPE (originally THOMSON), **GEORGE JULIUS POULETT** (1797–1876), English geologist and political economist, best known for his study of volcanoes, was born in London on March 10, 1797, the second son of John Poulett Thomson. He assumed the surname of Scrope on his marriage in 1821 to the daughter of William Scrope. Educated at Harrow and St. John's college, Cambridge, he visited Naples, Italy, as an undergraduate in 1816–17, where his interest in volcanoes was stimulated by the actions of Vesuvius. In 1821 he examined the extinct volcanoes of the Auvergne and collected material for his work *On the Geology and Extinct Volcanoes of Central France* which he published in 1827.

Scrope commenced his researches at a time when the doctrines of Abraham Gottlob Werner (*q.v.*) were still in the ascendant, but his studies were soon to play a part in their overthrow. His first work, *Considerations on Volcanoes* (1825), is to be regarded as the earliest systematic treatise on volcanology, being the first attempt to frame a satisfactory theory of volcanic action and to show the part volcanoes have played in the earth's history. He early appreciated the important part played by water in igneous action and he effectively disposed of the elevation theory of craters.

In his work in the Auvergne he demonstrated the volcanic origin of the basalts and the formation of the valleys of the region by river action. He was elected a fellow of the Royal society in 1826.

Soon after his marriage, Scrope settled at the family seat of Castle Combe, Wiltshire, eventually devoting his attention largely to social and political questions. He was a member of parliament from 1833 until 1868 and published a long series of pamphlets and reviews advocating free trade and social reforms, especially with regards to the poor law.

Scrope died at Fairlawn, near Cobham, Surrey, on Jan. 19, 1876. (C. E. T.)

SCROPHULARIACEAE, a family of seed plants belonging to the sympetalous section of Dicotyledons and a member of the series Tubiflorae. It is a cosmopolitan order containing about zoo genera with about 2,600 species; the majority of them occur in temperate regions, the numbers diminishing rapidly towards the tropics and colder regions. About 30% of the species are annual herbs, such as eyebright *(Euphrasia officinalis)*, cow-wheat (*Melampyrum*), and species of *Veronica;* more than 60% are biennial or generally perennial herbs and undershrubs, such as species of *Veronica,* mullein *(Verbascum),* foxglove *(Digitalis purpurea)*, etc., while shrubs and trees are rare; *Paulownia,* a native of the mountains of Japan, a tree with large leaves and handsome panicles of violet flowers, is grown in European gardens.

The stem is sometimes prostrate and creeping, as in ivy-leaved toad-flax *(Linaria cymbalaria)* and some of the native British Veronicas, but generally erect as in foxglove, figwort, mullein, etc.; a few are climbers as *Rhodochiton* and *Maurandia.* The South African genera *Hyobanche* and *Harveya* are parasites almost devoid of chlorophyll with scale-like leaves; and many genera are semiparasitic, having green leaves, but attaching themselves by root suckers to roots of grass, etc., from which they derive part of their nourishment; such are *Euphrasia, Rhinanthus, Pedicularis,* etc. A few genera are aquatic, e.g., *Limnophila* (Old World Tropics), and have much divided submerged leaves and entire aerial leaves. The flowers are solitary in the leaf-axils, as in *Mimulus,* species of *Linaria,* etc., or form spikes or racemes which are terminal as in foxglove, species of *Veronica,* etc., or axillary, as in *Veronica (Chamaedrys* section). The flowers are hermaphrodite, hypogynous and zygomorphic in the median plane, being often more or less two-lipped, and having five sepals joined below and persisting in the fruiting stage, five petals uniting to form a corolla of various shape, generally four stamens, the fifth (posterior) being suppressed or represented by a rudiment, while the anterior pair are longer than the posterior, and two generally equal carpels in the median plane forming a two-celled ovary containing numerous anatropous ovules on a thick axile placenta, and bearing a simple or bilobed style.

When a terminal flower is present it becomes regular as in toad-flax, where radial symmetry is produced by development of a spur to each petal—such flowers are termed peloric; all the flowers in a spike are sometimes peloric. In *Euphrasia* and many species of *Veronica* the posterior sepal is suppressed. The form of the corolla shows great variety, depending on the length and breadth of the tube—which in *Veronica* is almost obsolete, while in foxglove it is large and almost bell-shaped—and the development of the limbs, which are spreading in *Veronica,* small and almost erect in figwort, or form a pair of closed lips as in *Linaria* and *Antirrhinum.* In *Verbascum* the five segments are almost equal, forming a nearly regular corolla; the approach to regularity in the corolla in *Verbascum* is associated with the presence of five fertile stamens, but the three posterior are generally larger than the two anterior. In *Veronica, Calceolaria* and other genera only two stamens are present. Honey is secreted by a disk surrounding the base of the ovary or by special nectaries below it. *Verbascum* and *Veronica* with a short-tubed corolla represent an open type of flower with more exposed nectar; in foxglove the honey is at the base of the long tube, and a bee crawling to reach it will rub with its back the anthers or stigmas which are placed on the upper side of the bell. The closed flowers of *Linaria* and *Antirrhinum* can be visited only by insects strong enough to separate the lips.

The fruit is generally a capsule surrounded at the base, or sometimes as in yellow-rattle *(Rhinanthus)* enveloped in the persistent calyx; it opens by two or four valves, or, as in *Antirrhinum,* by pores. Occasionally it is a berry. In *Linaria cymbalaria* the fruit becomes buried by the stalks bending downwards when ripe.

The family is divided into tribes by characters derived from the number of fertile stamens present and the form of the corolla. It is well represented in Britain by 13 genera, viz., *Verbascum* (mullein), *Linaria* (toad-flax), *Antirrhinum* (snapdragon), *Scrophularia* (figwort), *Limosella, Sibthorpia, Digitalis* (foxglove), *Veronica* (speedwell), *Bartsia, Euphrasia* (eyebright), *Rhinanthus* (yellow-rattle). *Pedicularis* (louse-wort) and *Melampyrum* (cow-wheat). The best known representatives in North America are *Verbascum* (mullein), *Pentstemon* (beard-tongue), *Mimulus* (monkey-flower), *Veronica* (speedwell), *Gerardia, Castilleja* (painted cup), and *Pedicularis* (louse-wort). Common in cultivation are European species of *Antirrhinum* (snapdragon), *Digitalis* (foxglove), and *Linan'a* (toad-flax). Several genera are well known in gardens; such are *Calceolaria, Collinsia, Pentstemon* and *Mimulus* (musk).

SCRUBBIRD, the name applied to species of an Australian genus of birds and especially to *Atrichornzs clamosa.* This bird is brown above, each feather barred with a darker shade; the throat and belly are reddish-white and there is a black patch on the throat; the flanks are brown. It inhabits the thickest "scrub" and the males are noisy and imitative. A second species, *A. rufescens,* from New South Wales, is brown all over. They form the family *Atn'chornithidae* of the perching birds (Passeres).

SCRUTIN DE LISTE, a system of election of national representatives by which the electors of a department vote for all the deputies to be elected in that department, comparable to the "general ticket" in the United States (Fr. *scrutin,* voting by ballot, and *liste,* a list). It is distinguished from the *scrutin d'arrondissement,* under nhich the electors in each arrondissement vote only for the deputy to be elected in it. *See* also REPRESENTATION.

SCRUTINY, careful examination or enquiry. The word is specifically applied in the early Church to the examination of the catechumens or those under instruction in the faith. They were taught the creed and the Lord's Prayer, examined therein and exorcized prior to baptism. Scrutiny also indicates a method of electing a pope in the Roman Catholic Church, in contradistinction to two other methods, acclamation and accession. *(See* CONCLAVE.) In the law of elections, scrutiny is the careful examination of votes cast after the unsuccessful candidate has lodged a petition claiming the seat, and alleging that he has the majority of legal votes.

SCUDERY, GEORGES DE (1601–1667), French writer, was born at Havre, on Aug. 22, 1601. He first served in the army but conceived a fancy for literature before he was thirty, and during the whole of the middle of the century he was one of the most characteristic figures of Paris. He gained the favour of Richelieu by his opposition to Corneille. He wrote a letter to the Academy criticizing the *Cid,* and his play, *L'Amour tyrannique* (1640), was patronized by the cardinal in opposition to Corneille. He was appointed governor of the fortress of Notre-Dame de la Garde, near Marseilles in 1643, and in 1650 he was elected to the Academy. During the troubles of the Fronde he was exiled to Normandy, where he made his fortune by a rich marriage.

He was an industrious dramatist, but *L'Amour tyrannique* is practically the only piece among his numerous tragi-comedies and pastorals that has escaped oblivion. His other most famous work was the epic of *Alaric* (1655). He lent his name to his sister Madeleine's first romances, but did little beyond correcting the proofs.

Scudéry died at Paris on May 14, 1667. His swashbuckler affectations have been rather exaggerated by literary gossip and tradition. Although possibly not quite sane, he had some poetical power. a fervent love of literature, a high sense of honour and of friendship.

SCUDERY, MADELEINE DE (1607–1701), French novelist, sister of Georges de Scudéry (*q.v.*), established herself in Paris with her brother. She was at once admitted to the Rambouillet coterie, afterwards established a *salon* of her own under the title of the *Société du samedi,* and for the last half of the 17th century, under the pseudonym of "Sapho" or her own name, was acknowledged as the first blue-stocking of France and of the world. She formed with Pellisson a close friendship only terminated by his death in 1693. Her lengthy novels, such as *Artamène, ou le Grand Cyrus* (10 vols. 1648–1653), *Clélie* (10 vols. 1654–1661), *Ibrahim, ou l'illustre Bassa* (4 vols 1661). *Almahide, ou l'esclave reine* (8 vols. 1661–1663) were the delight of all Europe, including persons of the wit and sense of Madame de Sevigné. With classical or Oriental personages for nominal heroes and heroines, the whole language and action are taken from the fashionable ideas of the time, and the personages can be identified either really or colourably with Mademoiselle de Scudéry's contemporaries. In *Clélie,* Herminius represents Paul Pellisson; Scaurus and Lyriane were Paul Scarron and his wife (afterwards Mme. de Rlaintenon); and in the description of Sapho in vol. x. of Le *Grand* Cyrus the author paints herself. It is in *Clélie* that the famous Carte de Tendre appeared, a description of an Arcadia, where the river of Inclination waters the villages of Billet Doux, Petits Soins and so forth. The interminable length of the stories is made out by endless conversations and, as far as incidents go, chiefly by successive abductions of the heroines, conceived and related in the most decorous spirit, for Mademoiselle de Scudéry is nothing if not decorous.

In that early day of the novel prolixity did not repel. "Sapho" had really studied mankind in her contemporaries and knew how to analyse and describe their characters with fidelity and point. Moreover her novels had the interest always attaching to the *roman à* clef. She was a real mistress of dialogue. She had a distinct vocation as a pedagogue, and is compared by Sainte-Beuve to Mme. de Genlis. She could moralize—a favourite employment of the time—with sense and propriety. Though she was incapable of the exquisite prose of Mme. de Sévigné and some others of her contemporaries, her purely literary merits were considerable. Madeleine survived her brother more than thirty years, and in her later days published numerous volumes of conversations, to a great extent extracted from her novels, thus forming a kind of anthology of her work. She outlived her vogue to some extent, but retained a circle of friends to whom she was always the "incomparable Sapho." She died on June 2, 1701.

Her Life and Correspondence were published *at* Paris by MM. Rathery and Boutron in 1873. An amusing sketch of her is to be found in vol. iv. of Sainte-Beuve's *Causeries du lundi.* Georges de Scudéry is sketched by Théophile Gautier in his *Grotesques.* See also V. Cousin, La *Société française au XVII^e siècle,* vol. ii.

SCULL, a light oar with blade more concave than the ordinary racing oar and with shorter helm, thus allowing the user to hold one in each hand. *See* ROWING.

SCULPTURE is the art of representing observed or imagined objects in solid materials and in three dimensions. The field of sculpture is too vast to be conveniently covered in a single article. Therefore this short survey has been divided into sections under epochs and countries and the names of living sculptors have been omitted.

PRIMITIVE PEOPLES

Ages before the dawn of history Magdalenian cave dwellers worshiped the supernatural, and modelled animals in clay perhaps to exercise sorcery over the hunted prey. These have been preserved in the innermost recesses of the caverns of Tuc d'Audoubert in Southern France. Man, since he first smoothed the handle of his club or rubbed sharp the point of his spear, has felt the impulse to make pleasing surfaces or to render in form his impressions of the life seen about him. He made and decorated utensils, implements, vessels and ritual images.

The similarity of the primitive artisan's approach to his problems and technique in the use of the same materials leads to a related sculptural treatment in widely separated countries. Geometric forms based on the circle and the square are common to the art of all primitive peoples. The whirl, the zig-zag, the meander and the wave are elementary in nature as they are in design. The symbolization of fire, water. earth and air are found within the rhythms of these forms. The hand of man, the tool and the observation of nature, as well as physical contacts and spiritual impulses, all combined in the making of a universal pattern..

The taste of primitive man for symmetry of design. whether of Asia, Europe, Africa or America, was closely related. The carvings of a Maori canoe and the decorations on Carolingian objects in Central Europe have a resemblance in rhythmic feeling. Characteristics of sculptural symmetry and pattern crossed Asiatic seas and relate the carvings and totems of Polynesia and New Zealand to the Indian sculptures of the Americas from Alaska to Peru.

The sculptural art of primitive peoples is much appreciated in modern times. The student and connoisseur turn to it as to a fountain-head from which streamed an art, ageless in simplicity and virility. Negro sculpture from the Ivory Coast. Benin and other parts of West Africa is influencing sculptural trends in schools of art today The powerful stele sculptures, carvings from ruined temples of Mexico, Honduras, and Guatemala, and Central American pottery figures have aesthetic appeal Terra-cotta masks from Vera Cruz in some cases suggest, by subtle modelling and facial expression, the smiling angel of Reims. Chimu pottery sculptures of Peru convey impressions of amazing vigour and portraitlike reality. All these types of art appeal because of their nai've genuineness, energy and originality and are in contrast to the complex tendencies of European art. Objects which a generation ago were considered of ethnical interest only are now taking a prominent place in art collections.

EGYPT

The spiritual approach of the Egyptian sculptor-builder to his problems was influenced by the environment in which he lived; the austerity of the mountains and the vast bleakness of the desert affected his conception of form. His material approach was tempered by the hardness of the granite in which he worked and the limitation of his tools. The treatment of surface became an established formula for the working of all sculpture and even small figures carved in soft limestone or wood had surfaces characteristic of hard-material monumental sculpture.

During more than three millenniums of Egyptian culture, art obeyed the rigid dogmas of ritual representation. Based on solid geometrical conceptions, nature was expressed in architectonic form relationship within the limits of the block of granite or other material; so in the "Colossi of Memnon" on the Plain of Thebes the seated figures of the Pharaohs conformed to the rectangular shapes of the stones, while the same general formulas applied to the gigantic Sphinx by the great Pyramid. Sculpture was characterized by simplicity of form with four-sided relief surface treatment. Human proportions were adhered to with remarkable truth and the accuracy of detail accorded with the demands of a race of hieroglyph carvers. The consistent scale of the parts to the whole gave to the small statue, by proportions1 geometrical relationship, the sense of grandeur and dignity possessed by the colossal statue of the same subject.

In pre-Dynastic Egypt, sculpture was well advanced as a form of expression, developed in response to practical and religious demands. It was the custom from prehistoric times to bury with the dead, articles of domestic usage and sculptured images. The tombs of the Old Empire contained portraits of the deceased with accompanying figurines of servants and domestic animals. Examples of these interesting objects are preserved in many museums. The most important collection is in Cairo.

In the vicinity of Memphis and on the western bank of the Nile are the remains of the Old Empire pyramids, where the kings and nobles were buried. Stone structures were built above their sarcophagi. structures which, in the course of generations, evolved into the final form of the pyramid.

It was at Saqquara as early as the Third Dynasty (30th century B.C.) that sculptured reliefs on the walls of the tombs revealed naturalistic drawing of high excellence, work which was characterized by freedom of spirit, good humour and the delight of the artisan in his craft. These showed processions of slaves, men at work in the field or in the barnyard, animals, wrestlers and hunters, sail- and row-boats. Schematic rhythm of surface pattern lent dignity to the composition. These reliefs were painted in strong local colour and the carved contours served to intensify the design and the rounding of the surfaces helped impart a three-dimensional reality. In cases where the tomb was unimportant the wall was decorated in colour only and the carving dispensed with; similar to the instances in the Middle Ages when painting served to replace mosaic or more permanent and expensive materials. A stone figure of Queen Nofret of the same dynasty conveys a feeling of sensuous realism. Plaster masks from life in the Museum at

Cairo prove the desire to imitate nature. The "Seated Scribe" in the Louvre Museum is a limestone figure combining vitality and symmetry of composition. He looks up from his tablet with keen alertness, his eyes are inlaid with rock crystal, alabaster and black stone with realistic effect and are set with silver eyelids. The surface treatment of the famous "Shekh-el-Beled." the wooden image of a fat functionary, is that of hardest stone. save that the arms are made separately and attached to the body. Here again the eyes are inlaid.

The sculpture of this epoch seems to presage the attainment of artistic liberation, but the development which had reached its fullness at Saqquara was to stop with the formal conventions imposed upon it by the dictates of dogma, from whose confines it was not again to escape except for a brief moment during the period of religious revolution of Ikhnaton.

During the Middle Kingdom (2160–1090 B.C.) the wealthy kings promoted temple building on a magnificent scale. In the hypostyle hall of the Temple of Amon at Karnak the Egyptians achieved a vast and enduring form of construction, a manifestation of supremacy over materials unsurpassed in the world. The unity of the whole depended on the harmonious relationship of the parts, in which painting, sculpture and architecture were indissolubly blended. In tremendous figures the form was impressive and monumental, but the vivacity and freshness had diminished. Walls were covered with polychromed reliefs picturing kingly conquests and supernatural configurations. From the Temple of the Nile the processional avenue was flanked with closely set heroic rams in which monumental sculpture complemented stern architecture.

At Abu Simbel on the Upper Nile, Rameses II (about 1250 B.C.) cut in the living stone a temple. the facade of which conformed to the face of the cliff in which it was carved. Four gigantic figures of the king, 65ft. high, flanked the central entrance. It was incredible and marvelous and a triumph of art and engineering skill. The ceiling of the great hall of the interior was supported by colossal figures of Rameses and, true to tradition, the walls were engraved with the glories of the king and gods.

MESOPOTAMIA

In the valleys of the Tigris and Euphrates, there grew rich, martial civilizations based on agriculture—first the Sumerian, followed by the Babylonian, Assyrian, Chaldean and Persian Empires.

The excavations at Ur of Ancient Sumeria have revealed interesting sculptures of the Fourth Millennium B C. In the University of Pennsylvania at Philadelphia and in the British Museum are finely executed objects in beaten copper from Ur. representations of men and animals strikingly lifelike and of forcefully conventional form. The use of inlaid stone, bricks, metal and carved wood was common.

The Age of Sargon in the 28th century B.C., and the Babylonian Empire under Hammurabi produced pomerful and simple sculpture, disclosing an understanding of great principles of form harmony by which the human figure was rendered with dignity and robust realism.

At Nineveh the capital of Assyria (885–612 B C.) the Palace of the Kings was richly sculptured Stone friezes on the walls were carved with banquet scenes. processions of warriors. tribute bearers, incidents of battle, royal hunting parties in which dogs and lions, horses and men were rendered with virile clarity of design. Relief sculptures excax-ated from the Palace of Ashurbanipal are among the most powerful and vivid expressions of this type of art ever produced Mighty monolithic granite groups of winged bulls with human heads flanked the great entrance stairs of the palaces.

Within the limits of a geometrically shaped mass the established conventions of sculptural art were a language eloquent with authority and simplicity. The grammar of form was uncomplicated and comprised a series of simple rules and recipes for the interpretation of anatomy and the delineation of the body.

Sculptured friezes of warriors and life-like animals in stone and glazed terra-cotta at Persepolis were admirable Lions in full colour against a blue ground were modelled with swift moving lines and sensitive form, but lacked the rugged energy of the Assyrian and Babylonian work. The characteristics of design and treatment of form in these latter Southwestern Asiatic sculptures influenced the artistic taste of the Greeks.

GREECE

The civilization of Mycenae and Crete flourished from the 19th to the 12th century B.C. leaving monuments which influenced the Doric artists. The impressive Lion Gate at Mycenae shows relationship to the art of Babylon, and the excavations at Knossos have yielded treasures of small sculptures in faïence, ivory and metal. There is a famous gold cup showing men and bulls in violent action, done with a naturalistic feeling associated with sophisticated art.

A newly liberated and expanding intelligence, born of a phenomenal spirit of enterprise and curiosity in the laws of science and nature, and spurred by competitive individualism, produced a new art expression in Greece. Sculpture was its noblest flower. Architecture dealt with the problems of utility and the appropriate use of materials; in it the poetry of rhythmic form was limited to the abstractions of geometrical composition. The temple was the jewel case, the setting and frame for the glorified form of the deity it enclosed and the edifice became a vehicle for sculpture and painted decoration.

The rise of culture in Greece was extremely rapid and developed a sculptural art as remarkable as any the world has known. From crude beginnings in the 7th century B.C. in less than two centuries it attained the perfection of the Golden Age of Pericles. This beauty of expression and fulfilment may well be compared to that which occurred in the Isle de France in the 12th and 13th centuries with the fruition of Gothic art.

There was similarity between the Greek archaic frontal type sculpture and its prototype in the Valley of the Euphrates or Egypt. The sculptor had not learned to liberate the arms from the body, nor yet to turn the head on the neck or give movement to the pelvis or shoulders. Standing figures of the early 6th century B C. had a severe architectonic feeling as though carved from columns, but it was not long before the freedom-loving Greek artist reached out to solve the problems beyond which Near-Asiatic and Egyptian art had not advanced Although imitating the style and the technical procedure of their predecessors, Greek archaic sculptors later in the century gave movement to their figures and new concepts of composition appropriate to their advancing intellectual and social liberation.

The abundance and beauty of the marble of Greece, Ionia and the Islands of Paros and Naxos, veritable mountains of marble, gave the sculptors a material the working of which they soon mastered.

With the building of the Siphnian Treasury at Delphi (530 B.C.) sculptural decoration of architecture advanced in originality of conception and freedom of style, though still archaic and not completely liberated from Asiatic traditions. The caryatids which support the entablature of the facade are statues of luxurious rhythms and sensuous forms. The building, although small. is a rare masterpiece of harmonious unity in which sculpture complements the abstract beauty of the architectural proportions. The frieze of the entablature carries figures of gods, horses, chariots and warriors and is one of the great sculptural compositions surviving from that age The drawing of the horses has movement, virility and essential feeling of nature; the design has clarity, spirit and distinction in its ensemble, as well as consummate rendering of detail The ornamental motifs on the mouldings are carved nith the same consideration for beauty of form as the figures themselves. Belonging to the same type as the caryatids of the Siphnian Treasury are the "Smiling Maidens" of the Acropolis of Athens, which were presumably erected as votive offerings and date from the time immediately preceding the sacking of Athens by the soldiers of Xerxes They are of a robust beauty and charm, though archaic and belonging to the class of frontal figures.

Archaic sculptors yearned to give their figures a sense of reality which their limited form conventions restricted, so they added colour, and many early statues were embellished with earth pigments, leaving the flesh parts in the warm tones of the marble, in effect very much like the vase figure paintings of the period. In some marble images there is evidence that the ears were pierced to receive metal earrings. These sculptures seem animated with an inner life, testimony of the struggle within the artist to liberate himself from the limitations of static and geometrical abstractions and to achieve within the planes of his material the aspects of reality. The application of polychromy to attain naturalism was common to the primitive sculpture of America, Egypt, China and Romanesque Europe When imitation of nature had been mastered, the sculptor dispensed with these accessories.

The sculptors of the pediments of the Temple of Aphais at Aegina (500 B.c.) though still of the archaic period, emancipated themselves to the extent of being able to turn bodies in any desired position and give them attitudes of activity and struggle. It was in the rendering of facial expression that the archaic mannerisms persisted.

After the defeat of the invading Persian armies of Darius and Xerxes (490–479 B.C.) the exaltation of Greek genius knew no bounds and found expression in masterpieces of art, poetry, philosophy and science. Rapid colonial and economic development brought wealth which furthered the building of sumptuous temples, of which the Temple of Zeus at Olympia and the Parthenon at Athens were the most magnificent.

Pheidias, director of art and an indelible influence upon the Athens of Pericles, created for the sanctuary of the Parthenon a colossal statue of Athena (chryselephantine) made of various coloured materials—ivory and gold predominating—a mighty jewel, majestic in conception, noble in execution and masterly to the smallest detail. It was destroyed centuries ago but was described by Pausanias and is known to us in feeble copies. The pedimental architecture of the temple was the frame wherein gods were humanized and heroes deified in compositions of eternal beauty. The groups of the metopes and the continuous reliefs of the friezes were accents and ties in the great rhythms of abstract architectural and natural sculptural forms. In all these the genius and controlling spirit of Pheidias are felt. The harmonious carving of mouldings and architectural details attest the perfect collaboration of all the workers The head of a statue, the detail of a foliated moulding or the fluting of a column were carved with harmonic appropriateness like that of great musicians playing in a noble symphony.

Ancient commentators considered the Olympian Zeus of Pheidias the finest fruit of his genius and the greatest masterpiece of Greek art. The statue, seven times life size, executed in gold and ivory and seated on a throne elaborately sculptured and inlaid, was the embodiment of benign majesty. Unfortunately, it has been destroyed. In the opinion of many, the pediment groups of the Temple of Zeus at Olympia, together with the great figure within the structure, were the highest peaks of achievement which Greek sculpture attained, combining consummate knowledge, nobility of characterization and unity of form rendered in harmony with the materials in which they were worked. Within the compositions of the pediments and metopes marble figures moved in noble posture, detailed but harmonious in relationship; each item took its place in the rhythm of the ensemble. Figures of gods and men, centaurs, lapiths and amazons moved in varied attitudes of complete emotional appropriateness. The human body has never been more nobly conceived or more imaginatively and intelligently interpreted, all rendered in three-dimensional plastics, powerfully simple and with the feeling of inner life.

The cult of bodily perfection found expression in physical culture and athletic contests. Bronze and marble figures of athletes were typical of Hellenic art and of a race which exulted not only in athletic prowess, but in the study of anatomy and the mysteries of nature. The "Charioteer of Delphi," a life sized bronze figure, part of a group erected in commemoration of a Syracusian Olympic victory (462 B.C) is one of the most perfect examples of bronze craftsmanship from any period or country and comparable in technical skill to those of the great periods of Chinese art. The hands and feet are realistic to a degree and the posture of the body suggests subtle movement, the folds of the long garment fall in lines like the fluting of a column. It is exquisitely finished in every detail. The eyes are inlaid and the eyelashes are executed in separate hairs of bronze, while the ribbon around the head is inlaid with a silver meander. Far from diminishing the feeling of simplicity or giving a sense of over-refinement, this elaboration enhances its beauty. As early as the 6th century, Doric artists produced figures of the discus thrower, a type which was later carried to noble heights by Myron, whose "Discobolos" is an outstanding masterpiece. Primarily a worker in bronze, Myron's statues have survived in Roman marble copies. He was a contemporary of Pheidias (middle jth century B.C.) as was Polycleitus, another of the renowned sculptors of the athletic school.

Praxiteles (b. about 380 B.C.) carried sculptural freedom to personal and emotional heights. Form mas suavely and loosely modelled. Marble was rendered with soft and delicate naturalism. Elegance and sensuous grace replaced the rugged virility of the preceding century, as the slender and ornate Corinthian order, feminine in its beauty, contrasted with the sturdy Doric column, masculine and simple. In the "Hermes with the Infant Dionysus" at Olympia the world possesses an original marble by Praxiteles of greatest beauty.

The Hellenistic period following Alexander the Great (323 B.C.) saw the direction of sculpture continue in the path to flamboyant freedom-exemplified by the Altar of Zeus at Pergamon (175 B.C.) now at Berlin, in which grandiose and contorted deities and giants srruggle in controlled composition. As with the sculptors of Baroque Italy, marble presented no problems but was made to obey complicated emotional and physical design. Technique had mastered the material and thereafter the decline of art was rapid.

ROME

At the time of the Roman conquest Greek art had lost its vigour. Centres of Greek culture were looted and hundreds of bronze and marble statues were sent to ornament the gardens and palaces of Rome. Greek artists were put to the employ of Roman masters, whose lower cultural standards were easily satisfied. Native Roman carvers imitated the Greek manner and produced copies of Greek masterpieces. Quantities of portrait statues and busts were made which under the emperors attained a degree of merit in that field. The sensitive appreciation of form relationship and design was gone. The marble sculpture was colourful with deep cut folds of drapery, oftentimes of complicated composition and lacking structural solidity. The cities of the Roman Empire were elaborately decorated mith sculpture as attested from excavations. In the minor arts, Pompeiian bronze statues reveal considerable humour, charm and delicacy.

INDIA

Great periods of art were born of the mystical forces of religion —Christianity in Europe and Buddhism in Asia—while in Greece the urge was not only that of religion, but of spiritualized adventure searching for nature's truths and those of art, harmony and beauty.

Alexander's conquest of northern India left in its wake a Hellenistic imprint of technical mannerisms which were superficially assimilated in the prevailing style, noticeable especially in the sculptures of Gandhāra and the excavations in Afghanistan (Guimet Museum, Paris). The latter were Graeco-Buddhistic, strangely reminiscent in many details of form and facial expression of florid European art. Together with that Hellenistic feeling grafted to the Aryan Hindu stem was the branch derived from the Persian.

Characteristic of Hindu art was the translation into stone of structural forms which originally must have been suggested by wood construction. Forms were richly undercut and rounded and gave the impression of having been produced in a soft material, even though carved in hardest stone.

Early examples of this style were the gates of the Sanchi Stupa (3rd century A D) in which the story of Buddha was carved in relief with figures of men and women, elephants and lions, winged beasts, birds, trees, architectural motifs and plant ornamentation. Not only in richness of decoration was the fertility of Hindu nature felt, but also in the sensuous treatment of individual figures and forms. The female figure was rendered with voluptuous fullness rather than with the idealized contours of Greek art or with the cold impersonality of the Egyptians.

The idealistic theology of Buddhism was gradually lost in the renascent faith of the Trimūrti (triple aspect God—Brahma, Vishnu and Śiva). Aryan invasion brought their racial legends to the uplands of India and the epic stories of the Mahābhārata and the Rāmāyaṇa became incorporated into the pantheism of Indian faith and constituted a rich section of the background of Hindu art, comparable to that of the epic poems of the Iliad and Odyssey in Greece.

Typical of racial or religious art expressions in all great epochs is the dominance of formulas on the attitude of the sculptor toward his material and technical approach to his subject matter. The strict reproduction of natural forms was not usual in India, but emphasis was placed upon the interpretation of spiritual values. The human figure was rendered in canons of proportion conforming to the abstract requirements of religion and philosophy. So the seated Buddha may be represented in profound meditation, or in a gesture of cosmic serenity in which the sculptural treatment is one of extreme simplification of form. The shoulders are broad and the waist slender; the head arbitrarily ovoid and the expression of the face benign and introspective. The Buddha may be draped with a delicate tracery of folds closely adhering to the body, suggested rather than materialized. Anatomy is reduced to essentials. Again the figure may be seated against a stele-like background on which are lightly carved symbols of his divinity and small-scale Bodhisattvas in postures of placidity with the attributes of the progressive stages to the attainment of Nirvana.

Indian sculpture reached great heights in the Saivaites cave temples. The Saivaites were believers in the ascetic ideal and their rock-hewn temples of Ellora, Elephanta and Ajaṇṭā, dedicated to Śiva. were monuments of incredible human effort. Living rock was carved inside and out in great architectural ensembles. Their temples of the 5th to 8th centuries are overwhelming in the elaboration of figures and ornament, revealing a magnificent conception of their deities. Granite walls vibrate with figures in violent gesture or seated in calm repose; attendant maidens and adorers observe the dance of the titanic Śiva, executed in high relief. The mysticism of the Indian world found expression in vast creative power. mastery of material forms and the spiritualization of the elements of nature. On the sides of gigantic rocks at Miimallapuram sculptors carved in imposing disorder a myriad of figures depicting episodes from the Mahābhārata; figures in all conceivable postures; spirits of the world beyond; fearsome monsters and wild beasts; great elephants and birds; gods and demons —materialization of the imaginings of a race nho looked for their inspiration to the spirit rather than to the incidents of external fact. A just relationship was maintained between the spiritual realm and the material universe. Unknown sculptors u-ho fashioned these works in the living granite equalled in power of visualization and bold technical skill any monumental achievement of man. Though executed with ritual formalism, they are full of creative vigour and have none of the over-elaboration and flaccid detail characteristic of later periods of Indian art

At Koṇārak in Orissā and Mudhera in Gujarāt (11th to 13th centuries) the Vaishnava cult built great sun temples to Vishnu. Although in a state of ruin they are magnificent monuments of architecture and sculpture. Heroic stone elephants and war horses stand by the Temple of Koṇārak, executed in rotund conventionalized masses and mark the eminence to which animal sculpture was carried by the Hindus. The luxuriance of nature's forms is reflected in art, and sculptural groups and figures throng the temples with the orderly profusion of the crowds in the market place. Temples of the 16th and 17th centuries abound in exaggerated decoration, hosts of superimposed sculptural figures adorn their edifices and, as in the case of the decadent periods of all great art movements, technical facility replaces inner spiritual significance.

The Indians attained great mastery in the working of bronze, while they retained the superficial conventions and mannerisms of stone and wood sculpture, the ad antages of the tensile strength of metal was skillfully employed and in bronze chasing they carried elaboration to the ultimate degree.

As a result of India's colonization of Java, a peaceful state far removed from the strife of the mother country, Buddhistic sculpture reached maturity exemplified in the great shrine at Borobudur (9th century). It is described as the most magnificent monument of Buddhistic art in the whole of Asia. The central motif is surrounded by terraces and galleries sculptured with a wonderful series of bas-reliefs, the total length of which is nearly three miles. This work must' have occupied hundreds of artists over a period of several generations; it depicts scenes from the life of Buddha and the legends of his reincarnations—more than 200 panels in all. The subject matter is sympathetically rendered and the simple, straight-forward artistry of these reliefs may be compared to the best in Gothic art. The figures are small in size and sculptural detail is treated with reverential care. The whole great work emanates a spirit of eternal peace, contrasting in gentleness and grace with the more turbulent art of India. The compositions are not formally arranged! but seem to be the inspired result of spontaneous exuberance.

The city of Prambanam in Java was famed for its prosperity and about the 11th century a great temple was dedicated to Vishnu. The malls of the courtyards were carved with legendary scenes from the Rāmāyaṇa. Although a masterpiece of Indian art, it lacks the compelling simplicity of the sculptures at Borobudur. In Cambodia, Khmer sculptors created monumental groups and covered vast walls with animated reliefs: stories of the Mahābhārata, on the magnificent temples at Angkor (9th to 12th centuries).

CHINA

Sculpture occupies a most important part in the vast field of Chinese art. The objects remaining from the ancient culture of the Shang and Chow dynasties are for the most part ritualistic objects, libation urns, ceremonial bells and vessels, rather than figure sculpture. Many European and American museums possess fine examples of Chow bronze sacrificial urns; often in the form of animals. The ornamentation of the vessels or bells sometimes carries abstract representations of the birds and beasts of Chinese mythology. In surface treatment these objects are remarkable and in the realm of bronze sculpture nowhere has the mastery of material been brought to a fuller and more perfect expression of detail. This technical excellence and pride of workmanship persisted from the earliest periods of Chinese art to recent times, but the inspired perfection of the early Chow vase has remained unsurpassed in spirit or quality.

Art is measured by waves which rise and fall depending upon appreciation of the particular type of culture and the purity of its expression; thus is charted the rise and decline of Egyptian, Greek or Gothic art and the millenniums of culture in China have been marked by corresponding waves of artistic achievement. The sculpture of the Six Dynasties and the T'ang period carried the crest to its highest point of spiritual exaltation and artistic excellence.

The Han period (2nd century B.C. to 2nd century A.D.) produced many masterpieces of sculpture, among nhich are tomb bas-reliefs in stone showing mythological figures and animated scenes of contemporary life; strange animals leaping at high speed, men on horseback or in chariots, depicted with realism and fertile imagination. Objects of preciously wrought metal; bronze inlaid with gold and silver; carvings of abstract design; animals and fantastic dragons; finials of ceremonial staffs and decorations of chariots, indicate the creative imagination and high artistic standards of the time.

The element of time in the production of the work of sculpture was of no great importance as compared to that of quality of execution. The sculptor spent years working a block of jade, transforming it into mythological figure or beast or a composition of abstract design.

With the spread of Buddhism from India to China in the jth century, stone sculpture received powerful religious stimulus. Buddhist monks carved the walls of the grottoes at Yun Kang and Lung Men with myriads of figures of all sizes from the colossal to the miniature, representing Buddha and his attendants and the world of unreality. In this movement sculptural art developed highly in one part of China and remained relatively stiff and archaic in another.

Chinese art was subjected to Indian form conventions, Buddhistic philosophy and ideographic symbols. The benign serenity of the images of Buddha and his attendants is akin in Indian and Chinese sculpture. The Alexandrian influences upon Indian sculpture found their way via Gandhāra, across the Gobi Desert and the mountains and valleys to be reflected in the art of China. The imprint of a remote, indigenous tradition was apparent in the imagery of mythological scenes, in the fantastic forms of contorted dragons, in the rendering of flames and clouds and in that of mountains and water. This sculptural symbolism in the 6th and 7th centuries was vital and impetuous and in spiritual significance was comparable to 13th century Gothic.

The Chinese did not idealize the physical development of the human form as did the Greeks or the masters of the Renaissance. but rather symbolized through abstractions those qualities to which man aspired—qualities of the soul and imagination rather than of palpable fact. At the same time the sculptor was most ingenious in solving the problems of representing nature. He knew how, without destroying the basic form of a cube or rounded mass, to construct within its confines fantastic animals, moving in broad curves from side to side and composing harmoniously from every point of view. In his mastery of the medium of terra-cotta, the T'ang sculptor arrived at amazingly unrestricted freedom of expression. Realistic life-sized pottery figures of sages, glazed and in full colour, are among the masterpieces of this period. Terra-cotta horses, men, camels and grotesque animals, executed with an audacious sense of reality, were buried in tombs.

Emperors and great generals raised monuments to their followers or to commemorate a victory. Typical of these were the battle horses in bold relief on slabs of dark stone set into the tomb of the Emperor Tchao-Ling, and avenues flanked by heroic monolithic images of animals and men lead to the tombs of the emperors.

The sculpture of the Sung Dynasty (960–1280) represents advanced investigation into naturalistic treatment in which the rugged virility of early forms was softened and replaced by a calmer and more charming expression. Interest in technical proficiency was substituted for religious zeal with its sterner silhouettes and harder carving Sculpture was produced as an essential part of the cultural life of the people and in great quantity. Stone, terra-cotta in uhich colour was happily used, bronze of fine finish, and jade and semi-precious materials lent themselves to highly polished surfaces in which the patient Chinese delighted.

The great tradition persisted with ever-diminishing force and quality until but a shadow remained of one of the finest and longest art manifestations the world has known. The machine age and quantity production will doubtless change its form and may destroy its soul.

ROMANESQUE AND GOTHIC

During the Dark Ages which followed the dissolution of the Roman Empire, sculpture was little practiced and such examples of that period as remain are interesting for their crude simplicity. Under the Byzantine Empire in Asia Minor the art was principally that of bas-reliefs in beaten metal and carved ivory for church decoration.

In 11th century Europe, as the church grew richer, its buildings became more important and with the development of architecture based on crude interpretation of Roman structure, a need was felt to humanize and embellish the masonry. French sculptors were developing skill in handling the materials of their craft. The subject matter, dictated by the church, was influenced by the graphic style of manuscript painters. The treatment of form, as in all primitive sculpture, concerned itself with simple masses and low relief surface carving.

Along the great pilgrimage route from Tours in France to St. James at Santiago de Compostela in Spain a series of shrines and churches were erected (12th century). The marked similarity between the carvings on these edifices is evidence that the same sculptors worked in various localities and went from one country to another.

The sculpture of Spain and Southern France was influenced by Moorish sources, especially noticeable in the interesting monastery at Silos, where the handicraft of the individual carvers showed itself on the capitals in the cloisters. These were rarely duplicated in design and many showed Saracenic tracery and pattern. At Moissac (A.D. 1100) in France the capitals also varied in subject matter from boldly executed Old Testament figures to grotesque animals, birds and interlaced foliated ornament with evidence again of Saracenic craftsmanship. The southern portal of the Moissac church is remarkable for the imaginative beauty of its carving In the tympanum, Christ nith symbols of the Evangelists and the Elders of the Apocalypse are modelled in bold relief with nobility and variety of attitude. The effect is at once pictorial and decorative, as well as sculpturally solid. The lintel of the portal is supported in the centre by a column or trumeau richly carved and crossed with lions and figures The sculptor had freed himself to a considerable degree from technical restraints and was learning to interpret tangibly his emotional urge. Forms were rhythmical, decorative and powerful, although still somewhat abstract and conventional. Artists mere striving to achieve the realities of nature.

Religious enthusiasm animated the sculptors working in Burgundy to create the stirring compositions on the Cathedrals at Autun (1130) and Vezelay. The figures of the tympanum at Autun are drawn with a strange elongation in the manner of the illuminators and calligraphers, or suggesting the style of Buddhistic stele sculpture Drapery is draun with long sweeping parallel or fluted folds, carved in fine harmonious masses and detail, expressive of elegance combined with crude strength. The style was free and aspiring, though held uithin the dogma of Catholicism. Always searching for new and more revealing forms, the sculptors sought to correct their limitations of style and expand their knowledge in the pursuit of truth.

Christian fervor expressed in the ecclesiastical buildings in Western Europe found its counterpart in the great wave of religious enthusiasm which swept toward Islam with the first crusade (1095) and monks and clergy returning from the nars brought new ideas of architectural forms and decorative motifs.

In the third quarter of the 12th century France saw the building of the great cathedrals at Chartres and Bourges. With the religious fervor of the people, architecture sought to surmount the limitations of primitive construction; artisans worked joyfully for the glory of God with pride in their creations; they strove to surpass in nobility and beauty churches previously erected; sculptors banded together in guilds and worked in happy co-operation. In the cathedral of Chartres, as in the Parthenon at Athens, there was the intelligent collaboration of the sculptor, the painter and the architect, united by a common impulse. Art arrived at its noblest expression under the exaltation of spiritual or religious inspiration, as in Buddhist China and India, in Greece and Egypt, and then in 13th century Christian Europe.

The western portal of the Chartres cathedral was of late 12th and early 13th century construction and the figure sculpture obeyed the laws of primitive stylization; it was inspired and decorative. but not yet freed to conform to the proportions of nature. Drapery in long vertical folds echoed the rhythms of fluted columns. Architects were learning that the pointed arch allowed them to build more lightly, higher and stronger, but their masonry mas still earth-bound by the restraints of Romanesque tradition. The carving of friezes on lintels and of figures on arches and tympanums had, within the limitations of archaic forms, living structural unity and beauty of detail. The sculptors sought to outdo each other in inventing new forms, giving new gestures to their figures and enlivening the facial expressions.

Enthusiasm for the beautification of the church structure together with competitive achievement in artistry, contributed to the fulfilment of Gothic art. That culmination was developed in tno or three generations and became manifest in the north and south porches of Chartres cathedral where eventually 10,000 figures were carved or painted; in the sculpture of the cathedral of Notre Dame in Paris (1163–123j); in the cathedral of Reims (1211–90) and in the cathedral of Amiens (1220–88).

Together with the usual subject matter of the church, the sculptor devoted himself arduously to the study of nature and in some of the figures of the western portal at Reims there was a reality and suavity of movement comparable to that of the great art of Greece. Mouldings and capitals were carved with elaborately designed foliated motifs in widely varied application.

The influences of French architecture and sculpture of the 13th century spread throughout Europe to Germany. Belgium, England and Spain. It was conspicuous in the churches of Bamberg, Bruges and Wells, also in Burgos and the south portal of the Leon cathedral in Spain. Figures were carved in lively attitudes, freely translating the movements of the human body into stone.

In the sculptural carvings of the cathedral at Reims were figures from the scriptures and legends of the saints; of men and women toiling at seasonal agricultural occupations; the personifications of the virtues and vices as well as allegories of the arts and sciences; fantastic representation of mythological animals, and decorative elements derived from plant life. There was a wealth of subject matter harmonized to architectural decoration, unsurpassed except by the lavish temple embellishment of the Hindus and Chinese. Hundreds of artisans were employed in the execution of the rich adornment of the cathedrals. Aside from ecclesiastical sculpture the artists created many beautiful tombs and memorial statues in wood, ivory, bronze and marble.

ROMANESQUE AND RENAISSANCE IN ITALY

Italy is the country of Europe most rich in sculpture. The galleries and museums in its cities abound in treasures; its churches from mediaeval times to the present are adorned with statues; and in remote villages and forgotten byways unexpected relics of the Middle Ages and the Renaissance amaze and delight the traveller.

The builders of churches in mediaeval Italy turned to the ruins of temples and buildings of ancient times as quarries from which to procure materials; columns and entablatures were transported to new settings and it followed that the carver. wishing to carry on the embellishment of the building, imitated the character of the ancient fragments already incorporated. The development of this Romanesque architecture persisted through the centuries, for the Italians rarely made their buildings integrally Gothic.

Outstanding constructions of the late 12th and early 13th centuries included the cathedral at Pisa, decorated about 1180 with fine bronze doors by Bonano Pisano, in which the conception was Romanesque in spirit and the style of composition apparently inspired by that of the mosaicists. It is a combination of high and low relief, with panels nailed to the wood door framed with ornamental bands rich in decorative play of form.

A generation or two after the anonymous sculptors of the magnificent portals of Reims and Chartres. Niccola Pisano, called the Father of Renaissance sculpture, imposed a contemporary Gothic spirit upon the forms of a complicated and decadent Roman art. In his carvings of the pulpit in the baptistery of the cathedral of Pisa (1260) he incorporated in his design figure panels in high relief, in which the subject matter conformed to the requirements of Christian theology, but the composition and style of his carvings mere taken directly from Roman sarcophagi.

Pisano's son, Giovanni (1250–1320), while continuing to work in the traditions of his father. departed to a degree from the imitation of Roman forms and developed more in the style of northern contemporary art.

On the south doors of the Florence baptistery Andrea Pisano (c. 1270–1348) created 28 panels dedicated to St. John, bronzes of great elaboration and high technical finesse, admirable in decorative feeling and rich surface treatment. At this period the development of sculpture swung high on the upward curve to full flower of the Renaissance

The beautiful Pisanesque reliefs on the façade of the Orvieto Cathedral (about 1300) were the blossoming of the Gothic branch grafted to the trunk of Italian tradition.

Giotto (1267?–1337) was architect, painter and sculptor. He built the Campanile in Florence and with Andrea Pisano carved many of the figure panels on its sides. These panels are beautiful, sensitive and pure in religious feeling.

Andrea Orcagna (d. 1368) made the wonderful tabernacle in the Florentine Or San Michele, an outstanding example of consummate craftsmanship in richly-combined coloured materials and mosaic background, with bronze effectively employed in the surrounding grille.

Jacopo della Quercia of Siena (1374–1438) evolved from the tradition of the Pisani. His works were original, robust and imaginative. His sculptural compositions inspired Michelangelo in a later generation to the fulfilment of the Renaissance. He carved figures of transcendent beauty in the fountain at Siena and especially in the monument of Ilaria del Caretto in the Cathedral of Lucca. The relief panels of the portal of San Petronio in Bologna had an intensity and breadth of modelling which marked them as masterpieces of the period when the late Gothic style merged into the Renaissance.

Lorenzo Ghiberti (1378–1455) made the north and east bronze doors of the Cathedral at Florence. The first pair were panelled in the balanced pattern of the Pisano tradition, though freer in line and richer in movement. The second ones, considered by Michelangelo worthy to be the "Gates of Paradise," were outstanding masterpieces of the Renaissance and represented great achievement in the art of bronze sculpture. Starting at the age of 47, he devoted 27 years to their creation. In spirit with the prevalent scientific research, Ghiberti solved in the panels of the doors, many problems involving figure composition and perspective. They were pictures in relief of graphic scriptural scenes idealistically interpreted with accessories of rocks, trees and edifices receding within the frame. While lacking the clarity of the earlier style, their dramatic intensity carried art to a new perfection.

The proficient Donatello (1386–1466) vastly enriched the world by his genius. He dominated the early Renaissance. His consummate technical mastery, together with his impulsive and adventurous nature gave him full freedom of expression; his gay and wholesome imagination, his power of visualization and sense of movement are qualities which combined to make him comparable to the Greek Myron. He went to Rome with his friend Brunelleschi to study the classics and dig in the ruins of antiquity and returned to work with him in the building of Florence's great cathedral; but his studies of the works of the ancient sculptors did not in any way hamper his personal style, for he loved nature and understood it intuitively. Donatello embellished the cathedral with vitalized statues and carved a singing gallery with a frieze of dancing putti, gay, original and spontaneous. In many of his works children are used as main themes or accessories, in which he captured their joyous purity, emotion and charm and established a precedent to which later Renaissance sculptors turned but never surpassed. Of the statues made for niches of the façade of Or San Michele, the marble St. George is an eternal masterpiece.

The Renaissance Tuscan school produced many fine sculptors. Desiderio da Settignano (1428–64) was conspicuous for the subtlety of his surface modelling and the charm which he gave to facial expressions. Realism, delicacy and vivacity characterized the work of Mino da Fiesole (1431–84) and Benedetto Rosellino (1427–78). One of the most distinguished artists of the school of portrait sculpture was Francesco Laurana (about 1425–1502) whose works reached heights of beauty and realism. Splendid examples of this period are in the Bargello Museum in Florence. Contemporaneously the inheritors of Donatello's more vigorous style were working in Florence. Antonio Pollaiuolo (1429–98) and Andrea Verrocchio (1435–88) were forceful sculptors. Their work was characterized by nervous contours and muscular movement. Verrocchio's masterpiece was the bronze equestrian statue of Colleoni in Venice. The martial rider arrayed in the sumptuous armour of the period is mounted on a powerful stallion in forward stride. The bronze is a splendid example of elaborate finish of detail upon boldly modelled forms, monumental and imposing in its ensemble and is considered one of the finest equestrian groups of all time. The pedestal which it surmounts is an excellent example of appropriate architectural setting.

The sculptor of the Renaissance was generally architect and painter; hence the perfection with nhich he developed the settings for his statues, whether the base of a portrait bust, the pedestal of an equestrian statue or the architectural background of a tomb The design and execution of architectural detail was done with the same care and feeling as the important sculptural element. With Florentine sculptor-architects, backgrounds often became overcharged with elaborate mouldings, festoons and ornate carvings which reduced the scale of detail to make the architectural parts seem covered with lace; the vigorous stem of the plant had become obscured in the richness of the foliage.

Luca della Robbia (1400–82) carried the new technique of glazed terra-cotta to a high development, specializing in ecclesiastical and architectural decoration. His nephew, Andrea, with his sons, also worked in this sculptural material and hundreds of pieces were produced in their studios.

Art through the Gothic period had been practical in its application. Statues were rarely made which did not serve as decoration of churches or other edifices, or objects for utilitarian purposes. In the Renaissance, Greek and Roman literature were translated into Italian; antique statues and monuments were excavated; princes made collections of paintings and sculptures; scientific investigation and broadened mental vision engendered skepticism and pagan subjects increasingly replaced episodes from the Scriptures and the lives of the saints. With the gathering of ancient art works, collectors began to stress purely aesthetic considerations and "Art for Art's sake" came into being. Sculptors made small decorative groups, charming in their imagery and good humour, in which they delighted to demonstrate their skill in composition, their knowledge of anatomy and ability to render mythological and romantic themes.

Michelangelo (147j–1564) was brought up in the studios attached to the court of Lorenzo dei Medici and worked as a boy under Verrocchio. The collections of Lorenzo inspired the youth to study and imitate the antique, yet his "Pieta" in St. Peter's was a masterpiece of Gothic sculpture, in which the details of drapery were executed with the technical recipes of that style; but his "Bacchus" and "Cupid," statues of the same early period, were conceived in the classical manner. His heroic marble "David" done at the age of 26, was a triumph of anatomical knowledge executed with the mannerisms of local traditions with a superimposition of antique influence, plus his own indomitable personality. This impatient and impetuous genius quickly assimilated the lessons of his masters; his versatility in the arts was such that he comprehended the perfect relationship of detail to ensemble and one medium to another. He was as great a draftsman as the world has known, if draftsmanship means the ability to represent that which the mind envisages, co-ordinated with the hand as perfect instrument. He quickly grasped the possibilities of movement within the human figure, with him never a literal rendering but always heroically ennobled His scientific mind understood the complicated anatomy of drapery and of the body, of engineering as well as the structure and subtleties of architecture. His mighty intellect was subordinate to his emotions. His nature was turbulent, his temperament audacious and his imagination fertile. Though physically powerful, the conflict of these qualities and external circumstances prevented his carrying out his many dreams and projects and so in sculpture he has left many unfinished masterpieces. He completed several figures on the tomb of Pope Julius II, an elaborate commission, but only sketched others. The "Slaves," details of this work, are most honoured treasures in the Louvre Museum in Paris. The marble "Moses" (S. Pietro in Vincoli, Rome), also part of this composition, is vibrant with emotion and of noble gesture and majestic mien It seems to pertain to the realm of the supernatural. The statues of "Juliano," "Lorenzo dei Medici," "Day," "Night," "Morning" and "Evening" were idealized representations of supermen and heroic women and were part of the incompleted Medici Tomb in Florence.

The magnetic influence of Michelangelo's genius created a host of imitators. With them muscular development became inflated exaggeration and the heroic gestures of the master oftentimes became bombastic and artificial.

The period of Baroque art was in full career. The new school led by Michelangelo derived its architectural forms from classical Roman examples. The pointed arch was despised. Flamboyant Gothic of the preceding period had become overcharged with detail and weakened in structural lines. Sculptur had lost its spiritualizing religious impulse and had become mere decoration carrying elaboration to extreme and meaningless detail. The new classical style demanded a simpler architectural and sculptural ensemble, composed of fewer and larger elements. As architect of St. Peter's in Rome, Michelangelo increased the scale of structural orders to heroic dimensions and surmounted the massive edifice with a dome worthy of the materialism of the period and the grandiose aspirations of the designer. The size of the sculpture was augmented to harmonize with the proportions of the building. Baroque sculptors delighted in creating a world of marble giants.

Benvenuto Cellini (1500–71) was primarily a goldsmith and metal worker. His bronze figure of "Perseus" in Florence demonstrated his great artistry.

THE BAROQUE

Gothic and Renaissance taste demanded adherence to the canons of established proportions, both in architecture and sculpture, in which the scale of figures and detail maintained sizes proportionate to those of man. The sculptured saints and personages who decorated the facades of the Christian edifices were intimate and personal conceptions related socially and culturally to the people of the locality.

The shape of the block was sensed in figure sculpture of the early periods, but the expansive spirit of the 17th century seemingly disregarded the organic structure of marble. The path to artistic freedom had been cleared by Michelangelo, whose heroic energy had removed restraint from individual expression. Fewer decorative elements were used in architecture but the size of these was enormously increased and exaggerated depth of carving and undercutting gave dramatic emphasis and strong effects of chiaroscuro.

Giovanni da Bologna (1524–1608) was a classicist of the school of Michelangelo and an artist of vivid imagination as well as a technician of remarkable excellence. He treated form with rich fullness and vigour and was successiul with the problems of spiral composition. The suriace of his sculpture mas finished with a sensuous suavity comparable to the best of Hellenistic art. Characteristic examples of the heroic art of this sculptor mere the marble groups the "Rape of the Sabines" and "Hercules and Centaur," in Florence, and his "Neptune Fountain" at Bologna.

Giovanni Lorenzo Bernini (1598–1680) was the genius who carried the Baroque style to its fullest expression. He was architect as well as sculptor of the magnificent exedra of the Piazza of St. Peter's in Rome. Its colonnade is surmounted by a series of 162 figures of saints, according in dramatic flamboyance with the grandiose architecture which they crown. His marble portraits reflect the pomposity of the period while imbued with vitality and impressive qualities of resemblance. In his group "Apollo and Daphne," executed at the age of 17 with unbelievable mastery over marble, he made the figure seem to move freely in space. The realities oi material structure were skillfully concealed in disregard of an ancient principle that a marble carving to be properly expressed within the block, should be able to roll down hill without breaking any part and that the modelling should be contained within the marble to recognize the structure of the material. Bernini depicted "Daphne" turning into a laurel tree, whose naturalistic leaves were largely detached from one another, with a technique appropriate to metal, such was his desire to demonstrate his complete mastery of medium. The "Fountain of the Four Rivers" in Rome was a triumph of fantastic imagination and superb technical achievement in which dramatic effect was paramount and the elements of composition ireely organized. Marble draperies fly about his figures in flamboyant folds, deeply cut to give violent shadows. His art expression lacked sobriety and the material supplanted the spiritual. The technique of art became an end unto itself, whereas in periods of sculpture's noblest manifestation excellence of craftsmanship was subordinate to the spiritual impulses of the race or religion. Bernini worked in Paris for Louis XIV, where the taste for the Baroque was current. However, in France that style was not carried to the extreme reached in Italy and the classical Renaissance tradition evolved with minor distortion and exaggeration.

16TH-17TH-18TH CENTURY FRENCH SCULPTURE

Jean Goujon (1520–66) carved the "Fountain of the Innocents" in Paris in the gay spirit of the late Renaissance. Charm of feeling, delicacy of modelling, sensitivity to decorative relationships, rhythm and grace were the qualities which marked his sculpture.

Puget (1622–94) and Girardon (1628–1715) worked in the Baroque manner of Bernini and executed many admirable portraits and figure compositions in marble.

In the middle oi the 18th century, art returned to greater sobriety. The style of Jean Antoine Houdon's (1740–1828) sculpture was unpretentious, though influenced by the traditional Baroque mannerisms.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, NEW YORK

GREEK BRONZE, BELIEVED TO BE OF ATTIC OR SOUTH ITALIAN ORIGIN

The statuette, 15 13/16 inches in height and 14¼ In length, is believed to have been made about 470 B.C. Although there is uncertainty about the identity of the artist, the beauty and grace of the conception of the design point to the possible workmanchip of Calamis, a well-known Athenian sculptor. Indeed, there is considerable basis for the conjecture that this statuette is a part of a miniature model of the charioteer group which Calamis was commissioned to execute by the Syracusan tyrant Deimonides. The tail, parts of the legs and one ear, and the eyes, which may have been inlaid, are missing. It is cast solid, weighing 25½ pounds

GOTHIC ARCHITECTURAL SCULPTURE

1. Tympanum above the left portal of the façade of Notre Dame, representing the entombment of Christ and coronation of the Virgin, 13th century. (Cathedral severely damaged in World War II)
2. Bas relief from the Chateau de la Ferté-Milon, 14th century
3. Right side of the central door, North Porch, Chartres cathedral, France. The figures, admirable examples of 13th century northern France Gothic, represent Isaiah, Jeremiah, Simeon with the Child Jesus in his arms, John the Baptist, and Peter
4. Statue of King Solomon and the Queen of Sheba, formerly at Corbeil, now at St. Denis
5. Statues of Edwy (Eadwig) and Edward the Martyr, kings of England, on the front of Wells Cathedral, part of a group of ten kings and princes in an exterior decoration scheme of statuary comprising 180 figures, many life size, executed in polychromed stone. First half of the 13th century

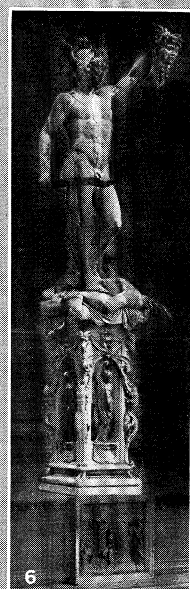
SCULPTURE IN ITALY AND FRANCE FROM THE 13TH TO THE 16TH CENTURY

1. "Madonna and Child," the earliest known work of Giovanni Pisano (1250–1320), a forerunner of the Gothic in Italy. In the Campo Santo, Pisa
2. "Creation of Eve" by Jacopo della Quercia (1374–1438), Italian; on the door of the Baptistry, Bologna
3. "David" by Donatello, Italian sculptor (1386–1466); the first nude statue of the Renaissance, executed in bronze about 1430 during the artist's classic period
4. "Herakles and Antaeus," a bronze statuette by Antonio Pollaiuolo (1429–98), Italian realist. In the Bargello, Florence
5. "Moses" by Michelangelo (1475–1564); designed between 1513 and 1516 for the mausoleum of Pope Julius; now in the church of S. Pietro in Vincoli, Rome
6. "David" modelled in bronze in 1476 by Andrea del Verrocchio (1435–88), Italian realist
7. "Meeting of Saints Francis and Dominic," an enamelled terra cotta lunette by Andrea della Robbia, nephew and pupil of Luca della Robbia, the first artist in Italy to apply the art of glazing terra cotta to monumental sculpture. Executed between 1490 and 1495 in the loggia of the Hospital of S. Paolo, Florence
8. "Apollo," one of four statues by Jacopo Sansovino (1486–1573) surmounting the arches of the Loggetta dei Cavalieri, Venice
9. "Diana and the Stag," a fountain designed by Jean Goujon (c. 1520–c. 1566) for the château d'Anet. Now in the Louvre



PHOTOGRAPHS, ALINARI

ITALIAN SCULPTURE, FROM THE 14TH TO THE 19TH CENTURY

1. St. John tho Baptist by Donatello (1386?–1466). In the Museo Nazionale, Florence
2. Bronze fountain figure of boy holding a dolphin, by Andrea Verrocchio (1435–88). In the Palazzo Veochio, Florence
3. Statue of Victory by Michelangelo (1475–1564). In the Palazzo Vecohio, Florence
4. Mercury by Giovanni Bologna (1524–1608). In the Museo Nazionaie, Florence
5. Pauline Bonaparte by Antonio Canova (1757–1822). In the Museo della Villa Borghese, Rome
6. Perseus with the head of Medusa, by Benvenuto Cellini (1500–71). In the Loggia dei Lanzi, Florence

SCULPTURE OF THE 19TH AND 20TH CENTURIES

1. "Ugolino and his Sons" by Jean Baptiste Carpeaux (1827-75). Formerly in the Jardin des Tuileries, now in the Louvre
2. "The Kiss," a marble group by Auguste Rodin (1840–1917) representing Paolo Malatesta and Francesca da Rirnini. First exhibited 1898
3. "The Hewer" by George Grey Barnard (1863-1938)
4. "Lion and Snake" by Antoine Louis Barye (1796–1875). Now in the Metropolitan Museum of Art
5. "Madonna of Alsace" by Emile Antoine Bourdelle (1861-1929)
6. "The Millmore Memorial," also known as "Death and the Sculptor," by Daniel Chester French (1850-1931)
7. Portrait of Mme. Warroquier by Charles Despiau (1874–1946)
8. "Baigneuse Acoudée" by Aristide Maillol (1861-1944)
9. Puritan Statue by Augustus St. Gaudens (1840-1907) representing Deacon Samuel Chapin, one of the founders of Springfield, Massachusetts

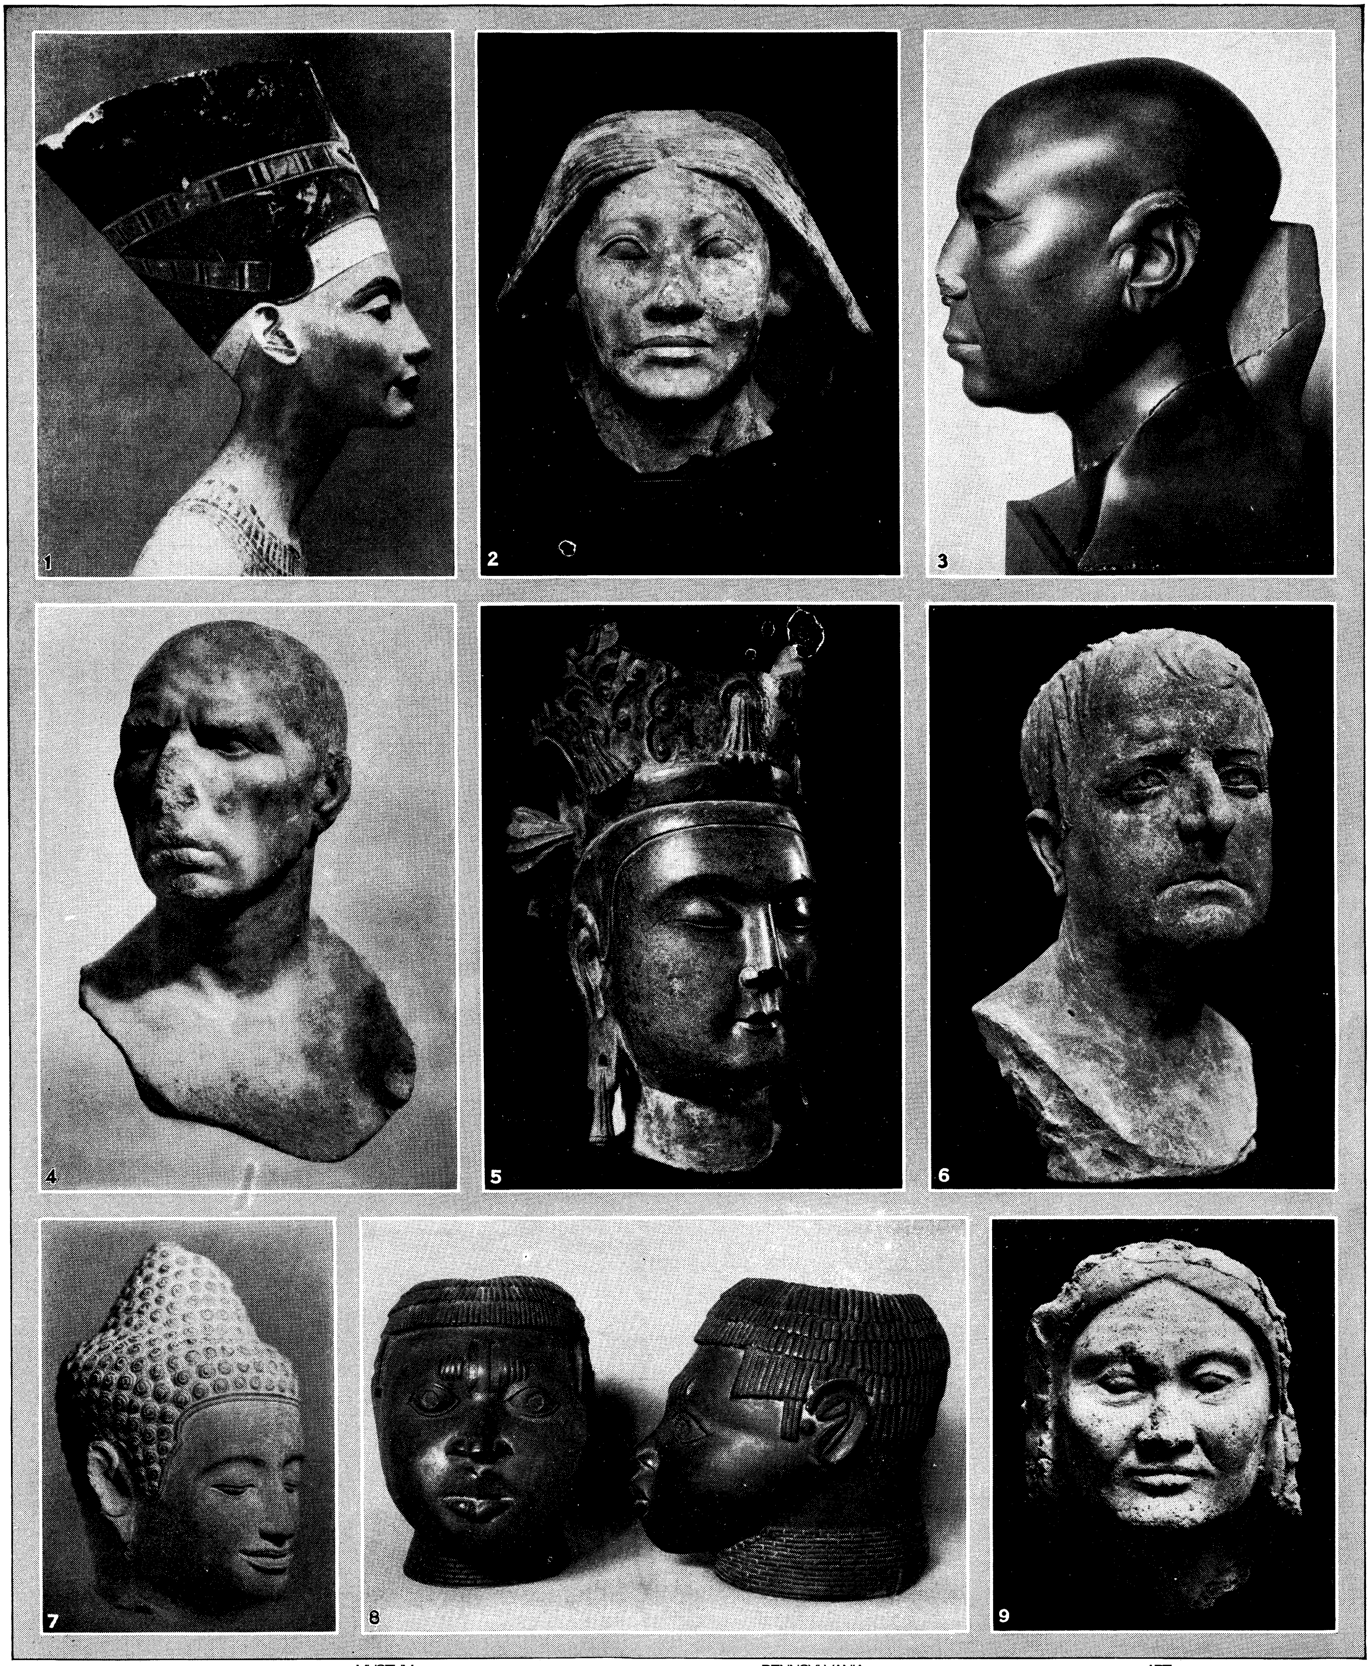
RENAISSANCE GARDEN SCULPTURE AT VERSAILLES AND FLORENCE

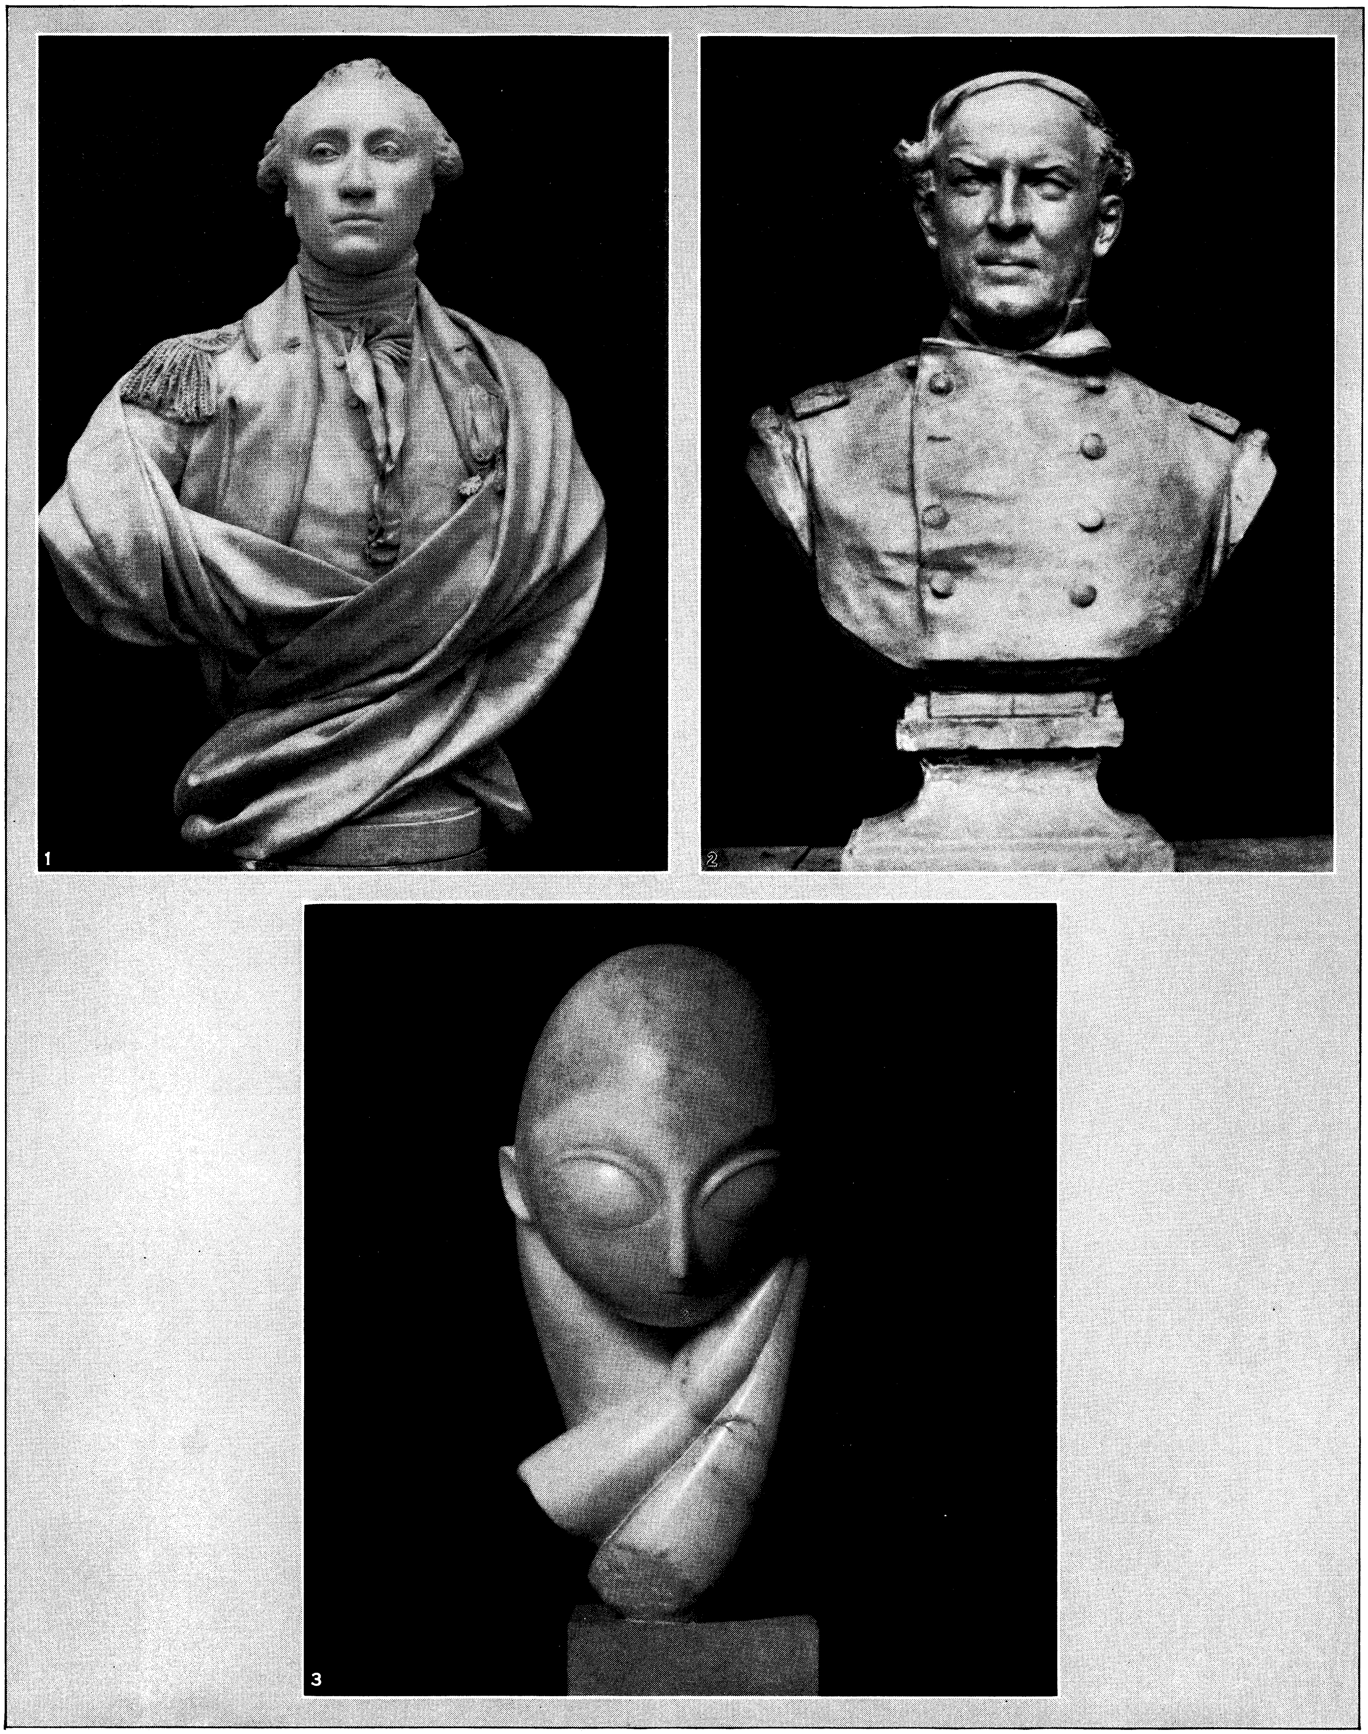
1. Fountain of the Pyramids executed in lead by François Girardon (1628–1715) from drawings by Claude Perrault (1613–88). In the Parterre du Nord, Gardens of Versailles
2. Springtime by Simon Mazière (1649– ?). In the Gardens of Versailles
3. The river Achelous by Simon Mazière. In the Gardens of Versailles
4. Ceres by J. B. Poultier (1653–1719), one of a row of marble statues near the entrance to the Lawn in the Gardens of Versailles
5. One of the 22 leaden vases forming part of the Fountain of Neptune, a great semi-circuiar fountain in the Gardens at Versailles, begun by André Le Notre (1613–1700), and Jules Hardouin Mansard (1646?–1708), architects of the park, and completed in 1740
6. The River Dordogne by Charles Antoine Coysevox (1640–1720), cast in bronze by the Keller brothers (1635–1700 and 1638–1702), one of eight statues representing the principal rivers of France. In the Gardens of Versailles
7. Fountain by Alfredo Paragi in the Boboli Garden, Florence, a park laid out by Tribolo in 1550 for Cosimo I.
8. The Garonne river by Charles Antoine Coysevox, cast in bronze by the Keller brothers. In the Gardens of Versailles
9. The Lyric Poem, marble statue by Jean Baptiste Tubi (1635 or 1630–1700) (with C. A. Coysevox). In the Gardens of Versailles
10. Fountain of Venus by Giovanni Bologna (1524–1608) in the Royal villa of Petraja, Florence
11. The Heroic Poem, marble statue by Jean Drouilly (1641–98). In the Parterre du Nord of the Gardens of Versailles



BY COURTESY OF (1, 3, 9) THE STAATLICHE MUSEUM, (2, 5, 8) THE MUSEUM OF THE UNIVERSITY OF PENNSYLVANIA, (4) THE METROPOLITAN MUSEUM OF ART, NEW YORK, (6) THE MUSEUM OF FINE ARTS, BOSTON, (7) THE PENNSYLVANIA MUSEUM

EARLY PORTRAITURE FROM VARIOUS PARTS OF THE WORLD

1. Portrait of Queen Nefertiti, an example of painted sculpture in Egypt about 1370 B.C. 2. Painted limestone head of an Egyptian official showing realistic treatment about 2750 B.C. 3. Portrait called "The Green Head," an example of simplified form, Egypt about 600 B.C. 4. Roman portrait, showing form and construction treated in a way that emphasizes the man as an individual. 5. Stone head of a Bodhisattva, late 6th or 7th century A.D. showing characteristic conventionalized treatment. 6. Roman terra cotta head; an example of details drawn or etched on the modeling. 7. Cambodian head, showing conventionalization, especially in the treatment of the coiffure. 8. Bronze conventionalized heads from Benin, West Africa. 9. Gypsum mask, an example of realism in Egyptian art about 1370 B.C.



BY COURTESY OF (1) THE PENNSYLVANIA MUSEUM AND THE COMMONWEALTH OF VIRGINIA, (2) CHARLES GRAFLY, (3) THE PENNSYLVANIA MUSEUM AND MR. AND MRS. EARL HORTER

REALISM AND CONVENTIONALIZATION IN RECENT PORTRAITURE

1. Portrait of Lafayette by Jean Antoine Houdon (1741–1828)
2. Portrait of Admiral Farragut by Charles Grafly (1862–1929)
3. Portrait of Madam Pogany by Constantin Brancusi (1876–1957)

HEADS BY CHARLES GRAFLY ILLUSTRATING SUBTLETIES OF CONSTRUCTION AND COLOUR

1. Sketch showing how a smile affects the construction of all features. 2. Portrait which gives an impression of the size of the man by the careful treatment of the neck and shoulders. 3. Portrait showing treatment of fluffy blond hair. 4. Portrait showing treatment of dark hair turned gray

SCULPTURE

ANCIENT ARCHITECTURAL SCULPTURE

1. Relief panels on the birth house of Isis at Dendera, Egypt, depicting Isis feeding her son Horus, the father Osiris, and Ra, the highest God offering a gift
2. Massive carving in the Mortuary Hall of Rameses II., at Karnak, Egypt
3. Carvings adorning the wall of the Temple of Hathor at Abu Simbel, Egypt, as they appear when viewed from the Nile
4. Relief from the palace at Ashur Nasir, 9th century, B.C., Assyria
5. Relief from Harpy tomb in Xanthos, predecessor of many other Lycian tombs of the 4th and 5th century
6. Complete frieze of the Theatre of Dionysus at Athens, Greece
7. **Relief from the frieze of the Parthenon, Athens, Greece**
8. Portals of a 13th century cathedral in Italy
9. Detail of the Arch of Titus at Rome. The relief show [illegible] branched candlestick from the Temple at Jerusalem

ARCHITECTURAL SCULPTURE OF EUROPE AND THE ORIENT

1. The Porte Royale, or central doorway of the Cathedral of Chartres, adorned with statues of royal saints. 12th century. 2. Kings of Judah, a group of 16 figures on the gallery above the Porte Royale, Cathedral of Chartres. 3. Middle portal of the fapade of Notre Dame Cathedral, Paris. With the exception of the modern figure of Christ on the central pillar, the sculpturing (partly restored by Viollet-le-Duc) is early Gothic. 4. Detail of the fapade of the Basilica of St. Mark, Venice, showing the famous bronze horses modelled by a Greek artist of the 3rd century. The fapade, which is divided into two tiers of 5 arches each is pillared with marble and inlaid with scenes in mosaic. 5. The "Marseillaise" by Jean Franpois Rude (1784–1855), on the east façade of the Arc de Triomphe de L'Etoile, Paris. 6. The Arc de Triomphe du Carrousel, Paris, erected (1806–07) by Pierre F. Fontaine (1762–1853) and Charles Percier (1764–1838) in commemoration of Napoleon's victories of 1805. Forty-eight feet in height, it is a reduced copy of the arch of Severus at Rome. 7. Panel by Jean Goujon (*c.* 1520–c. 1566) from the Fountain of Innocents, erected by Pierre Lescot (*d.* 1578) in 1550. In the Louvre. 8. View of the Huang Ssu (Yellow Temple), Buddhist monastery in Peking, China, showing the Pan Ch'an Lama Memorial built by Chien Lung in the 18th century. Designed on Thibetan lines, its marble sides are elaborately sculptured and it is surmountea by a cupola of gilded bronze. 9. Lion by Antoine L. Barye (1796–1875) in the Tuileries gardens. 10. Eauestrian statue of the four princes in the great temple of Sri Rangam (built 11th–16th century A.D.) near Trichinopoly, South India

EXAMPLES OF ARCHITECTURAL SCULPTURE

1. Group in glazed terra cotta by Carl Paul Jennewein (1890–) for the pediment of the Philadelphia Museum of Art. This is part of an unusual exterior decoration scheme in polychrome in the manner of the ancient Greeks, conforming with the classic design of the building
2. **Pediment by Adolph Alexander Weinman (1870–1952), north façade,** U. S. Archives building, Washington, D. C.
3. Statue in front of the Custom House of New York city. Executed by Daniel Chester French (1850–1931)
4. Buttress figures, "Wisdom and Justice" for Nebraska State capitol, Lincoln, Neb., by Lee Lawrie (1877–)
5. Ornamental clock for the New York Central building in New York city. By Edward McCartan (1878–1947)
6. **Statue of George Washington** by Alexander Stirling Calder (1870–1945) on Washinaton's Arch at Washington Square, New York city
7. "Music" by Emile Antoine Bourdelle (1861–1929) for the Théâtre des Champs Elysées, Paris, France
8. Central group representing Farel, Calvin, Bèze and Knox, designed by Henri Bouchard (1875–) and Paul Maximillian Landowsky (1875–1961), for the Reformation Monument at Geneva, Switzerland. Laverriere. Monod and Taillens, architects
9. "The Burden of Life and Labour" by George Grey Barnard (1863–1938). On the capitol at Harrisburg, Pennsylvania

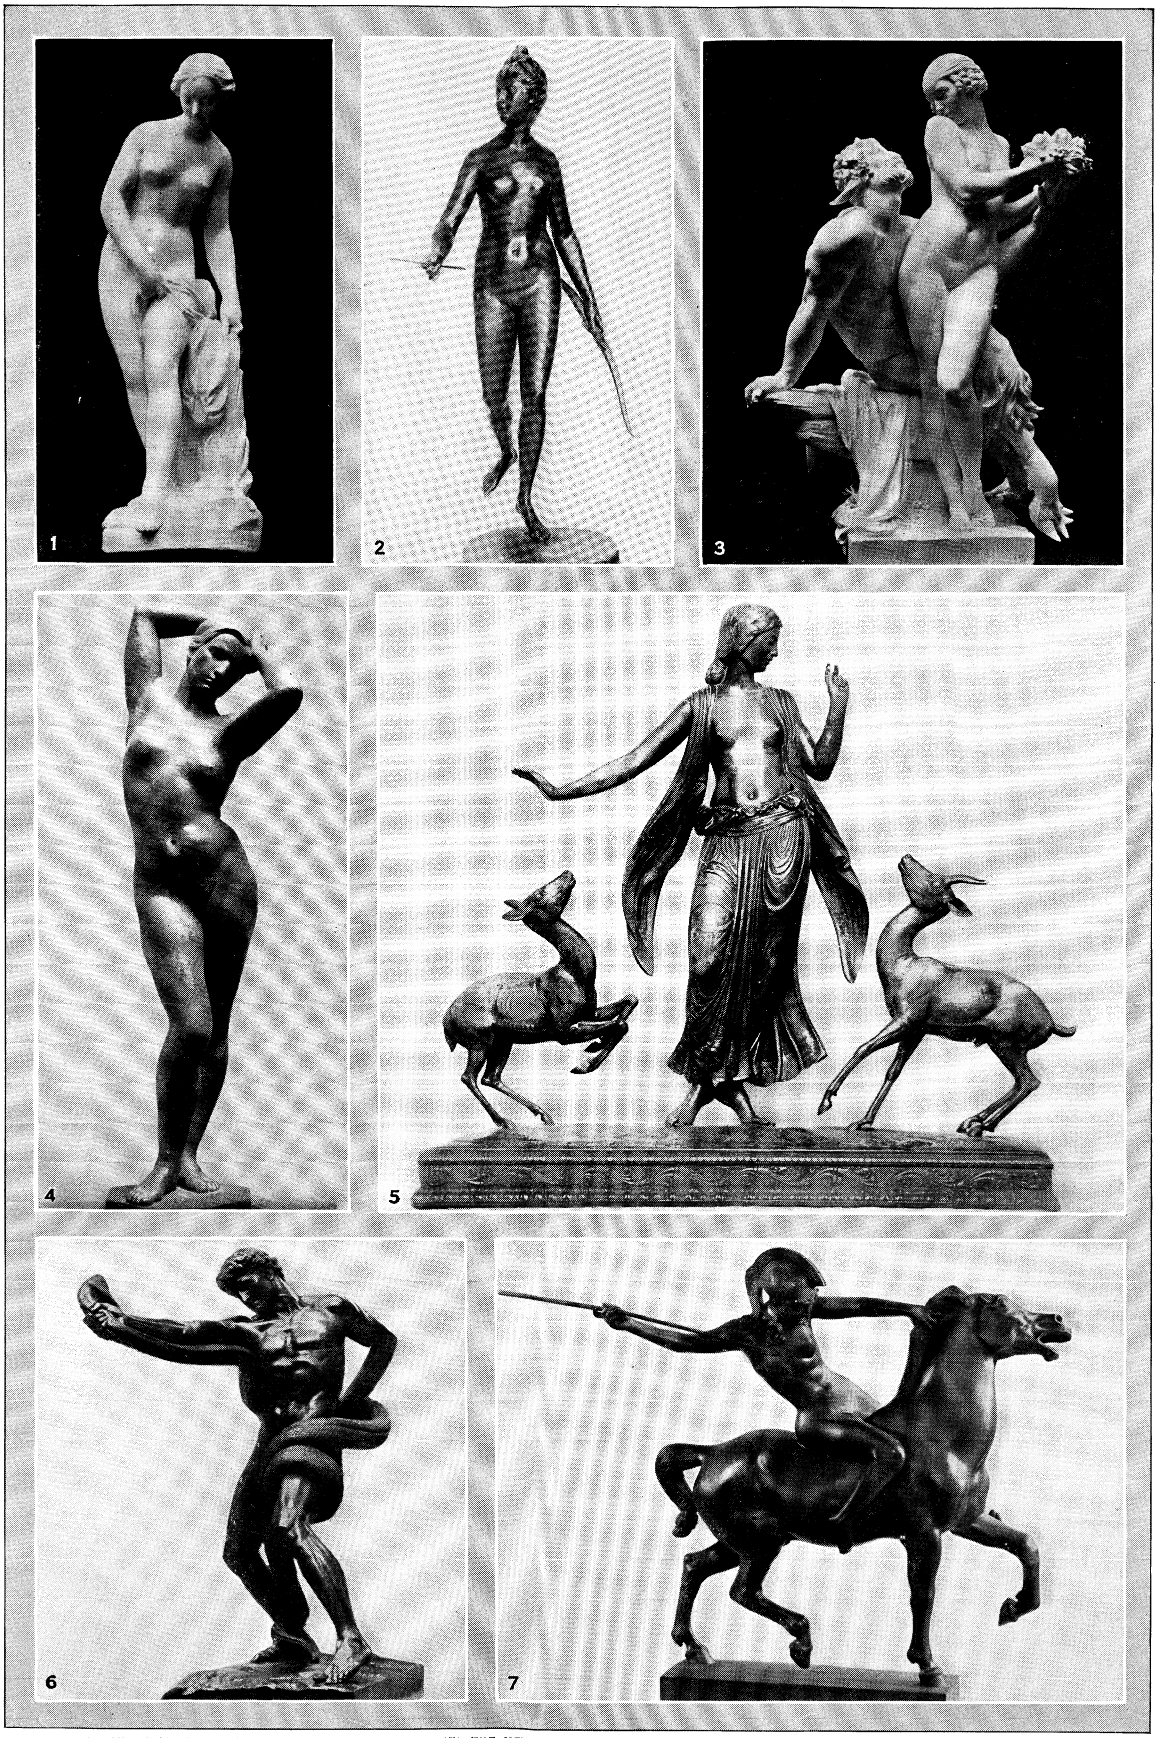
EXAMPLES OF EARLY DECORATIVE SCULPTURE

1. Carved prow of a Maori canoe
2. Egyptian lion, 4th century, now in the Vatican Museum, Rome
3. Grotesaue aquamanile (water ewer) of bronze representing St. George and the Dragon, 13th century, England
4. Copper figure of Siva (post-Vedic god of Hindu Mythology), 18–19th century, South Indian
5. Bronze griffin, Campo Santo, Pisa, Italy
6. Crozier of carved ivory, French, 14th century
7. Saint Nicaise and the angel called "The Smile of Reims," two of more than 500 statues that form part of the decorative sculpture in the 13th century cathedral of Notre Dame at Reims. The statues are shown in restored condition after having been damaged during the World War
8. "The Descent From the Cross," a group in the Louvre, Paris
9. Ivory statuette "Virgin and Child," Gothic, end of 13th century



BY COURTESY OF (6) THE NATIONAL GALLERY, MILLBANK, (7) THE METROPOLITAN MUSEUM OF ART, NEW YORK; PHOTOGRAPHS, (1) COLLECTION ARCHIVES PHOTOGRAPHIQUES, (2) GIRAUDON

TYPES OF DECORATIVE SCULPTURE

1. "Baigneuse," an example of decorative sculpture by Falconet (1716–91), French. In the Louvre. 2. "Diana," by Houdon (1741–1828), French. Now in the Louvre. 3. "Nymph and Satyr," a group by E. McCartan (1378–1947), American. 4. "Dawn," a bronze statue by Arthur Lee (1881–1961), American. 5. "Dancer and Gazelles" by Paul Manship (1885–), American. In Cleveland Museum. 6. "Athlete Struggling With Python" by Lord Leighton (1830–96), English. In Tate Galleries. 7. "Mounted Amazon" by Franz von Stuck (1863–1925), German. In Metropolitan Museum of Art

SCULPTURE

DECORATIVE SCULPTURE OF THE 20TH CENTURY

1. "Mare and Foal." bronze statuette group by Herbert Haseltine, English animal sculptor
2. "Deposition," wood relief by Ivan Mestrovid (1883-1962). Yugoslavic
3. "Horse" by Carl Milles (1875-1955). Swedish
4. "Danae," bronze figure by Aristide Maillol (1861-1944). French
5. "Black Panther," by Mateo Hernandez (1888-1949), Spanish animal sculptor
6. "Hounds." by Wilhelm Hunt Diederich (1884-1953). American
7. "Woman at Her Toilet," bronze statue by Jane Poupelet. French
8. "Heracles Drawing His Bow Against the Stymphalian Birds," a group in bronze gilt by Emile Antoine Bourdelle (1861-1929). French
9. "Diana," bronze statuette (24 in. high) by Charles Despiau (1874-1946). French

He went to America to execute his famous portrait of Washington and his busts of notables were outstanding and of great historic interest. Among those were Benjamin Franklin, John Paul Jones, Lafayette and Voltaire.

NEO-CLASSIC AND 20TH CENTURY SCULPTURE

The so-called neo-classic period of the 18th and early 19th centuries came as a result of renewed interest in Roman archaeology and especially in the finds from the excavations of Pompeii and Herculaneum.

Canova (1757–1822) based his style upon that of Praxiteles and imitated many of the mannerisms of the late Hellenic school. He was master of the rendering of the human body to whose lines he gave classic elegance More intellectual than emotional, his work lacked spontaneous warmth of feeling. His work was very popular during his lifetime and he executed many important commissions.

Thorwaldsen (1770–1844), a Dane who worked in Rome, was a follower of Canova who adapted the themes of Graeco-Roman art to his personal expression. There is a collection of his work in Copenhagen.

Also of the neo-classical school whose work savored of archaeological reconstruction, though tempered with personal idiosyncrasies, were Flaxman in England and Danneker and Schadow in Germany.

In France sculpture carried on the indigenous tradition and, while influenced by academic classical tendencies, characteristic creations of the first half of the 19th century had vigour and the sculptors went largely to nature for inspiration. François Rude (1784–1855) a classicist in treatment of form, endowed his figures with powerful gestures, based upon intense observation of nature. His "Marsellaise" of the Arc de Triomphe in Paris stands as one of the most forceful compositions of 19th century sculpture, which, while dominated by the romanticism of the period, is imbued with life. Other notable works by this master are his portrait statue of Marshal Ney and those collected in the Museum at Dijon.

David d' Angers (1789–1856), a master who excelled in portraiture, has left an interesting series of medallion profiles of notable men of his time.

Antoine Barye (1796–1875) the animal sculptor, was an individualist of enormous energy who, while affected by the current classical manner, found in intense study of nature the fulfilment of his aesthetic dreams. Egypt, India, China, Babylon and Greece have left noble monuments of the sculptors' observdtion of animal life. The cat in Egyptian sculpture was a synthesized realization of generations of artists working with the same conventions on the same subject and were impersonal masterpieces. No sculptor has understood anatomical construction of animals better than Barye. Taste in art and the manner of interpreting it changes with each generation and it is difficult to judiciously appraise his creations without the perspective of time.

Carpeaux (1827–75) was of liberalized neo-classic tradition. His groups of dancing figures are notable decorations to the façade of the Opera in Paris.

Falguière and Frémiet belonged to the group of sculptors who revolted against the soft mannerisms of the classical school. They were followers of the style of Barye and executed many animal groups. Frémiet's monumental equestrian statue of "Joan of Arc" marks him as a vigorous personality who based his conception of form upon observation of nature. A notable example of his work is the "Sea Horse Fountain" in the Observatoire, Paris.

Auguste Rodin (1840–1917) was primarily a modeller in clay; the subtleties of the soft medium characterized his style and he enveloped form with a sense of atmosphere. An ardent student of nature, his standing "Statue of a Youth" (Bronze Age) was so real that it seemed to have moulded from life, such was his ability to imitate the appearance of the model. The "Burghers of Calais" were impressionistic, vital and pictorially graphic, while his portraits were often astonishingly real and fluently modelled. Rodin came at a time when art was seeking liberation from the cut-and-dried formulas of the Academy and his commanding personality left a strong influence upon a large group of students in the early years of the 20th century.

Antoine Bourdelle (1861–1929) was a student of Rodin and there is evidence in his work of much of the latter's facility in the handling of clay, but upon this background is superimposed the influence of early Greek and French Gothic masters. He too has largely swayed the modern French school.

Constantin Meunier (1831–1905) was the outstanding 19th century Belgian sculptor. He has left many admirable statues of the workers of his country, executed with powerful directness, sympathy and honesty.

The romantic and classical school of English sculpture is represented by Alfred Stevens (1818–1875) and Lord Leighton (1830–96).

In Germany Max Klinger (1857–1920) was a notable exponent of the academic school with a fine basis of naturalism. Adolf von Hildebrand (1847–1921) and Lehmbruck (1881–1919) created works full of individuality and emotional energy.

Nineteenth century sculpture in America has left many fine monuments. Henry Kirke Brown (1814–86) created the magnificent equestrian statue of George Washington, New York. John Quincy Adams Ward's (1830–1910) standing figure of Washington, New York, is dignified and monumental.

Augustus Saint-Gaudens (1848–1907) studied as a youth in France. He was an unassuming but brilliant modeller and his work strongly influenced the American school of sculpture of the late 19th and early 20th centuries. His statue of Abraham Lincoln in Chicago is an outstanding and noble conception of the Great Emancipator. His many relief portraits, impressionistic and pictorial, are admirable. Other fine monumental works are his statues of Admiral Farragut, the equestrian General Sherman in New York, and the Adams Memorial in Washington.

Daniel Chester French (1850–1931) carried on the American neo-classic traditions of Ward. His rich, creative career has left many fine monuments, conspicuous among which are his four great groups of the façade of the New York Customhouse. His "Death Staying the Hand of the Sculptor" is a work of noble sentiment, combining figures in the full round against a background modelled in low relief.

George Grey Barnard (1863–1938), a sculptor of powerful imagination, was educated in the French impressionistic school. His figures are imbued with a feeling of nobility and inner life.

Present day (1940) tendencies in sculpture are diverse and seem chaotic. There is a survival of the impressionistic academic school of Rodin in which form is interpreted through the medium of soft clay. Using the same medium, but with a severer architectonic treatment, are the followers of Bourdelle. In contrast to that tendency there is the group which carves directly in stone, working either on a solid geometric basis or in the impressionistic manner. Abstractionism expresses itself in various ways. Non-representational forms are in vogue in certain schools, expressed in cubes, spheres and ovoid forms which are carried to infinite variations and combinations. Symbolic abstractions are invented and forms which in nature are convex may be conceived in the fantasy of the sculptor's mind in concave inversion based on emotional impressionism. Surrealism and psychopathic introspection influence sculptural trends, as well as those of painting. The archaeological tendencies are ever-present, expressing themselves in neo-classicism or reflecting Egyptian, Babylonian, archaic Greek and Gothic art or sources of Oriental derivation and those from Negro and South Sea Island sculpture. Modern architecture demands new conventions and formalizations. Investigations into the possibilities of these are many and interesting.

The machine age and standardization influence craftsmanship and tend to remove the sculptor from popular contact. His art has become generally eclectic and has lost the essential and spiritual basis of folk or religious expression.

GARDEN SCULPTURE

Strictly speaking garden sculpture is not in a class by itself. Very often we may find in a garden a figure taken from the ruins of some old Gothic cathedral which makes a perfect piece of garden sculpture, or again we may see a fragment of a Greek statue or even an old Chinese idol which when given just the right setting seems to be a necessary part of the garden in which it is placed. Not all sculpture, however, is suitable for a garden decoration even though it be very fine sculpture from the point of view of composition or modelling or the expression of an idea or an emotion. Therefore, it would be well to consider here the things which make a piece of sculpture take its proper place in a garden or park.

One of the first requisites of a successful garden decoration is that it be something that will make a pleasing spot and be part of the ensemble. It may be an old well-head or a great stone or terra-cotta vase which will serve the purpose best; it may be a great jet of water shooting straight up from a pool or simple basin; it may be a statue in stone, lead or bronze. Regardless of what it is, in order to take its proper place in a garden it must have just the right scale and colour.

This question of colour is a very important one. Quite often a fine statue in bronze placed against a background of thick dark foliage is completely lost and counts for nothing as a decoration, whereas a statue in stone on just the right scale, though it may be crudely executed, will be much more successful as a decoration because it counts as a spot of colour where the dark bronze was lost as a silhouette against the trees or shrubbery. Where bronze is used it should be shown silhouetted against the sky or against a garden wall or terrace where the dark bronze will be in contrast to the lighter background, for even though the bronze be light in colour when first placed out of doors it will soon lose its original patina, and gradually grow darker in colour. It is practically impossible to give to bronze an artificial patina which will not change colour when exposed to the elements. Marble or stone, on the other hand, when placed out of doors will most often take on a beautiful mellow tone which is in perfect harmony with the landscape and at the same time make a perfect silhouette against the green.

When placed in the open, lead will also take on a very pleasing colour, a soft warm grey which always makes an agreeable spot. Lead is especially suited to fountain figures, and very often when seen in the moonlight it takes on a beautiful silvery tint, an effect which can be obtained by the use of no other material.

There are, of course, various forms of landscape gardening, each requiring a different treatment with regard to its sculptural decoration, but they divide themselves into two general classifications. First, there is the large formal garden or park with its long straight paths, its carefully planned vistas and beautifully kept lawns; then, there is the small informal garden with its nicely arranged flower-beds and its small intimate nooks. One thinks of the park in Versailles or of some of the beautiful old gardens of Italy which were designed as settings for the villas of aristocracy in the time of the Renaissance as fine examples of the large formal garden. At Versailles there is a profusion of sculpture all taking its proper place in the surrounding landscape and though the work was done by several different men there is no lack of harmony in design or execution and each figure is simply a part of a beautifully planned ensemble. Where they placed rows of statues against a heavy mass of foliage bordering some broad grassy avenue they always used stone; when they placed statues out in the open where they were silhouetted against the sky or against the water of some great pool they used bronze or lead, with the result that the sculpture always counts as a spat of colour and adds greatly to the beauty of the ensemble. One may feel that a piece of sculpture which is to be placed in the open should be rugged in treatment and massive in design. This may be true in regard to sculpture to be placed in a large open square or plaza of some big city, or of a monument or a group for some great building, but a single figure or group for a garden must have a certain refinement of detail and elegance of design such as nature has given to the flowers and trees, and all the things with which to make the garden a thing of beauty.

One may again feel that a piece of sculpture should be more or less of a solid mass free from holes which pierce the composition. This may be true of certain kinds of sculpture, but in garden sculpture where the single figure or group in stone is silhouetted against the dark green of the trees it is sometimes well to have carefully designed holes which will give to the group a certain lightness and freedom which is in keeping with the design of the trees where the branches sometimes part and allow a glimpse of the sky beyond.

While the small informal garden requires a different type of sculpture from that of the large formal garden the same principles of scale and colour should he applied here as in the larger gardens. If the setting calls for a statue. say, 3 ft. high, it does not necessarily mean that any statue 3 ft. high, however charming, will suit the place. A statuette which may look well indoors is clearly lost when placed outdoors because its mass and details are out of scale with the things of nature which surround it.

While the subject matter of garden sculpture is not perhaps of first importance one nevertheless feels that there are certain subjects more suited to the garden than others. One is inclined to think of the mythical woodland creatures and of subjects that are joyous and which have to do with life in the open. However, whether the statue be a small chubby child or a goddess done in a fine architectural style it must first of all be a thing which takes its place in the garden and is in harmony with the trees and flowers which are its neighbours.

Thus it is that many garden decorations though crudely executed make pleasing spots when seen from a distance and are therefore in a way successful, but the really successful garden decoration is the one which makes a good spot when seen from a distance and which at the same time is designed and executed in such a manner as will repay anyone who comes near enough to inspect it as a work of art. (See also LANDSCAPE ARCHITECTURE; SCULPTURE TECHNIQUE.) (E. McC.)

PORTRAIT SCULPTURE

Good portrait sculpture has remained essentially the same throughout the ages. Only its trappings and its ornamentation have undergone changes, just as conventions of dress have changed periodically, characterizing a particular epoch. Thus we may recognize an Egyptian portrait bust by the indication of its wearing apparel or its mode of arranging the hair, while excessive attention to personal adornment indulged in the late 18th and in the 19th centuries leaves its stamp also upon the portraiture of that period.

In essentials, however,—in the fundamental construction of the human head,—the fine portraiture of these remotely associated periods remains the same. You see on the city streets to-day types that coincide exactly, except for the non-essentials of dress, with the types richly revealed in the best portraiture of the Egyptians and of the Romans. This fact leads back to the very foundations of portrait sculpture and of human construction. Everyone knows, for example, that the nose is in the centre of the face and that, accepted as the centre, it can give the alignment of the other features. Yet many portrait busts neglect this simple first principle, and, in consequence, destroy the normal perfect balance of the head.

GEOMETRIC BASIS

The fundamental law of head construction is, in consequence. as much a truism as a law in geometry and must be accepted without reservation by the portraitist. If it were actually reduced to mathematical principles it could be indicated'by a line drawn down through the centre of the head from the apex of the skull to a point marking the centre of the mass attaching the neck to the body. This imaginary line might be described as the "flow" of the mass (A–B, fig. 1).

In order to complete the geometry of portrait bust construction a straight line may be drawn at right angles to the general line of the "flow" running from the eye to the back of the skull and centring eyes and nose (C–D, fig. 1).

Structure and Likeness.—Once this framework of fundamental construction has been produced the matter of obtaining a likeness is comparatively simple, and the features with their individualizing characteristics are at once seen to be ornaments on the general flow of the head construction just as buttons or embroidery are ornaments on the coat or dress.

The sculptor who has spent years studying the human head knows well that good portraiture is concerned with the individuality of the simple head construction as indicated by the "flow" of the mass rather than by the meticulous copying of the features, He knows from studying the work of his fellows that there are two types of portrait sculpture, one type preoccupied with features and the other with the fundamentals of construction. There is a unity in the bone structure uhich he perceives is not built brick on brick as is a man-made work of architecture and which if grasped in its entirety lends a semblance of life; a quality of convincing sureness which cannot otherwise be obtained.

It is quite possible to achieve a likeness without adhering to fundamentals, but as the years pass and the subject dies the portrait bust must rest on its merits as a work of art and not as a likeness. The Romans who posed for some of the finest examples of ancient portraiture have long since passed from the land of the living. No one living to-day has an interest, sentimental or otherwise, in the tilt of the ancient's nose or the dear and familiar lifting of the ancient's eyebrow. The personal element in portraiture is stripped from consideration by the impersonal passage of time, and the work is left to stand or fall on its value as a piece of head construction. It is not at all improbable that some of the ancient portraits preserved to-day as the finest relics of antiquity in the museums of the world won less acclaim in their own era than other works more effective as Likenesses than as art.

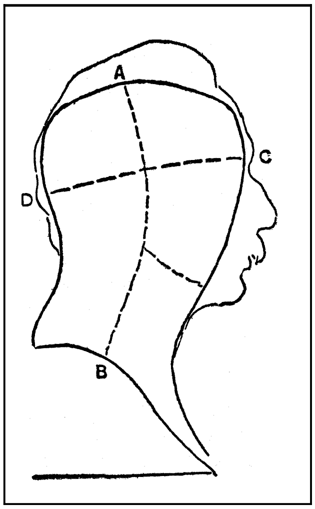

FIG. 1.—DIAGRAM SHOWING FROM A TO B THE PLANE OF THE STRUCTURAL MASS OF THE HEAD; FROM C TO D A SECOND LINE PASSING AT RIGHT ANGLES, CENTRING EYES AND NOSE WITH BACK OF SKULL

GOOD PORTRAITURE UNIVERSAL, NOT RACIAL

Granting the fundamental principle upon which the human head is built it follows naturally that good portraiture is universal and not racial. Because a portrait is primitive African or Egyptian or Chinese does not mean that it is any better as a portrait than a bust produced in Rome, Paris or New York. Racial differences occur from the frontal bone to the chin and do not affect the real mass structure of the head.

By the same reasoning it would be a thankless task to establish the superiority of any one period of portrait sculpture over another. The factor of time is unimportant. A portrait that was good in the days before Christ is good to-day and takes its place with the best portraiture produced by the succeeding ages down to the present time.

The fundamental construction of a head, while of paramount importance in its valuation, is less striking to the layman than external characteristics It is difficult, for example, to appreciate the structural kinship between a highly conventionalized portrait bust of an Egyptian king and a work emphasizing the individuality of a less exalted personage. Yet the difference between the highly individualized and the highly conventionalized portrait may lie solely in the treatment of externals.

Externals Establish the Period. — It is the outer convention rather than the inner structure that brands a portrait bust as the work of some particular period.

The mode of life, the customs and manners and environment of the age invariably affect the outer appearance of the individual.

Sometimes the mode of dress or the coiffure establishes what might be considered a symbol of the time. and this symbol or convention finds echo in the nork of the portrait sculptor.

A study of Cambodian heads or those produced in Egypt and in Rome shows the influence of the current mode on the work of art. The Cambodian portraitist in particular followed a definite symbolism in the rendering of the hair, while the popular coif of other lands is repeated with more or less conventional emphasis in the fashioning of the portrait bust.

Thus, although the individual was an individual in ancient lands quite as much as in the Europe and America of to-day, certain characteristics of dress stamp him with the life of a definite period.

Conventionalization and Realism in Portraiture. — It is interesting that many periods of art production showed equal interest in conventionalization and in realism. The 20th century tendency to reduce all forms to their simplest essentials is no new thing. It merely serves to emphasize and accept the principle of fundamental construction, and to publish to the world that details are merely details and have very little to do with the basic character of a work of art. Conventionalization of human forms and simplification with the resultant absence of personal characterizing details may be found in portrait sculpture from earliest times to the present era.

In Egypt, as well as in China, India and Cambodia, the conventionalization of forms was particularly favoured. Many of the fine renderings of kings and queens are so highly conventionalized that the personal characteristics are lost or obscured.

If one may judge by the mass of portraiture that has come down to us the high dignitaries of the religious and governmental life were placed on a plane above human characterization and were considered more as symbols of the church and state than as individuals. Yet, paralleling the conventional in portraiture there was a wealth of individual representations indulged usually in subjects of lesser rank, but presenting a definite individual character with all the eccentricities, all the imperfections of the ordinary man.

Realism in the development of the portrait bust began almost with the first known portrait and marched triumphantly through the centuries, cropping out in unexpected places even in the great cathedrals of the middle ages where, carved on choir stools or as incidental architectural decoration, there are hundreds of little portrait busts characterizing the artisan or the ecclesiast or even the aristocrat of the time. Occurring as they did in an epoch devoted not to portrait sculpture but to architecture, they serve to demonstrate the tremendous urge of the human race toward the perpetuation of the individual.

There is a slight shade of difference in viewpoint between conventionalizing and idealizing the human head. In conventionalizing the sculptor chooses the characteristics of subject and period and reduces them to decorative forms and symbols.

Thus we find the hair of the African or the coiffure of the Cambodian expressed not realistically but by means of conventionalized decoration.

It remained for Rome, however, to lay final stress upon the individuai as an individual. The long succession of portraits that issued from that city in the centuries of its world dominion show clearly the swing of the art pendulum from idealization and conventionalization to the frank acceptance of human imperfections. Sculptors delighted in these imperfections, these marks of personality, and expressed them with a realistic force that is as powerful to-day as it was in the long ago. Realism so held the portraitist in its grip that he often forgot the dress of a man and centred his attention upon the fundamental characterization of his subject as a timeless individual. The finest of these heads are. in consequence, forever modern as they reveal the human being stripped of period identification.

The Decline of Portrait Sculpture.——For many years after the Roman era portrait sculpture declined with the other arts. appearing only incidentally through the middle ages, and not returning to prominence much before the 18th century when as in the past, it mirrored in its externals the modes of the elaborate elegance, following through almost two centuries an overornate career, yet, under its outer trappings, producing some fine examples of sculptural portraiture.

The 20th century is witnessing a return to the general simplicity found in the portraiture of the ancients.

DIFFERENCES IN VIEWPOINT AND MODELLING

A study of portrait heads produced throughout the ages reveals a rich variety of viewpoints and of modelling. Everyone is familiar with the unanimated face. You see it sitting opposite you in the public conveyance. Its expression has settled to that of hopeless, inactive monotony. For purposes of characterization it might be termed a "streetcar face." This aspect of portraiture may have a variety of underlying causes. The sculptor may be frankly bored with the subject. He may lack understanding of the subject and be unwilling to exert himself sufficiently to establish mutual sympathy.

He may be faced with a personality that refuses to give that sympathy. Or, through lack of experience and inability to handle his medium, the sculptor may neglect the life-giving structural essentials.

In his effort to achieve simplicity a sculptor often gives the big essentials of head construction but so covers them with a general modelling that the richness of surface is lost. This type of portraiture reminds one of a figure neatly enveloped in a veil. or generalized by the use of tights. It is the antithesis of rich form sculpture in which detail is held in perfect scale to and is supported by the mass.

At the other pole is the portrait head that achieves likeness and individuality by thinness of form, as if the artist were working with a drawn line upon the clay, emphasizing detail rather than construction, a type of work implying a pen and ink mental approach and readily defined as "pen and ink sculpture."

The exaggeration of individual characteristics with extreme emphasis upon striking details supplies another classification under the head of caricature (*q.v.*).

PRODUCING A LIVING PORTRAIT

To produce a portrait bust that gives the impression of life the sculptor must have behind him a wealth of experience. He must know that a man does not laugh nith his mouth or his eyes alone but with his entire head, and that when he smiles there is a concerted movement of all the features.

Every subject has a definite life flavour that reveals itself in some individual characteristic or series of chararteristics. The successful portrait head discovers these characteristics Needless to say, the sculptor who has personal knoaledge of his subject can produce a more living bust But he is seldom called upon to execute a portrait of an intimate friend The portrait commission concerns itself almost exclusively with the perfect stranger, and when faced with such a sitter the sculptor must draw largely upon his knowledge of human nature and his ability to rend facial characteristics in the light of the subject's environment and profession. What he does and is contributes largely to the basis for character analysis.

When the sculptor gropes unsuccessfully for this revelatory contact he produces the unanimated street-car face, visualizing the man on the model stand as impersonally and monotonously as he would the man beside him in a tram The features are there; the likeness may be there also, but the personality, the life-giving quality of understanding between subject and artist, is absent

Sculptor and Sitter. — In many respects a portrait head created from memory may have more life than one executed after many sittings. Sitters vary greatly in what they give of themselves. Some are sympathetic and establish at once a bond of sympathy with the sculptor, thus enhancing his creative power. Others sit through hours without a spark of understanding It is often true that more can be gained by talking to a subject during rest periods and by studying the reaction of the man when he is unconscious of a pose than when he sits through the long hours on the stand After a time the expression of any face sets, and there is danger of reproducing a deadened countenance.

One of the most difficult tasks that a portrait sculptor is called upon to face is the commission to make the head of someone no longer living. Many busts of historical personages are created solely from contemporary prints, photographs or portraits, the character of the data varying according to the period in which the individual lived. Seldom is there adequate material from which to work. If the portrait desired is that of some notable who lived many years ago the artist may wield a freer hand and use his own knowledge of the human head and his conception of the msn's character without being forced to meet the criticisms and suggestions of relatives or friends whose impressions of the individual may be vivid but conflicting. The one hope of success in this task lies in the sculptor's knowledge of construction and in the wealth of his experience as a portraitist, and with this knowledge and experience he must portray that intangible quality known as character. It is no task for the novice.

Studying Colour in Portraiture. — The experienced portraitist understands many subtleties of construction that are missed altogether by the literal copyist. He appreciates, for example, the structural differences between the blonde and the brunette. He knows that dark hair and light hair fall in different masses and that even when dark hair whitens with age it still preserves the mass quality of its original colour. Thus hair of different colours is essentially differentin form.

Black hair falls in heavier masses and gives a solid effect. Where it separates and one lock appears distinct from another the separation is sharp and produces a strong shadow. Blonde hair, on the other hand, has very few solid masses It is fluffy and light in effect and does not possess either the solidity or the sheen of dark hair. The difference between blonde and brunette indicates at once the need for a corresponding difference in the modelling of each type.

Forms that are definite and that produce definite shadows give a brunette colouring while blonde colouring is obtained through a negation of the shadows and by the modelling of subtle, less well defined forms.

How Colour Impression Is Produced. — The portrait bust of the past few centuries has relied for colour quality almost entirely upon gradation of shadow produced by modelled form. Dark skin, light skin; dark eyes, light eyes; dark hair, light hair, — such colour differences are translated in terms of light and shade.

This sculptural interpretation of pigments was aided by the ancients through actual colour application as seen in many a portrait discovered on Egyptian soil. Chinese portrait heads were also coloured, while a similar tradition reappeared in the ecclesiastical heads of the middle ages. It was possible for the Egyptian portraitist to paint on the bust the elaborate necklaces and jewel arrangements that give a clue to the mode of dress and of life. Crowns and head-dresses, first expressed in terms of form, were then painted in designs and colours characteristic of the period.

When the actual application of colour fell into disuse it became necessary for the portraitist to indicate pigments and design solely through the modelling of form. Folds of the toga might appear in Roman portraiture, while the coiffure of the lady of antiquity, changing with the style of each succeeding era, writes its chapter in the conventions of the portrait head.

The Influence of Externals on Portraiture. — The elaborate over-decoration of the 18th century and the heavier decorative trend of the 19th found echo in the accessories of dress used by the portrait sculptor in his effort to establish the individual in point of time as well as in point of character.

Externals thus leave their stamp upon the portrait bust as it marches through the ages, but externals have never made the portrait a finer work of art. It stands or falls by virtue of its construction, its modelling and the artist's own knowledge of human nature.

THE CHOICE OF MATERIAL

The modelling of a portrait head and the choice of size, whether life-size or over, is largely conditioned by choice of the material in which the head is to be cut or cast.

Wood, stone, metal and terra cotta provide a range of choice for the portrait sculptor, and each of these materials has its own technique. In Egypt stone was a favourite material, and the great simplicity of many an Egyptian portrait head may be due to the fact that the sculptor chose porphyry as his material for expression. Porphyry presents its own problems in the matter of carving. It is very hard, and necessitates the simplifying of surface treatment and the reduction of forms to their basic essentials. In Greece and Rome, on the other hand, where marble was so largely used, the sculptor had more opportunity to display his skill in the handling of intricate surfaces with greater attention to detail

The control of the material over the modelling and even over the general conception of the work undertaken may be readily understood if a porphyry head of the Egyptians, with its simple forms, is placed side by side with a Gothic group of the middle ages, carved from Caen stone or from some other soft stone material. No such flowering of detail and intricate design in sculpture would have been possible had the carvers of the middle ages and the Renaissance been confined to the use of a hard, unyielding stone.

The hard stone thus lends itself to conventionalization, urging the sculptor on to express form more or less symbolically, while the soft stone allows him to indulge his fancy for absolute realism and for intricate ornamentation.

The Effect of Material on Size.—The sculptor who wishes his portrait bust to assume life-size proportions must, again, understand the material in which the head is to appear. If the portrait is to be cast in bronze it must be modelled slightly larger than life. Bronze shrinks $\frac{3}{16}$ in. equally in length, breadth and thickness, to the foot, and the heavier the bronze employed the greater the shrinkage.

Terra cotta, or dried clay, shrinks 1 in. to the foot, and does not shrink equally unless the model is so constructed that the shrinkage shall be equal. When the sculptor does not understand the terra cotta material the Darts shrink unequally and the original model is either distorted, cracked, or both. Distortion of terra cotta pieces that have come down to us from antiquity may often be attributed to this cause.

In dealing with the portrait head carved in wood the sculptor must appreciate that a solid block of wood checks or cracks. Many African and Chinese portrait carvings show serious cracks. This tendency, however, can be controlled if the wood is built up by dove-tailing or glueing together smaller blocks to produce the required volume, or by boring and excavating the interior of the large solid block.

The Material May Aid Characterization.—It is not impossible that, in studying the character of the individual the sculptor discovers forms or traits that may be best expressed in some one particular material, thus utilizing the material as a direct agent in the characterization.

The artist who feels for his material understands that it requires a technique in keeping with its nature, and does not attempt to force upon it some alien treatment. For example, the beauty of wood lies in the fact that it is wood, and the sculptor who uses it as a carving basis should treat it as wood and not give it a surface peculiar to the nature of marble. If, on the other hand, he desires for characterization the surface of wood as a base, he should not choose marble.

PORTRAYING STATURE IN THE PORTRAIT HEAD

The portrait sculptor must indicate in the head alone the characteristics of his sitter. He is, therefore, faced with another interesting and difficult problem. How can he impart through the head the movement and form of the body? How can size, weight and stature be indicated in the bust?

Incidental decoration can do little to achieve this goal. The stature of an individual is a basic thing and conditions all parts of the body from the head to the feet. In fashioning a portrait statue it is a simple matter to indicate size and weight. In the portrait head, however, such characteristics can be suggested in the setting or base. A portrait head, for example, must end somewhere and when ended must be mounted upon a block or base.

The Treatment of the Base.—The sculptor who studies the stature of his subject completes his portrait bust with a general form indicating the bulk of the sitter. If he happens to be a tall, thin person, the artist creates a tall, thin base. It he be a short, heavy-set man, the base is wide and broad. Any such setting goes back to a fundamental appreciation for form sensed by the ancients, and almost entirely forgotten in the over-ornate art of the 18th and 19th centuries.

GOOD PORTRAITURE TIMELESS

To-day, therefore, the sculptor stands as he stood thousands of years ago, face to face with the same problems of natural form that conditioned the portraiture of Egypt and of Rome. He has passed through centuries of experimentation during which his art became incrusted with extraneous and often meaningless details. Busts of this nature belong so exclusively to a certain period in the world's development that they give the impression of being out of date. They provide a gauge for the study of their own contemporary modes of dress, and because they are so localized they appear less modern than portraits executed thousands of years before by the sculptors of antiquity.

Many a fine portrait head created in Egypt or in Rome and produced purely as a study in structural forms and resulting life is ageless and periodless in its adherence to the universal principles of the sculptor's art. Conventions of dress, conventions of execution have come and gone, but the art of the portrait bust, in its fundamental aspect, has changed not one whit from the first efforts of a master hand to reproduce its kind.

MONUMENTAL SCULPTURE

By monumental sculpture is meant that sculpture which is intended to perpetuate the memory of a person or an event. Included in this definition are all types of memorials in which sculpture is the important part, even though architecture or mosaic or some other art may play an important part in the composition; but it is not intended to include that sculpture which forms merely a decorative accessory in a building such as the sculptures in temple pediments, in the portals of a cathedral, or on the piers of a triumphal arch even though these adorn a memorial structure. Sculpture of that type will be defined as architectural sculpture or as decorative sculpture. (See other sections of this article.) In the definition of monumental sculpture we include all public memorials that are sculptural in quality and intended to commemorate historic, literary or scientific events such as military victories, the signing of treaties, the discovery of new lands, or a mechanical invention; all memorials to persons—to statesmen, soldiers, poets, martyrs; all sculptural monuments intended to decorate a city; and all funerary sculptures, whether built within the walls of a cathedral or in the open air.

Monumental sculpture, to serve its purpose as memorial, must be permanent, and must clearly express the character of the person or event that it is meant to honour. Enduring materials, such as bronze or granite, so arranged as to be in perfect equilibrium and so modelled as to minimize the possibility of fractures would seem to be essential to this art; and it would seem obvious that these modelled forms should be those of men and women and should recall, either by direct representation, by association or by the more subtle emotions which may be evoked by arrangements of mass and line, the qualities or the significance of the thing commemorated. Heroic scale and simplicity, because they lend both dignity and permanence, are the most frequent attributes of monumental sculpture, and that idealization of forms and of attitudes which leads to the elimination of all that is ephemeral or mean is an almost universal characteristic. More than any other form of plastic art, monumental sculpture strives to express those qualities of structural truth, of harmony in mass and movement, which good architecture also embodies. A realistic or pictorial treatment, although often used for the decoration of memorials, is apt to be less effective for monuments which are intended to illustrate, not accidental or trivial aspects of nature but rather those heroic qualities of the human spirit that attest its enduring greatness. A romantic or symbolic treatment which depends upon knowledge or upon understanding for its appreciation and a purely decorative style which offers only sensual delight, are also unsatis-

fying in a memorial. That monumental sculpture is best that imposes upon natural human forms the architectural logic of mass and structure.

The desire to leave some record of his sojourn on earth seems to have been instinctive with man from the beginning, and no doubt this instinct is closely associated with his desire to represent the human form in stone or wood. From the earliest ages man *seized upon the hardest and most enduring materials in which to carve representations of his own form.* With *the development of the first civilization, in Egypt, Chaldea, Mexico, these instincts found expression in a wide range of monumental sculptures*

Ancient **Civilizations.**—We *shall omit a detailed description of the monumental sculpture of Egypt, Mesopotamia, Greece and Rome, since this is described elsewhere. (See* EGYPT: *Archneology and Art;* GRLEK ART; ROMAN ART.) *Both the Egyptians and the archaic Greek peoples set up in the precincts of their temples sculptured memorials which are concise and solid in character. After the end of the 6th century these monuments shared the growing naturalism of all Hellenic art: the memorial set up in Athens to "Harmodius and Aristogiton"* (514 B.C.—copy *in Naples) is an example. An equilibrium between naturalism and idealism is characteristic of the finest Greek memorials, such as the "Victory of Samothrace," set up in 306 B C. to celebrate a naval victory. In the later phases of Greek sculpture, realism, to which are added dramatic and narrative qualities, becomes dominant, as the "Dedication of* Attales *I."* (241–179 B.C.) *at Pergamum, commemorating a victory over the Gauls, attests.*

In Rome, memorial sculpture is almost always an accessory of architecture; but it is, nevertheless. almost *wholly pictorial in character. The vigorous and realistic frieze which envelops in a superb spiral the column of* Trajan *(a war memorial set up* in AD. 113) *is an example, as are also the fine reliefs of the arch of Titus* (AD. 71), *set up to celebrate the capture of Jerusalem The sculpture of the* "Ara Pacis *Augustae" (13 B.C), one of the few monuments set up to commemorate a peace, are more idealized, as is also the contemporary "Augustus of the Prima Porta," one of the finest achievements of Roman monumental art.*

The **Middle** *Ages.—No sculptors understood more profoundly the principles and technique of monumental sculpture than the sculptors of the* middle *ages, particularly those of the* 13th *century in France, but since their greatest achievements were the sculptural ensembles of the cathedral portals, it will be more convenient to discuss their work at another place. (See section on Architectural Sculpture;* also **GOTHIC** *ART.) We shall* **speak** *here* only *of a phase of their art less dependent on architecture: the execution of sepulchral effigiesand tombs.*

From the beginning the Christian Church marked the graves of her apostles and her martyrs with a stone or bronze memorial. The character of these did not at first differ from other contemporary memorials except by the occasional use of Christian symbols. The vast number of sarcophagi in Rome, executed for the most part after the reign of Constantine, illustrate the development of this Hellenistic art, in which classic forms and drapery, not without dignity and grace, are united intricately with the conventional decorative motives of orientalized Antioch or the genre detail of Alexandria. After the 5th century they share the technical decadence of Rome.

The revival of the arts under Justinian—and later under Charlemagne—found a wide expression in intimate sculpture such as ivory carvings and architectural ornament, but left few examples of monumental art. The bronze Easter column, set up it is said by St. Bernard, in the cathedral at Hildesheim is little more than a piece of constructed ornament. It was not until the 10th *and* 11th *centuries, when the sculptor was called upon to decorate the new monastic buildings, that the monumental spirit was once more revived. Developed in the abbey doorways, where the sculptor had to learn anew the technique of stone carving and of rendering the human figure, this spirit gradually entered once more the sepulchral art of Germany and France. It is felt first perhaps in that form of tomb in which a sculptured figure of the deceased is cut or moulded on top of a sarcophagus or on the sepulchral slab let into the floor of abbey or cloister. Although these figures continued for a long time to be only flat reliefs scratched into the flat surface of the stone they are idealized and simple forms.* When, *after the* 11th *century, they begin to be carved in bolder relief and finally in the round, the figure is still conceived, as in the incised reliefs. in a standing posture, but iaid on his back. The form is rigid, the head erect, and the draperies, unaffected by the change in position, drop in stiff, thinly cut folds from shoulder to feet. Germany was the centre for the production of these grave reliefs, which show a progressive development in technique. The relief grows higher and higher, the figure and the features gain steadily in idealism and in dignity, and the draperies show an increasing beauty of pattern and line The series of* effigies at Ovedlinburg, *representing the abbesses of that monastery, illustrate this* evo*lution.*

The sepulchral effigies of the 13th *century share those ideal and simple qualities which are manifest in the cathedral doorways, but the preoccupation of the sculptor with architecture prevented a wide or sustained development in this field That development had to await the* 14th *century when the decoration of the architectural structure of the cathedrals seemed gradually less important than their embellishment with furniture,* with retables *and chapel screens, and with* tombs *wherein an individual patron, rather than a community, might be commemorated. This new patronage, which removed the sculpture from the geometric lines of the building, accelerated the growth of naturalism which can be traced more continuously in the tomb figures than in any other field. The body, laid at full length on the stone slab, begins to lose its rigidity. Its forms are clearly defined below the drapery which flows over it in an increasing complexity of fold. The features attain first a realism that approaches portraiture and then, as the influence of St. Francis permeates religion, they take on an emotiona! or sentimental quality. Accessories, symbols, details of costume and heraldry are rendered with greater and greater elaboration.*

The tombs in the Abbey of St. Denis, *near Paris (1264) built by St. Louis for his ancestors and his sons* are *characteristic examples of* 13th *century tombs. In these the figure is modelled not in relief but in the round. Each figure, represented as in early manhood, and rendered as a standing figure laid upon the ground,* is graciously *idealized. Each has a simple architectural framework,* low *in relief, and each is placed on a base embellished with pictorial reliefs. The expression is calm and benign and the draperies straight and simple with long clearly incised lines. The tombs for Rollo and William* Longue-Epée, *in the cathedral of Rouen (c.* 1270), *the bronze figures of Geoffrey* d'Eu, *in the cathedral at Amiens, are other interesting examples of these austere effigies.*

Characteristic of the 14th *century is the tomb of Charles V., at St.* Denis *by* André *Beauneveu;* where *the advancing realism of the century expresses itself in accurate portraiture* and *in more flowing and natural draperies. The figure is portrayed in the stiffness of death, and about him are grouped representations of his relatives in the costumes and attitudes of mourners. The fine tombs of the popes at Xvignon—one of which is elaborated with a canopy—and the* effigy *of Robert* d'Artois *at St.* Denis, *clad in full* armour *with a lance in his hand, are other examples which illustrate the growing interest in actuality. In the 1 jth century, when this principle reached its widest acceptance, Flanders and Germany became the most important centres for sepulchral art At Tournai there was developed the type of tomb in which the figure of the deceased, no longer dead and recumbent, kneels before the* Virgin *or some religious object; and these tombs, the production of which amounted to an industry, were exported to all parts of England,* France *and Germany, and widely imitated. The "Monument to* Isabella *de Bourbon" in the cathedral at* Antwerp *(c. 1465) and the "Tomb of Louis de* Male, at Lille" (1455), *both of which are of bronze, are characteristic examples of this Flemish art in which the elaboration of detail and the representation of action and of personality are clearly the preoccupation of the sculptor. Burgundy, which after the beginning of the Hundred Years'* War *became the sculptural centre of Europe, produced a funerary art not less realistic than that of Flanders The famous Tomb of Philip the Bold (completed* 1411) *is an elaborate example of this art, in which the recumbent figure* of *the king is placed on a* high pedestal elaborately decorated with traceries and with the modelled forms of draped mourners. The effigy is clothed in ample and flowing robes and at his head are the kneeling forms of two angels. German tombs, after the 13th century, are notable for their profusion of accessory and for the occasional introduction of narrative and action into the sculptured figures. Escutcheons are developed in Germany into elaborate decorations and early in the 15th century the baldachino or canopy makes its appearance there as in Italy. Ornate canopies are also common in 15th-century England as are also the, multiplication of angels, heraldry and symbolic ornament, and the realistic trend is so far developed as to lead to examples wherein the base of the tomb is left open to reveal the corpse within.

The custom of placing the tomb in a niche in the wall received wide acceptance in Spain and in Italy in the 15th century. In Spain these niches, framed in wide arches. received a lavish embellishment in which Moorish ornament frequently appears. The "Tomb of the Two Knights" in the church of S. Esteban at Cuellar and the "Monument to Archbishop Lope de Fontecha" in the cathedral at Burgos are examples. In the elaborate "Tomb of Juan de Padilla" by Gil de Siloé, acquired by the museum at Burgos, the effigy kneels before a relief of the *Pietà* against a background of delicate tracery. In Italy the influence of the antique and the example of Nicola d'Apulia is shown in the substitution of a sarcophagus, covered with figure carvings, for the northern tomb base. The effigy, lying on this sarcophagus, is revealed by angels who pull aside sculptured curtains. In the more sumptuous examples a great baldachino or marble canopy, supported by four piers, surmounts the tomb and is covered with a wealth of Gothic ornament. The three "Tombs of the Scaliger Family" (1350–74) in Verona, where the canopy is surmounted by a bronze equestrian statue, and the "Tomb of Mary of Hungary" (1325) in Naples are examples of these canopied monuments.

The Renaissance. — The tombs of 15th-century Italy are among the most perfect examples of that exquisite fusion of decorative architecture and classic sculpture which characterized this century. Although often greatly increased in size as compared with their Gothic prototypes, and most profuse in detail, they seldom attain a truly monumental character; they are. rather, accumulations of ornament. schematically arranged in a great niche set in the wall of a church. The vast Gothic churches of the Franciscans and Dominicans — S. Annunziata in Verona, S. Croce in Florence. SS. Giovanni e Paolo in Venice, for example — are lined with these tombs — the work of the Lombard ornamentalist — that contrast strangely with their laconic architecture.

A characteristic design for these tombs is that of an enframement of marble architectural forms — of arabesqued pilasters delicately wrought; with moulded and carved archivolts, entablatures and bases — enriched with statues placed in niches or in a pediment and surrounding a sarcophagus upon which rests the effigy of the deceased. All parts of this enframement are exquisitely carved.

The "Tomb of Pietro Mocenigo" (c. 1462) by Pietro Lombardi in the church of SS. Giovanni e Paolo, Venice, is a superb example of this sepulchral art. The doge. in his robes of state, stands upright upon the sarcophagus, which is borne on the shoulders of three soldiers clad in classic armour. The "Tomb of Christolphe Felici" (1486) by Ambrose Lorenzetti in Siena; the "Tomb of Leonardo Bruni" (1444) by Bernardo Rossellino in S. Croce. Florence; the "Tomb of Carlo Marsuppini" (1455) by Desiderio da Settignano. also in S. Croce, are other examples of this art that attains at its best a perfection of technique never surpassed.

In the 16th century the Italian tombs lose this exquisite ornament. A more sober and studied style in which scale, dignity and classic correctness are the ideals sought appears. The new feeling is foreshadowed in the almost perfect "Tomb of Ilaria del Carretto" (1405) by Jacopo della Quercia in the cathedral at Lucca. The 16th-century master of tomb design is Andrea Sansovino, whose "Tomb of Ascanio Maria Sforza" in the church of S. Maria del Popolo, Rome. takes the form and dignity of a Roman triumphal arch. The "Tombs of the Medici" (1523–34) in San Lorenzo, Florence, and the "Design for the Tomb of Julius II," only partly executed, both of which are by Michelangelo, are the greatest examples of the mature and powerful art of this century. (See MICHELANGELO.)

The monumental sculpture of Renaissance Italy was not, however. confined to tombs. Donatello revived the equestrian statue in his "Statue of Gattamelata" (1443–53) in Padua, bringing monumental sculpture into the open air and giving it once more a civic rather than a religious significance. The "Statue of Colleoni" (1465) by Verrocchio in Venice and the "Designs for a Statue to Francesco Sforza" (1506–10) by Leonardo da Vinci followed. Michelangelo set his heroic figure of the nude David (1501) in front of the Palazzo Vecchio of Florence, while Niccolo' Tribolo, also a Florentine, created the precedents in fountain design which were to be developed into the monumental fountains of the next century.

In France the Renaissance created many decorated tombs of the greatest beauty among which the "Tomb of Cardinal Amboise" (1525) in Rouen cathedral, the "Tomb of Francis II of Brittany" (1507) by Michel Colombe in the cathedral of Nantes and the "Tomb of Francis I" (1525) at St. Denis by Pierre Bontemps are perhaps the most celebrated. Jean Goujon, the greatest of French sculptors. has given an example of his vital and gracious style in the "Fountain of the Nymphs," Paris; and Germain Pilon, whose work exemplifies the noblest classic tradition, achieves in his "Effigy of René Birague" in the Louvre a most perfect balance between a sympathetic naturalism and monumental restraint.

The splendid "Tombs at Brou" (1505–26) near Bourg, built for Margaret of Austria by Konrad Meit of Worms, are characteristic of the somewhat ornate Renaissance of Germany, where the Thirty Years' War greatly limited the production of monuments. In Spain an army of Flemish and Italian ornamentalists, attracted by the prosperity which followed the discovery of America. embellished with sumptuous tombs the newly built Gothic cathedrals and founded with their Spanish pupils a school of decorative art which lasted well into the 16th century. "The Tombs of the Catholic Kings, Isabella and Ferdinand" (1517) by Dominico Fancelli of Florence and "Doña Juana la Loca y Don Felipe el Hermoso" (1j20) by Bartolomé Ordofiez, both of which were preserved in the splendid Capilla Real of Granada cathedral, are two of the finest sepulchres of Europe. Other examples are the "Tomb of the Infante Don Juan" (1512) in the church of Santo Tomas, Avila; the "Tomb of Bishop Gorzalo de Terma" (c. 1525) by Diego de Silve in Burgos cathedral; and recessed "Tomb of Enrique II and Catherine of Lancaster" (1534) by Alanso de Covarrubias, in Toledo cathedral.

The **Baroque.**—No field was more congenial to the spirit of baroque art than sculpture carried out on a conspicuous scale. The baroque mas a large style, delighting in impressiveness of heroic mass and deep shadow even when, in its effort to achieve a dramatic effect, it ignored not only structure and the laws of equilibrium but also that repose and dignity which in most ages have been considered the first essentials in monumental art.

The tombs of Bernini are magnificent dramas in which symbolic figures, clothed in sweeping draperies. with rhetorical gesture and expressive features, share in some emotional experience, theatrically depicted. An example of this virile art is the "Tomb of Alexander VII" in St. Peter's, Rome. The pontiff, set in a great apse, kneels on a high pedestal about which Charity. Truth, Justice and R'isdom weep disconsolately while Death, a skeleton, raises the great draperies of polychrome and gold that veil a darkened doorway. The "Fountain of the Triton" in the Piazza Barberini, Rome. from which all clarity of profile or of shadow, all definiteness of plane, are removed, is also characteristic of Bernini's style, widely imitated throughout Italy.
