Males mate with the females during the nuptial flight (mating is often on the ground), and the single copulation stores viable sperm in the spermatheca that may fertilize millions of eggs for as long as 15 years. After mating, the queen breaks off her wings and seeks or excavates the first chamber in the ground, under the bark of a dead branch or in some other appropriate place. The large thoracic wing muscles are absorbed and assist in nourishing the first larvae, which are fed by salivary secretions. The new queen may eat some of her own eggs during the early stages of colony founding before the new and usually dwarf workers emerge to take over the food-gathering activities. Each stage in the life cycle from egg through larva and pupa may take two weeks or more, although a few ants emerge as adult workers in as little as 35 days from the laying of the egg. In a few very primitive ponerine ants of Australia, the fertilized female forages for insect food and feeds her young with chewed up pieces of prey, but the large majority of ants including most ponerines never revert to the solitary behaviour of their ancestral wasps. In a few instances, notably in the new world army ants, the queen is wingless and resembles a worker in her structure. New colonies are formed by budding from the old colony, a newly developed and fertilized queen together with a large number of workers separating from the old colony. In some cases *(Formica ulkei)*, the new queens may be accepted back into the old nest after the nuptial flight, and new colonies are formed by a budding of the populations. Some species of *Formica* are temporary social parasites, the new queen invading the nests of another species of the same genus and replacing the host queen. The social parasites *(Anergates atratulus)* have no workers and no independent colonies from their host ants *(Tetramorium caespitum)*.

The food of ants is much more diverse than that of the social wasps or bees. Primitive ants resemble their solitary wasp ancestors in preying upon living insects. A few may specialize on a single kind of prey (*Termitopone commutata* on termites of the genus *Synterntes*). The army and driver ants of the new and old world are raiders on animal prey, mainly insects of the earth surface. These primitive predatory ants retain the sting of the ancestral wasps. Many of the higher ants are scavengers, feeding alike on dead insects, dead animals of various sorts and decaying fruit. Some of these scavenger ants supplement their diet with the sweet secretions of homopterous insects such as the Coccidae, Aphidae, Membracidae and Psyllidae. Shelters are sometimes constructed for these "ant cows" and occasionally caterpillars of the family Lycaenidae may also be tended and sheltered. The "honey ants" of the genus *Prenolepis* (fig. 1) exhibit a remarkable specialization of "pastoral" activities. Honeydew obtained from aphids may be stored in the crops of some workers until they become so distended with the sweet liquid that they become immobilized. In some species they hang on the ceiling of the subterranean burrow and function as animated honey jars. These distended workers are called repletes, but so far as is known they are morphologically identical with the other workers in the colony. Harvesting ants collect, husk and store seeds in special granaries. In some species the soldiers or major workers appear to function solely as seed crushers. The fungus-growing ants belong to a tribe, Attini, of the subfamily Myrmicinae. The correlation of structure and behaviour in a supergeneric taxonomic category is an obvious indication that the fungus-growing "agricultural" behaviour is an inherited instinct. The fungi are cultivated in chambers in the nest, usually under the ground. Primitive fungus growers use a substratum of insect feces for the garden. The more advanced species harvest pieces of leaves from living plants and transport them to their underground nest chambers where small workers chew up the leaves into a moist mulch that is formed into a spongelike base in which the fungus mycelium grows. The gardens are tended by the small workers and ultimately produce small spherical swellings that are cropped and used for food. The species of fungi seems to be unique for each type of ant, but much further study is necessary before the evolutionary relationships of the fungi can be established. Before her nuptial flight the queen of *Atta* takes a pellet of fungus mycelium with some of its substrate in a pouch below the mouth. After impregnation she excavates a burrow in the soil and carefully tends the incipient garden on the floor of her sealed chamber, often manuring the fungus with her own feces. The eggs are laid in the developing garden, and the larvae are fed on the fungus or on some of the eggs. The first small workers appear in 40 days or more and soon start foraging for leaves to be used to nourish the fungus gardens. When larger workers appear, the smallest workers are confined to the nest. In a few years the largest workers and soldiers are developed and the soldiers function only to protect the nest from invaders.

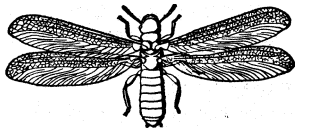
FIG. 1.—AN ANT (PRENOLEPIS IMPARIS) MAGNIFIED

(A) An ordinary worker; (B) a worker greatly distended with a saccharine matter

The slave-making ants of the genus *Formica* (subgenus *Raptiformica*) and its relative, *Polyergus,* present one of the most astonishing of social relationships. All species of *Raptiformica* do not make slave raids, but the European *Formica sanguinea* and several of its North American relatives are often found with slaves belonging to other species of *Formica*. The slave-making colony is founded by a queen invading a nest of the slave species and adopting some of the slave brood. The resultant workers feed and attend the slave-making queen and her brood as they would their own. When the temporary parasitic brood emerges as workers, they will start making raids on slave species in the vicinity and by this means replenish the dwindling population of slaves. These raids are rather casual and may have evolved from predatory hunting by ancestral species. The loosely organized army of slave makers finds the nest of the slave species, invades it against some resistance and captures the grown larvae and pupae with an occasional young adult worker. These are carried off to the home nest, raised as slaves and perform the nutritive and shelter-building activities of the colony. The facultative slave makers are capable of living and performing their own work without slaves. The proportion of slaves in colonies of slave makers varies among species and also among colonies of the same species. The amazon ants of the genus *Polyergus* of Eurasia and North America are obligatory slave makers and are always found in mixed colonies. The slave raids are made by workers (sometimes called soldiers) that have no other function. One or two hundred slave makers emerge from their nest and travel together in an excited milling manner reminiscent of the predatory raiding bands of army ants. The direction taken by the slave raiders is a straight line to the nest of a neighbouring species of *Formica*. There they crowd around the opening of the nest and enter as rapidly as possible, occasionally removing small pebbles or obstructions that block their passage. Any *Formica* worker offering resistance is immediately killed by the sickle-shaped mandibles of the amazon ant. After 10 or 15 minutes, a line of amazons returns to its nest carrying larvae, pupae and a few slave workers. These ultimately develop into mature slaves and perform the activities of the colony as if it were their own. In observation nests it is found that one slave can keep ten slave makers well fed. but slave makers starve in the presence of abundant food if they are deprived of slaves. Slave making has evolved independently among unrelated ants. Two species of myrmicine ants of the genus *Harpagoxenus* enslave ants of the genus *Leptothorax*. Slave making among ants is fundamentally different from human slavery, as is readily demonstrated by the fact that ant slaves are always of a different species or genus than the enslaving ants.

Inquiline species or "guests" occur in the nests of both the social insects and many other animals. Ant nests, however, harbour a great variety of insects with varying types of relationship to the hosts. Inquilines that live in ant nests without close relations to the ants may be called myrmecocoles, while those that have evolved adaptive dependence upon the ant society are called myrmecophiles. Numerous groups of insects and a few other animals have independently evolved predatory and scavenger behaviour in ant nests, but the most specialized myrmecophiles enter into trophallactic relations with the ants and often possess excretory glands that produce substances that attract the host ant. Tufts of hairs, called trichomes, that disperse liquids and scents from glands at their bases have convergently evolved in myrmecophilous Stapliylinidae, Pselaphidae, Paussidae and Histeridae.



FROM MARLATT ENTOMOLOGICAL BULLETIN (U S DEPT. OF AGRICULTURE)

FIG. 2.—RETICULITERMES FLAVIPES, FULLY WINGED MALE

The plant and animal inhabitants of ant nests exhibit web relationships of great variety and many degrees of specificity. The biocoenoses, or relationships, of ants, including the host relations to predators, parasites, scavengers, trophobionts, myrmecocoles, myrmecophiles and nest inquilines, form interspecific community units of great complexity. There seems little doubt that natural selection has directed the evolution of independent genetic systems' toward adaptive interdependence, exploitation and mutualism.

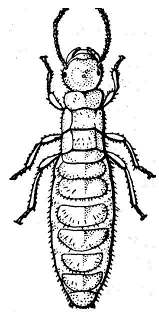
FIG. 3.—RETICULITERMES FLAVIPES, APTEROUS QUEEN MAGNIFIED ABOUT FIVE TIMES, WITH ABDOMEN SWOLLEN WITH EGGS WITHIN

Termites. — Termites, sometimes inappropriately called "white ants," show a remarkable convergence (tendency to similarity) to the ants in their social life. The order to which they belong (Isoptera) is derived from roaches, a group of insects considered among the most primitive of living forms in their structure and development. The termites share many structural and developmental characters with their roach relatives. All develop by gradual metamorphosis through nymphal stages. The primitive Mastotermes of Australia, unlike the more advanced families, has a large folded anal lobe in the hind wing and lays its eggs in the oöthecal mass similar to the roaches. All termites are social, but gradations from simple to complexsocial organization occur among the living groups. Like the ants, all known fossils are Tertiary with the exception of one Permian species of doubtful assignment. Circumstantial evidence (A. E. Emerson, 1954) indicated evolution of advanced types occurred in Mesozoic times. Although it has been stated that important social advances have not occurred in ants and termites since early or mid-Tertiary, there is no reason to believe that major social evolution has ceased. Many genera of termites now living probably had already appeared in the Cretaceous, but some modern genera give indications of origin in the Miocene or possibly later. Over 2,000 species are now recognized, grouped into 168 living genera and 5 families. Sixty-eight fossil species are known. All termites possess soldiers for defense except for two genera (Anoplotermes and *Speculitermes*) in which soldiers have been lost secondarily. Most primitive termites do not have an adult worker caste, the function of feeding and caring for the colony being performed by the workerlike nymphs. Notably in the highest family (Termitidae), an adult worker caste functions for nutriment and nest building with soldiers specialized for protection and with kings and queens specialized for reproduction. There is every reason to believe that soldiers differentiated before the adult worker caste evolved, while the contrary is indicated among ants.



FROM BANKS AND SNYDER, "REVISION OF THE NEARCTIC TERMITES" (SMITHSONIAN INSTITUTION)

FIG. 4.—RETICULITERMES VIRGINICUS, BRACHYPTEROUS QUEEN. MAGNIFIED ABOUT FIVE TIMES, WITH SHORT WING PADS

Winged males and females (fig. 2) differ from their ancestral roaches by possessing a breakage suture at the base of the wings. After the colonizing flight, the wing beyond this suture is broken off in a fraction of a second, leaving only the base of the wing ("scale") on the thorax. The male is attracted to the female by her odour and follows her in tandem as she seeks a crevice or excavates a chamber in dead wood or in the earth. Among the higher termites, the queen develops enormous ovaries and soft parts of the abdomen and after several years of growth is capable of laying 8,000 eggs a day continuously for many years. The kings and the queens of some of the primitive termites grow little from their size at the time of the colonizing flight. The king lives with the queen throughout life, and copulation occurs at short intervals. Upon the loss of the primary king or queen, reproductive nymphs with or without wing pads may develop reproductive capacities and substitute for the original pair. These "supplementary" reproductives (fig. 3 and 4) are developed when needed in many species. and it is thought that inhibiting or activating agents in exchanged secretions ("social hormones") play a part in such development. Soldiers have reduced or undeveloped wings, eyes and reproductive organs of either sex. Primitive soldiers (fig. 6) have enlarged mandibles and head musculature used solely for defense. A remarkable nasute soldier (fig. 7) is characteristic of the more advanced genera of the subfamily Nasutitermitinae. In this soldier, the front of the head is prolonged into a sort of squirt gun for the forceful ejection of a sticky and irritating secretion from a large head gland. This defense is highly effective against most predatory ants. Specialized soldiers in the advanced genera of another subfamily (Termitinae) have asymmetrical snapping mandibles for defense. In some instances two or three differently formed types of soldiers are found in the same colony. The most extreme case of two soldier types is found in the genera Rhinotermes and *Dolichorhinotermes* of the new world tropics. The major soldier has large defensive mandibles, but the minor soldier has reduced mandibles incapable of inflicting a wound on an attacking ant. The secretion of a large gland in the head and body emerges from an opening at the base of the elongated grooved labrum, or upper lip. The fluid runs out on the labrum until it rests on hairs at the tip where it volatilizes as a repellent gas.

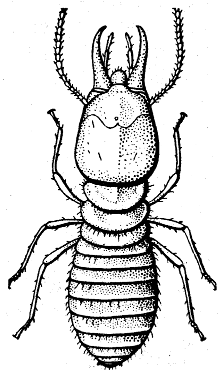
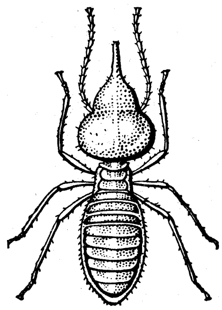
FIG. 5.—GNATHAMITERMES PERPLEXUS WORKER. MAGNIFIED ABOUT TEN TIMES



FROM BANKS AND SNYDER, "REVISION OF THE NEARCTIC TERMITES" (SMITHSONIAN INSTITUTION)

FIG. 6.—PRORHINOTERMES SIMPLEX, SOLDIER, MAGNIFIED ABOUT 10 TIMES

Working nymphs of the primitive families Mastotermitidae, Hodotermitidae and Kalotermitidae are not structurally specialized. Their mandibles are similar to those of their roach ancestors, and are used primarily for chewing wood. A few hodotermitin termites have "workers" that range over the surface of the ground harvesting dead grass or plant materials which they store in elaborately constructed subterranean nests. Most primitive termites are damp-wood or dry-wood eaters, living in their excavated galleries in stumps or dead branches of trees. Many of the Kalotermitidae invade dry wood in houses and cause considerable economic damage. These termites build simple partitions from excrement, but do not construct elaborate visible nests. The Rhinotermitidae



FROM BANKS AND SNYDER, "REVISION OF THE NEARCTIC TERMITES" (SMITHSONIAN INSTITUTION)

FIG. 7.—NASUTE SOLDIER OF TENUIROSTRITERMES TENUIROSTRIS, MAGNIFIED 15 TIMES

are more advanced in social organization than their more primitive relatives (Hodotermitidae). Their nests are usually in fallen branches or logs on the ground and only a few (*Coptotermes*) exhibit much architectural ability. They dig soil burrows some distance from their nest which contains a large queen. and they may also build covered tunnels leading from the nest to their source of food. The most advanced family (Termitidae) contains three-fourths of the known species and exhibits a variety of social specializations. The queens are usually large, some extreme specimens attaining a length of four inches. True workers are present. resembling the working nymphs of the lower families. The workers collect wood or leaves for food and feed the other castes and young. Some harvest grass. and a few feed upon organic materials in the soil. One subfamily (Macrotermitinae) of the old world tropics, with about 250 species, cultivates fungus on excrement built into elaborate fungus gardens. Various types of nests are constructed by the Termitidae. Some are excavations in the soil. Others are mounds rising above the soil and forming conspicuous features of the landscape. Large mounds may rise 2j to 30 ft. above the surface in great conical hills. The mound nest of the meridian termite of northern Australia (*Amitermes meridionalis*) is about 10 to 12 ft. high with a width of 8 to 10 ft. on the north-south axis, and only about 2 ft. on the east-west axis. The top of the mound is sharp. The nest shape probably stabilizes the radiant heat from the sun during the tropical day. Globular arboreal nests constructed by cementing particles of wood and excrement with saliva are characteristic of the genus *Nasutitermes* found throughout the tropics. Probably the most elaborate architecture is found in the genus *Apicotermes* of tropical Africa. Nests of different species of this genus are subterranean and have geometrically arranged ventilation pores in the walls constructed of claylike excrement by the workers. An evolutionary series of nest types (R. Schmidt. 1955) indicates a remarkable history of the nest-making instincts. These nests not only show an evolutionary series of instinctive group behaviour. but they exhibit social symmetry, replication, homology, recapitulation and vestigial patterns of behaviour.

No social parasites analogous to those among the social Hymenoptera are known among termites, nor do any species make slaves of others, probably because of the cellulose-eating adjustments in contrast to the predatory ancestry of wasps, bees and ants. A few inquiline termites are known that always nest in the nests of other termites. Termes *fur* and Termes *inquilinus*, respectively, nest only with Constrictotermes cyphergaster and Constrictoternzes cavifrons in South America. S. H. Skaife (1955) stated that Termes *winifredae* of South Africa is only found in the nests of other termites. Although the mound nests of termites often contain a number of termite species, obligatory inquilines are rare, and the few inquiline species are attacked viciously by their hosts if the partitions separating them are broken.

The advanced termites harbour in their colonies a host of termitophilous beetles. flies, bugs and caterpillars with remarkable exudatory organs adapted to trophallactic exchange. The most common characteristic of the most specialized termitophiles is a swollen or physogastric abdomen, the soft portions exuding glandular secretions that are avidly licked by the termites. Many termitophilous larvae belonging to several orders of insects may show "exudatoria" or prolonged glandular structures, and a few adult beetles, such as the staphylinid *Spirachtha* and the scarabaeid Scarabaeinus, have conspicuous glandular appendages that develop subsequent to emergence from the pupal case. The studies of C. Seevers (19j7) demonstrated a reciprocal evolution of the termitophiles and their hosts that has probably been advancing together since Cretaceous times.

In spite of the defensive soldier, a large number of animals have evolved special adaptations for preying upon termites. Some large ponerine ants of Africa and South America confine their diet to termites, their sting efiectively overcoming the biting jaws of the soldier termites. The spiny anteater of Australia (Monotremata), the banded anteater of Australia (Marsupialia), the aardvark of Africa (Tubulidentata), the scaly anteaters of Africa and the orient (Pholidota) and the new world anteaters (Edentata) are examples of convergent adaptation to a diet on termites. All these animals have reduced or undeveloped teeth. long cylindrical tongues coated with a sticky saliva and strong forelegs that can burrow into termite nests, whether in the soil, on the surface of the ground or high in the branches of trees Some of these anteaters have prehensile tails enabling them to seek their prey in the tree tops. A great many other animals, both vertebrate and invertebrate, are specialized predators on termites whose concentrated social populations offer a rich food supply to those animals capable of overcoming the defenses of the nests and the protective adaptations of the soldier caste.

GENERAL REMARKS ON INSECT SOCIETIES

Social organization with division of labour among adult castes has evolved four times among the insects with subsequent elaboration of the social system in each of the separate branches. Subsocial family systems are much more numerous and have doubtless evolved group systems many times in various orders.

The insect society may be compared to an individual organism possessing group attributes that collectively indicate a fundamental biological unit (A. E. Emerson, 1952). An individual cellular or multicellular organism is an open system with orientation, adaptation and interaction with its environment; it maintains a relatively steady state with self-regulation of optimal conditions of existence; it has a capacity of reproduction based upon exact self-duplication of genes with genetic continuity between generations; it exhibits functional specialization of its parts with integration of the parts into a whole; and it exhibits temporal development and temporal evolution with an order and regulation of its temporal dimensions, including the capacity to change and adjust. Levels of organismic systems occur. some of which may include units of a lower level as parts of a higher level system. The insect society is a high level, intraspecies supraorganism composed of individual multicellular organisms. but exhibiting all of the organismic properties mentioned above. The protoplasmic contact between the parts, characteristic of the cellular and multicellular levels, is absent in the insect society except through genetic continuity. but integration is achieved through behaviour interaction by means of sensory stimulus and response. Some biochemical integration is possible, however, through trophallactic exchange. Analogous similarities between levels. such as the evolution of sterile somatic cells in the organism and sterile castes in the social insect colony, result from natural selection of whole units favouring division of labour, integration and improved homeostasis. Communication through behavioural specializations and trophallactic exchange is characteristic of insect societies. However, improvement of division of labour with consequent improved efficiency, and improvement of integration and co-operation with consequent complexity of organization, are means to an improved self-regulation of optimal nutritional, defensive and microclimatological conditions (homeostasis). All the detected trends of the evolution of social insects are toward improved homeostasis, and the evolution of all organismic levels of integration seems to indicate a universal trend for all living systems toward improved homeostasis. Homeostasis must be construed as dynamic and characteristic of many types of individual and group systems (Emerson, 1954). The level of organization may also be between species with the unit composed of integrated species exhibiting ecological division of labour. Interspecies biocoenoses without germinal continuity between the species composing the system, but with natural selection of genetic traits of the component species through their relationships to each other and their environments. are particularly well illustrated by the social insects, their nest constructions, and the array of adapted animals and plants found living together arid together controlling their physical and biotic environment through geological time.

The societies of man are analogous to insect societies in such common attributes as division of labour among adults of the same sex, communication and integration of individuals into more inclusive organismic systems (social institutions. tribes. nations, etc.) and an evolutionary trend toward increased self-regulation or homeostasis of more optimal conditions of existence. In these senses, human societies are social supraorganisms. They differ in the basic behaviour integration, however. Organisms and insect societies are integrated largely by genetic replication and inherited physiological and behaviour co-ordination. Humans have a social heredity, a social reproduction and a social organization based upon learned symbolic communication. No animal has symbolic communication in this human sense. One of the most elaborate social communication systems known is that described for the honeybee. but the honeybee has an inherited instinct for responding to food quantity, quality and position by its dance on the comb, and the response by other bees to the dancer is likewise instinctive and genetic. Human language is composed largely of symbols learned through experience and education. 'There are no genes for a particular language, for a particular style of architecture or for a particular type of agriculture. Among the social insects, complex gene patterns determine communication, architecture and agriculture. For these reasons, evolution of insect societies is slow. while evolution of cultural traits is rapid; social systems of the insects are relatively simple. while social organization of humans is relatively complex. insect organization is more stereotyped and automatic. while humans exhibit much greater versatility and functional adaptability The human brain has evolved a great capacity for learning and intelligent thought and this ability has led to greater social and ecological homeostasis through social co-operation and organization. With the small insect body. the development of a brain of human dimensions is impossible. and even if the insect had such a capacity for learning, it could probably learn little of benefit during its relatively short life cycle compared with the long individual life of the human. Through the millions of years of their germinal evolution, however, insects largely have eliminated destructive individual competition and intraspecies warfare. Co-operation between individuals in a society is smooth and efficient, and all individuals seem to work for the welfare of the group.

SOCIALISM. The words socialist and socialism came into use in Great Britain and France soon after 1825, and were first applied to the doctrines of certain writers uho were seeking a complete transformation of the economic and moral basis of society by the substitution of social for individual control and of social for individualistic forces in the organization of life and work Socialist seems to have been used first in Great Britain *(Co-operative Magazine,* 1826) to describe the followers of Robert Owen, and the word *socialiste* in France *(Globe,* 1832), with reference to the followers of Claude Henri de Rouvroy, comte de Saint-Simon. In Great Britain the followers-of Owen officially adopted the name Socialists in 1841. The nord socialism was popularized as the antithesis to individualism by P. Leroux and J Reynaud in their *Encyclopédie nouvelle* and in their other viritings. and by 1840 had come to be used freely in Europe to describe the schools of Saint-Simon, Franqois Fourier. Owen and others who attacked the existing system of commercial competition and put forward proposals for a new way of life based on collective control. Later, these early schools of socialism were categorized by Karl Marx and Friedrich Engels as "utopian socialism," in contrast with the "scientific socialism," based on the materialist conception of history, of which they were the pioneers.

Later writers, delving back into the past, found anticipations of socialist doctrine in many earlier theorists, and applied the name over a wide field—for example, to Plato among the ancients, to a number of medieval writers. to Sir Thomas More *(Utopia,* 1516), T. Campanella *(City of the Sun,* 1623) and other utopia makers, and to such 17th-century social critics as the cur6 Jean Meslier in France and the Leveller Gerrard Winstanley *(The Law of Freedom,* 1652), Peter Chamberlin *(The Poor Man's Advocate,* 1649) and the Quaker John Bellers in England. Among 18th-century writers the name is applied to Gabriel Bonnot de Mably *(Entretiens de Phocion sur le rapport de la morale avec la politique,* 1763) and Morelly *(Code de la nature,* 1755), the foremost critics of economic and social institutions among the philosophers who prepared the way for the French Revolution.

Among those who took part in the Revolution the name socialist is given to Jacques Pierre Brissot (1754–93), the Girondin leader, and sometimes to Jacques René Hébert, and above all to Franqois Noel (Gracchus) Babeuf (1760–97), leader of the Société des Égaux, whose unsuccessful attempt to overthrow the Directory government in 1796 is commonly regarded as the starting point of the modern socialist movement. Babeuf's revolutionary group set forth the first practical program, and the *Manifeste des égaux* was the first socialist pronouncement. Babeuf and his followers regarded socialization of land and industry as necessary to complete the revolution begun in 1789. They proclaimed the equal natural right of all men to the enjoyment of the goods provided by nature, the universal obligation to labour and the universal right to education, and the necessity of abolishing both riches and poverty in the interests of human happiness.

Babeuf sought to establish his system by revolution carried through under a revolutionary dictatorship. His ideas were popularized later by his collaborator, Philippe Michel Buonarroti (1761–1837), whose *Conspiration de Babeuf* (1828). translated by Bronterre O'Brien. influenced the English Chartists. His views on landed property had something in common with those of the British 18th-century land reformers (Robert Wallace, 1697–1771; William Ogilvie, 1736–1813; Thomas Spence, 1750–1814; and Thomas Paine, 1737–1809), but he went far beyond them in the amplitude of his social designs. Spence is nearest to him. and the Society of Spencean Philanthropists, formed by Spence's followers in 1812. can he claimed as the first organized socialist body in Great Britain. Spence stood for the collective ownership of the land by local communes, which would take over the government and provide by federation for the simple needs of administration under a communal system Paine, on the other hand, was not a socialist, but a social reformer who. apart from his doctrines about land, anticipated many modern social service projects in part ii of his *Rights of Man.*

Nor can William Godwin (1756–1836) be rightly described as a socialist. In his *Political Justice* (1793) he declared for the abolition of all government, and advocated a free society in which property would go to those who could make the best social use of it Godwin believed in the possibility of a completely rational social system without government, based on right education in moral and social principles. He inspired much later socialist as well as anarchist thinking, and had a considerable influence on' Owen's ideas as well as on those of the British radicals of the 1790s, including Wordsworth. Southey and Coleridge in their early days. Shelley's *Prometheus Unbound* was largely based on the ideas of Godwin, whose daughter he married.

The Saint-Simon and Fourier Doctrines. — Socialist thought took a quite different turn with the comte de Saint-Simon (1760–1825), a French aristocrat whose outlook was formed not only by the French Revolution but also by a keen awareness of the impending revolution in industrial technique and in the role of science in human affairs. Saint-Simon held that the new social forces that had been unloosed by political revolution and scientific advance called imperatively for planned organization and control in the general interest, and was the first to see clearly the dominant importance of economic organization in the affairs of modern society and to grasp the concept of economic evolution as the key factor in social adjustment. In his most important works (*Introduction aux travaux scientifiques du XIXe siècle*, 1807; *Nouvelle Encyclopédie*, 1810; *De la Re'organisation de la société européenne* [with the historian Augustin Thierry], 1814; *L'Industrie*, 1816–18; *La Politique*, 1820; *Catéchisme des industriels*, 1823–24; *Nouveau Christianisme*, 1825) he put forward. not a system, but a series of originative ideas which were worked up by his disciples into a system. He stood, not for a struggle between employers and workers, but for a community among the productive classes against the parasitic nonproducers, on a basis of social ownership of the means of production and their administration by men of the requisite scientific and business knowledge. He believed in unequal rewards, corresponding to real differences in quality of service, and in the conferring of large powers on a directing authority constituted on a basis of merit. The state. he held, was under an obligation to provide work for all, and all were under an obligation to labour for society according to their powers. Saint-Simon vigorously denounced the exploitation to which the labourer was subject under the existing system of property rights. and anticipated Marx in holding that the property relations sustained by any social order conferred upon it its essential character. He believed that human society tended in the march of history toward a system of universal association. which would be the guarantee of peace; and he regarded the Roman Catholic Church as having been a step toward this association. Holding its doctrines outmoded. he put forward in his *New Christianity* (1825) a nontheological religion for the new era, based on science and expressing his faith in a "science of sciences" — a field of thought in which he was the predecessor and inspirer of Auguste Comte. Saint-Simon's great contribution to socialist thought was his insistence on the duty of the state to plan and organize the use of the means of production so as to keep continually abreast of scientific discovery. and his insistence on the master functipn of the industrial experts and organizers, as against the politicians and the mere "men of business," in the society of the future.

François Charles Marie Fourier (1772–1837) was a younger contemporary of Saint-Simon. His first book, *Théorie des quatre mouvements,* was published in 1808 and was followed by others in which he repeated and expanded the same ideas (*L'Association domestique et agricole,* 1822, *Theorie de l'Unité universelle; Le Nouveau Monde industriel et socie'taire,* 1829; *La Fausse industrie morcelée,* 1835-36). Fourier is best known as the advocate of the *phalanstère*, a form of co-operative settlement which he believed to be the essential unit of social organization. It was to consist of 1,500 or 1,600 persons — a number which Fourier held to be the minimum for securing a right mingling of the many different tastes and temperaments. It was to be at once a working unit and a community of persons living together in a single great building; but the members were not to be equals in income or status, and each was to be rewarded for his own share in the common labour. Moreover. Fourier accepted property rights, providing for the division of the total product five-twelfths to labour, four-twelfths to capital and three-twelfths to special talent. His proposed division was in fact more favourable to labour than this makes it appear; for he advocated a very high rate of interest on small investments of capital, falling very sharply as the amount belonging to any one holder increased. In effect. he contemplated that most people would be capitalists as well as workers.

Fourier's system rested on the belief that most forms of labour could be made highly attractive if they were rightly organized, and that no one need, or should, be made to work at anything except of his own free will. He held that everyone should have many different jobs, never spending more than an hour or two consecutive!~at the same work, and that all work should be organized by groups or series of workers, between whom there would be natural emulation to do well. He stressed the predominance of intensive agricultural and horticultural work both over other forms of agriculture and over manufacturing labour. which he believed should be cut down to a minimum by making things to last and by the elimination of unnecessary products. The "dirty work" he said should be done by children, to whom it could be made attractive by the spirit of emulation and service. He advocated education through doing things rather than through learning about them, and gave children a large part in the work of his utopia. He stood for the equality of men and women, regarding the advancement of women as the crucial test of social progress.

Fourier's theories were based throughout on a psychological approach. He believed that civilization erred in seeking to repress the passions. which could by right social organization, under his system, be allowed to work beneficently, as God had meant. He claimed that his system would work without any need to change human nature: which he regarded as immutable. Fourier's methods of expounding his doctrines were often fantastic, but men found much sound sense in his writings. He was entirely opposed to state action for the establishment of his system, holding that its basis must be wholly voluntary. and believing this to be possible because he thought he had discovered the form of association that really fitted in with men's natural desires. Though usually regarded as a socialist, he is in reality rather the ancestor, jointly with Owen. of voluntary producers' co-operation.

Both Saint-Simon and Fourier were the inspirers of influential schools of thought. The disciples of Saint-Simon created a formal school, headed after his death by Armand Bazard (1791–1832) and Barthélemy Prosper Enfantin (1796–1864), who separated when Enfantin developed the religious sides of his master's doctrine on extravagant lines. including a form of community living which involved "free love." This aberration over. Enfantin. like others influenced by Saint-Simon (notably the famous engineer, Ferdinand de Lesseps), became a leading industrialist. while Comte went on to build his positive philosophy on Saint-Simonian foundations. Of Fourier's disciples, the most important was Victor Prosper Considérant (*La Destinée sociale*, 1834–38; *Manifeste de l'école sociétaire,* 1841), and in England Hugh Doherty (*The Morning Star*, 1840). In the United States Fourier greatly influenced Albert Brisbane (1809–90), C. H. Dana, Horace Greeley, Margaret Fuller, Hawthorne and Emerson; and the famous Brook Farm community (1841–47), described in Hawthorne's *Blithedale Romance,* was largely Fourierist in inspiration.

Owenism. — Robert Owen (1771–1858), generally regarded as the founder of British socialism, had much in common with Fourier. but approached the social problem from an essentially different angle. A highly successful master cotton spinner, at the head of the great factory at New Lanark which he made a model for good labour conditions. Owen was a powerful critic of the manufacturing system introduced by the Industrial Revolution and of the exploitation of labour which it involved. He denounced competition as leading necessarily to this exploitation, and advocated in its place a co-operative system based on villages of co-operation in which men and women would work and live together on a basis of communal enjoyment of the fruits of labour in both field and factory. Fourier advocated differences of individual payment and the allowance of interest on capital. Owen was prepared to allow interest until the owners of capital voluntarily gave it up, as he believed they would; but he favoured fully communal living in his villages and elsewhere payment to producers on a basis of "labour-time" instead of money — that is, of the time necessary for the various kinds of work, which Marx later called "socially necessary labour time."

The basis of Owen's doctrine was that the social character of men (*i.e.*, their social behaviour) is made for them and not by them: it is the product of environment and education and can be changed by improving these things. Me was led to denounce all established religions because they taught that men were responsible for their evil doings, instead of attributing them to bad environment, and he set out to preach social rather than moral reformation. These views were first expounded in Owen's *New View of Society* (1813–14) and more fully in his *Report to the County of Lanark* (1821). They came into prominence after the end of the Napoleonic wars. when Owen appealed to the government both for factory legislation to protect the workers and for state action to cure unemployment by setting up villages of co-operation. Unlike Fourier. Owen did not exclude state action: he appealed first to the state and then. when it failed to respond, next to private philanthropists and subsequently to the working classes directly.

Owen's views attracted a large working-class following. From about 1830 to 1834 he was in effect the leader of a vast trade union movement aiming at the emancipation of labour by setting up co-operative productive societies, labour exchanges (for the exchange of the products of different trades on a basis of labour time). and great national associations, such as the Guild of Builders, designed to take over whole industries. On the collapse of this movement in 1834 Owenism remained the creed of a substantial body of followers. who turned back to the attempt to establish villages of co-operation. Some of these had been tried already—New Harmony, in the U.S.. in 1825; Orbiston, in Scotland, in 1826; and Ralahine, in Ireland. in 1831. A last Owenite community mas started at Queenwood, in Hampshire, in 1839, on a basis that incorporated some elements of Fourier's doctrines. It failed in 1845; and Owenism thereafter gradually faded away, giving place on the one hand to secularism and other forms of "rational religion" and on the other to the great successful movement of consumers' co-operation, instituted in 1844 by the Rochdale Pioneer's Co-operative society, who were ardent Owenites. *(See* CO-OPERATIVES.)

Meanwhile, in France, Fourier had a successor in utopia building in Étienne Cabet (1788–1856), author of *Voyage en Icarie* (1842) and of an unsuccessful attempt to found a community in Texas and later in Illinois. Cabet's work was much influenced by Sir Thomas More's *Utopia.* It presented the picture of a perfectly symmetrical state. owning all the main industries and dividing the product on a basis of equality. Cabet's rulers were to be chosen by popular election, hut were to have large powers, analogous to those of Saint-Simon's industrial leaders. Cabet borrowed some of the features of Fourier's *phalanstères*, but departed from Fourier in laying great stress on the state and on uniformity of dress. status and behaviour among the citizens. Like Saint-Simon, he put much emphasis on the role of science and, like Fourier, on education, which, with Owen. he regarded as the means of training children in the right social ideas. Pending the establishment of Icaria, he was a strong advocate of minimum wage laws and of progressive taxation of the rich.

First Anticapitalist Writers. — Cabet was the last of the group of utopia makers who represent socialism in its first phase of evolution. Saint-Simon. though contemporary with this group, does not belong to it; and Owen is notable not only as a utopia maker, but even more as a leader of great working-class movements and an acute critic of the doctrines of orthodox political economy. In this last field he was the first of a group of writers who took the accepted principles of classical economics and based on them anticapitalist or socialist deductions. Owen's *Report to the County of Lanark* in many respects anticipates Mars; and Owen's leading follower in the realm of theory. William Thompson (1785–1833) (*Principles of the Distribution of Wealth Most Conducive to Human Happiness*, 1824), develops further the doctrine that, as labour is the sole true source of value, the labourers by hand or brain should receive in common the entire product. to be distributed on a basis of the greatest practicable social equality. Thomas Hodgskin (*Labour Defended Against the Claims of Capital*, 1825; *Popular Political Economy*, 1827; *The Natural and Artificial Right of Property Contrasted*, 1832) similarly turned the doctrines of the Kicardians against capitalism, but, following Godwin, arrived at anarchist rather than socialist conclusions about the new social order. Apart from Godwin, the sequence of British anticapitalist writers began with Charles Hall *(The Effects of Civilisation,* 1805) and continued with the Spencean Thomas Evans' *Christian Polity* (1816), Piercy Ravenstone's *Doubts on the Correctness of Some Opinions Generally Entertained on the Subject of Political Economy* (1821) and John Gray's *Lecture on Human Happiness* (1825). The Christian Owenite John Minter Morgan contributed *On the Practicability of Mr. Owen's Plan* (1819). *The Revolt of the Bees* (1826) and *Hampden in the Nineteenth Century* (1834); and William Thompson followed up his magnum opus with *An Appeal of One-Half the Human Race* [women] (1825), *Labour Rewarded* (1827) and *Practical Directions for the Establishment of Communities* (1830). T. R. Edmonds' *Practical, Moral and Political Economy* (1828), John Gray's *The Social System* (1831), J. F. Bray's *Labour's Wrongs and Labour's Remedies* (1838–39) and Mary Hennell's *Outline of the Social Systems and Communities Founded on the Principle of Co-operation* (1844) are the other leading works of the British Owenite and anticapitalist schools. Most of these writers mingled socialist deductions from Ricardian economics with ingredients drawn from Owen's co-operative doctrines. Bray wrote in England. but was born in America.

After the collapse of the Owenite trade-union and co-operative movements in 1834, the emphasis in Great Britain shifted to Chartism. with its demand for parliamentary reform based on manhood suffrage and annual parliaments. *The People's Charter,* published in 1838, crystallized this program, behind which was the driving force of acute economic distress arising out of the new Poor law of 1834 and the prolonged industrial depression that began in the 1830s and continued into the "hungry '40s." Chartism, resting on economic distress, had no clearly defined economic program: it was a hunger revolt, without much theoretical basis in its early stages. Under the leadership of Feargus O'Connor (1794–1855) it developed in the 1840s a "back-to-the-land" program based on individual peasant holding in collectively acquired land settlements (O'Connorville, Charterville), as against the Owenite advocacy of collective tillage in villages of co-operation. The Chartist land scheme collapsed in 1848. and thereafter Chartism broke up into a number of sects, with which it will be more convenient to deal later.

French Socialism. — While Chartism was running its course in Great Britain, socialism was taking on new forms in France after the revolution of 1830. The revolt of the Lyons weavers in 1831 is often regarded as the starting point of the French proletarian movement; and under the monarchy of Louis Philippe began the insurrectionary career of Louis Auguste Blanqui (1805–81), who passed more than 40 years in prison for various conspiracies. Blanqui. whose essential writings were collected in 1885 as La *Critique sociale,* was the successor of Babeuf in the advocacy of the seizure of power by a revolutionary minority, which would at once proceed to institute a socialist system. He organized conspiracies in 1836 and again in 1839. Released in 1848, he promptly attempted a new conspiracy, and was in prison until 1859. In 1861 he was again imprisoned for four years. In 1870 he headed the extreme left in Paris, but was imprisoned by Louis Thiers before the Commune. in which his followers played an important part. Blanqui's theories of revolutionary dictatorship contributed much to the French syndicalist doctrine of *la minorité consciente*, but were opposed by the Marxists, with their rival theory of mass dictatorship of the proletariat as a whole.

Blanqui was always the leader of small groups of ardent socialist revolutionaries. Under Louis Philippe, the main body of French working-class and socialist opinion followed. not him. but either Louis Blanc (1811–82) or Pierre Joseph Proudhon (1809–65). Blanc can be claimed in many respects as the forerunner of modern social democratic doctrines. His most important work, *L'Organisation du travail* (1839), demanded that the state should give full recognition to the "right to work," and should provide capital for "national workshops" (*q.v.*) to be managed collectively by the workers under public ownership. In the revolution of 1848 Blanc became a member of the provisional government, but was unable to get his ideas carried into effect, the so-called "national workshops" started by his opponents being mere relief works which were meant to fail so as to discredit his proposals. Blanc went into exile when Louis Bonaparte came to power, and spent many years in England. writing a series of important books on British social and political conditions. His other main socialist writings are *Le Socialisme: droit au travail* (1849); *Catdchisme des socialistes* (1849) and *Histoire de dix ans, 1830–40* (1840). Blanc was the originator of the socialist formula "From each according to his abilities: to each according to his needs." He stands for a socialism resting on public ownership, combined with workers' control in industry, and for a democratic parliamentary system as the instrument of socialist advance.

The idea of co-operative workshops, without that of state control, was also actively urged in the 1830s by the follower of Saint-Simon. Philippe Benjamin Joseph Buchez (1796–1865), who became the foremost advocate in France of Christian socialism and largely inspired the English Christian socialists. His views are embedded in his periodical. *L'Européen,* and in his *Essai d'un traité complet de philosophie* (1839) and *Traité de politique et de science sociale* (1806).

Much more important than Buchez was that singular genius, P. J. Proudhon (1809–65), whose work belongs essentially to the history of anarchism rather than of socialism. From *Qu'est-ce que la propriété?* (1840), with the startling answer "*La Propriété, c'est le vol*" ("Property Is Theft"), to *De la capacité politique des classes ouvrières* (1865). Proudhon poured out a spate of books in which he mingled devastating criticism of the institutions of capitalism with emphasis on the inherent capacity for self-organization of the working class. He became the leading advocate of *mutuellisme,* whether it took the form of co-operative societies or labour banks or trade societies, or any form of working-class organization in which might be descried the germ of the classless, nongovernmental society of the future. Proudhon called himself a socialist as an opponent of capitalism and individualism and private property; but his positive doctrine always laid the main stress on personal freedom and voluntary association in a society freed from the tyranny of monopolist property rights. He favoured personal property and inheritance under a moralized system of property rights designed to exclude exploitation, and laid great emphasis on the abolition of interest and the provision of free credit to the producers. His best-known books, in addition to those already cited, are *Systbme des contradictions économiques ou, Philosophie de la misère* ("The Philosophy of Poverty") (1846), which provoked a famous reply from Marx: *Misère de la philosophie* ("The Poverty of Philosophy") (1847); *Confessions d'un révolutionnaire* (1849); *Idée générale de la révolution au XIXe siècle* (1851); *La Révolution sociale* (1852).

Proudhon was addicted to complicated logical arguments, based iargely on the idea of inherent "contradictions" in capitalist society. He used, or, as Marx held. misused, the Hegelian dialectical method extensively. He was not a system maker but a critical and suggestive writer of great force. Marx classed him as a *petit bourgeois,* because he had little grasp of historical evolution or of the power of great industry, and because his mutualist doctrines were taken up by the declining class of small-scale producers and were inapplicable to large-scale capitalist conditions. Proudhon's ideas had great influence on the development of French syndicalism and he ranks, with Mikhail Bakunin, as the principal philosopher of 19th-century anarchism.

Marxism.— Up to the 1840s socialism developed almost exclusively as a French and British mevement. Industrial evolution was much more advanced in Great Britain than elsewhere; and France had been. from the 18th century, the principal seedbed of revolutionary political ideas. In Germany, which was politically divided and economically much more backward, socialism began as a movement when the more radical followers of Georg Hegel came into contact with advanced French social ideas in the course of the '30s and '40s. Johann Fichte (1762–1814), has sometimes been claimed as an ancestor of German socialism. because he exalted, as a nationalist and a social reformer, the claims of the state; but there is no substance in this view, unless all statist doctrines (including modern national socialism) are to be regarded as socialist.

German socialism really begins with the materialist philosophy of Ludwig Feuerbach (1804–72), who much influenced Marx, and with the "left" Hegelians, such as Bruno Bauer (1809–82), Moses Hess (1812–75) and Karl Grün (1813–87). Beginning as a realist or materialist critique of religion and of the established German philosophy *(see* Karl Marx and Friedrich Engels, *German Ideology),* this "left" Hegelianism, in which Marx was brought up, broadened out under French influence into Marxist "scientific socialism," taking the materialist conception of history, first clearly formulated by Karl Marx (1818–83) and Friedrich Engels (1820–95) in the *Communist Manifesto* of 1848, as its essential foundation. This famous manifesto, the starting point of the modern socialist and communist movements, was issued in the "year of revolutions," 1848. by the Communist league, which Marx had created on the basis of the Gennan societies of exiles that had been preaching various forms of utopian socialism from the late '30s. Wilhelm Weitling (1808–71) *(Guarantees of Harmony and Freedom,* 1842) was the principal leader of this pre-Marxist German socialist movement, but was pushed out of the way by Marx and Engels as a moralist-utopian as soon as they had formulated their essential ideas. The League of the Just (1836–47) gave place to the Communist league, which at its congress in Dec. 1847 authorized Marx and Engels to draft the *Communist Manifesto.*

The Communist Manifesto.— This most celebrated of all socialist documents is the first clear proclamation of the revolutionary role of the proletariat, or working class. It sets out from an interpretation of all human history as a sequence of vast class struggles for power. Behind these struggles, and as their cause, lies the development of the "powers of production," or, in other words, of man's command over the forces of nature. Every stage in this development demands a corresponding organization of social forces for its exploitation—a particular arrangement of property rights and class relationships. sustained by an appropriate political and ideological system. This political and ideological system, however, though it is used to enforce obedience to the class conditions required, is not their cause but their result. The driving force lies in, the powers of production themselves; and, as these develop, a disharmony arises between them and the social and political structure based on what they were at an earlier stage. This disharmony expresses itself in class struggles and leads to social revolution, which, when it comes, rapidly destroys the obsolete social structure and replaces it by a structure in harmony with the changed needs of the time. Such social revolutions involve and include revolutions in ideas as well as in institutions: they are the major turning points of human history.

Marx and Engels were far from supposing. as some of their critics have taken them to suppose, that all historical events could be explained in terms of this formula. It applies only to the great revolutions of history, and not to day-to-day events outside moments of historic crisis. Nor did Marx and Engels ever suggest that men are moved only by economic or self-interested motives. That is not the point, which is that, whatever may be the motives that move men, they are impelled by historical necessity to adapt their social structures and ideas to the requirements of the development of the powers of production. "Man," Marx writes, "always makes his own history," but he goes on to say that man makes it within the limiting conditions set by the problems and material realities of his own time and place.

The *Communist Manifesto* throws out, on the basis of this conception of history, a resounding challenge to the governing class, which is warned that the proletarian revolution is on the march. It includes also a searching criticism of other schools of socialists who fail to take their stand upon the principle of the class war. The work of the utopian socialists is passed under review; the followers of Proudhon are castigated; adverse comment is passed on Christian socialism and on the so-called "professorial socialism" which was becoming fashionable among a school of German economists. The communists, on the strength of their understanding of the historical role of the proletariat, put themselves forward as the natural leaders of the coming revolution, and sweep aside the *petit bourgeois* radicals whom they regard as in process of being rapidly superseded by the development of economic forces. This is not meant as an adequate summary of the Communist *Manifesto*: there is no space to deal with it adequately. All that can be attempted is to select the points most important for the history of socialism.

The defeat, in Germany and all over Europe, of the revolution of 1848 naturally involved a setback for European socialism. The Communist league disappeared; the leaders of socialism were again scattered and mostly in exile. But from this time on Marxism, though not yet fully developed as a system, found adherents in most of the leading countries. In England it influenced the later stages of Chartism, which became more consciously socialist as it ceased to be a mass movement. Of the Chartist leaders the three who have some claim to a place in socialist history are George Julian Harney (1817–97), Ernest Charles Jones (1819–69) and James Bronterre O'Brien (1805–64). Harney, who first published the *Communist Manifesto* in England, was a revolutionary who looked back to 1789 and regarded the proletarian revolution as the necessary completion of the French. He was influenced by Marx, but presently Marx discarded him as too unstable, and transferred his hopes to Ernest Jones, who became the principal English exponent of Marxism in his speeches and journals (Notes for the People, 1851–52; The People's Paper, 1852–58). O'Brien, also much influenced by the French Revolution and especially by Babeuf, never became a Marxist. Originally an Owenite, he developed into a state socialist, looking forward to nationalization of the land, public utilities and industries subject to monopoly. His principal work is his unfinished "Rise, Progress and Phases of Human Slavery" (in Reynolds' Political Instructor 1849, republished 1885). By 1860 Chartism in these later forms had flickered out, and socialism hardly existed in England except in the form of sympathy for utopian socialism in the writings of John Stuart Mill and some other leading economists.

Christian Socialism. — There had been in England, however. in 1848 and the following years a movement for what was called "Christian socialism" (*q.v.*) but was in fact rather co-operativism. This was mainly due to John Malcolm Ludlow (1821–1911) who had been much influenced by Philippe Buchez, Louis Blanc and the development of co-operative workshops in France, and succeeded in enlisting John Frederick Denison Maurice (1805–72), Charles Kingsley (1819–7j), Edward Vansittart Neale (1810–92), Thomas Hughes (1822–96) and others in support of a movement to set up similar workshops in England, on a definitely Christian basis. The English Christian socialists were moved by horror at the appalling conditions prevailing in the workshops and factories and at the un-Christian spirit of the spreading industrial system, but were skeptical of the Chartist remedy of political reform. Kingsley announced that in his view the "French cry, Organization of Labour" was worth a dozen of the People's Charter. Immediately, the Christian socialists set out to establish small working associations which they financed, in the hope of sowing the seeds of a neu social order. These soon failed; but they were led to give great help to the growing consumers' co-operative movement, especially in securing for it a legal status under the Industrial and Provident Societies act of 1852. Later, the Christian socialists made many further attempts to foster producers' co-operation and also to secure the acceptance of profit sharing and copartnership in capitalist industry. They also transferred their activities to education, founding the Working Men's college in London (1854) ; but by the later 'jos the Christian socialist movement, as such, had practically ceased to exist.

Christian socialism developed also on the continent. in somewhat different forms, largely connected with the Roman Catholic Church. In France. its forerunner was Bishop Claude Fauchet (1744–93), the Girondin, who preached a form of Christian communism at the time of the Revolution. Hugues Félicité Robert de Lamennais (1782–1854), co-founder of *L'Avenir* (1830–32), can also be regarded as a forerunner (Paroles d'un croyant, 1834). Buchez, as we have seen, influenced Ludlow; and there has always been in France a Catholic social movement with some affinity to Christian socialism. The movement, honever. developed much more strongly in Germany. partly under the influence of the Protestant Victor Aimé Huber (1800–69), founder of the Association of Christian Order and Liberty and leading advocate of co-operative production, and partly under that of the Roman Catholic bishop Baron Wilhelm Emmanuel von Ketteler (1811–77), who also advocated co-operative production as a means of curing the ills of capitalism and promoting reconciliation of classes. The movement spread to Austria and Belgium. but, like English Christian socialism, it belongs rather to the realm of social reform than to that of socialism in the usual sense of the word.

Also on the borderline of socialism is the German economist, politician and landowner Karl Rodbertus (1805–75) (Social Letters, 1850–51; Illumination of the Social Question, 1875), who expounded the subsistence theory of wages and the labour theory of value, and proposed state action to increase the labourer's share in the product by preventing the owners of capital from appropriating the fruits of rising productivity. Rodbertus regarded society as in process of evolution from the wage system to one in which the means of production would be publicly owned, and private property would survive only in respect of income, which would correspond to the value of each man's labour. He also threw much light on the theory of economic crises, and considerably influenced the later formulation of Marx's ideas.

A much more central figure in the development of German socialism is Ferdinand Lassalle (1825–64), founder of the Universal German Working Men's association (Allgemeiner Deutscher *Ar*beiterverein) (1863), the first organized German Socialist party, in opposition to the Liberal party headed by Franz Schulze-Delitzsch. Lassalle, who was a great orator, caused this body to spread with extraordinary rapidity, but he was killed in a duel the year after its definite formation. It languished in his successors' hands and was finally fused in 1874–75 with the rival Marxist Social Democratic party formed in 1866 under the leadership of Wilhelm Liebknecht (1826–1900) and August Bebel (1840–1913). Lassalle laid great stress on the "iron law of wages," *i.e.*, the theory that wages tended under capitalism always to subsistence level, and attacked proposals for credit associations, consumers' co-operative societies and similar bodies as useless to help the workers in face of this inexorable law. Instead. he urged that "the working class must become itself a monster employer," not in little producers' co-operative societies, but by taking over large-scale industry "in the massed and concentrated form of the factory, with its enormous advantage in productivity." As the workers could not do this by voluntary action, it mas necessary to invoke the power of the state, which "exists only to expedite and assure the march of culture." The state should place the necessary credits at the disposal of the associated workers, who should proceed to take the conduct of industry into their own hands, and should receive, in addition to their wages, dividends based on the profits of the several collective undertakings. The state, says Lassalle, "is the consolidated people"; but it can be made an instrument for the proposed change only by universal and direct suffrage, which must therefore be won by means of universal association and agitation. Under universal suffrage, the state will stand ready to execute the people's will (Open Letter to the German Working Men's Association, 1863). Lassalle was thus an advocate of socialization, to be achieved by means of political agitation and action, through a democratization and democratic conquest of the machinery of the state. But he was also, pending this democratization, ready to appeal to the existing state to extend help to the workingmen's associations. He discussed his plans with Bismarck, who undoubtedly learned something from Lassalle both in constituting the German Reich and later in introducing the social measures sometimes called "Bismarckian state socialism."

The First International. — Meanwhile Marx, in London, had published in 1859 his Critique of Political Economy — virtually an advance sketch of Capital, and containing a plain exposition of the essentials of the materialist conception of history. The first volume of Capital appeared in 1867 — the only volume published during Marx's lifetime. But before this Marx had succeeded in bringing into existence in London the International Working Men's association, or "first international" (1864) (see INTERNATIONAL, THE), consisting at the outset mainly of continental exiles and British trade-union leaders who sympathized with foreign revolutionary aspirations, however little they were disposed to foment revolution in their own country. The project of an international association had come in the first instance largely from the followers of the liberal nationalist leader Giuseppe Mazzini; but Marx succeeded in pushing them aside and in securing a body ready to follow his own lead. He drafted the address and statutes, and soon branches were founded in a number of European countries, including Germany. France, Belgium, Italy, Switzerland and Spain. The new international played a considerable part in the labour troubles of the later '60s in France and elsewhere; and the outbreak of the Franco-Prussian War in 1870 found it active all over western Europe. In France and Belgium it was at first largely dominated by the followers of Proudhon and the Belgian collectivist socialist Jean Guillaume César Alexandre Hippolyte Colins (1793–1859), in Germany by the Marxists. in Italy and Spain and parts of Switzerland by the anarchists, of whom the Russian Mikhail Bakunin (1814–76) became the acknowledged leader. The first international held congresses in London (1865), Geneva (1866), Lausanne (1867), Brussels (1868), Basel (1869) and, after an interval caused by the war, at The Hague (1872). Its statutes and addresses were widely drawn, to attract adherents from a number of different schools: and its general council was composed largely of British trade-union leaders, who left the running to Marx and the group of exiles he had gathered round him. In 1867 there was a struggle between the Marxists and the followers of Proudhon, who were driven out; and thereafter until 1871 Marx was practically in control.

The testing time for the first international came with the proclamation of the Paris Commune in 1871, after the defeat of France by Prussia and the fall of Napoleon III. Marx had advised his French followers against the rising, but when it took place he rallied at once to its defense. In Paris. members of the first international took part in the Commune side by side with the followers of Blanqui and of Proudhon. The Paris Commune was the first occasion on which the working class actually achieved political power, albeit only for a few weeks; and the rising was of immense symbolic importance for socialists everywhere. Marx, in the manifesto upon it (published as The Civil War in France, 1871) which he wrote in the name of the international, seized on its significance for the strategy of socialism as a whole. The proletariat, he held, could not assume power merely by taking over the existing apparatus of the bourgeois state. It needed to break the old state in pieces and to construct in its place a new proletarian state of its own. He praised the Communards for what they had done in this way, while criticizing them for having proceeded too slowly and too mildly to meet the need. At a time when the entire capitalist world'was denouncing the Commune for its revolutionary excesses, Marx stressed rather the hesitancy and the clemency with which the proletariat had employed its new power.

There was acute controversy in socialist and labour circles about the Paris Commune. Marx's defense was too strong meat for many of the English trade-union leaders who had hitherto lent their names to the lnternational Working Men's association; and in all countries the more timid or reformist adherents of socialism were scared off. The defeat of the Commune by Thiers and the reactionary French national assembly which wiped it out in blood was fatal to the international, already torn asunder by the dispute between the Marxists and the anarchist, or antipolitical. followers of Bakunin. At the Hague conference of 1872 Marx, in order to get rid of what had become an embarrassing child and to prevent its appropriation by the followers of Bakunin, obtained a vote removing the seat of the international to the United States, where, after lingering nominally for a few years, it was ingloriously wound up. The followers of Bakunin maintained for a time their rival international in Europe; but it struck no lasting roots except in Spain.

The question posed by Marx in connection with the Paris Commune—should the proletariat aim at conquering the bourgeois state in order to use it as the instrument of proletarian power, or should it set out rather to destroy the bourgeois state and replace it by a new, proletarian state of its own?—continued to divide the socialist movement. This very question came to a head when it was proposed, a few years after the Commune, that the German followers of Marx and of Lassalle should combine to form a single Social Democratic party. Lassalle, as we have seen, had stood for the conquest and use of the state, which he had regarded as needing only to be based on universal, direct suffrage in order to become an instrument of social progress. Marx, on the other hand, held that the bourgeois state was incapable of such conversion, and indeed that every state was essentially a class institution, made in the image of a particular ruling class—so that each class, on coming to power, would need to break the state of its predecessor and make a new state of its own as the instrument of its "dictatorship." This is the theory of the dictatorship of the proletariat, which the Bolsheviks claimed to apply in the Soviet Union after 1917.

Social Democracy.—Liebknecht and Bebel, Marx's leading supporters in Germany, were not prepared in 1875 to jeopardize union with the Lassalleans by insisting on this principle. The Gotha program, on the basis of which the German socialist forces were united in that year, accepted by implication Lassalle's view of the state. Marx, to whom the draft was sent, protested violently in a memorandum to the German Social Democrats (subsequently published as Critique of the *Gotha* Programme); but the leaders in Germany actually suppressed his criticism. and pushed the amalgamation through. The German Social Democratic party thus came to birth with a contradictory set of objectives. Most of the language of its program was that of Marxism, but embedded in it was the objective of winning power by taking over the control of the bourgeois state, rather than by overthrowing it, together with an advochcy of co-operative production on the lines proposed by Lassalle. In effect, the German Social Democratic party became a parliamentary party, aiming at the assumption of political power by constitutional electoral means. Its leadership, however, was in the hands of men who regarded themselves as devout Marxists but who refused to accept the dictatorship of the proletariat as part of the essential Marxian doctrine.

This was of vital importance for subsequent socialist history, for over most of western Europe German social democracy became the model on which national Social Democratic parties were organized. In France Jules Guesde (1845–1922), after several years of agitation, was joined by Marx's son-in-law Paul Lafargue (1842–1911) in founding the Marxist Parti Ouvrier Français in 1880. In Belgium the followers of César de Paepe (1842–90) formed a similar party, but closely linked up with the trade-unions and co-operative societies, in 1885. In Spain Pablo Iglesias (1850–1925) created a Marxist party, in rivalry to the anarchists, in 1879. In Scandinavia, the Danish party dates from 1879, the Norwegian from 1887, the Swedish from 1889 and the Finnish (the first to secure a parliamentary majority) from 1899. The Italian Socialist party dates from 1892, the Polish Socialist party from the same year and the Dutch Social Democratic party from 1893. The Russian Socialist party was founded, as the Emancipation of Labour group, by G. V. Plekhanov (1856–1918) and P. B. Axelrod (1850–1928) in 1883. Thus Marxian socialism spread over Europe during the final quarter of the 19th century. In some countries. such as Russia and Poland (mainly under Russian rule), the political conditions made parliamentary activities impossible, and the parties maintained a decisively revolutionary and underground character. In most countries, however, they became national parliamentary parties, compelled by the exigencies of electioneering to put forward programs of social reform. to be pressed for in advance of the full conquest of political power and the establishment of a socialist system.

In Great Britain the attempt to establish a Marxist party mas made by Henry Mayers Hyndman (1842–1921), who was chiefly responsible for founding the Democratic federation in 1881. This body had at first only a semisocialist program, as it was attempting to attract into its ranks the radical workingmen's clubs which had followed Charles Dilke and Joseph Chamberlain in their radical phase. Rut in 1884 the federation became the Social Democratic federation and adopted a completely Marxist program. The same year it split, William Morris (1834–96), the socialist poet and artist, and others, with the support of Engels, breaking away to form the Socialist league. Neither of these bodies attracted a large following; but their influence was felt indirectly in the great outburst of strikes among the less skilled workers about 1889 and in the formation of new trade-unions, with a largely socialist outlook, among the dockers (London dock strike 1889), gasworkers and other classes of previously unorganized workers.

At the same time there arose among the miners, under the leadership of James Keir Hardie (1856–1915), a movement for the legal minimum wage and the legal eight-hour day, backed by the newly formed Miners' Federation of Great Britain (1888). The socialists, notably John Burns (1858–1943) and Tom Mann (1856–1941), placed themselves at the head of the less skilled workers, adding the demand for the "right to work" to those for the minimum wage and the eight-hour day. Hitherto British trade-unionism had been for the most part attached to the Liberal party under W. E. Gladstone; but from the late '80s there arose a widespread movement for independent labour representation, and the local bodies formed on this basis joined forces in 1893 in the Independent Labour party (I.L.P.) under the leadership of Keir Hardie, with an evolutionary socialist program. Powerfully reinforced by the *Clarion*, founded in 1891 by Robert Blatchford (1851–1943), whose *Merrie England* (1894) sold more than 1,000,000 copies, the I.L.P. set out from the first to induce the trade-unions to enter politics on the socialist side. In 1900 it was successful in bringing into existence the Labour Representation committee as a federation of trade-unions and socialist bodies, but without a fully socialist program.

Fabianism.—We must now retrace our steps to 1884. The Social Democratic federation, after the split, fell almost completely under Hyndman's control and pursued a narrow and doctrinaire form of Marxism which alienated the trade-unions interested in immediate reforms and drove one working-class leader after another out of its ranks. Morris' Socialist league, which had seceded partly as a protest against Hyndman's dictatorial methods and partly because it objected to the running of Socialist candidates aided by Tory gold in order to split the Progressive vote. turned aholly antipolitical and was captured by anarchists. who drove William Morris out of it and deprived him of his paper, the *Commonweal,* in which originally appeared his socialist romance, *News From Nowhere* (1891).

In the same year as the Socialist league (1884), the Fabian society was founded, of which Sidney Webb (1859–1947) and George Bernard Shaw (1856–1950) speedily became the outstanding leaders. The Fabians were a small group of intellectual socialists, standing for an evolutionary conception of socialism in sharp contrast with Marxism and endeavouring, by progressive reforms and the nationalization and municipalization of industries, to turn the existing state into a "welfare state." The name they adopted was derived from that of Quintus Fabius Maximus, known as Fabius the Delayer because of his deliberate, long-range strategy. They declared themselves the inheritors of the Benthamite tradition of promoting "the greatest happiness of the greatest number," and maintained that this principle now pointed to extensive state intervention as plainly as it had once seemed to point to *laissez faire*. In *Fabzan Essays* (1889) and in a host of well-informed Fabian tracts the society laid down its essential doctrine and the practical applications of it; and the Fabians also proclaimed a policy of "permeation," by which they meant a readiness to get their ideas taken up by any party or person that would listen to them. Their work considerably influenced the policy of Keir Hardie's Independent Labour party, and their hold on the norking-class movement was strengthened by the careful and constructive studies of trade-unionism and other working-class organizations carried out by Sidney Webb in collaboration with his wife Beatrice Webb (1858–1943). The Fabians can be regarded as the group which first clearly worked out the philosophy and practical implications of that form of "gradualist" socialism which became in practice the policy of the Labour and Socialist parties in most of the countries with parliamentary constitutions, whatever theoretical doctrines they continued to proclaim as the basis of their faith. *(See* also SOCIALISM: PRIKCIPLES AND OUTLOOK; FABIAK SOCIETY.)

Socialism in the **U.S.**—In the United States, socialism followed a different course. After the decline of Owenism and Fourierism which had at one time a considerable hold, socialism practically died out. The single tax doctrines of Henry George (1839–97) obtained a large folloning in the 1870s and helped to prepare the way for socialism, which was reintroduced mainly as the doctrine of immigrants from various European countries. each bringing with him his particular brand. Largely under German influence, the Socialist Labour party was formed in 1877 and ran its first presidential candidate in 1892. It continued to grow until 1898; but then came a split. Daniel De Leon (1852–1914), its leader. insisting on its duty to form a socialist trade-union movement in opposition to the American Federation of Labor. which was strongly antisocialist. De Leon was a Marxist of the extreme left, following Marx's view of the state and the necessity for the dictatorship of the proletariat, and his attempts at industrial unionism were the forerunners of the later attempt to create the Industrial Workers of the World (1905) (*q.v.*), with the difference that De Leon aimed at industrial unionism closely linked with a revolutionary Socialist Labour party, whereas the Chicago I.W.W., led by W. D. ("Big Bill") Haywood, was antipolitical and syndicalist in outlook. In 1901 the seceders from De Leon's S.L.P. joined forces with other groups to form the American Socialist party, under the leadership of Eugene V. Debs (1855–1926), and the new party soon greatly outnumbered the S.L.P., polling nearly 1,000,000 votes for Debs in the presidential election of 1912.

Modern National **Developments.**—Meanwhile, the developing Socialist parties in uestern Europe were being compelled to define their political attitudes. In France, the Parti Ouvrier had split in 1882 into two sections. Guesdists, or Marxists, and Possibilists, the followers of Paul Brousse (1844–1910), with a more moderate program. The Possibilists split again in 1890, when a left wing broke away under Jean Allemane (1843–1935). The followers of Blanqui held together in a separate Comité Révolutionnaire Central; and yet another party, the Independent Socialists, grew out of a group originally created in 1885 by Benoît Malon (1841–93), the author of an extensive *History of Socialism* (1881–84) and the apostle of Le *Socialisme intégral*—the title of his best known book (1891–92). The Independent Socialists attracted a group of highly influential leaders. including among them Jean Jaurks (1859–1914) and Alexandre Millerand (1859–1943). All these groups wooed trade-union support; but the French trade-unions, under the influence of Fernand Pelloutier (1867–1901), held aloof from politics and went over gradually to the doctrines of revolutionary syndicalism and direct action, which were definitely proclaimed, with the general strike, as its policy at the Lyons congress of 1901. This tendency was already well established when, in the middle 1890s, all France was set in turmoil by the Dreyfus affair. This famous affair caused a big reorientation of political forces, including the establishment in 1899 of the ministry of "republican defense" of Pierre Marie René Ernest Waldeck-Rousseau, in which the socialist Millerand was offered and accepted office. The ensuing dispute led to the regrouping of French socialism in two rival parties, the Parti Socialiste de France (Guesdists and Blanquists) and the Parti Socialiste Français (Broussists, Allemanists and Independents), the latter supporting the participation of socialists in a progressive capitalist government. The split lasted until 1905, when the rival parties joined forces in the Parti Socialiste Unifié, under Jaurks, which pursued a stormy course up to the outbreak of World War I in 1914. The assassination of Jaurks, the outstanding leader of French socialism, on the eve of war in that year was a severe blow to French socialism and opened the door wide to fresh dissensions.

The rift in French socialism occurred on the practical question of socialist participation in a capitalist government. In Germany the dispute, with the same fundamental basis, took a different form. In 1891 the German social democrats, in their new Erfurt program, eliminated the Lassallean clauses of the Gotha program of 1875, In 1899 Eduard Bernstein (1850–1932) published ***Die** Voraussetzungen des Sozialismus,* translated under the title *Evolutionary Socialism,* in which he declared the need for a fundamental revision of Marxist doctrine. Bernstein had lived long abroad, first as an exile in Switzerland and from 1888 as correspondent in

London of the Social Democratic *Vorwärts;* and he had been greatly influenced by Fabianism and by the British Independent Labour party. Bernstein denied the imminent collapse of capitalism, the progressive crushing out of the middle classes, the concentration of capital in fewer and fewer hands, the "increasing misery" of the working class and the necessarily reactionary character of the state. He affirmed the importance of working for immediate social reforms rather than for revolution, and asserted that the gradual movement toward socialism was everything, and the ultimate goal of socialism in effect nothing. He attacked the orthodox formulation of the materialist conception of history and emphasized the importance of noneconomic and moral factors in the making of social change; and he regarded the Marxian theory of value as a merely abstract concept remote from actual conditions. Finally, he denied that the industrial proletariat could hope, by itself. to conquer political power and, relying on parliamentarism as against dictatorship, pleaded for a moderate socialism which could be regarded as the heir of liberalism and for an appeal to men and women of all classes rather than to the workers alone.

The demands of "revisionism" led to a tremendous controversy, in which Karl Kautsky (1854–1938) appeared as the principal champion of Marxist orthodoxy. The revisionists were defeated at the congress of the German Social Democratic party, and the letter of Marxism was faithfully preserved. But in practical politics the German Social Democrats to an ever increasing extent accepted Bernstein's precepts, though the very limited elements of democracy in the German constitution greatly limited their practical influence and effectively prevented them, up to 1918, from being confronted with any such problem of participation in the government as had disturbed the French Socialists in 1899.

The rise of national Socialist parties in the leading countries was followed by attempts to create a new socialist international. Periodical international socialist congresses were held from 1889; and in 1900 the International Socialist bureau (the second international) was set up to act as a permanent link between the national parties. Unlike the first international, however. it was not a centralized body claiming to dictate policy to its sections, but a loose federation of independent parties, each claiming to follow its own line in accordance with national conditions. It was much occupied with the questions of antimilitarism and the prevention of war, but refused to endorse the policy of the general strike against war sponsored mainly by the French, and succeeded only in passing ambiguous resolutions which furnished little practical help in the crisis of 1914.

The years immediately before World War I were a period of great labour unrest in many countries. They were marked by a reaction against parliamentary social democracy, by a rapid growth of trade unionism in various forms and by the development of new doctrines of direct action and syndicalism radiating mainly from France. The French syndicalists proclaimed the preponderance of economic over political power, and contended that parliamentarism necessarily involved compromise and a weakening of the will to revolution. The workers, they maintained, must fight their battle on their own terrain—that of industry—by strike action, which could be used to secure political as well as industrial concessions. They must act alone, without invoking the aid of politicians, and must take as their aim the transference of industry into their own hands. The French syndicalists, influenced by Proudhon and Pelloutier, looked forward to the reorganization of France into self-administrating communes under the control of the workers' *syndicats* and *unions de syndicats,* loosely federated nationally and internationally on a basis of pure "workers' control." They were strongly antimilitarist and antipatriotic, favouring the general strike both as a measure against war and as a means of accomplishing the social revolution. In the hands of certain theorists, notably Georges Sorel (*Réflexions sur la violence,* 1908) and Hubert Lagardelle *(Le Socialisme ouvrier,* 1911), the general strike was elevated to the rank of a "social myth," powerful in inspiring the workers to resolute action, even if it never happened in the form supposed.

This syndicalist doctrine owed much to anarchism and had much in common with the anarchist-communism of the great Russian revolutionary Prince Peter Kropotkin (1842–1921), author of *Fields, Factories and Workshops* (1899), *Mutual Aid, a Factor of Evolution* (1902) and other books of wide international influence. It was much like the doctrine maintained in Spain by the Iberian Anarchist federation (F.A.I.) and the Spanish National Confederation of Labour (C.N.T.). Transplanted to the U.S., where capitalism was much more advanced and centralized, it assumed a different form, the attempt to form a single, all-inclusive big union, designed to overthrow capitalism by revolutionary direct action, and to take the great industries into the workers' hands through the Industrial Workers of the World. In Great Britain it appeared in an industrial syndicalist movement led by Tom Mann *(The Industrial Syndicalist,* 1912) and in a modified form in guild socialism. an attempt to reconcile state socialism with the syndicalist doctrine of "workers' control." *(See* SYNDICALISM.)

Guild socialism (*q.v.*), first preached by A. R. Orage (1873–1934) and S. G. Hobson (1868–1940) in the *New Age* about 1911 (see *National Guilds,* by Hobson and Orage, 1912), spread rapidly during World War I, under the auspices of the National Guilds league. The guild socialists stood for state ownership of industry, combined with "workers' control" through delegation by the state to national guilds including all the workers by hand and brain and organized internally on democratic lines. About the state itself they differed, some believing that it would remain more or less in its existing form, and others that it would be transformed into a federal body representing guilds, consumers' organizations, local government bodies and other social structures (G. D. H. Cole, *Guild Socialism,* 1920; S. G. Hobson, *National Guilds and the State,* 1920). Guild socialism was much stimulated during World War I by the rise of the left-wing shop stewards' movement, demanding "workers' control" in the war industries. After the war, the building workers, led by Hobson and Malcolm Sparkes, founded building guilds which built houses for the state; but after the slump of 1921 the state withdrew financial help, and the movement collapsed. The shop stewards' movement also disintegrated when the war ended; and the guild socialist movement fell to pieces, leaving behind it an effect in the incorporation of some element of "workers' control" into the programs of trade unionism and of the Socialist and Labour parties.

Over most of the world, World War I sharply divided the socialist forces. In Great Britain, France and Germany the majorities in the Social Democratic and Labour parties supported their respective countries, whereas in Italy and Russia the majorities were against the war. In Great Britain there was no formal split, but the Independent Labour party, while remaining part of the federally organized Labour party, opposed the war. In Germany, in 1915, the Social Democratic party virtually split, a minority breaking away to become the "Independents," under Kautsky and Hugo Haase, and a group further to the left, the *Spartakusbund* (Spartacus union), appearing a little later under Karl Liebknecht (1871–1919) and Rosa Luxemburg (1870–1919), one of the principal latter-day theorists of Marxism *(The Accumulation of Capital,* 1913). In France, *majoritaires* (for the war) and *minoritaires* (antiwar) waged incessant conflict without positively forming rival parties. In Italy Benito Mussolini broke away from the Socialist party to lead a militant prowar group, which formed the nucleus of the Fascist party. In Poland Joseph Pilsudski, previously a Socialist, sided with Germany in the hope of securing Polish liberation from Russia, while Rosa Luxemburg's followers, who had formed a Polish Social Democratic party in 1893, sided with the Bolsheviks in opposing the war.

Russian Socialism.—The outbreak of the Russian Revolution in 1917, followed by the Bolshevik revolution later in the year, exercised a deep influence on the socialist movement throughout the world. Russian socialism, at the time of the revolution, was divided into four main parties—Social Revolutionaries and Left Social Revolutionaries, active mainly among the peasants, and Bolsheviks and Mensheviks, the rival Social Democratic parties, into which the Social Democratic party of Plekhanov and Axelrod had split. Conditions in Russia were so different from those in western Europe that Russian socialism had followed a largely independent course. The earlier Russian exponents of socialism, Alexander Herzen (1812–70), Peter Lavrov (1823–1900) and Nikolay Chernyshevsky (1828–89), sought to apply western socialist ideas to Russian conditions, whereas Bakunin applied ideas that were indigenously Russian to the conditions of the west. Herzen believed that the survival of the commune as the basis of Russian village life made Russia, despite its industrial backwardness, an appropriate country in which to institute the socialist revolution, which he conceived as above all else a peasant revolution. Chernyshevsky developed these ideas, regarding the overthrow of tsarism and the landlord system and the institution of political democracy as the first steps toward agrarian communism. Lavrov (Letters on History, 1868–69), the philosopher who inspired the Narodnik (People's) movement among the Russian intellectuals, preached a gospel of self-devotion by the educated classes to the cause of the people, and then looked forward to the achievement of socialism by the leavening of the people with socialist ideas, which could be built on the foundations of the communal tradition of Russian village life. Out of the Narodnik movement sprang the Narodnaya Volya, the idealist movement of organized terrorism which was responsible in 1881 for the assassination of Alexander II. This in turn was the precursor of the Socialist Revolutionary party, which came into formal existence in 1901 and, representing many different tendencies, was by far the largest of the Socialist parties at the time of the revolution of 1917. From it split off, under M. Spiridonova, the Left Social Revolutionary party, which joined the Bolsheviks in the second revolution, and for a short time occupied a place in the soviet government.

As against the Social Revolutionaries, whose main appeal was to the peasants, the Russian Social Democrats had their strength among the urban workers. Russian factories were relatively few, even in 1917, but the few were mostly very large and used mass-production methods. The urban proletariat was small, but highly concentrated, and lived under conditions of intense exploitation. We have seen how in 1883 Plekhanov and Axelrod took the lead in setting up in Geneva the Emancipation of Labour group, based partly on local societies established inside Russia in the '70s. This group spread the knowledge of Marxism in Russia. In 1895 Vladimir Ilyich Ulyanov (Lenin; 1870–1924) united the groups in St. Petersburg (Leningrad) into an Emancipation of Labour society, which put itself at the head of the industrial struggles then in progress. Out of this and other local bodies arose the Russian Social Democratic party, which was formed at Minsk in 1898 but did not take definite form until after the foundation of *Iskra* ("The Spark") (1900), a social democratic journal published abroad in which Lenin collaborated with Plekhanov and Axelrod.

The second (and first real) conference of the Social Democratic party was held in Brussels and London in 1903, and adopted a revolutionary program largely drafted by Lenin, including an assertion of the rights of national self-determination, a series of demands for land reform in the interests of the peasants, and a pronouncement in favour of the dictatorship of the proletariat. A dispute arose over the conditions of admission to the party, Lenin demanding a closely knit, disciplined party, whereas the majority favoured open membership for anyone who accepted the declared principles. The leader of the majority against Lenin was Julius Ossipovich Zederbaum, known as Martov (1873–1923), subsequently the leader of the Mensheviks. But on the other issues Lenin's group won, and they were thereafter knomn as the Bolsheviks (majority) whereas Martov's followers mere the Mensheviks (minority). In 1904 the split became definite: the Bolsheviks and hlensheviks holding separate congresses and organizing two rival parties. The basic difference was that the Mensheviks wished to create a Social Democratic party on the model of the national parties in western Europe, and to work in alliance with the bourgeois left for a democratic revolution, holding that the time for socialism in Russia would come when the country had passed through a regime of capitalist democracy, whereas the Bolsheviks wanted a centralized and disciplined party that would aim directly at power and would seek to rouse the peasant masses to rally to the side of the industrial proletariat. The Bolsheviks were prepared to work with the bourgeois left for democratic revolution, but set out to capture at once the leadership of the revolution and refused to make concessions to the bourgeoisie in order to enlist its help.

This is not the place to tell the story of the Russian Revolution —of the disintegration of the large but amorphous Socialist Revolutionary party. the conquest by the Bolsheviks of a majority in the revolutionary soviets of workers and peasants, and the crushing out of the Mensheviks on the Bolshevik assumption of power. (See RUSSIA.) What is relevant here is that the Bolshevik revolution was based throughout on Lenin's interpretation of Marxism, putting in the forefront the dictatorship of the proletariat, the complete destruction of the old state machine and the creation of a new proletarian state as the instrument of the dictatorship (Lenin, The State *and* Revolution, 1917; The Proletarian Revolution and *Kautsky* the Renegade, Eng. trans., 1920). This view of Marxism was combated not only by the Mensheviks in Russia but also by most of the leading social democratic theorists in western Europe, notably Karl Kautsky (The Dictatorship of the Proletariat, 1918; Eng. trans., 1920), and by Émile Vandervelde (1866–1938), the Belgian president of the Labour and Socialist international, which was established in 1920 and reorganized in 1923 as the successor of the pre-1914 second international and continued its traditions practically unchanged, as well as by the British leaders.

The Bolsheviks sent out to the workers of the world a new *Communist Manifesto* (1919) and set out to organize a new third international—the way for which had been prepared by the antiwar international Socialist conferences held at Zimmerwald (1915) and Kienthal (1916), and by the attempt to organize a world conference at Stockholm in 1917—with the design of stirring up revolution throughout the world. At this stage it was widely believed that the Russian Revolution could not succeed in establishing itself unless it were speedily followed by socialist or communist revolutions in the advanced capitalist countries. Leon Trotsky (1879–1940), at that time Lenin's closest collaborator and the creator of the Red army, was especially associated with this view, which was part of his doctrine of "permanent revolution." Trotsky was also an advocate of rapid Russian industrialization as a means of consolidating the power of the revolution and an opponent of concessions to the peasants, which he held would delay this process.

Communism, as developed theoretically by Lenin and later by Joseph Stalin (1879–19j3) and others, was no new doctrine. It was Marxism, applied practically without change to the conditions of contemporary Russia. It could be so applied, because Russia in 1917 was still much like the countries of western Europe at the time when Marx and Engels formulated their essential doctrines. Western social democracy, while it retained its nominal allegiance to Marxism. had in fact so modified Marx's doctrines, especially about the state and dictatorship, as in effect to deny them. It had been working in practice for the peaceful democratic conquest of state power, and for an evolutionary socialism that would set out to use the existing state machine and to transform it gradually. The Russian socialists could not possibly have attempted so to use the tsarist state machine, as was plainly shown in the events that followed the abortive Russian revolution of 1905. They could only seek to overthrow it and to replace it either by a state modeled on western parliamentarism (the Menshevik policy) or by a state based on proletarian dictatorship (the Bolshevik policy). The western social democrats, wedded to parliamentarism, supported the Mensheviks and denounced the Bolsheviks as betrayers of democracy. whereas the Bolsheviks denounced them as counter-revolutionaries and traitors to the socialist cause.

The world revolution hoped for by the Bolsheviks did not come, but neither did the crushing out of the Russian Revolution by the capitalist countries. Through many vicissitudes, the Soviet power was able gradually to consolidate its strength. Trotsky was driven into exile; Stalin became the unquestioned leader and set out to, as he conceived of it, build up socialism nithin a single country under the successive five-year plans and the statute of nationalities, which conferred wide autonomy on the many peoples of the Soviet Union. In 1930 the policy of agricultural collectivization was taken seriously in hand, a form of village co-operative (the *kolkhoz,* or "collective farm") replacing individual peasant cultivation. Industrialization was pressed on fast, and in World War II the Soviet Union plainly demonstrated its might and power of survival. In 1935 Sidney and Beatrice Webb. the theorists of Fabianism, surprised many by publishing their monumental work (Soviet *Communism:* a New *Civilisation*) largely in support of the policies and achievements of Russian Communism. This did not mean that they regarded the Soviet form of revolution as applicable to western Europe They did. however, sharply differ from the social democratic theorists in regarding it as having justified itself fully under Russian conditions.

Later European Developments.—Meanwhile, in the west, the end of World War I brought with it a great increase in the strength of the Social Democratic parties. In Great Britain, the Labour party had been up to 1918 only a small minority group. Profiting by the disintegration of liberalism, it reorganized itself in 1918 under Arthur Henderson (1863–1935) as a nationwide party standing for evolutionary socialism (see its manifesto. Labour and the New Social Order, 1918. written by Sidney Webb). By 1924, under James Ramsay MacDonald (1866–1937), it formed the first (minority) Labour government, which lasted only a year. In 1929 it returned to office. again in a minority. but the second Labour government collapsed in the crisis of 1931, MacDonald seceding with others to form a "national" coalition government. During the 1930s Labour gradually regained strength. It remained a moderate, evolutionary socialist party, and was a partner in the nar coalition formed in 1940. In 1945, in the election that followed hard upon the end of the European phase of World War II. the Labour party for the first time gained a considerable clear majority over all other parties, winning not only the industrial areas, but also most of the suburban residential districts near London and other big cities. Labour thereupon formed its third government, with a definite mandate for the policy of evolutionary socialism on nhich it had fought the election. This policy was set out in its manifesto, Let Us Face the *Future* (1945). In Feb. 1950, by a narrow majority, a Labour government was again elected, but in 1951 the Conservatives regained office.

In Germany, the fall of the Hohenzollerns and the proclamation of the Weimar republic raised the Social Democrats to the position of the first party in the state. But they made no attempt to establish socialism and were soon involved in suppressing left Socialist and Communist groups. The German workers became disastrously divided into rival Social Democratic and Communist parties: and severe economic distress reinforced feelings of national humiliation in stimulating the rise of Adolf Hitler's Nazi, or National Socialist, party, which ultimately seized power in 1933. "National Socialism" (*q.v.*) was not a form of socialism. but its bitterest enemy The so-called "Socialist" element in it consisted in its exaltation of the claims of the national state, regarded as a metaphysical being beyond good and evil, above all individual or sectional claims; but in practice it worked as the ally of large-scale capitalism and militarism and remorselessly crushed out all free ;\orking-class organization. It was the national state, organized to the limit for imperialist war and conquest—the very antithesis of the socialism which it is the function of this article to describe. After 1939, however, Naziism won the allegiance of a few notable socialist renegades, such as the French neosocialist Marcel Déat.

Fascism (*q.v.*), of which Naziism was the German variety. made its first appearance in Italy. under the leadership of Mussolini. Italian socialism, which had opposed the war, adopted a semirevolutionary line after 1918. The Italian workers in 1920 occupied the factories but made no attempt to turn their industrial struggle into a political revolution. Their defeat prepared the way for the march on Rome, by which Fascism seized power in 1922. Italian Fascism, like German Naziism, glorified the state, to which it professed to give a corporative form, based on corporations representing industries and professions. (See CORPORATE STATE.) In fact, behind this facade. it meant dictatorial control by the Fascist party, working in alliance with large-scale capitalism and suppressing all independent working-class or political organizations.

In France. after 1918, the communists were a majority in the Socialist party. which they converted into a Communist party. A large section broke away and reconstituted the Socialist party (known as S.F.I.O.—Section Française de l'Internationale Ouvrière), of which Léon Blum became the leader. In Fiance, as in Germany, socialism was greatly weakened by the conflict between communists and socialists, and the position was made worse by the development of two rival trade-union movements. At length, in 1935–36, the trade-union split was healed, and both communists and socialists allied themselves with the radicals in the popular front. A wave of strikes followed, and many concessions were gained. But the front broke down, and French politics were in disorder at the outbreak of World War II. Following the collapse of 1940, most of the French socialists joined the resistance movements associated with Gen. Charles de Gaulle, and the communists, while maintaining their separateness, took part in the Gaullist and postwar coalition cabinets from 1944 to 1947. In the latter year they were excluded from the government.

In Spain, where the working-class forces were traditionally divided between socialists and syndicalists (with a strong anarchist element, chiefly in Catalonia), a popular front, extending to the radicals, achieved power in 1931, but was overthrown in the ensuing civil war by the Fascist counterrevolution under Gen. Francisco Franco, supported by Germany and Italy, while the western parliamentary countries stood aloof. The U.S.S.R. gave some help. but on conditions that split the socialist forces. In Austria, where the Social Democrats, headed by Otto Bauer (1881–1938), a leading theorist of the movement, were the strongest party in Vienna but had little hold on the Catholic countryside, a Catholic semi-Fascist dictatorship was set up by Engelbert Dollfuss in March 1933, and in Feb. 1934 a rising of the Viennese workers was crushed and the Socialist movement was disrupted or driven underground. In 1938 the Nazis seized Austria and incorporated it in "greater Germany," applying the entire apparatus of suppression.

The social democratic movement enjoyed its only successes between the wars in Scandinavia, especially in Sweden, where. under the leadership of Karl Hjalmar Branting (1860–1925) and later of Per Albin Hansson (1885–1946), it carried through a moderate policy of liberal semisocialism with considerable economic success. Denmark had a similar experience; and in Norway, where socialism was on the whole farther to the left, much progress was also made. The Scandinavian parties made no attempt to introduce socialism, but adopted advanced policies of social reform and economic planning without disturbing the institutions of capitalist property. Their fortunate economic position made this possible to a degree not possible elsewhere. In eastern Europe, under the tutelage of the U.S.S.R.. Socialist parties by mid-century had disappeared or had been absorbed by the Communist parties.

In the U.S., socialism remained backward. The U.S. Communist party took away a good deal of the former support of the Socialist party, but failed to gain a really large following. The American Federation of Labor remained strongly antisocialist and even more anticommunist, refusing all association with the trade-unions of the U.S.S.R. The newer Congress of Industrial Organizations, which arose in 1935 as the result of a breakaway from the A.F. of L., had a more leftist though hardly less anticommunist policy, but did not result in the growth of any nationwide Labour party, although Labour parties arose in a few states, notably New York. The U.S. produced no great socialist thinker, though Upton Sinclair became world famous for his socialist novels (The Jungle, 1906; The *Brass* Check, 1919; Oil, 1927) and there was much acute social criticism, notably in the work of Thorstein Veblen (1857–1929) (Theory of the Leisure Class, 1899; Theory of Business Enterprise, 1904). In Canada, socialism made advances after the establishment in 1932 of the Co-operative Commonwealth federation, the Canadian Labour and Socialist party, which appealed to farmers as well as industrial workers.

In Australia the Labor party, based mainly on the trade-unions, was a powerful political force. It formed the government in 1941 and remained in power for eight years. In New Zealand the

Labour party, having won the elections of 1935, remained in power also until 1949. In South Africa, on the other hand, mainly because of the divisions between African and white workers, socialism made no headway.

Eastern Socialism. — In the far east, Chinese socialism began with Sun Yat-sen (1866–1925), the leader of the revolution of 1912, whose famous Testament is an application of socialist principles to Chinese conditions. The Chinese National party. the Kuomintang, was at the outset partly under socialist inspiration; but following the rise of a Communist movement in China, under Russian influence, there were violent dissensions leading to civil war (1929) until the Chinese communists came to power in 1949–51. The new regime, although closely allied to the Soviet Union and entirely dominated by the Communist party, was adaptable enough to use the services of noncommunists, including small capitalists as well as socialists, in many specialist services and branches of production. Great projects of industrial development were embarked upon with Soviet help, and rapid progress was made with various forms of rural collectivization and co-operation. Many in the west hoped that Chinese communism would before long deviate sharply from the Russian model, but Chou-en-lai (chairman of the state administrative council), in his world tour of 1956–57, was careful to emphasize China's entire solidarity with the Russians, and gave no encouragement to these hopes.

In Japan a Socialist party was formed in 1901 but was speedily suppressed, and there was renewed persecution during the Russo-Japanese War of 1904–05, which the socialists opposed. After 1918 there was for a time a renewal of socialist activity; but no stable socialist movement was established, and by the 1930s the movement had again been wiped out by militarist persecution, or driven wholly underground. Japanese socialism became politically important after 1945, establishing itself as the leading opposition force in the postwar parliament.

Meanwhile, in India, independence put into power a Congress party government, headed by Jawaharlal Nehru, himself a socialist; and this government's second five-year plan, issued in 1956, included large provisions for public investment as well as for welfare development. The Indian National Congress became formally committed to a sort of democratic socialism as a long-term objective, but continued to be largely under nonsocialist leadership and to claim to stand for national unity. The Indian Socialist party operated at first inside the Congress, but presently seceded from it and thereafter experienced considerably fluctuating fortunes and underwent a split in 1955, when a section headed by R. M. Lohia broke away from it. Its outstanding leader was J. Prakash Narayan (*q.v.*). The Communist party was outside the Congress throughout, and achieved considerable strength in some parts of the country, notably in Bengal and the south.

In the Arab countries substantial Communist and Socialist parties made their appearance; but nationalism remained the predominant issue, and the socialists were active mainly in the left wing of the various nationalist movements, though in Syria and Lebanon, as well as in Egypt, social questions — especially land reform — were forcing their way to the front.

In Indonesia the communists became a powerful opposition group; the socialists after playing a considerable part in the early years of independence subsequently lost ground. Burma established itself under broadly socialist rule.

The Asian Socialist parties, after refusing to join the postwar Socialist international, established an Asian Socialist international of their own, which entered into fraternal relations with it.

Socialism at Mid-20th Century. — The wartime alliance between the Soviet Union and the west temporarily eased animosity between European socialists and communists but did nothing to overcome their fundamental differences. Later, such factors as the communist seizure of power in Czechoslovakia, the Korean crisis and Stalin's growing despotism caused further deterioration of this relationship. But the death of Stalin led to a substantial modification of Soviet totalitarianism by 1956, in which year the 20th congress of the Communist party of the Soviet Union was marked by a sharp denunciation of Stalin's methods and by a recognition of the possibility of advance toward socialism by nonrevolutionary methods in certain countries.

Immediately great debates opened both inside the Communist parties of all countries and among left-wing democratic socialists, who foresaw some prospect of improving international working-class relations and of further approaches toward world *détente*. As against this the western socialist parties and the Socialist international uniting them maintained their anticommunist vehemence. The suppression of the Hungarian revolution in Nov. 1956 suggested that the Soviet government was potentially as ruthless as ever and by hardening anticommunist feeling in the west thoroughly confused the over-all situation.

The issue of parliamentary democracy continued to occupy socialist thinkers. In Yugoslavia and, subsequently, Poland one-party rule appeared capable of substantial liberalization; nevertheless democratic socialists continued to stress the virtues of free elections and rival political parties. Doubtless these were indispensable wherever their traditions were established; it was not clear whether they could be insisted upon in countries lacking parliamentary experience and where nonrevolutionary advance was blocked by feudal and absolutist rule. Nor was parliamentary progress toward socialism possible in countries such as France and Italy where the working-class movement was divided into factions unable to co-operate in any way.

Interpretation of Socialism. — The foregoing historical account has been designed to describe the socialist movement by denotation, rather than to attempt any precise definition of socialism, which cannot indeed be accurately defined. Socialism is essentially at once a movement and a theory, and takes different forms under different historical and local conditions. It is fundamentally a movement aiming at a classless society based on the socialization of property in the essential instruments of production and appealing primarily to the working class as the exploited class whose historic mission it is to bring the class system to an end. This description (it is not meant as a definition) admits of many different views of the methods of social and economic organization appropriate to a socialist society and of the steps to be taken for its establishment.

Socialism can be either statist or libertarian, Marxist or "liberal," revolutionary or gradualist, cosmopolitan or only internationalist in a sense that lays stress on the importance of the national unit.

Marx drew a sharp contrast between "utopian socialism," basing itself on moral principles conceived as absolute. and "scientific socialism," resting on the materialist conception of history, with its corollary, the class struggle. As Bfarxism developed, the first great controversy was between the Marxist advocates of disciplined and centralized proletarian mass action and the anarchist (or later syndicalist) upholders of the theory of local mass spontaneity and federalist "free communism," sponsored by the followers of Bakunin and, in a less revolutionary sense, by those of Proudhon (the mutuellistes).

Still later, after the rise of social democracy, the controversy shifted to the question of whether socialists should set out to capture and use the existing state (Fabianism, evolutionary social democracy) or should seek to destroy the existing state and build up a new one by means of proletarian dictatorship (bolshevism, communism).

In these controversies, means and ends were mixed up together. It was partly a question of revolutionary versus evolutionary methods, partly a question of parliamentary democracy versus dictatorship, partly a question of libertarianism versus centralized state authority. Naturally, doctrines and emphasis varied from time to time and from country to country. Marxism, in its emphasis on the scientific basis of the materialist conception of history, tended at the extreme to throw over altogether the moral basis and to regard morality simply as a reflection of the forces of economic evolution. It is, however, difficult to see why anyone should trouble to work for socialism merely because he believes that it is in the line of historical evolution, or unless he also believes it to be good and that what is good ought to be pursued. Moral indignation is not the least of the weapons in Marx's own powerful armoury..

In essence, what Marxism opposes is the view that socialist judgments of value can be reached a priori, without taking account of the conditions of time and place. Man makes his onn history; but the choices open to him are limited by the circumstances in which he has to act, and among these the condition of the "powers of production" holds a key place.

Socialism is essentially a movement for the promotion of the well-being and happiness of individual men and women (the "greatest happiness of the greatest number"), and not of any metaphysical entity such as the state, which should exist only to promote the ends of individuals. That these individuals are grouped in classes, and that social action in its major manifestations takes a class form in no wise invalidates this generalization, which is common to all schools of socialists (but not to "national socialists" or to some forms of so-called "Christian socialism"). Anarchist communism, social democracy and Leninist, though not Stalinist, communism all aim in their several ways at the establishment of a classless society and at the liberation of the human spirit, as well as at the abolition of physical want. Communist dictatorship, however perverted in practice, is intended only as a transitional measure, leading up to the "withering away" of the state. The ideal of world-wide human brotherhood and liberty is common to all schools of socialists, by whatever route they attempt to advance toward it. This holds good even for those socialists who reject "idealism" as a bourgeois doctrine and insist on speaking in terms of class rights and historical necessity rather than of humanistic ideals.

SOCIALISM: PRINCIPLES AND OUTLOOK.' Socialism, reduced to its simplest legal and practical expression, means the complete discarding of the institution of private property by transforming it into public property and the division of the resultant public income equally and indiscriminately among the entire population. Thus it reverses the policy of Capitalism, which means establishing private or "real" property to the utmost physically possible extent, and then leaving distribution of income to take care of itself. The change involves a complete moral *volte-face.*

In Socialism, private property is anathema and equal distribution of income the first consideration. In Capitalism. private property is cardinal and distribution left to ensue from the play of free contract and selfish interest on that basis, no matter what anomalies it may present.

I

Socialism never arises in the earlier phases of Capitalism, as, for instance, among the pioneers of civilization in a country where there is plenty of land available for private appropriation by the last comer. The distribution which results under such circumstances presents no wider departures from a rough equality than those made morally plausible by their association with exceptional energy and ability at the one extreme, and with obvious defects of mind and character or accidental hard luck at the other. This phase, however, does not last long under modern conditions.

All the more favourable sites are soon privately appropriated, and the later comers (provided by immigration or the natural growth of the population), finding no eligible land to appropriate, are obliged to live by hiring it at a rent from its owners, transforming the latter into a *rentier* class enjoying unearned incomes. which increase continually with the growth of the population until the landed class becomes a money-lending or capitalist class also, capital being the name given to spare money.

The resource of hiring land and spare money is open to those only who are sufficiently educated to keep accounts and manage businesses, most of whom spring from the proprietary class as younger sons. The rest have to live by being hired as labourers and artisans at weekly or daily wages; so that a rough division of society into a proprietary class. a middle or employing and managing class, and a wage proletariat is produced. In this division the proprietary class is purely parasitic. As the operation of the economic law of rent makes this class richer as the population increases, its demand for domestic servants and luxuries creates parasitic enterprise and employment for the middle class and the proletariat, withdrawing masses from productive industry and fortifying itself politically by a body of workers and employers who vote with the owners.

Meanwhile, the competition of employers for custom, which leads to the production of a dozen articles to satisfy the demand for one, leads to disastrous crises of feverish overproduction alternated with periods of bad trade ("booms" and "slumps"), making continuous employment of the proletariat impossible. When wages fall to a point at which saving also is impossible, the unemployed have no means of subsistence except public relief during the slumps.

It is in this phase of capitalistic development, attained in Great Britain in the 19th century. that Socialism arises as a revolt against a distribution of wealth that has lost all its moral plausibility. Colossal wealth is associated with unproductiveness and sometimes with conspicuous worthlessness of character; and lifetimes of excessive toil beginning in early childhood leave the toiler so miserably poor that the only refuge left for old age is a general workhouse. purposely made repulsive to deter proletarians from resorting to it as long as they have strength enough left for the most poorly paid job in the labour market. The inequalities become monstrous: hard-working men get 4s. or 5*s*. a day (post-war [World War I] rates) in full view of persons who get several thousands a day without any obligation to work at all, and even consider industrial work degrading. Such variations in income defy all attempts to relate them to variations in personal merit.

Governments are forced to intervene and readjust distribution to some extent by confiscating larger and larger percentages of incomes derived from property (income tax, super-tax, and estate duties) and applying the proceeds to unemployment insurance and extensions of communal services, besides protecting the proletariat against the worst extremities of oppression by an elaborate factory code which takes the control of workshops and factories largely out of the hands of their proprietors, and makes it impossible for them to exact grossly excessive hours of labour from their employees, or to neglect their health, physical safety, and moral welfare with complete selfishness.

This confiscation of private property incomes for public purposes without any pretence of compensation. which is now proceeding on a scale inconceivable by Victorian ministers, has destroyed the integrity of private property and inheritance; and the success with which the confiscated capital has been applied to communal industries by the municipalities and the central Government, contrasted with the many failures and comparative costliness of capitalist industrial adventure, has shaken the super-

'This article by George Bernard Shaw is presented for its historical interest as the expression of a leading figure in the Socialist movement, although his analysis does not tally at all points with equally widespread notions and practices of Socialist theory.—Ed.

stition that private commercial management is always more effective and less corrupt than public management. In particular, the British attempt to depend on private industry for munitions during the World War of 1914–18 nearly led to defeat; and the substitution of national factories was so sensationally successful, and the post-war resumption of private enterprise, after a brief burst of illusory prosperity, uas followed by so distressing a slump that the reversal of the relative efficiency prestige of Socialism and Capitalism was vigorously accelerated. leaving Capitalism unpopular and on the defensive. whilst confiscation of private capital for communal enterprise and nationalization of the big industries grew steadily in popularity in and out of Parliament.

This change in public opinion had already deeply penetrated the middle class because of the change for the worse in the position of the ordinary employer. He, in the 19th century, was admittedly master of the industrial and. after the reform of 1832, of the political situation. He dealt directly and even domineeringly with the proprietary class, from which he hired his land and capital either directly or through agents who were his servants and not his masters. But the sums required to set on foot and develop modern industrial schemes grew until they were out of reach of ordinary employers. The collection of money to be used as capital became a special business, conducted by professional promoters and financiers. These experts. though they had no direct contact with industry, became so indispensable to it that they are now virtually the masters of the ordinary routine employers. Meanwhile. the growth of joint-stock enterprise was substituting the employee-manager for the employer, and thus converting the old independent middle class into a proletariat and pressing it politically to the left.

With every increase in the magnitude of the capital sums required for starting or extending large industrial concerns comes the need for an increase in the ability demanded by their management: and this the financiers cannot supply: indeed, they bleed industry of middle class ability by attracting it into their onn profession. Matters reach a point at nhich industrial management by the old-fashioned tradesman must be replaced by a professionally trained and educated bureaucracy; and as Capitalism does not provide such a bureaucracy the industries tend to get into difficulties as they grow by combination (amalgamation). and thus outgrow the capacity of the managers who were able to handle them as separate units.

This difficulty is increased by the hereditary element in business. An employer may bequeath the control of an industry involving the subsistence of thousands of workers. and requiring from its chief either great natural ability and energy or considerable scientific and political culture. to his eldest son without being challenged to prove his son's qualifications. though if he proposes to make his second son a doctor or a naval officer he is peremptorily informed by the government that only by undergoing an elaborate and prolonged training, and obtaining official certificates of qualification. can his son be permitted to assume such responsibilities. Under these circumstances, much of the management and control of industry gets divided between routine employers who do not really understand their own businesses. and financiers, who. having never entered a factory nor descended a mine shaft. do not understand any business except the business of collecting money to be used as capital and forcing it into industrial adventures at all hazards. the result being too often reckless and senseless over-capitalization, leading to bankruptcies (disguised as reconstructions) which reveal the most astonishing technical ignorance and economic blindness on the part of men in high repute as directors of huge industrial combinations. who draw large fees as the remuneration of a mystical ability which exists only in the imagination of the share-holders.

II

All this steadily saps the business prestige of Capitalism. The loss of popular faith in it has gone much farther than the gain of any widespread or intelligent faith in Socialism. Consequently, the end of the first third of the 20th century finds the political situation in Europe confused and threatening: all the political parties diagnosing dangerous social disease, and most of them proposing disastrous remedies. National governments, no matter what ancient party slogans they raise. find themselves controlled by financiers who follow the slot of gigantic international usuries without any public aims and without any technical qualification5 except their familiarity with a rule-of-thumb city routine quite inapplicable to public affairs, because it deals exclusively. with stock exchange and banking categories of capital and credit. These, though valid in the money market when conducting exchanges of future incomes for spare ready money by the small minority of persons who have these luxuries to deal in. would vanish under pressure of any general political measure like—to take a perilously popular and plausible example—a levy on capital. Such a levy would produce a money market in which there were all sellers and no buyers, sending the Bank Rate up to infinity, breaking the banks, and bringing industry to a standstill by the transfer of all the cash available for wages to the national treasury. Unfortunately, the parliamentary proletarian parties understand this as little as their capitalist opponents. They clamour for taxation of capital; and the capitalists, instead of frankly admitting that capital as they reckon it is a phantom, and that the assumption that a person with an income of £5 a year represents to the State an immediately available asset of £100 ready money, though it may work well enough as between a handful of investors and spendthrifts in a stockbroker's office, is pure fiction when applied to a whole nation, ignorantly defend their imaginary resources as if they really existed, and thus confirm the proletariat in its delusion instead of educating it.

The financiers have their own *ignis fatuus,* which is that they can double the capital of the country. and thus give an immense stimulus to industrial development and production. by inflating the currency until prices rise to a point at which goods formerly marked £50 are marked £100, a measure which does nothing nationally but enable every debtor to cheat his creditor, and every insurance company and pension fund to reduce by half the provision for which it has been paid. The history of inflation in Europe since the World War of 1914–18, and the resultant impoverishment of pensioners and officials with small fixed incomes, forces the middle classes to realise the appalling consequences of abandoning finance and industry to the direction of unskilled, politically ignorant, unpatriotic "practical business men."

Meanwhile, the mobility of capital leads to struggles for the possession of exploitable foreign territories ("places in the sun"), producing war on a scale which threatens not only civilization but human existence; for the old field combats between bodies of soldiers. from which women were shielded, are now replaced by attacks from the air on the civil population, in which women and men are slaughtered indiscriminately, making replacement of the killed impossible. The emotional reaction after such wars takes the form of acute disillusion. which further accelerates the moral revolt against capitalism without. unfortunately, producing any workable conception of an alternative. The proletarians are cynically sulky. no longer believing in the disinterestedness of those who appeal to them to make additional efforts and sacrifices to repair the waste of war. The moral mainspring of the private property system is broken; and it is the confiscations of unearned'income, the extensions of municipal and national communism, above all the new subsidies in aid of wages extorted from governments by threats of nationally disastrous lock-outs and strikes, which induce the proletariat to continue operating the capitalist system now that the old compulsion to work by imposing starvation as the alternative, fundamental in Capitalism, has had to be discarded in its primitive ruthlessness. The worker who refuses to work can now quarter himself on public relief (which means finally on confiscated property income) to an extent formerly impossible.

Democracy, or votes for everybody, does not produce constructive solutions of social problems; nor does compulsory schooling help much. Unbounded hopes were based on each successive extension of the electoral franchise, culminating in the enfranchisement of women. These hopes have been disappointed, because the voters, male and female, being politically untrained and uneducated, have (*a*) no grasp of constructive measures, (*b*) loathe taxation as such, (*c*) dislike being governed at all, and (*d*) dread and resent any extension of official interference as an encroachment on their personal liberty. Compulsory schooling, far from enlightening them, inculcates the sacredness of private property, and stigmatizes a distributive state as criminal and disastrous, thereby continually renewing the old prejudices against Socialism, and making impossible a national education dogmatically inculcating as first principles the iniquity of private property, the paramount social importance of equality of income, and the criminality of idleness.

Consequently, in spite of disillusion with capitalism, and the growing menace of failing trade and falling currencies, our democratic parliamentary oppositions, faced with the fact that the only real remedy involves increased taxation, compulsory reorganization or frank nationalization of the bankrupt industries, and compulsory national service in civil as in military life for all classes, dare not confront their constituents with such proposals, knowing that on increased taxation alone they would lose their seats. To escape responsibility, they look to the suppression of parliamentary institutions by *coups d'état* and dictatorships, as in Italy, Spain, and Russia. This despair of parliamentary institutions is a striking novelty in the present century; but it has failed to awaken the democratic electorates to the fact that, having after a long struggle gained the power to govern, they have neither the knowledge nor the will to exercise it, and are in fact using their votes to keep government parochial when civilization is bursting the dikes of nationality in all directions.

A more effective resistance to property arises from the organization of the proletariat in trade unions to resist the effect of increase of population in cheapening labour and increasing its duration and severity. But Trade Unionism is itself a phase of Capitalism, inasmuch as it applies to labour as a commodity that principle of selling in the dearest market, and giving as little as possible for the price, which was formerly applied only to land, capital, and merchandise. Its method is that of a civil war between labour and capital in which the decisive battles are lockouts and strikes, with intervals of minor adjustment by industrial diplomacy. Trade Unionism now maintains a Labour party in the British Parliament. The most popular members and leaders are Socialists in theory; so that there is always a paper programme of nationalization of industries and of banking, taxation of unearned incomes to extinction, and other incidentals of a transition to Socialism; but the trade union driving force aims at nothing more than Capitalism with labour taking the lion's share, and energetically repudiates compulsory national service, which would deprive it of its power to strike. In this it is heartily seconded by the proprietary parties, which, though willing enough to make strikes illegal and proletarian labour compulsory, will not pay the price of surrendering its own power to idle. Compulsory national service is essential in Socialism, which is thus deadlocked equally by organised labour and by Capitalism.

It is a historic fact, recurrent enough to be called an economic law, that Capitalism, which builds up great civilizations, also wrecks them if persisted in beyond a certain point. It is easy to demonstrate on paper that civilization can be saved and immensely developed by, at the right moment, discarding Capitalism and changing the private property profiteering state into the common property distributive state. But though the moment for the change has come again and again it has never been effected, because Capitalism has never produced the necessary enlightenment among the masses nor admitted to a controlling share in public affairs the order of intellect and character outside which Socialism, or indeed politics, as distinguished from mere party electioneering, is incomprehensible. Not until the two main tenets of Socialism—abolition of private property (which must not be confused with personal property), and equality of income—have taken hold of the people as religious dogmas, as to which no controversy is regarded as sane, will a stable Socialist state be possible. It should be observed, however, that of the two tenets, the need for equality of income is not the more difficult to demonstrate, because no other method of distribution is or ever has been possible. Omitting the few conspicuous instances in which actual earners of money make extraordinary fortunes by exceptional personal gifts or strokes of luck, the existing differences of income among workers are not individual but corporate differences. Within the corporation no discrimination between individuals is possible: all common labourers, like all upper division civil servants, are equally paid. The argument for equalizing the class incomes is that unequal distribution of purchasing power upsets the proper order of economic production, causing luxuries to be produced on an extravagant scale whilst the primitive vital needs of the people are left unsatisfied; that its effect on marriage, by limiting and corrupting sexual selection, is highly dysgenic; that it reduces religion, legislation, education, and the administration of justice to absurdity as between rich and poor; and that it creates an idolatry of riches and idleness which inverts all sane social morality.

Unfortunately, these are essentially public considerations. The private individual, with the odds overwhelmingly against him as a social climber, dreams even in the deepest poverty of some bequest or freak of fortune by which he may become a capitalist, and dreads that the little he has may be snatched from him by that terrible and unintelligible thing, State policy. Thus the private person's vote is the vote of Ananias and Sapphira; and democracy becomes a more effective bar to Socialism than the pliant and bewildered conservatism of the plutocracy. Under such conditions the future is unpredictable. Empires end in ruins: commonwealths have hitherto been beyond the civic capacity of mankind. But there is always the possibility that mankind will this time weather the cape on which all the old civilizations have been wrecked. It is this possibility that gives intense interest to the present historic moment and keeps the Socialist movement alive and militant. (*G.* B. S.)

SOCIALIST PARTY (U.S.). On March 29, 1900, representatives of the Social Democratic Party of America, of which Eugene V. Debs (*q.v.*) and Victor L. Berger were leading members, met in New York city with representatives of the moderate branch of the Socialist Labor party led by Morris Hillquit, Max Hayes and others, and agreed to nominate Socialist candidates for president and vice-president in the 1900 campaign. Their nominees were Debs, former president of the American Railway union, for president, and Job Harriman, California attorney, for vice-president. The two groups waged a joint campaign that resulted in a vote of 96,878 for the Socialist ticket.

Following the campaign the two groups issued a call for a "unity convention" to be held July 29, 1901, in Indianapolis, Ind., with the view toward officially launching a united party. At this convention the older groups dissolved, and formed the Socialist party to serve as "the party of the working class and those in sympathy with it" dedicated to the bringing about of "a system of collective ownership by the entire people of the means of production and distribution." The immediate demands in the party's platform included planks for woman suffrage, old-age pensions, unemployment insurance, health and accident insurance, the increase of wages, the reduction in working hours, direct legislation, and public ownership of public utilities.

During the next 11 years, from 1901 to 1912, the party grew steadily in numbers and influence. Its dues-paying membership increased from 16,000 to 118,000; its presidential vote, with Debs as candidate, from 96,000 to nearly 900,000; its representation in public office from zero to more than 1,000, including 56 mayors, over 300 aldermen, numerous state legislators and one congressman, Victor L. Berger from Milwaukee.

The year 1912 likewise found the party engaged in a vigorous internal struggle with the followers of William D. Haywood, leader of the Industrial Workers of the World (I.W.W.), who emphasized direct, industrial action, including sabotage and the general strike, as a means to a co-operative social order, based on syndicalistic principles. The majority of the party adhered to their belief in parliamentary action and amended the constitution to exclude from membership advocates of sabotage and violence. In 1913 Haywood was expelled from the party's executive committee. The controversy led to the withdrawal of numerous "direct actionists" from the party.

In the following year, 1914, the European war broke out. Some Socialists felt that the United States should immediately enter the war on the side of the Allied powers. The majority took the position, as did millions of other Americans, that the United States should remain neutral and later offer itself as mediator or arbitrator, with a view toward bringing about a just and lasting peace. In 1916 the party nominated Allan L. Benson, writer and antimilitarist, as its presidential candidate and rolled up a vote of more than 585,000.

When the U.S. entered the war in April 1917, the Socialist party at its St. Louis convention declared "its unalterable opposition to the war just declared." During the next year many of the party's journals and meetings were suppressed by the government, and Debs was arrested for delivering an antiwar speech at Canton, O. and sentenced to a federal penitentiary for ten years. While Socialist activity came to a standstill in many parts of the country, it took on renewed vigour in other sections. In New York city, Morris Hillquit, Socialist candidate for mayor on a platform that called for an early and democratic peace, received a record vote of 146,000. He helped to bring into office ten assemblymen and seven aldermen.

On Nov. 7, 1917, the Russian Bolsheviks staged their successful revolution. Many members of the Socialist party were of the opinion that the United States was ripe for a similar revolution and urged the adoption by the Socialist party of Bolshevik tactics and the joining of the Communist International. To aid their cause, they swelled the party membership rolls with recent immigrants from countries of eastern Europe who were better acquainted with the institutions of their homelands than with those of the United States.

The struggle over socialist *v.* communist tactics culminated in the Chicago convention of the party in late Aug. 1919. The left wing elements in the party were defeated and withdrew to form the Communist and Communist Labor parties. Though the party's membership during the struggle was greatly reduced (numbering 26.766 after the convention), the party's vote in 1920 with Debs, still in prison, again as its nominee, exceeded 900,000.

During the early 1920s labour was faced with widespread unemployment, with a concerted attack by employers on the trade union movement, and with attempts of the government to suppress civil rights. At the same time government corruption reached new heights. As a result of these and other conditions. many trade unions turned to independent political action as one method of fighting reaction and an unstable economy. In 1922 a number of leaders of organized labour, particularly in the railway trades, led by William H. Johnston, president of the machinists, formed a Conference for Progressive Political Action. Hillquit was invited to represent the Socialist viewpoint on the conference's governing board. The conference called with others a convention to meet in Cleveland on July 4, 1924, to nominate a Progressive presidential candidate. It nominated Sen. Robert M. La Follette of Wisconsin.

In his acceptance speech, La Follette expressed his belief that a new party would be born following the election. Socialists, seeing in this campaign the beginning of a Progressive or Farmer-Labor party, supported the La Follette ticket, which also received the endorsement of the executive council of the American Federation of Labor. Although the Progressive ticket received nearly 5,000,000 votes, no new party materialized and the Socialists returned to their traditional policy of supporting Socialist candidates, while continuing to work for a national farmer-labour political alignment.

Debs, five times Socialist presidential candidate, died in 1926, two years after the La Follette campaign. In the 1928 elections the party turned to Norman Thomas, writer, lecturer, former Presbyterian minister and co-executive director of the League for Industrial Democracy, as its new standard bearer. In that year, when many were predicting that the "new capitalism" was guaranteeing to the country permanent prosperity, Thomas received but 267,200 votes. Four years later, however, in the midst of the depression, his vote increased to 884,781.

During the next four years various factions developed within the party. They differed in opinion as to "the road to power" and the possibility of limited co-operation with the Communists in the fight against world fascism and reaction. This controversy led in 1936 to the withdrawal of several hundred party members and their organization of a Social Democratic federation. The 1936 convention decisively repudiated any political united front with the Communist party. During the next few years antagonism to the Communist party was progressively sharpened by the American Communists' support of Stalin's policies.

During this four-year period (1932–1936), the Franklin D. Roosevelt administration, in its drive to surmount the depression, embodied in its "New Deal" legislation many immediate demands of the Socialist party platform in the fields of social security, housing, public power and labour-management relations. The enactment of section 7-a in the National Industrial Recovery act gave an impetus to labour in its drive to organize many of the giant industries, while labour leaders came into more cordial relationship with the president of the United States than ever before in the nation's history. As a result of these developments, many trade unions felt politically obligated to give active support to the Democratic administration, and made it increasingly difficult for their members to remain active in the Socialist party and other minority political groups. In the 1936 campaign, therefore, labour's support fell off and the vote for Thomas decreased to 187.720.

During the 1940s and 1950s the party continued to nominate presidential candidates—Thomas in 1940, 1944 and 1948, and Darlington Hoopes, Pennsylvania lawyer and former Socialist assemblyman, in 1952 and 1956. After the outbreak of World War II, and before Pearl Harbor, Socialists opposed America's entrance into the war. When war was declared by the U.S. the majority of Socialists gave it their critical support, while urging the maintenance of civil liberties, democratic controls over war and postwar collectivism and the winning of the earliest peace that promised permanency, followed by the establishment of an inclusive international organization.

In its presidential campaigns the party emphasized increasingly that its economic goal was not the public ownership of all industry, but an economy aimed at equality of opportunity in which public, co-operative and private ownership existed side by side. The 1956 platform urged "the ownership by genuine cooperatives and publicly owned and democratically managed corporations," of public utilities, banks, insurance companies and certain basic industries. Its immediate demands included the expansion of public educational, health, recreational, housing and social security services; the conservation of natural resources; the strengthening of labour legislation; the end of racial discrimination; economic and cultural aid to underdeveloped countries; and international agreements for disarmament with strict inspection and controls.

In 1957 the Social Democratic federation reunited with the Socialist party, forming the Socialist party-Social Democratic federation (S.P.-S.D.F.). Frank Zeidler, mayor of Milwaukee, was elected chairman of the executive committee. A few months after the merger the party was readmitted as a full member into the Socialist International. In 1958, emphasizing its increasing role as a political educational, rather than an electoral organization, the party voted to permit its individual members to enter the primaries of other parties and to support labour and avowedly progressive candidates of other political parties. In 1960 the majority of the party decided against the nomination of a presidential candidate, but campaigned for the party platform, emphasizing the necessity of an honest, meaningful political realignment. While the party's electoral successes have been less than its founders had hoped, since the beginning of the century the party has served as a potent educational force in the social and political life of the nation. SOCIAL PSYCHOLOGY: see PSYCHOLOGY, HISTORY OF.

SOCIAL SCIENCES. The social sciences are concerned with the orderly investigation of the behaviour of man in society with the aim of cumulating a body of relevant theory. Theories concerning group behaviour, whether economic, political or social, are legion. They are implicit in men's actions, transmitted in customary beliefs and elaborated in literature. The distinctive quality of social science is that it attempts to formulate such theories unambiguously and in a way which permits the testing of theory against fact.

Method.—Much of the difficulty in science, contrary to popular misconception, is not to produce theory but to test it. For this reason, together with the relatively low level of development of their subjects compared with the natural sciences, social scientists tend to be as much concerned with method as with result in their inquiries. Indeed what John Maynard Keynes said of economics is likewise true of all social science: "It is a method rather than a doctrine, an apparatus of the mind, a technique of thinking, which helps its possessor to draw correct conclusions." Moreover, though the social sciences may be defined as the study of man in society, it must not be concluded that this is held to be the only method available for the understanding of social phenomena. On the contrary, much insight into the nature of communities, associations, classes, nations and races comes from the poet, the novelist, the traveler and the moralist. The social sciences can claim a special place in the vast body of writing on social life only insofar as they aim to produce generalizations which are verifiable because arrived at by scientific procedures.

The lack of maturity of the social sciences compared with the physical and biological sciences is often attributed to the use of quantification in the latter and its relative absence from the former. Certainly science is refined by measurement, and the conversion into numbers of such concepts as social distance, moral density or political allegiance sets peculiarly intractable problems. Nevertheless it must be recognized that the use of quantitative methods distinguishes the natural from the social sciences only in degree; such methods are used with conspicuous success in economics and demography. and statistical techniques form part of the indispensable equipment of all modern social scientists.

More generally it is characteristic of the modern development of the social sciences that they are modeled on the aims and methods of the natural sciences. What these aims and methods are remains, to some extent, a matter for debate and throughout the 20th century, especially in America, there has been much criticism of misguided imitation of the natural sciences in the quantitative pursuit of the trivial, the substitution of scientism for science. and susceptibility to "testomania and quantophrenia." as Pitirim A. Sorokin said in his *Fads and Foibles in Modern Sociology and Related Sciences* (1956). Nevertheless it is increasingly recognized that there is a unity of method in all generalizing or theoretical sciences which is sometimes called the hypothetico-deductive method and which is admirably expressed in the writings of Karl Popper, for example, in *Poverty of Historicism* (1957), *Logic of Scientific Discovery* (1959) and *The Open Society and Its Enemies* (1945).

"What is important to realise is that in science we are always concerned with explanations, predictions and tests and that the method of testing hypotheses is always the same. . . From the hypothesis to be tested—for example a universal law—together with some other statements which for this purpose are not considered as problematical—for example some initial conditions—we deduce some prognosis. We then confront the prognosis whenever possible, with the results of experimental or other observations. Agreement with them is taken as corroboration of the hypothesis, though not as final proof; clear disagreement is considered as refutation or falsification." (Karl Popper. *Poverty of Historicism,* p. 132, Routledge and Kegan Paul, London, 1957.)

Three Examples.—This brief statement of the fundamentals of theory and method in all science, natural or social, may be illustrated by reference to three examples, one from economics, one from sociology and one from political science. The first comes from Lord Keynes's *General Theory of Employment, Interest and Money* (1936). The pre-Keynesian or neoclassical theory of the level of employment and wages held (1) that the demand for labour is determined by the marginal product of labour and (2) that the supply of labour is determined by the marginal disutility of work. These two schedules when put together would determine the wage of labour and, in consequence, would assure full employment, apart from "frictional" and voluntary unemployment. From this theory it could be deduced that the mass unemployment in the United States in 1932, for example, must have been due basically to a refusal by the unemployed to accept wages corresponding to their marginal productivity. This deduction or prognosis, Keynes argued, was not supported by the facts. He therefore set to work to show that the classical postulate—that the general level of real (as distinct from monetary) wages is determined by the character of the wage bargain—%<-asan illicit assumption which limited the validity of classical theory to the special case of full employment. He then tried to generalize the theory by putting forward a new hypothesis concerning the forces which determine the general level of wages. income and employment, emphasizing, in particular, the level of effective aggregate demand. In the new theory some initial conditions—for example the skill and quantity of available labour and the existing technology—were taken for granted. The level of employment (and the national income) was then explained in terms of variations in three variables—the propensity to consume, the marginal efficiency of capital and the rate of interest—which determine the rate of investment and saving. In contrast to "classical" theory, the rate of interest was explained not in terms of savings and investments but as a function of a new concept of liquidity preference together with the quantity of money. In this way it was possible to deduce the existence of underemployment equilibrium in an economy.

A second example may be taken from the work of the German sociologist Max Weber. His theory that the development of western bourgeois capitalism was necessarily preceded by Calvinist and other Puritan religious movements as creators of indispensable psychological preconditions offers an illustration of theoretical advance by methods akin to those used in the natural sciences. Weber started from the then well-established Marxist theory of the genesis of capitalism through an emerging *bourgeoisie* seizing favourable opportunities for capital accumulation, the creation of a propertyless proletariat and the exploitation of a new technology permitting factory production. He then extended the theory by showing that these "material" conditions, though necessary, were not sufficient. They existed elsen-here, whereas Calvinism or its equivalent social counterpart of capitalism did not. As a result Weber contributed to the cumulation of theory in the social sciences. From the point of view of method Weber's work is one of the best examples of the use of history as a kind of natural laboratory for the testing of a hypothesis. He first established, in his famous essay on "The Protestant Ethic and the Spirit of Capitalism" (1904), that there is a high degree of congruence between the ethic of Protestantism and the organization of economic activity in capitalist societies. He then turned to an immense comparative study of other religions and other civilizations to seek for the negative instance of indigenous capitalism without the ascetic spirit of Protestantism. Of course the vagaries of history could not provide more than a rough approximation to the rigorous controls of an experiment in chemistry, and the Weber thesis remains controversial; but the plan of the work is an impressive demonstration of Popper's doctrine of the unity of method in science.

The third example, taken from political science, begins with German economist and sociologist Robert Michels' "Iron Law of Oligarchy" expounded in his *Political Parties* (1911), which held that political parties and other membership organizations inevitably tended toward oligarchy, authoritarianism and dictatorial leadership. This example again illustrates the paradoxical nature of science as advancing by looking backwards critically at the existing state of theory and specifying the limits within which its hypotheses are valid. Thus a later American study (Seymour M. Lipset, Martin Trow and James Coleman, *Union Democracy* [1956]) produced a set of specific hypotheses concerning the factors which will support or undermine member participation and democratic control in private organizations and thereby showed the limited conditions under which Michels' law applies and replaced a somewhat vague generalization by a clearer set of related propositions. The later study also illustrates a method increasingly followed in social science in that it used the economy of investigating the deviant case in order to delimit application of a hypothetical generalization—in this case the International Typographical union, as the one outstanding exception to tł · general rule among private organizations of government by one-partv oligarchy. The results constituted another example of cumulative research, the purpose of the study being, as the authors remarked, "not to 'refute' Michels or other previous workers in this area, but rather to refine and build on their insights and findings, paying them the respect of using them more often than we quote them."

Historical Origins.—All science can be traced back to antiquity. In the modern world the disparity of achievement between the natural and the social sciences is sometimes put down to the youth of the latter, or on a more sophisticated view, to the relatively small number of hours spent on it. But it is doubtful whether either explanation is borne out by the facts. What is certainly true, however, is that the sciences of man and of nature have been the objects of oscillations in the attentions of scientifically minded men. In the contemporary world the natural sciences are plainly dominant. From roughly the beginning of the 17th century the advance of first the physical and later the biological sciences has not only outstripped that of the social sciences, but has been the basis of a continuous revolution in human life. There have been previous dramatic advances in the material and cultural conditions of mankind—for example the Neolithic revolutions of some seven or eight thousand years ago which gave men control over their food supply through the development of the techniques of cultivation—but none of these stages in social evolution are comparable, as judged for instance by their effect on population size, with the rise of modern industrial society based on the application of natural science. Nevertheless the inferiority of the social sciences is not inevitable and indeed it is arguable that, at least at one stage in the development of Greek science, the works oi Plato and Aristotle had put politics ahead of physics.

lhe crucial period in the growth oi the modern disparity between the sciences was the 150 years from the beginning of the 17th century. Scientific interests had penetrated but never dominated the humanism of the Renaissance. Niccolò Machiavelli's *Prince* (1513) stands out as a monument to the release oi men's minds irom medieval preoccupations and is still read by the modern political scientist. But, as natural scientists, Leonardo da Vinci, Tycho Brahe, Kepler and Copernicus in the 15th and 16th centuries have to be seen as precursors of the great astronomers and physicists of the 17th century, above all oi Galileo and Newton. Even in the 20th century the social sciences are often said to await a Galileo, and only mathematical economics is thought of as having passed through its Newtonian revolution.

Again it must be emphasized that the remarkable concentration of human intelligence on the sciences of nature in the century and a half aiter 1600 was not absolute. In the same period the Italian Giambattista Vico had published his *Principles of a New Science Dealing With the Nature of Nations, Through Which are Shown Also Sew Principles of the Natural Law of Peoples* (1725) in which he set out to study human history by the methods which Francis Bacon had proposed ior the study of the world of nature. In Vico's *Scienza Nuova* we find, as Edmund Wilson has put it *(To the Finland Station,* Doubleday, p. 2, 1940), "the modern sociological and anthropological mind waking amidst the dusts of a provincial school of jurisprudence of the end of the 17th century and speaking through the antiquated machinery of a half-scholastic treatise." But Vico's vision was not shared by his contemporaries and his work was leit to be rediscovered by Jules Michelet a century later. Similarly in England in the 17th century the scientific pursuits of the Royal society had as a minor theme the study of human life by similar principles of empirical science. Sir William Petty's population studies, John Graunt's analysis of mortality rates in the London plague and Edmund Halley's construction oi the first liie table mark the beginning of an English tradition oi "political arithmetic" which, adding moral and administrative concern for the consequences of urban industrialism to its scientific interests, has flourished down to the present day.

However, the beginnings oi modern social science may be traced directly to the 18th century Enlightenment with the first flowering of rationalism in France and the stern pursuit of a secular moral philosophy in Scotland. The revival oi interest in society at this time also illustrates the general truth that social science is the child of social change. The rise of capitalist society with its attendant social upheaval of urban growth, industrialism and mobility of men and ideas, imparted a powerful impetus to social enquiry. In France, through the work of the physiocrats, economics was launched as an empirical science, and in books like Voltaire's *Age of Louis XIV* (1751), the notion of progress was involved in the study of history and society in a way which broke sharply with medieval thought and to a degree which was unshaken until the rise of functionalism in anthropology at the beginning of the 20th century. The second half of the 18th century also saw notable advances in Scotland by a remarkable group of moral philosophers connected with the Scottish universities including Adam Smith, John Millar, Francis Hutchison and Adam Ferguson — all influenced by a growing mood of skepticism and empiricism in philosophy of which perhaps the greatest exponent was David Hume. Adam Smith's *An Inquiry Into the Nature and Causes of the Wealth of Nations* (1776) remains, with Karl Marx's *Das Kapital* (1867) and Alfred Marshall's *Principles of Economics* (1890), to this day among the great comprehensive treatises in economics, but the Scottish moralists also contributed in their lesser known works some of the foundations of modern sociology, psychology and anthropology. Thus, ior example, John Millar's *Observations Concerning the Distinction of Ranks in Society* (1771) is probably the first scientific analysis of social stratification, and Adam Ferguson's *An Essay on the History of Civil Society* (1767) is an admirable early example of the comparative study of social institutions.

Specialization and Synthesis. — In the 19th century the location of initiative in the social sciences shifted irom Scotland to Germany and other European countries. During the course of the century what would now be thought of as the main divisions of social science—economics, anthropology, sociology, political science and social psychology — began to emerge and, toivard the end of the century, to receive academic recognition. The 19th century was also characterized by an opposite tendency toward the construction of a synthesis of social science, especially at the hands of Auguste Comte, Karl Marx and Herbert Spencer.

In economics the first three-quarters of the century was devoted to the building of the synthesis of theory known as "classical economics" — a term invented by Marx to reier to Ricardo and his predecessors but which was Iater extended to include also the followers of that tradition, notably John Stuart Mill and Alfred Marshall, This phase came to an end with the clarification of the doctrine of marginalism *(see* ECONOMICS: *The Marginal Utility Analysis).* In the last quarter of the century attention was transferred to methodological problems and especially to the *Methodenstreit* controversy in Austria and Germany between Karl Menger and Gustav von Schmoller, the latter asserting that economics could be no more than a historical science in the sense that its laws could only apply to the unique circumstances of particular historical periods; the iormer insisting on the status of economics as a theoretical science searching ior universal laws governing the behaviour of supply, demand, price and the level oi employment. The victory of Menger's point oi view has since proved to be an emancipating iorce not only for economics and economic history in Germany but ior the social sciences everywhere. On the other hand the models of rationality (*e.g.* "economic man") which permitted conspicuous advances in 19th century economics leit problems for the 20th century development of theory in the social sciences, particularly that of finding a place for the nonrational determinants oi human behaviour. For the most part these tasks fell to sociology and psychology, but economic theory itself was also extended to include problems of choice and expectations through applications of the mathematical theory of games.

The 19th century also saw considerable advances in those branches of the social sciences which were oriented more toward biology and history. The social scientists of this period inherited the 18th century achievements of Linnaeus and Bouffon in the classification of living organisms and the Lamarckian hypothesis that the hierarchy of species was due to a natural process of evolution. In seeking to classify and date types of culture and to formulate generalizations concerning the social evolution of man, scholars like Lewis Morgan *(Ancient Society* [1877]) in the United States, Herbert Spencer *(Principles of Sociology* [1876–96] and *Descriptive Sociology* [1873–1934]), Sir Henry Maine (*Ancient Law* [1861]) and Sir Edward Tylor *(Primitive Culture* [1871]) in England, Johann Bachofen *(Das Mutterrecht* [1861]) in Switzerland and F'riedrich Ratzel *(Volkerkunde* [1885]) in Germany laid the ioundations for modern comparative anthropology and sociology. Spencer gave modern sociology most oi its terminology (the word sociology is attributed to Auguste Comte), advanced the theory of supraorganic evolution beiore Darwin's *Origin of Species* appeared in 1859 and attempted a comprehensive classification of societies according to their social structures. Morgan too produced a developmental theory of cultural evolution through three "ethnical periods" — savagery, barbarism and civilization. Maine followed the same line of inquiry in respect to legal and political institutions and Bachoien did similar work on kinship systems, attempting in particular to establish that matriarchy was an earlier evolutionary iorm than patriarchy.

These advances in the social sciences, though the basis for specialization in ethnology, physical anthropology, comparative sociology, etc., also linked the social sciences to geology, paleontology and biology. In other words they linked history to natural history to yield a scientific account of the vast sweep oi human fortune since the first appearance of man over 500,000 years ago. There is no more exciting reading in all the literature of the social sciences than the modern summary oi this branch of knowledge which is to be found in the writings of V. Gordon Childe *(Man Makes Himself* [1936], *Social Evolution* 119511). These integrative developments were iurther stimulated by Darwin who had himself been influenced in his thinking about natural selection by the previous work oi social scientists and particularly by Thomas Malthus' *Essay on the Principle of Population* (1798). Thus sociology and social anthropology became recognized and, under the banner of the great synthesizing idea oi evolutionism, respected as worthy to march in intellectual company with economics.

There were also other movements toward a synthesis of the social sciences in the 19th century, including earlier the positivism of Auguste Comte and later the elaborate conceptualizations of German sociology. But the most powerful of these, and itself much influenced by classical economics and evolutionary theory, was Marxism. If biological and cultural evolution explained the development of nature and the primitive history of man, Marx seemed to offer the laws of motion governing not only the past but also the future of civilized societies.

Thus, by the beginning of the 20th century the social sciences gave promise oi iollowing quickly on the heels of the biological sciences into scientific maturity and academic acceptance. True, the basis ior existing generalizations was being challenged and especially the theories of progress and unilinear evolution. But there was widespread optimism that the emerging specialties, or specialisms, would provide evidence for a more soundly based general sociology, the role of which in the 20th century would be to correct the bias of each particular discipline and relate it to the general body oi theory. Meanwhile the universities were opening their doors to the scientific newcomers. Political economy had gained recognition in all the major countries by 1830. Edward Tylor was appointed as an anthropologist at Oxford in 1884. The University of Chicago recognized sociology irom its foundation in 1890 and all of the social sciences were to be studied at the London School of Economics and Political Science founded in 1895. In Germany in 1897, Max Weber went to teach at Heidelberg and, in France, Emile Durkheim held a chair of education at the Sorbonne from 1902.

20th Century **Developments.**—If the outcome in the 20th century has fallen short of Victorian hopes, and certainly the continued advance in the power oi natural science with its unending implications for social, economic and political change has lent urgency to the challenge faced by the social sciences, the advance oi the sciences of man nonetheless has been considerable. The grand theoretical structures of 19th century evolutionism, Marxism and Comtean sociology have not' survived. But four modest plants of 19th century origin were established in sturdy growth.

First may be cited a tendency for high standards of empirical method to spread throughout the specialisms in alliance with modest theory (sometimes called middle-range). The revolt against overambitious theorizing may be seen, for example, in the antievolutionary movement championed by the Polish-born British anthropologist Bronislaw Malinowski and by such men as Franz Boas in the United States. The subsequent trend in anthropology toward the detailed study of particular societies and communities within complex societies, using meticulous methods of observation and recording, has produced numerous examples of empiricism at its best. Social surveys in the 20th century have amassed great quantities of carefully collected data on the social structure of urban industrial societies while political science has built up a store of precise knowledge on voting behaviour, political parties, pressure groups and the social composition of political elites, against which may be tested new theories of political behaviour.

Perhaps the greatest benefit of this period of concentration on more modest and detailed work was that the old and still valid problems oi economic growth and social development could he approached anew after World War II. The urge toward improved standards of life through the spread of industrialism over the "underdeveloped" areas of the world stimulated renewed search for theories of political, social and economic development adequate to encompass the accumulated body of iact. The problem oi economic growth loomed large in postwar economic writing as may be seen from such examples as W. Arthur Lewis' *Theory of Economic Growth* (1955), *W. W.* Rostow's *The Stages of Economic Growth* (1960), or Simon Kuznets' *Six Lectures on Economic Growth* (1959).

This substantive concern with industrialization and social and political development has had integrating effects in the social sciences in that no one specialism is adequate to tackle the problems involved. The consequent tendency to a breakdown of specialist boundaries has involved the second trend which has been characteristic of the 20th century, namely the spread oi a sociological approach into the various specialisms; *i.e.*, the recognition of the interdependence of the social, political and economic iorces which determine behaviour. Historical studies have also been affected by this development. Thus Richard Hofstadter's *The Age of Reform* (1955) is an example of a sociological orientation in history and Neil Smelser's *Social Change in the Industrial Revolution* (1959) is a direct application of sociological theory to the Lancashire cotton industry between 1770 and 1840. Similarly, books like David Apter's *The Gold Coast in Transition* (1955) illustrate the use oi sociological theory in the analysis oi political change. It is from the interpenetration of the established disciplines that a new synthesis of theory is looked for and, indeed, at least one 20th century attempt to build a unifying conceptual iramework ior sociology. anthropology and social psychology has appeared in the writings of Talcott Parsons (*The Structure of Social Action* [1937], *The Social System* [1951]).

The third noteworthy development has been the rise of several branches of psychology having relevance ior the analysis of social behaviour. Among the more important oi these are psychoanalysis, behaviourism, Gestalt theory and the study of individual differences. Above all the influence of Freud on the social thought of the 20th century is comparable only with that of Marx and Darwin in the 19th century. Quite apart irom his voluminous clinical writings Freud made direct excursions into anthropology *(Totenz and Taboo* [1918]) and social psychology *(Group Psychology and the Analysis of the Ego* [1921], *Civilization and Its Discontents* [1930]). But no branch of the social sciences has escaped the influence of psychoanalytical ideas. They were introduced into political science by Harold Lasswell in his *Psychopathology and Politics* (1930) in a way which gave iresh impetus to the neglected insistence by earlier writers like Graham Wallas (*Human Nature in Politics* [1908]), Arthur F. Bentley *(The Process of Government* [1908]), and Charles Merriam (*New Aspects of Politics* [1925]) on the relevance of psychological and sociological factors in the study of political man. Psychoanalytical ideas were carried further into social anthropology by Abram Kardiner and into sociology by Talcott Parsons.

Movements in psychology other than those inspired by Freud and his earlier associates have made contributions both to theory and more especially to rigorous methods of experiment, testing and measurement. Examples include the contribution of Clark Hull to learning theory (*4 Behavior System* [1952]), Wolfgang Köhler's work on perception *(Gestalt Psychology: an Introduction to New Concepts in Modern Psychology* [1947]), Kurt Lewin's influential *Field Theory in Social Science* (1951), and Donald Hebb's integration of Gestalt theory with neurophysiology in his *Organization of Behavior* (1949). Out oi these movements there has also developed a recognized specialism of social psychology concerned with such topics as the scientific study of attitudes, public opinion, the social determinants of perception and motivation and the interaction processes of small groups; and each of these topics boasts a considerable literature.

The fourth line of advance in 20th century social science has been the steady improvement and extension of quantitative methods. At the end of the 19th century mathematical and statistical techniques for social analysis were in their iniancy. Simple quantification had always been part and parcel of demography and the political arithmetic tradition. But, at least until after World War I, mathematical economics was not taken seriously in the English speaking world, being largely confined to France, Italy and Switzerland and such men as Léon Walras, Augustin Cournot and Vilfredo Pareto. Thus the first systematic exposition of economic theory in mathematical terms, Walras' *Éléments d'économie politique pure* (1874–77), was not available in English until 1954. However, during the course oi the 20th century mathematical treatments have tended to displace literary discussion and statistical techniques have generated a new discipline of econometrics and transformed research in economics, sociology and political science. Sampling procedures based on probability theory were introduced between World Wars I and II to make social surveys, public opinion polls and electoral studies both economical and reliable. Psychological research has developed refined methods of factor and multivariate analysis, tests of ability and aptitude and assessments of the significance of differences in the distribution oi attributes between groups. Advances in computor technology have also revolutionized the possibilities of complex large scale analysis of social phenomena.

SOCIAL SECURITY.

The main purpose of any plan for social security is insurance against interruption and destruction of earning power and for special expenditure arising at birth, marriage or death. Social insurance and social security are based on a common principle: protection against those hazards of life which threaten health or economic existence. In order that the protection afforded in any contingency may be reasonably adequate, not only must the rate of the benefit meet some standard of adequacy, but the benefit itself must be payable as long as the loss resulting from the contingency persists and be available whenever the contingency occurs, subject only to such limitations of rate and availability as are necessary to prevent substantial abuse on the part of claimants. There are thus three aspects to the question of adequacy of protection: (1) the rate of benefit; (2) the duration of the benefit; and (3) the qualifying period of work or contribution which must have been fulfilled at the time the contingency occurred.

After a brief historical sketch of the growth of social insurance, this article is divided into the following sections:

I. United States
II. European Social Security Systems
III. Social Insurance in Great Britain and the Commonwealth

The Growth of Social Insurance.— In Great Britain until late in the 19th century relief of poverty incurred through any cause could only be given under the poor laws (*q.v.*) or by private charity. The position was even worse in some other European countries where this matter was left almost entirely to the church. In many countries some provision was made independently of the state by the workers themselves through mutual provident associations; but only part of the field was covered by this means. In 1883 a compulsory scheme of insurance was introduced in Germany and this was extended in 1889 to cover permanent incapacity. The example of Germany was followed by Austria in 1888 and by Hungary in 1891. About the beginning of the 20th century. public opinion in most European countries began to favour some organized provision to meet the contingency of sickness among the workers. In Great Britain compulsory health insurance began in 1912, following the National Insurance act of

1911, and was made general in 1920. The first Old-Age Pensions act giving noncontributory pensions at the age of 70, subject to a means test, was passed in 1908. In 1925 came the act which started contributory old-age, widows' and orphans' pensions. Unemployment insurance was put on a fresh basis by the Unemployment act, 1934, which set up at the same time a national system of unemployment assistance. (For the first U.S. Social Security act, see I. *United States,* below.)

In the meantime the local machinery for the relief of destitution had been changed by a transfer of the responsibilities of the ad *hoc* boards of guardians to the major local authorities who undertook this work as part of their general local government activities. The granting of assistance on the basis of need, as distinct from national insurance benefit, became increasingly the responsibility of a centrally financed board. This development culminated in the abolition of local outdoor relief and the assumption of total responsibility in this field by the National Assistance board under the National Assistance act, 1948. In most other countries, however, assistance or relief still remained a local responsibility.

Separate provision for special types of disability—such as blindness—was made from time to time but it was the tendency for this also to be included in a comprehensive scheme. With the growth of social insurance went development of medical treatment; services for the welfare of children; and much voluntary provision for death and other contingencies through industrial life offices, friendly societies and trade unions. In no country does social insurance cover all needs, and all contingencies and assistance provided under a local or national scheme is normally available to those persons in need who are not entitled to some form of insurance benefit and, in some countries, as in Great Britain, for the supplementation of such benefit. Whereas social insurance implies that grants are made to contributors according to a formula relating payments into and out of an insurance fund, assistance rates have some relation to the cost of living or to a minimum subsistence level. In the German Federal Republic, unemployment assistance rates are fixed in relation to the earnings of the unemployed person during his last employment, and are about 10% to 15% below the rates of unemployment benefit; in Great Britain national assistance rates are generally higher than benefit rates.

After World War II attention was given to social security in most European countries, as in other parts of the world. The International Labour conference, at its meeting in Philadelphia, Pa. (1944), had urged that the sphere of protection of income-security schemes should be progressively enlarged in order to ensure that every worker having dependents should have at least the means of subsistence in every common contingency that might cause the involuntary loss of earnings or make them insufficient for the necessities of life. The matter was also mentioned in the Universal Declaration of Human Rights, adopted by the general assembly of the United Nations on Dec. 10, 1948.

The extension of social security by the middle of the 20th century can be seen in the fact that social security schemes were gradually being brought into operation in the more progressive Asian countries. One of the most comprehensive was in Israel where an act of 1953 provided for old-age and survivors pensions at a fixed rate subject to revision according to the cost-of-living index. Allowances were also provided for mothers who were either insured workers themselves or the wives of insured workers, at the rate of 75% of wages for 12 weeks absence from work before and after confinement. Contributions for maternity insurance were 0.8% of wages, shared by the worker and the employer. Under accident insurance 75% of wages was paid to the injured worker; for permanent disability there was a pension of from 10% upward. Contributions for accident insurance were paid by the employer at the rate of 0.5% to 3% of wages according to the degree of danger to which the worker was exposed. (JN. M.)

I. UNITED STATES

In the United States the general public is often confused as to the meaning of "social security." But its nature may be determined in part by the programs included in the Social Security act. When that act was passed in 1935 a Social Security board was designated as the agency to administer five programs: the federal old-age Insurance system, a program for federal co-operation with the states in unemployment insurance, and federal assistance to the states for public assistance to the needy aged, needy blind, and dependent children. The other programs included in this act—provision for maternal and child health services, services for crippled children, child welfare services, vocational rehabilitation and assistance to the states for public health—were to be administered by other federal agencies. In 1939 the Federal Security agency was created and five organizations were placed under its jurisdiction—the Social Security board, the public health service, the office of education, the Civilian Conservation corps and the National Youth administration. By the middle of 1943 the last two organizations were liquidated. In 1940 the Food and Drug administration was transferred to this agency. In 1946 the Social Security board was abolished and its functions transferred to the federal security administrator, who established the Social Security administration to carry on the programs of the Social Security board; in the same year the children's bureau, which to that time had been responsible for certain health and welfare provisions of the Social Security act was transferred from the department of labour to the Federal Security agency. In 1953 the department of health, education and welfare was established, with a secretary of cabinet status. The Federal Security agency was abolished and all its functions transferred to the new department. Under this reorganization the Federal Security agency became the Social Security administration in the department of health, education and welfare.

A broad definition of social security might include many of the functions performed by the department of health, education and welfare and many other types of social legislation—wage and hour laws, other types of labour legislation, public housing, recreation and general public assistance—and this list might be extended. This section discusses social insurance in the U.S., the special types of public assistance for which grants to states are administered by the Social Security administration and the assistance to states for health and welfare services that are included in the Social Security act. Although provisions with respect to two social insurance programs are found in the Social Security act, two other social insurance laws entirely within the jurisdiction of the states must also be included—workmen's compensation and state disability insurance. Social health insurance would, of course, be included in this definition. In the United States, however, except for the workmen's compensation laws and the few disability insurance laws, social insurance legislation has not been applied to this type of protection. There exist many private health insurance plans, but these are not properly considered to be social insurance.

Social Security Legislation to 1935.—The development of social security legislation was slow and uneven in the United States. The recognition of social welfare as a governmental problem was late in developing.

Both social attitudes and government organization held back legislation in this field. During the 19th-century period of expansion, the vast land resources of the U.S. offered most people a chance to obtain a livelihood. The old agricultural economy set the pattern of life except in larger towns and cities. Commerce and industry were conducted on a relatively simple scale, in general, though business was expanding and mass production was beginning.

Those years were characterized by a generally accepted belief that personal initiative and industry were all that was necessary for the achievement of material success. This attitude tended to support the traditional belief that indigence is always synonymous with incompetence, and any governmental aid given the financially unfortunate carried with it the taint of pauperism. The traditional concept of public welfare as a function of local rather than state or federal government tended to retard progress. Gradually there was a weakening in the old exclusive reliance on the town or county to provide for all welfare needs, and as needs increased the states came to recognize that they would have to share responsibility with local communities.

Special assistance programs for certain categories of the population had been established in many states by 193j. Social insurance was much slower in developing. Workmen's compensation, which had its real beginning in 1908, was the first type of social insurance to be developed in the United States, and with the minor exception of an unemployment insurance bill passed by Wisconsin in 1932, it was the only form of social insurance in the United States until the Social Security law was enacted in 1935. (See *Unemployment Insurance* and Industriul Injuries, below.)

Social Security Act

In June 1934 Pres. Franklin D. Roosevelt in a message to congress called for legislation to safeguard men, women and children against misfortune. A committee on economic security subsequently drew up recommendations for a social security program. The Social Security act was signed into law on Aug. 14, 193j.

The Social Security act initiated one of the most comprehensive programs for social welfare ever undertaken through direct legislation. It established a federal old-age insurance system and made provision for federal co-operation with the states in unemployment insurance systems and in programs for giving financial aid to three groups of the needy—the aged, the blind and dependent children. The measure also extended federal aid. available to the states, for four health and welfare services and for vocational rehabilitation. On May 24, 1937, the supreme court of the Cnited States upheld the state unemployment insurance laws and provisions for the payment of federal old-age benefits and taxes levied by the act.

It was recognized from the first that in a program of such proportions changes would have to be made as experience and study pointed the way for improvement. On the basis of reports made by the Social Security board and by the Advisory Council on Social Security, and after extended public hearings, the Social Security act amendments of 1939 were passed in August of that year. The results of these amendments were liberalization of the protection provided by the program and improvement of its administrative procedures.

Old-Age and Survivors Insurance.—The old-age and survivors insurance program established by the original Social Security act was designed to provide a basic retirement income after the age of 65 for wage earners insured under the system. Prior to consideration of the Social Security act there had been created various retirement plans for public employees, and private pension plans had also been adopted by some business organizations. In 1930, however. the number of employees affected by private pension plans was only about 3,500,000.

The Social Security act of 1935 provided old-age insurance for many types of wage earners. and later amendments covered new occupational groups. The estimated average number of insured workers was 24,000,000 in 1940; by the late 1950s the number had increased to approximately 75,000,000.

Coverage.—Chiefly because of the administrative difficulties involved in their inclusion, certain types of employment were at first excepted from coverage under the system. Some groups or their employers also resisted inclusion then and later. The act of 1935 provided the folloaing exceptions: agricultural labour; domestic service; casual labour not in the course of the employer's trade or business; service as an officer or member of a crew of a documented vessel; employment for any federal, state or local government or its instrumentality; and service for certain religious, charitable, humane and educational institutions not organized or operated for profit. Employment after the age of 65 was also excepted. Railroad employment was excepted because it was covered by the separate system for railroad workers under the Railroad Retirement act.

Under the amendments of 1939 some of the employments previously excepted were brought under the system. These included maritime service on U.S. vessels and employment in national banks, building and loan associations and certain similar organizations. The exception of employment after the age of 65 was removed as of Jan. 1, 1939, thus enabling many workers previously ineligible because of age to qualify for monthly benefits and others to increase the amount of their benefits.

Certain additional exemptions were provided by the amendments: agricultural labour was defined so as to extend exemptions not only to farming activities but also to certain closely related services. Certain part-time or intermittent employment providing only nominal wages. such as services for fraternal and other nonprofit organizations, and services of newsboys under age 18 were excepted by the amendments. as were family employment and service by employees of foreign governments.

Cnder the 19jo amendments coverage was broadened to include the self-employed (except farmers and those in certain professions) and regularly employed agricultural and domestic workers; voluntary coverage was permitted for employees of nonprofit institutions and employees of state and local governments not already under a retirement system. Certain civilian federal government employees not under a retirement system and workers in Puerto Rico and the Virgin Islands were included, as well as members of small occupational groups under a broader definition of employee.

Amendments in 1954 extended coverage to about 10,000,000 additional workers. The largest group of newly covered workers was self-employed farm operators, and coverage was given to additional members of state and local retirement systems and to larger numbers of farm and domestic workers.

In 1956 coverage was extended to several additional groups of the self-employed. Larger numbers of farm owners and operators were brought within the coverage of the act. and except for doctors of medicine all self-employed professional workers were included under these amendments. Coverage was also given to almost 3,000,000 members of the uniformed military services. Beginning in 1957, 92 out of roo jobs were covered under old-age and survivors insurance on a contributory basis.

Contributions (Taxes).—From the beginning, old-age and survivors insurance was financed by an equal contribution (or tax) from the employee and his employer. The 1935 act provided that the contributions were to begin in 1937 at 1% from employer and employee and increase 0.5% every three years to 1948 when the tax would have been 2.5%. This schedule called for a final 0.5% increase in 1948 which would have resulted in a tax of 3% from both the employer and the employee. Wages in excess of $3.000 in a year for any one year from any one employer were excepted from these taxes. The amendments of 1939 eliminated the 0.5% increase for the years 1940–42, and because of subsequent acts of congress the tax did not actually increase to 1.5% until Jan. 1, 1950.

Under the 1950 amendments the 1.5% tax on wages was retained for three more years, and the tax for self-employed persons was set at 2.25%. At the same time the maximum income on which these taxes were to be imposed was raised to $3.600. In 1954 the contribution rate was set at 2% of wages and 3% of self-employment income until 1959 with a schedule of gradual increases to a maximum of 4% of wages and 6% of self-employment income in 1975. In 1955 the maximum taxable income was increased to $4,200 and in 1957 the schedule of rates was increased by 0.25% to cover the cost of disability benefits. The tax on wages in 1957 was, therefore, 2.25% from the employer and his employee and 3.375% from self-employed persons. The schedule called for gradual increases in the 2.25% rate to 4.25% (6.375% from the self-employed) in 1975 and after.

Financing.—Under the act of 1935 an old-age reserve account was established in the United States treasury. Congress was charged with the duty of appropriating yearly to this account an amount sufficient as an annual premium to provide for the payments required under the old-age insurance system, the amount to be determined on a reserve basis in accordance with accepted actuarial principles. The act specified that reserve funds in the account must be invested in government obligations or government-guaranteed obligations bearing 3% interest.

The 1939 amendments provided much more liberal benefits to all persons who qualified for benefits in the early years and extended protection to certain dependents and survivors of insured persons. In order to compensate in part for the cost of these additional benefits, the benefits for single individuals with long periods of coverage were reduced by the 1939 amendments. Those amendments increased the cost of the program in the early years, but an actuarial study estimated that the long-range cost of the 1939 amendments would be at least as low as that of the original act and probably lower.

Although the 1939 amendments increased the cost of benefits in the early years, congress froze the contribution rate at 1% until 1950. In spite of this freezing, the trust fund grew more rapidly than had been expected, partly because of high wartime employment and earnings. and partly because of increased employment opportunities for older persons. The total assets in the trust fund were $11,816,000,000 at the end of 1949. Between 1950 and 1956 there were three changes in the benefit formula, the first of which nearly doubled the benefits, while the other two allowed more moderate increases. Although individual benefits increased substantially and contributions remained at 1.5% until 1954 and were then raised to 2%, the total assets in the fund continued to increase. Throughout most of 1956 and early 1957 the total assets were about $22,500,000,000. In 1957 a disability trust fund was also established and in Oct. 1957 the assets in this fund were $548,000,000.

Benefits —The system established by the act of 1935 provided for payment of monthly benefits, beginning in 1942, to insured workers 65 years of age or over when they retired Benefits were based on the employee's total wages during this qualifying period (exclusive of amounts in excess of $3,000 received in one year from any one employer). The formula used to determine benefits at this time as well as later was weighted in favour of the low-paid worker; i e., the lower-paid worker received a benefit representing a larger proportion of his wage than did the higher-paid worker. The maximum monthly benefit was set at $85, the minimum at $10. A lump-sum payment equal to 3.5% of the employee's total wages was provided for those reaching age 65 without qualifying for monthly benefits; and a death payment of similar amount was provided subject to deduction of any benefits the worker might have received during his lifetime.

The 1939 amendments made material changes in the benefits provided under the system. The principal revisions were: advancing initial payment of monthly benefits to 1940 instead of 1942; increasing benefits during the earlier years of the system and increasing security for the family group by providing monthly benefits for certain dependents and survivors of insured employees. Because of the extension of the system to afford protection for the families of workers, the title mas changed to old-age and survivors insurance Under the amended system the basis on which benefits were determined was the employee's average monthly wage.

From 1939 to 1950 the average monthly wage was determined by dividing a worker's total accumulated wages, exclusive of amounts in excess of $3,000, by the number of months he could have worked under the system; *i.e.,* the number of months between 1936 (or his 22nd birthday if later) and the quarter in which he became eligible for benefits or died In 1950 the benefit formula was amended to include in the computation wages up to $3 600 a year and to make it possible to determine average monthly wage on the basis of employment after 1950. The reason for this change was that the coverage was greatly expanded. and thus those persons newly covered would have had little or no earnings in covered employment betneen 1936 and 1950. In 1955 the maximum wage taken into account in computing benefits was increased to $4,200 a year.

In addition to increases in the maximum earnings on which benefits were based, the formula for determining benefits was several times revised to provide larger benefits. Between 1940 and 1950 benefits were related not only to wages but to years of coverage. There was a 1% increase for each year of coverage. A worker with an average monthly wage of $200 a month in the period 1940–50 would have received a benefit of $41.20 per month if he had been in covered employment for three years, and if he had been in covered employment up to 1950, his benefit would have been $45.20. In 1950 the benefits were increased, but the additional sum for years of coverage was eliminated; thus, the worker who qualified for benefits received the same amount regardless of years of coverage. A person with earnings of $250 a month would have received $72.50 per month and if his earnings were as much as $300 per month, his monthly benefit would have been $80. The benefit formula was again changed in 1952 and in 1954. After the 1954 amendments the man with $250 monthly earnings could receive $88.50, but if his earnings were as high as $350 a month his benefits would be increased to $108.50 a month. Average old-age benefits were $22.60 a month in 1940, $26 in 1949, $43.86 in 1950 and $64.48 in Nov. 1955. There were also changes in the minimum and maximum monthly benefit payable. The minimum benefit for an insured person was $10 from 1940 to 1950, $20 in 1950 and $30 after 1954. Similarly. there were changes in the maximum benefits. In 1940 the maximum benefit to the insured worker could have been $60 (assuming 50 years of coverage) ; this maximum was gradually increased and was $108.50 after 1954. Maximum family benefits also increased from $85 in 1940 and were $200 after 1954. There was also a provision that the benefit could not be more than 80% of the average monthly wage.

The act as passed provided benefits for the insured person and no other. With the 1939 amendments supplementary benefits became available for certain family members and certain survivors in the case of death of an insured person. Beginning in 1940 benefits equal to one-half the retired worker's benefit were paid to a wife 65 years of age and over and to unmarried dependent children under 16 years of age or under 18 if regularly attending school. To survivors the nionthly benefits were three-quarters of the monthly benefit rate for a widow 65 years or over or for a widow of any age with dependent children as defined above. Benefits equal to one-half the worker's benefit were paid to these dependent children and. if there were no other persons eligible for benefits. to dependent parents. With the 1950 amendments the wife of a retired worker. regardless of her age, was entitled to benefits if she had a child in her care. For the first time benefits were payable to a dependent husband (age 65 or over) of a retired or deceased insured woman. Benefits for dependent parents and for the first survivor child were raised to 75% of the insured person's benefit.

Under the 1956 amendments women could elect to receive benefits between the ages of 62 and 65. If a retired woman elected to take her benefit at age 62. the benefit would be reduced by 20%; in the case of a wife the reduction would be 25%. There were smaller reductions in these benefits for those who elected to receive benefits at ages 63 and 64. Widows could receive such benefits at age 62 with no reduction in amount.

The amendments of 1954 included a "disability freeze" that permitted a person totally disabled for six months or longer to have this period disregarded in determining eligibility for benefits and amount of the benefit. The 1956 amendments for the first time included disability insurance benefits payable to totally disabled persons from the age of 50. Disability benefits also were to be paid to dependent children 18 years of age and over if they became disabled before the age of 18. In addition to the monthly benefits described above, from 1940 to 1950, if there was no survivor entitled to monthly benefits, a lump-sum death payment equal to six times the worker's monthly benefit rate was paid to certain relatives or to the person who paid the burial expenses. After 1950 lump-sum death payments equal to three times the worker's monthly benefit amount were paid in the case of all insured deaths. Under the 1939 act the maximum lump-sum death benefit was $360 (assuming 50 years' coverage). The 1950 amendments set a maximum of $240. and after 1952 it was $255.

Eligibility for Benefits.—After 1939 there were two types of requirements as to the length of coverage in order to be eligible for benefits. One was described as "fully insured" and the other as "currently insured" status. An employee was fully insured if he received $50 in covered employment in each of 40 calendar quarters: or if he received $50 in each of enough calendar quarters to equal half the quarters elapsing between Dec. 31, 1936 (or his attainment of age 21, if later). and the quarter in which he died or attained the age of 65, and in no fewer than six calendar quarters. Any calendar quarter in which he earned at least $50 was considered a "quarter of coverage." Such quarters of coverage counted toward benefits even if they occurred before the employee was 21 years old or after he was 6j. but they had to be subsequent to 1936. The requirements for fully insured status remained the same except that the 1950 amendments provided that fully insured status could be attained by coverage for half the calendar quarters after 1950 instead of after 1936.

If an insured wage earner died without meeting the requirements necessary to be fully insured. but received $50 or more a quarter for at least six calendar quarters during the three years prior to his death. he would be currently insured. and monthly benefits were provided for any minor children and for the widow if she had such children in her care.

In general. all benefits were available to those with fully insured status, but the less restrictive requirement of being only currently insured allowed benefits to widows of any age with children in their care and to children of deceased workers.

The law as originally passed denied benefits to any person working regularly in covered employment. The amendments of 1939 allowed benefits if earnings in covered employment were less than $15 a month. In 1950 benefits were paid if earnings in covered employment were less than $50 a month. and in 1952 the maximum earnings in covered employment that could be disregarded increased to $7j. The 1955 amendments permitted benefits to be paid if earnings in both covered and noncovered employment were as much as $1.200 a year. Between 1950 and 1955 benefits were paid regardless of earnings after the age of 75, and from 1955, after the age of 72.

Unemployment Insurance. — The provisions of the Social Security act relating to unemployment insurance mere designed to stimulate adoption of state systems that would insure employees against total loss of income during periods of unavoidable unemployment. Because of constitutional problems this appeared preferable to a wholly federal system of unemployment insurance. In a number of state legislatures. unemployment insurance bills had already been presented before congressional consideration of the Social Security bill in 1935. But the disadvantage in interstate competition had deterred state action in all states except Wisconsin. By levying a federal tax on employers and then allowing credit against the tax for contributions to a state unemployment fund, the federal act helped to remove the interstate competitive factor, and by June 30, 1937, all states had enacted unemployment insurance laws. Under the terms of the act. wide latitude was allowed the states in adopting unemployment insurance systems. However. the state laws followed certain general trends.

Financing. — The unemployment insurance provisions of the Social Security act levied a payroll .tax on employers with eight or more employees. certain types of employment excepted. The rate of this tax was set at 1% of wages up to $3.000 per year in 1936, 2% in 1937 and 3% thereafter. Federal legislation in 1954 required employers of four or more employees to pay this tax beginning Jan. 1956. Against this federal tax, employers were allowed credit for the amounts they contributed to unemployment insurance funds under a state law approved by the Social Security board. The maximum credit allowed was 90% of the amount of the federal tax. The tax paid to the federal government met necessary administrative costs. The federal law allowed an employer credit for any reductions in his state rate of contribution due to favourable experience in regard to payment of unemployment benefits. As a result of the experience-rating provisions in 1955, the average employer contribution to state unemployment insurance funds was 1.2% of taxable payroll. The employer's contribution, like the federal tax, was ordinarily based on the first $3.000 of earnings. In 19jj. however, there were four states that had raised the taxable wage base to $3.600. Employee contributions were at one time required by nine states, but by 1958 only Alabama and New Jersey required these contributions.

All money collected by the states for unemployment insurance is deposited in the U.S. treasury in the unemployment trust fund to be drawn upon by the states to pay benefits. Until an amendment was enacted in 1954, the unemployment tax paid to the federal government became part of the revenue of the federal treasury. and funds necessary for administration were appropriated annually. Tax collections consistently exceeded these appropriations, and thus part of these funds were not available for the employment security program. A 1954 amendment earmarked these taxes collected in excess of administrative expenses, and the funds became available for noninterest-bearing loans to states whose funds fell below a specified level. This amendment substantially increased a continuing ability to pay benefits in states with relatively high levels of unemployment.

Coverage.—The 1939 federal law excepted from the employer's tax wages paid for the following services: agricultural labour; domestic service; shipping on navigable naters of the Cnited States; employment for the immediate family; federal, state and local government service; and employment by certain religious, charitable and educational organizations not organized or operated for profit. Railroad employment, covered by the Federal Railroad Unemployment Insurance act was excepted from the unemployment compensation provisions of the Social Security act. as well as from state unemployment compensation laws.

The amendments of 1939 extended coverage of the federal unemployment insurance tax to include wages paid for employment by national banks. building and loan associations and similar employments. In 1946 maritime employment was included. In 1954 a federal unemployment insurance law provided compensation to federal employees for wage loss because of unemployment. Most of the state laws closely followed the occupational exclusions of the federal unemployment tax act. Twenty-eight states also folloned the federal tax act and required contributions of employers of four or more workers. Eighteen extended coverage to employers of one or more employees. however. and the remaining laws covered employers of tno or three norkers.

When the norkers covered by the 1954 federal amendments and the 1955 amendments to the state acts were included, the covered group represented about 61% of the labour force and 80% of workers earning wages or salaries.

Benefits. — From the beginning all state laws provided that weekly benefits be related to the weekly wage of the individual covered uorker. In 1939 average benefits in the country as a whole were about 40% of the average wage of covered aorkers, and although benefits increased substantially thereafter, the increases lagged behind rising wages. Thus. in 1954 the average benefit mas only about one-third of the wage.

Between 1954 and 1957 many states increased benefits. In spite of these increases, however, in 1957 fewer than 5% of the nation's covered workers received benefits equal to 50% or more of average weekly wages in covered employment, and in 13 states, with 30% of the covered workers. a claimant earning the average weekly wage in the state received less than 40% of his wages.

Both the amount of the benefit and the length of time for which benefits are paid have differed substantially among states. In Nov. 1957 average neekly benefits for the United States as a whole were $29 44 but they varied from $19.89 in North Carolina to $39 58 in Nevada. As unemployment insurance developed in the United States it was a program for relatively short periods of unemployment. In the early years of this legislation most laws provided benefits for a maximum of 16 weeks. By 1957 nearly 60% of the states set the maximum at 26 weeks and only three at less than 20 weeks. Only one law provided benefits for as long as 30 weeks. Although there was a tendency in the direction of uniform duration of benefits for all claimants. a majority of the laws paid benefits for shorter periods to some workers. A aaiting period of one week was required before benefits become payable in all but four states (where the waiting period was eliminated). On June 15, 1958. the "temporary unemployment compensation act" became effective.

All the state laws denied benefits to claimants who were unavailable for work or were unable to work; were involved in a labour dispute, voluntarily left their jobs or refused work without good cause; or were discharged for misconduct.

When a worker applied for unemployment benefits he registered at a state employment office, reported to that office each week as evidence that he was able and willing to work and was obliged to accept any "suitable" employment (as defined by the state) offered him.

Public Assistance.— The act of 1935 made provision for granting federal funds to the states to aid them in giving financial assistance to three groups of needy persons—the aged, the blind and dependent children. In contrast with social insurance benefits, which are available to all persons who qualify as to age, disability or inability to find a job and who meet the requirements as to length of time in covered employment, public assistance is available only after proof of need—a means test. The states adopt and administer their own public-assistance plans, but each state plan must be submitted to the Social Security administration for approval. Standards for approval of state plans specified by the federal act of 1935, furthermore, were designed to assure efficient administration and equitable distribution of assistance.

The act of 1935 placed the amount of federal funds available to the states for old-age assistance and aid to the blind at one-half the state's total assistance payments, up to a monthly federal-state maximum of $30 to each recipient. For aid to dependent children, the act provided federal grants equal to one-third of the amount paid by the state. As a basis for computing the federal share of aid, the act set a maximum of $18 a month for the first child and $12 for each additional child in the same home. A dependent child was defined as one who is under age 16 (18 if in school after the 1939 amendments), is without parental support because of the death, disability or continued absence of a parent from home, and who is living in his own home or with certain near relatives.

In the two decades after 1935 the federal grants to states for public assistance were increased several times, and in 1950 these grants also became available for aid to the needy who are permanently and totally disabled. Under the 1956 amendments the amount of federal funds available for needy persons who were aged, blind or disabled was four-fifths of the first $30 of average monthly payment per recipient plus one-half the balance up to a maximum of $60. In the case of dependent children the federal government shared in the monthly allowance up to a maximum of $32 for the first child and the relative with whom the child lived and to $23 for each additional child. The federal share was fourteen-seventeenths of $17, that is, $14, plus one-half the balance up to the maximum. The federal government also made grants to the states that covered one-half the cost of administration.

Public assistance grants with federal financial participation went into effect in all states for the aged, the blind and dependent children, and there were 48 approved programs for aid to the permanently and totally disabled. In order to secure federal funds the state law had to meet certain administrative and eligibility standards set by the federal act. Each state, however, was free to determine the amount of the assistance grant and its own eligibility conditions so long as they were not more restrictive than those required for approval by the federal act. The state laws thus differed considerably, some being distinctly more liberal than others, both in respect to eligibility conditions and to the amounts of payments.

As more aged persons as well as children became eligible under the old-age and survivors insurance program, there was a considerable effect on the public assistance program for these two groups. After 1951 there were more aged persons receiving retirement benefits under the federal old-age and survivors insurance law than under old-age assistance, and by 1956 about twice as many received old-age insurance retirement benefits. The number of children receiving benefits under the old-age and survivors insurance program increased greatly after 1940, and this reduced the number of children who would have received public assistance.

Health and Welfare Services.— The Social Security act of 1935, in addition to its provisions for social insurance and public assistance, included federal grants to assist states in developing maternal and child health services, services for crippled children and child welfare services. In order to receive federal funds for these purposes, financial participation by the state and a plan approved by the secretary of health, education and welfare were required. At the federal level, these programs were administered by the children's bureau of the Social Security administration. During the period 1935–56 the sums granted for these purposes were increased several times.

The act of 1935 also provided funds for distribution to the states to assist them in extending public health services. The approval of the surgeon general was required for all state programs, and the federal public health service assisted the states in improving them. In the late 1950s grants were made to states for general public health, tuberculosis control, cancer control, venereal disease control, mental health and heart disease control.

Federal grants to states for vocational rehabilitation were made after 1920. The Social Security act of 1935 continued this program and increased the grants. The purpose of this legislation was to assist the states in providing disabled persons with the necessary services and aids to enable them to engage in remunerative employment. Any person who had a physical or mental disability and could reasonably be expected to become employable was eligible to participate in the program. This, like the other programs mentioned above, required the financial participation of the state.

Other Social Welfare Measures

Industrial Injuries.— It was not until about 1900 that the tremendous losses due to industrial accidents in the United States began to be recognized, and it was nearly a decade later when the first workmen's compensation law was passed. Prior to this legislation, if an injured worker sued his employer he had to prove that the employer was negligent. The court procedure was slow, costly and uncertain.

Workmen's compensation legislation was based on a new legal and economic principle. The concept of individual fault was abandoned, and the cost of industrial injuries was considered to be part of the cost of production, not because the accident was the fault of the employer, but rather because accidents are the result of the inevitable hazards of modern industry.

The first U.S. workmen's compensation law was passed by Maryland in 1902, but this law was declared unconstitutional two years later. The real beginning of this legislation was in 1908, when congress passed a compensation law covering civilian employees of the federal government. From that time state legislation developed rapidly, and by 1915, 30 states had enacted workmen's compensation laws. By 1920 all but six states had this type of legislation, and in 1948 workers in every state were protected.

Although there is great variability in the state workmen's compensation laws, it is possible to indicate some general principles that have been adopted in most of them. No law covers all workers, and accurate coverage statistics are not available, but it was estimated that in 1952 nearly four out of five civilian wage and salaried workers were covered by workmen's compensation. The largest groups of workers not covered by state laws were domestic servants, casual labour, interstate railroad and agricultural workers.

Workmen's compensation benefits in the United States have generally been financed exclusively by the employer. In all the laws except that of Louisiana, the employer has been required to give assurance of his ability to meet his compensation obligations. This could be done by a private insurance company or a state insurance fund, or by proof of ability to carry his own risk called "self-insurance." Most other types of social insurance require that this protection be provided by a government insurance organization. In the United States employers could insure with private insurance companies except in eight states where they were required to use a state insurance fund. In 11 states where there were state funds, employers were allowed to choose a private insurance company.

All the workmen's compensation laws provided cash and medical benefits for insured workers, and in all but two states these benefits also were provided for occupational disease. The laws vary greatly with respect to both cash and medical benefits. Although most of the state laws expressed the intent that the cash benefit be two-thirds of the wage, there were also limitations as to the maximum benefit that would be paid. For this reason, in 1953 a person in receipt of the average 1952 wage was paid less than 50% of his wage under two-thirds of the laws.

Although medical benefits are provided by all the laws, the amount of medical and hospital care varies greatly among the states. Two-thirds of the laws placed no limits on the amount or on the time during which medical benefits would be paid. The remaining one-third of the states, however, had restrictions of these kinds.

Temporary Disability. — Attempts were made to secure enactment of laws providing cash payments for temporary disability resulting from nonoccupational illness and injury. The first law of this kind was passed by Rhode Island in 1942. In 1946 the Railroad Unemployment Insurance act was amended to provide disability benefits, and by 1950 three additional states — California, New Jersey and New York — had passed this type of law. These laws, in general, protect the workers who are covered by unemployment insurance.

Temporary disability insurance in California and Rhode Island was financed entirely by employee contributions. In New Jersey and New York. employers paid part of the cost; for railroad workers these benefits were financed entirely by contributions from employers under the Railroad Unemployment Insurance act, uith no additional or separate contribution for disability insurance.

In Rhode Island all contributions were paid into a state fund. and the funds for railroad workers are deposited in the federal unemployment trust fund. As in the case of workmen's compensation insurance, California, New Jersey and New York permitted the employer a choice between carrying this insurance in a state fund or a private insurance company; they also allo ed self-insurance.

Cash benefits provided under these laws are on the whole similar to the benefits provided for unemployment. California was the only state in which the disability insurance system included hospital benefits. Any person eligible for disability insurance received $12 a day for each day of hospitalization ordered by a physician up to 20 days in any disability period.

Social Insurance for Special Groups. — Retirement and unemployment insurance are provided by special legislation for railroad workers. The Railroad Retirement act was passed in 1934 but was declared unconstitutional the next year. It was not until 1937 that an act was passed whose constitutionality was not challenged. This act with subsequent amendments included the same types of benefits as were provided under federal old-age and survivors insurance, but higher contributions were required and the benefits, in most cases, were more liberal for railroad workers. Railroad workers and their employers together contributed 12 5% of wages up to $4,200 a year. A railroad porker with 30 years of service at $3,600 a year received a benefit of $165.60 a month. and a worker with similar service under the federal old-age and survivors insurance program received $108.50 a month. Railroad workers with wages of $4,200 after 1954 received still larger benefits. Because railroad workers with relatively short periods of service in the industry would receive lower benefits than under old-age and survivors insurance, an amendment was passed in 1951 that provided benefits equal to those under old-age and survivors insurance for this group of railroad workers.

A federal railroad unemployment insurance law was passed in 1938, and as mentioned above this legislation after 1946 also included temporary disability benefits. These two types of benefits were financed by a tax on employers fixed at 3% of the first $3,000 of wages until 1954 and after that date on the first $3,600. After 1948, however, because of high employment and a large reserve, employers were permitted to pay a tax much lower than 3%, the actual tax on the employer being 0.5% of wages. The Railroad Unemployment Insurance act is similar in many respects to the state acts. The average benefits, however. are higher (about $35 a week in the mid-1950s in contrast with an average benefit paid under the state unemployment insurance laws of about $26) Another difference between this federal act and the state laws is that all railroad employers pay the same tax rate. whereas the state acts allow the individual employer's contribution to vary on the basis of the amount of unemployment of his workers.

There are many different types of retirement systems for employees of state and local governments. After 1951 it was possible for employees with no retirement systems of their own to be brought under the federal old-age and survivors insurance law on a voluntary basis. After 1954 employees covered by a state or local retirement system could be brought under federal old-age and survivors insurance.

A federal civil service retirement system was established in 1920, but it was improved and liberalized many times. The vast majority of employees of the federal government were covered by this system. In 1950 the federal old-age and survivors insurance law was amended to cover a considerable group, mainly temporary employees. of the federal government who were not covered by the civil service retirement system. The civil service retirement system was financed by contributions of 6% of the employee's total wage or salary. The government made no specific contribution but assumed responsibility for any deficiencies in the fund. The benefits were based on total wages and on length of service. They were in most cases much larger than those paid under federal old-age and survivors insurance, although civil service benefits might be lower for employees with short periods of service.

Bibliography. — U.S.Department of Health, Education and Welfare, *The Social Security Bulletin* (monthly), gives regular statistics. "Basic Readings in Social Security: Social Welfare — Social Insurance," U.S. Department of Health, Education and Welfare *Publication No.* 28 (Washington, D.C., 1956), is a bibliography. Two textbook treatments are Eveline M. Burns, *The American Social Security System* (Boston, 1949); and Domenico Gagliardo, *American Social Insurance* (New York, 1955). Workmen's compensation is treated in Herman Miles Somers and Anne Ramsay Somers, *Workmen's Compensation* (New York, 1954); articles in U.S. Department of Labor, *Monthly Labor Review* (April–Aug. 1953), *Employment Security Review* (monthly). Vaughn Davis Bornet, *California Social Welfare* (Englewood Cliffs, N.J., 1956), shows federal-state-county interaction in social welfare. Adequacy of programs is discussed in *Vanderbilt Law Review* (Feb. 1955); Arthur H. Reede, *Adequacy of Workmen's Compensation* (Cambridge! Mass., 1948); Wilbur J. Cohen, *Retirement Policies Under Social Security* (Berkeley, Calif., 1957). *See* also articles in *Social Work Yearbook* (New York, biennially). (E. H. Hn.)

II. EUROPEAN SOCIAL SECURITY SYSTEMS

As it is not possible to refer fully to all the various systems operating in different countries, the British system introduced in 1948. which was generally more comprehensive than others. is described in some detail below as an example, but first the general principles governing other European systems will be explained. In some countries provision for pensions was less adequate than for unemployment, injury and sickness, mainly on account of the heavy expenditure involved, though improvement in this respect was achieved.

The fixation of the level of short-term benefit depends on the policy, or sometimes the financial position, of the country concerned. In some countries, such as Belgium, France and the German Federal Republic, the view was taken that the rate of benefit should be such as to enable the individual to maintain his previous standard of living by being calculated on the basis of wages, normally at about 50%. In many countries family allowances made these rates more adequate than the figure of 50% would suggest. In France, benefit for temporary disability was reckoned at a minimum of 50% of wages and in some cases at 66% of the average for the last three years; the old-age pension varied between 20% and 40% according to the age of retirement. In the U.S.S R. benefit was fixed at from 50% to 100% of wages according to the type of employment and length of service. In many countries — as in Great Britain — the principle adopted was the provision of benefit at a flat rate.

Rates of benefit in some countries, such as the Netherlands, were geared to the cost of living, but in other countries, such as Great Britain, a fresh act of parliament was required before rates could be increased. In the countries of northern Europe (Denmark. Iceland, Finland, Norway and Sweden) social security plans began to evolve at the end of the 19th and during the first half of the 20th century. In Spain a compulsory old-age insurance scheme. for lower-paid workers only, was instituted in 1921; compulsory maternity insurance in 1929; and invalidity insurance in 1933. But implementation of the various schemes was slow because of political troubles. An act passed in 1945 under which the state undertook to put into force legislation affording complete social insurance and protection to the family had not been fully implemented by the late 1950s.

In some countries pensions were payable to the widow of an insured person or of a pensioner irrespective of her age. whether she was an invalid, employed, or hon many children she had. There were limitations, however, in not a few of the pension insurance schemes; either the widows' pension was payable only from a certain age or the widow had to be an invalid; or she might not undertake any paid employment or exercise an independent occupation; or she had to have a certain number of dependent children. The amount of the nidows' pension was fixed in various ways; in many countries it consisted of one-half to six-tenths of the pension payable to the husband. Orphans' pensions varied from four-tenths to one-half of the pension payable to an insured person.

Accident insurance contains elements of both sickness and pension insurance; the family of an insured worker was usually afforded protection during his treatment under the same conditions as under sickness insurance. Even when an insurance scheme did not generally provide for dependents other than the wife and children it was usual in accident insurance to provide for parents and grandparents if they had been supported by a person who died as the result of an accident. Such provision was sometimes subject to a means test.

Social insurance may pay regard to the problem of housing and in some countries the social insurance reserves were used for housing projects. This served two purposes: to create new houses in nhich new families might be founded and at the same time to provide an investment for social insurance funds nhich nould keep its value.

Groups Covered. — The various systems may be divided into three classes. according to whether they apply in principle: (1) to all citizens; or (2) to all gainfully occupied persons and their dependents; or (3) to smaller and specified classes of people.

The first class, by the 1950s. comprised the systems of Great Britain. Iceland, Norway and Sweden. In some countries certain benefits, such as pensions and children's allowances. were universal whereas others, such as those granted on account of employment injury and unemployment, were reserved for employees. Sickness benefit in Great Britain was granted only to the gainfully occupied, but in some countries this benefit was available to any person of working age. Special provision was made for employees in agriculture in Bulgaria, Yugoslavia and France and for domestic servants in Bulgaria and Yugoslavia. Before World War II it was usual in many countries for social insurance schemes and especially pension schemes to exclude public employees, who were covered by special schemes.

The bringing of the self-employed within the scope of social insurance, adopted in Great Britain. was one of the most difficult matters which had to be considered; partly on account of the cost involved and also of the difficulty in enforcing payment of contributions. At first there were many prosecutions for nonpayment but the number steadily declined and the practical difficulties did not prove to be as great as had been expected.

Benefits Provided. — The majority of the systems at mid-century covered the loss or reduction of earnings caused by sickness, maternity, old age and death. Only a minority, however, provided benefits for the unemployed. For instance, the French system did not cover unemployment. The dominant concern of France had for several years been the increasingly rapid fall in the birth rate and the resulting serious threat to the future of the country and its population: hence the outstanding importance attached to family benefits in the French system.

When a new social security scheme was introduced in any country, there was a tendency to limit the coverage in the first stage. One factor underlying all the schemes was, however, the need to provide means to enable persons who have become ill to resume their employment as soon as possible, not only on humanitarian grounds but in order to meet the manpower situation. In France persons who had to give up their employment because of sickness were entitled to special medical benefit and sickness benefit for three years if they were considered likely to recover after prolonged sickness.

Old-age pensions were payable at different ages. This was probably because of environmental and possibly racial factors which determine the early or late onset of senescence, but the cost of the scheme was no doubt an important factor. One unusual feature in providing for payment of pensions mas the introduction in some countries of different retirement ages corresponding to the different degrees of arduousness of particular occupations. In most countries the pension was payable at the age of 65 for men and 60 for women.

Family Allowances. — The rapid extension of the provision of family allowances was a striking development. The first country to provide family allowances was New Zealand. but the principle was later extended to most European countries and commonwealth self-governing countries. In Great Britain the Family Allowances act. 1945, provided for payment to every family with two or more children of an allowance for each child, other than the elder or eldest, at the rate of 5*s*. a week, increased later to 8s. for the second child and 10*s*. for the third and younger children. These allowances were payable out of the national exchequer and did not depend upon insurance contributions. A person was treated as a child. for this purpose, if he was under the upper limit of the compulsory school age—I j—but if he remained at school after the school-leaving age. or was apprenticed, the allowance would continue up to the 18th birthday.

In Belgium family allowance was payable to employed and self-employed persons and to social-insurance beneficiaries with one or more children. In France it was payable to families (with two or more children) of gainful workers. widows, social-insurance beneficiaries, registered unemployed persons and persons incapable of gainful work. There the allowance, however, was not at a uniform rate. as was more general, but was fixed on a wage basis. In Ireland the allowance was payable only to families with three or more children. In Italy it was payable to families of employed persons and recipients of sickness or accident benefits with one or more dependents. The allowance varied by industry and for wage and salary workers. It was payable in the Netherlands to families of employed persons with one or more children. in Norway to families with two or more children and in Sweden to families with one or more children. In Portugal it was provided for families of employees in industry, commerce. the professions and government service with one or more children, the rate being fixed by individual funds to which employers and employees contributed. In Rumania it was payable to families of employees in industry and commerce with one or more children. In Spain it was provided for families of employed persons. small farmers and pensioners with two or more children and families of deceased workers with one or more children; and in Switzerland it was provided for families of employed persons with one or more children.

Administration and Finance of Social Insurance. — It is usual for each social insurance scheme to be administered by a government department under a minister or by a national institution which is self-governing subject to some governmental supervision. Local administration is usually entrusted to agencies of the central department, but in France it is undertaken by elected bodies. In the German Federal Republic social security insurance is administered and financed through statutory corporations whose administrative bodies are composed of representatives of insured persons and employers. In Finland and Sweden there is a unified scheme of administration of old-age and disablement pensions but other branches of social security are administered separately. In Sweden the national pensions board administers the pension scheme; the labour board. unemployment insurance; the national insurance office, employment injuries and health insurance.

In the Scandinavian countries much of the cost of providing benefits, especially old-age and disablement pensions, is met from national taxation but contributions meet a major proportion of the cost of health and unemployment insurance. The cost of benefits for employment injuries is met entirely by the employers. In Denmark and Sweden health insurance was started by the formation of health insurance societies which remained. as the scheme became more embracing. largely responsible for their administration. In Denmark old-age pensions were continuously financed entirely from national taxation.

Reciprocal Arrangements. — .+I feature of social security at mid-20th century was the making of reciprocal arrangements betn-een countries. The British act. for instance. empowered the making of arrangements with British Commonwealth countries and foreign countries for reciprocity in matters relating to benefits for unemployment. sickness. widowhood. orphanhood, retirement or old age. General reciprocal arrangements were made between Great Britain. Norway and Sweden. and between Great Britain and Australia and New Zealand in the British Commonwealth. Arrangements were also made between Great Britain and Ireland and between the five nations of the Brussels treaty powers (Belgium. France. Luxembourg, the Netherlands and Great Britain). Each of these countries. with some exceptions. agreed not to discriminate between its own citizens and those of the other countries concerned in the giving of social assistance or medical care. Each country also undertook not to repatriate a citizen of one of the other countries solely because he was in need of assistance which was likely to be long and costly. unless he was a recent arrival to the country. Provision was also made for any case where a national of any of the other countries concerned had been insured in three or more of the other countries, and for the preservation of acquired rights to benefit in the case of a change of residence. The arrangements with Norway and Sweden enabled British residents or tourists to make use of the health services. including hospital treatment. of those countries on the same terms as their own nationals. During the late 1950s general or limited reciprocal arrangements were also being negotiated between Great Britain and Denmark. Finland, Yugoslavia, the German Federal Republic and Austria.

III. SOCIAL INSURANCE IN GREAT BRITAIN AND THE COMMONWEALTH

The system of compulsory contributions for social insurance in Great Britain came into operation on July 5, 1948. as a result of the report of Sir William (later Lord) Beveridge. The statutes under which the various parts of the scheme were initiated were the National Insurance act. 1946. the National Health Service act, 1946. and the National Assistance act. 1948. The rates of contribution and benefits were altered by later acts. The cost was to be shared by the insured persons, the employers and the state. Every insured person was enabled to obtain any of the benefits by making a weekly contribution on a single card.

In general every person in Great Britain over school-leaving age and under pensionable age became insured in one of the following classes: (1) employed persons, *i.e.*, persons gainfully occupied in employment under a contract of service: (2) self-employed persons. *i.e.*, persons gainfully occupied hut not under contract of service; and (3) nonemployed persons. *i.e.*, those not gainfully occupied. Married women might choose whether or not to contribute under special conditions applicable to them.

Contributions. — The weekly rate of contribution paid by an adult employed man under the 1957 act was 9*s*. jd. and by an adult employed woman. 7*s*. 8*d*. This was reduced to 5*s*. 11*d*. in the case of a man and 4*s*. 10*d*. in the case of a woman earning remuneration at a weekly rate of 60*s*. or less. Boys and girls under the age of 18 contributed js. 3d. and 4*s*. 6*d*., respectively. In addition there was an employer's contribution of 8s. 1*d*. a week for a man and 6s. 7*d*. for a woman, increased to 11*s*. ;d. and 9s. jd., respectively, where the remuneration was 60*s*. a week or less. For boys and girls under the age of 18 the rates were 4s. 9*d*. and 3s. 10*d*., respectively. For self-employed persons. the rates for men and women were 11*s*. 6d. and 9s. 8*d*., respectively, and for boys and girls under the age of 18. 6s. ;d. and 5*s*. 9*d*., respectively. For nonemployed persons the rates were 9s. 1*d*. for men between the ages of 18 and 65; 7*s*. 3d. for women between the ages of 18 and 60; and for boys and girls between 16 and 18, 5*s*. 3*d*. and 4*s*. qd., respectively. For employed persons the employer was required to pay the whole contribution in the first instance but could deduct from wages the portion for which the employee was liable.

Benefits. — The rates of benefit were generally similar regardless of the need (unemployment, sickness, widowhood or old age). For an adult person (over the age of 18), other than a married woman, the weekly rate was 50*s*. with an allowance for an only child or the elder or eldest child of 15*s*., 7*s*. for each additional child and 30*s*. for an adult dependent. The benefits for children were in addition to the family allowance payable for other than the first child. A married woman over 18 received 34*s*. unless she was supporting an invalid husband or not residing with and unable to obtain any financial assistance from her husband, when she was paid the full 50*s*. rate. Boys and girls under 18 without dependents received 28s. 6d.

Unemployment Benefit. — To qualify for unemployment benefit, a person had to be available for class 1 employment and to have paid 26 contributions. The standard rate of benefit was payable during a benefit year if in the previous contribution year there had been paid or credited jo contributions. Unemployment benefit was payable for 180 days, plus up to 312 additional days calculated on the claimant's recent record of contributions and benefit. Xfter that he would not be entitled to further benefit until he had been back at work for 13 weeks.

Sickness Benefit. — To qualify for sickness benefit a person must have paid 26 class 1 or 2 contributions since entry into insurance. The standard rate of benefit was payable during a benefit year if in the previous contribution year there had been paid or credited 50 class 1 or 2 contributions. If between 26 and 50 contributions had been paid or credited, benefit was payable at a reduced rate. Certain disqualifications were laid down for receiving sickness benefit, such as if the person had become incapable of work through his own misconduct.

Maternity Benefits. — These were divided into: (1) maternity grant; (2) home confinement grant; and (3) maternity allowance. A maternity grant of £12 10*s*. was payable in respect of each baby born. Either the mother or her husband must have paid 26 contributions of any class before the date of confinement and must have had at least 26 contributions paid or credited in the last complete contribution year before the benefit year in which the confinement took place. A home confinement grant of £5, in addition to other benefit, was payable if the confinement did not take place in a hospital provided under the national health service scheme or in accommodation provided under the National Assistance act or in the course of transit thereto. This grant was intended to encourage women to be confined at home. The contribution conditions were the same as for maternity grant. A maternity allowance was payable to an employed or self-employed woman who gave up paid work for the period for which the allowance was granted. This was normally a period of 18 weeks beginning 11 weeks before the expected week of confinement. As in the case of other benefits the required contributions must have been paid or credited.

Widows' Benefits. — There were three kinds of widows' benefits, each being dependent upon the husband's contributions only: (1) widow's allowance; (2) widowed mother's allowance; (3) widow's pension. The widow's allowance of 70*s*. was payable for 13 weeks together with allowances for children (in addition to family allowance). The allowance was not payable if the widow was over 60 and her husband was entitled to a retirement pension. If the widow had a family which included a dependent child she would receive a widowed mother's allowance of jos. when she had finished drawing her widow's allowance, with an extra allowance for each child after the first. The allowance would be reduced in respect of earnings above 60*s*. in any week. Under certain circumstances, but not universally. a widow could obtain a widow's pension at the rate of 50*s*. a week when her other allowance ceased.

Guardians' Allowance.—Any person who had in his care a child who had lost both parents, one of whom must have been insured, was entitled to a guardian's allowance of 27*s*. 6d. a week.

Retirement *Pension.*—The expression "old-age pension," for which provision was made in previous statutes, was replaced by "retirement pension." This was paid to an insured man aged 65 or over or to an insured woman aged 60 or over who had retired from regular employment and satisfied certain prescribed conditions. The wife of a retirement pensioner even though she was not herself insured could qualify for a pension of her own at the age of 60, provided that she was retired. The standard weekly rate of retirement pension was 50*s*. or 30*s*. for a wife over 60 on her husband's insurance (increased to 50*s*. on his death). An increase of 30*s*. was payable to a retirement pensioner if he had an adult dependent; also 15*s*. for the eldest dependent child and 7*s*. each for younger children.

"Retirement" as understood under the act did not necessarily mean that the person had ceased to do any paid work. He could be treated as retired notwithstanding that he was engaged or intended to engage in a gainful occupation provided that such occupation was only occasional or inconsiderable in extent or otherwise not inconsistent with retirement. The amount a retirement pensioner could earn without reduction of his pension was limited. There were certain advantages if a person remained at work after pensionahle age. He could still obtain unemployment and sickness benefit within certain limits up to the age of 70 (65 for women) and could also earn a higher rate of pension. For every 2j contributions paid as an employed or self-employed person during the five years after reaching pension age, the retirement pension would be increased by 1s. 6*d*. a week. The rate of the wife's retirement pension would also be increased. At the age of 70 (65 for women) the full rate of retirement pension then earned would be paid though the pensioner might continue to work.

Death Grunt.—A death grant toward the cost of funeral expenses was payable on the death of an insured person, or on the death of the wife, widow, husband or child of the family of an insured person. This was £25 for an adult and smaller sums for persons under 18 years.

National Assistance.—The National Assistance act, *1948*, provided a unified state service of financial assistance according to need in place of various services provided previously by the state or local authorities. It was placed under the administration of the national assistance board, with offices throughout the country. It was the duty of the board to assist persons who were without resources or whose resources (including benefits receivable under the National Insurance acts) were insufficient to meet their requirements. The question of whether a person was in need of assistance and the nature and extent of any assistance to be given were decided by a local officer of the board in conformity with general regulations made by the minister of national insurance, but provision was made for consulting a local advisory committee in special cases. The board's officers themselves. however, used considerable discretion in applying the regulations. There was special provision for blind persons and persons who suffered a loss of income in order to undergo treatment for pulmonary tuberculosis. The cost of national assistance was met out of national taxation.

Noncontributory Old-Age Pensions.—Noncontributory old-age pensions, as distinct from contributory old-age pensions (or retirement pensions), were payable under the Old Age Pensions act, *1936*. They were a direct charge on the national exchequer and did not come out of the insurance fund. They applied to a diminishing number of old people who had not become entitled to retirement pensions by contributing under the national insurance acts, Ultimately this class of pensioner would disappear. Unlike retirement pensions. which were payable at 65, a noncontributory pension was not payable until the age of 70. Further, a noncontributory pension was not granted to every person who had attained that age, as eligibility was subject to a means test.

Workmen's Compensation.—Provision was made under the National Insurance (Industrial Injuries) act, *1946*, for the compulsory insurance of all persons engaged in insurable employment against personal injury caused by accidents, or the contraction of certain industrial diseases arising out of or in the course of such employment. The provisions of the act therefore replaced the former provision for the payment of workmen's compensation under the various workmen's compensation acts, the first of which was passed in 1897.

Health Services.—Various health services without direct payment were made available to the whole population under the National Health Service act. *1946*. These included: (1) hospital and specialist services; (2) certain domiciliary services provided by local health authorities; and (3) general medical, dental, pharmaceutical and ophthalmic services.

Under former schemes, free medical attention and medicines were available only to insured persons and not to members of their families. Cnder the later scheme, everyone became entitled to these services for himself and members of his family, if any, and had the free choice of a medical practitioner from whom treatment might be obtained. provided the medical practitioner had agreed to serve under the scheme. The doctor was paid a capitation fee for each person on his list, together with certain additional allowances. Medicine prescribed by the doctor could be obtained free from any pharmacist taking part in the service. Later a charge of 1*s*. was made for each prescription. Dental treatment, in respect of which a fixed charge was imposed later, was also available from dentists taking part in the service. Their remuneration was provided by scales of fees for various types of work. General responsibility for the national health service scheme was vested in the minister of health, who acted through regional hospital boards and hospital management committees; the domiciliary service was administered by local executive councils in different parts of the country.

National Insurance Administration and Finance.—The minister of national insurance, later designated the minister of pensions and national insurance, was made responsible for the administration of the scheme. His department worked through regional and local offices in close association with the local employment offices of the ministry of labour and national service. A national insurance advisory committee was established to assist the minister in discharging his iunctions under the act with the special task of considering any draft regulations before their submission to parliament. There were also local advisory committees throughout the country to assist local officers of the ministry. Contributions were paid by the purchase of special stamps at any post office; one of these stamps was to be affixed to the insured person's contribution card ior each week of employment but special arrangements could be made for stamping in bulk. When the national insurance scheme came into operation the invested assets of the former health, unemployment and pensions schemes, amounting to about £900,000,000, were taken over. Of this, £100,000,000 was credited to the national insurance fund (under the control of the minister) to meet the payment of insurance benefits and the cost of administration. Into this fund was to be paid the money received from the sale of insurance stamps. The remaining £800,000,000 of the old funds was used to constitute a reserve fund. The interest on the investment of this fund was to be paid into the main fund. In addition to bearing the cost of benefits under the national insurance scheme, contributions bad to be made from the fund toward the cost of the national health service. The balance in the national insurance fund at March 31, 1955, was £381,069,000; the reserve fund balance was £1,068,600,000.

British Commonwealth Systems.—At mid-20th century schemes of social security were operating in most commonwealth countries to a varying degree. In Australia there was no contributory insurance scheme, but the social security services were administered by the commonwealth department of social service and the cost was met by the exchequer. The rates of assistance apart from maternity and child allowances were based on a means test. In New Zealand the general social security benefits, apart from orphans' pensions and family benefit, were also subject to a means test, but legislation provided for the gradual elimination of age benefit subject to a means test by the substitution of superannuation benefit, available to persons aged 65 and over who satisfied certain residential qualifications. A person in receipt of any other benefit under the Social Security act, 1938, except family benefit, was not entitled to superannuation benefit. The rate for this benefit was fixed at £75 a year from Oct. 1, 1951, to rise by fj a year annually until the rate of pension under the means test was reached. In Gibraltar a comprehensive insurance scheme came into operation in 195j, while in Malta National Insurance and Assistance acts establishing a comprehensive scheme took effect in 1956. (*Sue* also SOCIAL SERVICE.)

SOCIAL SERVICE. The term "social service" is defined broadly as the provisions made by governmental or voluntary efforts to meet income maintenance, medical care, housing and recreational needs and provisions for the care and protection of special groups which have become recognized as essential community responsibilities in industrial society. The term is somewhat differently used in the United States and Great Britain and the social services do not follow identical patterns of administration, finance and use of professional personnel. Yet the experience of one country influenced that of the other, so that by the 1950s there was far less difference in the design of social service within Great Britain and the United States than there had been prior to the 1930s, when significant changes took place in the United States.

While essentially the origin of social service is ancient, stemming from the tenets of the Judaeo-Christian teachings, the modern institution took shape with the impact of the industrial revolution upon family and community life, substituting as it did an industrial for an agrarian economy, urban living for rural living, and creating dependence upon the wage system as a means of livelihood. The effect of the industrial revolution was felt in Great Britain long before it reached the United States. This is an important factor in understanding the history of social service in the two countries.

Methods of Social Service.—The methods of social service, whether or not carried out by professionally trained personnel, characterize a formalized way of helping people to help themselves. Social service is based on the recognition of variations in individual capacities and variations in the social structure. The objective is to help the individual utilize his abilities for his own welfare and for that of the community. The helping process of social service is formalized and is made available both through community-sponsored agencies, governmental or nongovernmental, and through community institutions such as the courts and the schools which desire to function more fully in their service to individuals with particular problems or handicaps. The process is limited in use to those services or agencies for which there is a defined social goal, a stated social purpose and responsible sponsorship, all designed to promote the social welfare of individuals and groups in the community.

Three generally accepted methods are identified in social service. The first is social casework, which aims through understanding the individual in his total situation to help him make maximum use of the established community institutions. The second is social group work, which seeks through an understanding of the behaviour of individuals in a group setting to help them utilize their fullest capacities for their own welfare and for the welfare of the group as a whole. The third is community organization, which attempts to help groups of individuals or groups of agencies so to work together that their combined efforts will be conducive to the social welfare of the whole community. Community organization has thus a two-way emphasis—helping groups to examine and co-ordinate their efforts and helping them take definite steps of an educational or legislative nature that will accomplish changes in the community pattern of living. Social work research plays an important part in evaluation and program planning which are basic to the three methods described above.

Governmental (public) responsibility for people in need took form first in Great Britain with the enactment of the Elizabethan poor law ("old poor law") in 1601. Subsequently the American Colonies adopted the essential principles of this statute in providing for assistance to people who were in need. Xongovernmental (voluntary) responsibility reached its peak of development in Great Britain by the end of the 19th century, in the United States not until the end of the second decade of the 20th century. The principle of social insurance nas accepted in Great Britain in 1897 with passage of the first Workmen's Compensation act; and in the United States in 1908, when the first Workmen's Compensation act was passed covering federal civil employees. In both countries the philanthropic individualism of the 19th century was succeeded by a partnership of governmental and nongovernmental activities, in which governmental responsibility became an accepted instrument through which citizen responsibility for citizen welfare could be expressed. This development was paralleled by an increasing comprehension of the needs of all individuals in contemporary society and a growing awareness that social service should be available to all who need it and can use it. This was in contrast with concentration on the problems of a single segment of society associated with the late 19th century. As against a general belief that social maladjustment has its origin in the physical or emotional make-up of the individual, it became recognized as having both individual and environmental causation, with an interdependence between the two as the principal factor to be considered.

GREAT BRITAIN

In Great Britain, the term "social service" includes governmental and nongovernmental provisions in the field of social insurance, social assistance, medical care, housing, education and recreation as well as in the field of care and protection of special groups. The inclusion of education as a social service in Great Britain is significantly different from United States practice.

Social Insurance.—The key to the British social insurance system is found in the famous Beveridge plan outlined in *Report on Social Insurance and Allied Services*, prepared by Lord (then Sir William) Beveridge in 1942 at the request of the British government. This report identified as "five giants" in the path of social progress "want, disease, ignorance, squalour and idleness"; stated that social insurance should be considered an attack on want and that a comprehensive social security service should be achieved by co-operation of government along with efforts of private individuals. which -would "combat" these "five giants." In contrast to specific efforts directed at specific problems in which government had long been engaged and in nhich voluntary efforts had participated, Lord Beveridge stated the principle of comprehensive social security which would cope simultaneously with all five of the major problems he had identified. Subsequently the Education act of 1944, the Family Allowances act of 1945, the National Insurance act of 1946, the National Insurance (Industrial Injuries) act of 1946, the National Health Services act of 1946, the Children act of 1948, the National Assistance act of 1948 and other measures either amended existing statutes or established new provisions, all of which were designed to implement the principle of comprehensive social security.

Under the National Insurance act of 1946, a system of social insurance provided income maintenance benefits covering the "main eventualities" from birth to death. Employed persons, self-employed persons and persons not gainfully employed constituted the three groups into which population was divided for insurance purposes. "Eventualities" included unemployment, sickness, retirement, death, maternity, widowhood and surviving children of school age. The National Insurance (Industrial Injuries) act of 1946 provided benefits for the worker injured during employment and for surviving dependents in the event of accidental death of the worker. Under the Family Allowances act of 1945, allowances for each child beyond the first in every family were paid at the rate of five shillings per child per week. These provisions were administered by the ministry of national insurance, through local offices of the ministry, through employment exchanges and through the post offices. The National Insurance act and the National Insurance (Industrial Injuries) act provisions were financed on a tri-partite basis, with contributions from insured persons, employers and the government. The Family Allowances act provisions were financed by general taxation.

Social Assistance.—The terms "social assistance" and "public assistance" are used synonymously in Great Britain and describe, in general, provisions for income maintenance not a part of the National Insurance act and the National Insurance (Industrial Injuries) act, and auxiliary services which are specifically defined. such as domiciliary care for persons who need such care and for whom it is not otherwise available. This is a residual provision for those outside the scope of the acts, either because of the nature of their need or because of their inability to qualify for benefit.

The administration of social assistance remained in the hands of the local assistance authorities. empowered by the national assistance board to perform specific functions. These services were financed by local authorities, by grants from the national government for specific services and by equalization grants under the Local Government act of 1948 available to local political units whose general financial condition fell below that of the average in its particular group.

Health, Housing, Recreation. — The provisions of the National Health Services act covered medical services, hospital care and preventive or auxiliary health services. Medical services became available to everyone without respect to insured status, age or other circumstances. Medical practitioners under contract with local executive councils were made responsible for the provision of personal medical services. These councils were appointed by the local health authority, the minister of health and local medical, dental and pharmaceutical committees. Hospital care. similarly available, was planned and supervised through a systern of regional hospital boards appointed by the ministry of health. Administration of hospitals was placed in the hands of hospital management committees appointed and responsible to the hospital board. Preventive, auxiliary and related services in the health field became the responsibility of the local authorities. These included health centres and home nursing and substitute housekeeping services in homes where illness handicaps the homemaker.

The national health services were financed in part from contributions from the National Insurance act, from local authorities and from the national government. As indicated, they were placed under administration of the minister of health with professional guidance from the central health services council appointed by the minister after consultation with appropriate organizations.

In connection with the administration of "housing estates" by the local housing authorities, the social-service function of administration was conceived of as help to the tenants in establishing equitable rent. in utilizing most fully the facilities of the housing project and as help in referring tenants in need of social services to any one of the existing services available to them in the community.

While local educational authorities retained as their main function the provision of educational facilities for children under the compulsory school age of 15 years and for technical and commercial education for persons over compulsory school age, they also assumed responsibility for school medical care service through the national health service; for psychological services; for physically and mentally handicapped children; for nursery schools, school milk and lunch programs; and for obtaining recreational facilities for school children and young persons between the ages of 15 and 20 years. So far as public responsibility was concerned, recreation thus became the task of the local educational authority. To implement this function, the authority might make grants to voluntary organizations or establish provisions directly. At the same time national voluntary organizations in the field might also receive direct grants from the central government through the National Council on Social Service.

Children; Handicapped **Persons.**—Under the Children act of 1948 local political unit authorities through duly appointed children's committees became responsible for children under 17 years of age who were without parents or appropriate guardians or whose parents or guardians were unable to provide for them. Both temporary and long-time care of the child became the responsibility of the children's committee appointed by the local authority. Furthermore. the authorities might assume the power of guardianship subject to the approval of the court having jurisdiction in juvenile cases. For juvenile offenders, juvenile court hearing, probation, commitment to approved schools and commitment to a Borstal institution for young persons between 16 and 21 years of age were provided.

Services to the physically handicapped, other than financial assistance, were provided by the local authorities either directly or through voluntary agencies. These services included provision of sheltered workshops, suitable home work, and general welfare of the handicapped person. Those handicapped by industrial accident became the responsibility of the local authority of the ministry of labour, which administered the services of industrial rehabilitation and employment.

Provisions for the mentally ill and mentally handicapped became the initial responsibility of the local health authorities. Hospitalization and custodial care were assigned to the regional hospital board. When noninstitutional provision was made. the responsibility remained with the local authority. which might also make provision for aftercare as directed by the ministry of health to which over-all responsibility was assigned.

An especially interesting feature of the social service program of Great Britain uas the provision whereby citizens' advice bureaus or information centres were to be established either by the local authorities or by voluntary organizations which might be aided by the local authority.

Nongovernmental or Voluntary Social Services. — Voluntary efforts, many of which had pioneered in methods. continued to be encouraged and aided with little supervision except where specifically required by a statute In contrast with the situation in the United States. where administrative and financial separation between the governmental and nongovernmental agencies was sharply defined. there were provisions under the Education act, the National Health Services act, the National Assistance act and the Local Government act, whereby financial grants might be made to voluntary organizations in special fields. Examples were youth organizations, discharged prisoners' aid societies, aftercare associations, national old people's welfare committee, and information centres.

The National Council on Social Service became the principal instrument for making governmental grants to nongovernmental agencies. This co-ordinating and planning body, to which voluntary organizations were affiliated, worked in close co-operation with governmental agencies.

Local councils and rural community councils of social service were both affiliated with and independent of the Kational Council on Social Services. They were engaged in studying conditions, in discussions and in joint planning in order to make agencies serve more effectively. *(See* also PENSIONS; SOCIAL SECURITY.)

UNITED STATES

In the United States, the term "social service" is less broadly defined than in Great Britain. For example, education is not generally considered a social service, although there are special provisions established within the system of popular education that are distinctly social in character and in many instances are staffed by proiessional personnel from the social-service field.

Social Insurance.——Under the Social Security act of 1935, as amended in 1939 and in 1950, an income maintenance program known as old-age and survivors insurance included retirement benefits and survivor benefits for the dependent relatives of the insured person. The coverage of the first act (193j) was expanded by the amendment of 1950, bringing under insurance systems domestic workers, certain agricultural workers and self-employed and on an optional basis employees of nonprofit organizations and of state and local governments. This became a federally administered program financed by contributions from employers and employees. Benefits depended upon the length of covered employment and upon the record of wages paid during this period of employment. Under the act of 1937, railroad workers were covered under a separate program known as the railroad retirement system.

A second income maintenance program established by a social insurance principle was that of unemployment compensation. **A** pay-roll tax was levied on employers of eight or more persons in covered industries, and by the device of "tax offset," 90% of funds so accumuiated were being made available to the states with laws and procedures meeting certain minimum standards. The federal government paid the administrative costs incurred by the states. Once minimum standards were met, the states, in turn, acquired latitude, and in some instances enacted legislation requiring employees' participation and extending coverage to the small establishments and providing a higher benefit payment. The covered industries excluded domestic and agricultural employment, employees of nonprofit organizations and employees of state and local political units. Unemployment compensation was provided for railroad workers under the railroad unemployment insurance system.

A third income maintenance program was workmen's compensation or industrial accident compensation which, except as it affected federal employees and railroad workers, was the result of state legislation.

Public Assistance.—Under the Social Security act as amended in 1950, a federal and state partnership was established, enabling the states to provide public assistance for four categories of persons in need. Aid to dependent children, old-age assistance, aid to the blind and aid to the totally and permanently disabled comprised the four categories for which the states with approved programs could obtain federal reimbursement according to a matching basis specified in each category. The state might, in turn, bear the total share of the state cost or establish some combination of local and state financing. A residual category of individuals not belonging in any one of the four mentioned above was known as "general assistance," and for this program the state and local political units carried full financial responsibility.

Housing and Recreation.—Governmental participation in health and medical programs was much smaller at mid-20th century than in Great Britain. Through a network of federal, state and local provisions and with participation of the federal government through grants-in-aid to the states, a system of local public health units was being established. These local units and the supervising state health departments held the key position in the preventive health program. Medical care for individuals in specific diagnostic groups—such as tuberculosis, venereal diseases, certain other communicable diseases, mental illness and remedial care of crippled children—had been established as a governmental responsibility. Grants from the federal government for research in cancer, in heart, in the care of the mentally ill and in the training of personnel in the mental health field had also become available.

Under the provisions of the Hospital Survey and Construction act of 1946 and amendments of 1949, federal funds were made available to enable the states to make surveys of hospital needs looking toward a regional distribution of hospital and diagnostic centres; and funds were also made available for aid in hospital construction. Personal medical care, except for the diagnostic groups mentioned above, was limited to veterans, merchant seamen, Indians and to the group known as "the medically needy." Amendment to the Social Security act of 1950 permitted federal matching of funds for the medical care of public-assistance recipients and for the domiciliary care of these persons in public and private institutions. A few states had defined "medically needy" to include self-sustaining groups of persons with incomes insufficient to purchase adequate medical care. But such provisions were limited in extent and in income levels. Other than these provisions, personal medical care was still under private auspices, with considerable expansion of group hospital and medical care insurance plans either under community auspices or under labour-management agreements.

Under the Housing acts of 1937 and 1949, local housing authorities, established in accordance with state law, could receive long-term loans (40 years) from the federal government to cover 90% of the cost of low-cost public housing projects, available to low-income families. Slum clearance and redevelopment of properties and guarantees of long-term financing for the meeting of housing needs of middle-income families also became available.

The low-cost public and scattered private housing projects were recognized as a social welfare service. It was recognized also that families with low incomes, selected primarily because they had been living under substandard housing conditions, would include persons of different races, nationalities and religious faiths who could utilize community facilities to aid them in the various adjustments to living in close proximity. Community agencies, both public and private, were encouraged to make these available to the housing community, and the responsibility of housing management, other than the property maintenance and tenant selection. became that of informing and interpreting the facilities to the housing residents.

Although the U S. system of popular education had never been considered to be among the social services. there were nevertheless auxiliary services established in connection with the system which were properly so designated in that their function was to help children of compulsory school age make fuller use of the facilities of the schools. Preventive school health services. student counselling, school social work and psychological services—all had an emphasis on helping that properly designated these provisions as "social service."

Public recreation remained primarily the function of local political units as defined by state law, and it was divided between two local authorities—the board of education and the local governmental authority. Co-ordination of the two was sometimes effected by voluntary effort at the local level and sometimes aided by state legislation. providing certain benefits for a co-ordinated program. State recreational authorities, the first of which was established in 1945, became engaged in making available information and advice concerning local recreational developments. Recreational areas were developed within the state parks. especially those with resort possibilities, and attempts were made to make them available to voluntary agencies providing summer camps and recreational programs. A system of national parks (*q.v.*) was begun in 1872 as the responsibility of the federal government. Established in areas of great natural beauty or of historic significance, they became important recreational facilities for the entire population. Any co-ordination of these federal. state and local facilities. however, remained on a voluntary basis. Up to the 1950s, with some important exceptions, they had been regarded as recreational facilities and not as recreational programs in which professional leadership had its place. However, the use of these areas by nongovernmental agencies with professional leadership was generally encouraged.

Children and Handicapped Persons.—Services to children, except as they had been established and expanded in rural areas and in areas of special need through federal grants under the Social Security act, remained the responsibility of the local communities and the states. Care of dependent, neglected and delinquent children was still the responsibility of the child welfare authority or the juvenile court. Determination of custody in case of neglect or dependency is in the last analysis a judicial procedure, nhich may assign custody or guardianship to a governmental or nongovernmental agency as well as to an appropriate relative. Similarly. adoption is a judicial determination, but there remained variations within the states concerning the extent of state or local administrative responsibility for adoption studies and supervision of children placed in adoptive homes. Foster home care, temporary or long-time and institutional provision continued to follow different patterns in the various states. No phase of social service in the United States had so many variations in administration. In some. the use of voluntary agencies, nith or without grants of state or local funds, had become extensive. In others, governmental agencies, local and in a few instances state. were used.

The provision of care for the mentally ill and mentally handicapped remained a state responsibility. Preventive efforts were both local and state. as was aftercare responsibility; but, because of expense and type of problem, the principal provisions for care and treatment had long been regarded as belonging to the larger unit of government. Except for direct administration of Saint Elizabeths hospital. Washington. D.C., and U.S. Veterans administration hospitals. the federal government played no part in these programs other than through the National Mental Health act, enacted in 1945, which made funds available for research, training and the extension of community facilities for preventive care.

In the field of care for the physically handicapped, other than those injured through industrial accident, the federal government, through grants to the states under the Vocational Rehabilitation act of 1943 and through the crippled children services of the Social Security act of 1935, assumed a major though not exclusive responsibility for the corrective educational and vocational training needs of these groups. There was still a substantial participation, however, by governmental agencies and nongovernmental agencies at both the state and local levels.

Nongovernmental or Voluntary Social **Agencies.**—With the assumption by government of responsibility for meeting basic income maintenance needs and other social services in health, housing, recreation and in care and protection of special groups of persons — notably children — the function of nongovernmental social service in the United States became increasingly that of research, experimentation, demonstration, supplementation and maintenance of those services not yet recognized as proper for the governmental authority to institute. This change first became notable in the 1930s. Nongovernmental or private social services, however, continued to maintain important leadership in the total field.

In the field of family welfare, family-service associations emphasize counselling, voluntarily sought by those who wish this service, and certain auxiliary services, such as income supplementation or family life education directed toward the strengthening and development of the family. Considerable attention is given to the development of high standards of service, and to this end the Family Service Association of America became recognized as the standard-setting agency.

Child welfare agencies occupy an important place in the scheme of nongovernmental agencies in the United States. Child-caring institutions are for the most part under private auspices, and the importance of the sectarian institution should be especially noted here.

Noninstitutional agencies are engaged principally in foster-home placement and supervision, adoption study and supervision, protective care of neglected children in their own homes and provision of services for especially handicapped children, such as those with severe behaviour disorders or requiring unusual facilities for education and development.

In the field of medical care, nongovernmental agencies play an important part in the preventive field where public interpretation and public education are stressed. Examples are the National Tuberculosis association, American Cancer society, American Heart association, National Foundation for Infantile Paralysis, a few of which have state or local affiliates. Some of these efforts lead later to legislative provisions for services supported by taxation.

Voluntary hospitals and outpatient services play an important part in provision of hospital and personal medical care for the medically needy, in some instances supplementing the public provisions and in others carrying major responsibility, with or without government aid,

Auxiliary services include medical social casework and psychiatric social casework. Voluntary medical care insurance, such as Blue Cross and Blue Shield plans, provide limited hospital and medical care.

In mental health also, nongovernmental agencies carry important responsibilities for preventive programs, either in the educational area or in treatment of incipient disorders, through community or hospital-sponsored clinic services. Such organizations as the National Mental Health foundation, and local and state mental hygiene societies are examples of these educational efforts. One of the contributions of the voluntary agencies has been to stimulate agencies, such as schools and courts, to recognize the importance of mental-hygiene aspects of the service provided.

In youth programs, the voluntary associations dominate the field in the United States. The Y.M.C.A., Y.W.C.A., Y.M.H.A. and Y.W.H.A., Boy Scouts and Girl Scouts, Camp Fire Girls, girls' and boys' clubs and others have long-established traditions and are generally accepted. The 4-H club programs under agricultural extension service play an important role in rural areas.

Similarly social settlements and neighbourhood and community centres are recognized as the province of the nongovernmental agencies. Some tendency for government to assume responsibility for community centres was observable at mid-20th century, but this trend was not extensive. Both traditions and the conviction that nongovernmental auspices would serve citizen participants more effectively accounted for the continued leadership of the voluntary agencies in this field.

Social planning bodies such as councils of social agencies, federations of health and welfare and neighbourhood councils are nongovernmental in character. At the national level, examples are the National Social Welfare assembly and the American Public Welfare association. At the state level may be cited such organizations as the Pennsylvania Citizens Association for Health and Welfare and the New York State Charities Aid association. At the local level, social planning councils with autonomous agencies as constituent members exist either in connection with or independent of the central financing bodies. In this same connection, social-welfare forum bodies such as the National Conference of Social Work and the state conferences of social welfare; the National Catholic Welfare conference and the National Conference of Jewish Social Welfare perform an important function in discussion and education that affects social planning.

Government also plays a part in the discussion-forum type of social-welfare planning. The White House conferences held at the end of each decade, the National Health conference of 1938 and the National Conference of the Aging in 1950, are all examples of initiative taken by the federal government in organizing nation-wide conferences dealing with timely subjects. They had profound effect on trends both in the governmental and nongovernmental fields.

The social planning council may or may not be an integral part of the central financing body in the local community. The community fund or community chest is the accepted mechanism for raising voluntary funds for the financing of voluntary agencies. A national organization known as Community Chests and Councils of America, composed of and partly financed by local community chests, was giving leadership in the whole field at mid-century. Member agencies of the local chest are limited to those for which a single financial appeal is practicable, thus excluding agencies which may not be widely accepted.

PERSONNEL

In Great Britain, the recruitment of personnel to staff the governmental services at the national level is achieved by the method of open competitive examination to which individuals under 25 years of age and, under special exceptions, veterans are eligible. It is generally assumed that experience and in-service training will prepare personnel for promotion to more exacting responsibilities. Local authorities having power to appoint personnel are not governed by the general civil service act and have wide latitude in recruitment.

At both the national and local levels of recruitment, the place of the specialist in social service is a limited one. Depending on the nature of the service, there are specialists in housing management, in child welfare, in hospital social service and in psychiatric social casework. Where so designated, the social-service worker is asked to meet generally accepted professional qualifications in the particular field. These qualifications involve training in social science, for which 24 universities or university colleges were making provisions at mid-20th century, or demonstrated experience or some combination of the two.

In the voluntary field, social workers are employed in family casework agencies, in child-welfare agencies, in youth-service agencies as youth leaders, in agencies under religious auspices as moral welfare workers, and in neighbourhood work, community centres and settlements.

In the United States, with the exception of federally financed and administered social-service programs, the recruitment and assignment of personnel in the public social services is within the responsibility of the states and local political units. The services just indicated as exceptions are covered by regulations of the U.S. civil service commission, which permit the fixing of requirements for the selection of specialists in various fields.

These include specialists in the field of social work identified both by training and experience as requisite for the responsibilities to be performed.

Under the system of federal grants-in-aid to the states under the Social Security act, all state services in the field of public assistance, child welfare and unemployment compensation are obligated to use what is known as a merit system of selection. This is also true of the federally aided services in the field of health under the Public Health Services act. A merit system follows the general principle of civil service but is to be distinguished from it.

Except as they are guided by the general principle of merit selection, the states have latitude in fixing eligibility requirements. salary and tenure provisions. and there are substantial variations within the state systems concerning. for example. the extent to which special training is required. Local political units such as counties and municipalities establish their own systems of personnel selection. The extension of civil service and merit systems in the states was rapid after 1939. This was due in part to the transfer of large numbers of social workers from private nongovernmental agency employment to governmental agency employment. It was also due to the development and interest of schools of social work in preparation for the public services and to the active support of professional standards by such professional organizations as the National Association of Social Workers and similar organizations in special fields of psychiatric, medical social and group work.

In the field of nongovernmental social services, the standards of personnel selection are subject to the determination of individual boards of directors and sponsoring bodies. They are generally affected by standards recommended by national organizations of which the agencies may be local affiliates. In addition, the influence of the schools of social work and the influence of professional membership associations are important factors in establishing and maintaining personnel standards.

At mid-century, there was a serious disparity between demand and supply of trained personnel. This situation constituted the greatest single barrier to progress in the use of professionally-trained social workers in the nongovernmental agencies.

As social service becomes a significant field of professional activity in which both men and women are employed. the nature, length and educational level of preparation are increasingly important. In both countries. university sponsorship of programs of professional preparation and liberal arts studies as desirable preprofessional preparation are generally recognized. The program of professional study itself combines theory of the practice of social service methods. concurrent with or followed by field instruction within social agencies and knowledge of the history, structure and administration of social welfare programs. The schools of social service in the United States place greater emphasis on the theory of practice and on field instruction than do similar schools in Great Britain. Professional training for the field of social service in the 1950s, however. was moving toward a common base which recognized the process of "helping" as something which requires actual practice in the use of theory as essential for this purpose. *(See* also PENSIONS; **SOCIAL** SECURITY.)

OTHER COUNTRIES

Social service. social work, social welfare services and welfare work are variously defined by the other countries of the world. Through the United Nations current and authoritative information became available from member nations. Two surveys (*Methods of Social Welfare Administration* and *Training for Social Work, an International Survey*) issued by the United Nations Department of Social Affairs contributed greatly to the understanding of the various systems and comparisons and contrasts between them.

According to Mrs. Katherine Kendall (*Training for Social Work, an International Survey*), the 33 countries reporting social-service systems may be grouped as (1) those regarding social work as individual charity expressed in terms of almsgiving and voluntary services by individuals on behalf of the indigent; (2) those regarding social work as organized activity under governmental or nongovernmental auspices directed toward the solution of problems connected with economic dependency and (3) those regarding social work as professional service under governmental and nongovernmental auspices potentially available to every member of the community irrespective of his means, to assist him in achieving his full potentialities for productive and satisfying living.

These differences in definition are reflected in the characteristics of the systems. such as the relative importance of governmental and nongovernmental provisions, the place of tax-supported and voluntary or sectarian institutions, the use of the social insurance principle in comparison or contrast with the use of the social assistance principle in meeting economic and medical care needs of the population, and the roles of the central government and the states or regions and the local political units in the administration of the services. Political and social philosophies, the economic structure and development of the countries and the nature of social needs in large measure determined these characteristics. A country-by-country study is necessary to a full understanding of the individual systems.

A characteristic common to all, however, was the increasing use of the "social-security concept" during and following World War II.

Provision for old-age. invalidity, survivors insurance and pension (or assistance) programs were established in 33 countries by 1939. By 1949, the number had increased to 44. In general these systems were financed by contributions from employer and employees in covered industries and supplemented by governmental contributions. Benefits were dependent upon length of covered employment and extent of earnings. At mid-century. seven countries used the method of pension with a means test to meet the needs of these groups. Others employed some combination of insurance and assistance in their programs.

Medical care provisions as a part of social insurance systems were established in 36 countries by 1949. an increase from 24 in 1939. Medical care provisions not a part of the social insurance systems were established in other countries.

Workmen's compensation providing cash benefits and medical care for persons injured or disabled in employment had been extended by 1949 to 57 countries. To a limited extent only was disability caused by occupational disease included with these provisions. The trend in legislation had been to require that insurance to guarantee this compensation be carried and administered by a governmental agency.

Protection against a wage loss through unemployment was provided in 22 countries either through compulsory unemployment insurance, governmental subsidies of voluntary insurance programs. public works, government aid to the unemployed or through some combinations of two or more of these methods.

Family allowance systems provided regular cash benefits to families with one or more dependent children. These provisions were especially characteristic of continental European countries where substantial expansion of such programs characterized the period during and immediately following World War II.

Professional and technical training of personnel employed in the administration of social insurance and social welfare programs was also increasingly recognized.

SOCIAL SETTLEMENTS are social welfare agencies established to provide a variety of services to people who live in given geographical neighbourhoods. These agencies may also be called settlement houses, community centres, neighbourhood houses, neighbourhood centres, neighbourhood associations or guilds. In Great Britain there are both residential settlements, where members of the professional staff live as well as work, and community centres founded by city and borough councils after World War II. Settlements. under a variety of names, are to be found in most countries of western Europe and in southeast Asia and Japan.

History. — The settlement movement began with the founding of Toynbee hall (*q.v.*) in London in 1884. Samuel A. Barnett (*q.v.*), then vicar of St. Jude's parish, invited a number of university students to join him and his wife in "settling" in a deprived area. The movement spread to the United States when Stanton Coit, nho was one of the early visitors to Toynbee hall, established Neighborhood guild, now University settlement, in the lower east side of New York city in 1886. In 1889 Jane Addams (*q.v.*), another Toynbee hall visitor, and Ellen Gates Starr bought a residence in the near west side of Chicago, Ill., and started Hull house. In the same year Jane E. Robbins and Jean Fine (Mrs. Charles B. Spahr) opened the College settlement in New York city. Two years later Robert A. Woods established Andover house. later called South End house, in Boston. Mass. The movement spread to other countries mainly through the influence of visitors from those countries to settlements in England or the Cnited States.

Purposes. — The purpose of a settlement is the development and improvement of a neighbourhood or a cluster of neighbourhoods. It differs from other social agencies in that it is concerned about neighbourhood life as a whole, not with providing selected social services. In a sense the neighbourhood is its client Settlements seek consciously to develop harmonious relationships among community groups of different cultural, economic, religious and social characteristics. While they may have sponsorship and support from a religious organization, their purpose is to serve all kinds of people who live in the neighbourhood regardless of race, class or creed.

Settlements seek to help people act together as an active and informed citizenry for the improvement of their living conditions and environment. Under the leadership of pioneer workers such as Lillian D. Wald (q v.) at the Henry Street settlement in New York city, Jane Addams and the many outstanding persons who served as residents and volunteer leaders (Joseph Moss and Sophonisba Breckinridge, to mention only two from Hull house, for example), social settlements helped win the enactment of laws providing for juvenile courts, mothers' pensions, workmen's compensation and the regulation of child labour; they promoted playgrounds and recreation centres. maternal, infant and child health clinics and services, adult education programs and took part in housing and other reforms.

Services. — The services of settlements and the names they adopt vary from country to country and within any given country. However. all are alike in that they are committed to bringing together people of all ages who live in the same geographical area for the purpose of following common interests and of improving neighbourhood life generally. The settlement's program of service and action is determined by the needs and interests of the people in a particular neighbourhood. It varies from one period of time to another in accordance with changing needs and conditions. One settlement serving two or more neighbourhoods, which differ in composition or condition, may offer different services to each. In general, services fall under three main categories: work with individuals and families; work with groups; and work with, or in behalf of, the neighbourhood as a whole.

Work with Individuals and Families. — Informal counseling and home visiting are done by almost every member of a settlement's staff. Where problems are such that specialized skill is needed, settlements have employed casenorkers. psychologists, psychiatrists, home economists and vocational counselors. In neighbourhoods lacking adequate health services, medical or dental clinics have been provided, while at the same time settlements have campaigned for the extension of public health services to meet neighbourhood needs. Nursery schools and day care for children have been provided for families needing them, because of employment of mothers. home conditions or other reasons.

Work with Groups. — There is a dual purpose in work with groups; *i.e.,* to enrich the social life and experience of the individual members and to provide opportunities for the group as a whole to contribute to an improved neighbourhood. Settlements serve two types of groups, namely membership groups sponsored by the agency and autonomous neighbourhood groups or organizations. Membership groups include friendship clubs, classes, athletic teams, interest or hobby groups.

Among their membership are people of all ages and of varied interests and abilities. To such groups the settlement provides a place to meet and a group leader, teacher or coach, whichever is appropriate. For younger groups it may also provide program materials and equipment. Older groups are encouraged to provide at least part of these essentials for themselves. Members join these groups for fun and satisfaction and often for personal and social development. The settlement's worker with the group seeks to develop feelings of neighbourliness, mutual respect and social responsibility. These groups use most of the space and staff-time of settlements.

Independent neighbourhood organizations and groups often seek and use certain services of the settlement. It may be only the use of a room for meetings. It may also be the counsel and guidance of a staff member for help on organizational or program problems. Settlements by request have helped to develop parent-teacher associations in neighbourhood schools. They have helped local churches to develop social and recreational programs for youth. They have provided guidance in the development of youth, recreational or welfare programs for labour unions, veterans', civic and fraternal organizations.

Work with the *Neighbourhood.*—Toynbee hall in Great Britain and some settlements in other countries have followed the tradition of having some professional staff members as well as university students and other volunteer workers live in the settlement's building in order that they might become in fact as well as in feeling a part of the neighbourhood. In all settlements, the staff workers, wherever they may live, are expected to become very familiar with neighbourhood people, conditions and problems. Moreover, they are expected to identify themselves with attempts to improve conditions and to solve problems. They work together with the people, with governmental officials and with citizens of the larger community to this end. Local individuals and groups are encouraged and helped to organize and to take appropriate action to secure enforcement of housing. safety and sanitation codes. Reliable information about proposed public improvements. such as highways, slum clearance and urban redevelopment. is made available to neighbourhood people and they are encouraged to express their concerns and their wishes to appropriate governmental agencies and officials.

Neighbourhood action may be directed toward legislation as well as to administrative decisions. Settlements seek to acquaint social welfare and other planning bodies with facts about living conditions and social needs in their neighbourhoods and as social agencies participate, through their representatives on community welfare councils or similar groups, in social planning for cities and metropolitan areas. This continuing concern of settlements has given the movement a reputation as an agent of social reform.

Administration. — The responsibility for operating each settlement is vested in a board of directors composed of citizens, some of whom live outside the neighbourhood but in the general metropolitan area, and some who live in the vicinity of the settlement. This board is the policy-making body and is responsible for securing and administering funds necessary to support the settlement program. It usually determines and carries out the program in partnership with the staff and with persons in the neighbourhood, whose opinions and help it seeks.

Workers with professional education in social work most frequently make up the administrative and supervisory staff. Workers trained in informal education: in nursing, in early childhood education, physical education and recreation also are employed extensively in settlements. In the United States most settlements secure financial support from community chests or united funds.

Some settlements, both in the United States and Great Britain, have substantial endowments, the interest from which furnishes considerable support. Funds are provided by governmental agencies to settlements in most countries. This is more common in European countries than in America. Local, national and international religious organizations support a considerable number of settlements. In countries other than those in North America, industrial corporations and private individuals often directly contribute to the support of settlements. Charitable trusts and foundations frequently support settlement programs, particularly new or demonstration projects.

The buildings used for settlement programs vary greatly. Some are large and well equipped. Many settlements have a modest central building but use rooms in buildings owned by housing authorities, public schools and churches for some of their activities. Some groups meet in private homes of members. Professional leadership, rather than meeting space, is seen as the primary contribution of the settlement. However, in a congested and deteriorating city neighbourhood, the settlement house often furnishes a hospitable and permanent common ground where diverse and transitory groups gain a feeling of security and of belonging which they cannot find elsewhere in such a neighbourhood.

The Settlement and the City.—Historically the social settlement was a method of solving certain problems inherent in urban living, particularly for the economically underprivileged. Crowded conditions, preoccupation with one's own urgent problems and the lack of concern of one's neighbours made difficult the maintenance of neighbourly feeling and responsibility characteristic of rural and village life. In the United States, before the adoption of the quota laws of 1921 and 1924, waves of immigrants successively crowding into transitional, depressed or slum areas faced additional problems of coping with strange customs and a strange language. The settlement attempted to restore under urban conditions some sense of belonging and of caring which seemed necessary in a humane society. The settlement movement was essentially an urban phenomenon.

The difficulty of finding financial support in smaller, less well organized (for purposes of social welfare) communities has tended to confine settlements to metropolitan areas nhere such support could be found. However, because of the concern of religious organizations particularly, some small agricultural and newer industrial communities have been helped to establish and maintain a community centre, similar to a settlement. Dispersion of industry outside of metropolitan areas has brought into being new towns which need this general-purpose type of community service. Communities of migratory agricultural labour, particularly where children are involved, have claimed the attention of religious organizations in the United States, with the result that a settlement type of nork has been established.

City, National and International Organizations.—In the larger cities of the United States and in some cities of Europe the settlements have formed voluntary city federations. In most instances, these federations have not employed any staff. but have provided opportunities for employed workers especially and for some board members, to discuss common problems. This discussion frequently has led to joint action on matters of legislation, publicity or specific service programs. The first such federation was formed in Chicago before the turn of the 20th century and the second in New Tork city shortly thereafter. In a fan smaller cities all of the settlements have combined to form one agency which operates several centres in different neighbourhoods of the city.

The founders of early settlements in the United States found it helpful to meet periodically to discuss common problems, especially conditions which seemed to require national co-operation and action of the federal government for their remedy. In 1911 they established the National Federation of Settlements, with Jane Addams as its first president. Robert Woods of Boston's South End house was the first executive secretary. on a volunteer basis. From 1929 on the federation employed a full-time executive secretary to facilitate the co-operation of the settlements on matters of national concern and to help improve standards of neighbourhood work throughout the country.

The British settlements established the British Association of Residential Settlements for the same purposes. Several European countries also have national organizations of settlements, most of them established after World War II.

The first international conference of settlement workers was held in London in 1922. This led to the organization in 1926 of the International Federation of Settlements. Except for a hiatus immediately before and during World War II, this federation has met every four years. After World War II its headquarters were at the French Association of Social Centres in Paris. In 1956 they were moved to the Dutch federation in Utrecht, Neth. The International federation is represented through observer status as a nongovernmental organization at the United Nations.

SOCIAL WELFARE has been defined by a United Nations, expert group as "organized activity that aims toward a mutual adjustment of individuals and their social environment." There are very few activities of modern democratic governments or private nonprofit organizations, however, that would not fit this definition in its broadest sense. More specifically and for the purposes of this article. social welfare is considered as including the attempts made by governments and voluntary organizations to help families and individuals by maintaining incomes at an acceptable level, by providing medical care and public health services, by furthering adequate housing and community development, by providing services to facilitate social adjustment and by furnishing facilities for recreation. In addition, social welfare includes legislation and facilities designed to protect those who might be subject to exploitation and to care for those special groups considered to be the responsibility of the community. Although educational services are usually considered as social welfare provisions, they are excluded from the discussion that follows.

All nations have developed social welfare services as they have moved from agrarian to industrial economies. In preindustrial societies the family group cares for its own young, its own aged, its own sick and disabled; what food and shelter is available is distributed among all members: whatever social maladjustment occurs is dealt with by the family. Such a system of mutual responsibility becomes impossible under modern industrial organization which demands mobility and the congregation of a large proportion of the population in crowded urban centres. It has become necessary, therefore, for society to provide substitutes in the form of social services, subsistence, medical care and protection. In all countries these have been provided both by private associations and by the authority of the state.

EARLY DEVELOPMENTS

The early history of social welfare in most western nations is the history of the poor law (*q.v.*) and of the private charities and foundations nhich supplemented it. Until the latter half of the 19th century, therefore, most social welfare services carried only negative implications. They were to assuage abject poverty and suffering; they were to prevent epidemics of deadly disease; they were to protect the population against begging and thieving; they were to appease the lower classes and so prevent revolution and maintain order. Earlier improvement in social welfare services was deterred by two enduring concepts: first, that government should avoid to the greatest extent possible any interference with the economy or social relationships; second, that all was well with the economic and social organization and that any poverty or social maladjustment could be attributed to inherent inadequacies or moral infirmities of the individuals concerned.

These two concepts were emphasized during the 18th century Enlightenment and became most effective as the middle classes obtained political power. The demand for limited government, a reaction to the excesses of monarchies and mercantilism, was, of course, at the heart of the struggle for modern constitutional government. Social welfare services, except those provided by private benevolence, could not be developed as long as the function of government was thought to be limited to the protection of private property and the conduct of foreign affairs. Less theoretical concern about the propriety of governmental responsibility for social welfare services was expressed during the latter part of the 19th century and early 20th century, particularly in the United States. There the public services were usually manned by political appointees with no civil service tradition or security of tenure. Graft and other political chicanery was to be expected.

The second concept had its origins in Judaeo-Christian philosophy and was articulated in secular terms during the 18th century. Recognizing first the supreme importance of the individual, the philosophers of the Enlightenment saw the greatest fulfillment of the individual and therefore the greatest welfare of society in the operation of the free market. Since each individual, according to natural immutable laws, was bound to operate rationally in his own self-interest, any interference with the freedom of an individual to choose, for example, a path which leads to poverty instead of wealth would be in violation of natural law and inimical to the general welfare.

These ideas. which found ready acceptance among the middle classes, were buttressed by the theories of such men as Joseph Townsend, English clergyman, geologist and author of *A Dissertation on the Poor Laws* (1786), who considered the spectre of poverty and suffering necessary to entice men to work at menial occupations; T. R. Malthus who considered any aid given to the poor as encouraging them to increase their numbers and so to diminish the subsistence available to the rest of the population; and David Ricardo who saw in the "wage fund" the impossibility of improving the condition of the labouring classes. Also delaying improvement in social welfare was Protestantism in general and Puritanism in particular with its emphasis on hard work and frugality and its equating of worldly success with divine election. The acme of this trend in ideas was achieved by the Social Darwinists during the last half of the 19th century. Herbert Spencer, for example. believed that men who advocated social welfare measures were "blind to the fact that under the natural order of things society is constantly excreting its unhealthy. imbecile, slow, vacillating. faithless members." Suffering by some must be endured so that the welfare of the many may eventually be achieved.

Poor Law Reform (1834).—The poor law reform of 1834 in England was the most specific expression in legislation of such ideas concerning the nature of poverty and the proper role of the state in its relief. All relief to the able-bodied in their own homes was forbidden and all who wished to receive aid must move into the workhouse. This law established officially the principle of "less eligibility" which was to plague the development of social welfare in the United States and England for the next hundred years Since poverty was due to individual fault, since any encouragement to laziness or thriftlessness was a threat not only to the proper operation of the economic system but the very survival of the nation, all efforts should aim at making the application for and receipt of poor relief as odious and degrading as possible. In the United States during the early 19th century no such national statement could have been expected because of the limited powers and responsibilities of the federal government at that time. The Yates report of 1824 in New York state and the Quincy report of 1821 in Massachusetts, however, both recommended that all the poor be cared for in public almshouses, the latter stating "that of all the modes of providing for the poor, the most wasteful, the most expensive, and most injurious to their morals and destructive to their industrious habits is that of supply in their own families."

Voluntary Welfare. — The ideas of the Enlightenment, which were so congenial to the middle classes during the 19th century, also had the effect of encouraging voluntary social welfare. While the discipline of *laissez faire* economics and devotion to natural law impelled the commercial classes to permit suffering and allow poverty to go unrelieved by government, the humanitarian aspects of the Enlightenment emphasized the importance of good works and the benefits of charity to the giver. Benjamin Franklin, for example, was an insistent opponent of all forms of public relief yet was a well-known philanthropist whose time and money had been given to the creation of a large number of welfare organizations This humanitarianism also caused men of influence to be repelled at the condition of the working classes resulting from the free operation of economic forces. The paradoxical quality of their attitude toward social welfare is illustrated by the fact that in England the first substantial factory act, providing for the appointment of factory inspectors and requiring that employed children between the ages of 9 and 13 attend school for two hours each weekday, was passed during the year prior to the restrictive poor law reform of 1834.

Lavish expenditures for private charity were possible during the early period of industrialization because of the accumulations of great wealth in the hands of a few individuals. Many of the endowed hospitals. schools, universities and charitable foundations had their origins in the era of unrestricted capitalism in England, the United States and throughout western Europe. The unrestrained giving typical of the 19th century. however, was disturbing to the conscience of the middle-class liberal as it too could pauperize the recipients, discourage thrift. sacrifice and hard work and so interfere with the free operation of natural economic law. Their answer was "scientific philanthropy" which aimed at separating the "deserving" from the "undeserving" poor and assisting the former to self-support. In England and the United States this rationalization of benevolence was carried on by the Charity Organization societies.

The humanitarian impulses of liberalism also gradually led to a less rigid attitude toward the supposed evils of public poor relief. While the leaders of private charity were concentrating on saving the "deserving" poor from the evils of the workhouse or almshouse, the public authorities were attempting to make a similar distinction. Special provisions were made first for the mentally ill, then for dependent children. Relief in their own homes was permitted the aged and infirm. By the early 20th century in England and later in other countries special provisions were instituted for the able-bodied who were unemployed for reasons considered to be beyond the scope of personal fault By categorizing the poor on the basis of the supposed causes of their destitution, it was possible to relieve suffering without moral damage to the recipients of relief and without interfering with the free operation of the economic system.

Social Insurance. — Even more acceptable to the middle classes than categorization of the poor was social insurance. Here was a term and a concept borrowed from the commercial world Social insurance would place the relief of poverty on a "businesslike" basis. It would encourage thrift and provision for the future and would in no way pauperize the recipients of its benefits. Social insurance in most countries, therefore, developed during the early 20th century and has gradually been expanded to include most common risks and to cover most of the population. Poor relief on the other hand has never recovered from the slander of the 19th-century liberals and remains in most places a "residual category."

Credit for the development of modern social welfare services should not be given to the humanitarianism of the middle classes exclusively. The rise to political influence of the urban proletariat was perhaps more important. It was not possible to convince the labourers that an economic system which brought hardship and suffering to so many of their numbers was what nature intended or was divinely sanctioned. They had experienced or witnessed poverty which could not be attributed to moral infirmities but was the result of economic conditions beyond their control. The evil of government intervention was much less serious to them than the evils of free competition bridled only by monopoly. This relationship between the rise of organized labour to a position of political significance can be seen most clearly in the case of England There the acceleration in the enactment of labour and social welfare legislation coincided with the entrance of the trade unionists into parliament beginning in 1874.

On the continent of Europe the influence of socialism was probably more effective than either the labour movement per se or the humanitarianism of the liberals. In the United States the influence of organized labour was not crucial to the furtherance of social welfare measures until the period of the 1930s. The earlier advances there can be attributed to agitation by middle-class reformers and intellectuals.

In a sense it can be said that modern social welfare programs are the result of both the middle classes and the urban proletariat being willing to abandon their apocalyptic hopes and to attain their ends within the framework of constitutional democracy. The middle classes were the first to move from their original position. As the progress of industry led to larger accumulations of capital, men with small or middle-sized financial resources found it harder and harder to survive in competition with wealthy rivals. In practice it became apparent that the free market was an obstacle to all but a few. Although free competition continued to be considered the basis of society, genuinely competitive conditions called for positive action by the state. for tariff protection and antimonopolistic and other forms of remedial legislation.

By the 20th century most socialists also realized that they would be able to achieve their aims only by reforming the existing system through established institutions and they too turned to positive state action. The working-class movement had been able to accomplish much improvement in working and living conditions by strikes and other nonpolitical means but the only way to consolidate these gains was through legislation. Organized labour had also been able to protect its members to some extent from the risks of sickness, injury, old age and unemployment by collective bargaining and mutual benefit societies. but in order to provide wide coverage and adequate benefits it was necessary to turn to compulsory insurance which could be enforced by the taxing power of the state and subsidized from general revenues.

In the United States the movement from the poor laws to modern social welfare provision followed much the same pattern as in England and on the continent but at a much slower pace. This was probably because the nation was almost exclusively dominated by the middle classes during the 19th and early 20th centuries. Not only were there no groups comparable to the nobility and peasantry of Europe but, in addition, a politically conscious and influential labour movement did not appear until relatively late. Early reforms, therefore, were essentially the product of middle class activity and were concerned more with the regulation and control of business and with attempts to improve legislative and administrative processes than with the provision of social welfare services. Only with the impact of the economic depression of the 1930s and the rise to political influence of the labour movement during that period did public social welfare arrangements begin to equal those of Europe.

The change in attitude toward the poor and other unfortunates and toward the responsibility of the community which occurred in western nations generally between the early 19th century and World War I cannot, of course, be attributed solely to the disillusionment of the middle classes or the extensions of suffrage which brought the influence of the working classes to bear directly upon public policy. Other forces subtly altered the outlook of the public toward the social ills which beset those nations which were being industrialized at a rapid rate. For example, there was the fear of revolution threatened by socialists. communists and anarchists. Concern for the poor and for the plight of the working classes was encouraged by the papal encyclical *Rerum novarum* (1891) and by the Christian socialists; in the United States the Social Gospel movement encouraged Protestants to seek a solution to the social problems of the day (see LEO: Leo *XIII;* CHRISTIAN SOCIALISM). Improved means of communication and the spread of literacy brought to increasing numbers of people the facts of poverty and suffering and the remedies proposed by militant reformers. Recurrent business depressions began to dispel the idea that all was well with the economic and social system and that poverty could in many cases be attributed to individual fault.

Whatever the causes, the results of this change in attitude can be illustrated by the extent to which social insurance measures had been adopted by western industrialized nations prior to 1914. Laws providing compensation for industrial accidents were in force throughout practically all of Europe, in many of the British dominions and colonies and in about half of the United States. There were compulsory sickness insurance programs in Germany, Austria, Hungary, Great Britain and Norway and voluntary insurance was subsidized by government funds in most of the remaining European countries. Compulsory old-age insurance was operating in France and Germany. The first compulsory unemployment insurance system had been instituted in Great Britain and subsidized voluntary unemployment insurance coverage was available in many large European cities and nationally in Norway and Denmark.

In most countries the progress of social insurance continued after World War I. By 1930 practically the entire industrialized world had workmen's compensation in some form or another. Practically all of Europe had some form of social health insurance. Of the 27 countries in Europe. 23 had either old-age insurance or old-age pensions or both. By 1935, 19 European countries had nationwide unemployment insurance on either a compulsory or voluntary basis. Also in 1935 the United States adopted the Social Security act which provided a nationwide program of contributory old-age insurance, unemployment insurance, grants to the states for public assistance to the aged, the blind and dependent children, and for various health and child welfare services.

Other Developments. — Social welfare developments during the early 20th century were not, of course. limited to those in social insurance and public assistance. A few examples concerning the welfare of children will illustrate the range and nature of other improvements. As children were removed from the workhouses and almshouses there was resort first to free foster homes and private and public specialized institutions. Later, emphasis was placed on the value of boarding homes supervised by professionally staffed social agencies. The first juvenile court was established in Chicago in 1899 and the idea spread rapidly throughout the world. Great Britain and Canada adopted juvenile court laws in 1908, France and Belgium in 1912, Hungary in 1913. Austria and Argentina in 1919 and Germany and Brazil in 1923. Except for the Scandinavian countries, which adhered to the theory that children should not be tried in courts at all and gave responsibility for delinquent children to child welfare councils, the juvenile court system was gradually adopted throughout most of the world. Treatment of delinquent children was greatly improved by the development of probation services, and all nations gained from the experiences of the Borstal institutions for young offenders established in England in 1908 (see BORSTAL SYSTEM). The importance of family life to child development was emphasized by the first mother's pension act passed by the state of Illinois in 1911. (See also CHILD WELFARE.)

Perhaps the greatest advances in social welfare during this period were in the area of health and medical care. Medical research developed means to immunize whole populations against major epidemic diseases. Improved medical care and knowledge both decreased infant mortality and increased longevity. Advances in public health removed important obstacles to further urbanization and industrialization. Improved facilities for sewerage, water purification and food preservation diminished the dangers to health inherent in city living. The assumption of responsibility by the state for town and country planning. for standards of housing and for the provision of recreational facilities all contributed to the health and welfare of industrial communities. (See also PUBLIC HEALTH.)

A final example of the change in attitude toward social and economic conditions and individual maladjustment is the growth of the new profession of social work. particularly in the United

States and Great Britain. From the "scientific philanthropy" of the Charity Organization societies of the 19th century the knowledge and methods of social work developed to a point where university degrees were awarded for their mastery. By 1930 professional social workers were being called upon in increasing numbers to staff the public social services and to provide the leadership necessary to ensure that services provided would be of the greatest possible assistance to individuals for whom they were designed. See also SOCIAL SERVICE.

DEVELOPMENTS SINCE THE 1930S

The world-wide economic depression of the 1930s and World War II added new dimensions to the concept of social welfare and furthered its acceptance by all classes in the major industrialized democratic nations. The trend emerging during the 19th century had been from palliative and punitive measures to the provision of services and financial benefits which wouid compensate for the failings of the economic and social systems. Emphasis during the postwar period has been upon the responsibility of the community through voluntary and governmental action to correct such deficiencies.

The Atlantic Charter of 1941 proclaimed the intention of democratic nations to abolish poverty and establish freedom from want. It was realized by all countries that another prolonged depression might lead to the destruction of democracy and submersion of the free enterprise system. In addition, the industrial output and progress during the war that made possible a condition of full employment of all resources served as a challenge to all nations to maintain full employment after' the cessation of hostilities. If full employment could be maintained then freedom from want was a goal which could be realized, and each nation could establish a "national minimum" standard of living. Increases in productivity accompanying full employment would permit each individual to have a basic income which would supply his essential needs no matter what vicissitudes of life he experienced.

The ideas of full employment and of a national minimum both received detailed exposition in the Beveridge report published by the government of Great Britain in 1942. This report gained world-wide attention and was the inspiration for many of the social welfare developments during the postwar years. Among other matters the report emphasized the importance of family or children's allowances as it had been determined that about a quarter of all want in Great Britain was due to failure to relate income during earning to the size of family. The influence which this report had upon western nations is illustrated by the rapid increase in the number of family allowance plans following the publication of the report. Ireland and Canada established universal family allowance plans in 1944, making payments to all children of certain ages regardless of the income of their parents. New Zealand made its plan universal in effect during 1946, and Norway and Sweden instituted such programs in 1946 and 1947 respectively.

The Beveridge report was able to assume that full employment could be maintained not only because of the wartime record but also because of the "new economics" developed by John Maynard Keynes and his disciples throughout the world. Their theories rejected the classical economist's fear of government interference and instead emphasized the positive role which government must play in maintaining full employment and expanding production. They believed that there are many ways in which an economy can be helped by government toward full employment but they all must be aimed at encouraging consumption and investment and discouraging excess saving. Because of the emphasis on consumption, social welfare expenditures have come to be considered as instruments of fiscal policy as well as means for the relief of destitution and the improvement of social conditions. Their effectiveness from a fiscal point of view depends upon the extent to which they serve to redistribute income and maintain or increase consumption during periods of threatened economic recession.

It would be impossible to summarize all the social welfare developments since the 1930s as their complexity in any one country defies analysis. Progress has been made by all nations and this progress has been due to a great extent to increases in productivity and thus in national income. In order to establish freedom from want a nation must be producing sufficient goods and services to provide a basic minimum for all its inhabitants. For underdeveloped nations, therefore, the greatest contribution to over-all social welfare has been an increase in investment to increase productivity.

Some appreciation of the range in the proportion of total income devoted to social welfare services following World War II can be obtained from data published by the International Labour office in 1958. This report attempts a comparison of the total expenditures by various nations for compulsory social insurance, certain voluntary social insurance schemes, family allowances, special schemes for public employees, public health services, public assistance and benefits granted to war victims. The percentage of national income which was being expended for these services ten years after the war was for the United Kingdom 10.7%, for Canada 9.1% and for Australia 8.1%. In western Europe the percentage for the Federal Republic of Germany was 21.4%, for France 18.5%, for Italy 16.1%, for Sweden 11.1% and for Denmark 11.1%. The percentage for the United States was 6.6%. To account for these differences it would be necessary to study in detail the social, economic and political situations in each of the nations involved. Decisions regarding the appropriate level of social welfare expenditure are essentially political and made within the context of constitutional democracy in these countries. Crucial factors affecting such decisions are the total income available, the nation's concept of its national minimum and the relative influence of competing interest groups.

Some idea of the progress that has been made by the more wealthy nations can be obtained by examining in some detail the history and status of social welfare provisions in Great Britain and in the United States as representing the two major trends of governmental responsibility. In Great Britain, the trend has been toward the guarantee of a national minimum social security, with children's allowances, comprehensive health insurance, etc., available to all. In the United States, on the other hand, the trend has been toward the provision of public assistance for specified categories—dependent children, the needy aged, the needy blind and the needy disabled.

GREAT BRITAIN

Social welfare in Great Britain during the 19th century was characterized on the one hand by the brutal and repressive philosophy of the poor law reform of 1834 and on the other by a new reform movement by which the principle of governmental intervention in the interest of the well-being of the people was firmly established. As in most other western nations this progress toward modern social welfare was accomplished first by members of the middle and upper classes who were disturbed by the suffering occasioned by the free operation of the economy. They were joined during the latter part of the century by organized labour and socialists.

The movement began with a campaign against child labour. In 1802 Sir Robert Peel secured passage of a bill restricting the employment of pauper apprentices to 12 hours a day between 6 A.M. and 9 P.M. In 1819 Peel was joined by Robert Omen in bringing about the passage of a law forbidding the employment of all children under 9 years and restricting the work of children under 16 years to 12 hours between 5 A.M. and 5 P.M. Although this act applied to all children, it had limited usefulness as it applied only to the cotton industry and no effective means of enforcement were specified. Britain's coal fields also were the scene of important struggles concerning the regulation of working conditions, especially of women and children, and the development of trade unions (see COAL AND COAL MINING: *Mining and Miners*). The Factory act of 1833 both restricted child labour and provided for inspection. This protection granted children was the first of a long succession of laws designed to safeguard labour by providing better living and working conditions, by promoting health and sanitation, by developing housing and by encouraging education.

By 1847, for example, the working day for women and all persons under 18 years was limited to ten hours. A year later the first true sanitary measure, the Public Health act of 1848, was passed.

Labour's first attempt to gain influence in politics occurred during the decade which ended in 1848 when there were demonstrations and rioting aimed at achieving a people's charter which involved, among other matters, manhood suffrage. With the collapse of Chartism the workers turned from politics to the improvement of their economic status. In addition to bargaining for higher wages and better working conditions, they developed consumers' co-operatives, stemming from the teachings of Robert Owen. The beginnings of social insurance also were apparent as trade unionism emphasized mutual benefits through insurance against sickness, unemployment and old age. The improved position of labour resulting from these activities won respect and in 1867 suffrage was granted to urban workers and in 1874 the first trade unionist entered parliament.

The defeat of Chartism also brought the socialists to influence; of these the most important groups from the point of view of social welfare were the Christian Socialists and the Fabians. Christian Socialism was started in 1848 by J. M. Ludlow, Frederick Denison Maurice and Charles Kingsley and emphasized co-operative associations among the workers and education for the working classes. It did much to foster a sympathetic relationship between the church and the socialists and labour leaders. The Fabian society (*q.v.*) was founded in 1883, and among the nucleus which determined its policies were George Bernard Shaw, Sidney Webb, Sydney Olivier and Graham Wallas. The Fabians were concerned with immediate and practical reforms which they helped accomplish by issuing scores of publications, and by having individual members enter politics and public administration. The interests of the society were far-ranging and included women's suffrage, an eight-hour day, a minimum wage, housing, public education and poor relief. *(See* also SOCIALISM and SOCIALISM: PRINCIPLES AND OUTLOOK, the latter by G. B. Shaw.)

During the last quarter of the 19th century two other groups had at least indirect effect on England's progress in the field of social welfare. The first was the Charity Organization society founded in 1869 in London by Edward Denison and Octavia Hill and guided for 39 years by its general secretary Sir Charles S. Loch. Although the society espoused the principles of the reform of 1834 and opposed all forms of public relief, it did recognize that there were some deserving poor to whom assistance might be given if the purpose of the aid was to preserve the family, strengthen character and prevent poverty by helping people to be self-supporting. In addition, in the process of social investigation to separate the deserving from the undeserving, much knowledge was gained concerning the living conditions of the poor and their habits. The formal and informal reports of the visitors did much to convince the well-to-do that all poverty was not due to individual irresponsibility and that general social reform was needed.

The second group were social investigators which included parliamentary committees, royal commissions and individuals such as Edwin Chadwick, whose report on sanitary conditions to 1842 set forth facts which showed how environmental conditions contributed to ill-health and mortality. The most influential investigator was Charles Booth who undertook in 1886 his study reported in *Life and Labour of the People in London.* His investigation was detailed and scientific. He studied people by trades and by the districts in which they lived; he surveyed the conditions under which they worked, the size and quality of their homes. Also examined were hours of labour, rates of pay and the extent of unemployment and irregular employment. It was a study of all the people and he found that one-third of the population was on or about the line of poverty or below it. These findings were confirmed for a small city by Benjamin Seebohm Rowntree's study of York in 1900 where it was discovered that 28% of the total population of that city was in poverty.

The struggle between uncompromising individualism and the concept of government as a social force continued throughout the 19th century and into the 20th when an attempt to resolve it was made by the Royal Commission on the Poor Laws and Relief of Distress appointed in 1905. The important protagonists were represented on one side by representatives of the Poor Law division and the Charity Organization society, who constituted a majority, and on the other by representatives of the Fabian society and Socialist-Labour interests. As might have been expected, although there was some fundamental agreement among the commissioners, no single set of conclusions and recommendations was acceptable to all and majority and minority reports, therefore, were issued. Although the commission's responsibility was to concentrate on the poor law, its deliberations and two reports had implications for all of social welfare.

The two reports were in agreement in their rejection of the spirit of the poor law reform of 1834. Indicative of this was their insistence that the title public assistance be substituted for that of poor law or poor relief and that the emphasis in administration should be changed from deterrence to help, prevention and social provision. Both also agreed that there should be a national system of employment exchanges, unemployment and invalidity insurance and regularization of employment. The crucial difference between the two reports was in their ideas as to the future role of poor relief. The majority report saw the existing functions of the poor law carried out by public assistance committees appointed by the county borough councils with treatment and preferred assistance being provided by voluntary aid committees in each community. The minority report, led by Beatrice Webb, wished to do away with the poor law entirely and assemble its activities under existing agencies. These old poor law functions would be assigned to divisions in the county councils responsible for education, health, pensions and mental disease, with relief to the able-bodied to be administered by a ministry of labour to be created. Although the recommendations of the commission were not enacted into law immediately as was the case in 1834, they did signify a new attitude toward poverty and social welfare and were soon followed by a rapid extension of social insurance and public assistance outside the poor law and finally by the abolition of the poor law itself.

20th-Century Reform.—The general election of Jan. 1906 also provided evidence of a new attitude and was a revelation of the new forces that had been released by the 19th-century enfranchisement of the workers. The Liberal party received an enormous majority and labour itself had substantial representation. The leadership in parliament saw government as a means of social change and proceeded rapidly to enact national social welfare measures. The first invasion of the poor law came with the Provision of Meals act of 1906 whereby the local education authorities were empowered to supply meals to children unable to take full advantage of education by reason of lack of food. This was followed during 1907 by the Education (Administrative Provisions) act which provided for medical inspection and attention to the health and physical condition of public school children. In 1908 came the Old Age Pensions act which provided a flat weekly benefit to all those over 70 years whose income was below a certain amount and who, until 1919, were considered to be "deserving." Also in 1908 the Coal Mines Regulation act established the principle of the eight-hour day. In 1909 the Labour Exchanges act created a system of labour exchanges designed to attack unemployment by increasing the mobility of labour, and the Trade Boards act made a beginning at setting minimum wages.

The culmination of this period of social legislation came with the National Insurance act of 1911 which provided for compulsory health and unemployment insurance for certain industrial workers. Leadership in sponsoring this program was provided by Lloyd George. The intention of the government to adopt the principle of compulsory insurance was announced by Winston Churchill, and the details of the schemes were worked out by Sir Hubert Smith in collaboration with Sir William H. Beveridge. Both the health and unemployment plans were to be financed by contributions from employers, employees and the state, setting a precedent to be followed by future social insurance programs in Great Britain. Participation in the insurance was limited to manual labourers and to persons in other occupations receiving less than a prescribed amount of wages. Health insurance was administered through approved nonprofit groups organized by friendly societies (*q.v.*) or labour unions or as adjuncts of commercial insurance companies. Unemployment insurance was administered through a national system of employment exchanges. In 1925 the principle of insurance was extended to cover the eventualities of old age and death by the Widows', Orphans' and Old Age Contributory Pensions act of that year.

The social legislation beginning in 1906 made it possible for many more persons to avoid applying for poor relief when their earnings were interrupted but did nothing to alter the structure of the poor law itself. In 1918, however, some of the harshness was reduced by the removal of the disenfranchisement provisions. In 1919 responsibility for national supervision was placed in the newly created ministry of health, and in 1929 the local boards of guardians were abolished and their functions turned over to the county councils. By 1930 the tenets of 1834 had been discarded to the extent that aid was regularly being given to the able-bodied unemployed in his own home. This change in philosophy of poor law administration can be attributed, in part at least, to the failure of unemployment insurance to meet the need occasioned by the widespread unemployment which followed World War I and continued into the 1930s. Those forced to apply for relief as a result of the decrease in the number of jobs available could hardly be held personally responsible for their plight.

By 1931 the unemployment insurance plan had ceased to have any actuarial basis and the fund had long been insolvent. This situation had been caused by successive extensions of the period of benefits and the payment of "uncovenanted" benefits which assumed that contributions would follow when employment was obtained. The National Economy act of that year put the scheme back on an actuarial basis by increasing contributions and decreasing benefits, and a system of transitional benefits from national funds mas instituted for those no longer eligible. Need for these payments was determined by county public assistance committees who also administered poor relief. Although it was required that these allowances be in cash and that no work test be imposed, there was great dissatisfaction with the plan because of the great variation in amounts paid from county to county from national funds. A centralized national administration of puhlic assistance to the unemployed was finally established by the Unemployment act of 1934 which created the Unemployment Assistance board. Allowances set on a national basis were administered by national civil servants whose decisions were subject to review by local appeal tribunals. War-related responsibilities as well as supplementation of pensions and insurance benefits were assumed by the agency, which in 1940 became the Assistance board.

By the beginning of World War II in 1039 Britain had a fairly comprehensive public social welfare system. There were public medical services, a national health and unemployment insurance system. widows' and orphans' pensions, old-age pensions. public assistance and provision for the control and subsidization of housing and the supervision of town planning. These were supplemented by an extensive network of voluntary services. Wartime experience, however. emphasized that there were serious gaps and weaknesses in the existing system. The problems of evacuation. for example, showed that there were considerable inequalities between some of the medical services provided in the towns and in the country.

The aspirations of the people of Britain for a better and more economically secure life after the war were given official expression in 1942 in the famous Beveridge report on Social *Insurance and Allied Services.* It recommended the extension of social insurance so that a true national minimum and "cradle to the grave" social security would be available to all no matter what exigencies might occur. This interdepartmental report signed by Sir William H. Beveridge insisted, however, that this plan would be successful only if there was a system of children's allowances, if there were comprehensive health and rehabilitation services for all and if mass unemployment could be avoided.

With the end of World War II. Britain's public social welfare services were reorganized and enlarged to form such a comprehensive system. A series of acts forms the framework within which this system is still developing. The Family Allowances act. 1945, the National Insurance act, 1946. and the National Insurance (Industrial Injuries) act. 1946, were all based on the Beveridge report. The National Health Service act. 1946, established the machinery for operating the new health services. while the New Towns act 1946, and the Town and Country Planning act, 1947. created the conditions necessary for rebuilding the nation in a rational and orderly way. The National Assistance act of 1948 removed the last traces of the old poor law by providing that anyone in need should be assisted out of central government funds, while the Children act of 1948 provided for a more nearly equal chance in life for the child deprived of normal parental care.

With the poor law specifically repealed in 1948. the only qualification for public assistance is need according to standards provided in regulations which are subject to parliamentary approval and are revised from time to time according to cost of living trends. The amount of grant payable is determined by comparing any resources already available to the applicant with the figure at which his needs are assessed according to regulations. The figures are subject to addition for rent according to the amount paid and may be altered when particular circumstances so require. The provision of welfare services under the act, as distinct from financial aid, is the responsibility of the local authorities.

Child welfare services are also the responsibility of the local authorities and their cost is shared by the localities and the exchequer. By the act of 1948 it is the duty of the local authorities to receive into their care any child under the age of 17 who appears to them to have no parent or guardian. or who has been abandoned or whose parents are unable to provide for him temporarily or permanently. They must also accept children committed to them by the juvenile court or under the Matrimonial Proceedings act in exceptional cases resulting from divorce. Children in care are. if possible. boarded out with foster parents or rnay be placed in a children's home managed by a local authority or a voluntary organization. The children's officer of each locality is assisted by a staff of social workers who undertake inquiries, give help and advise in planning for the care and upbringing of individual children and supervise them in foster homes.

The development of comprehensive public social services in Great Britain has not deprived the voluntary agencies of a useful role in social welfare. They complement the statutory services and can often undertake work which is outside the scope of national and local agencies. Much of their work is now aided with public funds and in many branches of social service they act as agents of the public authorities. The larger societies concerned with children are Dr. Barnardo's Homes, the Church of England Children's society and the Catholic Child Welfare council. all members of the National Council of Associated Children's Homes. Valuable community service is still rendered by the 50 or so social settlements found in the poorer districts of the cities. In all large towns and many small ones there are Citizens' Advice bureaus. The Family Welfare association, which was founded in 1869 as the Charity Organization society, receives in its area offices in London applications for help from over 4,000 families and individuals a year. There are about 180 other welfare agencies which help families in difficulty or distress, while marriage guidance is given in over 100 centres, and the Family Planning association maintains about 200 clinics. Welfare services for the sick continue to be provided by the British Red Cross society, the Order of St. John, St. Andrew's Ambulance association and many others.

The United States

The history of social welfare in the United States cannot be traced in as orderly a fashion as that of Great Britain. In the United States social welfare functions have traditionally been considered as being exclusively within the sphere of the state governments with financial and administrative responsibility devolving to counties. townships and municipalities and until the 1930s there were only isolated instances of federal concern. The status of social welfare at any particular time. therefore, must be described in general terms since each state developed its provisions at a pace which reflected its needs, the status of its industrialization and the attitudes of politically dominant groups toward social welfare and particularly toward poor relief. Any consistency results from the fact that as each state enacted social welfare programs it benefited from the experience of those which preceded it. In addition, it is difficult to assess the influence of interest groups and changing economic and social philosophies. At both the state and federal levels dissatisfactions tend to be met by changes in policy by one or both major political parties rather than be expressed in a separate political movement. The influence of organized labour on social welfare, for example, is difficult to appraise. Prior to the 1930s it was the avowed policy of the American Federation of Labor to concentrate on collective bargaining and not to sponsor remedial social legislation. With the formation of the Committee for Industrial Organization (later called Congress of Industrial Organizations) and a change in leadership of the A.F. of L. the labour movement began to assume a positive political role and exerted a powerful influence on public policy, but always within the framework of the two-party system.

The early colonists had brought with them from England the methods of the poor law of the 17th century with its emphasis on local responsibility and administration. Because of the necessity for individual initiative and hard work in developing and expanding a new country. harsh attitudes toward those unable to support themselves were common and the settlement laws designed to protect localities from being burdened by paupers from some other place were stringently enforced *(see* POOR LAW: *United States)*. As in England at the time. persons who were dependent because of physical and mental disabilities were treated no differently than those unemployed because of some other factor, By the beginning of the 19th century the general attitude to ard the poor and toward public relief became even more punitive as the ideas of the Enlightenment had their effect and as legislation in the United States reflected experiences in England leading to the reform of 1834. Increasingly the almshouse was considered the most suitable and economical method of caring for those in need. Many states made county or township almshouse care mandatory.

The reforming and humanitarian zeal typical of the middle classes of this period uas concentrated on the abolition of slavery and the struggle for free public education Some attention. however, was paid to the problems of poverty. Robert M Hartley founded the New York Association for Improving the Condition of the Poor in 1841. This organization aimed at saving the "deserving" poor from the almshouse and emphasized moral aid rather than material relief. In 1853 Charles Loring Brace founded the New York Children's Aid society which was a pioneer agency in removing children from the almshouses and orphanages and placing them in foster homes. During this period beginnings were also made for separate provision for special classes of dependents under state government auspices. A school for the "deaf and dumb" was established in Connecticut in 1816 and another in Kentucky in 1822, both of which received some federal aid In 1841 Dorothea Lynde Dix began her crusade for the improvement of the treatment of the insane. She carried her cause personally to every state east of the Rocky mountains and in almost every instance her memorial to the state legislature was folloued by the erection of a state hospital or the improvement of an existing one Her memorial to the congress of the United States finally resulted in a bill being passed which would have granted public lands to the states for the care of the insane. The bill was vetoed by President Pierce on the basis that it would establish the principle of federal responsibility for "all the poor in all the states." This veto was used as a precedent for denying aid to the states for social welfare until the 1930s.

The period between the American Civil War and the opening of the 20th century was one of rapid industrialization characterized by business practices which were ruthless and predatory Although evidence of social deterioration such as the growth of slums and the poverty of immigrant and native workers did not go entirely unnoticed. all could be explained by the theories of *laissez faire* and Social Darninism. Some attempts at improving conditions, however, were made by three groups. First there were the state boards of charity and corrections. By 1867, 16 states had established such boards following Massachusetts' example of 1863. Their responsibilities were initially limited to inspection and supervision but later included the direct administration of prisons, reformatories, mental hospitals and other state welfare institutions. The second group was the Charity Organization societies which were found in 92 cities by 1877. Their philosophy and methods were similar to those of the London Charity Organization society, with emphasis on the individualized treatment of deserving applicants for aid and opposition to all forms of public relief. Their "scientific philanthropy" developed over the years into modern social work and its principal method, casework. The third group were the social settlements. The first settlement house was established in New York city in 1887. Perhaps the most important from the point of view of social welfare reform was Hull House founded in Chicago by Jane Addams in 1889. since the group assembled there were outspoken in their belief that government has a responsibility for the well-being of all the people.

While Great Britain was embarking on its great period of social legislation beginning in 1906, the United States was in the midst of the Populist revolt and the Progressive party movement. which began in the 1890s and continued until the nation's entrance into World War I. Primary emphasis during this period was on reform of state and local government and the control of business, but progress in social welfare was also made. After overcoming constitutional difficulties in 1908. for example, reformers began the process of achieving state laws on industrial accidents. occupational diseases, factory inspection and safety measures, regulation of child labour and special provisions to protect women in industry. Attempts to achieve a national child labour law were twice defeated by adverse supreme court decisions; not unti! 1938 were they successful. In 1909 Pres. Theodore Roosevelt called the first White House Conference on Children, which emphasized the importance of the family and the home. One result of the conference was the establishment in 1912 of the U.S. children's bureau. Among the most important of the new social welfare programs enacted during this period of economic, political and social reform were workmen's compensation, mothers' aid and pensions for the blind. The first established the principle of social insurance in the United States and the others achieved the first breakup of the poor laws.

In 1908 a federal Compensation act covering civil employees of the federal government provided a stimulus to the states to enact workmen's compensation laws. The first law to be held constitutional by the state courts was passed in 1911 and by 1920 workmen's compensation laws were in effect in 43 states. Alaska and Hawaii. The White House conference had encouraged concern for the welfare of children left orphaned or abandoned or taken from poverty-stricken parents. and so laid the groundwork for the development of mothers' aid legislation. The first state-wide mothers' pension lam was enacted in Illinois in 1911 and, by 1913. 17 states had followed its example. The needs of the blind also gained early recognition. The first special pensions for them were provided by Ohio in 1898 and by Illinois in 1903.

Other important social welfare developments during this period included the expansion of public parks and playgrounds and the establishment of voluntary recreational agencies; the growth of state and local public health departments and the improvement of public health services; the strengthening of child welfare services and the spread of the juvenile court idea; and the rise of philanthropic foundations devoted to social welfare such as those of Carnegie, Rockefeller and Russell Sage. Finally there was the development of Community Chests and Councils of America to co-ordinate the financing and activities of the many social welfare agencies by then found in all population centres.

The social reform movement which haited at the time of the United States' entrance into World War I did not resume following the Armistice until the economic depression of the 1930s. During this period of relative complacency, however. some advances were made. In 1920 the federal government offered grants-in-aid for the vocational rehabilitation of disabled persons. The following year funds were provided the states to help support maternal and child health services. All but three states were receiving grants under this program when it was discontinued in 1927 Further breakup of the poor law occurred when Montana and Nevada passed old-age assistance laws in 1923. By the end of 1929. 11 states had such provisions.

1930s to World War 11.—The depression of the 1930s found the social welfare provisions of the United States wholly inadequate to cope with the needs of the millions of unemployed men and women. Except for the few categories already mentioned, poor relief was almost entirely locally administered and locally financed. The rapid increase in relief loads during 1930 and 1931 placed an impossible burden on local, and particularly municipal. finances. The first shift in responsibility was to the states. New York was the first to establish a temporary relief administration and was followed by seven states prior to May 1932. In that month congress passed the Federal Emergency Relief and Construction act, marking the beginning of federal responsibility, which ofiered emergency loans to the states to help meet the costs of relief. Only six states did not take advantage of the offer.

Franklin D. Roosevelt's inauguration as president in March 1933 marked the beginning of a new era. On the basis of the country-wide support he received in 1932 and 1936 he was able to insist upon the enactment of a wide assortment of social welfare legislation. Important in this regard was the backing he received from the now politically articulate labour movement.

The first measure enacted to relieve the plight of the unemployed established the Civilian Conservation corps (March 1933 to July 1942). This program provided workcamp employment to over 3,000,000 young, unmarried men during the ten-year period. In May 1933 the Federal Emergency Relief administration was established and given authority to make grants to the states for both work relief and direct relief. The administration mas created for two years and all powers were to be exercised by the administrator. Harry L. Hopkins. This program lasted until the autumn of 1935 and expended a total of $3,000,000,000. The FERA exerted a lasting influence on the administration of public assistance, particularly through its requirement that public funds must be administered by public agencies and its encouragement of relief payments in cash rather than in kind. Between November 1933 and March 1934 the FERA was temporarily discontinued and replaced by the Federal Civil Works administration, which was a gigantic federal works agency offering to pay wages to 4,000.000 unemployed if state and local governments would put them to work. Other social welfare programs enacted by congress prior to 1935 were the Public Works administration (1933–42) which aimed at stimulating the economy with large-scale construction projects, the U.S. employment service (1933) and the Federal Surplus Commodities corporation (1933—later called Surplus Marketing administration), which purchased farm surpluses and distributed them to public assistance agencies.

When the FERX was discontinued it was replaced by the Works Progress administration (1935–42) which was designed to give work to all needy persons who could work and to return responsibility for the "unemployables" to the states. The National Youth administration (1935–42), which was first a part of the WPA and later an independent agency, provided part-time employment for needy school and university students and others, helped establish job training and counseling programs and encouraged the development of constructive leisure time activities for youth.

In June 1934. President Roosevelt set up a special cabinet committee on economic security. to make recommendations concerning a comprehensive program relating to old-age security and uncmployinent, sickness and health insurance. A report of the committee was transmitted to congress on Jan. 17, 1935. The resulting Social Security act which became law on Aug. 14, 1935, marked a new stage in the acceptance by the federal government of responsibility for the welfare of all citizens. It established a national contributory old-age retirement annuity system for workers in industry and commerce and laid the basis for a nationwide system of insurance to protect persons against the risks of short-term unemployment. In addition it provided for federal grants-in-aid to the states for old-age assistance, aid to the blind and aid to dependent children and for maternal and child health services. child welfare services services for crippled children and vocational rehabilitation.

Since 1935 most impoitant social welfare developments have been extensions or improvements of the Social Security act. Three later federal acts, however, must be mentioned. The Fair Labor Standards act of 1933 prescribes national standards for wages, hours. working conditions and child labour applicable to firms producing goods destined for interstate commerce. In 1946 congress passed the Employment act. which declares that it is the continuing policy and responsibility of the iederal government to promote maximum employment. production and purchasing power. The National Mental Health act (1946) is designed to provide a method for financing research and training programs and to assist the states in establishing community mental health centres.

Social Insurance.— By 1060 the limited old-age benefits of the Social Security act of 1935 had become the Old Age, Survivors and Disability Insurance program. In 1939 benefits were extended to certain dependents and survivors of eligible persons. in 19.56 to disabled individuals 50 years of age and over and in 1960 to all eligible disabled persons and their dependents. Coverage of the program had been successively extended until nine out of ten workers were included. Since 19.50 congress has regularly revised the benefit schedule to reflect changes in the cost of living.

Unemployment insurance, adopted by all states shortly after the passage of the Social Security act, underwent little change during the ensuing years and in some aspects regressed. Coverage remained as limited as in 1935 except: that in 1954 it was extended from employers of eight or more persons to employers of four or more. No standards as to amount and duration of benefits had been imposed by the federal governrnent and benefits stated as a percentage of average wages had generally decreased since the prograni was introduced.

Workmen's compensation had remained since its beginnings in the early 1900s a state-controlled program providing benefits and medical care to persons injured, and benefits to survivors of those deceased, in the course of employment. Because of the complete lack of centralized supervision and standard setting. there was a confusing array of coverage provisions, benefit levels and administrative arrangements.

Public Assistance.— Despite the extension of social insurance, about 4 persons out of every 100 in the population were dependent upon some form of public assistance during 1960. They were in need and either ineligible for benefits provided by other public programs or, if eligible, received insufficient amounts. This assistance was provided by the states and localities with the help of the federal government under the three categories of the Social Security act of 1935 and a fourth category, aid to the permanently and totally disabled, established in 1950. Those in need but not eligible for any of the federally aided programs depended upon general assistance or poor relief, which in most states was still locally administered and financed.

All 50 states had programs of old-age assistance which provided aid to persons over age 65 who were in need, aid to dependent children which assisted needy families with children who had lost support or care because of a parent's death, incapacity or absence from the home, and aid to the blind. All but seven states had legislation providing aid to the permanently and totally disabled. Financial participation by the federal government in the case of each one of these programs was computed as a percentage of the average grant paid by each state up to a specified maximum. Since 1958 this percentage has varied to some extent in accordance with differences in per capita income among the states.

Federally aided public assistance is superior to poor relief primarily because of the requirements state programs must fulfill in order to be eligible for grants-in-aid. ' These requirements are aimed at protecting the needy individual's right to public assistance if he is eligible according to standards set by the state. For example. assistance must be available in all subdivisions of the state. all persons must have an opportunity to apply for assistance and have their applications acted upon within a reasonable time, and an opportunity for a fair hearing before the state agency must be provided anyone whose claim is not acted upon within a reasonable time. The federal government also requires that assistance be given in the form of money or medical care. This provision has been interpreted as preventing any restriction on the recipient's use of the money payment. He may spend it as do others in the community and continue to live in his own home without interruption of family life. This aspect has been particularly emphasized since 1956 when congress declared that a major purpose of public assistance administration was to promote the well-being of the nation by encouraging the states to place greater emphasis on helping to strengthen family life and helping needy families and individuals attain the maximum economic and personal independence of which they are capable.

The federal government in its requirements sets no standards as to what constitutes a national minimum for health and decency. Each state. 'therefore. is responsible for determining who are needy people and how much they will receive under a given program. States differ both in their definition of need and the degree to which they decide to meet need as determined. One state may provide for some medical needs in its old-age assistance program. but not for its aid to dependent children program, while another state may make no provision whatsoever for medical care. In 1960 average payments per recipient for old-age assistance, for example, ranged from a low of less than $30 per month in Mississippi to more than $100 per month in Connecticut. States not only differ in the amounts of assistance they are able or willing to pay, but also in their definitions of what resources an applicant may retain and still be eligible. Policies vary greatly, therefore, with respect to the responsibility of relatives, the value of life insurance, cash reserves and the ownership of real property.

The federal government also permits the states to require a certain period of residence in the state before an individual can be eligible for aid. Such provisions, reminiscent of the settlement provisions of the old poor law, occurred in the legislation in alinost all of the states. For old-age assistance, however, less than half the states required as long a period as the Social Security act permits; *i.e.*, five of the last nine years. The common residence requirement for aid to dependent children was one year.

Those needy individuals and families who cannot qualify for one of the federally aided categories of public assistance must resort to general assistance. which is administered in most states on a local basis in much the same manner as the poor law of the 19th century. Such aid is usually given in cash but frequently in the form of orders for groceries, rent and other items. In most states it is provided only to unemployable persons. and nonresidents are aided only in emergencies with arrangements being made for their return to their state of residence as quickly as possible.

Medical Care. — The greatest gap in social welfare is in the area of medical care., While in Great Britain health services are freely available to all, not even state-supported health insurance is available in the United States. The movement for compulsory health insurance began during the depression period of the 1930s. and was almost successful during the years immediately following World War II. As of 1960. however, the only government supported care available to all persons was that provided to needy individuals and families eligible for public assistance. and onlv ten states provided relatively comprehensive medical care under such auspices. More liberal eligibility requirements for medical assistance to the aged were made possible under the Social Security act amendments of 1960 if the states wish to adopt such plans. Most protection against the costs of illness is provided by voluntary health and hospital insurance plans contracted for by individuals or by employers for their workers. According to the Health Foundation study in 1953, 60% of the families having hospital expenses had 80% or more of their expenses met through insurance. (See HEALTH INSURANCE.)

Social Welfare and Collective Bargaining. — One of the important reasons for the relatively slow development of public social welfare services, especially those dealing with medical care, has been the fact that organized labour has apparently been able to obtain many health and welfare benefits more easily through collective bargaining than through legislation. In 1958 the total cost of these "fringe benefits" was about 6% of all wages and salaries; 70% of all wage and salary workers were covered by life insurance, about 65% were covered for costs of hospital care and surgery, 46% for regular medical care and 11% for major medical expense. In addition, over 50% of all private industry employees were eligible for temporary disability payments, 40% for supplements to retirement benefits available under the Social Security act and 4% for supplements to unemployment insurance.

Voluntary Programs. — Private social welfare agencies continue to fulfill an important function despite the expansion of governmental programs. Their services are so numerous and so varied as to make summarization impossible. In a typical urban community will be found both sectarian and nonsectarian family service agencies, child welfare agencies, mental health clinics, home nursing services, medical out-patient clinics and a variety of recreation and group work agencies. Certain national agencies such as the American Red Cross and the National Traveler's Aid association also have branches in many localities. The financial support for these agencies is for the most part obtained by private donations although public subsidy of private child welfare agencies and mental health clinics is common. Fund raising for local agencies and local branches of some national agencies is usually accomplished through a federated appeal. In most communities the co-ordination of services is the responsibility of a council of social agencies or health and welfare council to which most public and private agencies belong.

INTERNATIONAL SOCIAL WELFARE

International social welfare programs have increased and expanded with the growing realization that the development of human resources is the real key to a better way of life for the peoples of all countries and that relieving poverty. ill-health and misery is an important part of the task of maintaining peace. The focus of such activity is in the United Nations where the Department of Economic and Social Affairs of the UN secretariat administers a world-wide program of research. technical assistance, community development and information. The principal organ of the United Nations in the social field is the Economic and Social council. Policy recommendations for this group are developed by the UN Social commission and carried out by the Bureau of Social Affairs and Advisory Welfare Services.

Other social welfare activities are carried on by specialized agencies which have been established by intergovernmental agreement and are co-ordinated by the UN Economic and Social council. The World Health organization (WHO) helps combat disease and epidemics throughout the world. The United Nations Educational. Scientific and Cultural organization (UNESCO) assists governments to eradicate illiteracy. The Food and Agriculture organization of the United Nations (FAO) seeks. among other things. to overcome chronic food shortages. The U S high commissioner for Refugees supervises the application of the international convention relating to the status of refugees. The oldest of the specialized agencies is the International Labour organization (ILO) which gives special attention to problems of income security and labour legislation. See also SOCIAL SECURITY; SOCIAL SERVICE: WORKMEN'S COMPENSATION.

SOCIETY OF JESUS: *see* Jesus, Society of.

SOCINUS, the latinized form of the Italian Sozini, Sozzini or Soccini, a name borne by two Italian evangelical rationalists of the 16th century, whose influence survived in Socinianism and subsequently in Unitarianism (*q.v.*).

1. Laelius Socinus (Lelio Francesco Maria Sozini) (1525–1562) was born at Siena on Jan. 29, 1525, and was educated as a jurist at Padua. He later told Philipp Llelanchthon that his desire to reach the *fontes juris* led him to biblical research. At Chiavenna in 1547 Laelius came under the influence of Camillo Renato. He traveled extensively as a student, questioning the reformers, and in 1547 matriculated at Basel. He was successively at Geneva. Basel, Zurich, Wittenberg, Prague, Vienna and Cracow (1549–51). Political events drew him back to Italy in June 1552. He was at Padua at the time of Michael Servetus' execution (Oct. 27. 1553), and then was in Basel (Jan. 1554), Geneva (April) and Zurich (May), which became thereafter his principal residence.

Of the reformers, Heinrich Bullinger was Laelius' closest and wisest friend. Laelius' theological difficulties turned on the resurrection of the body, predestination, the ground of salvation (on these points he corresponded with Calvin). the doctrinal basis of the original gospel, the nature of repentance and the sacraments. The fate of Servetus directed his mind to the problem of the Trinity. At Geneva (April 1554) he made incautious remarks concerning the doctrine; and Bullinger questioned him as to his faith, receiving from him an explicitly orthodox confession with, however, a frank reservation of the right of further inquiry.

In 1556. after the death of his father, who had disinherited him, Laelius was involved in pecuniary anxieties. He visited in 1558 the courts of Vienna and Cracow to obtain support for an appeal to the reigning duke at Florence for the recovery of his patrimony; but. fearing the Inquisition. he did not go beyond Venice. In Aug. 1559 Laelius returned to Zürich. where he died on May 14. 1562.

In addition to letters and his confession of faith. two more radical writings recently have been ascribed to him. His library and unpublished writings greatly influenced his nephew and heir.

2. Faustus Socinus (Fausto Paolo Sozzini) (1539–1604) was born in Siena on Dec. 5, 1539. the only son of Alessandro Sozzini, brother of Laelius. Orphaned young, Faustus had no regular education, being brought up at home with his sister and spending his youth in desultory reading. When his uncle Laelius was pursued by the Inquisition. Faustus considered it advisable to leave Italy for Lyons (1559–63). where he engaged in business. In 1562 he identified himself with the Italian congregation in Geneva, and at the death of Laelius went to Zurich in May 1562 to gather up his uncle's papers and settle his affairs. About this time Faustus composed his *Explicatio* of the Prologue of St. John (related to an earlier work of his uncle's), in which he wrote of Christ as divine by office rather than by nature. In a letter from Lyons, dated 1563. to an Italian, he announced a second principle of his theology, the natural mortality of the soul.

Toward the end of 1563 he returned to Italy, outwardly conforming to the Catholic Church. and for 12 years was in Florence in the service of Isabella de' Medici, daughter of the grand duke of Tuscany. He apparently studied law at this time. At the instance of "a great personage" he wrote (1570) his treatise *De auctoritate s. scripturae*. In 1571 he was in Rome. probably with his watroness. He left Italy suddenly at the end of 1574 and settled at Basel. There he began translating the Psalms into Italian verse. and. in dispute with Francesco Pucci, composed *De statu primi hominis ante lapsum,* arguing again for the natural mortality of man even before the Fall. His discussion with Jacques Couet, Protestant minister in Paris. on the doctrine of the atonement was issued in a treatise, *De Jesu Christo servatore,* finished July 12, 1578. and published in Poland in 1594. In it, as earlier in the *Explicatio,* he stressed Christ's humanity and passibility. The Word or will of God appeared in the form of flesh, a man. Christ's resurrection, rather than his death. is the action that enables his devout followers likewise to look forward to resurrection in spiritual bodies. After the resurrection, Christ ascended to take his place at the right hand of God, henceforth sharing in God's power. Thus Christ, though in nature purely human, as the adoptive Son is worthy of adoration, for to him God Almighty bestowed after the ascension the government of the world.

The Basel manuscript of *De Jesu Christo servatore* was read by Giorgio Blandrata (*q.v.*), court physician in Transylvania (*q.v.*). It was Blandrata's object to limit the judaizing innovations of the eloquent Unitarian bishop Francis Dávid (1510–79), which might jeopardize the religious settlement reached earlier under King John Sigismund. Socinus' full justification of the adoration and invocation of Christ within a forthright unitarian theology commended his treatise to Blandrata, who thereupon called Socinus to Kolozsvár to reason with Dávid. During a visit of four and a half months (1578–79) Socinus tried in vain to persuade Dávid to adopt his doctrine. Dávid instead from his pulpit exerted all his powers in denouncing the cultus of Christ, and his civil trial followed. Faustus cannot be accused of complicity with what he himself called the rage of Blandrata, but his references show that theological aversions froze up his native kindness.

The remainder of Socinus' life was spent in Poland. The main positions in his theological system had been worked out before he became involved in the struggles of the Unitarians of Transylvania and the Polish Brethren. He considered the Bible as a revelation of the way to eternal life through following the teachings and example of the man Jesus Christ. who, like all men. was mortal but who, by obedience unto death, had been vindicated by God in the resurrection and ascension. Socinus held that all who accepted the good news of biblical obedience and persevered in evangelical belief and behaviour to the end would be resurrected at Christ's second advent. Those who failed to live evangelically would remain in the dust. Socinus recognized two ordinances, the Lord's Supper and baptism, the latter reserved for converts from outside the Christian community, such as Jews and Muslims.

Excluded at first by his views on baptism from the antitrinitarian, anabaptist Minor Church centred in Raków, Socinus acquired by degrees a predominant influence in its synods. He converted the Arians of Little Poland from their avowal of Christ's preexistence. and most of the Lithuanian Unitarians under Simon Budny from their rejection of the invocation of Christ. Through correspondence with friends he continued to influence the policy in Transylvania. Against Budny and Jacob Palaeologus, and in line with the anabaptist Racovians, he insisted on the unlawfulness not only of war but also of the taking of human life in any circumstances, hence, his contention that magisterial office is unlawful for a christian.

A pacifist, he left Cracow to reside (1583–85) with a Polish noble, Christopher Morsztyn, whose daughter Elizabeth he married (1586). In Oct. 1590 the inquisition at Siena deprived him of his inheritance. He began, therefore, to publish in his own name, with the result that in 1598 a mob finally expelled him from Cracow. At the end of his life he was working on *Christianae religionis brevissima institutio,* which became the basis for the Racovian Catechism, a statement of Socinian principles published at Rakow in 1605. He died at Luslawice on March 4, 1604.

Wilbur, *A History of Unitarianism: Socinianism and Its Antecedents* (1945); L. Cristiani, in *Dictionnaire de théologie catholique,* xiv:2, coll. 2326–34 (1941); G. Piolo, *Fausto Socino: Vita-Opere-Fortuna* (1952). Two works ascribed with reasonable certainty to Laelius were published by D. Cantimori and E. Feist. *Per la storia degli Eretici Italiani del secolo XVI in Europa,* pp. 56–78 (1937). The works of Faustus are printed in the first two volumes of the *Bibliotheca Fratrum Polonorunt* (1656). The letters of Faustus have been calendared and fully annotated in Polish translation by Ludwik Chmaj, *Listy,* 2 vol. (1959). (A. Go.; G. H. Ws.)

SOCIOLOGY. Sociology is one of the several specialized social sciences. Its primary objective is to gain a knowledge of man and society insofar as it may be achieved through investigation of the elements, processes, antecedents and consequences of group living.

Sociology is differentiated from the other social sciences primarily by the basic fact with which it starts. the fundamental assumption which underlies its activities. and the problems with which it is concerned. The basic fact is the relative helplessness of the human infant at birth who is always born into, and depends for his survival upon, a social group. The fundamental assumption is that the conduct of the person—his ways of thinking and ways of acting—and the nature of the social orders—its structure. function and values—are to be understood as a product of group life. The problems with which sociology is concerned may be stated as a long list of specific items but, more appropriately, may be generalized into broad groupings oi subject matter such as those represented by social organization, social psychology, social change, social disorganization, human ecology and population. Each of these broad fields of sociology may be further divided into subfields, and all are concerned with problems of theory and method.

As a science, sociology. contrary to popular misconception justified in part by its early history, does not have as its objectives the determination or modification of social values, the proposal of reforms. the design or administration of welfare programs or the direct promotion of a better social order. These are important objectives to be sure. but they are the tasks of the social engineer such as the statesman, the administrator, the legislator, the educator, the social worker, the clergyman. the labour leader, the agitator and the propagandist. rather than that of the sociologist as such. As a scientist the sociologist is concerned only with the pursuit and funding of knowledge about man and society. In such knowledge which ideally comprises generalizations drawn from empirical and verified investigation. the sociologist strives to understand and to achieve prediction of human conduct and social phenomena. To the sociologist, values are among the data which he studies and not the end product of his labours.

HISTORY OF SOCIOLOGY

The word sociology was first used by August Comte (1798–1857) in 1837 in a series of lectures on which his famous work Positive Philosophy (6 vol., 1830–42) was based. His coining of this term, a hybrid of Latin and Greek still disliked by many users of the king's English! has led him to be regarded by a number of writers as the founder of sociology. Yet, his conception of sociology as an all inclusive general social science—a synthesis of all knowledge about "humanity" which he used in the sense of the universal society—and his promotion of "positivism" as the foundation for the mystical religion of humanity which he proclaimed in his later life, are widely divergent from contemporary conceptions and practices of sociology. Comte did make a great contribution to the social sciences in general in producing a synthesis of the social thought of the century which preceded him, beginning with the work of David Hume, in laying great stress on the application of the positive method to social phenomena—a method of observation, experimentation and comparison—and in his evaluation of the importance of studying laws of succession and association of phenomena rather than cause. It is more accurate to say that Comte in his classification of the sciences and his description of their development made a place for and heralded the approach of sociology, rather than that he founded it.

The history of sociology. in a loose sense, began centuries before Comte. but, like all history, has no clear-cut beginning. Historians of sociology, at least those who have published histories of sociology or of social thought. have variously begun their accounts with ancient civilizations (*e.g.,* Pitirim Sorokin, Joyce O. Hertzler or Emory S. Bogardus). with the Greeks (*e.g.,* Floyd N. House, Harry E. Barnes or James P. Lichtenberger) or with 19th-century thought (*e.g.,* P. Barth. Albion W. Small).

If the genesis of sociology is traced to folk, philosophical. political and legal thought about man and society, then sociology had its beginnings in the earliest records of human thought in the ancient civilizations of Egypt, Babylonia, Assyria, Persia, India and China. If sociology is rigidly defined as a specialized empirical social science, then it may be said that it certainly did not begin before the 20th century. It is much less important, however, to fix a precise date for the beginning of sociology as a science than it is to have an understanding of what it aims to do, of the problems with which it is concerned and of some of the main currents of thought which led to its emergence.

Social Thought Prior to the 19th Century.—The history of sociology, in the loose sense referred to above, is essentially the history of social thought through the ages—a heritage which sociology shares with all the sciences, natural and social. Although various aspects of social thought, from the earliest human records which can be traced back 5,000 to 6,000 years to the dawn of the 19th century, have special implications for the development of sociology, only the briefest mention can be made of them. Ancient literature and relics contain keen insights into interpersonal relations. group life, social control, social organization, social stratification, human nature, and social institutions, including the family, the state and property. But early social thought was essentially of a pre-scientific character, for it was largely of a common-sense nature, sporadic, traditional and unverified, and suffused with the interventionism of the supernatural.

Systematic social thought, at least in a form which has been reasonably well preserved, originated with the Greek philosophers. Beginning with about 600 B.C. a remarkable series of Greek thinkers became preoccupied first with the ,world of nature and then with the world of man. The Greek philosophers. and especially Plato and Xristotle, provided penetrating analyses of the relation of man to society, of social institutions and of social processes; contributed to important methodological developments; and originated basic elements of social theory which have remained in the focus of intellectual discussion ever since.

Despite the setting of the stage for the development of science by the Greeks. natural science did not develop until 2.000 years after Thales (c. 640–*c.* j46 B.c.) and social science until more than 2,000 years after Xristotle (384–322 B.c.).

By the 15th and 16th centuries: however. the combined influences of a number of events produced the revival of learning manifested in humanism and naturalism. and the way was clear for the resumption of critical social thought. By the end of the 17th century, natural science had forged a relatively secure place for itself, and thought about the social as well as the natural world had become largely secularized.

Nineteenth-Century Influences.—By 1800, many interrelated intellectual pathways led to the consideration of various aspects of man and society and a number of them contributed to the emergence of the science of sociology. The way had been paved for the application of scientific method to social phenomena by such men as G. B. Vico (1668–1744) and C. Montesquieu (1689–175j); quantitative methods had been applied to population phenomena by the "political arithmeticians" such as William Petty (1623–87) and John Graunt (1620–74); and important insights into central sociological problems had appeared in the writings of the "Scottish moralists," Francis Hutcheson (1694–1746) and Adam Ferguson (1723–1816).

Major influences on the development of sociology in the 19th century were exerted by scholars who dealt with substantive and methodological problems n·hich, at least implicitly, helped delineate a field and methods for the social sciences, in general, as well as for sociology in particular. These writers may be classified into groups, not mutually exclusive, organized around leading ideas. The ideas may be broadly grouped into three categories: first, those focusing on problems which set the stage for, or themselves became, central problems in sociology; second. those emanating from biology, which exerted an important influence on early sociology; and third, those concerned with methodology and techniques of research. In addition to these ideas, the emergence of sociology was also influenced by ideas and programs of social reform, which on the one hand stimulated interest in sociology and on the other confused its role as a science.

Ideas Related to Central Problems.—The writers contributing to this category of ideas may be classified into a number of groupings, also not mutually exclusive. These included the scholars who dealt with the nature of the historical process, the distinction between the state and society, the nature of culture, folk psychology, the analysis of self-consciousness, the influence of the physical environment, the role of "social forces" and "interests," the economic activity of man and the population problem.

The writers who inquired into the nature of the historical process sought to relate successive events and to generalize from the experience of history. They devoted considerable attention to the question of whether history could or should generalize as against reporting unique events. Important participants in this development included Immanuel Kant. J. G. Fichte. G. W. F. Hegel, Karl Marx, Wilhelm Dilthey and Wilhelm Windelband.

In early social thought the "social" was largely synonymous with the "political." Preoccupation with the state precluded attention to other aspects of society. The scholars who differentiated between the state and society helped to point up the need for the study of the nonpolitical aspects of the social order. Thus they made explicit in their affirmation or opposition the need and place for a new science. They included such men as Robert von Mohl (1799–1875), H. von Treitschke (1834–96) and Ludwig Stein (1859–1930).

Also made explicit during the 19th century was the idea of culture as a thing in itself. It was emphasized that culture, both in its material and nonmaterial aspects, could be studied historically and comparatively to illuminate the nature of man and society. Early culture historians and anthropologists included Friedrich Ratzel (1844–1904), Adolf Bastian (1826–~yoj), Alexander von Humboldt (1769–1859) and Lewis H. Morgan (1818–81). These men, and others, collected a mass of data on the cultures of diverse people, and their efforts to compare. analyze and explain similarities and differences helped stimulate the sciences of anthropology and sociology.

Another group of writers were expressly concerned with "folk psychology" and with the relation of folk psychology to the individual mind. Their analysis of folk psychology and the "collective mind" led them to explanations of human nature and of individual traits as arising from culture. These writers defined one of the central problems of sociology in its contemporary sense in highlighting the dependence of a person on the social group and describing personality as a subjective aspect of culture. They included such men as Johann F. Herbart (1776–1841), the Grimm brothers Jacob (1785–1863) and Wilhelm (1786–1859), Moritz Lazarus (1824–1903), H. Steinthal (1823–99) and Wilhelm Wundt (1832–1920).

Closely related to the study of folk psychology and the nature of the mind was the analysis of the growth of self-consciousness. The description of self-consciousness as a phenomenon dependent upon society and arising in social interaction continued to play a central role in mid-20th century social psychology. Contributors to this analysis included Von Humboldt, Georg Simmel (1858–1918) and James M. Baldwin (1861–1934).

Although ancient and early modern scholars were concerned with the influence of environment, various streams of thought during the 19th century led to more intensive investigation into the influence of geographic factors on social organization and human behaviour. Geographers and anthropo-geographers who investigated this problem varied in their conclusions from strict environmental determinism to more modern indications of the limiting influences of physical environment. These writers helped pave the way for the science of sociology in general, and more specifically for contemporary sociological interest in human ecology and regional studies. They included such men as Karl Ritter (1779–1859), H. T. Buckle (1821–62), P. G. F. LePlay (1806–82) and Vidal de la Blache (1845–1918).

Another central problem in early sociology originated in the writings of the scholars concerned with "social forces," "interests" and the social process. The notion of social forces appeared in the historical literature in efforts to explain events in terms of their underlying and antecedent factors. The notion. however, was also used more generally to explain basic human and group behaviour. Among the writers who sought explanations of behaviour in social forces and interests were: Buckle; Ludwig Gumplowicz (1838–1909), Gustav Ratzenhofer (1842–1904) and Gabriel Tarde (1843–1904).

The development of economics during the 19th century represented the emergence of perhaps the first of the social sciences to a position of respectability and general acceptance. The description of the economic man as a rational, calculating. hedonistic person stimulated interest in individual motivation and in the analysis of rational behaviour. The emphasis placed by economic writers on the division of labour led to investigation into its relation to the social structure and process. Especially noteworthy among the writers on economic matters were Adam Smith, David Ricardo, Jeremy Bentham and J. S. Mill. An important offshoot of classical economic thinking was that represented by critics of the new industrial order and of classical economics, manifest largely in the writings on socialism. In this literature the names of Karl Marx and Friedrich Engels were outstanding.

Closely tied in with, and contributing to, economic thinking were the discussions of "the population problem." Dramatized by Nalthus, whose "law of population growth" was originally presented as a refutation of Condorcet's and William Godwin's notions of perfectionism, consideration of the relation between population and means of subsistence occupied considerable attention in the world of practical affairs, as well as among scholars. Writers concerned with population and with the antecedents and consequences of population growth included, besides Malthus, Francis Place (1771–1854), Archibald Alison (1792–1867), Adolphe Quetelet (1796–1874), Karl Marx and Herbert Spencer.

Ideas from Biology. — Important developments in biology during the 19th century, climaxed by the theory of evolution, contributed both directly and indirectly to early thought in sociology. The influence of biology on sociological thinking may be considered under four groups of ideas; namely, the theory of evolution, the "organic analogy," the problem of "heredity versus environment" and the theories of racism.

One of the most dominant influences on 19th-century thinking, in general. was that exerted by the theory of evolution. Stimulated by Malthus' discussion of the "struggle for existence" and with the taxonomic labours of Linnaeus available, Alfred R. Wallace and Charles W. Darwin independently published their epic making contributions which made evolution the cornerstone of social as well as of biological thinking for decades. Evolutionism was quickly adopted by students of social phenomena as a basic explanatory principle applied to the social order, as well as to the biological. Among the writers who adopted social evolutionism were Walter Bagehot (1826–77), John Fiske (1842–1901), Gumplowicz, Ratzenhofer and Spencer.

In addition to providing the principle of evolution, biology also exerted an important influence in the development of sociology in the writings of the scholars who compared society with an organism. Impressed by the organic character of society, a number of writers described the social order in terms paralleling the biologist's description of an organism. The organic analogy. while subject to the limitations of all analogies. did perform the function of directing attention to the organic character of society and stimulated more intensive inquiry into the nature of the structure and function of the social order. It led special attention to consideration of those aspects of society that made the social whole more than a sum of all its parts. Among the writers to utilize the organic analogy were Comte. Spencer. Albert Schaffle (1831–1903), Paul von Lilienfeld (1829–1903), René Worms (1869–1926) and J. Novicow (1849–1912).

Influenced by the prominent place of variability in the theory of evolution, and on the basis of studies of individual differences, the attention of a number of scholars was devoted to the consideration of the relative roles of heredity and environment in human behaviour. Individual differences were recognized as attributable to both hereditary and environmental factors. Writers with a biological orientation tended to stress the greater importance of the former. Their work took the form of emphasizing the hereditary factor in two respects: first, as the basic factor in explaining individual differences in abilities and behaviour: and second, as the basic factor underlying social change. Especially prominent in the development of these ideas were Sir Francis Galton (1822–1911) and Karl Pearson (1857–1936).

A special variation' of the efforts to explain human behaviour in biological terms was found in the ideas of a number of writers on racial superiority and inferiority. On the whole, this literature, while often ornamented with the trappings of biological findings. was propagandistic in character and tended to play up the alleged superiority of the Aryan or Nordic race. They are mentioned here because they stimulated a widespread controversial literature which helped to focus attention on historical and cultural. as well as biological, factors in accounting for racial as well as individual differences. Among the writers who contributed to the literature of racism were Arthur de Gobineau (1816–82), G. V. de Lapouge (1854–1936) and Otto Ammon (1842–1916).

Ideas Relating to Methodology and Techniques.—The writers briefly treated above contributed to some of the central substantive problems of emergent sociology. Equally important were the writers who helped develop a methodology for sociology. These writers may be considered in three groups: first, those who contributed to general methodology; second, those who contributed to statistical techniques; and third, those who contributed to the "social survey."

Noteworthy, first of all, were the methodological contributions of a number of historians who, in grappling with the problems of method in history, made important contributions to social science in general. F. K. von Savigny (1; 79–1861) stressed the methodological implications of continuity in the historical process; K. F. Eichhorn (1781–1854) called attention to the complexity of social phenomena and the importance of the idea of multiple causation; B. G. Niebuhr (1776–1831) emphasized the necessity of being critical of sources and of the role of the investigator; and Leopold von Ranke (1795–1886) gave great impetus to the habit of documentation and annotation. Also of great importance were the methodological contributions of Comte. Dilthey and Windelband, who grappled with the general problems of social science methodology as contrasted with method in the natural sciences.

Simultaneously with the consideration of general problems of method there were important developments in the application of mathematics to the analysis of social data. Building particularly on previous work in probability theory, as well as in general mathematics, statistical techniques were evolved during the 19th century suitable for the treatment of social phenomena. Important contributors to these developments included P. S. Laplace (1749–1827), Adolphe Quetelet; Karl Frederick Gauss (1777–1855), Adrien Marie Legendre (1752–1833), Francis Galton and Karl Pearson.

Significant from the standpoint of method as well as for the substantive data it provided was the "social survey" as it developed during the 19th century. The social survey was essentially a fact-finding enterprise designed to illuminate social and economic evils in a specific area for purposes of ameliorative action. Although action oriented, the social survey provided basic data for research and stimulated widespread interest in the study of social. economic and political problems. Some of the more important social surveys were those conducted by LePlay; Sir Edwin Chadwick (1800–go) and Charles Booth (1840–1916). The latter's famous report, *Life and Labour of the People in London* (16 vol., 1889–1903), set a pattern for similar surveys in other countries.

Other 19th-Century Influences.—In addition to the developments outlined above. sociology was greatly influenced by the increasing attention during the 19th century to the social, economic and political problems arising from the accelerated pace of the industrial revolution and urbanization. These problems were dramatized by extreme manifestations of poverty, high mortality rates, urban slums. abuses of labour. political unrest and political corruption. Nineteenth-century critics of the industrial order, philanthropic and utopian efforts to deal with the more severe social and economic conditions, the literature on socialism and anarchism, and increasing awareness of and efforts to deal with the problems of a rapidly changing social order constituted an important part of the 19th-century climate in which sociology emerged as a distinctive field.

Pioneer Sociologists.— Sineteenth-century writers included a number of men who are generally regarded as the founding fathers of sociology. Early sociologists were not the product of any one nation. In France they included, in addition to Comte. Emile Durkheim (1858–1917), Lucien Lévy-Brühl (1857–1939). Gabriel Tarde and Gustave LeBon (1841–1931); in Germany. Ferdinand Tönnies (1855–1936), Georg Simmel (1858–1918) and Max Weber (1864–1920); in Austria. Ludwig Gumplowicz and Gustav Ratzenhofer; in Russia. J. Novicow and Maxim Kovalevsky (1851–1916); in Italy. Scipio Sighele (1868–1913) and Vilfredo Pareto (1848–1923); in England. Herbert Spencer (1820–1903), Leonard T. Hobhouse (1864–1929) and Patrick Geddes (1854–1932); and in the United States. Lester F. Ward (1841–1913), William Graham Sumner (1840–1910), Albion W. Small (1854–1926). Franklin H. Giddings (1855–1931), Edward A. Ross (1866–1951) and Charles Horton Cooley (1864–1929). Other countries also developed pioneer sociologists. but their works were, for the most part. untranslated and they did not enter into the mainstream of sociological development.

Of the pioneer sociologists, perhaps the most influential in terms of the impact of their work on other sociologists were Durkheim, Weber and Cooley. Durkheim provided a clear delimitation of the field of sociology as a science devoted to the study of "the social fact." Social facts. which included forms of behaviour. thought and feeling. could be studied, he emphasized, as things in themselves. The social fact was exterior to the individual. anterior to him and exercised a constraint upon his behaviour. It was to be studied as a collective representation and not in its individual manifestations. In his *The Rules of Sociological Method* (George E. G. Catlin. ed.), he described what he regarded as the field and the method for sociology. In other publications. notably *Suicide, a Study in Sociology* (1897, translated by John A. Spaulding and George Simpson), the *Division of Labor in Society* (1893, translated by George Simpson) and the *Elementary Forms of the Religious Life* (1912, translated by J. W. Swain). Durkheim provided examples not only of the application of his methods but also of notable pioneer empirical investigations.

Weber also delimited a field for sociology. To Weber, sociology was a science devoted to the interpretation and understanding of social behaviour so as to achieve its prediction. He defined "social behaviour" as behaviour carried out according to the intention of the acting individual in reference to the behaviour of others. Sociological analysis was to be devoted mainly to getting at the intentionality of social behaviour. This was to be achieved through gaining an "understanding" of social behaviour: intellectually, if the behaviour was rational. by recognizing the logic of the means-end relationship; by means of empathy, if the act was irrational, by projecting oneself into a situation and experiencing the emotional context involved. Weber made an important methodological contribution in his description and use of "ideal type" concepts as tools of analysis against which to observe and analyze real situations. He also recognized the utility of statistical methods, especially the fundamental notions of probability and association as tools of research. Weber's consideration of bureaucracy and social stratification contributed materially to sociological investigation of these subjects. Some of his more important publications available in English are *The Theory of Social and Economic Organization* (translated by A. M. Henderson and Talcott Parsons). *From Max Weber: Essays in Sociology* (translated by H. H. Gerth and C. Wright Mills) and *The Methodology of the Social Sciences* (translated by Edward A. Shils and Henry A. Finch).

Cooley, in his doctoral dissertation *The Theory of Transportation* (1894), contributed in an important way to interest in human ecology as a field of sociology. In this work he dealt with transportation and the general economic base as a substratum of social organization. His subsequent work resulted in major contributions to general sociology and social psychology. He began with a theory of human nature and the genesis of the self, as set forth in his *Human Nature and the Social Order* (1902). His study of personality led him to the study of social structures and forms as treated in his *Social Organization* (1909). He completed what may be regarded as a system of sociology in his analysis of collective life in *Social Process* (1918). Cooley's treatment of the "primary group." the '(looking-glass self," communication and the problem of society and the individual provided subsequent sociologists with an important part of their conceptual framework. His methodological contributions lay largely in his suggestive work in ecology on the one hand, and in his description of "sympathetic introspection" as a tool of research on the other.

Mention should also be made of Small as one of the important pioneer sociologists. particularly for his contribution to the development of sociology as an academic discipline and as a profession. On the substantive side, Small, although he changed his position in the course of his career, helped define the scope of sociology as a science; played an important part in introducing European. and especially German, sociological thinking into the United States; and laid great stress on the development of method as a prerequisite to the advance of sociology as an empirical science.

It is not possible. of course, even to summarize the work of all of the individual builders of sociology. Most of the founders of sociology had in common a penchant for system building and, no doubt under the influence of the brilliant and dramatic 19th-century scientific successes in other fields such as that represented by Darwin's theory of evolution, attempted to account for man and the social order in terms of broad, comprehensive and global principles. Most of the systems were characterized by universal explanatory schemes. such as "evolutionism," or by monistic explanations of human behaviour such as "imitation."

A number of the pioneer sociologists subscribed to the view that sociology was essentially a normative, meliorative discipline. They engaged in great. debates over nominalism and realism, as manifested in the discussions of the "atomistic" or "organic" conceptions of society or the distinction between the individual and social aspects of the group; over the relation of sociology to values; over the priority of the study of the form as opposed to the content of individual and group behaviour; over the role of the "biological," the "psychological" and the "sociologistic" factors or levels of explanation; over the materialistic and idealistic conceptions of the historical process; over the suitability of natural science methods for the study of social phenomena and especially the applicability of quantification or statistical techniques; over the conception of sociology as the general social science or one of the special social sciences.

In the works of the pioneers these and other issues, as they bore on the emergence of a science of society. were clarified; and if the problems were not resolved. their discussion was, on the whole, exhausted. so that points of departure were provided for subsequent students.

The common and essential characteristic of these early sociologists was the fact that they were. in the main. still social philosophers rather than scientists. Their basic methodology was still grounded in speculative thinking rather than empirical investigation. although to be sure there were some notable exceptions (*e.g.,* Durkheim's *Suicide,* 1897, and Sumner's *Folkways,* 1907). These pioneers of sociology were concerned more with discussions of what sociology should be, and should do. rather than with the doing of it. But they performed an important function in crystallizing and making explicit some of the basic issues, consideration of which was perhaps prerequisite to the emergence of sociology as an empirical science; in delimiting an area of investigation; in posing many of the specific problems of sociology; in framing a methodology and providing a number of research techniques: in contributing materially to the development of sociological concepts; and in providing important insights which influenced the course of subsequent developments in sociology.

Twentieth-Century Developments.— System building in sociology continued into the 20th century, and for the first two decades there was also a sustained ipterest in the broad general problems of the type indicated above. The distinctive rnarks of 20th-century sociology. however. lie in its delimitation as a separate social science; in the emphasis placed upon research as the primary task of sociology; in the emergent conception of theory as a prelude to. and product of. research rather than an exercise in armchair speculation; in the broadened participation of sociologists in empirical investigation; and in the increasing use of statistical and experimental or simulated experimental methods. Accompanying these developments was a great increase in the number of sociologists and in the widespread appearance of sociology in university and college curricula: especially in the United States, as a recognized academic discipline. In these developments, sociology, if it did not become a science in a rigorous sense, at least definitely moved in that direction. By the end of the first half of the century, the great bulk of sociological publications comprised reports of empirical research, and broad social speculation had definitely ceased to be a major preoccupation of sociologists, especially in the Cnited States.

The shift from speculative social thinking to empirical research was led and fostered by the generation of sociologists who followed the pioneers and who, for the most part, were their students and sometimes their disciples. The trend toward empirical investigation was most manifest in the United States: partly because of the availability of greater resources for research. Generous research grants by the large foundations (such as the Rockefeller foundation and the Carnegie Corporation of New Tork), expanding research appropriations by the federal government, especially for agricultural research at the outset, and increased expenditures by action agencies for "applied research" provided the means for the conduct of empirical investigations. Research activities were stimulated, also, through the development of professional organizations whose primary objective was the encouragement of such activity. The most important of these were the American Sociological society, founded in 1905, and the Social Science Research council: which was organized in 1923. Sociological research activity, however, was by no means confined to the United States.

In the United States the transition from social speculation to empiricism was spearheaded by such men as W. I. Thomas. Florian Znaniecki. Robert E. Park, E. W. Burgess, W. F. Ogburn. Ellsworth Faris, Richmond Mayo-Smith, R. M. MacIver, L. L. Bernard. F. S. Chapin and H. W. Odum. Not all of these men themselves pioneered in research activity, but they all showed an enthusiasm for, and interest in, research which they passed on to their students. Early 20th-century examples of empirical investigation included such works as Sumner's *Folkways* (1907), Paul U. Kellogg's *The Pittsburgh Survey* (1909–14), C. J. Galpin, *The Social Anatomy of An Agricultural Community* (1911) and W. I. Thomas and Florian Znaniecki, *The Polish Peasant in Europe and America* (1918–20). In addition works which, while themselves not empirical investigations, contributed inestimably to the increasing tempo of research activity included R. E. Park. *The City: Suggestions for the Study of Human Behavior in the Urban Environment* (1915), and R. E. Park and E. W. Burgess. *Introduction to the Science of Sociology* (1921). The former provided a framework for urban and ecological research. The latter brought together in a systematic fashion the insights and concepts of earlier writers set in a framework oriented to research. Pursuant to these publications. a series of monographs were published by young sociologists. trained at the University of Chicago, which constituted the first mass series of empirical investigation in sociology.

After about 1940, the relatively large volume of discrete research reports in sociology led some sociologists to feel that the pendulum had swung too far away from sociological theory. Pure fact finding was criticized as being as unproductive as pure speculation. In consequence, there was a discernible attempt on the part of sociologists to tie their investigations to relevant theory, and to direct their research activities toward the testing of explicitly stated verifiable hypotheses.

Sociology was slower to develop in Europe than in the U.S. during the 20th century, especially in its research manifestation. Up to World War II, in England a mere handful of men had claim to the designation of "sociologist." although a number of prominent scholars had contributed to the development of various aspects of sociology. The situation was similar on the continent. with the exception of France and Germany. Although an important literature was developed which contributed materially to sociological insight and theory, empirical research did not reach the stage or magnitude of development in either France or Germany that it achieved in the Cnited States. In France. sociological activity was closely interwoven with that of anthropology and, in large part, not clearly differentiated.

After World War II, however, there was evidence of increasing interest in sociology in Europe and in other parts of the world. The number of chairs in sociology at recognized universities grew considerably. An International Sociological association was established under the sponsorship of the United Nations Educational, Scientific and Cultural organization in 1950, and Louis Wirth (1897–1952), of the University of Chicago, was elected its first president. At the meeting of the association in 1953, at Liège, Belg., more than 300 sociologists were in attendance from 46 countries.

FIELDS OF SOCIOLOGY

There is no generally accepted classification of the fields within sociology. The classification used below. for purposes of convenience in summarization, is an arbitrary one. The fields listed are closely interrelated and not mutually exclusive. They serve to denote general areas of specialized interest for research and teaching purposes. Most of the references to research and publications are restricted to sociology in the United States. partly because most of the specific research reports in other languages have not been translated into English. and partly because greater emphasis has been placed on, and greater resources available for, empirical research in sociology in the U.S. than in other countries.

Social Organization. — Social organization as a field of sociology is concerned primarily with the study of the structural; functional and dynamic aspects of group living. It includes investigation of the community. the family, the social group, social institutions. race and ethnic relations, social stratification and social mobility. It is concerned also with the problem of social control as achieved through the study of the various forms of informal and formal controls ranging from the constraints upon behaviour exerted by the mores and folkways to that by the law and formal sanctions. Especially prominent after 1930 were studies in the community. the family and race and ethnic relations; and after 1940, studies of social stratification! industrial sociology, bureaucracy and the small group.

Sociological study of social organization is in a number of respects similar to the research activity of social anthropology. Prior to World War II, social anthropology confined its investigations primarily to primitive societies, but the general approach and literature of the two fields is at some points a common one. This was especially true in France, but was evident also in England and in the United States.

Social organization is closely related to the other fields of sociology and, in a fundamental sense, constitutes together with social psychology the central core of sociology. Its ramifications are as diverse as the social structures in society, and the study of individual aspects of social organization has given rise to a series of sociological specialisms, as rural sociology, urban sociology, the sociology of law, the sociology of religion, the sociology of education. the sociology of knowledge, political sociology, industrial sociology. the sociology of work and sociometry. The latter is a field of research in which social structure and interpersonal relationships are graphically and quantitatively represented.

Social Psychology. — Social psychology studies human nature and personality as influenced by group life on the one hand. and collective behaviour on the other. With diverse origins in biological and psychological as well as social thought, it is far from a unified field. It is a branch of both sociology and psychology. The psychological approach has, on the whole, differed from the sociological in its greater emphasis on the study of the individual, as against the group, and by its greater use of laboratory and experimental methods.

The problems generally studied by sociologists in this field include the nature of human nature as a product of group life; personality and its formation, social attitudes, public opinion and propaganda, communication; interpersonal relations; crowd and mass behaviour; and social movements.

The general literature of social psychology reflects the variety of schools of thought. Among the more prominent general approaches, some more of historical than contemporary interest, are: the biological approach. represented by the "instinct" school which dominated social psychological thinking in the early part of the 20th century; the collectivistic approach which emphasizes the influence of the social group and culture on the behaviour of the person; the behaviouristic approach which places emphasis on the objective observable activities of the human organism; the symbolic interactionist approach which may be viewed as a form of social behaviourism in which the social act is the basic unit of analysis ; the psychiatric approach which includes Freudian psychoanalysis, modifications of the Freudian approach. and other psychiatric approaches; the Gestalt approach which stresses the importance of "functional wholes" as the elements of study; the group dynamics approach, a form of Gestalt psychology which studies changes in group structure and function under varying conditions.

Of these. the distinctively sociological orientations are largely the "symbolic interactionist" and forms of the "collectivistic" approaches. Sociologists. however, have been influenced by the other orientations and have. in turn. exerted influence upon them.

World War II greatly stimulated sociological research in social psychology in the United States. especially within the military establishment. Major empirical investigations were conducted in which measurement techniques were applied to a number of social psychological problems. This work marked the increased collaboration of social psychologists from both the disciplines of sociology and psychology who, at a number of points and especially in the study of small groups. communication and attitudes, have been working on common problems.

Social Change and Social Disorganization. — Social disorganization studies the disruption of established social relations that interfere with, or prevent, the functioning of the social group and that demoralize the person. Social disorganization is discernible in the breakdown of forms of social control and in the deviate behaviour of persons. Social change is concerned with changes in culture and social relations — their nature, the processes and mechanisms involved, the factors which underlie them and their consequences. The study of social disorganization is closely related to the study of social organization. The study of social change forms the link between the two. Social disorganization may be regarded as one phase of a continuous process of social interaction in which an equilibrium is achieved which constitutes social organization. which is subjected to social change, which may produce social disorganization, which, in turn) may be a first step in social reorganization.

The study of social change requires investigation into the conditions and factors producing change — economic, technological, demographic, political. cultural or other — and the characteristics and results of change. Specific subjects of investigation include the study of invention, cultural diffusion, crises. acculturation and resistance to change. Social change studies also include the various elements of time series analysis as applied to social data — the analysis of cyclical, seasonal and other short-run changes, as well as of secular trend.

Studies of social disorganization may be considered under three closely interrelated categories, individual disorganization, family disorganization and community disorganization. The study of individual disorganization includes analyses of such behaviour as crime and delinquency. mental disorder, suicide, alcoholism and vice; and also such subjects as poverty, unemployment and child labour. Research in family disorganization involves study of family tensions. separation and divorce. Investigation of community disorganization covers such topics as political corruption, the breakdown of formal and informal social controls, mass unrest, mob behaviour and revolution.

Human Ecology. — Human ecology studies the spatial and temporal relations of population aggregates, human behaviour and social institutions — the distributive and temporal aspects of society. It is concerned with symbiotic as opposed to social relationships; with the physical and technological bases of group living. the social substructure, which usually exerts impersonal but important influences on the structure and functioning of the social order.

Human ecology in a sense is a subfield of the study of social organization and is also closely linked with elements of population study. It is closely related to the interests of human geographers who. like the sociologists. have borrowed the framework and concepts of plant and animal ecology and applied them to the study of man and society in relation to the environment. The interests of the geographer and the sociologist in human ecology have differed in that the former has been concerned primarily with the relation of man and his works to the environment. and the latter with the relations of human beings to each other as well as to the social order as affected by the environment.

Research in human ecology has been concerned with such problems as the general structure of urban and metropolitan areas and their processes of growth; the delineation of "natural areas" as opposed to political or administrative units; the spatial pattern of social phenomena such as delinquency, insanity, fertility, mortality, divorce, forms of family organization, churches. retail establishments: the distribution, and changes therein. of social and ethnic groups, and other population groupings within an urban area: the relation between place of residence and place of work; the correlation of spatial patterns of human behaviour and social institutions; and the factors. geographic, economic, technological, historical arid political, as well as social. which underlie spatial and temporal patterns. Although studies in human ecology have been concentrated primarily on urban areas, work has also been done on the spatial and temporal aspects of rural communities. especially by rural sociologists, and on "regionalism" on a national and world basis.

Population. — The field of population, broadly conceived. is concerned with the study of population numbers, composition, change and quality as they are influenced by. and as they influence, the social, economic and political orders. Population study is by no means restricted to sociologists but. rather, attracts the members of a number of both the natural and the social sciences. Demographers, as students of population are called, include biologists, geneticists. medical men. public health specialists, biometricians. actuaries, statisticians and economists, as well as sociologists.

Population study as an interest of social science was primarily a branch of economics from Malthus to about the first quarter of the 20th century. Later. however. although some attention was paid to population in both economic theory and research, active social study of population phenomena became more the province of the sociologist,

Sociological research interest in population has focused on such problems as population size and distribution; composition of population, including the social and economic as well as the personal characteristics of the population; population growth; components of population gron-th, including fertility, mortality and migration; family numbers. composition and growth; family formation and its components — marriage. divorce, separation, widowhood; differences in birth, death and migration rates among various population groupings and the factors associated with the differences; and the interrelations of demographic and social factors. From at least 1930, sociologists also became interested in the study of the structure and dynamics of the labour force as a major element of the total population. and in demographic aspects of special population groups such as youth and the aged.

The nature of population data, much of which comes from such official sources as censuses and vital registration systems, involved and permitted the utilization and development of statistical techniques, so that population study is one of the most quantified and rigorous fields of social science in general. as well as of sociology. Sociologists interested in population study frequently also pursue research in human ecology. which is closely related.

Sociological Theory and Method. — Sociological theory comprises the generalizations or principles of group life as applicable to personal behaviour or the social order. In the 19th and early 20th century literature. most of the content of sociology was "theory" in the sense of being social thought variously related to the world of reality and. in the main. arrived at without benefit of empirical study. From the beginning of the second quarter of the 20th century. theory came more and more to be regarded as primarily a frame for and a product of sociological research. Moreover. theory in this sense tended to disappear as a separate field of sociology and, appropriately. to be diffused throughout the discipline in close relation to the subject matter to which it relates. Another important change in contemporary sociological theory, as contrasted with earlier writings. was its more modest character. Contemporary theory tended to be of "middle range" rather than global. and more concerned with its relevance to research.

The development of sociological method generally followed two channels — qualitative and quantitative. The former involved the use of case material based on interviews, correspondence. diaries and life histories — sympathetic introspection and participant observation. The latter led to increased use of statistical techniques and of census and sampling survey data; the construction of tests and scales: simulation of, as well as attempts at, experimental methods; and model building. Some links between the qualitative and quantitative methods developed in the form of "content analysis" and methods of controlled observation and recording. Of special import were the developments to predict behaviour, especially as exemplified in the fields of parole prediction. and the prediction of success and failure in engagement and marriage.

APPLIED SOCIOLOGY

Sociology also had increasing application to the solution of practical problems, especially after the second decade of the 20th century. The findings of sociological research have been utilized, particularly in such fields as criminology, social work: education, race relations, planning, government administration. marketing, communication. propaganda, public opinion polling. social psychiatry. industrial relations, and marriage and family counselling. Most sociologists continued in teaching and research activities at universities and colleges.

A number of sociologists, however. utilized their training as professional personnel in fields such as those listed above as well as in the conduct of applied research activities for agencies in these and other fields.

SOCIOLOGY, ANIMAL. The sociological study of organisms takes the group rather than the individual as the basic unit, and may fairly be called sociology in the broadest sense, defined as the science of organic communities. Sociology so considered includes communities of organisms with different levels of inclusiveness and of integration. Some of these may be described as follows: Biosociology deals with communities of plants and animals living together in nature: among the ecological communities that are the social units at this level of organization, the social bonds are weak and sociality is vague. The same is true in plant sociology. which is concerned with plant communities Animal sociology exists at this weaker level of sociality, but it also includes more closely knit groupings such as those of the social insects and, of course, of man. More appropriately defined, "animal sociology" deals with the social life of nonhuman animals, and "sociology" centres on the social life of man (see SOCIOLOGY).

Although biosociology and plant sociology are not closely related to human sociology, they have certain resemblances. Both deal with groups or communities of individuals and the mutual relations that bind them together rather than with the individual plant. or nonhuman animal, or man standing alone. Both are concerned with mutual dependence, with co-operation, with its opposite. dis-operation, and with competition.

The qualitative distinction between the sociology of man and that of other animals is not sharp, but since other animals lag far behind man in the development of abstract thought, in symbolic communication and in cultural institutions, there are very large quantitative differences. The distinctions are by no means absolute, however, and. in many relations, comparisons are continually being made between the social life of human and nonhuman animals. Indeed, the social life of animals is of interest to many only because of possible comparisons and, more especially, of contrasts with that of man. On the other hand, there are persons for whom the various patterns of behaviour of other animals are of prime importance in their own right. This animal-centred focus is often found among observers of the group life of animals; it is the dominant attitude among many bird watchers. Yet even the most extreme zoophiles are usually aware of some of the human aspects in the social behaviour of other animals.

All too often reports concerning animal sociology are given as though the animals observed were feathered or four-footed men. Such accounts are misleading. Man is the only animal we can know both objectively and subjectively. Except in the figurative sense, no person has ever been a worm. a fish, a snake-in-the-grass or even an ape. We have no inside information concerning the feelings or the outlook of such animals. The valid interpretation of all of their behaviour, social behaviour included, is difficult and often impossible except from the point of view of the outsider. This article attempts to be carefully objective. The story remains interesting even under such conditions.

The article is outlined as follows:

I. Aggregations of Animals
 1. Reasons for Aggregations
 2. Group Survival Values
 3. Modification of Behaviour
 4. Division of Labour
 5. Social Instinct
 6. Social Levels
II The Social Habit

  3. Conclusion

I. AGGREGATIONS OF ANIMALS

Animals and plants live in communities. Organisms in communities may live together because of common tolerances for the nonliving environment, or they may be unified by interactions between the organisms themselves. The latter form more closely knit units and are often called biocoenoses. Both biocoenoses and habitat-controlled assemblies are recognized as communities at the ecological level. Such matters are discussed in the article ECOLOGY, ANIMAL. The universality of this kind of community living is the important point here. Plant sociology is built almost entirely about the study of communities of plants, and animal ecology is much concerned with this relatively vague sort of sociality.

1. Reasons for Aggregations. — The ecological community is made up of several species living together. Animals do not spread themselves evenly throughout a community, rather they tend to collect in spaced or in contact aggregations of a few or of only one species. These so-called contagious distributions are the rule in nature. The simplest aggregations show very little integration; the more complex ones grade insensibly into closely knit insect or vertebrate social groups. Aggregations composed primarily of one species are more important in the development of society than are those of mixed composition.

The least social animal aggregations are represented by accidental collections. For example, animal drift lines occur along the margins of many bodies of water. They are particularly noticeable on the sandy beaches of the Great Lakes of North America, where they may extend for miles. In the animal drift along the shores of Lake Michigan may be found sizable collections of aquatic snails, small bivalves, crayfishes and even fishes, thrown up by the waves. Similar concentrations of insects are also deposited, with many of the individuals still alive; these have been carried out over the water by an offshore breeze, then caught in the water and tossed back on the land by currents and waves. So far as the animals are concerned, their aggregation is entirely accidental. They may remain aggregated through inability to move or simply as a result of inertia. Such aggregations are near the zero mark for sociality; the quality of inertia shown under these conditions has only slight social significance.

Animals aggregate under diverse conditions as a result of their own movements. Perhaps the simplest of a long, intricate series of aggregating behaviour results from so-called kineses (see ANIMAL BEHAVIOUR: Animal Behaviour Patterns), that is, from the unoriented reflex action of the whole animal. Thus animals that are stimulated by high light intensity slow down when they enter shaded areas. If many are moving about in a given locality, such photokinesis will cause them to aggregate in the shade somewhat as automobiles, moving freely along a highway. aggregate automatically when slowed down by entering a village or by any other agency that reduces their rate of movement.

Aggregations result from oriented reactions to light intensities, or to any other gradient of environmental forces, when an oriented response brings numbers of individuals into a restricted region. A positive reaction to odours, leading animals to a restricted source of food, gives a common example. The collected animals must have a certain amount of toleration for the presence of, often for contact with, other individuals if the aggregations are to form and particularly if they are to continue.

In contrast with the more or less automatic aggregation of animals in response to odours, light or shade, moisture, favourable niches and other environmental factors. there are the much more definitely social situations in which animals collect as a result of positive reaction to the presence of others like themselves. The aggregations of male midges dancing in the quiet atmosphere, or the formation of schools of fish or flocks of birds illustrate this widespread phenomenon.

2. Group Survival Values. — Group survival values often appear as a result of animals being congregated together. These can be found sometimes even in the accidental aggregations such as those of the drift line along Lake Michigan. Aquatic animals piled one upon another may retard drying to such an extent that the lower, most protected individuals may survive for some hours and so have an opportunity to escape should the waves arise or rains come and sweep them back into the water. Similarly, land insects may be shaded by the piled up mass and so escape death from drying or from heat and live to make their way across the sand to vegetation and greater safety. Aggregations also have disadvantages: surrounded animals may be smothered by their fellows, and the whole group forms a collection of foodstuff easily accessible to many predators. Some ecologists writing in anthropomorphic terms have called the drift line the "lunch counter of the beach" for mice, skunks and many other insect eaters.

Other types of aggregation also show group survival values, often to a high degree. Certain phases of these values are discussed below under the heading of natural co-operation. One common characteristic of these group effects is that as the animal aggregations become closely integrated there is a definite tendency for the group more and more to control a limited section of its own environment. Sometimes this control is gained by the death of those individuals that meet the full impact of the uncontrolled environment, to the distinct benefit of the remaining members of the group. The construction of nests, whether above or below ground, is a common method of securing partial environmental control. With the social insects (termites for example) the conditions within the nest often are quite distinct from those outside its walls. especially in reduced amplitude of fluctuation: they are much nearer to the termite optimum, particularly as regards humidity.

Groups with positive survival value, for some or all of the individuals present, serve a social function whether composed of protozoans, worms, insects or men or other vertebrates. The survival-value test of sociality must be based on real evidence, however, and even then it should be applied with caution. Aggregations are not necessarily beneficial for the aggregated animals, since overcrowded animals are often handicapped by long-continued close association with their fellows. Some of the relations between positive and negative survival values of the aggregating habit will be considered later in the present article.

3. Modification of **Behaviour.**—The effects produced by massed animals may not be of obvious or easily demonstrated survival value and yet give first-rate evidence of group influence. Group modifications of behaviour supply examples of this generalization. Each individual in a group of animals frequently shows decidedly different behaviour patterns from those given when the respective animals are isolated. When one animal behaves differently in the presence of its fellows from the way it would if alone, it is social to that extent regardless of survival values or other considerations. The behaviour of a group may be greatly modified by the presence of a single animal of an alien species; a migrating flock of birds often alters its behaviour decidedly in the sensed presence of a predatory ha k.

4. Division of Labour. — Aggregated social animals usually develop division of labour. In its earliest stages the division of labour may be quite informal — some animals are on the margin and others are protected within the group. It is as simple as that. Position may change from time to time without obvious reasons; the difference in function is temporary and, perhaps, accidental. Various complexities of division of labour are known, and lasting structural as well as behaviour differences illustrate the highest stage of its development. The castes of ants and termites give good examples.

The most common division of labour is that between the sexes This appears to some extent even among the Protozoa. In the simplest cases among higher animals, the fish. one sex produces eggs and the other sperm, both are shed into the surrounding water and that is the end of the matter so far as the parental generation is concerned. In other cases, of which common pigeons provide an example, both sexes are similar in size, appearance and to some degree behaviour; they differ in mating reactions as well as in primary sex functions. At the other extreme stand the many cases in which one sex is larger, showier, decidedly different in form or otherwise markedly differentiated from the other sex. The common domestic fowl, many other birds. most deer and other polygamous mammals such as the fur seal are examples. The concept of separate sexual castes fits the easily observed facts in such animals.

Another very common division of labour is that between continuing groups consisting of parents and their offspring. In its simplest and most widely distributed form, the division is between protector and those protected, or between food collectors that also eat and food consumers that do no collecting. In some instances, notably among certain termites, the developing nymphs act first as workers; later they become so-called soldiers or sexually mature reproductives.

Group modification of behaviour finds dramatic expression in the organization of social hierarchies, in territorial behaviour and leadership-followership relations. These are discussed at some length in a section below.

5. Social Instinct. — An instinct (*q.v.*) may be defined loosely as a rather complicated behaviour pattern transmitted from generation to generation by organic inheritance. Early naturalists thought highly of social instinct as a criterion of an animal society, and sometimes spoke of animal societies as organized at the instinctive level in contrast with human societies, which they regarded as being built at an intellectual level. A major difficulty arises, however, in demonstrating the existence of a social instinct as distinct from early learning. All too often the concept of instinct has been merely a convenient cover for ignorance. Although admittedly difficult to define with exactness, there is validity in the idea that animals aggregate as a result of inherited behaviour patterns and that the more complex animal societies develop among species with inherited patterns of sufficient complexity to be called instincts. Whether known as instincts, or appetites or drives, much of social behaviour appears to result from biologically inherited responses, modified in many instances by learned reactions.

The social appetite (to use a term more acceptable to many psychologists) can be compared profitably with the action of food-hunger or thirst. At relative peaks of intensity, the social appetite is usually feebler than the others. It is also more continuous in action and less dramatic. The peaks and depressions of its expression are smoothed out, hence it is less obvious. Sex-hunger is a special form of social appetite with many qualities obviously lacking in other phases of inherited drives toward sociability.

6. Social Levels. — The difficulties inherent in the further elaboration of any scheme of social levels among animals is evidence of the lack of natural divisions. The whole field of social interrelationships of organisms has a degree of unity untouched by any of its parts; some particular level of social appetite, group reaction, community integration, social value or exhibition of division of labour can be singled out only arbitrarily as forming the beginning of social life. Alfred Victor Espinas came to a similar conclusion in 1877 in *Les Sociétés animales,* which gave the modern orientation to comparative sociology. In effect, an early paragraph says:

No living plant or animal is solitary; animals especially are knit together by many ties. Even the most solitary of the sexual animals contract, ii only for a moment, an intimate union with another member of its species. Social life also exists among species in which the sexes are not distinct and separate. This is particularly obvious in colonial animals that remain physically attached to each other throughout life; the food eaten by one may be shared by many. Social liie is not an incident or an accident among animals; it is not the special privilege of some few that stand high in the evolutionary scale such as men, beavers, bees, and ants, but it is a normal, constant universal iact. The social relations may be summarized in the form of certain laws that are similar wherever they appear. The social facts indicate the existence of a homogeneous whole, well linked in all its parts, that iorms a natural domain with distinct unity.

Forty-six years later! William M. Wheeler! an American student of social insects, put the same set of ideas even more forcefully in almost the following words:

All living things are genetically related as members of one great family, one vast, living symplasm, which, though iragmented into individuals in space, is nevertheless absolutely continuous in time. In the great majority oi organic forms, each generation arises from the co-operation of two individuals Most animals and plants live in associations, herds, colonies or societies oi the same species and even the so-called solitary species are necessarily more or less co-operative members of groups or associations of different species. Living beings not only struggle and compctc with one another for food, mates and safety, but they also work together to insure to one another these same indispensable conditions for development and survival. (Adapted from *Social Life Among the Insects* by William Morton Wheeler, copyright, 1923, by Harcourt, Brace and Company, Inc.)

II. THE SOCIAL HABIT

Evidence indicates that the more specialized animal phyla are grouped into two main lines of evolution that sprang from a common general ancestor at or near the coelenterate level of organization. One branch passes through the forebears of the annelid worms and mollusks and culminates in the insects. The other line. after giving rise to echinoderms, evolved into ancestral chordates and culminates in modern vertebrates. Social insects thus are not near relatives of social vertebrates even in a zoological sense, and neither stands in the direct evolutionary line of the other. Whatever social traits they possess in common have either been separately evolved or trace back to the much more vague sociality of their unknown, common ancestral stock.

The relative numbers of different species of animals can also be given simply. If you will imagine that all the known animal species are represented by your own reach from the tip of the outstretched fingers of your right hand through to those of your left, the following approximate relations hold. the extreme end joint of the right middle finger represents all species of mammals; the second section of the finger stands for birds; reptiles and amphibians lumped together about fill the basal joint. The length of the palm represents the fishes. All the remainder of the entire outreach is taken over by invertebrate animals. The nonarthropod invertebrates account for the space from wrist to elbow of the right arm, and the arthropods make up all the rest, with the major part of this space needed to represent the insects. In all, there are more known species of animals than there are words defined in an unabridged English dictionary. Each of all these species, insects and noninsects, vertebrates and invertebrates, protozoans and nonprotozoans, has its own form of sociology. When sociology is restricted to the study of the relations between individuals of the same species. as it frequently is. the sociology of any species from all this multitude offers a wealth of problems. since no species is known that does not possess interindividual relations.

Social life reaches its apex with man (and the apes and monkeys), on the one hand. and with termites. wasps. bees and ants, on the other. In the main. the animal sociology below will centre on the social relations of the less definitely social animals. Treatment of insect societies may be found in the article SOCIAL INSECTS.

The vertebrates furnish notable examples of more-or-less social groups in each of the classes of that subphylum. There are schooling fishes and tadpoles. breeding assemblages of frogs, hibernating aggregations of snakes, hierarchies of grouped lizards, various stages of social organization and of communal living among flocks of birds and diverse social groupings among mammals. The latter include colonies of beavers, towns of prairie dogs. herds of hooved animals and hordes or families of various monkeys and apes.

The social habit has evolved among many kinds of arthropods. According to Wheeler (1923). social habits have arisen no fewer than 24 times in as many different groups of insects. Although the matter is by no means clear, it seems likely that the emergences of the social habit among vertebrates and insects do not come absolutely anew in each instance. Rather, it is an attractive hypothesis that they all develop from a common substratum of more vague presocial tendencies. Some of the evidence concerning the existence and nature of this more generalized forerunner of well-developed sociality will be presented and discussed in the following sections.

A. NATURAL CO-OPERATION *v.* DIS-OPERATION

The inclusive definition of sociality on which modern animal sociology is based assumes that integrations of two or more organisms into a supra-individualistic unity, on which natural selection can act, marks at least a beginning of social life. The most feeble units may be poorly integrated but still have demonstrable survival values. They may consist of small or large groups, and the survival value may or may not be obvious. The essential point is that all groupings of animals have some small amount of sociality whenever they are sufficiently integrated to behave as a group unit under natural selection. The aggregations may be natural or the existence of probable survival values may be tested when the organisms in question are placed together in experimental populations.

1. Interactions.— It may be helpful to consider some of the simpler conditions that are found in early stages of drop cultures of protozoans. First, take the situation in which one protozoan is washed free from bacteria and then placed alone in a drop of bacteriologically sterile medium. There is one living organism in a small environment that represents a habitat-animal complex reduced to simplest terms—an uncomplicated microcosm. The living animal modifies its nonliving environment, which at the same time affects the contained organism. The whole is an ecological action system.

If a second protozoan is introduced. the increases in complexity in the ecological system result principally from the direct or indirect effects of one animal interacting with the other. The interaction may be neutral, beneficial or harmful for either or both. (Actually complete neutrality is rarely found in any ecological action system.)

Any interaction between the two animals may have preliminary beneficial or harmful aspects regardless of end results; and. on the other hand, the final long-run effect may be helpful or harmful for the animals concerned regardless of the immediate or short-run effects. One animal may be benefited and the other harmed, but, in the end, it will be necessary to appraise the survival value for both organisms considered as representatives of their species.

Mating is one kind of interaction in which the habitat often plays a permissive, but beyond that, a passive role. This is an interindividual reaction in almost pure form, the results of which are normally beneficial to the race regardless of the immediate effect on the individuals themselves. Under several conditions the two protozoans may both be injured or killed as a result of mating.

2. Effects on Environment.— Besides the possibility of affecting each other, the animals modify their environment by living in it. In their reaction on the habitat. two protozoans may fix some toxic substance more efficiently or they may otherwise jointly condition their common medium more effectively than either can do acting alone. Many of the possibilities are considered in more detail and under more complex conditions in a succeeding section.

3. Co-operation and Dis-operation. — Interactions between organisms that prove to be helpful are evidence of the existence of co-operation, or at least of proto-co-operation, even in such a simple action system as that described above; opposing, harmful tendencies may be termed dis-operation. The two sets of processes are in fundamental opposition. With all lower forms of animal life. and often with higher ones, such co-operation or dis-operation is wholly nonconscious. The nonconscious character of the effects and of their underlying causation is especially evident in poorly integrated ecological systems in which man is not represented. This is a consideration that does not affect the fundamental nature of the resulting dis-operation or co-operation. It is essential to remember that. possible neutral effects aside, we are dealing with a system in which the survival values illustrate in simplest terms the basic social antithesis, that between beneficial (co-operative') and harmful (dis-operative) effects.

4. Competition. — Competition furnishes a special phase both of co-operation and of dis-operation. In general. competition occurs when there is a common demand for a limited supply. Among other situations this criterion applies to the competition of two males for the same mate. for a limited food supply or for limited space.

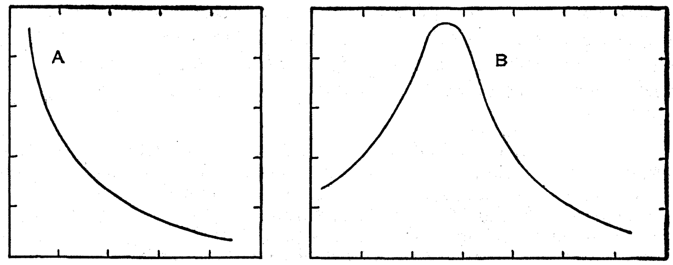
Competition frequently results in dis-operation, although the two are not synonymous. Two protozoans in a drop culture are in competition for a limited amount of food; the competition may result in the stunting or death of both or in one surviving at the expense of the other.

Co-operative competition also is known. A good example is furnished by the mass physiology of the sperm of sea urchins. In nature, these spermatozoa are shed into sea water where they may fertilize the eggs that have been similarly shed. In making sperm suspensions for experimental use, the male sea urchin is placed upside down in a clean dry watch glass. If sexually "ripe." the spermatozoa are shed through the aboral genital pores. Massed spermatozoa so collected live longer and retain their fertilizing power longer than sperm suspensions diluted with sea water. At least a part of the greater longevity of the crowded spermatozoa comes from the fact that the individual spermatozoa do not move when closely packed together. It seems reasonable to assume that the inactivity results from the lack of free space. Under natural conditions of dilution. if the available space is much restricted, the competition for it results in an inhibition of movement, a lowering of the rate of oxygen consumption, and is accompanied hy a decided increase in longevity. Competition here has distinctly beneficial results for all the competitors; it is co-operative as contrasted with being dis-operative.

The fact that, under certain conditions, competition for space results in a form of automatic co-operation as contrasted with automatic dis-operation is an important consideration for general sociology. The importance is greater since all the individuals present in the given illustration benefit from the competition. Under more usual conditions of competition. not all individuals benefit, and yet the end result may be favourable for the species under consideration: that is to say, the final outcome even of such competition is not necessarily dis-operative.

5. **Physiological** Effects of Aggregations. — Certain aspects of survival values and other physiological effects associated with aggregations of animals are summarized by the curves shown in fig. 1. Curve A shows results of biological processes in which the highest recorded value is given by the smallest possible population. A pig born as a litter of one normally grows faster than do members of larger litters, and this is a common relation for many animals.

In contrast, grouped animals often show increased efficiency that is sometimes reflected in longer survival, or they otherwise may grow better or live longer if neither too few nor too many animals are present; they have an optimal population density at some intermediate point of the possible range of numbers. This situation is summarized by fig. 1(B). As the population density increases, conditions become more favourable, or the rate of reaction is faster. or some comparable change occurs, until an optimal density is reached beyond which a further increase in density pro-



ADAPTED FROM ALLEE. "THE SOCIAL LIFE OF ANIMALS" (NORTON)

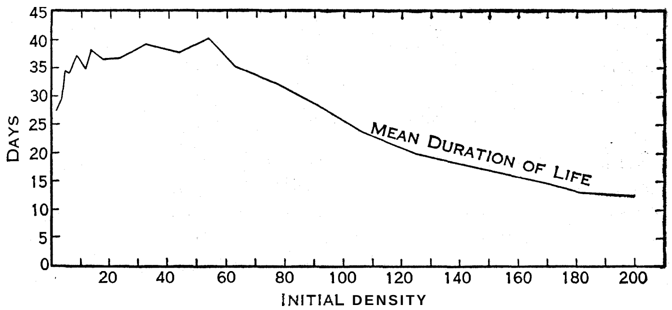
FIG. 1.—IN SOME PHASES OF POPULATION PHYSIOLOGY THE OPTIMUM POPULATION IS THE SMALLEST POSSIBLE (A); IN OTHERS, IT IS INTERMEDIATE IN SIZE (B)

duces a reversal of the observed trend.

Consideration of the two curves. A and B, and of the phenomena on which they are based, indicates that under most conditions overcrowding produces harmful results. This fact has long been known and can be verified easily. The existence of harmful results associated with undercrowding is a later and less well-known discovery. The biological results of undercrowding and of optimal population size imply the existence of natural co-operation just as the effects of overcrowding imply dis-operation.

B. Group Modification of Structure and Behaviour

The mass physiology of aggregated animals differs in various ways from the physiology of individuals. Illustrations include



FROM ALLEE, 'ANIMAL AGGREGATIONS' (U OF CHI. PRESS) AFTER PEARL

FIG. 2.—DROSOPHILA CULTURED IN I OZ. BOTTLES LIVE LONGER WITH FROM 35 TO 55 PRESENT PER BOTTLE THAN AT OTHER POPULATION DENSITIES

the acceleration of early development in certain aquatic eggs, the increased rate of asexual division in various protozoans and the decreased rate of mortality in populations of optimal density as contrasted with those more dense or more sparse (fig. 2).

Fundamental group effects are also known for size and structure and for behaviour. Even the determination of sex may be modified or controlled in several forms by the density of the interbreeding population.

1. Structure. — Crowding may affect the body size of animals. It is easy to demonstrate the stunting effect of overcrowding such as normally results from an inadequate food supply during the period of growth, or from the accumulation of excretions or of their decomposition products. Frequently an optimum population density. somewhat larger than the minimum, can be demonstrated at which larger animals are produced. *Drosophila*, for example, grow larger in small culture vials when from 8 to 16 are present than they do when fewer or more flies develop in the same volume.

Body form also may be directly controlled by population density. This is easily apparent among sessile animals which, like trees and many other plants. show decidedly different growth forms when crowded and when standing alone. The common barnacles and the ascidians of coastal marine waters grow much taller and more slender in the centre of a crowded group than they do when isolated. Even motile forms may be similarly affected; snails of the genus *Lymnaea* kept under crowded conditions for four successive generations became successively smaller and more slender until they were quite unlike the parent stock; the proportions of various body organs were also differentially altered.

Polarity.—The structural effects produced by crowding may be much more fundamental. Polarity is one of the basic structural properties of almost all organisms. In such marine plants as the algae *Fucus* and *Ascophyllum*, the polarity of the fertilized eggs can be experimentally controlled by a variety of environmental relationships, including the presence of other similar eggs in the vicinity.

The first cleavage of these eggs normally separates the developing zygote into two unequal cells, one of which gives rise to the apical part of the new plant; the other divides and redivides to form the rhizoid or holdfast section that anchors the alga to the substrate. The future axis was apparently undetermined at fertilization but has become fixed by the time of the first cleavage. When *Fucus* eggs are in a small group, as they often are in nature, the first cleavage plane divides the egg into an apical cell oriented away from the centre of the group and a rhizoidal cell that is pointed toward it.

Groups of two to four eggs show the phenomenon as well as masses of 50 to 100 do. Radiating designs of striking beauty are common in smaller aggregations. The rhizoids are directed toward the centre of the group regardless of the experimental arrangement and rearrangement of the eggs before germination. When large, compact masses of eggs are surrounded by others that are two egg diameters or less away from the periphery of the group, the latter develop their rhizoids toward the central mass. The eggs near the outer margin of a large group also show a similar orientation, while those in the very centre, surrounded by equal influences on all sides, tend to divide to form equal and similar cells at first cleavage.

Aphid Wings.—Aphids are the soft-bodied insects commonly known as plant lice. An aphid obtains its food by inserting its long, sucking mouth parts into a plant and sucking up the plant juices. The schematized life history runs as follows. sexual forms appear in the autumn and an overwintering, fertilized egg is formed that hatches out the following spring into a wingless female. This female, the so-called stem-mother. produces eggs that develop without fertilization—that is. by natural parthenogenesis (*q.v.*). Like the stem-mother, the new females are usually wingless and, in turn, soon give rise to young by parthenogenesis. The progeny settle near the mother and soon build up a densely crowded colony.

Winged females appear after a time and fly to new host plants where, still without sexual fertilization, each produces a new crop of wingless. parthenogenetic females. The induction of wings is distinct from the production of bisexual forms; in fact, most female aphids that require fertilization are wingless, although the males are usually winged.

The production of winged aphids by members of a wingless colony is often most opportune, corning as it frequently does when a given food plant is becoming overcrowded. Several environmental factors are known to affect the process. among them temperature, length of day and incipient starvation. The degree of crowding is also a potent factor for many species; sometimes it is the dominant influence. For such species, the more crowded the mothers the more winged forms develop among the offspring

The racial importance of such a control of wing production in aphids is easily seen. The power to emigrate thus attained by the progeny of a crowded colony facing a diminishing food supply brings survival values for the species. Here, more than in most instances among animals, man included. the dangers of overcrowding have been avoided by the evolution of adaptations that give an obvious illustration of the principle of unconscious, natural co-operation.

Sex Determination.—In certain widely distributed instances in the animal kingdom, the determination of the sex of the developing individual depends on association with another organism. The flagellate *Chlamydomonas,* a protozoan claimed by botanists to be one of the algae, shows much lability. It lacks the characteristic flagellum when grown in the dark in Knop-agar cultures. The flagella and resulting mobility develop if the cultures are placed in the light, or in darkness when weak solutions of certain sugars are added or when filtrates are introduced from cultures of actively swimming *Chlamydomonas*. In the last instance, swimming forms are induced by the addition of something given off by active cells.

The motility-producing compound, which has been isolated, is known to be the organic chemical crocin, a carotinoid derivative. It is effective even when only one part is present in 150,000,000,000 parts of water. Conditioning by related chemicals induces mutual attraction of the free-swimming gametes, which unite only if the water also contains the proper conditioning agent. The gametes of a hetervecious species are sex labile and may become all female or all male if treated by female-conditioned or by male-conditioned medium. In this plantlike animal, the sexes are not clearly differentiated, but there is a gradation of sexuality in which sex can be pushed toward maleness or toward femaleness by the presence of products of metabolism from previous or from current inhabitants of the culture water.

The large female of the worm Bonellia harbours small parasitic males within her uterus. The fertilized eggs are shed into the surrounding sea water. If the free-swimming young settle on the proboscis of a female Bonellia, they transform into minute males that become parasitic on the female worm. Those that do not come under female influence normally become functional females themselves. The sexually indifferent larva obtains some substance from the proboscis of the female that retards growth and produces a male. The external relations—usually the social relations, or lack of them—determine which of two alternative paths of development will be followed.

In several other well-studied cases, sex depends on population density. This situation has been worked out with care for certain nematode parasites of grasshoppers. If a few eggs are introduced into each of many grasshoppers, the resulting adult nematodes are females: if many eggs are given to each grasshopper, the nematodes are almost all males. The observed results cannot be ascribed to male-producing eggs having been killed off in one instance and female-producing ones in the other—a real transformation has been effected. The sex of the developing embryos must have been determined by the crowding of the nematode parasites within their hosts.

Change of Sex.—A variety of animals show consecutive sexuality. One and the same individual is first a male and later a female. With many, maleness is the juvenile, femaleness the more adult condition. This variety of sexual lability occurs in several invertebrate animals; among others, it is typical of some echinoderms, several mollusks, some annelid worms and certain crustaceans. In some cases the duration of the male phase depends on whether the animal has female associates.

Individuals of the Ophryotrocha, an annelid worm, in early maturity function for a while as males and then switch over and become females. The female phase may continue until the individual dies, or the male phase may be resumed. It depends in part on the surrounding conditions. When a few of the anterior segments of a functioning female are cut off, a tail regenerates on one piece, a head on the other, and both regenerated pieces become males. Later, if conditions are favourable, each becomes a whole female. A male may be continued as such for a long time by repeatedly removing the posterior segments. Many adverse conditions, including starvation, likewise cause females to revert to maleness or delay the fully developed male from becoming a female. The presence of waste products in the water pushes the reaction in the male direction.

When two females are placed together in a small dish in the laboratory—presumably something similar would occur under comparable conditions in nature—the more vigorous female may obtain a male mate by biting the other in two, by securing the major portion of a scanty food supply, or by being better able to resist the masculinizing effects of excreta-rich water. In time, the newly reverted male may become the more vigorous, develop into a female and cause the long-time female itself to become a male.

The sex of these worms is thus highly labile. The functional expression at any instant depends on a complex of factors that is not clearly understood. The complex includes the degree of conditioning of the medium. the presence or absence of other worms, and their degree of physiological dominance if present.

A similar case, with pertinent variations, is that of the boat-shell snails called Crepidula. Active sexual association with a female causes many males to remain members of that sex longer than they would if isolated. Among all species of *Crepidula* so far studied critically there are a few males that do not change sex; these are the so-called true males, as compared with the hermaphroditic males that constitute the majority of the population.

In the above instances, both sexes are normally present in the population. In one much-studied group, however, the species is carried for many generations by the female sex alone. This group is the cladocerans, or water fleas, primitive crustaceans of which *Daphnia* and *Moina* are examples. The sexual history of the cladocerans resembles that of aphids. Outbreaks of bisexuality occur usually as the pond becomes dry or as autumn sets in. The fertilized eggs are resistant and carry the species over a period of stress. They hatch into parthenogenetic females with the advent of better conditions and the race is made up for some generations of females only. Crowding the females of Moina is an effective method of inducing bisexuality. Crowding acts by decreasing the amount of available food, or by the overproduction of waste products, or perhaps by both of these combined with other unanalyzed factors. In any event, the close association of many parthenogenetic females results in the production of eggs with a prospective potency different from that of the eggs these same females would have produced if uncrowded.

Survival Value.—The adaptive value of a mechanism that produces when needed males, sexual females and the resulting resistant eggs is obvious. This frees all members of the race to be egg-producing members of the community when environmental conditions favour rapid expansion of the population. Each of the other instances cited can also be shown to have certain survival values.

As a result of the specialized method of sex determination that has been evolved in *Bonellia,* the potential loss of males is partially avoided. If the wandering, sexless larva reaches a suitable environment, it transforms into a female and is then able to direct the transformation of the next comer into a functional male. The survival value of the sex situation in *Crepidula* is similar; that in the nematode worms is more complicated and is associated with the necessity of avoiding overcrowding of the host species if the parasites are to persist.

2. Behaviour.—An animal shows social behaviour when its reactions differ in the presence of others from its normal solitary behaviour. The socially induced behaviour may or may not have survival value. A higher type of sociality is indicated when the behaviour of one animal is oriented with reference to another or to a group of other animals. A yet higher type of sociality is indicated by behaviour that differentiates between one individual and another. or between groups of animals.

As in many other aspects of sociology, it is interesting to apply the behaviour test to the Protozoa to find to what extent such evidences of social life can be found among animals without differentiated cells. Whatever sociality they show is a part of the life of a whole organism structurally limited to a single cell and represents sociality at the free-living cellular level. Protozoans reach primitive stages of the highest level of social behaviour, particularly in what has come to be known as the mating-type or sex-type reactions.

Sex-Type Reactions in Protozoa. — The full extent of the distribution of sex types among protozoans is unknown. Individual protozoans belonging to the same sex types do not conjugate with each other. They do conjugate readily with a member of the other sex type or types of their own variety; sometimes — though less readily — they conjugate with a sex type of a different variety. Often they will not conjugate across varietal lines.

An individual will bump into others of its own sex type and merely modify its course of swimming. If animals of a different mating type from within the same variety are introduced, individuals from the proper sex types will adhere, perhaps end to end. or in any other possible position, when they make contact with each other. They swim about clumsily and pick up others, each sticking to an individual belonging to the opposite sex type. A clump of some hundreds may collect thus in Paramecium bursaria. Later a reshuffling occurs; the clump breaks into conjugating pairs in which each animal is finally lined up parallel to its mate and with the oral surfaces adhering. The conjugation continues for 36 hours or more and involves the interchange of nuclear material. Then each breaks free and starts life as an ex-conjugant. All the asexual progeny of a given individual are said to belong to the same clone and. exceptions aside, continue to be members of the same sex type to which the parent ex-conjugant belonged. The clones show periods corresponding to youth, maturity and old age. They do not conjugate in early youth; the transition between youth and maturity is often marked by tentative conjugation; maturity is the period of normal conjugation; and in old age, the ex-conjugants usually die.

Other types of social behaviour of protozoans include the reaction pattern of some ciliates in which, after establishing contact. the members of a chance pair turn and swim side by side with their cilia touching though their bodies remain apart. This may be an example of exploratory behaviour related to the process of finding suitable mates, since in some species it is a regular preliminary to mating.

Lethal effects of one stock on another are known for P. *aurelia*. Such toxicity may be important in natural selection, for the producers of the toxic material would eliminate the members of a susceptible stock with which they were in close association. Such effects may well be an example of competition resulting in unconscious dis-operation for the susceptible stock.

Locust *Phases.*—Swarming locusts. or grasshoppers, are a widespread phenomenon, especially in or near the warm, semiarid regions of the world. Field observation indicates that in an exceptionally favourable season. the population density of grasshoppers in a given area increases notably. If the animals belong to species that lack swarming phases, no marked emigration occurs. and the numbers eventually fall when the environment becomes unfavourable. If the crowded population arises primarily from an increase in numbers of the solitary phase of a polymorphic species. then, when the nymphs become so abundant that individuals repeatedly come into close contact with one another, the latent tendency toward gregariousness is awakened and the development of a swarming phase has begun. The processes so started increase in intensity with continued crowding until swarming and emigration or other factors bring the population density below the critical level — that is, the level that awakens the drive toward close aggregation. The decrease in density may result from emigration, from changes in the physical conditions or from the increased activity of enemies (man included), or from some combination of these population-checking forces.

A growing mass of evidence' indicates the artificial crowding among polymorphic species tends to produce nymphs whose characteristics approach those of phase gregaria and that isolation brings trends toward phase solitaria. One striking characteristic of the crowded nymphs is their great increase in activity.

There is much that is not known about the underlying causal physiology of the behaviour of these locusts. Existing evidence indicates that mutual stimulation raises the rate of activity of the aggregated grasshopper nymphs. It is not known how the increased activity is related to the production of the distinctive black and orange or yellow coloration of the gregarious nymphs or how its absence results in forms lacking these colours. The important point contributed by these polyphasic grasshoppers to general sociology is the strong suggestion that, in these species, not only striking behaviour patterns but coloration and structural patterns as well are controlled by population density.

3. Social Facilitation. — In general, social facilitation reiers to any increment in frequency, intensity or complexity of the behaviour of one individual resulting from the presence of another. Social facilitation usually implies an increase in frequency, intensity or skill resulting from mutual action; it may also refer to an increased tendency to remain quiet. Social facilitation is involved in observational learning, although this is usually called imitation or contagious behaviour. The forerunners of social facilitation can be seen in many of the phenomena of mass physiology. Thus, grouped sea urchin (*Arbacia*) eggs are accelerated in their early cleavages, and grouped protozoans often undergo asexual divisions at a faster rate than would be shown if each were isolated Similar accelerations are known among bacteria, and the added activity of a number of bacteria working together, compared with the results when each works alone. is a measure of their communal action. Facilitation across species lines, called synergism, is also well known for bacteria.

Social facilitation in behaviour is shown by a variety of animals under diverse conditions. Rats fed in a group of five consume as much as 70% more food than is consumed when each eats alone. Hens may eat only half as much food when isolated as they eat when fed in small flocks. Hens showing no sign of hunger in the presence of food often begin to eat if they see another start to feed. Similar behaviour is known in children and has been demonstrated for many animals, including a number of species of fish.

The degree of social facilitation in the food-taking of fishes has been best studied by feeding the fishes known numbers of the common water flea *Daphnia.* Social facilitation does not occur if too many *Daphnia* are introduced, and a so-called confusion effect develops instead. In one instance, groups of goldfish ate more *Daphnia* than did four similar but isolated goldfish, until about 600 *Daphnia* were introduced at one time into the relatively small aquarium. The cloud of active small crustaceans darting in all directions seemed to confuse the fish and the rate of consumption fell off. When a similar number was introduced in small, successive lots, the fish again showed full group facilitation in food consumption.

The observations of fishes feeding on *Daphnia* give a good demonstration of both aspects of the confusion effect: the decreased consumption on the part of the predator and the added survival value that mere numbers furnish for the prey. This is another instance of the survival value of optimal numbers.

Caged rhesus monkeys eat oranges more readily than they eat bread. They eat more of both under controlled social conditions than they do when isolated, but the degree of social facilitation is much greater for bread. Chimpanzees are more likely to eat filter paper if they see a man eating similar stuff; this represents a kind of inter-species facilitation. Under some conditions, competition is a factor in social facilitation; for example, the presence of an imprisoned but clearly visible rat does not stimulate another to eat as does a free and active competitor. In other cases, the stimulus comes from seeing the activity of others without the presence of recognizable competition. Both factors enter into social facilitations in various learning situations with a variety of animals. The goldfish is not notably a schooling fish, and yet goldfish learn a simple aquarium maze more rapidly and with fewer errors if several are present together than they do when the same number of goldfish are trained in separate mazes. There is a tendency for the grouped goldfish to move together in a body and to be less disturbed by outside stimuli and so reduce their learning time. A trained leader mill accelerate learning even more.

Extra animals present in the learning situation may retard learning and so produce mutual interference in place of mutual acceleration. This has been found to be the case for a variety of animals. including cockroaches and shell parakeets. Both retardation and acceleration have been found in studying the effects of numbers on the rate of learning in children. The nature of the effect produced depends in part on the problem and, in part, on the personalities involved.

Social facilitation occurs among representatives of the highly social ants. Some species of *Camponotus* dig their nests in soil. They can dig when alone, but the rate of work varies with different individual ants apparently in correlation with deep-seated physiological differences. If marked ants are placed together in pairs, or in groups, they start digging sooner and work with more steadiness than they do when alone. The accelerating effect is greater for naturally slow individuals than it is for rapid workers: when ants intermediate in speed are used, they work faster in company with a rapid worker and are slowed down by the presence of one with slow working tendencies.

The presence of other animals of the same species frequently acts to reduce the activity of all present over that shown when each is alone. This social facilitation of relaxation has been carefully studied in the goldfish, in which activity was decreased from one-fourth to one-half in the presence of other similar fish. In this instance, sight of a single associated fish is sufficient to produce a decided quieting effect and even the presence of its own image reflected in a mirror reduces the activity of an isolated goldfish.

Some aspects of social facilitation approach what is called imitation in human behaviour. Often such behaviour is spoken of more objectively as contagious. Goldfish learn to swim a simple maze more readily if they have been placed so that they can see others learning. Song sparrows reared in the half-freedom furnished by an ornithologist's study were stimulated to contagious activity in a number of ways. When one sparrow ate, bathed or preened, the others were likely to do likewise; when one flew to the desk, another usually follo ed. Grouped chimpanzees that have some freedom of group movement show waves of activity that seem to be passed along by contagion. Social imitation as seen in man has its forerunners in the behaviour of other forms.

4. Co-operative **Behaviour.**—The literature of natural history contains many accounts of group co-operation of animals in nature. Often these anecdotes are more colourful than critical, but some are certainly trustworthy. Among the American pronghorns, if enough animals are present, an effective defensive group will be formed under pressure of attack by wolves or coyotes. Variants of group defensive action range from the "mobbing" of an attacker by a flock of birds, each individual of which is relatively weak, to the orderly retreat of a horde of baboons with the females and young in the places of least danger.

The group fishing of the double-crested cormorants gives an example of elaborate group co-operation. These birds may be seen fishing entirely alone and in small co-ordinated flocks of from 10 to 12 individuals. They also fish in giant flocks of as many as 2,000 birds. Fishing operations usually begin before the flock is fully formed. The basic pattern in the small flocks consists of a circular arrangement with all birds facing in the same direction. This pattern is changed when large flocks are formed; then, a long, narrow, well-packed line moves forward, fishing as it goes. Some of the cormorants swim at the surface. some swim at the same rate below the surface, and those left behind in the rapid advance take to the air and fly forward to catch up with the others. These large flocks pursue a given school of fish until the hunger of the birds is satiated or the school escapes. The small flocks swim at about two-thirds of the speed of the largest ones

Co-operative behaviour under laboratory conditions has been clearly demonstrated in mammals as far down the taxonomic scale as rats In the best experiments, pairs of rats were placed in an experimental situation that required the co-ordinated efforts of both animals if either was to obtain food and at the same time avoid an electric shock. Each rat was trained individually to feed when the region of the food was not electrified. When a shock was felt, the rat learned to go to a platform arranged so that the added weight of the rat cut off the electric current. When two rats, so trained as individuals, were placed together in this situation, they learned to take turns at the food dish and on the platform so that one cut off the current while the other ate. Pairs of rats even learned to co-operate in a more complicated situation in which the possibility of being shocked was present only 25% of the time. The co-operation disintegrated in the complete absence of the electric shock. Roughly similar evidence of co-operative food-getting has been recorded for cats even when the situation was complicated by one cat being socially dominant over the other.

Chimpanzees learn to execute still more complicated co-operative patterns. In a fairly complex situation, each of the selected chimpanzees learned by trial and error to operate four devices in a given sequence in order to obtain food from a mechanical vendor. Then pairs were caged close together and within easy sight of each other but separated by an open grille. Each chimpanzee could reach two of the four devices that must be operated. and each had a food vendor in its cage. If both operated the available devices rather steadily, food would be obtained now and then by a chance operation of the appropriate sequence. Co-operative behaviour was considered to have been given when one chimpanzee watched its partner's performance and pushed at the gadgets available to it at the proper time as indicated by the colour sequence. They often obtained food in a somewhat systematic fashion. The chimpanzees were also judged to show co-opelation when so-called solicitation was evident; at times the solicitation clearly indicated the location of the next device to be pushed. Meredith Crawford, who did these experiments, observed:

> The directive elements of the solicitation, that is. the bodily orientation of the partner, were clear and human-like. Perhaps it is significant that a soliciting animal never pointed but always used what seemed to be the more primitive method of pulling or pushing the partner. . . . It may be that an important transitional step in the development of language behaviour lies between the direct orientation of one animal by another through body manipulation and indirect orientation through pointing toward a distant object (Jour. Soc. Psychol., 13:278, 1941, Journal Press).

III. ORGANIZATION OF ANIMAL GROUPS

The most primitive of animal aggregations, sociologically speaking, show no discernible organization. Some of the highly integrated invertebrate groups--colonies of bees or ants, for example —have types of organization that can be perceived in part but about which real understanding of the fundamental relationships cannot be gained. The organizations of vertebrate groups are more obvious and more like our own. They are based on three general principles: (i) territory. (2) dominance-subordinance and (3) leadership, with. of course. the important complementary quality of followership.

These different. types of social organizations intergrade with each other to form complicated social patterns that fall into certain recognizable trends in the vertebrate groups beginning with fishes , There is some evidence of the operation of each oi the principles even among invertebrates. Thus hermit crabs display dominance based on size and force: crayfish show spaced aggregations in which a certain amount of territory about the individual is kept free of intruders, and some ants show leadership-followership relations. In the main, however, discussssion of group organization in this article is restricted to groups of fishes, reptiles, birds and mammals.

The study of organization requires the consideration of a set of phenomena that are not encountered in the analysis of the primitive. basic relations that make for survival of an organized aggregation or of group effects on behaviour. Defense of territory and the establishment and the maintenance of social dominance often call for hard fighting between the individuals of a contact pair. This aspect of intra-species struggle appears later in evolution than does primitive automatic co-operation. It is apparently made possible in part by the functioning of natural co-operation and of group-oriented behaviour which. together with gradients in the physical environment,, permit or condition the formation of aggregntions. It is only when animals are somewhat aggregated that organization becomes possible.

A. Territory

A territory, in the sense of comparative sociology, is a more or less restricted area that is actively defended against trespass by other individuals of the same species and sometimes against trespass by other species. Territorial behaviour is a complex phenomenon In full development, in its least complex form, this type of behaviour is based both on a positive reaction to a particular place and. within that area, on a negative reaction to other individuals of the same species, except for a mate or mates.

1. Types of Territorial Relations. — Information about the social aspects and implications of territorial organization is richer for birds than for any other animal group, and birds shon the following types of territorial relations. (1) mating, nesting and feeding ground for young: (2) mating and nesting but not feeding ground; (3) mating station only; (4) restricted to narrow surroundings of the nest: (*a*) solitary individual. (b) colonial birds; (5) winter territories; and (6) roosting territories This classification does not include all known instances of territorial behaviour among birds when territory is given the simplest, most inclusive definition of any defended area.

Blue geese (*Chen caerulescens*) were observed in' a bird sanctuary to defend the following territorial types: (1) family territory; (2) mated-female territory; (3) feeding territory; (4) nesting territory; (5j resting, or resting and sleeping, territory; and (6) moving territory. The last type was shown when a family of four kept a certain amount of nearby space clear from geese of their own and other species when they swam about as a family. These territories varied with time of day and with the season of the year. The defended area may be fixed and well-defined; the boundaries may vary or the whole territory may be established only transitorily.

Although the variations are great with different species, each of the types of territories possesses definite social implications. The territory may be taken up before or after mating. Some unmated males do not maintain permanent holdings: others do. Territories are often abandoned in winter. although some birds retain them even then. When one male has more than one mate, his holdings may be subdivided. The role of the female varies greatly in territorial behaviour; often she does not defend her mate's boundaries, though sometimes she does. Some flocks hold and defend definite areas, whereas others do not, and the flock territory may or mav not be subdivided.

Territories are often compressible depending on the population pressure in the given area and also on the ability of the male in territory defense. The defense of a given territory frequently entails active fights. With widely different species the combats may be formalized. Singing of birds and other sorts of defense short of direct use of force are well authenticated. Hordes of howling monkeys engage not in fighting but in howling encounters when they meet near their common boundary line.

When territoriality is well developed there is a reserve of unmated males and females that makes possible the prompt replacement of a lost mate in a functioning territory.

2. Biological Values. — Some of the general biological values associated with the territorial habit in birds are: (1) the unconscious organization of a local population into what may be regarded as a well-spaced aggregation: (2) promotion of monogamy, which is often important in rearing helpless young; (3) limitation of the breeding population and hence partially controlling population density; (4) provision of a relatively safe and defensible breeding place that often contains (5) insurance of an easily accessible, adequate food supply for adult and young birds during the rearing of the brood; (6) reduction in the rate of spread of diseases; and (7) reduction of fighting and thus conservation of energy. With suitable modifications, many of these values are to be found in the territorial behaviour of other kinds of animals, especially of fishes, lizards and mammals that defend restricted areas.

3. Relation to Dominance-Subordinance Hierarchies. — The territorial type of organization of populations is closely interrelated with the social hierarchies that often develop in smaller groups and that are based on dominance-subordinance relations. In fishes. for example, in a restricted amount of undivided space. certain species form a dominance hierarchy, whereas the same individuals in a larger aquarium. or in one that is partially subdivided, will establish defended territories. Usually, the lowest fish in the hierarchy is the last to obtain a territory and. if available niches are few. it may not establish one at all.

A territorial animal fights more fiercely within its own territory than when invading that of another animal. Sometimes, at least. the decrease in fighting power is related to relative distance from the territorial centres of the combatants. A bird that is socially subordinate in neutral. unclaimed territories tends strongly to become dominant in its home territory. Among various birds, especially pigeons. given individuals establish territories even in a sizable laboratory cage or small house. Records of fights under these conditions show now one of a pair and now the other winning, depending on the territory in which the combat takes place. Such relations furnish one transition from an organization based primarily on defended territories to social hierarchies of dominance and subordinance considered below.

There is no certainty as to whether territoriality preceded dominance hierarchies in evolution, or concerning the general sequence of these two forms of organization in social development. It is not even known that these social patterns are related in evolution; they are not necessarily so. even though they are often functionally interrelated. Young individuals of the green sunfish (*Lepomis cyanelltis)* in laboratory aquariums first form social hierarchies; later, with the approach of breeding, the males establish territories; similarly, with many animals, social hierarchies give way to territorial organization during the breeding season. On the other hand, certain ground squirrels of western North America, belonging to the genera *Eutamias* and *Citellus,* leave their individual territories and collect about food when this is locally abundant. The collected animals then form hierarchies that are revealed by definite chasing orders.

B. Dominance-Subordinance

There is little evidence among invertebrates concerning the existence of dominance-subordinance hierarchies resulting from contact relations between pairs of individuals. There is much evidence of the subordination of the individual to the whole social group such as occurs among the highly social insects. The causal relations whereby the entire group comes to dominate all the individuals composing it are only partially known.

In the higher fishes. social hierarchies based on individual dominance appear with many of their characteristics already in a high state of development. Final social status is typically determined after the first few contacts between two fishes and may harden soon into a fairly lasting despotic relationship in which the dominant member of the contact pair nips or drives or threatens the subordinate one without receiving nips or even threats in return. Such a social system is also known among the slow-moving turtles, as well as among the more active lizards. It is well developed in many birds and among mammals. Probably more is known about social dominance and subordinance in common chickens than in any other lower animal. The modern period in the study of social hierarchies was initiated by Thorleif Schjelderup-Ebbe in 1922.

1. Pecking Order. — The most fixed type of social hierarchies among birds is based on what has come to be called the peck-right. or pecking order. The higher ranking individuals are able to peck those of lower rank without being pecked in return. The relations within one flock of white leghorn hens are summarized in the table. The hen RG ired and green leg band) pecked all her subordinates except BR. Each hen of lower rank. except BR, was pecked by all those above her in the hierarchy and in turn pecked all those of lower rank. BY, the omega hen (lowest in the hierarchy), pecked none and was pecked by all.

A flock of hens may or may not be organized into a simple straight-line hierarchy. One of the commonest irregularities occurs when a hen with medium or even low social status has the peck-right over some individual that otherwise outranks her in general social position. In the flock shown in the table. RR. ranking fourth. was pecked by RW and YY and yet had the peck-right over RG, otherwise the alpha (highest ranking) bird of the flock. A commoner complication occurs when triangle situations arise in which A pecks B: B pecks C; and C pecks A. and then all three have the peck-right over those below them in the social scale and are pecked by all with higher social rank. Pecking triangles occur at all levels in the hierarchy of hens but they are more likely to be found in flocks of cocks than among hens. Sometimes, around a food bowl for example, the hens of a triangle will pass the peck around and around until something happens to break the combination.

The Social Order in a Flock of White Leghorn Hens

The organization in a flock of hens represents a type of social pattern in which dominance, once won, is relatively permanent. The same rank-order has been known to remain fixed for over a year. With pigeons, doves, canaries, shell parakeets and others, although the flock organization is no less real, the outcome of any given pair contact is less predictable. The social structure is based on a differential peck exchange in which dominance is indicated by the ratio of victories to defeats between the members of each contact pair. Such flocks are organized on what may be called peck dominance rather than on the more absolute peck-right relations existing among hens and certain other animals. The peck-dominance type of social order is related in part to territoriality in that animals tend to win contacts in or near their own territories and lose them in those of others. At least under laboratory conditions, peck dominance also occurs among some birds that have not established special territories.

Pecking organizations among birds are apparently based on the ability of birds to recognize and react to their flockmates as individuals. When territory enters as a factor, recognition of the individual's territory also becomes a part of the group reaction system. The space available for the flock often determines whether territory will or will not affect the system. When groups of canaries are caged in a small space, the social order becomes simple and definite; it is little complicated by territoriality. Given more space. individual territories tend to be established in which each bird becomes supreme in his own holding, regardless of how low his status may be elsewhere.

Early observations upon group organization in birds were limited to penned or caged flocks, in which individuals could be readily marked and observed. Later. such social order studies were extended to semiwild flocks and finally to several species of birds in nature.

With hens, under experimental conditions, individuals can remember and steadily give the same social reaction to each one of 25 or more individuals. Still larger flocks can be roughly divided by a human observer into upper. middle and lower thirds. Yet three weeks of absence from even a small flock will cause a hen to act and to be received as though she were a total stranger.

A hen can maintain social position in different flocks at the same time. Once her rank in four or five flocks has been established, she can be shifted back and forth in each flock every day or so and move fairly smoothly into her usual social position even though she has a different rank in each flock.

It must not be thought that hens. or animals in general, go about fighting their associates continually. There are hours together when no such social interactions can be seen. and watching for them becomes a tedious occupation. Hens. for example. spend much time in sunning. or dusting. or just sitting quietly: during such periods, even the omega hen of the flock. if she goes quietly about her own affairs with head held low, may escape blows from all her superiors If, however, she darts about actively. some one or another of her social superiors is likely to threaten or peck. and the pecks frequently are severe enough to draw blood.

2. Individual Differences. — Hens, and cocks too. behave differently toward their various associates. Some peck certain inferiors mildly and infrequently and give more and harder pecks to others than their position in the social order would lead the observer to expect A female despot may allow an inferior to pick food from her bill though others are pecked severely if they attempt to take a similar liberty An alpha cock may even allow an inferior to replace hiiii while mating but will react violently to a similar attempt by another associate There are many instances among these birds of what would be called favouritism and antagonism in human society.

High-ranking hens differ greatly in their reaction to socially inferior flockmates. Some are mild despots: others are severe, driving ones. Some allow inferiors to feed with them; others feed alone. Some inferiors feed quietly between pecks from those of higher social rank: others react strongly to being pecked and cease all attempts to feed for the time being. Often the omega hen feeds only after all others have left the food bowl and may not attempt to eat at all until hunger-driven to accept pecks in order to obtain food: she may even starve to death with only a social block between her and food. The range of individual reactions within a territorial or other social organization is very great.

3. Mammalian Dominance Orders. — Dominance orders are common also in mammalian groups, including mice, rats, hamsters, ground squirrels, cats, dogs. horses, cows, monkeys and apes. Each species presents its special set of variations from the general principle. Mice. since they stand relatively low in mammalian evolution, provide an interesting study. Little is known about their social organization in nature. Given hideaway niches, food in plenty and abundant space. the social picture would be different from that seen in laboratory cages.

Both males and females fight and, as usual, the males fight more frequently and harder. Small groups of male house mice caged together arrange themselves into various types of social orders. In one set of more than *4,900* observations, exclusive dominance of one male without resistance and without fighting among subordinate animals was found in *43%* of the cases. Sometimes there was resistance by one mouse, or a hierarchy of three ranks might be formed in a group composed of five mice. Often there was no fighting at all for several days. Once exclusive dominance in mice is established, it may persist unchanged for months, although the statistical expectancy of continued dominance for one individual in a long series of tests was found to approximate three weeks.

The temptation is great to summarize at length the details of social dominance in monkeys and apes. The reader should consult the books by S. Zuckerman (1932) on baboons and by Robert Yerkes *(1943)* on chimpanzees, cited in the bibliography, as well as the accounts by Clarence R. Carpenter of his observations of howling monkeys in Panamá (1934), of gibbons in Siam *(1940)* and of the semiwild rhesus monkeys on Santiago Island off Puerto Rico (1942).

Howling monkeys live in bisexual hordes with each group confined to a given territory. The usual adult sex ratio is three males to seven females. Complemental males roam through the tropical jungle between the groups and, if persistent, may gradually gain admission to some horde, or form the centre for a new one. The minimum observed size of these howler hordes was four, one male and three females. The largest numbered 35 animals of which *19* were adults — 5 males and *14* females. A co-operative group of adult males dominates and co-ordinates the howler clan.

Rhesus monkeys belong to the old world tropics. Those introduced on Santiago Island numbered about *350* in *1940.* After about two years on the island, they had organized themselves into five bisexual groups and two groups of males only. Typically the young male separates from his home group in early adolescence. joins a gang of other young males and lives with them until he is nearly adult; then he eases himself back into a bisexual horde and may gradually advance in social rank. On the average there are six females for each of the males in an adult group of these monkeys.

Dominance gradients exist in the unisexual groups of young males, and separate gradients are found for the males and the females in the bisexual hordes. The lowest-ranking male ordinarily outranks the female of highest rank. Females are characteristically subordinate to males in all the social groups of primates that Carpenter observed in nature with the exception of gibbons, whose adult males and females are co-dominant.

Groups of gibbons are smaller than those of howler or rhesus monkeys and may consist of only two individuals, a mature sex pair. They are essentially family groups in which headship rests equally on the two adults. Senile individuals may or may not be retained within the group. Gibbons of both sexes are very aggressive and now one, now the other dominates in such activities as feeding, play or sex behaviour.

Group life is normal for chimpanzees. Within the group, certainly in artificial segments arranged by man. dominance-subordinance relations form the chief means of social organization. Males usually dominate females, although regardless of sex the smaller, weaker, less enduring chimpanzee tends to be the subordinate member of a caged pair, particularly if these traits are combined with such psychobiological factors as sweeter temper, less courage and less social assertiveness.

One set of six female chimpanzees, observed in all possible pair combinations, showed a hierarchy of dominance in their success in competition for food. Mira and Nana showed a complete reversal of dominance during the period of observation. Nana, Cuba and Lita formed a social triangle somewhat like those existing among hens. Bentia and Lita were decidedly less dominant than the others. and members of the more dominant quartette associated with them more closely than with each other Often there is tension between aggressive animals with nearly the same social status.

These apes reacted socially with each other only 17% of the time they were together. Of this time, less than 1% was devoted to definitely aggressive action. (Groups of male mice similarly spend about the same amount of time in aggression.) Almost 63% of the social behaviour of apes consisted in grooming and about 33% of their interactions were devoted to play of one kind or another, not counting the approximately 3% spent in one form or another of sex behaviour.

4. Signs of Subordination. — Taking vertebrates in general, the most certain sign of dominance is the winning of a definite pair contact. Sometimes an individual gives ground because it has been temporarily out-fought or out-bluffed; it may return to the fray and win eventually. Defeat is often accompanied by easily observed signs of submission. A defeated fish often drops its challenging attitude of tense body and bristling fins; the whole length seems to hang limp in the water; the fish backs slowly from the victor and then turns and flees. Beaten lizards are known to give what is called the subordinate head nod, and the American "chameleon" *(Anolis),* with unconscious aspersion, has been described as turning a dirty yellow colour. Many animals, hens and mice among them, sometimes emit characteristic cries when defeated With hens, the face and head furnishings blanch, while those of the victor are literally flushed with victory. Defeated mice show submissive body postures.

Signs of social subordination also include the wary avoidance of superiors: moving quietly with head held low; hiding in obscure places or in protected corners; and accepting or even offering to assume the female position in pseudo-copulation. Yerkes was much impressed by many feminine aspects of the behaviour of socially inferior male apes.

5. Social Status and Sexual **Behaviour.**—Social status and sexual behaviour are closely interrelated. Although male animals usually dominate their associated females, this is not always true. and it can be demonstrated by a simple experiment that in some fishes, at least, social and sexual drives are distinct. Gradual cooling of the water around sword-tail fish (*Xiphophorus helleri*) causes them to lose their sexual appetite before the drive for social status disappears.

There is great variety in the relation between social rank and mating behaviour. The howling monkey hordes in the rain forests of Panamá, with their low dominance gradients, show no correlation between social dominance and the sexual possession of a receptive female. At the other extreme: in the half-wild rhesus monkey hordes on Santiago Island. the dominant male has exclusive possession of a single receptive female and, if more than one female is in sexual heat at the same time, the dominant male asserts his rights during the mid-period, when copulation is apparently most satisfactory.

When chimpanzees are paired in a cage, the male takes possession of limited or of unusually attractive food until the female comes to the sexually receptive stage in her regular cycle; then the dominant male gives way and the female gets first access to the food. The interplay of social forces here is complex and is affected by personality traits of both members of the sex pair. It is significant that when two females are caged together precedence of food also shifts from the socially dominant to the subordinate when the latter is sexually receptive. Yerkes *(1943)* reported many wiles by which a subordinate female chimpanzee may manage somewhat her dominant mate.

A socially dominant cock living with other males in a flock of hens may so suppress the subordinate cocks that the latter cease to mate with the hens. An essentially similar reaction has been reported for males of the sage grouse in Wyoming, in which so-called master cocks, comprising about 1[illegible] of all the males. make some 74% of the matings. and about 97% of the cocks make only 3% of the matings.

6. Survival Values.—Females standing high in the social hierarchies of flocks of hens, at least. under some conditions, are courted and mated less than are their lower-ranking subordinates. To the extent that this affects egg fertility. high social rank tends to lessen the long-term survival value for hens. This disadvantage is offset by some decided advantages. Briefly put, high social rank allows greater freedom of movement and certain essential priorities, notably as regards space, food and female mates. Low position in the social gradient carries restrictions that may be very severe and even fatal for the life of the individual. As indicated earlier, socially suppressed hens may starve within a few feet of food; and Arthur A. Allen observed that ruffed grouse, strongly subjugated by associates in a laboratory pen, may die for no known physical cause, though dominant grouse survive.

Dominance-subordinance organization among most vertebrate groups results from interindividual fights or threats. There is competition, often strong competition, for social status. The fighting may reach disruptive strength, as it does between males of the fighting fish, *Betta splendens;* but when the pair conflicts are not too severe they result in an organized group that has some rather definite survival values as a group in comparison with other aggregations in which organizational fighting is still in progress. Thus mating reactions are more normal in hierarchial groups when the organization is well established. and flocks of hens with an accepted peck-order produce more eggs, as a flock. than do similar lots of hens that are in the process of organization.

Competition at the individual level, in such instances. leads to the possibility of closer co-operation or to more effective competition between groups as units. Also, and obviously. co-operation between individuals produces similar results at the group level. Here again it is evident that, up to a certain degree. competition may be a form of co-operation or at least of proto-co-operation. When the interindividual conflicts become overintense, as in *Betta splendens,* competition is disruptive.

Conflicts and co-operation between small group units show similar relations with respect to larger, more inclusive group federations. If the intergroup struggles are not too severe, they yield more comprehensive organizations that have the increased power inherent in a generally accepted, smoothly working organization containing large numbers of individuals. The same effect may be produced by combining smaller co-operative units into a large whole, such as happens with many flocking birds.

C. Leadership

High-ranking members of a dominance hierarchy possess many social privileges that are not necessarily accompanied by social obligations. and alpha status in the social order is not necessarily correlated with leadership. The alpha hen in a foraging flock may or may not be at the apex in the line of advance; often she is not, and. in any event, the leading bird seems always more or less dependent on her followers.

In contrast. leadership may be closely associated with dominance as in the semiwild hordes of rhesus monkeys on Santiago Island, or it may exist without an obvious dominance order, This last relationship is approached in the Scottish herds of red deer that F. F. Darling (19373 watched, among which an old. experienced female—usually with a fawn of her own—is the leader of the herd. In pure development, leadership carries with it a variety of social obligations without corresponding social privileges.

Social organization based on leadership shows greater flexibility than does organization growing out of territoriality or from dominance-subordinance. Leadership can bring types of social efficiencies, in group protection for example, not provided by the other two organization types. The analysis of leadership is less complete than that of the others; much detail is known but generalization is difficult and the following treatment is in part tentative.

As with dominance and territoriality, individual leadership is better developed in groups of vertebrates than it is among invertebrates. Individual leaders are known among some species of ants in small artificial colonies: as in a Chinese species of *Camponotus;* and in nature as well, especially in *Eciton,* army ants of the American tropics. The raiding columns of these army ants show a shifting type of leadership with the ant or a small "pushing party" of ants at the apex advancing in a hesitant manner and then returning to a larger mass; as in hens, these ant pioneers are apparently much dependent on their followers.

With vertebrates, leadership is known among fish, lizards, birds and especially mammals. An experienced fish will lead inexperienced followers through a simple laboratory maze and so help them learn the shortest route much more rapidly than they can learn it when no experienced leader is present.

Leadership in flocks of birds presents many puzzling problems, of which the most basic deals with whether the front bird is really leading the flock or is merely the fastest flying or one of the least tired birds. In one well-authenticated instance, a mixed flock was composed of a dozen black-bellied plovers, two young dowitchers and a single golden plover. When the flock was flushed, the faster flying golden plover was soon ahead of all the rest. The dowitchers were slow and tended to fall behind, and when this happened the black-bellied plover wheeled. This affected both the apparent leader and the followers. The golden plover, finding itself alone, rose above the others, reoriented, and with a few rapid wing beats dived ahead again, apparently the leader of the whole flock. The slow-flying dowitchers caught up by taking the shorter course directly toward the circling flock. Soon they fell behind again and the whole series of reactions was repeated. There is almost as much reason for regarding the fast-flying golden plover as following along ahead of the flock as there is for thinking that the slow dowitchers were following behind it.

This whole set of phenomena illustrates pseudo-leadership. The essential orientation is furnished by the body of the flock and the stimulus for turning may originate on one of the flanks rather than being given by the leading individual. Pseudo-leadership is well known to exist in other animals.

In groups of gibbons leadership as well as dominance shifts back and forth between mates. Here. as often among mammals, high social status and leadership are closely correlated. A striking exception is shown in herds of red deer in the Scottish highlands. During the rutting season. stags enter the female herds and each rounds up as many hinds as possible. The stag dominates the hinds. If danger approaches, off goes the stag on his own, and the real leadership is seen to remain with the experienced female that usually leads the herd of hinds and their fawns.

Darling (1937) emphasized a striking difference between male and female-led herds. In the former, as illustrated by the roe deer of England, the group is small, held so by the aggressive intragroup behaviour of the dominant male and, to a smaller degree. of the female roe deer. In the female-led herds of red deer, in contrast. the group tends to be large and the young remain members of the home herd for a longer time.

From such data. the generalization has been reached that throughout the higher reaches of the animal kingdom males tend to be sufficiently aggressive so that they exert a disruptive social influence in contrast to the less aggressive females. Various devices have evolved that centre about this and other phases of the relations of the sexes. Many insects, such as aphids and the more social wasps, bees and ants! produce males in limited quantities and at limited times. The mammalian solution is different; in many gregarious mammals the males join the female herd only during the sexual rut and keep by themselves or gather in small male herds during the remainder of the year. Only among the termites have the males become as highly socialized as the females?and the evolutionary or physiological processes by which this came about are unknown.

D. The Family

Aggregations of both sexes, but of different species, form during the mating season, especially of species that mate at approximately the same time of year. Male frogs will attempt to clasp females of other species of frogs or toads, or, in fact, almost any moving object that they can grasp, even fishes. Coccinellid beetles of different species attempt copulation. Often there are unisexual aggregations of one sex or the other, or both, at or just before the breeding season.

1. Types of Mating Relationships.— Sexual congregations of the same species range down to conjugating aggregations of protozoans. Among higher animals the types of mating relationships include:

1. Polygyny, in which one male regularly mates with more than one female; the situation is fairly common among lizards, birds and mammals, the domestic cock and hens providing a well-known example.

2. Polyandry, in which several males breed interchangeably and successively with one female, is relatively rare in pure form; it occurs when several dwarf males are associated with each female, as in the barnacle *Alcippe* or the worm *Bonellia,* and is found in certain species of spiders in which each female consorts with two males.

3. Monogamy is fairly widespread among animals. It is found among beetles such as the wood-dwelling Passalidae, in which the adult sex pair remain together with their offspring. Seasonal monogamy seems common among many animals, having been reported for certain spiders, some reptiles and many birds and mammals. Longer duration of monogamous relations is also known, the common red fox furnishing an outstanding illustration. Among the apes in nature, gibbon families are based on monogamous mateship.

4. Sexual promiscuity is even more widespread, especially among relatively solitary animals. It occurs among many fishes where the sexes mingle at the spawning grounds. Certain lizards and gregarious bats have this sexual habit. Among mammals, the female muskrat accepts any male that may appear when she is in her short sexually receptive period.

5. The sex relations within a horde of howling monkeys present another variant. These animals form an almost closed group that contains more females than males. Sex relations are communal within the horde. Any female, on coming into heat, accepts the nearest male and, when he is satiated, moves on to another, with no sign of sexual jealousy in the part of either sex.

2. Parent-Young Associations.— The association together of young of the same brood, and still more, the association of offspring with either or both parents, is almost as potent a social force with nonhuman animals as are similar relations in man. Many variations occur. Primary aggregations exist in which the individuals are descended from a common father or a common mother. or from common parents. Such aggregations often remain near the place of hatching or birth and show all gradations between loose and quite firm integrations. The primary reason for the animals being together lies in their common origin, but their continuing aggregation often depends on the favourable character of the place or on the abundance of suitable food rather than on genetic factors. In other instances, social appetite appears to hold the group together.

Primary aggregations may arise as a result of asexual reproduction in Protozoa, of natural parthenogenesis in cladocerans or aphids, or from bisexual reproduction. *Lophyrus* caterpillars, which feed on pine needles, form a larval aggregation that arises in the beginning from the fact that the eggs are laid close together. The female moth departs after depositing her eggs and is not associated with her offspring. The common origin is not sufficient in itself to account for the young remaining together since many other kinds of caterpillars scatter as they become able to crawl about; other forms remain aggregated during early larval life and separate when partly grown; and still others remain together during their whole larval life, spinning a common silken nest and even pupating together, only to separate when adult.

Primary aggregations composed solely of young animals may be all of similar age and size, as in schools of young minnows; or they may consist of infertile workers and potentially sexual animals. as in a bee colony when the old queen has departed with her swarm. All may have one or both parents in common, as usually happens with the caterpillars just mentioned, or the offspring from different individual families may join, forming large groups of mixed parentage. This happens at times with young spiders and is commoner among juvenile fish.

It is much more usual for a mother to remain alone with her offspring than for the father to do so. Newly hatched leeches, tiny crayfishes or minute spiders, clinging to their respective mothers, help show how widely distributed this form of association is in nature. The aphid stem-mother and her brood, mole crickets (*Gryllotalpa*), earwigs (*Forficula*), colonies of ants or bees and red deer and many other mammals illustrate mother-offspring groupings. Each female may consort only with her own young, or two or more family groups may join as do some ants, seals and wild hogs.

In another smaller series of animals, well illustrated among certain fishes. the male guards the eggs after they are laid by itinerant females in the territory that he defends. Often he aerates them by fanning gently with his fins, meantime mounting guard over the developing eggs and newly hatched young. Males of the stickleback and of large- and small-mouthed black bass, among others, have this general habit. Males may establish still more intimate relations with eggs. The male midwife toad *(Alytes)* carries strings of eggs twisted about his legs, and a frog of the Chilean forests (*Rhinoderma darwini)* crams the fertilized eggs into his singing pouch, which becomes greatly enlarged during the breeding season. The eggs develop and transform in the paternal cavity and the young animals hop forth from their father's mouth as fully developed tiny frogs.

The variations from normal family patterns are numerous and sometimes important. Thus unmated wolves may be associated with a mated pair—the whole pack then hunts as a unit—and unmated bob-white quail of either sex adopt orphaned young. Such variations as these have great survival value.

The association of both parents with their offspring is by no means uncommon among insects and is the regular habit with many birds and mammals. Passalid beetles live with their young in the tunnels they make in rotting logs. *Necrophorus* beetles live similarly in decaying animal bodies. Both sexes of social wood roaches. the forerunners of termites, like termites themselves, live surrounded by their offspring. Song sparrows, robins, bluebirds and many others of the commonest birds have this habit. Foxes. wolves, roe deer and gibbons are among the mammals that react so.

It is not known what percentage of all the vast variety of known animal aggregations grow immediately from the family or from recognizable variations of family life. Many of them do. The higher forms of social development among insects arise from the association of parents with their offspring. as in termites, or from one or more females and their young, as in wasps, bees and ants. The family has also been very important in the development of social life of various vertebrates. Important as sex and the family are as integrating social factors, they do not form the sole outlet for the expression of the fundamental social appetites, nor are they the only foundation on which social structures have arisen. Even so, the most permanent societies appear to have developed when sexual and parental integrations have operated in addition to the more elemental aggregating tendencies.

Whatever the pathway taken, the social life of all animals rests in final analysis on the basic nonconscious drive toward natural co-operation that is co-incidental with all life and is especially developed among animals.

E. Extensions and Analogies

Great care must be exercised in forming judgments about the probable social behaviour in untested situations and especially about the inner social feelings of animals under any conditions.

It is unsafe to assume, without direct information, that one order of birds will show social patterns closely resembling those of some species belonging to a different order. It is still more hazardous to try to estimate the degree and kind of sociality across wider taxonomic gaps. For example, pending direct inquiry, it is unsafe to predict that individual-to-individual social hierarchies exist among sharks from the fact that such social rank-orders exist among many species of bony fishes.

Still greater caution must be exercised, again pending direct information on the precise point at issue. before making extrapolations between human sociality and the social life of other species. Men may and do disregard or compensate for inconveniences based on position in the social "peck-order," but we cannot judge therefrom that other animals do likewise. Despite the need for great restraint in such matters, stimulating cross comparisons can be made that help to integrate animal sociology into a unified whole despite the marked differences between the social relations of man and those of other animals.

1. The Organism and **the** Supra-Organism.— The analogy between the biological processes within the organism and the sociological processes within society long ago attracted attention. Thomas Hobbes' Leviathan and the jess cumbersome comparisons of Herbert Spencer in his discussion of the analogies between the organism and society are matters of historic interest only. but they did more or less vaguely foreshadow the modern realization, particularly by biologists. that similarities exist between individual organisms and organized social groups. Since even ecological communities, as well as more closely knit societies, behave as more or less integrated entities. they are often regarded by biologists as representing a set of emergent levels concisely designated as supra-organisms.

Even biologists do not stress the resemblances between societies and a closely co-ordinated organism such as an insect or a man. They do see pertinent resemblances between the social supra-organism and simpler invertebrates. Sponges. for example. often have one part of the individual colony working in direct opposition to another when the co-operation of both is needed for efficient operation of the whole. Starfish, in righting themselves, and even in walking across a smooth surface, often tear off some of their tube feet that were working in opposition to the movement of the whole.

Society, human society as well as an insect society based primarily on inherited behaviour patterns, shows many pertinent comparisons with these more poorly integrated organisms, and yet primitive organisms and primitive or advanced societies are somewhat integrated wholes.

Numerous social convergences exist between human and insect societies including the following:

Division of labour; social integration through signals, chemical agents, and activity gradients; social dominance; replication and duplication oi patterns; specialization of population units through classes or castes; ontogeny of social organization; phylogeny of social systems; divergence; convergence; recapitulation during ontogeny; degenerative evolution and vestigial characters; social variation and selection of social and familial units; and the dynamic maintenance of population equilibrium (Emerson, "Levels of Integration in Biological and Social Systems," *Biological Symposia,* vol viii, Jaques Cattell Press.)

Insects and mammals stand near the apex of their respective evolutionary branches of the animal kingdom. The similarities between the social life developed in each class are mainly matters of convergence and analogy. To the extent that the sociality of each develops from the co-operative tendencies of their common ancestors. their sociality is vaguely homologous. In many ways this is not a minor point. Even the sociality of man developed not alone from a distinctly human drive toward group co-operation but also grew out of the basic drives toward natural altruism that pervades all animal life.

2. Subsocial and Social.—For general and comparative sociology. the chief interest is not between extrapolations from the organismic to the supra-organismic level in organization--from the biological to the social. so to speak—but rather in the permissible extrapolations from the subsocizl to the truly social levels and in the opposite direction as well. Here again arises the problem as to where truly social life begins.

A part of the difficulty involved in answering this question may be avoided if it is recalled that rnany different levels of social organization exist and that these usually overlap. Among the groups that the biologist regards as somewhat more social than is implied by more vague ecological relationships the following may be recognized: (1) Those that show their social habit merely through the toleration of the close proximity of other similar animals in the same restricted space; these may exist without any positive mutual attraction and represent the toleration level of sociality. (2) Those groups that react more or less definitely as units—the group-integration level. (3) Those that show physiological division of labour. (4) Those that show morphologically distinct castes, each associated with some phase of the division of labour (the highest insect level). (5) Those that are organized to a large part by tradition and by symbolic communication and that frequently react to abstractions (the human level).

In presenting this abbreviated list of recognized social levels, there is no intention of assuming that the more complex types of social life evolved through the less complex ones. Such may or may not have been the course of social evolution. The insects do not stand in the direct line of man's ancestry. Their state of social development represents an insect evolution of sociality, not a stage toward that found in man.

Animals on the higher planes of sociality continue to show certain of the group attributes characteristic of the lower levels. Group survival values have been demonstrated throughout the whole series and apparently extend to the threshold of primitive life. Extrapolations forward from the lower to higher social levels can be made with more confidence than those in the opposite direction. It can be predicted, from studying the social survival values of primitive organisms, that, other conditions being equal, groups of more complex animals will have certain survival values as groups. It is much more hazardous to try to project highly developed human social traits, like social consciousness, back into the less complex social levels reached by other animals.

3. Conclusion.— For a final summarizing statement, it is necessary to turn back to evaluate two contrasting social forces discussed earlier in this article. The conclusion that emerges from cumulative studies on social biology is that co-operation and its opposite, dis-operation, both exist. There are egoistic and altruistic tendencies in nature, and both are important. The question arises insistently to which of these is the more fundamental and significant. Any such evaluation should be based on short-run and on long-run effects. Considering the evidence available, contrary to Herbert Spencer and the conclusions of social Darwinism, the co-operative forces are biologically and sociologically the more important and vital. The balance between the co-operative, group-centred tendencies and those that are dis-operative and egoistic is relatively close. Under many conditions, the co-operative forces lose. In the long run. however. the group-centred, more altruistic drives are the stronger.

If co-operation had not been the stronger force, the more complicated animals, whether arthropods or vertebrates, could not have evolved from simpler forms and the more complex social levels could not have arisen and persisted. Finally, so far as man is concerned, the weight of the-evidence from the sociology of other animals strongly indicates that. despite many appearances to the contrary. human altruistic drives are as firmly based on an animal ancestry as is man himself. As Espinas concluded years ago. social life is not an accident appearing sporadically among a few highly evolved animals. It is rather a normal and basically widespread phenomenon. Despite many well-known appearances to the contrary, human tendencies toward goodness on the personal community, national and international levels are as natural as is man's trend toward being intelligent.

SOCKMAN, RALPH WASHINGTON (1889–), U.S. clergyman. whose "National Radio Pulpit" program became the longest continuing radio program in the United States, was born at Mt. Vernon. O., on Oct. 1, 1889. After receiving his A.B. degree from Ohio Wesleyan university (Delaware, O.) in 1911. he went to Columbia university in New York city for graduate study. While there he became active as a member of the Madison Avenue Methodist Episcopal church and served as intercollegiate secretary for the Young Men's Christian association until he received his M.A. degree in 1913.

He then began study at the Union Theological seminary and when he was graduated in 1916 was appointed associate minister of the Madison Avenue Methodist Episcopal church and became minister in 1917. His epigrammatic and vivid sermons were popular from the beginning as were published collections of them and other religious writings. One of the first U.S. clergymen to broadcast sermons, in 1936 he succeeded S. Parkes Cadman, who had founded the "National Radio Pulpit" program in 1928.

Sockman was president of the Federation of Churches from 1927 to 1929 and after 1928 was head of the World Peace commission of the Methodist Episcopal church. In 1950 he was appointed associate professor of practical theology at the Union Theological seminary. Among his books are *Suburbs of Christianity and Other Sermons* (1924); *Men of the Mysteries* (1927): *Movals of Tomorrow* (1931); and *The Higher Happiness* (1950).

SOCORRO, a city of west central New Mexico, U.S., the seat of Socorro county, on the west bank of the Rio Grande river, 75 mi. S. of Albuquerque.

Socorro is the centre of a livestock, grain raising and dairying region. Cattle, sheep, goats and horses are the principal stock; and there are orchards and truck farming. To the west and southwest are the Socorro and Magdalena mountains and the Dátil, Black and San Mateo ranges, in which silver, gold, galena, copper. lead and zinc have been mined.

The name Socorro was given to the site in 1628 by Friar Alonso de Benavides. who found a Franciscan mission had been established in 1598 by two friars left by Juan de Oñate. Under De Benavides' direction the restoration of this mission began and eventually it became the Church of San Miquel, one of the oldest churches on the North American continent.

Socorro was prominent in the events of the Spanish occupation. the Pueblo rebellion in 1680 and in the reconquest of Gen. Diego De Vargas. Having been a centre for the protection of the Piro against the hostile Apaches, it was abandoned after the rebellion and not resettled by descendants of the original Socorrans until 1817. It was made a Union garrison for Ft. Craig during the Civil War and was a centre for the storing and transport of supplies.

Silver was discovered nearby in 1867, and Socorro became the largest city in the New Mexico territory in the 1880s. Mining became intermittent except for zinc ores after the drop in the price of silver in the 1890s.

Socorro is the seat of the New Mexico Institute of Mining and Technology, established in 1889.

For comparative population figures *see* table in NEW MEXICO: *Population.*

SOCRATES (*c.* 470 B.C.–399 B.C.), the great Athenian philosopher. was put to death in 399 B.C. at the age of 70. His birth thus falls in or about 470, ten years after Salamis. His father, Sophroniscus, was a friend of the family of the "Just" Aristeides; the tale that he was a sculptor first appears in the 3rd century in Timon of Phlius and seems to be only a misinterpretation of a playful remark in Plato. His mother. Phaenarete, acted as a "midwife," but no inference as to social status can be founded on this.

The memoir writer Ion of Chios mentioned meeting him at Samos in the company of Archelaus, the Athenian successor of Anaxagoras, presumably during the military operations of 441–440.

The connection between the two men is also asserted by Aristoxenus the Peripatetic and the doxographical tradition based on Theophrastus calls Socrates the "disciple" of Archelaus. Plato. Xenophon, Aeschines of Sphettus agree in depicting him as intimate with the leading figures of the Periclean circle (Xspasia, Xlcibiades. Xxiochus, Callias).

Xenophon (*Mem.* iv, 7) concurs with Plato in saying that he was well versed in geometry and astronomy. and this representation agrees with the narrative of Plato's *Phaedo* and the Aristophanic burlesque of the *Clouds.*

Socrates must already have been a conspicuous figure at Athens when Aristophanes and Ameipsias both made him the subject of their comedies in 423, and since the comedians made a special point of his neediness he had probably suffered recent losses. (The marked poverty of his old age is said in Plato's *Apology* to have been caused by his preoccupation with his mission to mankind.)

Socrates was married, apparently late in life. to Xanthippe, by whom he left three sons. one an infant. Xenophon speaks of her high temper; there is no evidence that she was a "shrew"; the sons. according to Aristotle. proved insignificant (*Rhetoric B.,* 1390, b. 31).

Socrates' record for prowess and endurance was distinguished. He served as a hoplite. perhaps at Samos (441–440), at Potidaea, where he saved the life of Alcibiades (432–430), Delium (424) and Amphipolis (?422 or ?437–436).

SOCRATES (*c.* 470 B.C.–399 B.C.), FROM A BUST (SCULPTOR UNKNOWN)

In politics he took no part. knowing, as he told his judges. that office would mean compromise with his principles. Once at least,[1] in 406–405, he was a member of the council of 500, and at the trial of the victors of Arginusae. being one of the *prutaneis,* resisted. at first with the support of his colleagues, afterward alone, the unconstitutional condemnation of the generals by a collective verdict. He shon-ed the same courage two years later in the "Terror" of 404. The "thirty" wishing to implicate honourable men in their proceedings, instructed Socrates with four others to arrest Leon. one of their victims. Socrates disobeyed, and says, in Plato's *Apology,* that this might have cost him his life hut for the counterrevolution of the next year.

In 399. four years after the amnesty, he mas indicted for "impiety." The author of the proceeding was the influential Xnytus. one of the two chiefs of the restored democrats. but the

[1]This was not, of course, a "magistracy." Plato, *Gorgias* 474*a,* seems to refer to another earlier occasion.

nominal prosecutor was the obscure and insignificant Meletus. There were two counts in the accusation, "corruption of the young" and "neglect of the gods when the city worships and the practice of religious novelties."[1] Socrates, who treated the charge with contempt and made a "defence" which amounts to avowal and justification, was convicted, probably by 280 votes against 220. The prosecutors had asked for the penalty of death; it now rested with the accused to make a counter-proposition. A smaller, but substantial, penalty would have been accepted, but Socrates took the high line that he really merited the treatment of an eminent benefactor, maintenance at the public table. He only consented for form's sake to suggest the small fine of one *mina,* raised at the entreaty of his friends to 30.

This incensed the court and "death" was voted by an increased majority,[2] a result with which Socrates declared himself well content As a rule at Athens the condemned man "drank the hemlock" within 24 hours, but in the case of Socrates the fact that no execution could take place during the absence of the sacred ship sent yearly to Delos caused an unexpected delay of a month, during which Socrates remained in prison, receiving his friends and conversing with them in his usual manner daily An escape was planned by his friend Crito, but Socrates refused to hear of it, on the ground that the verdict, though contrary to fact, was that of a legitimate court. and must therefore be obeyed. The story of his last day has been perfectly told in the *Phaedo* of Plato, who, though not himself an eye-witness, was in close touch with many of those who were present.

Socrates wrote nothing; therefore our information about his personality and doctrine has to be sought chiefly in the dialogues of Plato and the *Memorabilia* of Xenophon. Both men were nearly 45 years younger than Socrates, and can therefore only speak from first-hand knowledge about the last ten or twelve years of his life. Xenophon's relations with him seem not to have been close, and he has even been suspected of deriving much of his material from Plato's dialogues. His admitted deficiencies in imagination and capacity for thinking do not make him the more faithful exponent of a philosophical genius.

To call him a "Boswell" does poor justice to the intellect of Boswell. (It must also be remembered that Boswell collected his material largely during Johnson's life, and with his knowledge and help) We need also to discount Xenophon's apologetic purpose. His most valuable statements are those which appear most at variance with his main thesis that the prosecutors of Socrates were mistaken from their own point of view. Plato's more vivid picture has been suspected on the ground that Plato used Socrates as a "mouthpiece" for speculations of his own. What this really means is that the so-called "Ideal Theory" expounded in the *Phaedo* is held to have been originated by Plato after the death of Socrates. There are serious reasons for denying this assumption though they have not yet convinced all scholars; in any case it is a *petitio principii* to employ it, without investigation, as an argument to discredit Plato's testimony. Xenophon's silence at most only proves that Socrates did not converse on such matters with him. In some important respects Plato's testimony is confirmed by the remains of Aeschines of Sphettus. The *Clouds* of Aristophanes yields valuable information about Socrates in his middle "forties," when allowance is made for its character as a burlesque. It should be compared carefully with the autobiographical statements put into the mouth of Socrates in the *Phaedo* (96*a*–100*a*). These are not "contemporary evidence," but they are clearly meant to express Plato's *bonn fide* belief about his master's intellectual history.

Personal Characteristics. — Though Socrates was a good fighting man, his outward appearance was grotesque. Stout and not tall, with prominent eyes, snub nose, broad nostrils and wide mouth, he seemed a very Silenus. But, as his friends knew, he was "all glorious within," "the most righteous man of the whole age" (Plato, *Ep.* vii. 326 *e*). His self-control and powers of endurance were exemplary; "he had so schooled himself to moderation that his scanty means satisfied all his wants."

But he was no self-tormenting ascetic; he "knew both how to want and how to abound," and could be the soul of the merriment at a gay party. He had no sympathy — this was a main point in the *Telauges* of Aeschines — with the slatternliness of his friend Antisthenes or the godly dirtiness affected by "Pythagorists" There was nothing of the complacent self-righteousness of the Pharisee, nor of the angry bitterness of the satirist, in his attitude towards the follies or even the crimes of his fellow men. It was his deep and life-long conviction that the improvement not only of himself, but of those with whom he might have to do, was a task laid upon him "by God," but the task was not to be executed with a scowling face and an upbraiding voice. Like St. Francis Xavier, he thoroughly understood how important it is to one who would win men's souls to be "good company." Conscious of his own infirmities, he felt a real and profound sympathy for those who had not learned to master their frailties and passions.

He was a true patriot, and his devotion to the city in which he had been born and bred was only made the more evident by his conviction that he could best prove it by setting his face resolutely against the attractions of specious and popular, but deadly, false theories of public and private morality. When the city brought him to trial and threatened him with death his sense of civic duty forbade him to withdraw into exile before the trial, or to accept the opportunity of escape during his unforeseen imprisonment. It was his very patriotism which made him an unsparing critic of the "democracy," which means, in Nietzsche's phrase, "one flock and no shepherd," and so led directly to the accusation which proved fatal to him.

Nothing was more marked in his character than an unusually keen sense of humour, an appreciation of the comic in human nature and conduct which protected him at once against sentimentality and against cynicism. This is what his opponents in Plato call his "irony," and treat as an irritating affectation. "Intellectually the acutest man of his age, he represents himself in all companies as the dullest person present. Morally the purest, he affects to be the slave of passion" (W. H. Thompson). No doubt. in part this irony was "calculated"; it "disarmed ridicule by anticipating it." But its true source is the spontaneous sense of "fun" which makes its possessor the enemy of all pretentiousness, moral or intellectual, in himself and in others. And it is certain that, though the purity of Socrates is beyond question, he really had an ardent and amorous temperament.[3]

Religion. — Socrates was clearly a man of deep piety with the temperament of a "mystic." Like other educated men of his age, he regarded mythology, with its foolish or immoral tales about gods, as a mere invention of the poets. But he found it easy to combine his own strong belief in God, the all-wise and all-good ruler of the world, with the view that in practice we could worship Gad in the way prescribed by "the usage of the city." God's existence is shown, he held, not only by the providential order of nature and the universality of the belief in Him, but by warnings and revelations given in dreams, signs, oracles. The soul of man partakes of the Divine; the concluding pages of Plato's *Apology* prove that Socrates had a strong belief in its immortality. (Xenophon for apologetic reasons is silent on the point, but has reproduced the argument in the dying speech of his Cyrus in the *Cyropnedia.* Aristophanes, too, makes Socrates combine the parts of "infidel" physicist and hierophant of a mysterious private faith, and in the *Birds* [1553, seq] represents him as presiding at a fraudulent *séance.*) He was regular. says Xenophon, in prayer and sacrifice, though he held that since only the gods know what is good for us, our prayer should simply be "give me what is good"; we must not dictate the form the blessing should take. It is clear from Plato that Socrates was deeply influenced by Pythagorean and Orphic religious ideas, though he regarded the ordinary Orphic mystery-monger with healthy contempt

[1] καινὰ δαιμόνια in the indictment means literally "novel practices in religion." not "novel deities" (though the second is insinuated).

[2] What offended the court was not the smallness of this sum—go *minae* was not a small sum in the economic circumstances of the time —but Socrates' description of himself as a distinguished public benefactor.

[3] Cf. Aeschines, *Alcibiades* Fr. 4 (Krauss), which confirms the representation of Plato on this point.

The evidence that Socrates had a markedly "mystical" temperament is abundant. Plato tells of his curious "rapts," in one of which he stood spellbound for 24 hours in the trenches before Potidaea, and there seems to be an allusion to this singularity in the *Clouds* (171 seq.).

The familiar "Divine sign" tells the same story. This, according to Plato, was a "voice" often heard by Socrates from childhood. It forbade him to do things; but never gave positive encouragement. (Xenophon, who makes more of the matter, says, less probably, that it did give positive directions.) Plato treats the "voice" very lightly; by his account, it merely gave prognostications of good or ill luck, and the occasions of its occurrence were often "very trivial." Thus it was neither an "intuitive conscience," nor a symptom of mental disorder, but an "interior audition," a "psychic phenomenon" of a kind now known to be not specially uncommon.

Mode of Life.—Socrates' whole time seemed to be spent "out of doors," in the streets, the market-place, and more particularly, the *gymnasia.* He cared little for the country and rarely passed the gates. Though he frequented by choice the society of lads of promise, he also talked treely to politicians, poets, artisans about their various callings, their notions of right and wrong, the familiar matters in which they might be expected to take an interest. The object of all this, he says in the Apology, was to test the famous Delphic oracle which had pronounced him the wisest of men. It is clear from the Apology that the oracle had made this declaration, no doubt because the Delphic authorities knew from the form of the question what answer was desired. The presupposition of the *Apology* is that this happened before Socrates had become conscious of his mission to his fellow men; even at that early date, it is implied, he had the highest of reputations in circles interested In wisdom.[1] Acutely sensible of his own ignorance, Socrates set himself to convict "the god" of falsehood.

But when experience showed that those who thought themselves wise were unable to give any coherent account of their wisdom, he had to admit that he was wiser than others, just because he alone was aware of his own ignorance. This account is plainly tinged with the usual "irony." Socrates did not take Apollo and his oracle very seriously. But that he was quite serious in believing himself charged with a mission, not from "Apollo," but from God, to preach to his fellow men the supreme importance of knowledge of what is for the soul's good is proved by his declaration that he is more than ready to face instant death rather than to neglect his commission. The poverty in which this mission had involved him. and the austerity of the rule of life it entailed were notorious.

Summer and winter, his coat was the same; he had neither shoes nor shirt. "A slave who was made to live so," the sophist Antiphon said, "would run away." This self-imposed life of hardships was the price of his spiritual independence. His message was variously received Some of those whose false pretentions were exposed by his trenchant criticizing regarded him with ill-will; many thought him an officious busybody. Among the younger men, many merely thought it good sport to see their elders silenced. Others (Xenophon says that this was the case with Alcibiades and Critias), deliberately attached themselves to him for a time "for private ends," believing that to learn the secret of so acute a reasoner uould he the best preparation for success in the law courts, the council and the assembly. Others sincerely hoped by associating with him to become good men and true, capable of doing their duty by house and household, by relations and friends, by city and fellow-citizens.

Finally, there was an inner circle who entered more deeply into his principles and transmitted them to the next generation. But these were not "disciples" united by a common doctrine. Socrates finally repudiated all claim to have "disciples." The bond of union was a common reverence for a great man's intellect and character. It was, in the main, this group who were collected round Socrates in the day of his death; many of them, *e.g.,* Eucleides from Megara, and the young Theban Pythagoreans, Cebes and Simmias, were foreigners from States which had been enemies of Athens in the Peloponnesian War.

[1]This is also proved by the attachment to him shown by Eleatics from Megara and young pupils of the Pythagoreans from Thebes and Philius These connections must have been founded before the Peloponnesian War

The Accusation and Its Causes.—The explanation of the attack made on Socrates is simple. He had been on terms of close friendship with the two men whose memories were most obnoxious to the democrats. Critias, the fiercest spirit among the extremists of the "Terror" of 404, and Alcibiades, whose self-will had done so much to bring about the downfall of the Athenian empire. The charge of "educating Alcibiades" was made prominent in the pamphlet written a few years after the trial by the "sophist," Polycrates, in justification of the verdict. More than half a century later, the orator Aeschines reminds his audience that Socrates had been put to death because he was believed to have educated Critias. In point of fact, it was absurd to make Socrates responsible for the ambitions of Alcibiades, and, as he reminded his judges, he had disobeyed an illegal order from Critias and his colleagues at the risk of his life. But it is natural that he should have had to suffer for the crimes of both men, the more that he was known to have been an unsparing critic of democracy, and of the famous democratic leaders. These suspicions would be made the more acute by the remembrance that Socrates had not, like the advanced democrats, withdrawn from Athens during the "Terror."

He was, in fact, suspected of using great abilities and gifts to pervert his younger associates from loyalty to the principles of democracy, and the convinced democrats who had recovered the city in 403 were unwilling, as Burnet has said, "to leave their work at the mercy of reaction." That they took no steps for four years is probably explained by the state of complete confusion and congestion into which the disorders of 404 had thrown the law courts. The motives of Anytus, an upright, unintelligent democrat, are thus quite explicable. From his point of view, Socrates would be at the best a "whig," and democrats who remembered the career of Theramenes could not be expected to make a fine distinction between the "whig" and the traitor.

The real grounds for the attack could not be disclosed in the indictment, since the amnesty which terminated the struggle of 404–403, and of which Anytus himself had been a main promoter, covered all offences committed before the archonship of Eucleides (403). Hence the charge had to be couched in the form of a vague accusation of "corruption of the young." Probably for the same reasons Anytus was ashamed to appear as the principal in the matter and put forward the obscure Meletus, who might venture on "indiscretions" more openly. If Meletus was the same person who also prosecuted Andocides in the same year on the same charge of 'impiety," and if, as is not unlikely, he is the real author of the speech Against *Andocides* ascribed to Lysias, he must have been a half-witted fanatic, and this may explain why the chdrge of irreligion was added. The real nature of this "irreligion" appears never to have been explained. Xenophon suggests that the allusion was to the "Divine sign" but this cannot be correct. It is clear from Plato's *Apology* that Meletus said nothing about the "sign" at the prosecution, and that Socrates is speaking with his "usual irony" when he pretends to guess that the mention of "religious novelties" in the indictment referred to it. In the *Apology,* Socrates says that the prosecution is, no doubt, relying on memorirs of Aristophanes' *Clouds,* where he had been made to talk "atheism" as part of the burlesque on men of science.

But there must have been more behind the charge, and it seems likely that Burnet is right in reminding us that the prosecution of Andocides revived the old scandal of the "profanation of the mysteries," which had thrown Athens into a ferment on the eve of the Sicilian expedition in 416–415. The two chief victims, Alcibiades and his uncle Axiochus, were both among the intimates of Socrates, and there is reason to think that others of his friends were affected. If this is what lay behind the charge, we can understand why its real meaning seems never to have been explained Owing to the terms of the amnesty, the matters in question were not really within the competency of the court Socrates himself. in the account of Plato, who was present at the trial, treats the whcle matter with contempt. His defence consists in narrating the facts of his past life, which proved that he was equally ready to defy the populace and the "thirty" in the cause of right and law, and in insisting on the reality of his mission from God and his determination to discharge it, even at the cost of life. The prosecutors had no desire for blood They counted on a voluntary withdrawal of the accused from the jurisdiction before trial; the death penalty was proposed to make such a withdrawal certain. Socrates himself forced the issue by refusing at any stage to do anything involving the least shade of compromise. The prosecution had raised the question whether he was a traitor or, as he held himself to be, an envoy from God; Socrates was determined that the judges should give a direct verdict on the issue without evasion. This is what makes him a martyr, but also what forbids us to call Anytus a murderer.

Doctrine and Method. — Socrates was a man of the Periclean age, and the Periclean age witnessed one of the periodical "bankruptcies of science." Cosmological speculation, which had been boldly pursued from the beginning of the 6th century seemed by the middle of the 5th to have led to a chaos of conflicting systems, each of which could establish only one point, that all its rivals were wrong. Parmenides of Elea had apparently cut away the ground from science by showing that the real world must be quite unlike anything which our senses reveal to us, and that, consequently, the method of cosmology, interpretation of the world by analogies from familiar sensible experiences, is inherently fallacious. His pupil Zeno seemed to have shown that even the postulates of mathematics are mutually contradictory.

Science, then, seems impossible, and this is why the ablest men of the generation before Socrates, such as Protagoras and Gorgias, turned away from the pursuit of it and tried to find a use for the intellect in professions which concern themselves, not with the discovery of truth, but with making a success of human life. "Probability is the very guide of life," and in practical matters "useful" points of view may be attainable, even if scientific certainty is beyond our reach. According to the narrative of the *Phaedo*, Socrates, as a young man, began with an experience typical of his age. He was enthusiastically interested in "natural science," and familiarized himself with the various current systems, being specially interested in the contrast between the old Milesian type of cosmology with its flat earth and the Italian type with its spherical earth. He was also interested in the mathematical puzzles raised by Zeno about "the unit" (*i.e.,* the problem of continuity). He discovered, to his distress, that though each authority was quite sure that the views of the others were wrong, none of them could give any proof that his own were right.

There was a complete lack of critical method. For a moment he hoped to find salvation in the doctrine of Anaxagoras that "mind" is the source of all cosmic order, since this seemed to mean that "everything is ordered as it is best that it should be," that the universe is a rational teleological system. But on reading the book of Xnaxagoras, he found that the philosopher made no effective use of his principle; the details of his scheme were as arbitrary as those of any other. After this disappointment, Socrates decided that he had "no head for physics" and must fall back on his own mother-wit. Accordingly he resolved henceforth to consider primarily not "facts" but λόγοι the "statements" or "propositions" we make about them. His method should be to start with whatever seemed the most satisfactory "hypothesis," or postulate, about a given subject, and to consider the consequences which follow from it. So far as these consequences prove to be true and consistent, the "hypothesis" may be regarded as provisionally confirmed; if they are false or mutually inconsistent it is discredited. But it must be a strict rule of method not to confuse enquiry into the consequences of the "hypothesis" with proof of its truth. If the question of its truth is raised, the issue can only be settled by deducing the initial "hypothesis" as a consequence from some more ultimate "hypothesis" which both parties to the dispute are content to accept. The method, still familiar to us as that of true science, is manifestly suggested by reflection on the "antinomies" of Zeno, whom Aristotle called the creator of "dialectic," and whom Plato, in the *Parmenides,* afterwards described as meeting Socrates in the youth of the latter. So far, Plato's story has every appearance of being historical. But it is still the fashion to hesitate to follow it any further. According to him, Socrates next proceeded to take it as his own fundamental "hypothesis" that every term (such as "good," "beautiful," "man") which has a single unequivocal denotation directly names a single self-same object of a kind inaccessible to sense-perception and apprehensible only by thought. Such an object Socrates calls an ἰδέα or εἶδος, Form. (The transliteration "Idea" is misleading, owing to the psychologizing of the sense of the word by Locke and his followers.) The sensible things of which we predicate beauty, goodness, humanity, have only a secondary and derivative reality. Strictly speaking, we must not say that they are this or that, but only that they *become* this or that for a time, in virtue of the temporary "presence" (παρουσία) to them of the corresponding Form, or, as it is also expressed, in virtue of their "participation" (μέθεξις) in the Form. A sensible thing, in fact, is simply a temporary complex of Forms.

In the *Parmenides* of Plato Socrates is made to expound this doctrine to the great philosophers Parmenides and Zeno as his solution of the standing puzzle of the one and the many. This is the doctrine of Forms (the "Ideal Theory") as it is stated in the *Phaedo* and *Republic.* Though it is quite different from the version of the doctrine ascribed by Aristotle to Plato, it has been usual in the 19th century to assume that it is an earlier form of that doctrine consciously devised by Plato after the death of Socrates. The chief argument for this view is based upon the observation of Aristotle that Socrates rightly "did not separate" the universal from the particular *(Met. M.,* 1078 *b30)* as, it is apparently implied, Plato did. It is, however, not clear that Aristotle means by this, what he never says expressly, that Socrates did not teach the doctrine ascribed to him in the *Phaedo.* He might equally mean that the doctrine of the *Phaedo* does not itself involve the kind of "separation" of the universal from the particular to which he objects in what he describes as the Platonic theory, and, since the *Phaedo* is one of the Platonic dialogues to which he most frequently alludes, it is strange that he should never have said that it misrepresents the historical Socrates on a capital point, if he really thought so.

On the other side, the doctrine is expressly said in the *Phaedo* to be a familiar one which Socrates "was always" repeating, and it is hard to believe that Plato could have made such a statement about a speculation of his own, especially as most of the personages of the *Phaedo* were certainly still alive long after the dialogue was written. It is hard to see what could be the point of such a mystification, and harder to understand how its author could have expected it to be successful. Of course, demonstration is out of the question in such a matter; we can only be guided by considerations of probability. If we think the probabilities against the view which credits Plato with deliberate mystification, we must be prepared to admit the possibility that he is also reproducing the thought of Socrates in the further development of the *Symposium* and *Republic,* where we hear of a supreme Form, that of Beauty, or Goad, the vision of which is the far-off goal of all intellectual contemplation. We may fairly suspect that the thought of Socrates is undergoing development in the mind of Plato, but it will be natural to regard the development as, in the main, unconscious, and to recognize that no complete separation of the Socratic and the Platonic in the result is possible.

It is certain that on the logical side the thought of Socrates proceeded "as if" the doctrine of Forms expounded in the *Phaedo* were its point of departure. Both Plato and Xenophon bear out the remark of Aristotle that Socrates may fairly be credited with two things, "inductive arguments" and "universal definitions" (*Met. M.,* 1078 *b27*). The "universal definition" is an attempt to formulate precisely the meaning of a universal significant predicate, *i.e.,* to apprehend what the *Phaedo* calls a Form, and it is from the practice of Socrates, who aimed at the clarification of thought about the meaning of moral predicates as the first indispensable step to the improvement of practice, that the theory of logical division and definition, as worked out in Plato's later dialogues and the logical treatises of Aristotle, has arisen.

The "inductive arguments" mean the characteristic attempts to arrive at such formulations by the consideration of simple and striking concrete illustrations familiar to us from both Xenophon and Plato, the perpetual arguments about "shoemakers and carpenters and fullers," which the fashionable speakers in Plato profess to think vulgar. Induction, on this view of it, is not regarded as a method of proof. Its function is that of suggestion; it puts the meaning of a proposed "definition" forcibly and clearly before the mind. The justification of the definition, then, has to be sought in a consideration of the satisfactoriness of the "consequences," which would follow from its adoption. Socrates himself sought for his "definitions" principally in the sphere in which he was most interested, that of conduct, private and public. As Aristotle says, he concerned himself with the "ethical," character and conduct, not with "nature" at large. This is what Cicero means by saying that he "brought down philosophy from heaven to earth."

Before him cosmology had been the chief topic of interest, after him, the central problem of philosophy was to formulate a rule of life. With him the "practical use of reason" comes by its rights. In this respect Socrates stamped on philosophy a character which it has never lost. The main outlines of his philosophy of conduct are fortunately quite certain, and could be discovered if we had no more material than the Platonic *Apology* and the *Memorabilia* of Xenophon. As the *Apology* tells us, the specific message from God which Socrates brought to his fellow men was that it is the great business of life to practice the "care" or "tendance" (ἐπιμέλεια, θεραπεία), of one's *soul*, to "make one's soul as good as possible," and not to ruin one's life, as most men do, by putting care for the body or for "possessions" before care for the "soul."

The thought which is here fundamental is that of the "soul" (ψυχή) as that which is most truly a man's self. In Greek literature, down to the end of the 5th century, we can trace two main senses of the word ψυχή. (1) It means "the breath of life" which a man parts with in dying. It is this which, in popular superstition, is left as a mere "ghost," or "shade," when the man "himself," his body, has perished. In earlier Ionian science this is identified with the "air" which a man inhales so long as he is alive. (2) In circles influenced by the Orphic religion the soul is thought of as something which has a destiny beyond the grave, but this, too, is something different from the self. It is a sort of stranger inhabiting the body, but having little to do with the conduct of normal life. It "sleeps while the body is active, but wakes when the body sleeps," and reveals itself chiefly in dream and trance. From the beginning of the 4th century we find ψυχή coming at last to mean what "soul" means to us, the normal waking personality, the seat of character and intelligence, "that," as Socrates says in Plato, "in virtue of which we are called wise or foolish, good or bad," and as this usage of the word first appears in writers whom we know to have been influenced by Socrates (Isocrates, Plato and Xenophon), we may fairly ascribe it to his influence. The thought now works out thus. The soul is the man (in the later Academic formulation a man is "a soul using a body").

Our happiness or well-being, then, depends directly on the goodness or badness of the soul. It is no happiness to possess health, or strength, or wealth, unless we know how to *use* these advantages rightly. If we use them wrongly, they will only be so many means to misery. The reason why hardly any one achieves happiness is not that men do not wish to be happy. No one ever wishes for anything but true good, that is, true happiness, but men miss their happiness, in spite of the universal wish for it, because they do not *know* what it is. They mistake for real good things which are not really good (*e.g.,* unlimited wealth or power). In this sense, "all wrong-doing is involuntary." The first and fundamental requisite for happiness, then, is that men should *know* true good and not confuse it with anything else. The good state of the soul is precisely that state in which it never makes the mistake of taking anything to be good when it is not really good. To "make one's soul as good as possible" thus means to attain the knowledge of good which will prevent us from *using* strength, health, wealth, opportunity, wrongly. If a man has this knowledge, he will always act on it, since to do otherwise would be to prefer known misery to known happiness, and this is impossible. "*All* the virtues are one thing," *knowledge* of good, and all "vice" is one thing, ignorance of true good.

"Popular" goodness—what passes current as virtue—is mostly illusory, because it is mainly a matter of habit, not of assured conviction about good. It breaks down under temptation; but if a man really knew that, *e.g.,* to commit a crime is worse than to suffer loss or pain, or death, no fear of these things would lead him to commit the crime. The professional "sophist," again, claims to be able to teach "goodness," but the claim is shown to be unfounded by the very fact that the sophist treats "goodness" as though it were a neutral "accomplishment" which can be conveyed by mere instructions. Now an accomplishment, or "art," can always be put to either of two uses, a good or a bad, as the physician, for instance, can use his professional knowledge to cure or to kill.

Knowledge of good is the one knowledge of which it is impossible to make an ill use; the possession of it is a guarantee that it will always be used aright. Thus Socrates becomes, as against the relativism of Protagoras, the founder of the doctrine of an absolute morality based on the conception of a felicity which is the good, not of Athenians or Spartans, or even of Greeks, but of man as man. It is not in virtue of our allegiance to a particular city, nor even of our place in a particular historical civilization, but in virtue of our universal humanity, that we have the task of "making the soul as good as possible," or, as Socrates also said, in language influenced by Pythagoreanism, "making it like God."

Politics, from this point of view, does not differ in principle from ethics. The business of the statesman also is the "tendance" of souls, though his task is to aim at making, not only his own soul, but the souls of all his fellow-citizens "as good as possible." The knowledge of good is also the "royal" science or science of governing, the foundation of all statesmanship. The radical vice of ancient democracy, according to Socrates, is that of not demanding evidence of any special knowledge in its leaders; it suffers the destinies of society to be in the hands of men without true insight. Partly this means that by not demanding intellectual qualifications for office, democracy surrenders the control of affairsinto the hands of men with no adequate expert knowledge. But this is only a minor part of Socrates' indictment. His main criticism is that though in some departments, at least, the democracy refuses to take the advice of any one but a qualified expert, on the question of the morality and justice of a proposed policy it treats any one citizen's opinion as of equal value with another's.

Even a Themistocles or a Pericles plainly had no knowledge of true statesmanship, as we see from the fact that they neither taught the principles of it to their sons, nor had them taught these principles by others, and if we look at the actual achievements of these men we can see that they were, so to say, good "body-servants" of the *Demos,* they gave it the things which tickled its taste, such as a navy and a commerce; they were no "physicians of the body politic," for they did not promote "righteousness and temperance," the spiritual health of the community. That is, they measured national greatness by wealth and empire, not by character. According to Plato, Socrates maintained that he himself, who abstained all through from active politics, was the one Athenian of the time who deserved the name of statesman. He deserved it because he understood, as the men of action did not, that national, like individual felicity, depends on the knowledge of good which inevitably leads, where it is possessed, to the action which makes the soul "as good as possible."

The well-known Platonic *Republic* may fairly be said to be, on its political side, a picture of the life of a society in which the whole system of social and economic life is based on this Socratic conviction that "politics" is the application to the community at large of the principle that knowledge of the absolutely good is the necessary and sufficient condition of well-being. How far any of the special regulations of Plato's *Utopia* embody actual convictions of Socrates is more than we can say, though it is significant that the *Aspasia* of Aeschines represented Socrates as maintaining one of Plato's "paradoxes," the capacity of women for war and politics.

The Socratics.—The thought of Socrates has, in the main, been made fruitful for subsequent ages by being taken up and continued in the life-work of Plato. A more temporary influence was exercised by certain other members of the group of Socratic men whom it has become customary to speak of as the "minor" Socratics. The most important of them are Antisthenes of Athens and Eucleides of Megara, with whom the Cynics and Megarians of the 4th and early 3rd centuries are historically connected. With them it is usual also to mention Aristippus of Cyrene, often still spoken of as somehow connected with the Cyrenaic school of the early 3rd century.

It is probable, however, that the current accounts exaggerate the closeness of the connection between these men and the later schools. Aristippus of Cyrene figures in Xenophon's *Memorabilia* simply as a luxurious and refined man of the world who makes it his rule of life to extract personal enjoyment from existence, sitting loose to all attachments which might interfere with his ease and not allowing himself to take root anywhere. The later anecdotes about him bear out this representation. There is no good evidence that he had a philosophy or originated a school. Aristotle ascribes no doctrine to him and never mentions a "Cyrenaic" school of Hedonists, though he could hardly have avoided doing so in his discussions of Hedonism in the *Nicomachean Ethics* if he had known of one. Plutarch expressly describes the Cyrenaics as contemporaries of Epicurus, and all the names of members of the school known to us belong to the time of the successors of Alexander the Great. The one point of doctrine common to them appears to have been that they rejected the notion of a good more permanent than the pleasure of the moment. The supposed connection of Aristippus with them seems to be based on a confusion with his grandson of the same name, who, according to Eusebius, reduced his grandfather's practice to theory.

Eucleides of Megara was a friend both of Socrates and of Plato, who temporarily took refuge with him after the death of Socrates, and, at a later date, dedicated the *Theaetetus* to him. All we know of his teaching is that he held to the Monism of Parmenides, maintaining that nothing is real except "the One," which is also called "wisdom" *φρόνησις*, "intellect" (*νοῦς*) and "God" (*D.L.*, ii. 106). The mention of "wisdom" as a synonym for "the One" seems to reveal the influence of Socrates. Most of our notices of Megarians deal with men of a later time, Eubulides, a contemporary of Aristotle, Diodorus Cronus and Stilpo. These men were pugnacious formal logicians famous for their rejection of the notion of "possibility" which is so fundamental in the Aristotelian philosophy. According to them, nothing is possible except the actual. Aristotle resented the criticism so keenly that "sophist" in his terminology appears to be regularly equivalent to "Megarian logician." It is not clear how these *ἐριστικοί* are connected with the Monism of Eucleides. There are reasons for supposing the puzzling antinomies of Plato's *Parmenides* to be a parody of Megarian logic, and it is a view which has been widely accepted in recent times that they are also meant in Plato's *Sophistes* by the "friends of Forms" who are there contrasted with the materialists and said to maintain that reality consists of a multitude of "incorporal Forms" which can only be apprehended by thought. This identification is, however, uncertain (and, in the present writer's opinion, mistaken).

Antisthenes was a friend of Socrates of long standing, with a marked individuality of his own, and a voluminous writer much admired for his style. He does not appear to have been a "disciple," though he was personally attached to Socrates, and particularly admired his strength of will and mastery of his passions. In philosophy he is chiefly known for two things, his denial of the possibility of making judgments in which the predicate and subject terms are non-identical, and his insistence in ethics on the simplification of life by the reduction of our wants to an indispensable minimum. In virtue of the latter he was commonly regarded as the founder of Cynicism and it is certain that he personally influenced the famous Diogenes and that the later Cynics were in the habit of regarding him as a model man. But it is not clear either that the Cynics of the 4th century were a "sect" or "school" in any real sense of the words, or that the nickname "dog" was ever given to anyone before Diogenes. It was believed in later antiquity that there was a personal feud between Antisthenes and Plato, and it seems certain that one of the works of Antisthenes, called *Sathon*, was a virulent personal attack on Plato. But the ingenuity spent in the 19th century on discovering polemical allusions to Antisthenes in Plato's dialogues seems to have been mostly wasted. According to Plato, the logical paradox that "contradiction is impossible" was maintained by numerous persons in the days of Socrates. Hence it seems unreasonable to detect special allusions to Antisthenes in the frequent references to this paradox in the dialogues.

Bibliography.—The following may be specially mentioned among recent works: J. Burnet, *Greek Philosophy, Thales to Plato* (1914), *Plato's Plzaedo* (1911), *Plato's Eutlzyphro, Apology of Socrates and Crito* (1924), *Early Greek Philosophy* (3rd ed., 1920), *The Socratic Doctrine of the Soul* in Proceedings of the British Academy (1915–16); A. E. Taylor, *Varia Socratzca* (1911), *The Platonic Biography of Socrates,* in Proceedings of the British Academy (1916–17), *Plato, the Man and his Work* (1926); A. Dies, *Autour de Platon* (Paris, 1927); K. Joel, *Der echte und der Xenophontische Sokrates* (1893–1901); H. von Arnim, *Xenophons Memorabilia und Apologie des Sokrates* (Copenhagen, 1923); H. Maier, *Sokrates, sein Werk und seine gesclzichtliche Stellung* (Tiibingen, 1913); U. von Wilamowitz-Moellendorf, *Platon,* vol. i. (1919); A. Busse, *Sokrates* (1914); *I.* Bruns, *Das literarische Porträt in Altertum* (1896); T. Gomperz, *Griechische Denker,* vol. ii. (Leipzig, 1902; Eng. trans. *Greek Thinkers,* 1901–12); G. Zuccante, *Socrate* (Turin, 1909). Among earlier works, besides the standard histories of ancient philosophy, which, however, need revision in all that relates to Socrates, *see* particularly G. Grote, *History of Greece,* ch. lxviii. (last ed. 1907), and *Plato and the Other Companions of Socrates* (last ed. 1885); W. H. Thompson, *The Phaedrus of Plato* (1868), Appendix *I.*

SOCRATES, the name of a famous 5th-century church historian. The *Ἐκκλησιαστικὴ ἱστορία* of Socrates, still extant in seven books, embracing the period from 306 to 439, was written in 439, or within a few years thereafter. He was born about 380 and brought up at Constantinople. He was a "scholasticus" or advocate. His work is dedicated to one Theodorus, who had urged him to write such a history. He had no thorough preparation for the task, and for the period down to the death of Constantius (361) was practically dependent on Rufinus. After his work was finished he became a student of Athanasius's writings and came to see how untrustworthy his guide had been. He accordingly rewrote his first two books (see H.E. ii. 1) certainly before 450 and probably before 444 (*see* Geppert, p. 8), and it is only this revision that has reached us. The chief sources from which he drew were: (1) the *Church History,* the *Life of Constantine* and certain theological works of Eusebius: (2) the *Church History* of Rufinus; (3) certain works of Athanasius; (4) the no longer extant *Συναγωγὴ τῶν συνοδικῶν* of the Macedonian and semi-Arian Sabinus—a collection of acts of councils with commentaries, brought down to the reign of Theodosius I. (this was a main source); (5) the *Constantinopolitan Chronicle;* (6) possibly a collection of imperial biographies; (7) lists of bishops; (8) collections of letters by members of the Arian and orthodox parties.

The theological position of Socrates, so far as he can be said to have had one, is at once disclosed in his unlimited admiration for Origen. All the enemies of the great Alexandrian he regards merely as empty and vain obscurantists; for the orthodoxy of his hero he appeals to Athanasius. Closely connected with his high regard for Origen are his appreciation of science generally and the moderation of his judgment on all dogmatic questions. According to him, *Ἑλληνικὴ παιδεία* is quite indispensable within the Church; many Greek philosophers were not far from the knowledge of God, as is proved by their triumphant arguments against atheists and gainsayers of divine providence. The apostles did not set themselves against the study of Greek literature and science; Paul had even made a thorough study of them himself. The Scriptures, it is true, contain all that appertains to faith and life, but give no clue to the art of confuting gainsayers. Greek science, therefore, must not be banished from the Church, and the tendency within the Church so to deal with it is wrong. This point of view was the common one of the majority of educated Christians at that period, and is not to be regarded as exceptionally liberal. The same holds true of the position of Socrates in regard to dogmatic questions.

EDITIONS AND LITERATURE.—Socrates' *History* has been edited by Stephanus (Paris, 1544; Geneva, 1612), Valesius (Paris, 1659 *sqq.*), Reading (Cambridge, 1720), Hussey (Oxford, 1853, reissued by Bright, 1878). It is also to be found in volume lxvii. of Migne's *Patrologia*, and there is an Oxford school edition (1844) after Reading. An English translation, revised by Zenos, is published in the Nicene and post Nicene Fathers, 2nd series, vol. ii.

See Harnack, "*Socrates u. Sozomen*" in Herzog-Hauck's *Realencykl.*, and ed., where bibliographical references will be found.

SODA. Under this somewhat loose title are included a number of substances of great industrial importance; viz., sodium carbonate, sodium bicarbonate, sodium hydrate or caustic soda, sodium sesquicarbonate or trona and sodium carbonate crystals or washing soda. The bulk of soda compounds is manufactured but there exist in various parts of the world, notably in Canada, the United States and east Africa. natural deposits of trona in the form of salt lakes. Washing soda. which is sodium carbonate combined with a proportion of water to form crystals, is a familiar substance as also is sodium bicarbonate in medical preparations. The remainder of the group provide raw material for other industries and are not commonly met elsewhere. See ALKALI; ALKALI MANUFACTURE. (A. E. H.)

SODA FOUNTAIN, a term used to designate the equipment from which carbonated water, flavoured and sweetened, is drawn and dispensed. An apparatus to serve soda water in a glass or tumbler instead of from a bottle came with the development of carbonating machinery. English and French manufacturers in the period from 1800 to 1825 devised improved equipment for making what was called soda water. One improvement was a strongly built metal tank, cylindrical in form and holding several gallons of water, in which carbonic gas entered.

This cylinder, as it was called in England, or fountain, as it was known in the United States, was mounted on a frame and was rocked back and forth to increase the saturation of the water by the gas. The cylinder was placed under the counter in the shop. and the soda water was drawn through a pipe which had a draft arm above the counter.

Various changes and improvements in the fountain were made by U.S. manufacturers. About 1855 the marble soda fountain was introduced, the apparatus being a marble box with an ice chest to cool the coil of pipe and a metal container for the sirups, which were drawn from a row of faucets. These early soda fountains changed from time to time as improvements were made. At first carbon dioxide was obtained by the interaction of an acid and a carbonate; then the gas was prepared from various sources—from natural gas, collected from brewers' fermenting vats, and from burning coke. The last-named source thereafter supplied most of the carbonic gas, which comes in liquid form in steel cylinders for carbonating beverages.

Other improvements mere mainly in perfecting the carbonating machinery, in mechanical or electric refrigeration, in extending the service of the soda fountain and in simplifying the working of the equipment so that the process or system is more or less automatic.

Modern soda fountains are built in a variety of forms, are thoroughly insulated and sealed to keep out air and heat and are divided into mzny sections and compartments. A fountain unit is commonly equipped with a cooling chamber for soda and ice water, compartments for chipped ice, cabinets for holding bulk ice cream in cans and for packaged ice cream, sirup jars with pumps, crushed fruit jars, dry cold storage compartments for fresh fruits, milk or bottled goods and open sections with drainboard and sink. (L. J. V.; X.)

SODALITE, a member of the group of rock-forming minerals comprising the isomorphous species sodalite, haiiynite, noselite and lazurite. Sodalite (so named because it contains soda) occurs as well-formed, colourless crystals in the ejected limestone blocks of Monte Somma, Vesuvius. In the nepheline-syenite of Dungannon. in Ontario, bright sky-blue material has been quarried for use as an ornamental stone. Haüynite, or haüyne (named after R. J. Haiiy) occurs as bright blue crystals and grains in the lavas of Vesuvius, Rome. the Eifel, etc. Noselite, or nosean. is found as grayish crystals in the sanidine bombs of the Eifel. Lazurite is an important constituent, together with some haiiynite and sodalite, of lapis lazuli (*q.v.*).

The chemical composition of the members of the group is as follows:

Sodalite	$Na_8(AlSiO_4)_6Cl$
Haiiynite	$(Na,Ca)_8(AlSiO_4)_6(SO_4)$
Noselite	$Na_8(AlSiO_4)_6(SO_4)$
Lazurite	$Na_8(AlSiO_4)_6S$

Crystals usually have the form of the rhombic dodecahedron and are often twinned with interpenetration on an octahedral plane. They are white, or often blue in colour. and have a vitreous lustre. The hardness is 5 and the specific gravity 2.2–2.4.

These minerals are characteristic constituents of igneous rocks rich in soda and they also occur in metamorphic limestones. (L. J. S.; CL. F.)

SODALITY OF OUR LADY, THE, a religious society which grew out of the middle ages. The founder, John Leunis, a Flemish Jesuit scholastic, established the first Sodality of Our Lady at the Roman college in 1563.

The purposes, essentially, were embodied in the first rule of the sodality:

"The Sodality of Our Lady is a religious body . . . which aims at fostering in its members an ardent devotion, reverence, and filial love towards the Blessed Virgin Mary. Through this devotion and with the protection of so good a mother, it seeks to make the faithful gathered together under her name good Catholics, sincerely bent on sanctifying themselves, each in his state of life, and zealous, as far as their condition in life permits, to save and sanctify their neighbour and to defend the Church of Jesus Christ against the attacks of the wicked."

The Sodality of Our Lady was approved by Pope Gregory XIII and later by other popes who granted indulgences for particular spiritual and good temporal works. Sodalities are erected by the bishop of each diocese and affiliation with the mother sodality in Rome is made, with his sanction, by the father general of the Society of Jesus, to whom the popes have given the right to communicate the privileges and indulgences of the primary sodality.

From Rome the sodality spread to Belgium, France, Bavaria, other parts of Italy, to Sicily and to England. In 1574 the first sodality in the Americas was established at the Colegio Maximo in Mexico City.

Limited at first to men, the sodality was later made accessible to women and girls by Pope Benedict XIV in 1751. In 194j the sodality existed in every part of the world. In 1940, when the last complete computation was made (before World War 11), there were 67.117 sodalities, established for men and women and children, of all classes and ranks. In the United States there were (1945) 13,502 sodalities.

The national secretariate for the United States was in St. Louis, Mo. The officialorgan. The Queen's *Work*, was published, as well as three other periodicals. and special program services for parish groups, college, high school and schools of nursing sodalities. and elementary sodalities. (D. J. W.)

SODA WATER: see SOFT DRINKS.

SODDY, FREDERICK (1877–1956), British scientist, Nobel laureate in chemistry. 1921, who predicted the existence of isotopes and named them, was born at Eastbourne, Sussex, on Sept. 2, 1877, and was educated at Eastbourne college, the University college of Wales, Aberystwyth, and Merton college, Oxford.

From 1900 to 1902 Soddy was demonstrator of chemistry at McGill university. Montreal: Que., where he worked with Sir Ernest Rutherford. Afterward he worked under Sir William Ramsay at University college, London, becoming in 1904 lecturer at the University of Glasgow. In 1914 he became professor of chemistry at Aberdeen university and next (1919–36) was Lee's professor of chemistry at Oxford.

With Sir Rutherford. Soddy developed the disintegration theory of the radioactive elements.

As a result of his study of the disintegration series of the radio elements Soddy concluded (1912) that certain elements should exist in two or more forms which may have diiferent atomic weights but are indistinguishable and inseparable chemically; these forms he called "isotopes." He was elected a fellow of the Royal society in 1910.

Soddy's numerous scientific publications, chiefly on radioactivity, include *Radioactivity* (1904); *The Interpretation of Radium* (1909; rev. ed., 1920); *Chemistry of the Radioactive Elements* (1912–14); *Matter and Energy* (1912); *Science and Life* (1920); *The Interpretation of the Atom* (1932); *The Story of Atomic Energy* (1949); and *Atomic Transmutation* (1953). He was awarded the Albert medal in 1955. He died on Sept. 22, 1956, at Brighton.

SODEN, HERMANN, FREIHERR VON (1852–1914), German biblical scholar, author of a new theory of textual history of the New Testament. was born in Cincinnati, O., Aug. 16, 1852, and was educated at the University of Tiibingen. He was minister of Dresden-Striesen in 1881 and in 1887 became minister of the Jerusalem church in Berlin. In 1889 Soden became *Privatdocerit* in the University of Berlin. and four pears later was appointed extraordinary professor of divinity. He died in Berlin on Jan. 15, 1914.

Soden's most important book is *Die Schriften des neuen Testaments, in ihrer altesten erreichbaren Textgestalt hergestellt auf Grund ihrer Testgeschichte* (1902–10).

Soden introduced, besides a new notation of manuscripts, a new theory of textual history. He thought that in the 4th century there were in existence three recensions of the text, which he distinguished as *K*, *H* and *I*. After establishing the texts. he reconstructed a hypothetical text *I-H-K*, which he believed to have been their ancestor. He then tried to show that this text was known to all writers of the 3rd and 2nd centuries, but had naturally to account for the fact that the quotations of these writers and the text of the early versions often diverge from it. The explanation that he offered was that the Diatessaron of Tatian was widely used and corrupted all extant texts: so that the Old Syriac, the Old Latin. the quotations of Irenaeus. Clement. Tertullian and others may be regarded as various combinations of the Tatianic text and *I-H-K*. Finally, he tried to show that the Tatianic text is itself in the main merely a corrupt form of *I-H-K* altered in order to suit the necessities of Tatian's plan.

Indispensable though they are to the specialist in textual criticism of the New Testament, Soden's notations for the various manuscripts or groups ,of manuscripts were so elaborate, and his classifications of readings were so recondite, that they never gained general currency even among biblical scholars.

(K. LE.; X.)

SODERBLOM, NATHAN (1866–1931), Swedish Lutheran archbishop, a champion of church unity and world peace, and Nobel laureate. was born on Jan. 15, 1866. at Trono, in Hälsingland. At the University of Uppsala he took degrees in classical and oriental languages and in theology. Influenced by Albrecht Ritschl's writings, he approached the problems of the faith with an open mind and a new enthusiasm for the original teaching of Luther. Ordained in 1893, after seven years as chaplain to the Swedish legation in Paris he was appointed professor of theology at Uppsala (1901), where he had an invigorating effect on the students and church life. From 1912–14 he also held a professorship at Leipzig. In 1914 he was appointed archbishop of Uppsala and primate of Sweden. Visits to the United States and other countries aroused an interest in Christian unity which bore fruit in the first World Conference on Life and Work in Stockholm in 1925 which Soderblom organized. The series of these conferences united with the conferences on Faith and Order to form the World Council of Churches (*see* REUNION, CHURCH). For this work Soderblom was awarded the Nobel peace prize in 1930. He died at Uppsala on July 12, 1931.

In theology Soderblom made an original contribution in the field of comparative religion and early published a study of Persian religion *La Vie future d'après le Mazdéisme* (1900). Of greater importance was his study which emphasized that the fundamental conception of religion was not the idea of God but the conception of ' the holy." (*Gudstrons uppkomst*, 1914: German trans., *Das Werden des Gottesglaubens*). He delivered the Gifford lectures at Edinburgh in 1931 (*The Living God: Basal Forms of Personal Religion*, 1933). Studies on Luther appeared in a collection, *Humor och melankoli och andra Lutherstudier* (1919). As an early pioneer of the ecumenical movement Soderblom wrote *Christian Fellowship* (1923). A saintly man, a scholar and a great ecclesiastical statesman, he had a remarkable personal influence on those who knew him.

BIBLIOGRAPHY.—P. Katz. *Nathan Soderblom: a Prophet of Christian Unity* (1949); Y. Brilioth, a biographical introduction to *The Living God* (1933); *Nathan Söderblom: In Memoriam* (1931); Tor Andrae, *Nathan Soderblom* (1931). (H. M. W.)

SÖDERHAMN, a seaport of Sweden, in the *lan* (county) of Gävleborg, on an inlet of the Gulf of Bothnia, near the mouth of the Ljasne river, 183 mi. N. by W. of Stockholm by rail. Pop. (1960) 12,951.

Vessels drawing 15 ft. have access to Branthäll. The harbour is usually icebound for about four months in winter.

SÖDERMAN, AUGUST JOHAN (1832–1876), Swedish composer, was born in Stockholm on July 17, 1832. He entered the Leipzig conservatory in 1857 and remained there two years, studying with Ernest Richter and Moritz Hauptmann (*q.v.*). In 1860 he became chorus master of the Royal Opera at the Stora theatre in Stockholm. Two years later he was appointed second conductor there and held that position until his death in Stockholm on Feb. 10, 1876.

Soderman's first operetta, *The Devil's First Rudiments of Learning*, was composed at an early age and first performed in Stockholm in 1856. After that time, he completed about 60 compositions including ballads, operettas and songs, as well as sacred and incidental music. It is for his vocal music that Söderman is best known. especially the quartet "A Peasant's Wedding" from his operetta *The Wedding at Ulfåsa*, and the "Bröllopsmarsch" for four female voices. But his beautiful and original mass forsoloists, chorus and orchestra is considered his finest work.

Like Schumann, he set poems and ballads to music, principally those of Carl Bellman (*q.v.*).

SÖDERMANLAND, a *lan* (county) in central Sweden, south of Lake Malar, extends about 75 mi. east to west and 64 mi. north to south. Pop. (1960) 227.615. Area 2.645 sq.mi. The relief is broken by geological faulting, but the ground nowhere rises above about 400 ft. There are ancient towns, such as Eskilstuna, with engineering industries. The county gains importance from the Sodertalje ship canal to the east of it; this bypasses Stockholm in linking Lake Malar with the Baltic. Although not a rich district, it gains through being crossed by trunk railways and roads.

Nykoping. the county town, lost iron-ore shipment traffic to Oxelösund, which is less icebound. (A. C. O'D.)

SÖDERTÄLJE, a town of Sweden, in the *län* (county) of Stockholm, 23 mi. W.S.W. of Stockholm by rail. Pop. (1960) 33,014.

Sodertalje is on a bay of Lake Malar, there connected with the Baltic by the Sodertalje canal, $1\frac{1}{4}$ mi, in length, with a minimum depth of ten feet. This is on the route followed by the Gota canal steamers between Stockholm and Goteborg; it was opened in 1819, though a canal was begun there in the 15th century at the instigation of Engelbrecht. The town contains a church, believed to date from *c.* 1100.

SODIUM (symbol Na; atomic number 11, atomic weight 22.991), a chemical element belonging to the group of alkali metals. The electronic structure of the sodium atom is: $1s^2$, $2s^2$, $2p^6$, $3s^1$, having in common with the atoms of the other elements of periodic group I a single electron in the outermost energy level.

Only one stable and naturally occurring isotope, mass number 23, is known. but radioactive isotopes with mass numbers 21. 22, 24 and 25 have been prepared. On account of its intense chemical activity sodium is never found free in nature but in the form of compounds it is widely distributed; its various combinations comprise about 2.75% of the lithosphere. Sodium chloride or common salt is exceedingly abundant and widespread, being the chief salt present in sea water besides occurring throughout the world in extensive deposits which probably owe their existence to the evaporation of prehistoric seas. Sodium chloride comprises about 80% of the dissolved matter ($3\frac{1}{2}$%) in sea water, and the great preponderance of sodium salts over potassium salts in the sea is due to the fact that land plants assimilate large amounts of the latter as essential food and at the same time require in most cases only negligible amounts of sodium salts. A common salt mine at Wieliczka in Poland, said to be 500 mi. long, 20 mi nide and 1,200 ft. thick, has been worked continuously for 600 years. while other deposits are found at Stassfurt in Saxony; Cardona and Castile in Spain; California, New York and Michigan in the U.S.; and at Nantwich and Droitwich in England. The names of the last two places indicate the antiquity of the salt industry since "wich" is a Saxon suffix indicating a place where common salt was mined.

Sodium carbonates are also widely dispersed in nature, forming constituents of manv mineral waters, and occurring as principal saline components in natron or trona lakes, as efflorescences in Lower Egypt, Iran and China and as urao in Mexico, Colombia and Venezuela. The solid crusts found at the bottom of the salt lakes of the Araxes plain in Armenia contain about 16% of carbonate and 80% of sulphate. In Colombia there occurs a double salt. $Na_2CO_3.CaCO_3.5H_2O$, known as gaylussite. In Wyoming, California and Nevada enormous deposits of carbonates, mixed in some cases with sulphate and with chloride, occur. Vast areas of the steppes in Hungary contain sodium carbonate in the soil.

Natural sulphate occurs in an anhydrous condition as thenardite, Na_2SO_4, at Tarapaca, Chile, and in the rock-salt deposits at Espartinas near Aranjuez, Spain. Hydrated sulphates occur at several localities in certain provinces of Spain, and at Mühlingen in Aargau, and copious deposits of glauberite, the double sulphate of sodium and calcium, are found in the salt mines of Villarrubia in Spain, at Stassfurt and in the province of Tarapaca. Chile, etc. A native nitrate of sodium is obtained in great abundance in the district of Atacama and in Tarapaca, and was formerly imported into Europe in enormous quantities as cubic nitre for the preparation of saltpetre. Cryolite, a fluoride of aluminum and sodium, is extensively mined in Greenland and elsewhere for industrial purposes. These form the principal natural sources of sodium compounds — the chloride as rock salt and in sea water being of such predominating importance as to outweigh all the others. But it is questionable whether, taken altogether, the mass of sodium they represent is as much as that disseminated throughout the rocky crust in the form of sodium felspar (*i.e.*, as silicate of sodium) and in other sodium-containing rocks.

Although many sodium compounds have been known from very remote times, the element was not isolated until 1807, when Sir H. Davy obtained it by electrolyzing fused caustic soda (sodium hydroxide). This method was followed by that proposed by Joseph Gay-Lussac and Louis Thénard, who decomposed molten caustic soda with red-hot iron; and this in turn was succeeded by H. Brunner's process of igniting sodium carbonate with charcoal. In spite of many attempts, however, the metal could not be cheaply produced until electrolytic methods were perfected, and that patented by Hamilton Y. Castner in 1890 formed the basis of subsequent successful methods. Castner's process is based on the same principle as that by which Davy first isolated metallic sodium; *viz.*, the electrolysis of fused caustic soda (melting point 320° C.). The apparatus consists of an iron cylinder heated by gas rings below, with a narrower cylinder beneath, through which passes upward a stout iron cathode rod cemented in place by caustic soda solidified in the narrower vessel. Nickel anodes are suspended around the cathode, and between the two is a cylinder of nickel gauze at the bottom. with a sheet iron continuation above, the latter being provided with a movable cover. During electrolysis, oxygen is evolved at the anode and escapes from the outer vessel, while the sodium deposited in globules on the cathode floats upward into the iron cylinder, within which it accumulates and from which it may be removed at intervals by means of a perforated iron ladle. The fused salt, but not the metal. is able to pass freely through the perforations. The sodium is then cast into moulds.

Considerable sodium is also prepared by the Downs process in which fused sodium chloride is electrolyzed to yield chlorine as well as the metal. The high melting point of the sodium chloride (775° C.), nhich is inconveniently near the boiling point of the sodium (892° C.), is lowered to about 600° C. by the addition of sodium carbonate.

Properties. — Sodium is a silvery white, lustrous metal which tarnishes instantly in air because of the formation of a film of the oxide or the hydroxide. Since the outer or valence electrons are loosely held and readily move from one atom to another under the influence of an applied electric potential, the metal has a high electrical conductivity ranking fourth to silver, copper and gold. The single outer electron does not permit the firm binding of a sodium atom to all its neighbouring atoms; as a result the solid metal is soft and has a low melting point. Other physical properties are as follows:

Density, 20° C.	0.97 g. per cubic centimetre
Melting point	97.5° C.
Boiling point	892° C.
Ionization potential in the gas phase	5.12 v.
Normal oxidation-reduction potential	2.714 v.
Atomic radius	1.57×10^{-8} cm.
Ionic radius in crystals	0.95×10^{-8} cm.

Sodium is one of the most electropositive elements; it readily loses by transfer one electron per atom and thus functions as a powerful reducing agent. It is excelled in this respect only by the alkali metals below it in periodic group I; viz., potassium, rubidium and caesium. In the ordinary chemical reactions of the metal the sodium ion with an oxidation state of +1 is formed: $Na \rightarrow Na^+ + e$. Because of its great reactivity, the metal must be kept either in a vacuum or under an inert liquid such as water-free kerosene or benzene. It combines directly with the halogens and with phosphorus, taking fire when heated with these elements. It combines vigorously with oxygen, burning in air with a brilliant yellow flame and forming a mixture of the normal oxide (Na_2O) and the peroxide (Na_2O_2). The vigour of its combination with oxygen is such that it reacts with most oxides, liberating the element previously combined with the oxygen. Sodium reacts less energetically with water. however, than does potassium. but more so than does lithium, and if kept in one spot on the water surface, the temperature may go high enough to ignite the evolved hydrogen. With mercury, sodium reacts vigorously to form an alloy, or amalgam, which is a solid if the sodium content is 2% or more. An unusual property of sodium and the other alkali metals is their solubility in dry liquid ammonia to form conducting solutions. The metal atom loses its electron to an ammonia molecule, forming the metal ion and the ammoniated electron which imparts a blue colour to the solution.

Metallic sodium is used in the manufacture of sodium peroxide, sodium cyanide and sodamide, all of which are of technical importance. It is extensively used as a reagent in organic chemistry, and its alloy with potassium (liquid at ordinary temperatures) is employed in high-temperature thermometers. (See THERMOMETRY.) Its alloy with lead is used in the manufacture of lead tetraethyl, the essential constituent of antiknock gasoline, a fuel especially adapted to internal-combustion engines of the high compression type. Sodium, like the rest of the members of the alkali group, possesses to a marked degree the photoelectric effect (emission of electrons when exposed to light) and hence is used extensively in the manufacture of photoelectric cells on which television, telegraphic transmission of pictures and other similar devices depend. On account of its relatively high specific heat and high heat conductivity sodium found considerable application during World War II and after as a heat transfer medium by conducting heat from the heads through the hollow stems of valves in rotary engines used for aviation.

Compounds. — In its chemical combinations sodium is usually univalent; its salts are generally soluble in water, the least soluble being the pyroantimonate, $Na_2H_2Sb_2O_7$, and the magnesium uranyl acetate, $NaMg(UO_2)_3(C_2H_3O_2)_9.6H_2O$.

Sodium hydride, NaH, is a crystalline substance obtained directly from sodium and hydrogen at about 360" C. It burns when heated in dry air, and ignites in moist air; it is decomposed by water, giving caustic soda and hydrogen. Dry carbon dioxide is decomposed by it, free carbon being produced; moist carbon dioxide, on the other hand, gives sodium formate. Like lithium hydride, sodium hydride evolves hydrogen at the anode when subjected to electrolysis. This bchaviour shows that hydrogen can form a negatively charged ion, whereas normally it forms a positive ion. Sodium hydride has all the reducing properties of sodium accentuated by the effect of the hydrogen.

The normal oxides of the alkali metals are difficult to prepare, the difficulty of the preparation increasing nith the atomic weight of the metals. When sodium is burned in air or oxygen it is difficult to obtain the normal oxide free of the peroxide even when a limited supply of air or oxygen is used. Normal sodium oxide is best made by heating sodium azide with sodium nitrite:

$$3NaN_3 + NaNO_2 = 2Na_2O + 5N_2.$$

Sodium peroxide (Na_2O_2) is formed when the metal is heated in air or in oxygen. Commercially it is manufactured by passing an excess of dry air over metallic sodium contained in boxes of aluminum, maintaining a temperature of about 300° C. Sodium peroxide is not easily decomposed by heat and is stable in dry air; however, in moist air or when acted upon by water, it readily decomposes with the evolution of oxygen and the formation of sodium hydroxide. It is a powerful oxidizing agent under some conditions and a powerful reducing agent under others, depending on the nature of the substance with which it is reacting and the acidity of basicity of the solution. It is used for the decomposition of some minerals, especially silicates. In carrying out a sodium peroxide fusion, care should be taken that the temperature does not go too high. The oxidation usually takes place at a rather low temperature and the reaction may be reversed if the temperature is too high. Sodium peroxide oxidizes lead salts to sodium plumbate and uranium salts to peruranate. Sodium peroxide combines with carbon monoxide forming sodium carbonate:

$$Na_2O_2 + CO = Na_2CO_3,$$

and it reacts with carbon dioxide which is absorbed with the liberation of oxygen:

$$2Na_2O_2 + 2CO_2 = 2Na_2CO_3 + O_2.$$

The principle of the last reaction found practicable application especially during World War II and thereafter for the revivification of air in confined combat space such as aboard submarines and also aboard aeroplanes at extremely high altitudes.

Generally speaking, sodium salts closely resemble the corresponding potassium salts. and their methods of preparation are usually the same. For sodium salts not mentioned below reference should be made to articles wherein the appropriate acid is treated, unless otherwise indicated.

Sodium sulphide, Na_2S, obtained by saturating a caustic soda solution with hydrogen sulphide and adding an equivalent of alkali, is employed in the manufacture of soluble soda glass. Sodium sulphite, Na_2SO_3, which is employed as an antichlor, is prepared (with $7H_2O$) by saturating a solution of sodium carbonate with sulphur dioxide, adding another equivalent of carbonate and crystallizing. The anhydrous salt may be prepared by heating a saturated solution of the hydrated salt. The acid sulphite, $NaHSO_3$, or probably $Na_2S_2O_5$ (*i.e.*, pyrosulphite) when solid, obtained by saturating a cold solution of the carbonate with sulphur dioxide and precipitating by alcohol, is employed for sterilizing beer casks. Sodium sulphate, Na_2SO_4, known in the hydrated condition (with $10H_2O$) as Glauber's salt, is used as a cathartic and in the manufacture of cheap glass and wood pulp. For many years sodium was not known to form an alum (*q.v.*), but if a supersaturated solution of sodium and aluminum sulphates is allowed to crystallize below 20° C.. the alum $Na_2SO_4.Al_2(SO_4)_3.24H_2O$ is obtained, higher temperatures giving monoclinic crystals. The acid sulphate, $NaHSO_4$, also known as bisulphate of soda, is obtained as large asymmetric prisms by crystallizing a solution of equivalent quantities of the normal sulphate and sulphuric acid above 50° C.

The manufacture of sodium carbonate, commonly called soda, is treated under ALKALI MANUFACTURE. The anhydrous salt is a colourless powder or porous mass, having an alkaline taste and reaction. It melts at 852° C. On solution in water, heat is evolved and hydrates formed. Common washing soda or soda crystals is the decahydrate, $Na_2CO_3\ 10H_2O$, which appears as large clear monoclinic crystals. On exposure, it loses water and gives the monohydrate, $Na_2CO_3.H_2O$, a white powder sold as "crystal carbonate"; this substance, which is also formed on heating the decahydrate to 34° C., crystallizes in the rhombic system. Both these hydrates occur in the mineral kingdom, the former as natron and the latter as thermonatrite. The heptahydrate, $Na_2CO_3.7H_2O$, is obtained by crystallizing a warm saturated solution in a vacuum; it appears to be dimorphous. The acid carbonate or bicarbonate of soda, $NaHCO_3$, is produced in the ammonia-soda process for alkali manufacture.

Another acid carbonate, $Na_2CO_3.NaHCO_3.2H_2O$, is the mineral trona or urao. We may here notice the percarbonates, obtained by acting was gaseous or solid carbon dioxide on Na_2O_2 or $NaHO_2$ at low temperatures.

For sodium nitrite *see* NITROGEN; for sodium nitrate *see* NITRIC ACID AND NITRATES; for the cyanide *see* PRUSSIC ACID; and for the borate *see* **BORAX.**

Of the sodium silicates the most important is the mixture known as soluble soda glass formed by calcining a mixture of white sand, soda ash and charcoal. or by dissolving silica in hot caustic soda under pressure. It is a colourless transparent glass mass, which dissolves in boiling water to form a thick liquid. It is employed in certain printing processes, as a cement for artificial stone and for mending glass, porcelain, etc., and also for making the so-called silicated soaps. *(See* SOAP.) Sodium silicates containing excess of silica in solution are useful adhesives.

Sodium is most distinctly recognized by the yellow coloration which volatile salts impart to a Bunsen flame, or, better, by its emission spectrum which has a line (double), the Fraunhofer D line, in the yellow (the wave lengths are 5896 and 5890). It is gravimetrically determined as the magnesium uranyl acetate, *(see* above) or as the chloride after separation from other cations in an ion exchange column. instrumental methods such as spectrophotometry and polarography are also employed.

MEDICINE

Pharmacology. — The metal sodium is not used in medicine, but many of its salts are employed. Besides *liquor sodii ethylatis* the following salts and preparations are used in the British Pharmacopoeia. (1) *Sodii carbonis,* known as washing soda which on heating yields *sodii carbonis exsiccatus; sodii bicarbonas,* from which is made *trochiscus sodii bicarbonatis.* (2) *Sodii phosphas.* From sodium phosphate are made *sodii phosphas efiervescens* and *sodii hypophosphis.* *(See* PHOSPHOROUS). (3) *Sodii sulphas* (Glauber's salt), with its subpreparation *sodii sulphas effervescens.* (4) *Soda tartarata* (Rochelle salt), a tartrate of sodium and potassium, from which is made *pulvis sodae tavtaratae effervescens,* known as Seidlitz powder. (5) *Sodii citvo-tartras effervescens,* a mixture of sugar, sodium bicarbonate, citric and tartaric acids. (6) *Sodii chloridum,* common salt. (7) *Sodii sulphis.*

For *sodii bromidum* and *salicylatum* see BROMINE and SALICYLIC ACID respectively. *Sapo durus* (hard soap) is a compound of sodium with olive oil, and *sapo animalis* (curd soap) is chiefly sodium stearate.

Poisoning by caustic soda is rare; the symptoms and treatment are the same as described under POTASSIUM. The salts of sodium resemble potassium in their action on the alimentary tract, but they are much more slowly absorbed, and much less diffusible; therefore considerable amounts may reach the small intestine and there act as saline purgatives. They are slowly absorbed into the blood, and are a natural constituent of the blood plasma, which derives them from the food. Sodium is excreted by all the mucous surfaces and by the liver and kidneys. On the latter they act as diuretics. but less powerfully than potassisum. increasing the flow of water and the output of urea and rendering the urine less acid.

Therapeutics: External Use.—The *liquor* sodii *ethylatis* is a powerful caustic and is used to destroy small naevi and warts. A lotion of sodium bicarbonate is useful to allay itching. Solutions of sodium sulphite are used as mild antiparasitics. Internal *Use.*—Sodium chloride is occasionally used in warm water as an emetic, and injections of it into the rectum as a treatment for thread worms. A 0.9% solution forms what is termed normal saline solution, which is frequently injected into the tissues in cases of collapse. haemorrhage and diarrhoea. It forms a valuable treatment in diabetic coma and eclampsia. acting by diluting the toxins in the blood. From this has developed the intramuscular injection of diluted sea water in the treatment of gastroenteritis. anaemia and various skin affections. Sodium chloride is an important constituent of the waters of Homburg, Wiesbaden. Nauheim and Kissingen. Sodium bicarbonate is one of our most useful gastric sedatives and antacids, relieving pain in hyperchloridia. It is the constituent of most stomachic mixtures. Effervescent soda water is a mild gastric sedative. Sodium phosphate and sulphate are cholagogue purgatives and are used in the treatment of gallstones. The sulphate is the chief constituent of Marienbad and Carlsbad waters. Large doses of these salts are used to remove fluid in dropsy. Soda tartarate is purgative and diuretic, as is the citro-tartarate. These purgative sodium salts are most useful in the treatment of chronic constipation. and of the constipation associated with gout and hepatic dyspepsia. They should be dissolved in warm water and taken in the morning, fasting. In visceral gout and chronic catarrhal conditions of the stomach a course of alkaline waters is distinctly beneficial. Sodium salts have not the deuressant effect so marked in those of potassium.

SODOMA (GIOVANNI ANTONIO DE' BAZZI) (1477–1549). Italian painter. the only representative of the High Renaissance in Siena, was born at Vercelli, in Lombardy, in 1477. His first master was Martino Spanzotto. from whom he acquired the strong colouring and other distinctive marks of the Lombard school. Sodoma was taken to Siena in 1501 by some agents of the Spannocchi family. and as the bulk of his professional life was passed in that Tuscan city he counts as a member of the Sienese school, although he is not related to it in point of style. He does not seem to have been a student in Siena, apart from some attention he gave to the sculptures of Jacopo della Quercia. With Pinturicchio he was one of the first to establish there the matured style of the 16th century. His earliest works of repute are a series of 31 paintings, executed from 1505 to 1508, in the Benedictine monastery of Monte Oliveto. on the road from Siena to Rome. illustrating the life of St. Benedict. in continuation of the series begun by Luca Signorelli in 1498 As a result of these he was invited to Rome by the celebrated Sienese merchant hgostino Chigi and was employed by Pope Julius II in the Camera della Segnatura in the Vatican. He executed two great compositions and various ornaments and grotesques. The latter are still extant but the larger works did not satisfy the pope, who engaged Raphael to substitute his "Justice," "Poetry" and "Theology." In the Villa Farnesina Sodoma painted some frescoes: "Alexander in the Tent of Darius" and the "Nuptials of the Conqueror With Roxana" (by some considered his masterpiece), probably painted about 1514. He afterward returned to Siena and in 1539 went to Pisa and Lucca in quest of work. From Lucca he returned to Siena, not long before his death. which took place on Feb. 14. 1549. He had squandered his property and is said (rather dubiously) to have died in penury in the great hospital of Siena.

It is uncertain whether Sodoma was a pupil of Leonardo da Vinci, though Giovanni Morelli (in his Italian *Pictures in German* Galleries) speaks of his having "only ripened into an artist during the two years (1498–1500) he spent at Milan with Leonardo"; some critics see in Sodoma's "Madonna" in the Brera at Milan (if it is really by him) the direct influence of this master. His most celebrated works are in Siena. In S. Domenico, in the chapel of St. Catherine of Siena, are two frescoes showing Catherine in ecstasy and fainting as she is about to receive the Eucharist from an angel—a beautiful and pathetic treatment. In the oratory of S. Bernardino scenes from the history of the Madonna—the "Visitation" (1518) and the "Assumption"' (1532)—are noteworthy. In the Academy are the "Deposition From the Cross" and "Christ Scourged"; by many critics one or other of these paintings is regarded as Sodoma's masterpiece. In the choir of the cathedral at Pisa is the "Sacrifice of Abraham" and in the Uffizi gallery of Florence a "St. Sebastian." Works by Sodoma also may be seen in many other public galleries of Europe and the Cnited States; there are several in the National Gallery of Art, Washington, D.C.

SODOM AND GOMORRAH, two of the five "cities of the plain" in the Dead sea region. the others being Admah, Zeboim and Zoar (Bela) (Gen. xiii, xiv, xix). They were destroyed by a rain of "fire and brimstone." Various identifications of these cities with modern sites have been suggested. based mainly on similarity of names. Jebel Usdum. for instance, the salt hill at the southwest corner of the Dead sea. has radically the same name as Sodom. which, indeed, may have been situated in its neighbourhood.

The element of history in the narrative of the "cities of the plain" is as difficult to assess as the sites are to determine. A scientific explanation of the catastrophe is not excluded. (See DEAD SEA.)

See "Report of the Joint Expedition of the *Xenia Seminary* and *the American School of Oriental Research* at Jerusalem *to seek for the* cities *of the Plain" in Bibliotheca Sacra* (1924). (E. Ro.)

SODOMY: see HOMOSEXUALITY.

SODOR AND MAN, the Manx bishopric reconstituted about 1134 by the Manx king Olaf I as the diocese of Sudhreyjar (Latin *Sodorenses*), the "southern isles" of the Norwegian dominions in Britain comprising Man and the Hebrides. The diocese remained in the Norwegian ecclesiastical province of Nidaros (Trondheim) from 1154 until the 15th century. Following the treaty of Perth in 1266, Man was separated from the Hebrides but. though Scottish bishops have been appointed for the Isles, since 1422 the Manx bishop still bears the title "Sodor and Man." The 13th-century cathedral of the diocese. dedicated to St. German, now in ruins, stands on St. Patrick's isle in Peel bay.

Bishopscourt, the episcopal residence since the middle ages, lies about 8 mi. to the northeast.

The diocese (in the province of York) still retains its ancient convocation. vicar-general and canon law. Further, its bishop has the same right as the archbishop of Canterbury to issue "special" marriage licences.

Since the Isle of Man has its own parliamentary system, and its bishop has a seat in the council of Tynwald, he is not entitled to speak or vote in the house of lords, but in the island he is a baron by right of his bishopric. (E. H. S.)

SOENDA ISLANDS: see SUNDA ISLANDS AND STRAIT.

SOEST, a town in the Land of North Rhine-Westphalia. Germany. 33 mi. E. of Dortmund. on the Cologne-Elberfeld-Berlin Ry. Pop. (1959 est.) 33,291. Mentioned in documents as early as the 9th century, Soest was one of the largest and most important Hanseatic towns in the middle ages. It was one of the chief emporiums on the early trading route between Westphalia and lower Saxony. Its code of municipal laws (Schran; *jus susatense),* dating from 1144 to 1165, was one of the earliest and best. and served as a model even to Liibeck. On the fall of Henry the Lion, Soest passed with the rest of Angria to Cologne. In the 15th century the strife between the townsmen and the archbishops broke out in open war, and in 1444 the fortifications of the town withstood a long siege. Papal intervention ended the strife, and Soest was permitted to remain under the protection of the dukes of Cleves.

Of its churches the most striking are St. Peter's, the Wiesenkirche. a gem of Gothic architecture, Maria zur Hohe, with beautiful mural frescoes, and the Roman Catholic cathedral. The town hall (1701) contains valuable archives; the gymnasium at Soest was founded in 1534, through the instrumentality of Melanchthon.

Ironworking, manufacture of soap, sugar, marmalade, machinery, lamps, cigars, bricks and tiles, linen spinning and brewing, together with market gardening in the neighbourhood and trade in timber and grain are the leading industries.

SOFFIONI (SUFFIONI), a name applied in Italy to certain volcanic vents which emit jets of steam, generally associated with hydrogen sulfide and carbon dioxide, sometimes also with a little ammonia and marsh gas.

The soffioni are usually arranged in groups and are best represented in the Maremma of Tuscany, where they contain a small proportion of boric acid (*q.v.*), for which they were for many years the chief commercial source. See FUMAROLE.

SOFIA, capital of Bulgaria, in an upland plain, about 1,700 ft. above sea level, between the western Balkans on the north and the Vitosha massif on the south. Two small tributaries of the river Isker, the Vladaya and the Perlovets, flow through the city.

History.—Serdica (from Serdi, the name given by the Romans to the inhabitants of the plain) was founded by the emperor Trajan. It became a Roman provincial town of considerable importance in the 3rd and 4th centuries A.D. Burned by the Huns in 441 Serdica was rebuilt later. Its name was converted into Sredets by the Slavonic newcomers who associated it with *sreda* (middle) and this form subsequently became the Byzantine Triaditsa. The town was taken by the Bulgars under Krum in 809 and. after Trnovo. became the second largest city of mediaeval Bulgaria. It successfully resisted the attacks of the emperor Basil II in 987 but between 1018 and 1186 it was under Byzantine rule, serving as a frontier fortress. It flourished again when Bulgaria recovered its independence. but in 1386 was captured by the Turks. In 1443 it was for a brief time occupied by the Poles under King Wladyslaw III and the Hungarians under John Hunyadi. Under Turkish rule the city was for nearly four centuries the residence of the *beylerbey* or governor general of the whole Balkan peninsula except Bosnia and Morea. During this period the population was mainly Turkish. Sofia was occupied by Russian troops in 1829 and 1878; by the British. French and Italian in 1918; and by the Russians again on Sept. 9. 1944.

Architecture and Growth of the Modern City.—The name of Sofia. which came into use in the 14th century. is derived from the Church of St. Sofia built by the Byzantines in the 11th century, now in ruins. The oldest building in Sofia is the round chapel of St. George. originally a Roman bath. Of the principal mosques built by the Turks. the large mosque, with nine metal cupolas, has become the National museum; the Black mosque has been transformed into an Orthodox church; the Banya-Bashi mosque is still used by Moslem worshippers. The old Orthodox cathedral of Sveta Nedelya (formerly Sveti Kral), in which the remains of the Serbian king Stefan Crosh II are preserved. was wrecked by the Communists on April 16. 1925, hut was later rebuilt. The new cathedral of St. Alexander Nevsky was built as a memorial to the Russians fallen in 1877–78. The royal palace, occupying the site of the Turkish *konak,* was built,by Prince Alexander in 1880–82 and enlarged by King Ferdinand.

When the constituent assembly sitting at Trnovo chose Sofia in 1879 as the capital of the restored Bulgaria, its population was only 20,858. It grew rapidly after the Balkan Wars of 1912–13 and World War I because of the influx of refugees from Macedonia. amounting to 154,025 in 1920. In 1947 it was 434.888, in 1956, 644.727 and estimated at 766,400 in 1560. Sofia forms the centre of a railway system radiating to Istanbul (300 mi.), Eurgas, Varna. Ruse (and Bucharest). Vidin, Belgrade (206 mi.). Kyustendil and Petrich. The station and railway yards were heavily bombed by the Allies in 1943 and 1944. After World War II a plan for the city's reconstruction and development was introduced. The Sofia university was considerably enlarged and many new public buildings and dwelling blocks were erected. The new Vasil Levski stadium can hold 45,000 spectators.

SOFTBALL is one of the most popular participant sports in the United States. Though there are conflicting claims of invention and origin, it is generally agreed that softball, closely akin to baseball. developed from a game called "indoor baseball" which was first played in the gymnasium of the Farragut Boat club in Chicago. Ill., in 1887. The game was introduced to the playgrounds and parks of Chicago and Minneapolis and later promoted by other public playground leaders throughout the country as a desirable outdoor game to be played in small public playgrounds. It became known in the United States by various names such as kitten ball, mush ball, diamond ball. indoor-outdoor and playground ball. Since there were wide variances in playing rules. size and type of playing equipment, and lack of uniformity as to dimensions of the playing field, a need developed to secure a uniform code of rules. In certain states. particularly Minnesota, Wisconsin, Florida and Colorado, the game rapidly progressed; playing rules were made more uniform and improved equipment was developed by manufacturers.

At the National Recreation congress in Springfield, Ill., in 1923, a rules committee was appointed by Joseph Lee, a United States pioneer in recreation. That year marks the start of the development of softball as it is known today. The Lee committee was later enlarged to form the International Joint Rules Committee of Softball. which came to include representatives of a number of organizations which promote and sponsor softball. The committee was formed to gain general acceptance of and to publish and circulate a standard set of rules; to study the game in order to recommend changes in rules that would benefit the largest number of players; and to co-operate with manufacturers of sporting goods to secure standard and satisfactory equipment.

The Amateur Softball Association of America must be credited for much of the successful growth of softball. Organized in 1932, it came to be the recognized governing agency for promotion and control of organized national competition. It became a member of the Amateur Athletic union, the U.S. Olympic commission, the National Recreation association, and the International Softball federation. Through its metropolitan, state and regional organization. it assumed responsibility for directing thousands of teams in competition, culminating in world championship tournaments for men and women, which have been held without interruption from 1933.

The International Softball federation acts as a clearing centre for the softball organizations of more than 20 countries, including Australia. Japan, Argentina, England and Canada.

Basically, the fundamentals of softball are the same as those of baseball (*q.v.*). Batting and fielding strategy are similar, but since the game is played on a much smaller area the action is much faster. It seldom requires more than an hour to complete seven innings for an official game.

A distinctive technique in softball is the underhand pitching. Special skills were soon developed in this art and pitchers developed baffling windups, followed by a release and throw of the ball that travels with a speed comparable to that of the overhand regulation baseball.

The regulation playing field for softball should have a clear, unobstructed area within a radius of 200 feet from home plate between the foul lines. It includes a diamond-shaped area with 60-ft. base lines. The pitching distance for men is 46 ft. and for women 38 ft. Bats must be round; not more than 34 in. long and not more than $2\frac{1}{8}$ in. in diameter at the largest part. The official softball is a smooth-seam ball. not less than $11\frac{7}{8}$ in. nor more than $12\frac{1}{8}$ in. in circumference. weighing between 6 and $6\frac{3}{4}$ ounces.

In summary. the rules for softball differ from those of baseball in the following respects:

(1) Softball base lines are 60 ft. long whereas baseball base lines are 90 tt.
(2) Softball pitching distance is 46 ft compared with baseball's 60 ft. 6 in.
(3) The official softball is heavier and larger than a baseball
(4) The official softball bat is shorter and lighter than a baseball bat.
(5) Softball games consist of seven innings whereas baseball games are nine innings.
(6) The chiei difference in the pitching rules is that in softball the ball is delivered by an underhand motion to the batter with a follow-through of the hand and wrist past a straight line of the body

before releasing the ball. The pitcher must pause for one second at the conclusion of his windup before delivering the ball.

(7) Base stealing is permitted in both games, but in softball the runner must keep contact with the base until the pitcher releases the ball on delivery to the batter.

Principal reasons for the great popularity of softball are that the game is played with speed, that it can be played at relatively low cost for equipment and uniforms, and that it can and is played by children and young and old men and women; and it has great appeal to spectators. Because of the smaller playing area, softball fans are continually thrilled by hard drives, bare-handed stops and fast throws. Close decisions are the rule on most plays. It gained wide acceptance, moreover, as an outstanding girls' and women's team sport; hundreds of women's softball teams are members of leagues which compete for honours in a world's championship tournament for women.

Softball demonstrated also its value as an informal recreational activity for industrial and business, church and school groups, at picnics and outings, and on the neighborhood vacant lots and playgrounds.

The widespread interest in softball in the United States was indicated by a broad geographic distribution of world championship teams after the formation of the Amateur Softball Association of America. In the 1960s it was estimated that in the U.S. alone softball was played by more than 20,000,000 participants annually. It was recognized as one of the five leading spectator sports with a probable yearly attendance of 125,000,000.

(A. T. N.)

SOFT DRINKS, or nonalcoholic beverages, may be divided into two classes: carbonated beverages (sometimes called aerated waters) and still beverages (those without carbonation). With the exception of club soda or sparkling water, carbonated drinks contain sugar and edible acids, as well as artificial flavours or natural flavours derived from fruits, nuts, roots, herbs or other plant sources. Still beverages generally contain natural or artificial fruit flavours.

History. — Carbonated beverages and waters developed from European attempts to imitate the popular and naturally effervescent waters of famous springs, with primary interest in their reputed therapeutic values. The effervescent feature of the waters was recognized early as most important. Jan Baptista van Helmont (1577–1644) first used the term "gas" in his reference to !he carbon dioxide content. Gabriel Venel referred to "aerated water." confusing the gas with ordinary air. Joseph Black named the gaseous constituent "fixed air."

Numerous reports of such experiments and investigations were included in the *Transactions* of the Royal Society of London in the late 1700s, including the studies of Stephen Hales. Joseph Black. David Macbride, William Brownrigg, Henry Cavendish, Thomas Lane, Joseph Priestley and others. Duplication of the waters of Bad Pyrmont. a spa in Germany near the city of Hameln, was one of the major objectives, probably because of the popularity of the spa and also because of the relatively simple nature of the mineral content of the waters there.

Priestley, who obtained "fixed air" for his experiments from a brewery near his house, published *Directions for Impregnating Water with Fixed Air* in 1772. For his reports concerning "fixed air" and the mixture of waters with it, but with special emphasis on the medicinal values shown by him to exist in artificially carbonated water (but since found to be illusory), he was awarded the Copley medal by the Royal Society of London in the following year.

Meanwhile, other European scientists were active in the field. Studies by Torbern Bergman, a Swedish chemist. were published in the reports of the Swedish Royal Academy of Science in 1775. Carl Wilhelm Scheele of Sweden was similarly engaged. Antoine Lavoisier. in France, identified the "fixed air" of Priestley as a combination of carbon and oxygen which he called *gas acide carbonique*. John Mervin Nooth, in England, developed special apparatus for the preparation of small quantities of the effervescent waters. His report appeared in the 1775 *Transactions* of the Royal society.

Improvements in the Nooth device were made by Jean Hyacinthe de Magellan in 1777, and in 1781–83 the English chemist Thomas Henry described apparatus for the production of carbonated waters on a commercial scale. Many others followed, and factories and bottling plants were opened in Geneva, Switz., Paris. London, Dublin. Ire., Dresden, Ger., and several other European cities during the period 1789–1821.

U.S. investigators also were interested in carbonated water and its health values. As early as the summer of 1807, in New Haven. Conn., Benjamin Silliman of Yale college began producing bottled soda water on a commercial scale, and he opened a public establishment for dispensing it. In Philadelphia! artificially carbonated waters were bottled and sold commercially by Joseph Hawkins, with machinery of his own invention. The firm was known as Shaw and Hawkins. Hawkins was issued a U.S. patent for preparation of imitation mineral waters in 1809, the first of record in this field.

The addition of flavourings to soda water to form the effervescent type of soft drink or carbonated beverage which became so widespread in America began early. Its exact origin is obscure, however. In 1768 Richard Bewley, in England, had introduced a form of soda water which he described as "mephitic julep," to be taken "with a draft of lemonade." He had followed a similar suggestion of Macbride concerning the medical efficacy of a mixture of fresh lime juice and alkaline salts taken as an effervescent drink.

Production Methods. — The basic ingredients in soft drinks are water, carbon dioxide, sugar, flavouring and, sometimes, artificial colouring.

Water, although most often taken from a safe municipal water supply. usually is given further processing to ensure uniformity of the finished product, because the amount of impurities in the municipal supply may vary from time to time. In some bottling plants the water-treatment equipment may consist simply of a sand filter to remove minute solid matter and an activated-carbon purifier to remove colour, chlorine and other tastes or odours. In most plants, however, water is treated by a process known as superchlorination and coagulation. In this process the water is exposed for two hours to a high concentration of chlorine as well as to a flocculant that removes such organisms as planktons (minute plants and animals); it is then passed through a sand filter and activated-carbon purifier.

Carbon dioxide gas gives the beverage its sparkle and tangy taste. and prevents spoilage. While it has not been proved that carbonation offers a direct medical benefit. carbonated beverages are used to alleviate post-operative nausea when no other food can be tolerated, as well as to ensure adequate liquid intake.

Carbon dioxide is supplied to the soft drink manufacturer in either liquid or solid ("dry ice") form, maintained under high pressure in heavy steel containers. As the pressure is released, the material changes into the gaseous form, in which it can be dissolved in water in quantities that vary with temperature and pressure. The amount of gas the water will absorb increases as the pressure is increased and as the temperature is decreased. Carbonation (of either the water or the finished beverage mixture) is effected by chilling the liquid and cascading it in thin layers over a series of plates in an enclosure containing carbon dioxide gas under pressure.

Flavouring sirups are made from sugar that is delivered from the refiner either in granulated form or as a 67% or 76% solution known as liquid sugar. The sugar is dissolved or diluted with processed water, and the desired flavouring substances are added. The resulting mixture is made more palatable by the addition of edible acids, principally citric acid, and its colour may be heightened by the addition of caramel (burnt sugar) or certified food colouring materials.

Two methods of producing the finished beverage are in use: either the sirup may be mixed with carbonated water prior to bottling or a precise amount of sirup may be measured into each bottle, after which the bottle is filled with carbonated water. In either case. the sugar content—51%–60% in the sirup—is reduced to 8%–13% in the finished beverage. The blending of sirups, mixing with carbonated water and filling of containers is carried out almost entirely by automatic machinery.

Most soft-drink producers use bottles of the returnable type. which reduce packaging costs, although some .are using nonreturnable. "one-trip" bottles and metal cans. Before filling. returnable containers are thoroughly flushed with hot solutions of caustic soda or other alkalies for a minimum of five minutes, and then rinsed with potable water.

The production of still beverages involves ingredients and techniques similar to those used for carbonated beverages. However. since they lack the protection against spoilage afforded by carbonation, still beverages usually are pasteurized. either in bulk or by continuous flash pasteurization prior to filling or in the bottle.

Some still beverages are sold in concentrated. frozen form. and these do not require pasteurization; however. they must be kept frozen until used. Since they are not under pressure, still beverages may be packaged not only in bottles and cans but also in cardboard cartons.

See also GINGER ALE. (JN. J. R.; H. E. K.)

SOFT FURNISHINGS: *see* INTERIOR DECORATION.

SOFT HAIL, precipitation of white, opaque or translucent. round or conical, snowlike grains 2–5 mm. in diameter. Soft hail is equivalent to the German *graupel*, a word often quoted in English meteorological literature, and to the *snow pellets* of U.S. terminology. From 1929 the International Meteorological Code has distinguished several slightly different forms of soft hail, giving soft hail a more restricted definition than theretofore. These are: small hail and soft hail.

Soft hail is a crisp compressible variety that bounces when it hits the ground, and falls steadily as a preliminary to ordinary snow. Small hail is soft hail that has become slightly rimed or glazed by passing through clouds, or by falling with rain, so that it is hard and does not bounce, and falls in showers, sometimes alternating with rain. Both types occur only at temperatures near the freezing point. Neither is a familiar occurrence outside of the western coasts of countries in higher latitudes: Norway, Chile. Iceland. British Columbia, Alaska. *See* HAIL. (R. G. SE.)

SOGA, the name of one of the great families of Japanese history, the first to usurp power and thus initiators of the tradition of dual government in Japan. In addition. Soga Iname was primarily responsible for introducing Buddhism into Japan, the first Buddhist temple in that country being in his home. Although descended from a collateral branch of the imperial family. the Soga's history is obscure until Iname became minister in A.D. 536. His son Umako also became minister. and. beginning with the death of the emperor Bidatsu in A.D. 585, executed a series of maneuvers that culminated in the enthronement of his niece as empress Suiko in 592. Between that year and 643 the Soga held undisputed power in Japan and could claim three emperors and one empress as their creations. In 645 Soga Iruka and Soga Yemishi were assassinated by the Fujiwara family who were to succeed them as regents, and with these murders Soga power ended. *See* also JAPAN : *History:* The *Clan Period.*

BIBLIOGRAPHY.—G. Sansom, *A History* of Japan *to 1334 (1958);* J. Murdoch, *A History of Japan,* vol. 1, ch. 4 (1926); R. Ponson-by-Fane. *History of the Imperial House of Japan* (1959). (J. A. HA.)

SOGA (BASOGA, WASOGA), an east African people of the Interlacustrine Bantu group who inhabit the area east of the Nile between Lakes Victoria and Kyoga. Although sharing a common basic culture. the Soga were divided among several small states: Bugabula, Bulamogi, Busiki. Luuka, Kigulu, Bukoli, Bugweri, Butembe, Bunya and Bunyuli. In economy. technoloav and religion they resembled the Ganda (*q.v.*). In each state there were several dozen patrilineal clans! one of which held the rulership. The northern states were often tributary to the Nyoro, while the Ganda dominated the south.

Since 1894 the Soga have formed an administrative district of the Uganda protectorate and have shared a common local government. In the 1960s they numbered about 600,000. See also BANTU (INTERLACUSTRINE). (L. A. FS.)

SOGDIANA, a province of the Achaemenian empire (O. Pers. *Sughuda*), corresponding to the modern districts of Samarkand and Bukhara; it lay north of Bactriana between the Oxus and the Iaxartes, and embraced the fertile valley of the Zerafshan (anc. Polytimetus). Under the Greeks Sogdiana was united in. one satrapy with Bactria. and subsequently it formed part of the Bactrian Greek kingdom till the Scythians (*see* SCYTHIA) occupied it in the middle of the 2nd century B.C. The valley of the Zerafshan about Samarkand retained even in the middle ages the name of the Soghd of Samarkand.

SOGNE FJORD, an inlet of the west coast of Norway, penetrating 109 mi. eastward into the mainland. It is the longest fjord in Norway. and the deepest, approaching 700 fathoms in some parts. Sognefest at its entrance is 50 mi. by water from Bergen, in 61° 5' N. For the first 50 mi. the flanking mountains are unbroken by any considerable branch, but beyond this point several deep. narrow inlets penetrate the Jostedalsbre and Jotunfjeld to the north. and the Hardangerfjeld to the south. being walled in at their heads by snow-clad mountains. The chief fjords are Fjaerlands. Sogndals and Lyster fjords to the north. Aardals fjord to the east. Laerdals and Aurlands fjords to the south. Branching from the last is the Naero fjord, with a precipitous valley of great beauty (Naerödalen) at its head.

SOHO, a district in the City of Westminster, London. Eng., bounded by Oxford street (N.), Charing Cross road (E.), Coventry street (S.) and Regent street (W.); Piccadilly circus is at the southwestern corner. A plan of 1585 shows the area as fields which in 1643 just came within the fortifications of London hurriedly put up against the royalists; a fort stood near the northern end of the present R'ardour street. Gregory King surveyed the area for building and in 1681 built King's, later Soho, square; the district soon becoming fashionable. Foreign tradesmen. especially French Huguenots, finding few opportunities in the City, settled in Soho. In 1700 there were about a dozen French churches near and in Soho, but by the early 20th century the French had been displaced by, among others, the Italians whose quarter was originally in Clerkenwell. Soho has many famous names linked n-ith it, including G. J. Casanova. William Blake, who was born in Broad (now Broadwick) street, and Karl Marx; William Hazlitt lies buried in St. Anne's church gardens not far from the bankrupt Theodore. king of Corsica. Soho, no longer a community. is known chiefly for its continental restaurants and food shops; Berwick market is within its bounds, and clothing firms. film companies and publishers. especially of music. are established. The name (*So* ho in ratebooks of 1632) is an old hunting cry.

SOIGNIES (Flemish *Zinnik*), a town of the province of Hainaut, Belgium, with important limestone (Carboniferous) quarries in the neighbourhood. Pop. (1955 est.) 10,843.

The forest of Soignies once extended over south Brabant up to the walls of Brussels and was part of the *Silva Carbonaria* of antiquity. Napoleon ordered 22,000 oaks to be cut down in it to build the Boulogne flotilla for the invasion of England. King William I of the Netherlands continued the process. A portion of the forest in the neighbourhood of Waterloo was assigned in 1815 to the duke of Wellington.

SOIL is the product of two processes: the decomposition of rock and the decay of plant and animal life. Volcanic action and the disintegration and decomposition of large masses of solid rock have left a blanket of unconsolidated mineral material over most of the surface of the earth. This collection of mineral particles is called the regolith. It is always mixed with varying amounts of organic materials that have been added by the partial decomposition of organisms having lived in or on the regolith. The few inches of productive topsoil on which agriculture depends required thousands of years for their development.

The formation, properties and scientific cultivation of the soil are of interest to farmers, soil scientists: geologists, mineralogists, engineers and other specialists. These aspects of soil study are discussed here under the following headings:

I. Soil Development
II. Soil Classification
  1. Development of Soil Science
  2. Systems of Classification
  3. Soil Survey

III. Physical Nature and Properties of Soils
   1 Component Parts of Soils
   2. Structure and Its Practical Significance
   3. Porosity and the Weight of Soils

I. SOIL DEVELOPMENT

The surface of the regolith seldom remains in the place where it was first formed; during its millions of years of existence it has been moved from place to place by wind. flowing water or advancing glaciers. Soil is any part of the regolith that has been in one place for a sufficient length of time and has been acted upon by natural physical, chemical and biotic forces of sufficient intensity to develop detectable surface and subsurface layers called soil horizons. Soil-horizon differentiation in the regolith involves the accumulation of organic materials in the shallower horizons and the movement of dissolved mineral materials from certain horizons into neighbouring horizons (*see* fig. 1).

The regolith was formed by the physical weathering or disintegration of massive rocks and minerals and by the chemical weathering or decomposition of some of the minerals in the parent rock. Rocks disintegrate or fracture into smaller and smaller particles due to alternate expansion and contraction resulting from heating and cooling, freezing and thawing, wetting and drying. Chemical weathering of rocks results from reactions of component minerals with oxygen and water and with carbonic, nitric and sulfuric acids of atmospheric and biological origin.

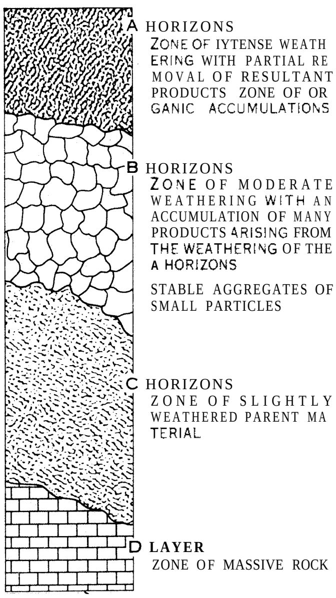

FIG 1.—SCHEMATIC REPRESENTATION OF WEATHERING IN THE REGOLITH OF THE EARTH'S CRUST AND SUBSEQUENT SOIL-PROFILE DEVELOPMENT

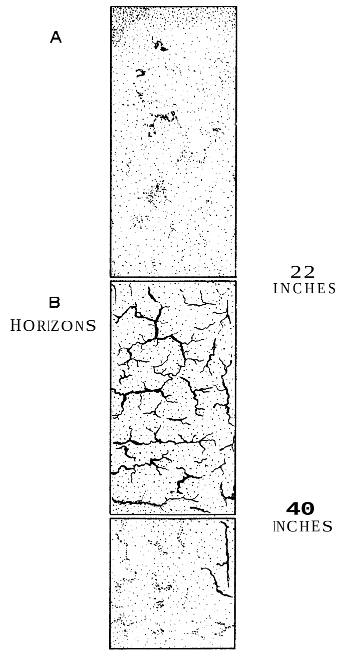
Soils develop from the regolith by a continuation of physical, chemical and biotic actions and reactions similar to those that originally formed the regolith and by a differentiation of the weathered regolithic material into a profile of horizons. For regolithic material to be classed as a soil. its surface must be differentiated from deeper material into from one to four possible master horizons designated from the surface downward as **A.** B and C horizons and D layer. Master horizons are usually several inches thick (*see* fig. 2, 3 and 4). If minor differentiations occur within the master horizons, the subhorizons are designated by appropriate subscripts such as A,, B_4, C,, etc.

Horizons become differentiated during soil development in the regolith because conditions vary with depth. In humid regions physical .and chemical reactivity and biotic activity are much more intense in the surface than in subsurface materials. Dispersed and dissolved products are moved from the surface horizons to the subsurface horizons or they are leached completely from the developing soil profiles. In desert regions chemical and biotic soil-forming processes are much less intense than in humid regions, and the zone of greatest chemical and biotic activity is usually within one of the subsurface rather than surface horizons. There is seldom enough water in desert soils to move products of weathering from one-horizon to a lower one. As a result of the above processes each horizon of a soil profile differs from the one above or below by one or more characteristics. such as colour, chemical composition, arrangement of individual particles or size distribution of constituent particles.



ILLINOIS AGRICULTURAL EXPERIMENT STATION
FIG 2.—A

The A horizons are the horizons of the surface layers of soil profiles. They contain more organic matter than the other horizons except in certain desert soils in which the production, preservation and accumulation of organic matter may be favoured somewhat more by conditions found lower down in the B horizons. The A horizons are the most weathered and leached of the various horizons. In the soils of the cold humid temperate regions. weathering and leaching have left residues in the A horizons which are high in silica and low in iron and aluminium oxides and other sesquioxides (*see* also *The Chemical Properties of Soils* below). The opposite is true of the soils of the humid tropics in which soil-forming processes have left residues in the A horizons which are high in the sesquioxides and low in silica (*see* also LATERITE).

The B horizons of the soils of the cold humid temperate regions may accumulate all or only part of the sesquioxides removed from the corresponding A horizons. In cases where only part of the sesquioxides has been deposited in the B horizons the remainder has been removed from the soil by drainage waters. Intermediate climates between the cold humid temperate regions and the humid tropical regions produce soils with A and B horizons having intermediate silica or sesquioxide residues and accumulations.

The humid temperate climates are conducive to-the formation in the A and B horizons of a group of very finely divided hydrated iron and aluminum sili-

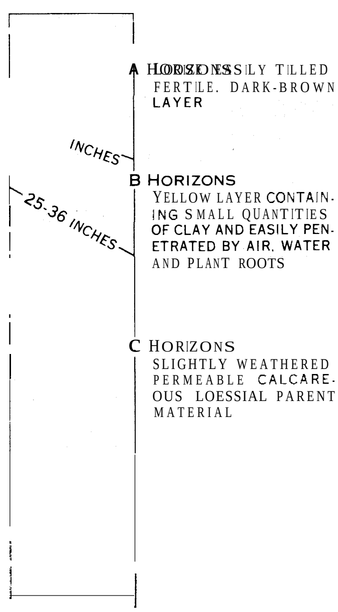


FIG 7 —TYPICAL FEATURES OF PROFILES OF SOIL WITH HIGH PRODUCTIVE CAPACITIES cates called clay minerals. The B horizons of soils occurring in these climatic regions have been enriched by clay minerals carried down by percolating nater from the A horizons.

The C horizons oi soils represent the types of material from which the A and B horizons were formed. These materials are called the parent materials of the soils of nhich they are a part and their characters are determined by the rocks from which they were originally iormed by weathering processes.

The D layers are beneath the soils and are not a part of the soil profiles. They are strata having properties much difierent from the overlying C horizons. They are strata which, by virtue of their properties and shallow position, exert a significant influence on the properties of the soils above.

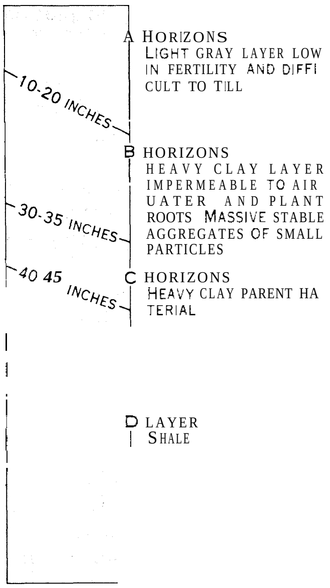

FIG. 4—TYPICAL FEATURES OF PROFILES OF SOIL WITH LOW PRODUCTIVE CAPACITIES

Some of the master horizons may be missing irom soil profiles. The A horizons may have been removed from come soils by erosion. Other soils may be too young and too feebly developed to shon B horizons In still other soils C horizons may be absent because the original regolith was so shallow that it became completely occupied by the A and B horizons. In opposite cases where the regolith is extremely deep. D layers usually are not recognized because they do not influence the properties of the overlying soils.

Soils may also develop from thick layers of organic materials found in the bottoms of naturally or artificially drained swamps or lakes occurring in regions with cold temperate climates. These organic materials accumulated. before drainage, from dead water plants and other organisms. These organisms were only slightly decomposed due to relatively low temperatures and a lack of oxygen at the bottom of the swamps and lakes. After the organic sediments become exposed to air by drainage, they differentiate into horizons and develop into organic soils. The A horizons are first formed by partial oxidation of the organic compounds and slightly mineralized fractions are left as residues. As organic soils become older they become more and more mineralized to greater and greater depths.

The factors that influence the rate and kind of soil development include: the nature of parent material, climate, biological activity, topography or drainage and the age of the developing soil profile. These factors, through combinations of many intensities, provide many environments and many possible variations in rate and kind of soil development. This can be illustrated by studies made on soils developed from regolithic materials deposited approximately 2,000, 10,000 and 200.000 years ago, respectively. The 2,000-year-old deposits are Indian mounds and the other two are continental glacial deposits, all occurring in humid temperate regions. The 2.000-year-old deposits show little if any soil-profile development; the intermediate regolithic materials have developed weak soil profiles; and the 200.000-year-old deposits have developed well-defined soil profiles. In contrast to this slow development in the temperate climates. in the tropics it is possible to find 50-year-old deposits of regolithic materials that have developed perceptible soil horizons.

Variations in age, parent material and environment have been responsible for the development of many kinds of soils on the earth's surface with many different physical. chemical and biological properties and with wide ranges in productive capacities. These soil characteristics have been influential in determining the kind of native vegetation best able to survive in various parts of the world. They are also influential in determining the methods man must adopt in using and managing soils for crop production.

II. SOIL CLASSIFICATION

Although soil covers the land as an almost continuous blanket, it differs greatly in character and in useiulness to man from region to region, from farm to farm. and even within single fields. Soil scientists. engineers, geologists, farmers and others have named and classified difierent kinds of soil, each group according to its special knowledge and interest.

The early attempts to classify soil were based on its products rather than on its intrinsic properties, because men in ancient times were interested in the fruits of the soil, not in the soil itself. Even educated people of the 18th and 19th centuries associated the soil with the lowly position held by those who tilled it. and few found it worthy of study as a natural object. The infant study of geology was a reputable subject for scientists of those times, however, and European geologists were the first to make serious attempts to classify soil. To the geologists. however, the soil was merely a kind of disintegrated rock, and they classified it accordingly. This was the principal concept expressed in soil classification throughout most of Europe and the United States and Canada from about 1850 to 1920. Terms like granite soils, transported soils and residual soils came from classifications by geologists.

1. Development of Soil Science.—While soil classification was dominated by geologic concepts throughout most of Europe, a group of Russian scientists led by V. V. Dokuchaiev began to study the soil itself, not as decomposed rock but as a natural substance warranting special attention. They found that different kinds of soil had distinctive layers or horizons. and that the kind and arrangement of these horizons at a given place were determined by climate, vegetation, topography and age as well as geo-

logic material. Using this concept of dynamic soil formation, Dokuchaiev proposed the first classification of soil as an independent natural body in 1886.

The language barrier between Russia and the rest of the world prevented dissemination of the Russian concept of soil for many years. *The Great Soil Groups of the World and Their Development* (1908) by Konstantin Dimitrievich Glinka (*q.v.*) of the Leningrad Agricultural institute was translated into German in 1914 and, 13 years later, in 1927, into English. This work revolutionized soil classification throughout the world when it finally became known. Under its influence, European soil scientists emphasized concepts of soil development in their classification systems. The system of A. A. J. de Sigmond, published in 1933, was based largely on selected chemical properties acquired during soil formation. That of W. L. Kubiena, published in 1950 as *Diagnostics and Systematics of the Soils of Europe,* depended mainly on theories of the changes that occur in soils with time under different conditions. Most of those best known dealt with the major genetic kinds of soil of large areas and little with the details of soil properties important within farmers' fields.

In the United States, as in Europe, the concepts of geology dominated soil classification until the Russian work became known. From 1860 to 1900, E. W. Hilgard developed a concept of soil similar to that of Russian scientists and published an accurate picture of soil properties. correlated with types of vegetation, later to become major bases of soil classification. Few understood Hilgard's concepts, however, and much of his knowledge went unnoticed.

The first major lasting contribution to soil classification in the United States came through the establishment of the soil survey in 1899. This work involved making maps on which areas of the different kinds of soils of farmers' fields were shown for predicting crop adaptation, productivity and land values. Different kinds of soils, called soil series, were named after places where they were first found, such as Norfolk and Hagerstown. Each series was divided on the basis of texture into units called soil types, which became the basic units of soil classification for practical application to the problems of fields and farms. Thus while the genetic kinds of soil of extensive regions were being classified as great soil groups in Russia, in the United States the soils of small areas important to the individual farmer were being classified as soil types and series.

2. Systems of Classification. — After the German edition of Glinka's work was published in 1914, C. F. Marbut, chief of the division of soil survey of the United States, who translated the work into English. combined the Russian concept of great soil groups with the U.S. concept of soil types and series into a single system of classification useful for describing and naming soils of both extensive areas and individual fields. Marbut's system was presented to the First International Congress of Soil Science in 1927 and received world-wide recognition.

Knowledge about soils increased rapidly after 1930, and many schemes for classifying soils were proposed in different countries. In spite of modification of Marbut's system in 1938 and again in 1949, the soil survey staff of the United States department of agriculture under the leadership of C. E. Kellogg concluded that a completely new system was required to incorporate new knowledge and to eliminate the confusion of names and poorly defined classes that had developed. In 1952 the soil survey staff began the first of six trial systems, each of which was circulated among leading soil scientists throughout the world for trial under their conditions and was revised to accommodate their findings. Linguists developed a terminology based on Latin and Greek and translatable directly into related languages. The sixth revision was a system based on measurable soil properties rather than on theories of soil formation, although characteristics used to distinguish different kinds of soils reflected major concepts of soil development. Soil series of the United States were classified in the svstem. presented at the Sixth International Congress of Soil Science in 1960.

In addition to the taxonomic classification of soil, mapping units of soil surveys were grouped in many ways to show such interpretations as crop adaptation, single properties, productivity, erosion hazard and need for fertilizer or lime. The land capability system of the United States soil conservation service. designed as a guide for planning use and management of farmers' soils, was one of the best known of many such interpretive groupings. Comparable but less-known groupings were developed for such special purposes as irrigation, drainage and land appraisal.

The units of classification and mapping of detailed soil surveys have also been interpreted for engineering uses. In addition, engineers developed independent systems of classifying soil material according to texture and other properties important in engineering construction. Some confusion of names resulted because the engineering soil classifications deal mainly with soil as a material for construction, while those of soil scientists deal with it as a substance formed by natural processes.

For detailed information about criteria and systems of soil classification, see *Soil Science,* vol. 67, pp. 77–191 (1949) and U.S. Department of Agriculture, "Soil Survey Manual," *Handbook* No. 18 (1951).

(M. G. C.)

3. Soil Survey. — The purpose of a soil survey is to provide an inventory of the soil resources of a given area, usually a county or its equivalent. First, the soils of the area must be classified. This is done by making a field study of the properties of surface and subsoil layers at numerous locations. Typical soil samples are sent to the laboratory for physical and chemical examination. Next, a map is prepared on which is shown the locations of the different soil groups recognized in the soil classification. Finally, a written report to accompany the soil map is prepared, giving general information about the area, descriptions of the soils and suggestions concerning their use and management. Soil surveys are made by experienced soil scientists who are often assisted by one or more junior scientists. Since 1935, most soil maps have been made with the aid of aerial photographs.

In the United States, soil surveys were begun in 1899 by M. Whitney of the department of agriculture. Maps and reports are usually prepared in co-operation with the state agricultural experiment stations, although other agencies such as the department of interior and state department of agriculture sometimes sponsor soil surveys. In Canada the soil survey is associated with the Experimental Farms service and the universities.

Soil maps based on soil texture (sands, clays, loams. etc.) were included in the agricultural surveys of Great Britain in the early 19th century, and on the same basis the soils have been marked on the Drift maps of the geological survey. More accurate methods based on chemical and mechanical analysis were used in the surveys made in the 1890s and early 1900s by C. M. Luxmore and T. B. Wood, and also by A. D. Hall and E. J. Russell, who based their survey of southeast England (1911) on the geological origin of the soils. A more widely applicable basis is the mode of formation of the soil studied in the U.S.S.R., the pioneer being V. V. Dokuchaiev (1883). A soil map of Europe on this basis was published in 1937 on behalf of the International Society of Soil Science, the co-ordinator being H. Stremme of Danzig. In Great Britain the soil survey was established in 1939 under the direction of G. W. Robinson at Bangor, Carnarvonshire; in 1943 it was transferred to Rothamsted, Hertfordshire.

In Australia J. A. Prescott at the Waite institute made the first soil map in 1931; much detail has since been added. In Africa attention is concentrated on agriculturally important areas, and the intervening spaces are filled in by aerial, ecological and reconnaissance surveys. G. Milne made the first east African survey in 1936.

Much has been done in west Africa by British workers and by the French and Belgians in their territories.

See U.S. Department of Agriculture, "Soil Survey Manual," *Agricultural Handbook 18* (1951), "Soil," 1957 *Yearbook of Agriculture* (1957); G. R. Clarke, *The Study of the Soil in the Field* (1957).

III. PHYSICAL NATURE AND PROPERTIES OF SOILS

The soil, in its relation to plants, provides a medium for root development and supplies nutrients for plant growth. To a considerable extent, the ability of soils to perform these functions is dependent upon their physical character and condition, which have much to do in determining moisture, air and temperature relationships. Hence, the physical make-up of soils. together with their resultant properties, exert a controlling influence on chemical reactions and biological processes.

1. Component Parts of Soils.—Soils are composed of solid, liquid and gaseous components. Materials in a solid state, soil minerals and organic matter, constitute the soil proper; the liquid and gaseous components, namely water and air, in the interstices between the solid materials, fluctuate continually, and frequently with conditions independent of the soil. The organic fraction varies widely, but seldom exceeds five per cent by weight. except in soils formed largely from plant remains. Organic soils, however, are of secondary importance to mineral soils.

The mineral constituents are extremely variable in size, shape and chemical composition. The size of particles is one of the most significant characteristics. Water absorption. air movement, rate of solution and ease of tillage are but a few of the numerous things affected by particle size. By mechanical analysis, which separates the particles into size groups known as separates, a quantitative statement of soil texture, illustrated in Table I, can be obtained. Results of a mechanical analysis do not include either organic matter or particles larger than two millimetres.

Each separate is characterized by definite physical properties, due chiefly to the size of the particles composing it. As the particles become smaller, their total surface area, hence their effectiveness in transmitting properties to soils, increases greatly. Particles less than 0.001 mm. in size, especially those making up the colloidal or gluelike portion of the clay, possess active internal as well as external surface, and therefore are much more reactive than the other clay and larger particles. Because of their cohesive nature, clay colloids play an important role in the arrangement of particles.

Table I.—Quantitative Statement of Texture by Mechanical Analysis

Name of separate	Diameter limits (mm.)	Amount present (per cent)
Very coarse sand	2.0 –1.0	2.3
Coarse sand	1.0 –0.5	6.7
Medium sand	0.5 –0.25	8.2
Fine sand	0.25–0.10	9.4
Very fine sand	0.10–0.05	12.5
Silt	0.05–0.002	44.8
Clay	Below 0.002	16.1

Every soil is a mixture of separates, hence the physical properties exhibited are determined by the proportions of separates present. A group of soils having the same range in particle size and physical properties based on texture constitute a soil class. Soils in which the properties of no one separate predominate belong in one class. This class, known as loam, contains more than 35% total silt and clay with less than 50% and 27% of silt and clay, respectively; the permissible amount of sand would be too low to exert a dominant influence on the physical properties exhibited. When the silt content exceeds 50% in a mixture with less than 27% of clay, the properties of silt predominate and the soil is classed as a silt loam. The transition from loam to silt loam, or between other soil classes, is not abrupt but gradual. Variation in properties of soils within a class is indicated by descriptive terms as light, friable and sandy; or heavy, plastic and clayey.

For practical purposes, soils of the common classes can be grouped as follows: coarse textured soils, the sands and sandy loams; medium textured, the loams and silt loams; fine textured, the clay loams and clays.

Even though mineral particles are the very foundation of soils, they always contain some organic matter; its accumulation is an integral part of soil development. Humus, the partially decayed organic matter accumulated in soils. is a dark-coloured, structureless material highly colloidal in nature. Unlike colloidal clay, the organic or humus colloids are not very cohesive and plastic; in general they tend to make sandy soils more cohesive and clayey soils less plastic. The efficacy of organic matter in changing soil properties depends on the amount present and the textural make-up of the soil. Thus, in determining soil class, it is necessary to take cognizance of the influence of organic matter in modifying physical properties associated with the mineral particles.

2. Structure and Its Practical Significance.—Structure deals with the arrangement of soil particles which occur as individuals, as groups or aggregates or as a mixture of the two. In coarse-textured soils, the particles exist and function largely as independent units, but in fine-textured soils different-sized particles are bound together with colloidal materials. The aggregate produced may be either a dense, continuous mass, exemplified by a clod, or an open. porous cluster typified by a granule. With greater pore space and effective surface, the granule represents the more desirable structure. These aggregates also vary in size, shape and stability. A composite of the single grain and aggregate structures occurs in medium-textured soils. These are neither too open and friable, nor too compact and plastic; their physical condition is generally favourable for plant growth and easily maintained.

Structural differences result from variations in the kind and amount of colloidal material present. In the absence of soil colloids, the single-grain arrangements predominate, while aggregate formations are never well developed. These colloidal materials, including various clay minerals, oxides and hydrates of iron and aluminum, together with soil humus, are the products of different chemical and biological processes involved in soil development. Factors and conditions influencing soil development naturally would affect not only the formation of colloids, but also their distribution and behaviour in soils. As a result, marked differences in the natural structure of soils have been developed. Structural differences of virgin soils, also of the undisturbed substrata in cultivated soils. are of great value in any scientific study and classification of soils; too, they are of practical significance because of their relation to drainage, aeration, root development, moisture retention and soil erosion.

When farmed, many soils soon lose much of their original aggregate structure. This change occurs primarily in the surface layer due to more rapid organic matter depletion, together with excessive and often improper handling. But, unlike texture, structure can be and frequently is changed; in fact, the main purpose of most tillage operations is to improve structure. Any control over many of the properties of a soil is possible only if its physical condition can be modified.

3. Porosity and the Weight of Soils.—Porosity means total pore space, the soil volume not occupied with solid materials, varying from 35% to 50% in dry soils. As texture becomes finer, the size of individual pore spaces decreases but total pore space increases. Any change in structure, or organic matter, also affects the size of pores and porosity. Both are reduced by compaction, often desirable in sandy soils. Porosity is increased in fine-textured soils by proper tillage and organic matter because of their influence in developing a granular structure in silty and clayey soils.

When compared on an equal volume basis, mineral soils when dry weigh more than water; organic soils, however, weigh less. The numerical ratio between the weights of equal volumes of dry soil and water represents the volume weight, or bulk density, of the soil. This fluctuates chiefly with differences in porosity, but is influenced also by the specific gravity, or particle density, of the various constituents in different soils.

Specific gravity is also a comparison of the weights of equal volumes of dry soil and water, but differs from volume weight since the equal water volume is determined by displacement and represents soil volume without pore space. Specific gravity is practically a constant for most mineral soils, with values of 2.65 to 2.70. Dark-coloured soils often are lighter due to more organic matter; organic soils have specific gravity values from 1.5 to 2.0, varying with their mineral content. In comparison with volume weight, specific gravity of soils is relatively less important. Volume weight usually ranges from 1.0 to 1.5 for fine-textured soils, and from 1.2 to 1.7 for coarse-textured soils. Changes in physical condition of the surface layer of soils under cultivation cause wide variation in volume weight. In all soils it naturally tends to increase with the deeper layers, especially the subsoil.

When the volume weight is known, the weight of dry soil per cubic foot, or per acre foot, or of any fractional part, can be computed readily. The average weight of dry soil per acre $6\frac{1}{2}$ or 7 in. deep, often called the "plowed section," is commonly given as 2,000,000 lb. Sandy soils are somewhat heavier, while organic soils weigh only about 1,000,000 lb. per acre 7 in. deep. These weight figures, either the averages or those computed directly from the volume weight, are useful in calculating the amount of soil water, the supply of organic matter or the quantities of plant-food elements present.

4. Soil Moisture and Its Relation to Plants. — Soil moisture, as here discussed, is exclusive of the water in chemical combinations occurring in certain soil minerals and organic compounds. The relative position of moisture with reference to the soil particles means that it is attracted unequally by the particles and acted upon by different forces. In consequence, soil moisture shows marked differences in its movement and availability to plants.

When air dry, a soil usually contains only hygroscopic moisture; that is, moisture which adheres to soil surfaces in very thin films, moves by diffusion and is unavailable to plants. Colloidal materials are chiefly responsible for hygroscopic capacity. Hence, it is never great in sandy soils, which are usually deficient in organic matter and have a low clay content.

Moisture, in excess of hygroscopic capacity, is retained in soil against gravity through the combined forces of adhesion. cohesion and surface tension. This moisture represents the capillary form. It exists as films around and wedges between particles; moves as a film due to surface tension; and is available to plants. The innermost portion of capillary moisture. however, is held so tenaciously as to preclude true film movement, or its use by plants. Thus the soil contains both hygroscopic and inner capillary moisture when permanent wilting of plants growing on that soil occurs.

Gravitational water, known also as free, excess or surplus water, is extremely variable: but is, in general, regarded as the difference between precipitation and a soil's capacity to absorb and hold water. Its presence in soils. contingent upon adequate drainage and a water supply in excess of capillary capacity, causes a deficiency of soil air and free oxygen, resulting in conditions which are inimical for seed germination, root development and other desirable soil processes. Ordinarily, gravitational water is more important as a reservoir to replenish useful capillary moisture than as a direct source of water to plants.

The ability of soils to hold capillary water is determined by their porosity and adsorptive power. As the particles become smaller, or the organic content higher, or the structure more granular, the capillary capacity increases due chiefly to the influence of clay or humus colloids. and/or more effective surface exposed. The moisture content of soils, at any particular time, represents the balance between additions and removals of water. Natural precipitation. the main source of soil water, is supplemented in certain areas by irrigation, and at times by water brought up from deeper soil layers by capillarity; however, this process is generally too slow to be of real significance in supplying the water needs of plants. Removals of water from soils result through evaporation at or near the soil surface, transpiration from plant surfaces, percolation downward due to influence of gravity and surface runoff. Loss by runoff decreases the potential supply of soil water.

Since water is often the chief limiting factor, even in humid regions, for crop production, every effort should be made' to increase and conserve the supply of available soil water. Cultural and tillage practices that increase water absorption reduce surface runoff; moreover: these same tillage practices control weeds, thus eliminating useless transpiration. Evaporation losses may be reduced through the use of windbreaks and mulches which may consist of either a protective cover of straw, paper or boards, or a layer of dry soil. The soil mulch, however, is effective in saving water only when the water table is within capillary reach of the surface; but under this condition, drainage to remove the excess water usually is more urgent than mulching 'to conserve water.

Of the soil water absorbed by plant roots, only a small fraction is retained by the plant; an enormous quantity is removed from it by transpiration. This varies widely with different plants and climatic conditions, and is controlled indirectly by securing efficient use of the water transpired. Control on many soils, therefore, may mean the use of fertilizers to meet some nutrient deficiency, or it may mean other practices such as drainage, liming or proper tillage to improve productivity. Thus the transpiration per unit of dry matter produced is decreased. (See also IRRIGATION.)

5. Soil Air and the Need for Aeration. — The pores in soils are occupied by air or water or both, the proportion of air to water decreasing rapidly as the particles become smaller. Differences in texture, structure and organic matter affecting porosity of soils also influence their capacity to hold water. Any increase in soil water decreases the amount of soil air. Thus, in poorly drained soils, and to a lesser extent in fine-textured soils having a compact rather than a loose condition, a deficiency of air exists.

Soil air, like the atmospheric air, consists of a mixture of gases, but it contains considerably more carbon dioxide and slightly less oxygen than does atmospheric air. With the gradual, but continual, depletion of oxygen and accumulation of carbon dioxide due to chemical and biological activities in soils, the need for soil ventilation becomes more urgent.

Aeration, the process by which stagnant soil air is replaced with fresh air, occurs naturally as a result of changes in temperature, variations in barometric pressure, movement of soil water or other processes. In practice, however, one of the chief controls over aeration is exerted by regulating soil-moisture conditions, particularly through drainage. Tillage may be used either to lessen or promote aeration since sandy soils, usually too well aerated, need to be compacted, whereas clayey soils, frequently too compact and often crusted over, should be stirred to facilitate aeration.

6. Soil Temperature: Its Importance and Control. — Seed germination, plant growth, and, in fact, all soil reactions proceed through a wide range in temperature but each has an optimum range where it is carried on most efficiently. Successful crop production is no less dependent upon proper soil temperature than upon suitable atmospheric temperatures.

Direct solar radiation is the chief source of heat to soils. Differences in texture, structure and organic matter that determine the moisture capacity of soils influence their ability to absorb and transmit heat. Dry soils, due to air in pores, have higher resistance to heat transfer than moist soils. Water is a better heat conductor than air, hence as soil air is replaced by water as the contact between particles, conductivity is increased; additional water. however, would retard the rate.

Heat generally moves from the surface downward as atmospheric temperature increases and from lower soil layers upward as it decreases. Changes in soil temperature lag considerably behind and are much less variable than those for atmospheric temperatures. Daily fluctuations in soil temperature are much greater in summer than in winter.

Differences in temperature of soils for the same degree of latitude are caused by variations in colour. moisture content, vegetative cover and direction of exposure. The relation of colour to heat absorption is well known; but darker colours in soils are due chiefly to organic matter, which increases the amount of soil water. Only when the surface becomes dry, would the dark-coloured soil likely be warmer than the light-coloured soil.

Dry soil has a low specific heat, only one-fifth that of water. The greater amount of heat needed to raise the temperature of water causes soil temperature to decrease as soil water increases. Thus. wet soils are cold and slow to warm up in the spring.

A bare, uncropped soil heats more rapidly, attaining a higher temperature in summer than a similar soil protected by vegetation. The vegetation acts as an insulator, reducing both absorption of heat and loss through radiation. When protected by vegetation, leaves or snow, heat is retained better and the soil remains warmer during the winter. In the northern hemisphere soils with southern exposure. receiving more heat per unit area, have higher temperatures than those with northern exposure, provided other conditions are similar.

Control of soil temperature is a matter of soil-moisture control. Excess water must be removed. if possible, by drainage. This will reduce evaporation, thereby conserving heat, and lower specific heat thus decreasing the amount of heat necessary to raise the soil temperature.

7. Soil **Colour** and Its Significance. — Colour provides information as to the conditions of and forces active in soil development, and represents an invaluable aid in soil classification. Since different colours are indicative of variations in conditions which influence productivity. colour is used as an important indicator of the agricultural value of soils. This use, however, necessitates that colour throughout the entire vertical section of soil be observed and interpreted in terms of soil properties affecting crop production.

Soil colours are of three main sources: decomposed organic matter. certain iron compounds and other soil minerals such as quartz, kaolin and mica. Soils low in organic matter with iron absent or unoxidized are coloured by soil minerais. Their colours are often dulled or concealed by organic matter or iron compounds, or both. Much of the humus. the most stable portion of the soil organic matter, is a dark-brown or black'residue coating the mineral soil particles. Under conditions of poor drainage and limited aeration, the reduced forms of iron together with anaerobic decay of organic matter favour the development of gray and drab coloration in soils.

Without good drainage and aeration, the iron could not be oxidized, nor the hydrated iron oxides produced to give the red and yellow colours. Red- and yellow-coloured soils are invariably low in organic matter; but when these colours, due mainly to hematite and limonite, are mixed with black from humus various shades of brown result.

With few exceptions. soil colour involves mixtures and is concerned with tints and shades rather than pure colours, so that ordinary colour charts are of little or no value in determining colour in soils. For this purpose standard soil colour charts, specifically made to include the colour range encountered in soils, are generally used.

8. Soil Tilth and Tillage. — The physical condition of the soil when considered in its relation to plant growth is known as tilth; its development must necessarily consider the requirements of the crop to be grown. Soil tilth, therefore, is more inclusive than structure, although the arrangement of the individual or aggregate structure particles is the fundamental basis of tilth in soils. While the textural make-up of soils cannot be changed practically, it is feasible to modify, through tillage practices, the structural condition of the surface layer.

Tillage, including any operation that stirs, inverts, fines, aggregates or firms the soil, is used not only to prepare a satisfactory seedbed but also to maintain optimum growth conditions throughout the season. While plowing is generally regarded as the basic tillage practice, many soils, especially those of coarse and medium texture, often can be prepared adequately by use of a disk harrow. Frequently much of the desirable aggregate structure in the finer-textured soils is destroyed by plowing too much, or when too wet. It is imperative to avoid all tillage practices on heavy, plastic soils when wet; otherwise the soil runs together and upon drying is in a cloddy condition, which may persist for several seasons. Volume changes which accompany moisture variations due to alternate wetting and drying break down the clods and tend to encourage the formation of granules; this effect is usually more pronounced in the presence of organic matter since it counterbalances the deleterious effect of an excessive amount of clay colloids on structure. The general lack of colloidal materials in coarse-textured soils prevents puddling, or even desirable aggregation, hence the possibilities of structural modifications are limited.

Cultivation, the intertillage given a crop, is used primarily to destroy weeds. This practice also modifies structure of the soil to the depth cultivated, thus affecting aeration, water absorption and evaporation. Conservation of moisture due to the formation of a mulch is of secondary importance to that due to the control of weeds. Furthermore, when cropped, the top portion of the surface soil is more valuable as a feeding zone for plant roots than as a soil mulch.

IV. CHEMICAL PROPERTIES OF SOILS

The upper portion of the earth's solid crust, to a depth of a few miles. was estimated by F. W. Clarke to consist, to the extent of about 98 3%. of eight chemical elements. They are, in order of decreasing abundance, oxygen. silicon, aluminum, iron, calcium, magnesium, potassium and sodium. The first four comprising, respectively, 47%, 27%, 8% and 5% of the earth's crust are acidic or weakly basic in character. The last four, totaling 11.3%, are strong bases. The do-odd other elements are contained in the remaining 1.7% (see also GEOCHEMISTRY: Abundance and ***Origin*** of *Elements*).

These elements do not occur free, for the most part, but to some extent as simple compounds, such as oxides and carbonates, and to a much greater extent as complex alumino-silicates and ferro- (iron) silicates of the four strong bases mentioned. These silicates, which compose the bulk of the rocks of the earth's surface, occur in a great number of variations as to colour, crystalline form and chemical composition.

In the weathering of rocks containing these primary or unaltered silicates, hydrolysis plays a dominant role. In hydrolysis, or decomposition by union with water, the strong bases mentioned above are split off as soluble compounds, such as hydroxides, carbonates and bicarbonates. These, in a humid climate. are carried downward and out of the soil by percolating water, unless stopped by other chemical reactions which change them to less soluble forms. The insoluble residue from this weathering of the primary silicates is modified into secondary silicates of aluminum and iron which contain lesser amounts or in some cases none of the strongly basic elements, calcium, magnesium, potassium and sodium. These secondary silicates are the clay minerals of soils, the principal component of the clay portion.

In addition to the silicate clay minerals, there occur in the clay size-range simpler compounds, the hydrated oxides of silicon, aluminum and iron, which have split off from the primary minerals in the course of weathering. Along with these changes, organic matter accumulates from partial decomposition of plant and animal materials, so that the chemical components of the soil may be grouped in a general way into organic substances and inorganic or mineral substances.

In the following discussion, the chemical characteristics of the surface soils of the humid and semihumid temperate regions will be considered. These are the regions which contain most of the earth's cropped land and which support most of the world's human population. **A** brief discussion will then follow, indicating variations in surface soil character in some other climatic regions.

1. Mineral Constituents. — The mineral constituents of soils may be grouped on a basis of size of particles. Sand and coarser particles, together with the coarser part of the next finer grade, silt. are essentially primary minerals. The silt size is between 2 and 50 microns (μ) in diameter. (A micron is $\frac{1}{1,000}$ mm. or $\frac{}{,00}$ in.) Primary minerals are defined as those which have undergone no appreciable weathering change. In soils, they include the complex silicates previously described, and simple compounds, chiefly oxides, of which the most abundant is quartz or silicon dioxide, SiO_2. Calcium carbonate and dolomite, which occur mainly as limestones, are frequently present.

The primary minerals generally amount to 70% or more of the soil mass. Most of them are resistant to weathering, undergoing profound chemical change only through geologic periods of time, and consequently may be considered as contributing little to the dynamics of soil chemistry.

2. Secondary or Clay Minerals — Below the silt size-range is the clay fraction, ranging in size from two microns down. In 1937 in the Gnited States the division point between silt and clay was changed from five microns to two, partly in order to conform with European practice and also because the latter point more nearly separates colloidal material from that which does not possess colloidal properties.

The clay portion for the most part is composed of the complex aluminum and iron silicates derived from the weathering of primary silicate minerals. They are known as clay minerals or secondary minerals. These minerals, particularly below the one-micron size-range, exhibit colloidal properties to a high degree. That is, their internal surface or sum of the surfaces of the individual particles is very great, commonly amounting to several acres in a single cubic foot of soil. Soluble, chemically active substances accumulate at the surfaces of these particles from the surrounding moisture, and the result is a great intensification of chemical processes because of the large internal surface. This is one important chemical property of soils.

Exhaustive research on the colloidal clay minerals, most of it done since 1920, revealed much about their chemical and physical nature. Chemical investigations, X-ray studies and determination of the optical properties, when applied to the clay minerals, especially after separation into different size groups, as 1 to $\frac{1}{10}$ μ, $\frac{1}{10}$ to $\frac{1}{20}$ μ and so on, have shown that they possess several properties in common. Research by W. P. Kelley. S. B. Hendricks, C. D. Marshall, R. H. Bray and R. E. Grim in the United States and by workers in other countries showed that they are definitely crystalline, the crystals being platelike or broad and thin in form. This form is a result of their laminated structure, consisting of a series of atom layers each with a characteristic pattern and repeated in a definite order. There are many species of clay minerals. They may be grouped, however, into three main families: each of which is characteristic of the climatic region in which it was developed.

3. Base or Cation Exchange. — Residing chiefly in the clay minerals is the soil property known as ion exchange. Ions are atoms or atom clusters which bear an electric charge. Those with a positive charge are cations, and the negatively charged ones are anions. Those with opposite charges tend to unite with each other, forming chemical compounds known as salts. When a salt dissolves in water a portion separates into the constituent ions. The sum of the positive ion charges always equals the sum of the negative charges. Positive hydrogen (H) ions will unite with negative hydroxyl (OH) ions to form water, which is neutral. The acidic property of solutions is due to hydrogen ions and the alkaline property is caused by hydroxyl ions. Cation exchange. or base exchange, has been known since the work of Thomas Way in England about 1850, but the mechanism of the reaction and its importance in soil fertility were recognized much later. Colloidal clay particles are negatively charged. Their negative charges probably result from the weathering loss of bases. As a result they attract and hold cations, either metallic ones such as calcium. or, in their deficiency, hydrogen. The presence of hydrogen ions is the cause of acidity. The adsorbed ions are not removed by water and are, as a consequence, protected in the soil against excessive loss in drainage waters through leaching. This fact is of great importance in the practical maintenance of soil fertility because large quantities of basic plant nutrient ions are thus preserved in the soil against loss in drainage water. The bases, however, are easily and instantaneously replaced from the clay by other basic ions, so that one can saturate a soil with a given base, like calcium, by leaching it with a soluble, neutral calcium salt solution, which of course contains calcium cations. The bases are not held with equal tenacity. The retention by the clay minerals of those commonly found in soils decreases in the following order: calcium > magnesium > potassium > sodium. Their relative abundance in the soil in the exchangeable form is usually in the same order.

The capacity of different clay colloids and of the soil itself to adsorb and hold cations is a definite quantitative value, usually expressed as milligram equivalents (m.e.) per 100 grams of sample. The base-exchange capacity of clay colloids ranges from about 20 m.e. to more than 200 m.e., and in soils the range is usually between 2 or 3 and 40 m.e.

4. Soil Reaction and Acidity. — Inasmuch as acid hydrogen cations, as well as metallic or basic cations, can be adsorbed by the clay minerals, it follows that a hydrogen-saturated soil is acid. Its degree of acidity depends mainly on the ratio of exchangeable hydrogen ions to basic ions held on the clay surfaces. Soils in humid regions gradually become more acid whether under native or cultivated conditions because calcium and other cations are gradually replaced from the colloids and removed from the soil by leaching. The replacing ion is chiefly hydrogen of carbonic acid and other acids from decomposing soil organic matter. The application of limestone or of slaked lime to acid soils reverses the process just described by replacement of exchangeable hydrogen from the clay by calcium.

The intensity of soil acidity is expressed by the term pH followed by a numeral. The pH value is the negative logarithm of the hydrogen-ion concentration in gram atoms per litre. Thus in a solution of pH 5 the H-ion concentration is 10^{-5} normal; *i.e.,* the solution contains .00001 gram ion of active hydrogen per 1,000 g. of water. Neutrality is pH 7, since at neutrality both the $(OH-)$ and the (H^+) ion concentrations are 10^{-7} normal. The pH value of soils varies with the degree of saturation of the exchange capacity with bases, in contradistinction to hydrogen. Thus the base saturation of neutral soils (pH 7) varies around 75%, the remaining 25% being hydrogen. Virgin soils, *i.e.,* those that have never been cultivated, in humid temperate regions range from about pH 4.8 (strongly acid) to slightly alkaline, approximately 8.3, the latter value representing equilibrium with solid calcium carbonate. In some arid soils higher pH values are encountered, the high alkalinity being due to soluble carbonates of the alkali metals, sodium and potassium.

Soil reaction is important agriculturally because crop plants, as well as others, vary widely in their requirements and tolerances in this respect. Alfalfa and many clovers require essentially neutral soils, having a minimum pH of 6.2 to 6.5. Cranberries, at the other extreme, require very high acidities, represented by pH values around 4.

5. Anion Exchange. — This property of soil colloids is not as well understood as cation exchange. In the latter case the adsorbed cations are not a part of the essential structure of the clay mineral crystal, but are attached at the surfaces. Consequently base exchange does not alter the colloid crystal itself. As a result of investigation by S. R. Dickman and R. H. Bray, J. S. Burd and H. F. Murphy and others, it was postulated that anions are adsorbed by displacing hydroxyl (OH–) ions from the crystal lattice, thus altering the latter. In the soil colloids characteristic of the temperate humid regions, OH– ions are distributed somewhat sparsely in the 'deeper positions in the crystals. They are thus exposed only at the broken edges of the platelike particles, at which points anion exchange may occur. Investigations by Bray indicated that phosphate anions so adsorbed are readily taken up by plant roots that make contact with them. A chemical soil test for phosphate availability, by Bray, depends on the replacement of phosphate by fluoride ions.

Anion-exchange capacity of soils and clays is not as quantitatively definite a value as is the base-exchange capacity. On the other hand, the quantity of anion adsorbed is a function of the concentration of the ion in solution in contact with the clay. The equilibrium between adsorbed ion and that in solution at different concentrations follows definite trends, which in most cases can be fitted to H. Freundlich's adsorption equations (see ADSORPTION). In another respect anion and cation exchange differ sharply. The range in tenacity with which the various cations are retained on the clay particles is fairly narrow, while the range among the common anions is extremely wide. Some, in fact, are not adsorbed at all, while others, notably fluoride and phosphate, form relatively stable combinations with the colloid particle.

Clay minerals or colloids of the kaolinite type, found in humid tropical regions of intense weathering, possess an entire surface lattice layer of OH groups. These clays adsorb large quantities of phosphate ions, which displace the entire OH layer. Burd and Murphy found a low degree of plant availability for such phosphate. (See also CLAY AND CLAY MINERALS.) (E. E. DeT.)

6. Alkali **and** Saline Soils.—The term alkali has been rather loosely applied to all soils containing sufficient amounts of soluble salts to cause injury to plant life. When correctly used, the term alkali soils refers only to those soils that have a high pH value (high alkalinity) caused by sodium ions absorbed by the clay particles and to those that sometimes have considerable amounts of the alkaline salt. sodium carbonate. Reaction between water and the sodium-saturated clay liberates sodium and hydroxyl ions into the solution, making it alkaline. These soils were formerly called black alkali in the U.S.

Saline soils are those that contain less absorbed or exchangeable sodium and that are high in nonalkaline salts such as sodium chloride and sodium sulfate, or those that contain enough salts such as sodium chloride t~ maintain flocculation and repress hydrolysis of the clay portion of the soil which is itself the insoluble salt of a strong base and a weak acid. The term white alkali frequently has been used for these soils. Alkali and saline soils are widely distributed in the drier areas of the world. On soils where salts may be a problem a great deal of foodstuff is produced. In regions of low rainfall, salts accumulate where drainage is poor, their origin being caused by insufficiency of percolating moisture to wash out and carry away in the drainage the soluble salts present in the parent soil material or those that are formed by its weathering. They are frequently formed in localized areas by seepage water from higher elevations. Soil-forming materials reclaimed from the sea, as on the coast of the Netherlands, are also saline. The salts that most frequently predominate are the carbonates, chlorides and sulfates of sodium, magnesium and calcium, or mixtures of two or more of these salts.

The tolerance of the various species and varieties of plants to soluble salts in soils is very different. Among the more tolerant agricultural plants are sugar beets, garden beets, milo, Bermuda grass, Rhodes grass, alfalfa, cotton, tomatoes and barley. The less tolerant ones include beans, field peas, red clover, vetch, oats and peaches. It has been found that the presence of high concentrations of salts in the soil solution (the liquid portion of the soil in which the plant roots obtain nutrients) limits the intake of aater by plant roots. Yields are reduced approximately in proportion to the osmotic pressure of the nutrient solution. Although definite limits cannot be set for the amount of soluble salts required to reduce the yield of plants, less than 0.2% of salts in a soil is usually not harmful to salt-tolerant crops; in an alkali soil, lower percentages are harmful because of more toxic effects of the ions present. Relatively large amounts of salts may be added to the soil in irrigation water. In order to maintain the "salt balance" as much salt must be removed in drainage water from the soil as is introduced in the irrigation water. Many irrigation projects have failed because of salinization caused by lack of proper drainage facilities or failure to use enough water to move excess salts down and out of the soil profile. Others have failed because of the high percentage of sodium in the irrigation water.

The chemical reactions by which a normal soil, the exchange complex of which (essentially the fine or clay fraction) is saturated with calcium and magnesium ions, is converted to an alkaline soil are as follows: Ca-saturated soil + $2NaCl \rightarrow$ Na-saturated soil + $CaCl_2$. When the sodium-saturated soil is leached by water, little happens to it until the excess of soluble salts is removed. Further leaching brings about the reaction that is involved in the formation of the alkali soils of columnar structure called solonetz (see also RUSSIA: Soils and Their Influence: Chestnut and Brown Soils). This reaction is Na-saturated soil + H_2O — H soil + $NaOH$. Then, in the presence of carbon dioxide of the soil air, the salt sodium carbonate is formed—$2NaOH + CO_2 + H_2O = Na_2CO_3 + 2H_2O$. Alkali soils are sticky, impervious to water and unfavourable for agriculture. At the high pH values of alkali soils, dissolved organic matter coats the soil grains and gives a black colour. The reclamation of alkali soils is the reverse of the above processes. A soluble calcium salt such as gypsum is applied to the soil — 2Na-saturated soil + $CaSO_4$ = Ca-saturated soil + Na_2SO_4. The sodium salt is then removed in the drainage aater. Sulfur may be used in place of gypsum if the soil contains calcium carbonate. By biological action sulfur is converted to sulfuric acid, which reacts with the calcium carbonate to give gypsum. Good drainage is necessary to remove end products so that the reactions can proceed. Sodium-saturated colloids, in the absence of flocculating salts, "run together" or "freeze up." Sodium-saturated colloids in the presence of excess sodium salts may not be high in pH and are flocculated. (See also DRAINAGE OF LAND; IRRIGATION; LAND RECLAMATION.) (L. T. X.)

7. Organic **Matter.**—Soil organic matter has been the subject of a great deal of chemical research, but in spite of these efforts comparatively little is known about its chemical nature. Fresh plant material decomposes very rapidly under favourable soil conditions, but as the process continues it is increasingly retarded until a residue which is resistant to decomposition gradually accumulates, forming the fairly permanent stock of soil organic matter. Few of the chemical compounds in soil organic matter are known, although much research has been done. Oswald Schreiner identified 30-odd compounds from a very small portion of the total organic matter. Attacks begun by A. G. Norman and others, using various solvents, yielded increasingly encouraging results in the classification of chemically related groups of soil organic compounds,

Plants. in their growth, incorporate nitrogen. phosphorus, sulfur and other essential elements into their organic tissue, and these elements become a part of the soil organic matter if the plant residues return to the soil. As a result, from 30% to 60% of the total phosphorus of the surface soil, all of it originally inorganic in the parent material, is now found to occur in organic forms. Most of the sulfur and almost all of the nitrogen in soils are also contained in the organic matter. Potassium, on the other hand, remains soluble until adsorbed by the clay colloids, and its percentage in the organic portion is low. These accumulations of organic forms are an important factor in the nutrition of growing plants. Most of the changes which occur in soil organic matter are biochemical in nature and are discussed under *Soil Microbiology*,

8. Plant Nutrient Supplying **Ability.**—Plants require for growth and reproduction the elements carbon, oxygen, hydrogen, nitrogen, phosphorus, potassium. calcium and magnesium in variable but fairly large amounts. In addition, iron, manganese, boron, zinc and copper are required in very small amounts and are, therefore, designated as trace, or minor, elements.

With the exception of carbon, hydrogen, oxygen and part of the nitrogen, the plant-nutrient materials are absorbed through the root system in the form of simple ions. This does not mean that adequate amounts of these ions are normally present in the free soil solution. The exchangeable form of the basic elements is the principal immediate source from which the nutrients in the soil solution are renewed as they are taken up by plants. The exchangeable form also supplies plants directly by attachment of root hair to colloid particles, forming an interface at which exchange can occur. An analogous situation can be conceived as a possibility in uptake of adsorbed anions by plants. This conception of nutrient absorption by plants should be considered as fairly well-supported hypothesis rather than as established fact. It places the soil solution in a position of less importance in soils from a plant-nutrition point of view than formerly.

The clay minerals contain basic elements, *i.e.*, potassium and magnesium, in their internal structure, in addition to those in the exchange form. Illite is such a clay mineral rich in potassium. These forms are the reserve from which the more available exchange forms are renewed in the soil, and their abundance is a measure of the durability of chemical fertility. An analogous situation may exist with regard to phosphates.

The organic matter is an important source for plants of the nonmetallic nutrient elements. nitrogen. phosphorus and sulfur. They are released to plant-available forms accompanying organic matter decomposition. Chemical soil tests for the plant-available forms extract and measure the adsorbed (exchangeable) bases and anions as well as the water-soluble nutrients, and they also dissolve the less soluble forms which contribute significantly, though to a less degree, to plant growth. Specifically the objective of soil testing is the measure of the amounts of exchangeable potassium, calcium and magnesium, the amounts of adsorbed and also easily acid-soluble phosphates and the amounts of the ammonia and nitrate forms of nitrogen. Close correlations between these forms and plant response to added nutrients have been established by chemical soil tests and fertilizer experiments.

The trace elements previously listed received increasing attention after the early 1930s because of wider recognition of their effects on crop growth. Failure of earlier recognition may be due in part to failure to notice plant symptoms of trace-element deficiency or to diagnose them accurately. It may also be true that soils are only beginning to fail in supplying the small quantities needed by crops. Of the five elements listed, boron is the most generally deficient in the United States. (See also FERTILIZERS AND MANURES.)

9. Soil Variations With Climatic Environment.— Very young soils reflect the character of the parent material, but as weathering and its effects proceed soils tend increasingly to show the effects of the climatic environment while the resemblance to the parent material grows gradually weaker or disappears.

With decreasing rainfall outside the humid temperate areas of the earth, chemical weathering becomes less intense and the colloidal clay tends to be coarse. retaining more of its basic ions, including magnesium and potassium, at the expense of the base-exchange capacity, which is low. The soluble bases released by weathering are not leached from the soil and the soil reaction consequently becomes more and more alkaline. Chemical fertility is high but lack of moisture may limit crop yields (see also Alkali and Saline Soils above).

As one passes to subtropical and tropical regions of high temperature and high rainfall with intensified weathering and leaching, the silicate minerals are more completely decomposed, bases and silica are leached away and the resulting soils, known as laterite (*q.v.*), contain high concentrations of iron and aluminum. They are low in exchange capacity, low in present and potential fertility and, since bacterial activity is high throughout the year, organic matter is so rapidly destroyed that its content is low in spite of its rapid production by vigorous growth of vegetation.

In the cool to cold humid zones, forest vegetation, mainly coniferous, combines with the climatic conditions to produce the typical podsol soil group. From the chemical point of view it is found that the decaying needles of the forest floor produce a highly acid leaching solution which not only removes the basic ions excessively, but also dissolves iron and leaches it downward. where, with some of the aluminum and dissolved organic matter, it is redeposited in a tight layer some two to three feet below the surface. The soil layer immediately above this deposition is bleached white and ashy. The surface strata are high in silica content in contrast to the high iron and aluminum in the laterites. Like the latter, however, they are leached of their plant nutrients, are low in initial productivity and capable of being brought only to medium productivity by good management. Geol., vol. 1, no. 3 (1942). (E. E. DeT.)

V. SOIL MICROBIOLOGY

Contrary to the opinion of many persons. the soil is not a dead, inert material. Actually. it is full of life, for a thimbleful of soil contains billions of living microorganisms. The organic matter already present in the soil, as well as that constantly being added by higher plants, animals and microorganisms serves as a direct source of carbon and energy for the heterotrophic soil organisms; that is, microorganisms that derive their carbon and energy from organic materials. Indirectly, organic matter serves as food material for autotrophic bacteria — organisms that obtain their carbon supply from the carbon dioxide in the soil air and their energy from the oxidation of simple chemical substances.

Bacteria. fungi, actinomycetes (a filamentous form, including *Streptomyces*), algae and protozoa—which have received the most attention from soil microbiologists — have a marked effect upon the productivity of soils. In general. highly productive soils contain an abundance of microorganisms. whereas less productive soils support a small population. While these facts do not prove that soils are productive because of their high microorganic population. or vice versa, there is much experimental evidence to show that microorganisms contribute to the productivity of soils through their varied activities.

1. Decomposition of Organic Matter. — One of the functions of soil microorganisms is the decomposition of organic matter added to the soil through the use of green manures — crops grown for soil-improvement purposes — animal manures, crop residues such as roots and stubble, and microorganisms. The sugars, siarches, cellulose and similar compounds in these organic materials serve as a source of energy for bacteria, fungi and actinomycetes. and largely disappear into the soil air in the form of carbon dioxide. Other compounds more resistant to decay remain in the soil longer and are important contributors to the humus in the soil. Bacteria, fungi and actinomycetes need nitrogen for their growth during the process of decomposition. Where the organic materials are low in nitrogen. microorganisms use the ammonium and nitrate nitrogen in the soil. Consequently. they may compete with grain crops for useful nitrogen where low-nitrogen organic materials are plowed under, resulting in a lower immediate yield than would be obtained in the absence of added organic material. Nitrate nitrogen is often lost in drainage water because of its high solubility. Such losses may be decreased by the use of low-nitrogen organic material on land having a high nitrate-supplying power during extended periods when no crops are grown.

Both farmers and city people, when preparing artificial manure, have taken advantage of the ability of microorganisms to decompose organic substances. In this process. leaves, lawn clippings, garden refuse and similar organic materials are mixed with ammonium sulfate or nitrate, superphosphate and crushed limestone. Microorganisms use the nitrogen in their growth processes; the limestone prevents the accumulation of acids; and the phosphate reinforces the manure. This process of making artificial manure is called composting. (See also FERTILIZERS AND MANURES.)

2. Solution of Minerals. — During the process of decomposition of organic materials. large amounts of carbon dioxide are produced. When dissolved in soil moisture, carbonic acid is formed and this weak acid may account for some solution of soil minerals. Some bacteria and fungi produce organic acids capable of dissolving minerals. Other microorganisms producing mineral acids are effective. to some extent at least. in releasing some of the nutrient elements from relatively insoluble soil minerals.

3. Nitrogen-Fixing Bacteria. — In the air above every acre of land there are about 69,000,000 lb, of elemental nitrogen. Curiously enough. most crop plants may be starving in this sea of nitrogen. Only when the nitrogen in the air is combined with other elements is it possible for crops to use this nitrogen in their growth processes. Similarly. most microorganisms need nitrogen that has been changed into either organic or inorganic combinations.

Some bacteria are able to use the elemental form of nitrogen that exists in the air. Thus. they can grow in the absence of combined nitrogen and, at the same time. produce nitrogenous substances which may be used later by crop plants.

The legume-nodule bacteria (rhizobia) are examples of organisms that can use air nitrogen. They grow in association with leguminous crops and are responsible for the nodules or tubercles which are associated with most leguminous or pod-bearing crops, such as peas and beans.

Role *of Legumes*.—The nodule bacteria furnish nitrogen compounds for the leguminous plant, and the leguminous plant furnishes energy material for the bacteria. Such a relationship, in which dissimilar organisms live together for their mutual benefit, is known as symbiosis.

Because leguminous plants are able to use air nitrogen indirectly, they will grow well, if nodulated, on soils that do not contain enough useful nitrogen for maximum growth of a nonleguminous crop, such as corn. A plentiful supply of nutrient elements other than nitrogen is necessary, however.

The amount of nitrogen nodulated leguniinous crops obtain from the air depends upon several soil conditions. Under favourable conditions, it is estimated that from 50 to 150 lb. of nitrogen per acre may be derived from the air. The amount of useful nitrogen in the soil, the kind of crops and the fertility of the soil (the relative amount of plant nutrients which are present) are factors affecting the amount of nitrogen that can be obtained from the soil.

The nodule bacteria vary also with respect to the amount of nitrogen they can take from the air. Some bacteria are highly efficient; other species have little capacity to obtain nitrogen from the air. Still others actually may be unable to secure air nitrogen and thus may be parasitic.

The supply of nitrogen in the soil may be replenished by growing nodulated leguminous crops if all or a part of the leguminous crops is returned to the soil. Obviously, the way the crop is handled determines the extent to which nitrogen-replenishment occurs.

No one kind of nodule bacteria will find a home on all leguminous crops. Of the approximately 10,000 species, only a relatively small number of leguminous crops and their nodule bacteria have been studied. These include about 20 kinds (strains) of nodule bacteria, recognized by their ability to produce nodules on different leguminous plants. There are some leguminous plants on which nodules never have been found.

Inoculation.—Because the success or failure of a crop may depend, in part, on the presence of nodule bacteria, farmers practise inoculation—the process of adding suitable nodule bacteria to the seed or soil—in order to be sure the leguminous crop will be nodulated. Where the leguminous crop is native to the area, inoculation is practised as a means of cheap insurance. Inoculation is very important for leguminous crops which are new to a locality.

Reliable commercial inoculants are sold by many seed stores. The information printed on the container gives the name of the crop or crops for which the inoculant should be used, as well as directions for its use. The cost per bushel of seed is comparatively low.

Other Bacteria.—In addition to the rhizobia, there are bacteria living independently in the soil; *i.e.*, they are free living and are capable of using air nitrogen in their growth processes. These bacteria are said to be nonsymbiotic. Some of the nonsymbiotic bacteria are aerobic, requiring free oxygen, while others are anaerobic, or able to live in the absence of free oxygen.

The Azotobacter are the most important among the aerobic nonsymbiotic nitrogen-fixing bacteria—those able to convert nitrogen from the air into nitrogen compounds. They are present in small numbers, rarely more than a few thousand in a spoonful of soil. However, the Azotobacter are found in most soils which are neither distinctly acid nor highly alkaline. Their importance in soil fertility is in doubt. Under highly favourable laboratory conditions. they fix appreciable amounts of nitrogen, but the evidence in natural soils is largely circumstantial. It has been estimated that the Azotobacter may fix from 15 to 40 lb. of nitrogen per acre per year.

Nitrogen fixation by free-living nitrogen-fixing bacteria may occur in poorly drained soils because several different microorganisms may live under anaerobic conditions and fix appreciable amounts of nitrogen. (See also NITROGEN, FIXATIOS OF.)

4. Nitrogen Mineralization.—Organic matter is the storehouse of nitrogen in the soil. The nitrogen fixed by both symbiotic and nonsymbiotic bacteria is present in the form of organic compounds such as proteins and proteinlike substances. Before this nitrogen can be utilized by growing crops. it must be converted into inorganic forms. Some of the processes by whichorganic nitrogen is changed into inorganic forms are carried on by several kinds of microorganisms, but the final steps in the formation of nitrate nitrogen, the form most readily used by higher plants, are the result of the activity of highly specific organisms.

5. **Ammonification.**—Ammonification is the process by which ammonium is formed in soils from nitrogenous organic compounds. It results from the action of microorganisms. The majority of the soil bacteria, many fungi and the actinomycetes decompose protein materials, utilizing the carbon for energy purposes and liberating ammonium produced in excess of the small quantities needed for growth of the microorganisms. Where large quantities of highly nitrogenous green manure crops are ploned under, correspondingly large amounts of ammonium are released. However, the ammonium that accumulates in most soils is transient, because it is utilized quickly by other microorganisms. Because of this quick utilization. it is not possible to measure directly the production of ammonium in soils, but accumulation at any specific time can be determined.

6. Nitrification.—Nitrification is the process of converting ammonium nitrogen to nitrate. When ammonium is oxidized, it is first changed to nitrite which, in turn. becomes nitrate upon further oxidation. Unlike ammonification, which is accomplished by numerous kinds of bacteria. fungi and actinomycetes under both aerobic and anaerobic conditions, the change from ammonium to nitrite is achieved by the specialized bacterium, *Nitrosomonas*. Another specialized bacterium changes the nitrite into nitrate. Both of these bacteria are strictly autotrophic and aerobic. Their activity in the soil is restricted by acid conditions; consequently, they are most active in well-drained soils where acidity has been corrected by a liming program.

Nitrification varies directly with the temperature and moisture of the soil within certain well-defined limits. In a cold, wet spring, little nitrate is formed and the leaves of higher plants often are yellowish in colour. indicating a lack of nitrogen. As the temperature rises and the soil reaches an optimum moisture content, nitrification increases and the leaves of the plants become darker green, indicating a supply of useful nitrogen. Higher plants growing in low areas in fields are more apt to show nitrogen starvation in the early spring because of water and temperature relationships.

In any good soil-management program, the aim of the farmer is to make sure that conditions are favourable for nitrification at the time of year when nitrogen is used most heavily by the growing crop. Because nitrate nitrogen is subject to leaching, the removal of substances in water solution, it is undesirable to have nitrate accumulate when crops are not growing on the land. For example. ammonium is not leachable, but under favourable temperature conditions it is changed by nitrification into nitrate, which is leachable. Therefore, when farmers wish to plow under nitrogen fertilizers in the autumn, it is desirable to wait until the soil temperature is about 50° F. or lower, to minimize the conversion of nonleachable ammonium into leachable nitrate.

7. Algae.—Soil algae occur in relatively small numbers in soils when compared with bacteria. Their numbers are in hundreds of thousands per gram of soil rather than in billions, as is the case with the bacteria. The algae contain chlorophyll—the green colouring matter in higher plants—and range in colour through greens, blue-greens, browns and reds. The volume of individual cells is roughly 3 times that of bacteria and 3 that of protozoa. Typical water forms of algae are much larger.

The blue-green algae are able to fix nitrogen and may be agents contributing to the maintenance of crop yields on low-producing soils. Because algae are capable of getting their carbon from the carbon dioxide of the air and fixing their own nitrogen, they are credited with the formation of organic matter on volcanic ash and on burned-over areas.

8. **Actinomycetes.**—Actinomycetes are somewhat intermediate in size and shape between bacteria and fungi. In some respects they resemble both. They occur in smaller numbers than the bacteria. but are larger in size and frequently surpass the bacteria in weight per given unit. One of their main functions is the decomposition of organic materials The characteristic odour of newly plowed soil is attributed to the activity of these organisms. Most actinomycetes are aerobic in nature and, like the fungi, are more abundant in dry than in wet soils. A few are parasitic on some plants and animals.

9. Fungi.—Fungi exist in soils in many different forms. Some may be seen only with a microscope, whereas others grow on the surface of the soil and have characteristic, visible shapes. Mush-

rooms are familiar examples.

The numbers and kinds of fungi present in soils depend upon moisture: temperature, the kind and amount of organic matter present and the acid condition of the soil. Many fungi are active under conditions of acidity and temperature that many bacteria cannot tolerate. For this reason, certain groups, particularly the heat-tolerant organisms. are important in the decomposition of grain straw and strawy manure. Others are involved in the decomposition of nitrogenous organic materials with the liberation of ammonia.

Some fungi are capable of living in association with higher plants. particularly trees. They enter the roots of these trees, forming an association called mycorhiza (*q.v.*). They appear to benefit the host plant by increasing the capacity of the roots to absorb nutrients.

Microorganisms in general, but particularly fungi, are important agents in maintaining in soils a granular structure called aggregation. The threadlike network that they form tends to hold soil particles together in crumbs—a condition favourable for the absorption of water and for the exchange of air between the soil and the atmosphere.

Neither the enumeration of the kinds nor a description of the characteristics and activities of individual groups gives a complete picture of the importance of microorganisms in the soil. Except under very unusual and highly unfavourable conditions, there is a continuous cycle of changes. Complex substances are broken down into simpler materials by some microorganisms, while the simple materials are combined to form more complex substances by other organisms. At any given time the status of the microbial population and its products are a result of the interaction of many group: of microorganisms. For instance. one-half of the phosphorus may be present in the organic fraction of the soil and the other half in the inorganic form. Microorganisms decompose a part of the soil's organic matter and change the phosphorus to an inorganic form that is useful for higher plants. At the same time, other microorganisms use the inorganic phosphorus as food and incorporate it in their bodies as organic phosphorus. This organic phosphorus is not available for the growth of higher plants until it is changed again into the inorganic form. Thus, in assessing the activity of the soil microorganisms, a series of checks and balances must be considered.

VI. SOIL PRODUCTIVITY

Soil productivity is the capacity of a soil, in its natural climatic environment, to produce a specified plant or sequence of plants under a specified system of management. In their natural state, soils differ widely in productivity because of differences in their ages and in the materials from which they are formed. Most silt loam soils. for example, are naturally more productive than sandy soils, and mature soils are more productive than soils that are either young, geologically speaking! or very old. The productivity of a soil is also partly determined by the way it has been managed in cultivation. In discussing soil productivity, it is appropriate to do so in terms of its relation to management.

1. Soil Management.—Management can be defined as the combination of tillage, cropping and soil-treatment practices used to produce a crop. The three practices compete with and complement each other. Desirable combinations of the three tend to eliminate the unfavourable effects on the soil of crop production, to reduce the adverse effects of climatic, insect and disease hazards, and to push crop yields toward their potential. Under continuing poor management (poor tillage, undesirable sequence or choice of crops andlittle or no soil treatment) the productivity tends to be lower and to vary widely. Under complete and balanced management, on the other hand, a soil can maintain or even improve its productivity: and consequently grow crops more economically. Good management increases the efficiency of the soil in meeting crop requirements and protects the soil from the deteriorating influences of crop removals, and from drainage and erosion.

In practical agriculture there is a tendency to underuse and neglect cropping and soil-treatment practices. which leads to soil exhaustion. greater susceptibility to hazards and declining productivity and lower economy of production. How cropping systems and soil treatments can affect soil productivity is shown in Table II; the corn yields shown there are from a plot of naturally productive dark-coloured silt loam soil, the differences resulting from the differences in management.

TABLE II.—*Effects of Cropping System and Soil Treatment on Soil Productivity*

(Data from University of Illinois Morrow Plots; original corn yields 50 bu. per acre)

Cropping systems	Acre yields of corn			
	No treatment		Treatment*	
	1904–57 (bu.)	1946–57 (bu.)	1904–57 (bu.)	1946–57 (bu.)
Corn every year	25	24	49	
Corn and oats, alternate years	35	36	73	
Corn, oats, and clover, one every three years	52	68	77	108

*Manure, limestone, and phosphate; legume green-manure crop included in corn-oats rotation.

Treatment practices (applying plant-food nutrients. liming materials and animal manures and plowing under green-manure crops) are used to restore constituents that are deficient in the soil. The amount to apply depends upon the needs of the crop for soil-derived nutrient elements and the ability of the soil to fill these needs. Background information for planning these practices is obtained from chemical analyses of crop plants and from various tests for soil deficiencies. Chemical analyses of crop plants show that species differ widely in their requirements for nutrient elements and that the requirements for the different vegetative portions of a plant differ widely.

The data in Table III, giving the approximate quantities of five elements removed from the soil in moderate yields, show these relationships for some of the more commonly gronn field crops. The legumes. such as alfalfa and soybeans. differ somewhat from the nonlegumes in that they can obtain from one-half to two-thirds of the nitrogen they need from the air if they are grown in association nith the proper nitrogen-fixing organisms.

Various tests for soil deficiencies can be used to indicate whether a particular soil can supply the requirements of crop plants. These include: (1) comparing crop yields and production practices for similar soils in the same community; (2) studying information that can be obtained from agricultural experiment stations; (3) natching crops during the groning season for symptoms revealing inadequate supplies of nutrient elements; (4) using chemical soil tests to detect deficiencies in available nutrients;

TABLE III.—*Nutrient Elements in Field Crops*

Crop	Acre yields (cwt.)	Pounds in acre yields				
		Nitrogen (N)	Phosphorus (P)	Potassium (K)	Calcium (Ca)	Magnesium (Mg)
Corn—grain	28	50	8	10	1	4

Timothy hay	40	44	6	52	11	6

*Trace

and (5) using plant tissue tests to learn whether the plant is obtaining sufficient nutrients at various stages of growth.

In humid regions, low nutrient-supplying powers can usually be improved by returning deficient constituents to the soil. The constituents most likely to be deficient and the materials most commonly used to restore them are as follows:

Organic Matter.—Many cropping systems bring about the destruction and loss of soil organic matter. Crop yields tend to decline in proportion to the reductions taking place. The unfavourable effects of these losses can be offset by the regular return of fresh supplies. In field crop husbandry, this is done with animal manure, legume and nonlegume green manures and crop residues.

Nitrogen.—Organic matter is the source of soil-supplied nitrogen. In some regions, as in the North American corn belt, the soil resources, the climatic condition, and the type of farming followed make it possible to provide a high level of nitrogen supply, with animal manures and the residues of legume and nonlegume crops used in association with each other. It is often necessary to supplement the farm resources of nitrogen with commercial supplies Even in the corn belt supplementary nitrogen is often needed. particularly if crop sequences are used that emphasize nonlegume crops and if little or no manure is returned to the soil. In some regions or under some conditions, it may be necessary to rely almost entirely on commercial nitrogen. Providing adequate supplies of nitrogen is a major problem in crop production.

Lime.—Lime affects soil productivity by modifying soil properties and supplying the nutrient elements. calcium and magnesium. Deficiencies are revealed by the development of soil acidity, to which most legume crops are especially sensitive. The proper use of lime as pulverized limestone, chalk, marl, or hydrated or burned lime occupies a place of first importance on many soils.

Phosphates.—Phosphorus is supplied from both mineral and organic soil constituents. Deficiencies may be reduced or temporarily eliminated on some soils by utilizing subsoil supplies with deep-rooted legumes. Effective correction, however, is dependent on the use of phosphatic fertilizers such as superphosphate, basic slag and rock phosphate. The economy of these carriers, which vary in chemical properties and behaviour, depends upon costs, soil conditions and the type of farming followed. The need for phosphatic fertilizers is widespread.

Potash.—Crops acquire potassium from various potash minerals. Some soils are not abundantly supplied with these minerals. Other soils are well supplied with some of the less available forms, but are unable to provide some crops with sufficient quantities of potassium for good yields. Deficiencies in potassium-supplying power can be reduced by returning crop residues and animal manure to the soil, but effective correction is usually dependent upon the use of potash fertilizers such as muriate of potash.

Minor Elements.—In addition to the nutrient elements supplied in the above mentioned materials, crops also depend upon the soil for small quantities of manganese, sulfur, zinc, copper, boron, iron and perhaps other elements. Deficiencies may be corrected by the direct application of suitable carriers or by the use of fertilizers containing the elements needed.

In correcting the nutrient-supplying deficiencies of soils, two general systems of practices have arisen. (1) the use of treatment materials in such ways as to improve the capacity of the soil for producing crops; and (2) the use of treatment materials in such ways, forms and rates as will favour the immediate response of specific crops in particular soil environments. The first system is directed toward the soil and involves a very careful planning of the cropping system and the incorporation, when needed, of liberal quantities of crop residues, animal manures. lime, phosphates and potash into the soil. The second system is directed toward the crop and involves the use of readily available nutrients, singly or in mixtures to provide sufficient quantities of nitrogen, phosphorus and potassium for effective growth and yield.

In the United States, the interest in this system has led to the large-scale manufacture of fertilizer mixtures in the form of grades for specific conditions. Either system is effective when properly used, but the most favourable long-time economy in crop production is more likely to be attained when the essential features of both systems are properly combined.

2. Soil Treatment as an Investment.—On most soils the use of some soil-treatment system will increase the yields of crops more than enough to cover the additional costs of the treatment. As would be expected, poorer soils benefit more from soil treatment than do soils that are naturally highly productive. Soil treatment does not entirely close the gap between soils of different productivity, but it reduces the amount of variation.

TABLE IV.—*Acres of Soils of Different Quality, With and Without Soil Treatment, Required lo Produce the Same Total Yield as 100 Acres of Untreated* Group *I Soils**

Soil Groups†	Management Practices		
	Tillage and cropping only (ac.)	Tillage, cropping and treatment (ac.)	Reduction for treatment (ac.)
I	100	75	25
II	107	85	22
III	123	86	37
IV	138	90	48
V	171	103	68
VI	174	102	72
VII	380	167	213
VIII	500	137	363
IX	648	156	492
X	884	136	748

*Based on average corn-equivalent yields of all crops grown on 21 Illinois soil experiment fields over time periods averaging 45 years, ending in 1956.

†The soil groups are listed in declining order of natural productivity, with Group I the most productive, and Group X, the least.

The results of applying treatments to soils of different productivity are shown in Table IV, where the benefits are indicated as reductions in acreages needed to produce the same amounts of crops. These reductions emphasize the importance of management systems that increase productivity, for if the same production can result from less acreage, land is released that can be used to produce more crops or converted to other economic or social uses.

SOIL ANALYSIS: see SOIL TESTING AND ANALYSIS.

SOIL EROSION AND CONSERVATION. This articie deals with the agricultural aspects of soil erosion and nith the development of conservation programs and conservation methods to protect farms and promote food production. For the mechanics of erosion see GEOLOGY. See also BREAKWATER; IRRIGATION; LAND RECLAMATION; RIVER AND RIVER ENGINEERING; WIND EROSION AND DEPOSITION.

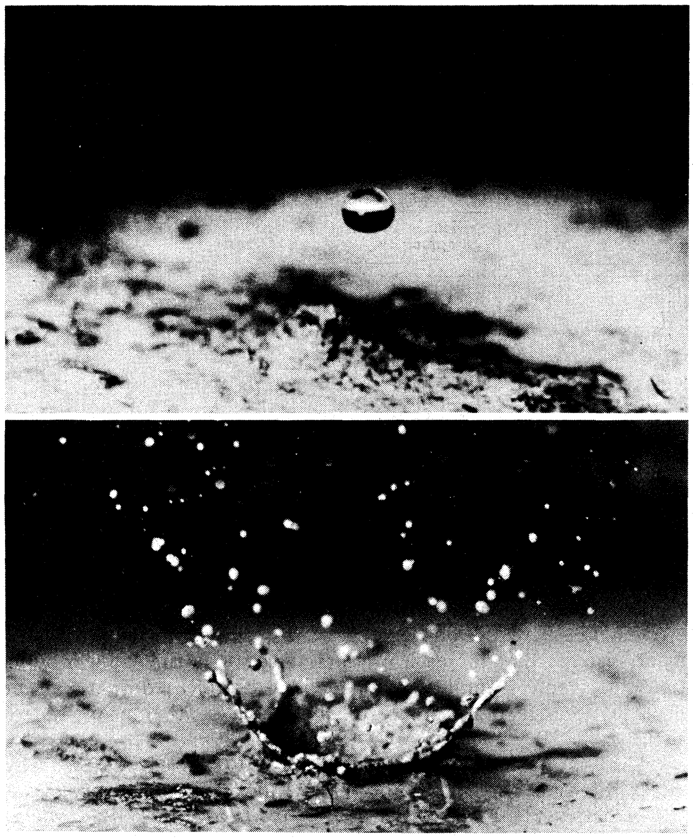
SOIL EROSION

Soil erosion is usually described as the carrying away of soil by either wind or water. The Grand canyon, the fiords of Norway or the sink-holes and caves of the Carso region of Italy and the Dinaric Alps are all examples of normal or geologic erosion. a slow process that occurs under natural conditions. Over long periods of time, usually thousands of years, it makes definite changes in the earth's surface. There is little man can do to change this process or the end result.

The erosion dealt with under this heading is less spectacular but much more vital to the welfare of mankind. It is the carrying away by mind or water of the soil from farms and ranches so necessary for the raising of food, fibre and other agricultural products. Erosion of this type has been greatly speeded up by man's mismanagement of land, even to the point of destroying it for practical agricultural use within one generation.

Factors Affecting Erosion.—Chief among factors affecting water erosion is the amount of cover given the soil. Erosion is slow wherever soil is covered by trees or grass. At Zanesville. O., on comparable watersheds, woodland lost almost no soil during a nine-year period and pasture land very little. but cropland lost an inch of soil.

Closely allied to the matter of cover is the amount and intensity of the rainfall and its distribution during the season. Often a few hard rains which come at a time when crop cover is light will cause most of the soil loss. At La Crosse, Wis., four storms a year during 1940 to 1943 caused 95% of the total soil loss and 84% of the runoff from cornland.



U.S. DEPARTMENT OF AGRICULTURE

FIG. 1.—A SINGLE DROP OF RAIN (TOP) AND THE AMOUNT OF SOIL IT CAN DISPLACE (BOTTOM)

Slope is another determining factor. The longer the slope the more soil and water are lost when cultivated. If the length of slope is doubled the soil loss is usually increased about 1.5 times. Similarly, steepness of slope affects the speed of runoff water and consequent soil loss. If the slope per cent is doubled the amount of loss is increased 2.5 times.

The nature of the soil affects the amount and seriousness of soil loss. The topsoil is generally the most valuable part of the soil profile because it contains more available plant food and organic matter. The surface soil can usually absorb water much faster than the subsoil. As the surface layer becomes thinner less water soaks into the soil and more runs off the surface, thus increasing the rate of soil loss. Losses from deep, open soils are less in amount and less serious than from shallow soils. The hazard increases for slowly permeable soils and those with tight, nearly impermeable subsoils.

The cropping system, kind and amount of tillage and conservation measures used all influence the amount of erosion. Heavy cropping of a soil causes the organic matter to decompose rapidly. Tillage hastens the process. Reduction of organic matter causes a change in the structure of the soil. The granular condition or clumping of the soil particles into more or less regular patterns is largely lost. The soil particles lose their tendency to stick together and are less able to resist the action of wind and water.

The main cause of wind erosion is lack of vegetative cover. This may be due to drought and high temperatures which reduce growth of vegetation; to tillage. and gro ing of cultivated crops which afford insufficient cover; and, in the case of pastures and ranges, to overgrazing. When soil is relatively bare, alternate freezing and thawing or wetting and drying loosens the surface soil and breaks down soil aggregates to granules that can easily be picked up by wind. The most critical seasons are late winter and early spring, when the wind usually blows strongest, the land is clothed with the least vegetation and the soil is most susceptible to movement. Wind erosion is particularly serious in arid and semi-arid regions.

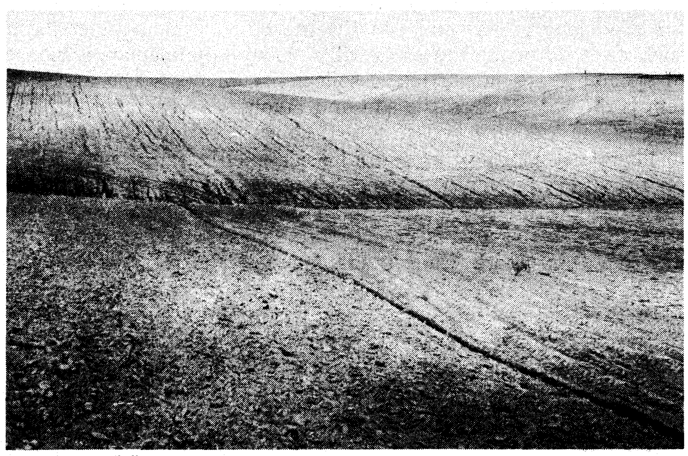
Progressive Erosion Damage.— Soil erosion may be so gradual that serious damage is done before the land occupant is aware of what is happening. Each time a hard rain hits bare land soil is torn loose and snept away. Each raindrop hits the bare earth like a tiny bomb, sending the wet soil in every direction. Not only is soil torn loose to be washed down the slope but available plant food is dissolved and carried away.

Soil damage occurs in successive stages. At first the principal loss is by sheet erosion; that is, each time it rains the runoff water will remove a thin layer of surface soil. As the surface soil becomes thinner small rills (miniature gullies) appear. On cropland these rills are erased by the next cultivation and the field looks much as before. After most of the surface soil is gone gullies may become the principal problem. In gully erosion, channels are cut by water that has concentrated in the natural drainage ways or draws in a field. These channels may vary from a few inches to many feet in depth and up to many rods in width. As a result of gullying soil is lost, tile lines are washed out and fields are divided into two or more parts. Gully erosion is the most familiar type of erosion, doing serious injury to farm land. In the most advanced stages gullies may render land unfit for practical use for cultivated crops or even pasture. Reclamation of badly eroded land is expensive in any case, and full restoration is usually impossible except by natural processes of soil formation which require long periods of time. Sheet erosion, however, is actually more common and more serious than gully erosion because it takes place so gradually that the damage is not recognized.

Soil damage by wind erosion is serious and extensive. Farmers in affected areas suffer crop damage or complete loss of crops. Serious as this may be, the greatest loss is that of the fine soil fractions (silt. clay and organic matter). The wind exerts a sorting action on some soils much like a sieve. The finer particles, which contain the major part of the plant food elements, are gradually sorted out and carried away. Left behind is the coarser portion, which is less fertile and is often more erodible than the original soil.

Water and wind erosion result in much additional damage. Productive lowland soils often are covered uith sand, gravel, stones and low-fertility subsoil washed from slopes above. Water-borne silt fills stream channels, drainage ditches and reservoirs, thus interfering with drainage and shortening the usefulness of lakes built for flood control, water supply and recreation. Winds often cover productive land nith infertile sand and bury railways, highmays, fences, hedges, shelter belts and even farm buildings.

Erosion as a World-Wide Problem.— Surveys made in different countries have shown that erosion has damaged or ruined for practical use hundreds of millions of acres of once-productive land all over the world. Induced erosion continues to be a major problem in every agricultural region in the world except in northwestern Europe. In Great Britain and other countries of northwest



SOIL CONSERVATION SERVICE, U.S. DEPARTMENT OF AGRICULTURE

FIG. 2.— SEVERE SHEET AND RILL EROSION

This field, plowed and disked in preparation for corn, lost an estimated inch of soil during spring rains. The light-coloured spots on the slopes indicate where the dark topsoil is gone and the light subsoil is showing through

Europe, well-distributed rainfall, lack of torrential rains and centuries of careful husbandry have preserved soil fertility remarkably well During World War II, increase in the misuse of land changed this situation, however, and serious erosion in parts of the uplands of England, Scotland and Wales was the result of up-and-down hill farming of potatoes and other row crops.

W. F. PURNELL

FIG. 3 — GULLYEROSION PRODUCED BY THE CONCENTRATION OF WATER IN THE NATURAL DRAINAGE WAYS OF A FIELD

The erosion problem appears to be common throughout the world. This conclusion is borne out by the Food and Agriculture Organization of the United Nations (FAO) in a bulletin, *Soil Conservation, an International Study* (1948). After reviewing conditions in the United States and citing examples of serious and widespread erosion in China such as. "The Yellow River is the muddiest great river in the world." the report continues: "But these are only examples—the problems of soil conservation are world wide. They are particularly acute in India, where, as in China. there is tremendous pressure of population on natural resources even more meager; in the Mediterranean region of Europe and the Near East, where centuries of human occupation and the nature of the climate and land forms have favored rapid soil erosion; in Latin America, where many countries with dense populations have rapidly eroding lands; and in South Africa and Australia, where conditions and problems and the history of occupation are similar to those of parts of the United States of America."

In the United States surveys show that erosion has severely damaged about 280,000,000 ac. of crop and grazing land. Another 775,000,000 ac. of crop, grazing and forest land have eroded to some extent It was estimated. in the latter half of the 20th century, that there were left in the farms and ranches of the country about 460,000,000 ac. of land suitable for cultivated crops. This included, besides land already in crops. about 95,000,000 ac. that needed clearing. draining. irrigating or other improvements to make them suitable for cultivation. All but about 100,000,000 ac. were subject to erosion if not protected.

CONSERVATION

Conservation and Productivity. — In its simplest sense, soil conservation means the saving or preserving of the soil. This would be a relatively easy problem were it not that while saving the soil it is necessary to use it. Man must depend on it for most of his food and fibre. The idea of "saving" recognizes the need to keep soil productive for future years; "using" recognizes the necessity of getting production from the soil now.

In addition to protecting and improving the land, soil conservation yields many side benefits. It helps lower the cost of farm production. This, in turn. increases farmers' profits and helps lower the cost of food and clothing to city dwellers. Soil conservation helps check drought damage in dry seasons and reduces flood crests in small and large streams in wet times. It reduces siltation of streams, reservoirs and harbours, thus helping to insure a cleaner water supply for cities and towns, improve navigation and provide a better habitat for fish and other forms of wildlife. It also provides a cleaner and more beautiful countryside.

The Conservation Movement. — Soil depletion and erosion began to take their toll early in the history of the American colonies. Most of the early colonists came from areas where rains fall gently. Therefore they were not prepared to handle soil in the North American climate, where rain often falls with great intensity. They cut down the forests along the eastern coast, built their homes and planted corn and other crops in the cleared fields. More and more land was plowed to produce food for the increasing population and for production of tobacco and grain that could be traded abroad for needed commodities.

Then a few farmers in the older sections noticed a change in the soil. At first it had been dark, in some places almost black, but it gradually became lighter in colour. When a heavy rain came, the loose soil mixed with the water and the muddy mixture flowed down the hills. carrying with it the richest portion of the soil—topsoil.

Destruction of soil by gullies and floods was noted by writers even before the Revolutionary War. By 1775 rivers that once ran clear were described as being black with mud. Early Massachusetts records indicate that most of the land near the coast was abandoned at least once before 1800.

Some of the leading men of that day were deeply concerned. Patrick Henry is credited with saying, "He is the greatest patriot who fills the most gullies." George Washington, who was an industrious farmer, was continually striving to conserve his land and check erosion. In his final message to Congress in 1796, he urged the creation of a board of agriculture, but it was not until Lincoln's administration in 1862 that the United States department of agriculture was created. Thomas Jefferson was constantly looking for ways to improve the productivity of his soil. While Jefferson was president his son-in-law~,Thomas Mann Randolph, introduced a system of horizontal plowing on his land that was the forerunner of contouring. The results delighted Jefferson. But people generally were not concerned about soil damage since there was so much virgin land. During the following century they moved west, clearing the forest for cropland, plowing the grasslands of the middle west and much of the Great Plains, and on to the Pacific coast.

U.S. DEPARTMENT OF AGRICULTURE

FIG. 4.—ERODED FARM LAND

Left unchecked, the combination of rain, runoff water and wind quickly renders land unfit for cultivation or even pasture

Conservation sentiment was built up slowly. Early in the 20th century Pres. Theodore Roosevelt called the first conference of governors to consider conservation of natural resources. Interest thus aroused led to the purchase of the first national forests and the establishment of the U.S. forest service.

Interest in soil conservation lagged during World War I and the agricultural depression of the 1920s. A soil surveyor in the bureau of soils, H. H. Bennett, was, during all this period, persistently calling attention to the serious erosion he had found in his survey work and trying to arouse! interest in a corrective program. The movement took a big step forward in 1929 when congress approved the establishment of soil conservation experiment stations to (1) measure the rates of soil and water loss; (2) determine the extent and location of damage by erosion; and (3) develop methods for controlling erosion. Soon there were 10 stations in operation gathering the information needed for an attack on the erosion problem.

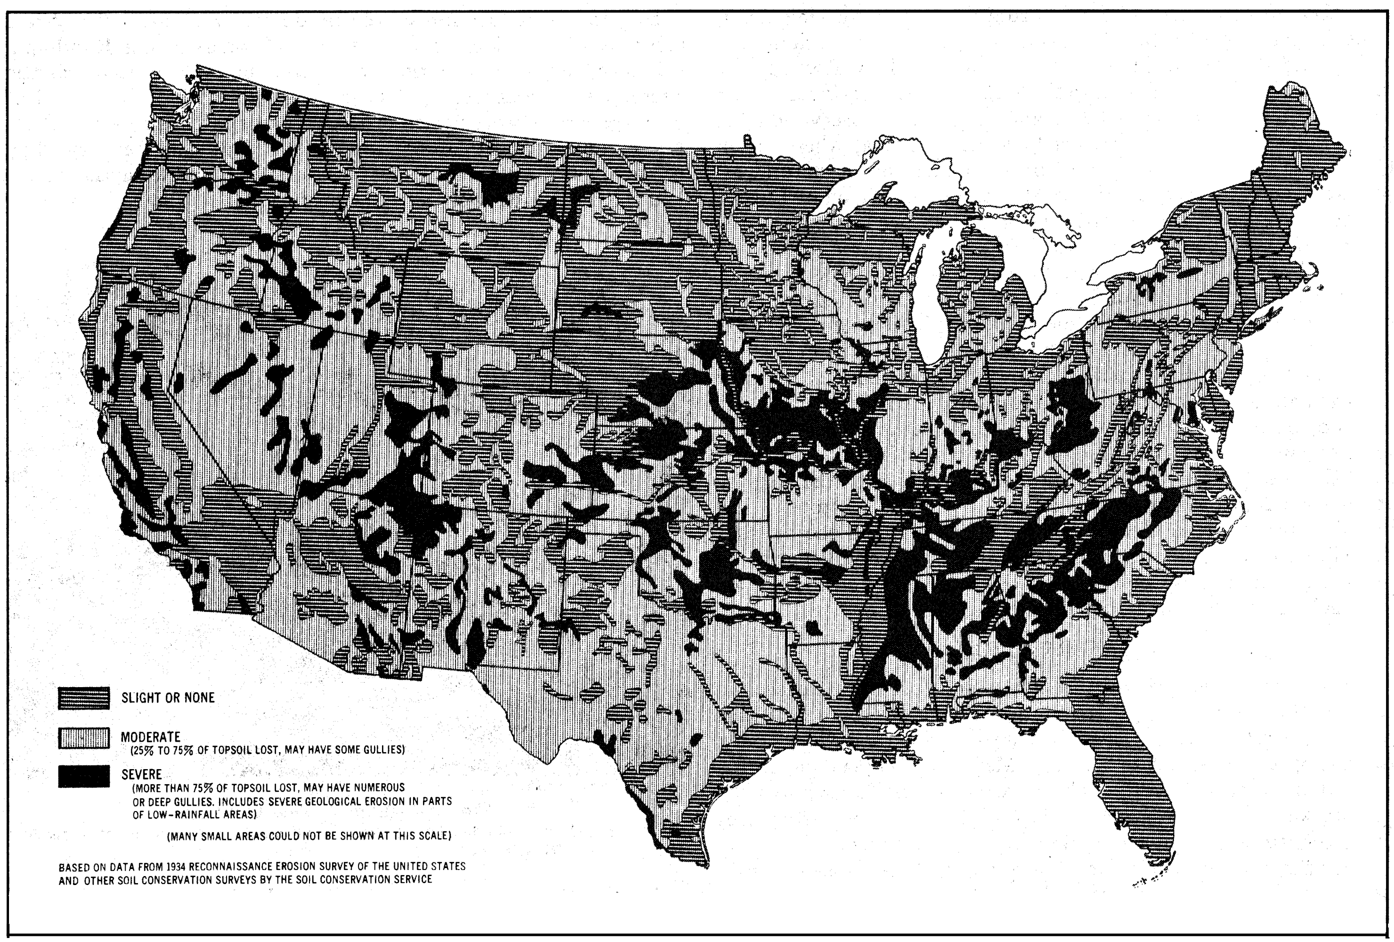
In 1933 the soil erosion service was set up in the department of the interior as one of the emergency agencies to help the country out of the economic depression of the early 1930s. Bennett was made chief of the first erosion control agency ever established by an important nation. In 1935, on the heels of the worst dust storm the U.S. had ever seen—dust from the Great Plains reached Washington, D.C.. and drifted far out to sea—congress passed public law 46, the first soil conservation act in the history of the United States or any other nation. The law established the soil conservation service in the department of agriculture. replacing the soil erosion service. The new agency was charged with carrying out, in co-operation with farmers, a program demonstrating good land use and erosion control. To facilitate the program, labour from the civilian conservation corps (CCC) was made available. The work was carried out first on farms in project areas covering representative watersheds throughout the country. Later it was extended to farmer co-operators in CCC camp areas in each state. But all this was demonstration of limited scope. There was need for farmers and government to work together to apply the lessons to all farm and grazing lands.

State and Local Programs.— Early in 1937 Pres. Franklin D. Roosevelt wrote to the governors of the states pointing out the need for state legislation to enable farmers to take necessary co-operative action in furthering the soil conservation program. With the letter a as a proposed standard state soil conservation districts act that provided for the organization by farmers of soil conservation districts as governmental subdivisions of the state to carry on projects for erosion control.

The suggestion was well received. Arkansas became the first state to have a soil conservation law on its books. In Aug. 1937 the Brown creek soil conservation district in North Carolina was organized and opened its doors as the first in the United States. By 1948 all states and territories had passed soil conservation district laws. More than 2,800 districts have been formed to include the major part of the land in farms and ranches throughout the United States and its territories.

After the coming of the soil conservation district the U.S. soil conservation service shifted its program to do most of its work in co-operation with these districts. The service assigns to each district one or more technicians to help farmers plan and apply conservation programs on their farms.' The assistance includes: (1) a detailed soil survey of the farm or ranch; (2) a conservation plan drawn up by the farmer and technician working together; (3) application of practices called for in the plan; and (4) maintenance of the established practices. Any farmer may participate by agreeing with the district directors to conserve and use his land properly.

Many conservation practices can be applied by the farmer without assistance. But drainage, terraces, strip cropping, farm ponds, diversions, land smoothing, gully control structures and the like require more technical skill than the farmer ordinarily has. The technical knowledge is supplied by technicians who work with the soil conservation district.



SOIL CONSERVATION SERVICE, U.S. DEPARTMENT OF AGRICULTURE

FIG. 5.—MAP SHOWING SOIL EROSION CONDITIONS IN THE UNITED STATES

The program of the soil conservation service has stressed work on a watershed basis. Early project areas were based on watersheds and the boundaries of many soil conservation districts are those of a watershed. In 1944 the service was authorized to apply special treatment for flood control on 11 watersheds in 12 states. In 1953 work was authorized and started on a pilot-watershed program covering 60 small watersheds in 34 states. In 1954 the service was designated as the U.S. department of agriculture representative agency to co-operate with local organizations in small watersheds throughout the nation in work aimed at upstream watershed conservation and flood control. Response to this program was widespread in all states. In all of these watershed efforts the work is carried on in co-operation with local landowners.

Results following high intensity. flood producing storms in several well-developed watersheds in different parts of the country have been most encouraging. Upstream retarding dams used along with recommended soil and water conservation measures on the watershed lands have greatly reduced flooding, erosion and siltation.

In 1956 a Great Plains Conservation program was authorized by congress to help farmers and ranchers of the region develop long-term plans for their land, including soil and water conservation measures and the land-use adjustments needed to achieve a more stable agriculture. It provided technical aid and cost-sharing assistance over a contracted period of years to farmers and ranchers in designated counties for applying measures as part of an approved plan. The soil conservation service is co-operating with local, county, state and regional agencies and organizations to promote this program.

Methods of Conservation. — Appropriate use of the land depends upon land contour, type of soil and climate. Land may be level, slightly or steeply sloping or even mountainous. Soil may be sandy or clayey, fertile or almost barren. Climate also varies. Therefore the farmer or rancher has a real problem in deciding how best to use his land, for there may be several kinds in his holdings. There are many examples of land that has been ruined or badly damaged because it was put to a use for which it was not fitted. To help a farmer or rancher with this problem, soil conservationists make a careful survey of the entire farm and put each area into one of eight broad classes of land-capability according to kind of soil, slope and degree of erosion. Each class is shown by a different colour or Roman numeral on the map of the holding. A farmer can refer to the map and quickly see whether a field can be safely cultivated or whether it should best be used for grazing, forestry or wildlife.

TABLE I. — Conservation Practices Applied in U.S. Soil Conservation Districts

Conservation practice	Total applied as of July 1, 1956	Remaining to be applied (preliminary est.)
Conservation crop rotations (ac.)	54,255,000	181,000,000
Contour farming (ac.)	32,736,000	110,000,000
Cover cropping (ac.)	19,438,000	60,000,000
Strip cropping (ac.)	13,815,000	56,500,000
Seeding ranges and pastures (ac.)	28,384,000	101,000,000
Tree planting on farm laud (ac.)	3,883,000	24,000,000
Farm areas improved for wildlife (ac.)	3,665,000	12,400,000
Drainage of farm land (ac.)	17,585,000	66,000,000
Land leveling for irrigation (ac.)	4,493,000	15,000,000
Conservation of water use for irrigation (ac.)	7,470,000	17,000,000
Terracing of farm land (mi.)	1,045,000	4,670,000
Water diversion ridges and channels (mi.)	58,500	402,000
Pond construction (no.)	748,617	1,500,000

Source: U.S. Conservation Service

An important point in land management is to treat each acre according to its needs. After the best use for land is determined the next problem is to treat each acre in such a may that it will produce as much as possible without injury from erosion. As stated above, good vegetative cover is the first defence against soil loss and runoff. Therefore, proper treatment of all classes of land will provide adequate cover.

For forest and woodland this involves protection from fire, managed cutting, and replanting if needed. For ranges and pastures approved practices include avoidance of overgrazing, resting to encourage growth of better pasture plants, renovating, fertilizing and reseeding. The program varies widely from the pastures of the humid eastern and southern United States to the semiarid ranges of the west and southwest.

Cropland is used more intensively than other land on the farm. More fertility is removed and cultivation encourages the breakdown of the organic matter which helps a soil resist erosion. The soil, when left bare, is open to the beating action of raindrops. This is especially true of row crops. such as corn, soybeans, cotton and potatoes, which are cultivated for weed control. Special care must therefore be taken to maintain and improve fertility, add new organic matter and protect the soil from erosion.

In the cropping system row crops are usually used in succession or rotation with small grains such as wheat, oats, barley or rye, and meadow crops — legumes or grasses or mixtures of the two. As protection against erosion, meadow crops are most effective, row crops the least and the small grains in between. How often each of the three classes of crops should be used in the rotation depends on the capability class of the land and the erosion-control practices employed.

TABLE 11. —Soil Loss From Crops in Various Rotations

Crops	Percentage of R-O-H
Row crop, spring grain, hay (R-O-H)	100
Continuous row crop (R)	422
Row crop, spring grain, catch crop (R-Ox)	242
Row crop, row crop, spring grain, hay, hay (R-R-O-H-H)	125
Row crop, winter grain hay (R-W-H)	86
Row crop spring grain' hay hay (R-O-H-H)	65
Row crop' spring grain' hay' hay, hay (R-O-H-H-H)	52
Winter grain, spring grain, hay, hay (W-O-H-H)	27

Results at experiment stations have shown the relative amounts of soil loss from different crops in various rotations. These are shown below in comparison with a standard three-year rotation of row crop (R), spring grain (O) and hay (H)—that is, R-O-H has the index number of 100. Added to some of the rotations are winter grain (W) and spring grain with a catch crop of legume for green manure (Ox).

Relative values of individual crops in different sequences also have been found.

Other Erosion Control Practices. — Even though good land use, a suitable crop rotation and soil treatment are used, some additional measures are often needed on sloping fields and where wind erosion is a problem.

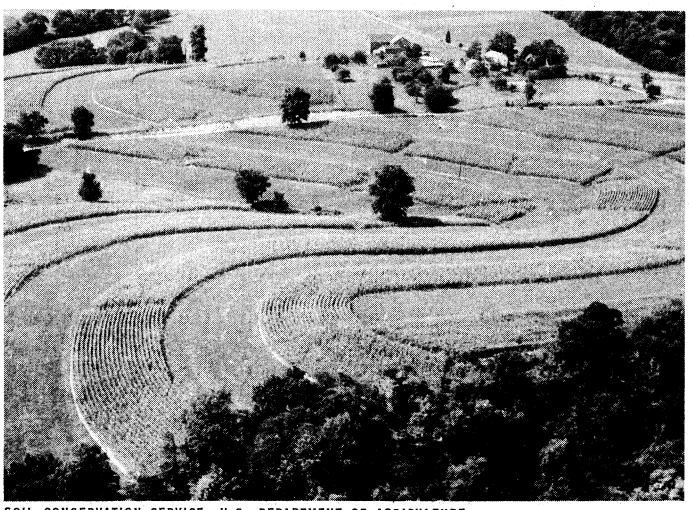
Grass waterways rank first in prevention of erosion and the control of runoff water from cultivated land. They are usually located in the natural drainage ways, but they may be constructed along field boundaries in some cases. Waterways are best made dished or saucer-shaped and rather shallow to keep water from concentrating to any great depth. Width should be sufficient to carry heavy rains without overflowing. A dense vegetative cover is required to keep the water from cutting a gully through the centre. Grasses that make a dense sod are preferred for this purnose.

Where a waterway discharges into an open ditch or stream at a lower level, some sort of structure is needed to keep the overfall from cutting a gully back into the waterway. These structures usually are constructed of concrete or masonry. Earth dams often are built across a large drainage way to prevent gullying and to form a pond for water supply, wildlife and recreation.

Contour tillage is one of the simpler practices that reduce soil losses about 50% from those occurring with up-and-down hill cultivation. In contouring, all furrows and rons follow around the slope and are level from end to end. Since they encircle the slope they are usually curved. The ridges left by farm machinery in preparing the soil and cultivating the crop act as small dams, holding back the water and giving it time to soak into the ground. Contour guide lines may easily be laid out by the use of a simple level fitted with sights. Contouring is most effective on gentle slopes not more than 300 ft. long.

On longer slopes, contour strip-cropping has proved very effective. Instead of the entire slopes being planted in one crop, as in simple contouring, strips of row crops are planted between strips of close-growing crops such as small grains or meadow. If the contour ridges in the cultivated crop are overtopped in a hard storm, the close-growing strip below will slow down the water and catch much of the soil it carries. Strip-cropping has been found to reduce soil losses about 75%.

Terraces are widely used, especially on long slopes, and give the most effective control if they are properly laid out and constructed and are given good care. A terrace is a low, flat ridge of earth built across the slope, with a channel for runoff water just above the ridge. Usually terraces are built on a slight grade so that the water caught in the channel moves slowly toward the terrace outlet. Where several terraces are used on a long slope they have the effect of breaking it up into a series of short slopes that lose less soil than one long one. Before graded terraces are built, suitable outlets should be prepared to receive the water discharged from the terraces. These waterways must be well sodded to avoid gullying. In areas where soils are able to take in water readily and rainfall is relatively low, level terraces may be used. These terraces merely impound the excess water until it can have time to soak into the soil.



SOIL CONSERVATION SERVICE, U.S. DEPARTMENT OF AGRICULTURE

FIG. 6. — CONTOUR STRIP-CROPPING

Strips of close-growing grass-ieoume meadow planted between strips of corn, a row crop

Diversion terraces, or diversions, are built in the same way as field terraces, but they are somewhat larger. They are often used to protect hillside fields from water falling on land above them, or to take water aaay from a gully and thus assist in controlling it. The practices already discussed are the major ones used in the control of erosion by water. Additional practices are in use but space does not permit their discussion.

Wind erosion control requires a somewhat different technique, which involves the following practices:

1. Protecting the soil surface with cover, usually vegetation. Tillage methods, called mulch tillage or stubble mulching, in which crop residues are kept on or in the surface of the soil, have proved effective.

2. Keeping the surface of the soil rough to slow down the wind and trap drifting soil.

3. Managing the soil so as to produce soil aggregates large enough to resist wind action.

4. Using barriers, such as crop strips, ridges or shelter belts to trap the drifting soil and keep it from spreading.

See also DRY FARMING.

World-Wide Conservation. — By the second half of the 20th century, conservation had gained support throughout the world. The conservation movement in the United States was widely studied and the programs of many nations were patterned after it. The United States sent many technicians abroad to study erosion problems and suggest courses of action. An extensive training program for technicians from various lands was established'and several hundred specialists from about 90 nations, colonies and protectorates were given training. More than 20 countries in North and South America, the Mediterranean region. Asia, Australasia and Africa had established organized conservation programs and about 30 other nations were applying conservation measures. Most of the programs were patterned after the one that had been developed in the United States and several included the soil conservation district as a part of their programs.

SOIL FAUNA. Many members of the animal kingdom are present in both cultivated and uncultivated soils. Some of the animals are found within the soil for their entire life cycle, occasionally coming to the surface for short periods, while others spend only some definite portion of their life span in this subterranean environment. The animal population of the soil consequently consists of both permanent and transient inhabitants.

The soil fauna is composed of a variety of animals ranging from microscopic protozoa to vertebrates such as moles and ground squirrels. The major group of significance, however, is the invertebrate population. The simplest forms of underground animal life are the single-celled protozoa; this group, although part of the fauna, is discussed elsewhere with other soil microorganisms (see SOIL: Soil *Microbiology*).

The group of invertebrates discussed here includes a variety of distinct types. some ubiquitous, others occurring only infrequently and in small numbers. The major animals include the flatworms, the nematodes. certain mollusks — especially the slugs and snails — the earthworms, wood lice, millipedes, centipedes, a variety of arachnids and a broad spectrum of insects. In addition, a few vertebrate species make their homes in the soil.

On the basis of their feeding habits, the soil residents may be divided into categories, depending upon whether they feed on decaying organic matter (saprophagous), on living plants (phytophagous), on other animals (predaceous) or upon animal excretory products (coprophagous). Those that attack cultivated plants are a great menace to agriculture; but others play a positive role by aerating the soil and in many other ways.

The abundance of invertebrates in soil is determined in large part by the supply of available nutrients and by certain physical characteristics of the environment. For their optimum development, good aeration and drainage are necessary. Moisture conditions are significant, and the fauna tends to be present in smaller numbers when moisture is inadequate. Temperature is another important environmental influence, with little animal activity occurring at low temperatures. The addition of organic materials increases the population of animals, and each of the major groups is more abundant in manured than in unmanured soil.

The number of invertebrates in soil varies widely according to the environment, but in fertile, well-aerated soils the population ranges from several million to several hundred million per acre exclusive of the protozoa. Most abundant are insects. nematodes (roundworms or eelworms), earthworms and millipedes. Although there are vast numbers of smaller animals, these are so small that they make up only a fraction of the total weight of the fauna. The larger invertebrates, such as the earthworms and the myriapods (millipedes, centipedes, etc.), therefore, make up the bulk of the total weight. sometimes up to 90%. The fauna contributes as much as several hundred pounds of animal tissue per acre.

The nematodes are nonsegmented worms, commonly from 0.5 to 2.0 mm. long but occasionally up to 10 mm. in length. They are endowed with the capacity for active movement when in a liquid film. Many different types maintain a subterranean habitat, and the number of species is immense (see also NEMATODA). Some are saprophytic, using organic materials and even microorganisms as food; others prey upon members of the soil fauna including other nematodes. while a very important group can attack and parasitize growing plants. Some of the plant parasites prey upon one or a few plants, but others seem to be nonselective.

Mollusks such as snails and slugs spend part of their life in soil, and many mollusks will leave only infrequently. They prefer a moist environment and are common in shady areas at the soil surface as well as under rocks and surface debris. Although they will sometimes attack plants. they tend to utilize decaying materials. The mollusks are never abundant but may be present in numbers up to about 50,000 per ac.

Since the classical studies of Darwin, soil scientists have appreciated the significance of the earthworm (*q.v.*). These segmented norms spend their entire life cycle in the soil, emerging only occasionally. They are unfavourably affected by desiccation, low temperatures and poor drainage, and they are generally absent when the soil reaction is highly acid. They show a distinct preference for well-aerated and well-drained localities. An available supply of organic matter is important, and the earthworm population is highest in soils receiving barnyard manure and in pasture and forest soils. Earthworms can feed upon organic litter but have certain distinct preferences in their nutritional habits. When present, animal manures are used. Not only is the number greater in organically rich soils, but the worms themselves are larger. Under optimum conditions, their numbers range up to several million per acre with a large bulk of the entire animal weight as earthworm tissue—up to a hundred or more pounds per acre. As they burrow, the worms excavate channels that increase aeration, improve drainage, loosen the soil structure and provide paths for plant roots. The casts left by the earthworms tend to promote soil crumb aggregation as well. Darwin estimated that earthworms bring about 20 tons of material per acre to the surface each year—an amount sufficient to cover a field to a depth of one-fifth inch.

There are three major arachnid representatives: mites. spiders and ticks. The arachnids are usually free-living in nature, although some can be parasites on plants or higher animals. Their burrowing habits probably improve the structure, aeration and water movement in the soil.

Only two myriapods are encountered in appreciable numbers, the millipedes and the centipedes. Of the two, the millipedes are the more numerous, and soils rich in earthworms usually support the gronth of many myriapods. with the population in each acre extending into the millions. Certain myriapods can utilize organic matter and living plants for their growth. while others are predaceous. This group requires adequate moisture in the soil.

Many genera and species of insects are present, either in the adult form or in the larval or pupal stage, and these are frequently the most abundant of the invertebrate animals in the soil. Among the more common insects are ants, springtails, termites, and beetle and fly larvae. Insects may feed upon subterranean portions of plants or may live saprophytically, while certain species lead a predatory existence. The plant parasites of this group pose a serious threat to agriculture.

Certain vertebrates burrow underground and spend part of their lives under the surface. Prairie, forest and desert have their characteristic, burrowing species. Among the mammals are the moles, ground squirrels. mice, hares. shrews, woodchucks, badgers and gophers; among the reptiles are snakes, lizards and some turtles. The rodents in particular can be quite active in their movements through the soil.

The soil fauna has a great significance in soil structure and fertility and in plant pathology. The invertebrates are capable of causing a number of injuries to plants as well as being parasitic. There is evidence that the fauna may play an appreciable role in promoting the decay of organic matter, particularly in forest areas, although its significance is secondary to that of the microflora. As the animals burrow through the soil, they leave behind openings that improve aeration and drainage, although they may damage a cultivated field or wreak havoc on a well-tended lawn.

The fauna also can move a considerable quantity of plant residues as well as large numbers of microorganisms for considerable distances. The animal population serves to mix surface plant debris and forest litter with the underlying soil and also to move soil upward and leave it in the form of mound. In all respects, the soil fauna provides an interesting area of study for the soil scientist. the zoologist and the plant pathologist.

SOIL MECHANICS is the branch of engineering science dealing with the behaviour of soil when subjected to stresses or to the action of percolating water. The subject furnishes a rational basis for foundation engineering and earth-dam design and provides new tools for geological investigation.

Soil is a natural aggregate of mineral grains, with or without organic constituents, that can be separated by gentle mechanical means such as agitation in water. It may consist of the products of rock decomposition found essentially in their original position after weathering, or of materials transported and deposited by glaciers, streams or wind. Soil differs from most structural materials in that it consists of three phases: solid mineral matter, water, and air or other gas. Many soils comprise two-phase systems, of mineral matter and water, and are then said to be saturated.

Principle of Effective Stress.—Although soils constitute possibly the oldest construction materials known to man, the arts of foundation and earth-dam engineering remained essentially empirical until about the third decade of the 20th century. largely because the implications of the interaction between the soil grains and water had not been correctly evaluated. In 1923 Karl Terzaghi published the first clear statement of the principle of effective stress, a concept that proved to be the key to an understanding of the engineering behaviour of soils. According to this principle, the intensity of stress p acting normal to any section through a mass of soil is equal to the sum of two parts. the intergranular or effective stress p' which is transmitted from grain to grain at points of contact, and the neutral or pore stress u which is transmitted through the water in the pore space; that is,

$$p = p' + u \quad (1)$$

Moreover. the engineering behaviour of the mass of soil is exclusively a function of the intergranular stress and is unaffected by the neutral stress.

The significance of the principle of effective stress is illustrated in connection with the strength of saturated cohesionless granular materials such as sand or gravel. As early as 1773, C. A. Coulomb expressed the resistance s possessed by such a material against failure by sliding as

$$s = p \tan \phi \quad (2)$$

where p was the pressure per unit area normal to the section along which sliding took place and ϕ the angle of repose of the material. The quantity ϕ, now more precisely designated as the angle of internal friction, is a soil property depending somewhat on the kind and shape of the mineral grains and primarily on the looseness or denseness of the arrangement of the grains. It may range between about 30° and **44".** Since slopes subjected to percolating water often proved less stable than those on dry sand, it was commonly assumed that the values of ϕ for wet sand were 6° or more smaller than those for dry sand. Yet, direct shear tests by Terzaghi indicated essentially identical values in either state. The discrepancy was resolved by replacing p by p' in equation (2), whence

$$s = p' \tan \phi = (p - u) \tan \phi \quad (3)$$

In this form. Coulomb's equation is valid.

Curiously enough, Coulomb himself made no measurements to determine ϕ and assumed a value of 45° in his application of equation (2). Indeed, until the principle of effective stress was understood, meaningful tests of the physical properties of soils could not be performed.

Seepage Pressure.—If water flows through a deposit of sand, the viscous drag tends to move the grains in the direction of the flow and produces a force, known as a seepage pressure, between the grains. The seepage pressure is an intergranular stress. If upward flowing water produces a seepage pressure just equal and opposite to the submerged weight of the sand above a given horizontal section, the intergranular pressure becomes zero and, according to equation (3), the strength of the sand becomes zero. The sand is said to be in a "quick" condition and is incapable of supporting a load on its surface.

Where flowing water emerges from a cohesionless deposit the seepage pressure has a component directed outward and away from the surface and tends to dislodge and remove some of the smaller particles. If the process continues, a tunnel-shaped cavity or "pipe" may develop. The formation of such pipes beneath or within dams has led to several catastrophic failures. It may be prevented by blanketing the surface where the seepage emerges with coarser materials that permit escape of the water but prevent erosion of the fines. If the seepage pressure has a great enough upward component, it may be necessary to add weight to the top of the filter to counterbalance the upward forces.

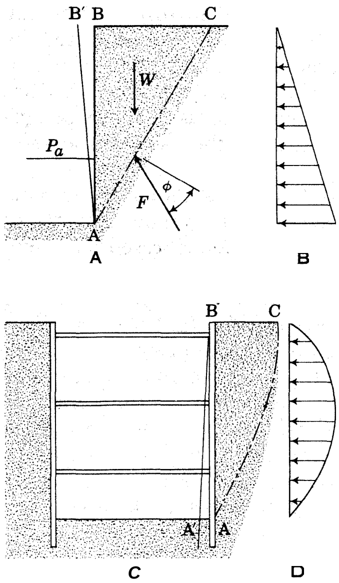

FIG. I.— SHEARING RESISTANCE
(A) Forces assumed by Coulomb in calculating earth pressure against retaining wall; (B) distribution of pressure against wall; (C) braced cut; (D) distribution of earth pressure against sheeting

Shearing Resistance.— The shearing resistance of soil is a primary factor in several problems of engineering importance. It governs the pressure against retaining- walls, bulkheads and the timbering of braced cuts. It also determines the bearing capacity of footings and piles and the stability of slopes, embankments and dams.

One of the first problems to receive attention in soil mechanics was the calculation of the pressure of earth against retaining walls. Coulomb solved the problem by considering the equilibrium of a triangular wedge of earth behind the wall (fig. 1[A]). He assumed the surface of sliding AC to be plane. The resultant force F on the surface of sliding was assigned the inclination ϕ to the normal to the surface, implying fully developed shearing resistance along AC. By allowing the inclination of AC to vary; Coulomb found the plane on which slip was most likely to occur, and the corresponding value of earth pressure $P_{a'}$ designated as the active earth pressure. He assumed this pressure to act horizontally at the lower third point of the wall.

Coulomb's theory proved, with slight modifications, to be satisfactory for ordinary retaining walls and is widely used today. However, it failed to account for the pressures that practical men observed against the bracing of open cuts. Experience indicated that the load in the upper braces was substantially greater than that given by the theory, whereas the bracing at the bottom was very lightly loaded.

Theorists generally ignored these observations. and practical men generally discounted the theories. The state of contradiction was not clarified until in 1920 Terzaghi recognized the great importance of the manner in which the support may yield. In connection with a retaining wall, the supporting surface AB yields into the position AB' and permits an uniform degree of lateral expansion in the entire sliding wedge XBC; the resulting lateral pressure increases linearly with depth (fig. 1[B]). On the other hand, in a braced cut, lateral expansion of the upper part of the wedge is restricted as soon as the uppermost brace is set; the deformation of the sheeting is likely to resemble BA′ in fig. 1(C). The large expansion at the bottom of the wedge is associated with a reduction of pressure at the bottom of the cut and an increase at higher levels. The corresponding pressure distribution is roughly parabolic (fig. 1[D]). Moreover, the surface of sliding is no longer plane but is curved. The general wedge theory of earth pressure (Terzaghi; 1939) took account of these factors and provided the means for calculating the loads in temporary bracing systems. The theory was confirmed by full-scale measurements on the bracing of the Berlin subway. Subsequently, it nas found applicable to clay soils and confirmed by numerous full-scale field measurements. including a series on the Chicago subway.

Slope Stability.— Closely related to problems in earth pressure are those dealing with the stability of slopes. Before about 1920 it was assumed that every soil possessed an angle of repose and that slopes would be stable if established at angles slightly smaller than the appropriate angles of repose tabulated in various handbooks. Occasional catastrophic slides, particularly in clay soils, indicated from time to time the inadequacy of the procedure. In particular, a series of slides on the Snedish state railways near the beginning of the 20th century, culminating in one with a loss of 41 lives. led to the appointment of a Royal Swedish Geotechnical commission to study the degree of safety of existing slopes and to suggest remedial and precautionary measures. The report of the commission, published in 1922, contained the most complete analysis of landslides up to that time. It made the first extensive use of what is now called the Swedish method of stability analysis. The method is based on the empirical observation that the surface on which a slide occurs is almost always an approximately circular arc. The principle of the method is shown in fig. 2. The mass ABC tends to rotate about O under the influence of the weight W_1. The rotation is resisted by the moment of W_2 and by the moment of the shearing resistances s acting along the circular arc AC. The value of s required to prevent a failure (factor of safety = 1) is

$$s = \frac{W_1 l_1 - W_2 l_2}{R\widehat{AC}} \tag{4}$$

The factor of safety of the slope may be determined by comparing s from equation (4) with the value of shearing strength determined by laboratory or field tests The position of the surface of sliding for nhich the factor of safety is a minimum is found by successive trials.

Most currently used procedures for stability analysis are derived from the Swedish method. Since slides frequently occur in clayey soils. information is needed regarding the shearing strength of clays. Coulomb expressed the relation between shearing strength s and normal pressure on the surface of sliding

$$s = c + p \tan \phi \tag{5}$$

as where c was called the cohesion. or the shearing strength at zero normal pressure, and the other symbols have the same meaning as in equation (2). However, even with the replacement of p by p', equation (1), Coulomb's equation was found to be inadequate because the value of s was found to be a function of the loading history of the clay. Research has not yet fully clarified this aspect of the subject. For saturated clays that do not experience change in water content under stress, however. the shearing strength with respect to total stresses is independent of the pressure. That is. such clays behave as frictionless materials and their strength is where q_u is the ulti-

$$s = c = q_u/2 \tag{6}$$

mate strength of a cylindrical or prismatic specimen tested axially in a simple compression test. Many problems of practical importance can be treated in this manner.

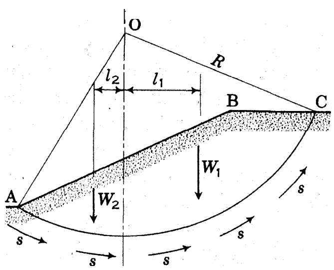

FIG. 2.— FORCES TENDING TO CAUSE AND PREVENT FAILURE OF A SLOPE ALONG A CYLINDRICAL SURFACE

Settling of Structures.— The settling of structures located above deep beds of soft clay long proved baffling to foundation engineers, particularly since such settlings often continued to increase many years after completion of the structures. Inasmuch as the damaging effects of the settling often did not develop until the settling had reached an advanced state, buildings frequently appeared to crack and deteriorate spontaneously. Several engineers had suspected that the settling was the result of slow squeezing of the water from the pores of the clay. but no satisfactory quantitative explanation was available until Terzaghi proposed the theory of consolidation in 1923. According to this theory, clay consists of mineral particles arranged in a structure that is at once relatively compressible and fairly impermeable. The voids between the mineral particles may constitute an appreciable fraction of the total volume, but the openings between the voids are very small and restrict the flow of water. The voids are considered to be filled with water, which is inherently less compressible than the mineral skeleton. Hence, a load when first applied to the clay soil is carried almost exclusively by the water. The compression of the clay structure: and hence the settling of the ground surface, take place. in accordance with the principle of effective stress, only as the stress is transferred from the water to the clay structure.

Terzaghi proposed an instructive analogue to the process of consolidation of clay. In its simplest form. it consists of a water-filled cylindrical container closed by a piston supported by a spring. The spring represents the clay skeleton. The piston represents the boundary between two void spaces in the clay. It is pierced by a hole AB which permits escape of water at a slow rate corresponding to the low permeability of clay. If a load P is suddenly placed on the piston. no shortening of the spring can occur at the first instant because no water has yet escaped from the cylinder. Since the spring must shorten to carry additional load, the load P must produce an additional pressure P/A in the water, and the pressure gauge will indicate this value. There is now set up across the opening AB a pressure differential equal to P/A, which produces a flow of water from the chamber. As the water flows out the spring correspondingly shortens and carries load in proportion to its shortening. With the spring carrying part of the load, the pressure in the water is less than P/A. The pressure differential across AB is reduced, the rate of flow decreases and the rate of settling decreases. The process continues at a decreasing rate until. after a very great time: the excess pressure in the water approaches zero. The rate of settling of the piston corresponds to the rate of transfer of the total pressure P/A from the water to the spring. By analogy, the rate of settling of a clay stratum is governed by the rate of transfer of the total pressure caused by the construction from porewater pressure to intergranular or effective pressure. The rate of transfer, in turn, is a function of the compressibility of the soil structure! the permeability of the clay and the viscosity of the water.

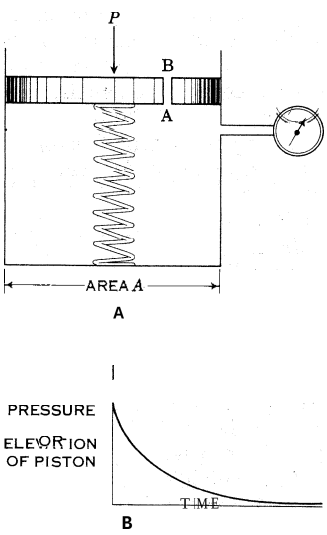

FIG. 3.— PISTON ANALOGY TO PROCESS OF CONSOLIDATION
Diagram (B) shows progress of consolidation with time

The mechanism of consolidation provides an explanation for several hitherto unexplained phenomena, including the settling of the ground surface associated with pumping from underlying aquifers. The reduction in pore pressure associated with pumping induces consolidation of any clay layers above or below the aquifer. Large settlings due to this phenomenon have occurred at many places, including Mexico City and the Santa Clara valley in California.

The accuracy with which settlings can be predicted on the basis of soil mechanics varies to a considerable extent with the geology and character of the deposits involved. Under the most favourable circumstances, computed and observed settlings agree satisfactorily until the settling reaches about 60% of the computed final value. Thereafter the real settlings are likely to exceed the computed ones by an amount that is usually, but not always, a small fraction of the total settling. The additional settling partakes of the character of a slow creep; the discrepancy is greatest for highly organic soils.

Sampling and Testing. — The structure of most compressible soils is sensitive to disturbance If the samples from which values of compressibility and other physical properties are determined have experienced disturbance. the predictions based on the test values may be seriously in error. To avoid this difficulty, drilling and sampling techniques have been devised to permit procurement of specimens as undisturbed as possible. The most refined samplers consist of thin-walled tubes that are pushed steadily, without driving, into the ground. with an internal piston that remains at a fixed elevation such that the length of sample recovered is equal to the distance of penetration. Techniques have been developed for investigating the properties of the soils in *situ;* research is actively being conducted in this field. Nevertheless, errors due to disturbance remain significant; their evaluation requires full-scale field observations.

The greatest source of error in the application of soil mechanics lies in the heterogeneous character of most natural soil deposits. The products of natural processes are almost always complex and cannot economically be investigated in sufficient detail to determine soil properties completely. In some instances. only average values can be estimated. together nith probable variations from the average. Kevertheless, useful predictions of settlement and other aspects of engineering behaviour can be derived from such estimates and the principles of soil mechanics.

See Karl Terzaghi. "Origin and Functions of Soil Mechanics," *Trans. Amer. Soc. Civ. Engrs.*, vol. *CT*, pp. 666–696, contains extensive bibliography (1953); Karl Terzaghi and Ralph B. Peck, *Soil Mechanics in Engineering Practice* (1918). (R. B. P.)

SOIL TESTING AND ANALYSIS. In studying and characterizing the properties of different soils, many kinds of soil analyses are used. Chemical analyses are made to determine the amounts of each element or chemical compound present and the chemical reactions that occur in soils. Analyses of the physical properties of soils provide information concerning soil texture (the proportions of sand. silt and clay), soil structure (the degree of aggregation) and the movement of air and water in soils. The minerals present are identified and studied by mineralogical analyses. Microbiological analyses are used to study the kinds and numbers of different microorganisms and the processes carried on by these microorganisms in the soil.

Research of this kind has led to the development of relatively simple soil analyses commonly referred to as soil tests. In agriculture such tests are used most extensively to evaluate nutrient availability in soils and to predict whether increases in crop yield or quality will result from applications of lime or fertilizer. The development of these simpler tests occurred largely after 1930. Previous attempts to relate nutrient availability in soils to the total amount of a nutrient element present in the soil or to that present in the soil water were not successful. Only when testing procedures were developed to remove and measure certain readily available portions of the nutrient elements present in soils could definite relationships between the soil-test results and plant availability of the nutrients be established.

Following World War II interest in soil testing increased rapidly. The United States. most of the European countries and many other countries developed or expanded soil-testing laboratories to test soil samples from farmers' fields and advise the farmers as to the lime and fertilizer practices best suited for their soil conditions. While the majority of the testing is done for field soils, some laboratories make special tests for soils used in greenhouses or for other special uses. Most soil-testing laboratories are operated by agricultural colleges or universities or by governmental agencies. However, a number of commercial laboratories, especially in the United States, offer this service to farmers.

Individuals may buy small soil-testing kits to test their own soils although this procedure is not generally recommended by soil scientists.

The first step in soil testing is the collection of the sample in the field. Proper sampling is essential if the advice based upon the soil test is to be reliable. If soil conditions in the field vary because of different types of soil or different previous treatments, each condition should be sampled separately. Usually 15 or more small samples from a uniform area are collected and thoroughly mixed to provide one representative sample.

In the laboratory different tests are made for different nutrient elements. The amount of lime that should be applied is usually estimated from the pH (a measure of the acidity) of the soil sample. While tests for phosphorus and potassium are made almost universally, the testing procedures used in different laboratories are extremely varied. Solutions of acids, bases or salts of various concentrations or mixtures of these reagents may be used to extract the phosphorus or potassium from the soil. Then the phosphorus or potassium in the extract is determined. Certain reagents may provide reliable tests of nutrient availability in some soils but not in others, so different reagents are used in different laboratories.

Chemical soil tests for nitrogen are less commonly used. Most of the nitrogen used by plants is made available by microbiological decomposition of organic matter. Tests to measure the rate at which nitrogen is released from the organic matter have been developed but have not been widely adopted. Some laboratories test for calcium and magnesium in soil extracts similar to those used for potassium. Many soils contain soluble salts in amounts that are detrimental to plants. Most laboratories test for soluble salts by measuring the electrical conductivity of a soil-water suspension or of a water extract of the soil.

The boron removed in hot-water extracts of soil samples is determined in some laboratories in areas where boron deficiencies occur. Adequate soil tests for other minor elements such as manganese, copper, zinc, molybdenum, iron, etc., have not been used extensively.

For advising farmers on the use of lime and fertilizer, the soil-test results must be interpreted differently for different crops, soils and environmental conditions. Laboratory tests can provide only a relative measure of nutrient availability, not the actual amount of a nutrient element that will be available to plants during a growing season. Furthermore, different plants have different nutrient requirements. Various environmental conditions and soil properties influence nutrient availability to plants growing in a field. but do not influence the soil-test results. Because of this, the soil-test results must be interpreted differently for these different conditions. The interpretation must be based upon relationships developed between the soil-test results and the results obtained in fertilizer experiments conducted in the field under each of the different conditions.

Where adequate relationships have been developed, soil tests are useful guides in advising farmers on the use of lime and fertilizer. Much research is continually devoted to the development of better testing methods and to improving the relationships between the laboratory and field results for various soils and crops.

SOISSONS, a city of France, capital of an arrondissement in the *département* of Aisne, 65 mi. N.E. of Paris by the railway to Laon. Pop. (1954) 18,901.

Soissons is generally identified with the oppidum of Gallia Belgica, called Noviodunum by Caesar. Noviodunum was the capital of the Suessiones, who occupied 12 towns, and whose king, Divitiacus, one of the most powerful in Gaul, had extended his authority even beyond the sea among the Britons. In 58 B.C. Galba. king of the Suessiones, separated from the confederation of the Belgians and submitted to the Romans. At the beginning of the empire Noviodunum took the name of Augusta Suessionum, and afterward that of Suessiona. and became the second capital of Gallia Belgica, of which Reims was the metropolis. The town was before long surrounded with a wall and defended by a citadel, and it became the starting point of several military roads.

Christianity was introduced by St. Crispin and St. Crispinian, men of noble birth, who, however, earned their livelihood by shoemaking, and thus became patrons of that craft. After their martyrdom in c. 286 their work was continued by St. Sinitius, the first bishop of Soissons. After the barbarians had crossed the Rhine and the Meuse Soissons became the metropolis of the Roman possessions in the north of Gaul, and on the defeat of Syagrius by Clovis in 486, the Franks seized the town. It was at Soissons that Clovis married Clotilde, and, though he afterward settled at Paris, Soissons was the capital of his son Clotaire, and afterward of Chilperic I, king of Neustria. It was not till the time of Chilperic's son. Clotaire II. that the kingdom of Soissons was incorporated with that of Paris. Pippin the Short was at Soissons proclaimed king by an assembly of *leudes* and bishops, and he was there crowned by St. Boniface before being crowned at Saint Denis by the pope himself.

Louis the Pious did penance there after being deposed by the assembly at Compiègne.

Under Charles the Fat (886) the Normans failed in an attempt against the town, but laid waste St. Médard and the neighbourhood. In 923 Charles the Simple was defeated outside the walls by the supporters of Rudolph of Burgundy, and Hugh the Great besieged and partly burned the town in 948. Cnder the first Capets Soissons was held by hereditary counts.

The communal charter of the town dates from 1131. At a synod held at Soissons in 1121 the teachings of Abélard were condemned, and he was forced to retract them. In 1155, at an assembly of prelates and barons held at Soissons, Louis VII issued a famous decree forbidding all private wars for a space of ten years; and in 1325 Charles the Fair replaced the mayor of Soissons by a royal provost dependent on the bailiwick of Vermandois, the inhabitants retaining only the right of electing four *échevins.*

The town had to suffer severely during the Hundred Years' War; in 1414, uhen it was held by the Burgundians, it was captured and sacked by the Armagnacs under the dauphin; and this same fate again befell it several times within 20 years. The treaty of Arras (1435) brought it again under the royal authority. It was sacked by Charles V in 1544 and in 1565 by the Huguenots, who laid the churches in ruins, and, supported by the prince of Condé, count of Soissons, kept possession of the town for six months.

During the league Soissons eagerly joined the Catholic party. Charles, duke of Mayenne, made the town his principal residence, and died there in 1611. A European congress was held there in 1728.

In 1814 Soissons was captured and recaptured by the allies and the French. In 1815, after Waterloo, it was a rallying point for the vanquished, and it was not occupied by the Russians till Aug. 14. In 1870 it capitulated to the Germans after a bombardment of three days.

During World War I Soissons was for most of the time just behind the Franco-British lines, but the Germans passed it in 1918 in their thrust for Paris (May 27) ; it was retaken in the Franco-British offensive of July 18, 1918.

In the middle ages Soissons was the chief town of a countship belonging in the 10th and 11th centuries to a family which apparently sprang from the counts of Vermandois. Renaud, count of Soissons, gave his property in 1141 to his nephew Yves de Nesle. By successive marriages the countship of Soissons passed to the houses of Hainaut, Châtillon-Blois, Coucy, Bar and Luxembourg. Marie de Luxembourg brought it, together with the counties of Marle and St. Pol, to Francis of Bourbon, count of Vendôme, whom she married in 1487.

His descendants, the princes of Condé, held Soissons and gave it to their cadets. Charles of Bourbon, count of Soissons (1566-1612), son of Louis, prince of Condé, whose political vacillations were due to his intrigues with Henry IV's sister Catherine, became grand master of France and governor of Dauphin6 and Normandy. His son, Louis of Bourbon (1604–41), took part in the plots against Marie de Medici and Richelieu, and attempted to assassinate Richelieu. He had only one child, a natural son, known as the Chevalier de Soissons. The countship passed to the house of Savoy-Carignano by the marriage in 1625 of Marie de

Bourbon-Soissons with Thomas Francis of Savoy. Eughne Maurice of Savoy. count of Soissons (1635–73), married the beautiful and witty Olympia Mancini, a niece of Cardinal Mazarin, and obtained high military posts through his wife's influence. He defeated the Spaniards at the battle of the Dunes in 1658; took part in the campaigns at Flanders (16673, Franche-Comté (1668) and Holland (1672); and was present as ambassador extraordinary of France at the coronation of Charles II of England. His wife led a scandalous life, and was accused of poisoning her husband and others. She was the mother of Louis Thomas Amadeus, count of Soissons, and of the famous Prince Eughne of Savoy. In 1734 the male line of the family of Savoy-Soissons became extinct, and the heiress, the princess of Saxe-Hildburghausen, ceded the countship of Soissons to the house of Orleans, in whose possession it remained until 1789.

Soissons, surrounded by wooded hills, stands on the left bank of the Aisne, the suburbs of St. Vaast and St. Médard lying on the right bank. The cathedral of Notre-Dame, partly ruined in World War I, was begun in the second half of the 12th century and finished about the end of the 13th. It is 328 ft. long and 87 wide, and the vaulting of the nave is 100 ft. above the pavement. The single tower dates from the middle of the 13th century and is an imitation of those of Kotre Dame of Paris, which it equals in height (216 ft.). The south transept. the oldest and most graceful portion of the whole edifice, terminates in an apse. The façade of the north transept dates from the end of the 13th century. The apse and choir retain some fine 13th-century glass.

Considerable remains exist of the magnificent abbey of St. Jean-des-Vignes, where Thomas Becket resided for a short time. These include the ruins of two cloisters (the larger dating from the 13th century). the refectory. and above all the imposing façade of the church (restored). Above the three portals (13th century) runs a gallery, over which again is a large window; the two unequal towers (230 and 246 ft.) of the 15th and early 16th centuries are surmounted by beautiful stone spires. which command the town.

The church of St. Léger, which belongs to the 13th century, was formerly attached to an abbey of the Génovéfains. Beneath are two Romanesque crypts. The royal abbey of Notre-Dame was founded in 660 for monks and nuns by Leutrade, wife of Ebroïn, the celebrated mayor of the palace.

The wealthiest of all the abbeys in Soissons, and one of the most important of all France during the first two dynasties. was that of St. Médard. on the right bank of the Aisne, founded about 560 by Clotaire I, beside the villa of Syagrius. which had become the palace of the Frankish kings. St. Médard, apostle of Vermandois, and kings Clotaire and Sigebert were buried in the monastery, which became the residence of 400 monks and the meeting place of several councils. It was there that Childeric III. the last Merovingian, was deposed and Pippin the Short was cron-ned by the papal legate, and there Louis the Pious was kept in captivity in 833. The abbots of St. Médard coined money, and in Abélard's time (12th century) were lords of 220 villages, farms and manors. At the battle of Bouvines (1214) the abbot commanded 150 vassals.

In 1530 St. Médard was visited by a procession of 300.000 pilgrims. But the religious nars ruined the abbey, and. although it was restored by the Benedictines in 1637, it never recovered its former splendour. Of the churches and the conventual buildings of the ancient foundation there hardly remains a trace. The crypt of the great abbey church dates from about 840. In it is a stone coffin said to have been that of Childebert II, and close at hand is an underground chamber, reputed to have been the place of captivity of Louis the Pious.

Among the industrial establishments are iron and copper foundries and factories for the production of boilers, agricultural implements and other iron goods, rubber goods, glass and sugar. There is a large trade in grain for the provisioning of Paris.

SOKOLNIKOV, GREGORY YAKQVLEVICH (1888–), Russian Communist, was the son of a doctor. He studied in Moscow and at Paris. From 1909 until the revolution of Feb. 1917 he lived abroad. After the Kovember Revolution, Sokolnikov at first worked in the Soviet finance department. At the end of 1921. immediately after the proclamation of the New Economic Policy. Sokolnikov was appointed to the committee of the people's commissariat of finance: at the beginning of 1922 he was deputy people's commiisar and commissar soon after. In four years (1922–25) the system of taxes was restored, and the budget was put in order. The reform of the currency was begun at the end of 1922, and the new state bank nas given the right of issuing notes: it nas completed in 1924 with the reorganization of the treasury bills and the stabilization of the Soviet currency. At the end of 1925, when dissensions arose in the Communist party on the economic-political question. Sokolnikov criticized the government policy After the 14th congress of the Communist party in Jan 1926 he mas removed from the post of commissar of finance and appointed deputy president of the Gosplan, or state planning commission. He was ambassador to Great Britain, 1929–32. In Jan. 1937 he was sentenced to 10 years' imprisonment for treason

SOKOLOW, NAHUM (1859–1936), Jewish writer and journalist was born in Wyszogrod Poland. He started writing at an early age, and soon became a regular contributor to many Hebrew periodicals. In 1881 he became editor of the Hebrew journal *Hatzefirah,* and under his direction it grew into the best informed Hebrew newspaper. Sokolow became known as the founder of modern Hebrew j journalism. He became associated with the World Zionist organization, headed by Theodor Herzl, and was made general secretary, and in 1931 president, of that organization. Sokolow founded and became editor of the weekly *Haolam*, official publication of the Zionist organization. He was the most prolific Jewish writer of his time, and among his works are: *Sinath Olam Leam Olam* (1882), a history of anti-Semitism: *Tzaddik Venisgab* (1883), a historical novel; *Eretz Hemdah* (1889), a geography of Palestine.

SOKOTO, a province of the Northern Region of Nigeria. It is bounded on the north by Nigcr and west by Dahomey, covers an area of 36,477 sq.mi. and had a population of 2,680,558 in 1953. The province is divided into two main physiographic zones: the northwestern part is dry and sandy while the south has heavier soils and a higher rainfall. The natural vegetation is thorn scrub. The Sokoto river and its many tributaries combine to drain almost the whole area. Guinea corn. millets and rice are the main food crops and where the soil is suitable peanuts and cotton are grown for export. There is aiso an important trade in the Sokoto red goatskins which are used for making the best "Morocco" leather. Large-scale mechanical cultivation of rice was introduced after World War I The town of Sokoto is both the provincial headquarters and the home of the sultan who is traditionally the religious leader of the Mohammedans of northern Nigeria. Gusau ranks next to Kano as a commercial centre in the north. (X.)

The Mausa States.—The years 1804–05, when Mungo Park was engaged in his last journey in quest of the Niger river, were the years when Shehu Usuman Dan Fodio. leader of the Nigerian Fulani, began his conquest of the seven Hausa states. The Hausas occupy the plains between the Niger and Lake Chad and were conquered about the 10th century by a pastoral people known as the Zaghawa or Berber. Since the Berbers were few in number they must have fused with the indigenous Negro stock. The caravan routes, via the Sahara, linked Hausaland with the Barbary states. In the 14th century Islam was introduced, and with Islam came Arab culture and civilization. Politically the Hausa states were never united; from rime to time each fell a prey to some foreign power. Large sections of the people embraced Islam but the Hausas never wholly abandoned their ancestral religion.

The **Fulani** Empire.—The Fulani (a Hamitic people) entered the Hausa country in the 13th century. From that date til! the last years of the 18th century they wielded no political power as a group and were, for the most part, herdsmen and devout Mohammedans who paid tribute to the Habbe rulers. At the end of the 18th century, however, they had become increasingly influential and not a few rose to positions of importance in the Hausa country. Gobir, militarily the most powerful of the kingdoms, was their stronghold. The Hausa rulers bitterly resented the growing power of their nomadic subjects. About this time arose a great Fula teacher. a fanatical Moslem and a man of vivid eloquence, Shehu Usuman Dan Fodio. His journeys among the people of Gobir produced a religious revival, and he won devoted disciples. His denunciation of the reversion to the ancestral religion, so prevalent at the time, brought him into collision with the Hausa rulers who feared his growing influence. He incurred the wrath of his former pupil, Yunfa, chief of Gobir, who in 1804 threatened to attack him and his followers. The threatened Fulani flocked to the banner of Shehu and so did a great number of Hausas. They elected him *Sarkin Musulmi* or "Commander of the Mohammedans." The Gobir forces marched against the Fulani but in a battle at Tabkin Kwotto they were severely defeated. Thereupon the Shehu unfurled the banner of Mohammed and preached a jihad or religious war. In a few years the Fulani subdued many of the Hausa states. Zaria fell in 1804. Katsina was captured after a long siege in 1805 and. later in the year, Kano fell to the invaders. Other states such as Gobir. Kebbi, Bornu and the hill tribes offered bitter resistance and were never wholly conquered. The shehu remained true to his religious ideal but his adherents degenerated into mere adventurers. Fulani soldiers raided pagans and Moslems alike.

Sokoto.—The Fulani town of Sokoto was converted by Dan Fodio into the headquarters of his growing empire. He and his successors came to be known as sultans of Sokoto and *Sarkin Musulmi,* indicating their spiritual authority. In 1810 nhen his jihad was practically complete, Dan Fodio turned his attention to the organization of his dominions. He divided them into two parts. To his son Bello he gave the east and to his brother Waziri Abdullahi, the west. Bello retained Sokoto as his capital and Abdullahi Gwandu. The empire was administered from those twin capitals for about a century. Shehu adopted the elaborate machinery of government and taxation, based on Koranic law, which he found already existing in the Hausa states.

Advent of British Power.—The rise of the Sokoto Fulani coincided nith the European exploration of the west African interior. Contact nith the outside world, by way of the Niger river, increased with the expansion of British trade, and the Fulani were drawn into the politics and diplomacy of the period when Africa was partitioned among European powers. In 1879 the United African company (later the National African company and in 1886 the Royal Niger company) was founded by George Goldie-Taubman (later Sir George Goldie; *q.v*) and became. from the 1880s, the chief instrument of the British penetration and conquest of Nigeria. In 1900 this company transferred to the British crown certain rights of sovereignty it had acquired through treaties with the Fulani rulers. In the same year the protectorate of northern Nigeria replaced the administration of the Royal Niger company. In March 1903 following the capture of Kano, the city of Sokoto submitted to the invaders. Within a hundred years of its foundation the Fulani empire collapsed Sir Frederick (later Lord) Lugard (*q* v), who completed and consolidated the subjugation of Hausaland, introduced the system of indirect rule. Through this system loyal Fulani rulers were retained as amirs or chiefs of their respective territories and became the instruments of British rule in northern Nigeria. The Fulani thus retained, although in modified form, their position as the rulers of Hausaland. (K. O. D.)

SOKOTRA (also spelled SUQUTRÁ, SOQOTRA and SOCOTRA), an island under British protection in the Indian ocean, about 150 mi. E.N.E. of Cape Guardafui; length, 72 mi., breadth, 22 mi., area, 1,200 sq.mi. It is the largest and most easterly of a group of islands, the others being Abd-el-Kuri, the Brothers (Semha and Darzi) and Kal Farun. Politically, it forms part of the Mahri sultanate of Kishin and Sokotra (or Qishn and Soqotra), within the eastern area of the Aden protectorate.

The centre of the island is formed of Archean gneisses and granites with slightly younger schists. These form the highest peaks, the Haggier mountains, 4.686 ft. Resting on these rocks are Cretaceous and Eocene strata (chiefly limestone), which, scarcely disturbed, form an undulating plateau between 1,000 and 1,500 ft. above sea level. Some of these limestones are pierced by dikes and in the southeast by a small volcanic centre with trachytic and rhyolitic lavas. At many parts of the north coast the edges of the plateau reach the shore in precipitous cliffs, but in others wide alluvial plains. dotted with bushes and date palms, front the heights behind. There are no harbours but there are anchorages off Hadibu (Tamrida), the capital, Qadhub and Kallansiya. The fauna contains no indigenous mammals: there is a wild ass. probably of Nubian origin; the domestic cattle may be a race developed from cattle imported from Sind or Indonesia. Of the flora aloes, dragon's blood *(Dracaena),* myrrh, frankincense, pomegranate and cucumber trees are the most famous species The flora and also the fauna present not only Asian and central African affinities, but, what is more interesting, Mascarene, south African and Antipodean-American relationships, indicating that the island represents part of Gondwanaland. (W. H. Is.)

History.—Sokotra has claims to be reckoned one of the most ancient incense-supplying countries, and it is probably referred to by the Egyptians under the name "Terraces of Incense."

To the Greeks and Romans Sokotra was known as the isle of Dioscorides; this name and that by which the island is now known are usually traced back to a Sanskrit form, Dvipa-Sakhadhara, "the island abode of bliss." The *Periplus* of the Erythraean sea speaks of the island as peopled only in one part by a mixed race of Arab, Indian and Greek traders. It was subject to the king of the incense country, and was a meeting place of Arabian and Indian ships. Cosmas in the 6th century says that the people spoke Greek and were largely Christian. uith a bishop sent from Persia. They appear to have remained Nestorian Christians. with a bishop under the metropolitan of Persia, through the middle ages, though there are indications pointing to a connection with the Jacobite church. As early as the 10th century Sokotra was a haunt of pirates; in the 13th century Abulfeda describes the inhabitants as "Nestorian Christians and pirates" but the island was rather a station of the Indian corsairs who harassed the Arab trade with the far east. The population seems in the middle ages to have been much larger than it is now; Arabian writers estimate the fighting men at 10,000.

The Portuguese under Tristão da Cunha and Alphonso d' Albuquerque seized Sokotra in 1507 in pursuance of the design to control all the trade routes between Europe and the east, but abandoned it in 1511. They found that Sokotra was held by Arabs from Fartak, but the "natives" (a different race) were "Christians." though in sad need of conversion. As late as the middle of the 17th century the Carmelite P. Vincenzo found that the people still called themselves Christians, and had a strange mixture of Jewish, Christian and pagan rites. The women were all called Maria. No trace of Christianity is now found in the island, all the inhabitants professing Islam.

On the withdrawal of the Portuguese the dependence of Sokotra on Arabia was resumed. In the 19th century Sokotra formed part of the dominions of the sultan of Kishin. The opening of the Suez canal route to India led to the island being secured for Great Britain. In 1876 the British government undertook to pay a small subsidy to the sultan of Kishin, and in 1886 he agreed to place Sokotra and its dependencies under the protection of Great Britain. (X.)

Population and Economy.—In 1958 the population was estimated at 15.000. In the coastal settlements the inhabitants are mostly Arabs and Africans, while the nomadic pastoral people in the mountains are the true Sokotri, supposed to be originally immigrants from Arabia. Some of them are light skinned, straight nosed, with straight black hair, while others are shorter and darker with features more resembling those of Semitic people. Their manner of life is simple They live in circular, clay-topped houses, or in caves. Their diet is mainly meat, milk and dates. The Sokotri language is allied to the Mahri language of southern Arabia. Both are probably daughter tongues of the old Sabaean and Minaean. Sokotri is the older of the two languages. and retains the ancient form, which in the Mahran has been modified by Arabic and other influences.

The chief export is ghee, or clarified butter. Aloes, some frankincense, and the resin of the dragon's blood tree are the most valuable vegetable products. Civet are captured to obtain the secretion used in perfumery.

During World War II the Royal Air Force had a base on Sokotra. This brought considerably more contact politically with the Mahri sultan. who had undisputed authority in the island.

Other Islands.—Abd-el-Kuri Island lies between Sokotra and Cape Guardafui, 60 mi. from Sokotra, and is 20 mi. long and $3\frac{1}{2}$ mi. wide. At either end the island is hilly. It is formed chiefly of Archaean rocks and on the north side is a sandy beach; on the south cliffs rise abruptly from the ocean. The highest part (1,670 ft.) is toward its eastern end. It is largely arid and there are no permanent streams. Its fauna resembles that of Sokotra but includes land shells and scorpions peculiar to Abd-el-Kuri. The inhabitants (less than 200), speak Sokotri and Arabic and are chiefly engaged in diving for pearl shell on the Bacchus bank. They live mainly on turtle (which abounds in the island), fish and molluscs. The land is nowhere cultivated.

Kal Farun is the name of two rocky islets rising nearly 300 ft. above the sea, 13 mi. from the western end of Abd-el-Kuri. Birds flock to them in great numbers; in consequence they are completely covered with guano, which gives them a snow-white appearance. The Brothers lie between Abd-el-Kuri and Sokotra. Semha is 69 mi. long and 3 mi. broad. It has rocky shores and rises in a table-shaped mountain to 2,440 ft. As in Abd-el-Kuri ambergris is found on its shores and turtles abound. There is running water all the year and it is a fishing ground of the Sokotri. Darzi lies 9 mi. E. of Semha, is $3\frac{1}{2}$ mi. long by 1 mi. broad and rises almost perpendicularly from the sea to 1,500 ft. The coral banks which surround Sokotra and The Brothers are united and are not more than 30 fathoms below sea level; a valley some roo fathoms deep divides them from the bank around Abd-el-Kuri, while between Abd-el-Kuri and Cape Guardafui are depths of over 500 fathoms.

(W. H. Is.)

SOL. The name Sol, the sun, was given to two distinct deities at Rome. The original Sol, or Sol Indiges. had a shrine on the Quirinal and an annual sacrifice on Aug. 9. The worship appears to be native. The Roman poets, however, equate him with the Greek Helios.

The worship of Sol assumes an entirely different character with the later importation of various sun cults (*e.g.,* Mithraism; *q.v.*) from the east (Syria). Heliogabalus built a temple to him as Sol Invictus on the Palatine and attempted to make his worship the principal religion at Rome. Aurelian re-established the worship and erected a magnificent temple to Sol in the Campus Agrippae. The worship of Sol as special protector of the emperors and the empire remained the chief imperial cult until Christianity replaced it.

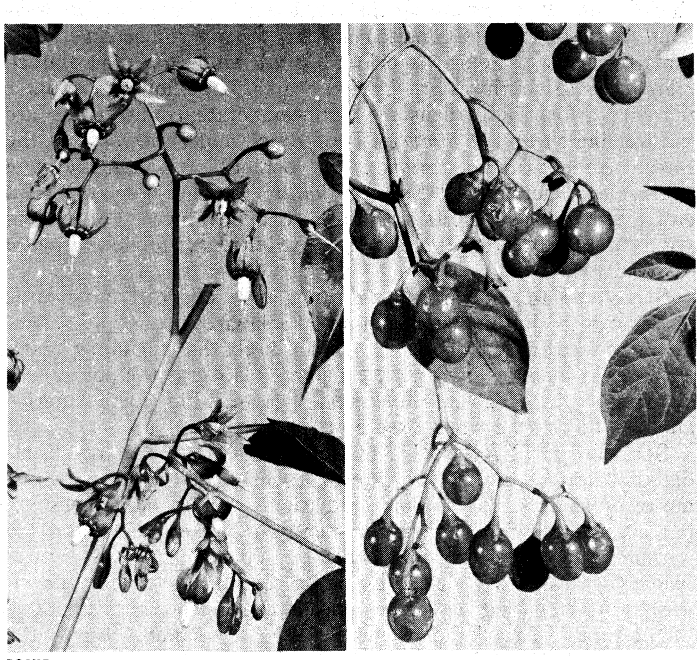
SOL, from 1863, the monetary unit of Peru, equal to roo centavos. Like all other countries of Spanish America, Peru had. at the attainment of its independence, a currency based on the peso (*q.v.*). The peso, or piece-of-eight, was equal at the beginning of the 19th century to about 48 pence, or roughly $1.00. When by a law of Feb. 14, 1863, the sol replaced the peso as the unit of the Peruvian currency it was defined as a silver coin weighing 2 j grams, 900/1000 fine. It was thus equivalent to the silver five-franc piece of the countries of the Latin Monetary union.

From 1872 on Peru was on a silver standard and, because of the decline of silver in terms of gold, the value of the sol fell from 48 pence to less than half that value in 1897. Because of its great economic dependence on Great Britain Peru at that time approximated its currency to the pound sterling and introduced the gold standard. The new exchange value of the sol was established at 24 pence, and a new unit, the Peruvian pound (£P) equal to 10 soles and 1 pound sterling was introduced. Although Peru coined some of its own gold coins, British sovereigns entered the country soon after the currency reform of 1897 and circulated freely.

Up to and during World War I the stable relation between the British and Peruvian pound was maintained, but from the end of 1916 to the early part of 1921 the Peruvian pound had a premium over the pound sterling, which at its peak, in 1920, amounted to $22\frac{1}{2}\%$. The Peruvian pound then stood at $4.59 in New York, whereas the pound sterling was as low as $3.64 In 1921 a gradual decline of the Peruvian exchange began nhich lasted, with few and short interruptions, until after World War II. The decline was caused at first by a flight of capital owing to distrust of the nenly established central bank, later to the weak international trade position of Peru and finally, after 1945, to severe inflationary pressure. Distrust in the stability of the Peruvian government also contributed to the neakness of the currency. (B. F. H.)

SOLANACEAE, a plant family of considerable economic importance, includes a number of species that produce food and drug narcotics or are used as fumitories or ornamentals. Prominent among these species are *Solanum tuberosum* (potato), *S. melongena* (eggplant), *Lycopersicon esculentum* (tomato), *Capsicum frutescens* (red pepper), *Physalis ixocarpa* (tomatillo), *Atropa belladonna* (atropine or belladonna), *Datura stramonium* (stramonium), *Hyoscyamus niger* (black henbane), *Duboisia hopwoodi* (pituri) and *Nicotiana tabacum* (tobacco). Some of the genera that contain ornamental species are *Petunia, Lycium, Solanum, Nicotiana, Datura, Salpiglossis, Browallia, Brunfelsia, Cestrum, Schizanthus, Solandra, Streptosolen* and *Nierembergiu.*

This family of dicotyledons belongs to the subclass Spmpetalae (or Gamopetalae) in the series Polemoniales. It includes about 90 genera with approximately 2,800 species which. though found throughout the world except in polar regions, are most abundant and widely distributed in the tropical regions of Latin America, where about 40 genera are endemic. Very few are to be found in temperate regions; and about 50 species are found in North America, north of Mexico. Only four species in three genera are known from Britain. The genus *Solanum,* which embraces more than two-thirds of all the species in the family, includes about 150 species in its section Tuberarium. This section comprises all the wild potatoes or tuber-bearing species, which are distributed primarily at high elevations in the mountains from Utah and Colorado southward through Mexico, Central and South America to the Island of Chiloe. Some of these wild potatoes, especially S. *demissum* of Mexico, have been widely used in the improvement of the domesticated potato. Alkaloids, especially the glucosidal alkaloid solanine, are the narcotic-poisonous principles prevalent in many of the species. These have given to the family its sombre vernacular name "nightshade." The alkaloids are of increasing interest and importance to the chemical and pharmaceutical industries. Many species in the Solanaceae have been used by primitive people in various parts of the world in their folklore and therapeutic



ROCHE

BITTERSWEET (SOLANUM DULCAMARA) FLOWERS AND FRUIT practices.

Included in the family are annual herbs, as *Solanum nigrum,* a common weed in waste places, and perennial herbs, as *Atropa belladonna,* the deadly nightshade; shrubs, as *Lycium halimifolium,* an old-fashioned garden plant; small trees, as *Datura sanguinea,* a South American ornamental with large reddish flowers; lianas, as *Solanum juglandifolium,* a showy rampant vine of South America; and prostrate creepers, as some Latin-American species of *Solanum.* The alternate leaves (or sometimes opposite near the inflorescence) are simple and entire, as in most species of *Lycium,* or are variously dissected, as represented by the extreme condition found in various species of *Lycopersicon* (tomato). The flowers are usually borne in extra-axillary cymes.

The hermaphroditic, generally regular, flowers have their parts in fives—five sepals, five petals, five stamens in alternating whorls and two carpels, which are generally placed obliquely. The corolla is regular and rotate, as in *Solanum tuberosum,* or bell-shaped, as in *Datura* and *Atropa* or somewhat irregular as in *Hyoscyamus;* in the tribe Salpiglossideae, which forms a link with the closely allied family Scrophulariaceae (*q.v.*), it is zygomorphic, forming, as in *Schizanthus,* a two-lipped flower. The stamens are inserted on the corolla tube and alternate with its lobes; in zygomorphic flowers only two or four fertile stamens are present. The flowers are generally conspicuous and honey is secreted on the disk at the base of the ovary or at the bottom of the corolla tube between the stamens. The ovary is usually bilocular but in *Capsicum* becomes unilocular above. while in some cases an ingrowth of a secondary septum makes it four celled, as in *Datura,* or irregularly three to five celled, as in *Nicandra.* The anatropous ovules are generally numerous on swollen axile placentae. The style is simple and bears a bilobed or capitate stigma. The fruit is a many-seeded berry, as in *Solanum,* or capsule, as in *Datura,* where it splits lengthwise, and *Hyoscyamus,* where it opens by a transverse lid forming a pyxidium. The embryo is bent or straight and embedded in endosperm. The persistent calyx may serve to protect the fruit or aid in its distribution, as in the bladdery structure enveloping the fruit of *Physalis.*

The family is divided into five tribes after Richard von Wettstein; the division is based on the greater or less curvature of the embryo, the number of ovary cells and the regular or zygomorphic character of the flower. These tribes are Nicandreae, Solaneae, Datureae, Cestreae and Salpiglossideae. The great majority of the genera belong to the tribe Solaneae, which is characterized by a two-celled ovary. Some additional species of less importance than those already considered are *Physalis alkekengi* (winter cherry) and *P. peruviana* (cape gooseberry); *Lycopersicon pimpinellifolium* (currant tomato) and *Cyphomandra betacea* (tree tomato), both of South America; *Datura metel* of India and *D. meteloides* of southwestern United States. large-flowered annuals that are grown in gardens in warm-temperate countries, as are the treelike shrubs *D. suaveolens* of Brazil and *D. arborea* of the central Andes; *Solanum muricatum* (pepino), *S. pseudocapsicum* (Jerusalem cherry) and *S. integrifolium* (scarlet eggplant), also cultivated for their fruits and aesthetic appearance. For *Atropa* *see* NIGHTSHADE; for *Hyoscyamus see* HENBANE; for *Mandragora* *see* MANDRAKE. (D. S. CL.)

SOLANUM, one of the largest genera of flowering plants. It belongs to the nightshade family (Solanaceae, *q.v.*) and comprises upvard of 1,200 species, chiefly herbs but including many shrubs. It includes important economic plants, as the potato and eggplant (*qq.v.*). Twenty-five species are found in North America and two in Great Britain (*see* NIGHTSHADE).

SOLAR ENERGY, UTILIZATION OF. Energy is radiated from the sun at the rate of about 43,000 kw. per square metre of solar surface. Solar radiation occupies only the small portion of the electromagnetic spectrum betneen 0.22 and 3.3 microns (μ). The invisibly short but potent ultraviolet naves below 0.4μ carry 9% of the incoming solar energy, while the invisible infrared heat waves beyond 0.7μ are responsible for 50% of the total. The "light" waves between these limits convey the remaining 41%, including the waves of maximum intensity at 0.48μ in the green portion of the visible spectrum. Both the amount and the spectral distribution of the energy radiated from the sun indicate that the effective temperature of its surface is close to 6,000° C. (10,800° F.).

Solar radiation falling on a surface normal to the sun's rays at the outer limit of the earth's atmosphere has an average intensity of 2 ($\pm 2\%$) cal. per minute per square centimetre (1.41 kw. per square metre; 442.2 B.T.U. per hour per square foot). This quantity, known as the solar constant, has apparently remained virtually unchanged, except for periodic minor variations, for several billion years. Only about 46% of the incoming solar energy actually reaches the earth's surface since, on the average, 35% is reflected back into space by clouds and the remaining 19% is absorbed by the atmosphere. The intensity of the sunshine which reaches any particular area on the earth varies from zero at sunrise through a noon maximum which may be as high as 300 to 350 B T.U. per hour per square foot on a cloudless day. Local weather bureau data must be consulted to obtain specific values for any particular locality (*see* SUN; SUNSHINE).

The total amount of solar energy reaching the earth is about 7×10^{17} kw.hr. per year, more than 30,000 times as much as is used in all man-made devices. This prodigious inflow of energy warms the earth and produces, through photosynthesis, all of the food, fuel and free oxygen upon which life depends.

Man has sought for many centuries to make direct use of the sun's radiant energy Thus far. his success has been meagre, primarily because sunshine is intermittent in availability; variable in direction; and relatively low in intensity. Apparatus intended for use with solar energy must in general be large in area; movable. so that it can follow the sun's apparent motion; and provided with some means for storing energy for use when the sun is not shining. Despite these formidable difficulties, significant advances have been made since 1750 in using solar energy to generate heat, to bring about chemical reactions and, most recently, to produce usable amounts of electricity.

Man learned long ago that heat is produced when the sun's rays are absorbed by a blackened surface. He found, too, that the amount of heat thus produced could be greatly intensified by using reflection or refraction to concentrate a large area of sunshine onto a small target. The concave silver mirrors left behind by the Incas and the convex quartz lens found in the ruins of Nineveh were probably used to light sacred fires by means of concentrated sunbeams. Archimedes is said to have devised a battery of mirrors to defend Syracuse in 212 B.C. by burning the sails of an invading fleet "at the distance of a bowshot." In 1747 G. L. L. Buffon set up a group of 140 flat mirrors in a Paris garden and ignited a stack of wood placed about 200 ft. from his reflectors, thus demonstrating that the feat attributed to Archimedes might indeed have been accomplished.

A. L. Lavoisier, who began to use solar energy for scientific purposes as early as 1772. was probably the originator of the device which is known today as the solar furnace. Enclosing specimens of various substances in transparent quartz vessels, he placed them at the focal point of a 52-in. diameter lens and used concentrated solar radiation to heat them in partial vacuum and in controlled atmospheres of oxygen and other gases. He first called attention to one of the principal virtues of the solar furnace when he wrote, "the fire of ordinary furnaces seems less pure than that of the sun."

Because of its unique ability to heat materials by intense radiation alone for long periods of time without contamination, the solar furnace has come into prominence as a tool for high-temperature research. Scientists have found that parabolic reflectors taken from antiaircraft searchlights can concentrate solar radiation so effectively that temperatures as high as 3,400" C. (6.100" F.) can be attained. Equatorial or altazimuth mountings are used to enable the concentrator to follow the apparent motion of the sun across the sky; sleeves or shutters are used to regulate the amount of radiation impinging on the target.

Most of the large solar furnaces in use avoid the inconvenience caused by target movement by using a flat mirror called a heliostat to track the sun across the sky and reflect its rays into a fixed paraboloidal concentrator. The largest furnaces of this type are those at Mont-Louis in the French Pyrenees and at Natick, Mass. Both use concentrators that are more than 30 ft. in diameter, made of many small curved glass mirrors arranged approximately in a paraboloidal configuration.

Solar sream generators were built by many pioneers during the 19th century. All of these used arrangements of movable mirrors to concentrate large amounts of solar radiation upon blackened pipes through which water was circulated and turned to steam. Both steam and hot-air engines were operated in this way with some degree of success as early as 1870, and ice was produced in Paris in 1878 in an ammonia-absorption refrigerator operated by a solar boiler. The use of solar energy for pumping irrigation water was tried in Arizona and California, employing a number of solar pumping stations using conical concentrators 30 ft in diameter. The largest of all solar-power installations was erected in 1912 on the bank of the Nile at Meadi, near Cairo, using a total of 14,000 sq.ft. of concentrating surface in the form of seven parabolic troughs, each 205 ft in length. The 100-h.p. steam engine connected to this great solar boiler actually produced between 50 and 60 h.p. continuously during one five-hour test, but the system was not economically competitive with other pumping apparatus and it nas abandoned during World War I.

All of these early installations suffered from the same deficiencies — irregularity of operation and excessive cost—and none survived. Interest in solar poner revived with the advent of artificial earth satellites, since these applications avoid such earthly problems as clouds, atmospheric absorption and low-cost competitive energy sources. Serious consideration is again being given to vapour cycles which would receive the full complement of solar radiation, 1.4 kw. per square metre, whenever their collectors turn toward the sun, and reject the unused energy by radiation into space.

When heat is needed at moderate temperatures for such purposes as distillation of salt nater, growing and drying of agriculturai products, cooking and the heating of buildings and domestic hot-aater supplies, solar energy can be used with considerable success, thanks to the "greenhouse" effect Common window glass and many plastic films have the property of transmitting nearly all of the solar radiation which falls on them, but they are relatively opaque to the long waves (8 to 40μ in wave length) emitted by any surface heated to 100°–200° C. (212°–392° F.). Thus a simple blackened wooden box, covered with several sheets of glass or plastic film, acts as an effective trap for solar energy when it is turned toward the sun. If its sides and bottom are insulated, the internal temperature can be raised as high as 150° C. (302" F.) by the unaided rays of a bright sun. M. K Ghosh in India (1945) and M. Telkes in the United States (1955) improved this simple solar stove by adding reflective wings to direct more sunshine into well-insulated ovens, achieving temperatures up to 200° C. (392° F.).

Solar water heaters have been in relatively wide use in Florida and the southwestern U.S. for many years. Most of these consist of flat sheets of blackened metal provided with tubes through which water circulates by natural or forced convection whenever the sun is shining. Wastage of the absorbed solar energy is minimized by covering the upper surface of the metal with a glazing of glass or plastic film, separated from the sheet by a small air space. The lower surface is insulated with rock wool, vegetable fibres or a reflective coating which cuts down radiation. Heaters of this type do not have to follow the sun's motion, since they operate efiectively if they are mounted in a fixed position facing the south (in the northern hemisphere) and tilted so that their angle nith the horizontal is equal to the local latitude plus 20". Temperatures up to 60° C. (140° F.) can readily be reached on sunny winter days, and the domestic hot-water requirements of a typical family living in regions south of latitude 35° S. can be met during most of the year by a heater having as little as 40 sq.ft. of surface.

Similar but much larger collectors can supply most of the heat needed in homes of moderate size in favourable localities. Storage of heat for use at night or during cloudy periods is accomplished by using large insulated tanks to store water heated during daylight hours. This system is particularly effective when radiant heating is used, with the warmed water flowing through tubes in floors and ceilings. Air can also be heated in suitably designed collectors and used in conventional warm-air systems. Heat storage can then be provided by using beds of gravel or containers filled with chemicals such as Glauber's salt which absorb heat at a suitable temperature when they melt and give off the stored heat nhen they solidify again.

Direct conversion of solar radiation into electricity can be accomplished on a small scale in several ways The thermoelectric effect, first discovered in 1821 and greatly improved during the 1950s by both Russian and U S. physicists, can be utilized by placing one set of thermocouple junctions in the focal region of a solar furnace while the other set is kept cool. The efficiency of conversion of solar to electric energy was extremely low, less than 1%, when only metallic thermocouple junctions were available. An important advance came with the development of semiconductors, nhich transmit electricity well but are poor conductors of heat; these give energy conversion efficiencies reportedly as high as 10%. The most efficient and most convenient way to convert solar radiation into electricity is through the use of the silicon photovoltaic cells developed in the U.S. in 1954 by the Bell Telephone laboratories. The Bell solar cell is made of thin wafers of ultrapure silicon to which traces of arsenic and boron are added. In bright sunlight it can produce direct current at 0.6 v. and approximately 0.030 amp. per square centimetre of exposed cell area, with a conversion efficiency as high as 16%. Since these cells are chemically inert, have no moving parts and are not harmed either by intense radiation or extremely low temperatures, they were used with marked success to supply power for radio transmitters in the first U.S. earth satellites.

The major areas of usefulness for solar-energy application are those regions such as India and north Africa where sunshine is plentiful, conventional energy sources are scarce and fuel is expensive. When heat is needed rather than electric poner, solar devices will prove to be important in helping the millions of people who live in sunny lands to raise their standards of living. In India, for example, the use of solar stoves and water heaters can go far toward returning to the soil as fertilizer the dried bullock dung nhich is now the principal fuel.

See Association for Applied Solar Energy, *Proceedings of the World Symposium on Applied Solar Energy, 1955 (1956)*; F. Daniels and J A. Duffie (eds.), *Solar Energy Research* (1955). (J. I. Y)

SOLARI (SOLARIO), **ANDREA** (ANDREA DEL GOBBO) (active 1495–d. 1524), Italian painter of the Milanese school and one of the most important followers of Leonardo da Vinci, was probably born at Milan. He received his early training from his brother Cristofano, a distinguished sculptor and architect, who was employed extensively on work at the cathedral at Milan and at the Certosa di Pavia. He probably accompanied his brother to Venice, where he seems to have been strongly influenced by Antonello da Messina, who was then active in the city. The fine portrait of a man with a pink (National gallery. London) displays Antonello's plastic conception of form and was probably painted about 1492. Solari's earliest dated work is a "Holy Family and St. Jerome" (Brera. Milan), with a fine landscape background, executed for S. Pietro at Murano in 1495. The Leonardesque type of the Madonna proves that Solari after his return from Venice became strongly influenced by the great Florentine artist, who was then carrying everything before him. To this period belong a small "Crucifixion" (1503, Louvre, Paris); the portrait of Charles of Amboise (Louvre): the portrait of Longono (1505, National gallery, London); "The Annunciation" (1506, Fitznilliam museum, Cambridge); the beautiful "Virgin on a Green Cushion" (Louvre), for which a sensitive drawing of the Virgin's head is in the Ambrosiana at Milan; and the "Head of the Eaptist in a Silver Charger" (1507, Louvre). In 1507 Solari aent to France with letters of introduction to the cardinal of Amboise and was employed for two years on frescoes in the chapel of his castle of Gaillon in Normandy (demolished during the French Revolution). It has been suggested that Solari may have visited Flanders before returning to his native country, and this may account for the Flemish character of his later work. In 1515 he painted the "Flight Into Egypt" (Poldi-Pezzoli, Milan), with its harmonious and detailed landscape background. To this period belong the "Procession to Calvary" (Borghese gallery, Rome); the portrait of the chancellor Domenico Morone (Palazzo Scotti, Milan); and the "Woman Playing a Guitar" (Hertz collection, Rome). Solari's last work was an altarpiece representing "The Assumption of the Virgin," left unfinished at his death and completed by Bernardino Campi about 1576. Solari died between Aug. 18 and Oct. 7, 1524.

See K. Badt, *Andrea Solario* (1914); W. Suida in *Art Quarterly*, viii, pp. 16 ff. (1945). (I. A. R.; X.)

SOLAR SYSTEM: see PLANET.

SOLDERING. Soldering and brazing are processes for joining metals by the application of heat. A common characteristic of both processes is the use of a filler metal or alloy which melts and wets the surfaces of the joint at temperatures below the melting points of the metals being joined. The distinguishing difference between the processes is the strength of joint and the temperature required for making it. Soldered joints are weaker than brazed joints and the soldering process relates to joints made at temperatures below 800° F. Brazing (including hard soldering) in most applications requires temperatures from 1,000° F. to 2,150° F. The specifications for Solders of the American Society for Testing Materials are given in the accompanying tables.

Soft Solders.—The common soft solders consisting of lead and tin are the principal alloys used in the lower range. The lead content may vary from 30% to 60% with the balance tin. The alloy containing equal parts of lead and tin is entirely liquid at 421° F. and is a general purpose solder suitable for joining copper, brass, nickel silver, iron, tin plate and galvanized iron. Additions of cadmium and bismuth lower the melting temperature: an example is 45% tin, 27.5% lead and 27.5% bismuth which melts at 300° F. A wiping solder for plumbers usually contains about 40% tin, the balance being lead. Lead-tin alloys high in tin can be used for joining aluminum but aluminum alloys in the melting range of 1,000" to 1,100" F. are preferred. Another composition in this lower range contains 5% silver, with the balance cadmium. Small percentages of antimony, arsenic and zinc are sometimes added to the lead-tin alloys. (See also FUSIBLE ALLOYS.)

Hard **Solders and Low-Temperature Brazing Alloys.**—Filler metals in the temperature range above 800° F. include a large number of compositions starting with aluminum solders melting at approximately 1,100° F. and running to copper at 1,983" F. and nickel alloys between 1,900" F. and 2,000" F. Proprietary aluminum alloys containing from 5% to 12% silicon with small additions of other metal are widely used.

Silver alloys composed of silver, copper and zinc with addition of cadmium or tin melt at temperatures from approximately 1,150" to 1,600" F. Formerly classed as hard solders, the term low-temperature brazing alloys is meeting with much favour. In

general, silver additions are used to produce low-melting alloys but an exception is an alloy containing 85% silver, 15% manganese melting at 1,780° F. Several copper and phosphorus, and copper-phosphorus-silver alloys are used for joining copper and brass but should not be used on nickel, iron or steel. They are fluid at temperatures from 1,300" to 1,500" F.

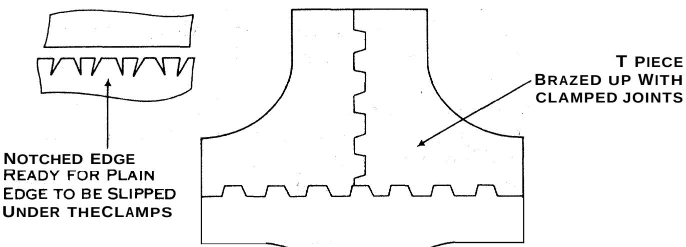

FIG. I.—THE NOTCHED CLAMP JOINT. USED EXTENSIVELY IN COPPERSMITHING

Brazing Solders.—The spelters or brazing solders are composed of copper and zinc with addition of 1% to 3% tin in some of the alloys. Those containing equal parts of copper and zinc are the common spelters which have been in general use for many years and are fluid at 1,600' F. Another group containing copper, zinc and nickel are used with iron, steel and nickel or nickel alloys and melt at 1,700" F. or higher. They are white and produce strong joints. Copper is used for furnace brazing of iron and steel parts at temperatures from 2,000° to 2,100° F. Other high-temperature alloys which form joints that will withstand temperatures of 1,600" F. are combinations of nickel-chromium, nickel-manganese, nickel-boron-silicon. These alloys melt at temperatures from 1,800" F. to 2,000' F.

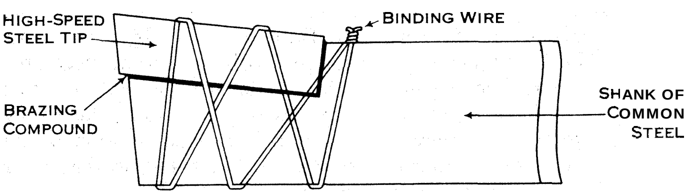

FIG. 2.—BRAZINGA HIGH-SPEED STEEL TIP ONTO A LATHE TOOL

All of these alloys are free flowing when heated to the proper temperature and are, therefore, suitable for those soldering and brazing processes which are limited to making closely fitted joints with clearances between the joint members from a press fit for copper to a maximum of .025 in. in some joints on aluminum. In most applications clearances are in the order of .001 in. to .005 in., and capillary forces play an important part in distributing the molten alloy over the surfaces and in the joint. There are a few exceptions such as the wiping process used by plumbers for joining lead pipe. The closely fitted joints made by these processes distinguish them from the bronze melding process in which the filler metal is fed into a V-shaped groove in layers.

One of the most important factors in the successful use of these processes is to have the joint surfaces clean. They must be free from oil or grease, dirt and oxides or other surface films. Cleaning can be done by mechanical or chemical means. The parts should be supported so that the space between the joint faces is uniform. The alloys may be preplaced between the joint faces or fed into the joint by hand or by spreading the alloys along the outside of the joint.

Fluxes.—Oxide films must be prevented from forming on the joint surfaces or the alloy during the heating process and some type of flux or protective atmosphere is necessary. When the copper-phosphorus alloys are used for joining copper the phosphorus acts as a deoxidizer, but on copper alloys some flux is desirable. For lead-tin alloys in the lower range. resin or zinc chloride made by dissolving zinc in hydrochloric acid is used. The latter is referred to as an acid flux and these lead-tin alloys are supplied in tubular form with resin or zinc chloride cores. When the alloy is used in granular form the flux can be mixed with the alloy. The flux must be fluid and active at a temperature below the melting point of the alloy being used as a filler metal. An effective flux for soft soldering iron. steel. nickel or nickel alloys is a mixture of 71% zinc chloride and 29% ammonium chloride. Plumbers use tallow or stearin when making wiped joints on lead pipe. The mild fluxes such as resin. tallow and stearin do not actively dissolve oxides but offer protective coatings.

Borax is a common flux for hard soldering or brazing processes which use filler metals melting above 1,300" F. The extensive use of the silver brazing alloys melting at temperatures below

1.200° F. has necessitated the development of fluxes that are fluid and active at 1.100" F. Combinations of borates, fluorides and chlorides provide fluxes which are fluid at temperatures from 700° to 1,100° F. For aluminum soldering, combinations of chlorides and fluorides are used. Borates combined with fluorine compounds are used with the low-temperature silver brazing alloys and are fluid and active at 1,100° F.

Heating.—There are many satisfactory methods of heating depending upon temperature required and size and shape of parts being joined. In the soft soldering range, soldering irons torches, induction heating and furnaces are used. Soldering irons are small blocks of copper pointed at one end. They are heated electrically or with a blowtorch or small furnace. They must be large enough and be heated to a temperature which will not only melt the filler metal quickly but also heat the surface of the joint to a temperature above the melting point of the filler metal as the soldering iron is drawn along the joint. This method of heating is suitable for soldering thin sheet metal, wires. electrical connections and small parts. Torches are used for large parts and special furnaces and conveyer systems are installed when large

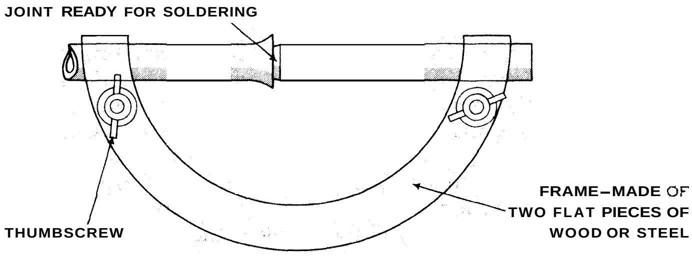

FIG. 3.—METHOD OF HOLDING PIPES IN POSITION FOR MAKING A JOINT

quantities are to be soldered. Baths of the molten filler metal are used when the parts can be securely fastened in jigs and the joint dipped just below the surface of the bath.

Heating for hard soldering or brazing is done with torches, inductive heating, electrical resistance, furnaces, molten salt baths and baths of molten filler metal. The wide use of these processes in industry has led to the development of special furnaces and automatic equipment with particular attention to accurate control of the temperature and careful regulation of the atmosphere. Chemical baths may be used when the parts can be held in position by proper jigs and the filler metal preplaced in the joint before dipping in the bath. Procedure with metal baths is similar but eliminates preplacing the filler metal.

(Ro. H. L.)

SOLE, the name of flatfishes (*q.v.*) of the genus *Solea*, which have the eyes small, on the right side, the head rounded in front and the mouth small, curved, with teeth in the jaws of the blind side only. Several species are known from the Indo-Pacific and the eastern Atlantic.

The common sole of Europe ranges from the North sea to the Mediterranean; it is a valuable food fish, which attains a length of two feet. It often burrows and ieeds mainly at night, seeking worms and other small animals of the sand or mud by smell and touch.

The American soles belong to another genus, *Achirus;* they are small and of no value.

SOLENOIDS, ATMOSPHERIC: *see* BAROCLINIC.

SOLENT, THE, a strait of the English channel, between the mainland (the coast of Hampshire. Eng.) and the coast of the Isle of Wight. It is the submerged valley of an eastward-flowing river of which the present Frome was the headstream and the Itchen and Test, two tributaries. Spithead, the drowned eastern portion of the same valley, is on the whole wider than the western part, and therefore affords a safer approach to Southampton for very large craft. From Southampton water to the Needles is 15 mi., and from Southampton water to Spithead about half the distance; the breadth is from $1\frac{3}{4}$ to 4 mi. Opposite the Needles there springs from the mainland a great shingle bank, nearly 2 mi. in length, on the end of which stands Hurst castle dating from the time of Henry VIII. At the mouth of Southampton water another shingle bar. projecting from the western shore, also bears a Tudor fortress. Calshot castle. The low coast of the mainland is broken by the estuaries of the Beaulieu river and the Lym; the coast of Wight, which rises more steeply, is cut by the Medina, Newton and

Yar estuaries. The Solent is frequently the scene of yacht races. especially from Cowes, and also of naval reviews, off Spithead.

SOLESMES, a village of western France on the left bank of the Sarthe in the *département* of Sarthe, 29 mi. W.S.W. of Le Mans by road. Pop. (1954) 477. In 1010 a priory was founded at Solesmes and placed under the authority of the abbey of La Couture of Le Mans. Suppressed at the Revolution, it became a Benedictine monastery in 1830. In 1837 it was raised to the rank of abbey and a nunnery was later founded beside it, but both institutions were abandoned in 1901.

SOLF, WILHELM (1862–1936), German colonial politician. was born on Oct. 5, 1862, in Berlin. After studying Sanskrit and oriental languages in Calcutta. he returned to Germany and entered the German colonial service, being. sent to Soma. There he was first president of the municipal council (1899) at Apia under the old "condominium" of Great Britain, Germany and the U.S., and afterward governor of German Samoa (1900). In 1911 he became German colonial secretary and effected considerable reforms in colonial administration. When Prince Max of Baden's ministry of desperation was formed toward the end of World War I. Solf was appointed foreign secretary, and as such conducted the negotiations for the Armistice. He resigned on Dec. 17, 1918. In 1920 he was German chargé d'affaires. and from 1921 to 1928 ambassador at Tokyo. He died Feb. 6, 1936.

SOLFATARA, a volcanic vent emitting vapours chiefly of sulfurous character. The typical example is the famous Solfatara. near Pozzuoli, in the Phlegraean fields west of Naples, an old crater which has not been in active eruption since A.D. 1198, but which is continuously exhaling heated vapours, chiefly hydrogen sulfide. sulfur dioxide and steam. Sal ammoniac occurs among the sublimates. The term solfatara has been extended to all dormant volcanoes of this type, and a volcano which has ceased to emit lava or ashes but still evolves heated vapours is said to have passed into the "solfataric stage." *See* VOLCANO; VOLCANISM; FUMAROLE.

SOLFERINO, 5 mi. W. of the Mincio river. was the scene of a battle between the Franco-Sardinians. commanded by Napoleon III, and the Austrians under Francis Joseph. Defeated at Magenta. June 4, 1859. the Austrians under Gyulai retreated across the Mincio and reorganized their forces around Verona. Francis Joseph then assumed personal command, aided by General Hess. His forces comprised two armies under Wimpffen and Schlick. 160,000 strong. Early on June 24, when neither army expected to encounter the other, the armies suddenly met at the Mincio, both having assumed the oifensive. The Franco-Sardinians, 150,000 men, moved on a 25-mi. front from Lake Garda to Castel Goffredo. Outpost firing began at 5:30 A.M.! developing later into more serious fighting. At 7 A.M. Napoleon, who watched the encounter from the church tower at Castiglione, ordered his forces to advance on Solferino, situated on an elevation, seemingly strongly occupied. After desperate fighting it was captured by the French guards, entailing the sacrifice of thousands of lives. This brought about a distinct tactical advantage to the French, the Austrians continuing to make further attempts to recapture this important point. Farther south of Solferino, MacMahon captured Cassiano. but the Sardinians, under King Victor Emmanuel. vainly assaulted the Austrian lines south of Lake Garda, being thrown back on Revoltella by Benedek. At 2 P.M. Francis Joseph gave a fresh order to Wimpffen to advance resolutely and to thrust back the enemy south of Solferino, but all his attempts mere abortive. About 4 P.M. the oppressive heat was succeeded by a severe thunderstorm, of which the Austrians took advantage to retreat, except Benedek's troops. They accomplished this unmolested, the French being too exhausted to pursue them. The Sardinians then again fell on Benedek, who. seeing the Austrian centre retreat, retired. keeping the enemy at a distance. The Austrians recrossed the Mincio that evening, having lost 22,000 men. the Allies 17,000. A meeting of the two emperors took place shortly afterward at Villafranca. after which hostilities ceased.

SOLI (mod. MEZETLÜ), an ancient town of Asia Minor. on the coast of Cilicia. Colonists from Argos in Greece and Lindus in Rhodes are described as the founders of the town. which is first mentioned at the time of the expedition of the younger Cyrus. In the 4th century B.C. it was so wealthy that Alexander could exact a fine of 200 talents. In the Mithradatic War, Soli was destroyed by Tigranes, but it was subsequently rebuilt by Pompey, who settled there many of the pirates whom he had captured. and called the town Pompeiopolis. Soli was the birthplace of Chrysippus the Stoic and of the poets Philemon and Aratus. The bad Greek spoken there gave rise to the term *soloikismos*, solecism. Little remains of the ruins

SOLI (mod. SOLIAIS), a Greek city on the north coast of Cyprus, in the metalliferous country round Karavostasi. Its territory was bounded by those of Marion, Paphos. Tamassus and Lapathus. It was believed to have been founded after the Trojan War by the Attic hero Acamas; and no remains have been found earlier than this Soli is probably the town "Sillu." whose king Irisu was an ally of Assur-bani-pal of Assyria in 668 B C. In Hellenic times Soli had little political importance. though it stood a siege from the Persians soon after 500 B.C.; its copper mines, however, were famous, and a neighbouring monastery is dedicated to "Our Lady of the Slag-heaps."

SOLICITOR, in England, an officer of the Supreme Court of Judicature qualified to conduct legal proceedings for his clients: *see* also LEGAL PROFESSION. Until 1873 there was a distinction between the terms "solicitor" and "attorney." Solicitors appear to have been at first distinguished from attorneys as not having the attorney's power to bind their principals; subsequently the distinction was between attorneys as agents in actions at law, and solicitors in chancery. In practice. however, the terms were synonymous. for it was usual for attorneys to be admitted as solicitors also The Judicature Act 1873 enacted that all persons admitted as solicitors, attorneys or proctors of an English court should thenceforth be called solicitors of the Supreme Court.

Every person, before he can become a duly qualified solicitor, must serve an apprenticeship or clerkship to a practising solicitor for a term of years varying from three to five. Since 1922 he has been required during one of those years to attend a law school provided or approved by the Law Society (long known as the Incorporated Law Society). Service under articles therefore combines academic training with practical experience. The clerk must pass all the necessary examinations, he must be duly admitted, and must take out an annual certificate to practise. The organization of the profession is in the hands of the Law Society. Established 1827, and succeeding a society dating back to 1739, it was incorporated in 1831. The Solicitors Act 1922 transferred to the Law Society disciplinary powers long exercised by the courts. Its Discipline Committee may, after inquiry, strike off the roll or suspend from practice solicitors convicted of crime or found guilty of professional misconduct. In conjunction with the provincial law societies it has taken over the organization of the voluntary services of solicitors in the conduct of poor persons' cases. Apart from its judicial and administrative authority the Law Society has frequently exercised powerful influence by the attitude which it has taken towards proposed legislation. Membership of the society, which is not compulsory, is open to any duly qualified practising solicitor.

No person can be admitted as a solicitor unless he is a British subject, and has attained the age of 21 years. Though admitted as a solicitor and his name entered on the roll, he is not at liberty to practise until he has taken out his annual certificate, the fee for which is larger for London than for country practitioners. The disqualification of women to become solicitors ceased in 1919.

Solicitors now have a right to practise in any court, *i.e.*, in every division of the High Court, in every inferior court, in the ecclesiastical courts (*see* PROCTOR). in the court of appeal, in the Privy Council and in the House of Lords Their right of audience, however, is restricted. They may appear as advocates in most of the inferior courts, as before justices, magistrates, coroners, and county courts. They have no right of audience, however, in the High Court of Justice (except in certain bankruptcy matters), nor in the Privy Council or House of Lords, where, from time immemorial, the right has pertained to rhe bar; but they have right of audience in chambers.

Solicitors have for more than two centuries done all kinds of conveyancing, which, at one time, was claimed to be the exculsive business of the bar and scriveners. The Conveyancing Act 1881 having made changes in the practice of conveyancing, the remuneration of solicitors was placed upon a new basis by an order which provided scales of fees based on the amount involved in the transaction, not, as was generally the case before, simply on the length of the documents perused or prepared.

All communications which pass between a solicitor and his client are privileged; so also is any information or document which he has obtained in his professional capacity on behalf of his client. The relation of solicitor and client disqualifies the former from dealing with his client on his own behalf, while it gives him a lien for his professional charges, over the deeds, etc., of the client in his possession. A solicitor's remuneration is minutely arranged by statute. He has no power of recovering more from his client than his statutory charges, and he is liable to be sued for damages for negligence in his client's behalf. Certain personal privileges belong to a solicitor. He is free from serving on juries, nor need he, against his will, serve as a mayor, sheriff, overseer or churchwarden.

In Scotland "law agent" is the general term devised by the legislature to embrace the various writers, solicitors and procurators entitled to practise as agents in the supreme and inferior courts. The Law Agents (Scotland) Act 1873 now regulates the admission of applicants to the roll of law agents entitled to practise in Scotland. The apprenticeship varies from three to five years and the applicant must also pass a general examination and an examination in law unless he is a university graduate. A law agent is removable from the roll upon a petition to the court of session. Separate rolls are kept of law agents entitled to practise (a) in the court of session and (b) in each of the sheriff courts. As in England, the law agent has a limited right of audience, *i.e.*, only in the bill chamber of the court of session and in the inferior courts. Many law agents are members of one or other of the incorporations of which the principal are His Majesty's writers to the signet, the solicitors in the supreme courts, the faculty of procurators in Glasgow, and the society of advocates in Aberdeen. In the United States the term solicitor is used in some States in the sense of a law agent practising before a court of equity.

Some of the great public offices in England and the United States have their solicitors. In England the Treasury solicitor fills an especially important position. He is responsible for the enforcement of payments due to the Treasury, and conducts generally its legal business and that of most Government departments. The office of king's proctor is combined with that of Treasury solicitor. The Treasury solicitor as nominee of the Crown acts as administrator of the personal estate of an intestate which has lapsed to the Crown, and as king's proctor intervenes in cases of divorce where collusion is alleged *(see* PROCTOR). In Ireland solicitors called Crown solicitors are attached to each circuit, their duty being to prepare the case for the Crown in all criminal prosecutions. In the United States the office of solicitor to the Treasury was created by Act of Congress in 1830. His principal duties were to take measures for protecting the revenue and to deal with lands acquired by the United States judicial process or vested in them by security for payment of debts.

See E. B. V. Christian, *A Short History of Solicitors* (1896); A. Cordrey, *The Law Relating to Solicitors* (1878); A. P. Poley, *Law Affecting Solicitors* (1897).

SOLICITOR-GENERAL, in England, one of the law officers of the Crown, first appointed by letters patent in 1461 as deputy of the attorney-general (*q.v.*), and so called because he was more concerned with matters in chancery. His duties are now practically the same as those of the attorney-general, to whom he is subordinate, and whose business and authority devolves upon him in case of a vacancy. The position of the solicitor-general for Scotland in the main corresponds with that of the English solicitor-general. He ranks next to the lord-advocate. In the United States the office of solicitor-general was created by Act of Congress in 1870.

SOLIDS, GEOMETRIC. The term solid is not widely used in geometry as a precise generic term, but it commonly appears in the names of certain special classes of geometric configurations. A geometric configuration is any set of points in space which, unless the contrary is stated, is understood to be the space of euclidean three-dimensional geometry. We may set down that any geometric configuration is a geometric solid, or simply a solid, if every point of the configuration is the centre of a sphere whose interior contains only points of the configuration, and if the configuration is not composed of two configurations which have no points in common and which are such that every point of each configuration is the centre of a sphere whose interior contains only points of that configuration. It will be seen readily that according to this definition the interior of a sphere is a solid, while the configuration consisting of that interior and the sphere, *i.e.*, the spherical surface, is not a solid. It is easy to modify the given definition so as to permit calling the latter configuration a solid. This requires making precise the idea of the boundary of a configuration. A *boundary point* of a configuration is a point such that every sphere having it as centre contains points of the configuration and also points which do not belong to the configuration. A boundary point of a configuration need not belong to the configuration. The set of all boundary points of a configuration is called the *boundary of the configuration.* We shall now define a solid as any configuration consisting of a solid according to the original definition and the boundary of the latter configuration, and shall refer to the latter configuration as the interior of the solid thus newly defined. There are simple solids such as those commonly referred to as the sphere, cube, pyramid, ellipsoid, cylinder and the less simple ones, such as the torus or anchor ring and a sphere with a number of holes bored through it, and so on to solids of great complexity; *e.g.*, the abstract analogue of natural objects, such as a sponge or the steel framework of a building. The task of making a complete detailed classification of solids is thus an enormous one. For certain restricted, though important, classes of solids the problem of classification has been solved to such an extent that the associated theory is an interesting and important chapter of mathematics. An example of such a class is the class of polyhedra, which is taken up in some detail below.

A useful procedure in attacking the general problem of classification is the study of the boundaries of solids. Although several solids may have the same boundary the ambiguity thus arising in the determination of a solid by its boundary is easily settled in the case of a great class of solids; viz., all those which have been studied in a systematic way. Thus a classification of the boundaries of solids determines a classification of solids. The boundaries of solids may be extremely complicated configurations, but in the case of the solids of the large class just referred to the boundaries have a speciality which is sufficient for a quite complete classification and theory. The solids referred to are those whose boundaries are closed surfaces. A sphere, a torus, a polyhedron are examples of closed surfaces, and a more complicated example of such a surface is the surface of the solid which results from boring any number (finite or infinite) of holes, properly located, through a sphere. A precise definition of the concept of closed surface will not be given now and an ordinary intuitive counterpart of that concept will serve provisionally.

In studying the properties of solids, it is helpful to divide those properties into metric and non-metric properties. A general property of the latter kind involves merely the way in which parts of the solid are attached to each other, *i.e.*, the connection of the solid; while a metric property refers to size and shape, thus involving a comparison with other solids in regard to such relations as congruence and similarity. A special kind of non-metric property, sometimes called descriptive, involves such notions as linearity, parallelism and convexity. The non-metrical properties are the more primitive and simple, but metrical relations (such as congruence) are also fundamental.

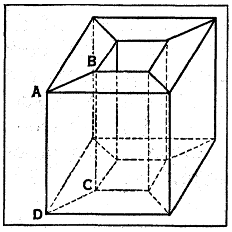
Polyhedral Solids.—In the study of solids aid is obtained from the study of a special class, polyhedral solids, *i.e.*, solids bounded by configurations formed by polyhedra. The theory of polyhedra suggests means of classifying more general solids and also methods of attack in the solution of problems of more general solids. Furthermore, the fact that any solid can be approximated to as closeiy as desired by a polyhedral solid adds to the importance of the theory of such solids to a study of solids in general. A precise formulation of the fact just alluded to is the following: If S denotes any solid, then there exists a sequence of polyhedral solids, P_1, P_2, P_3, . . ., P_n . . ., such that every point of the solid P, is a point of the interior of S and also of the interior of the solid P_{n+1}, and every point of the interior of S is a point of the interior a polyhedral solid P_m of the sequence. In particular, there exist such sequences of polyhedral solids such that each polyhedral solid is composed of a finite number of cubes such that no two of the cubes have interior points in common and every cube has a face in common with another one of the cubes. Another method of approximating to a solid by means of polyhedral solids is that in which the vertices of the approximating polyhedral solids are points of the boundary of the given solid, or, as it is usually stated, the polyhedron which bounds the polyhedral solid is inscribed in the boundary of the given solid. However, the existence of sequences of approximating polyhedral solids of the latter kind has been established only in the case of special solids.

POLYHEDRA

Definitions. — According to the definition of polyhedral solids, it is immediately evident that the theory of polyhedra is of much importance in the study of those solids. Preparatory to the consideration of the properties of polyhedra the following definitions are made. A *segment* is the set of all points of a (straight) line which are between two points of that line, and each of the latter points is called an end of the segment. A *simple* polygon is a finite set of points (vertices of the polygon) and segments (sides of the polygon) such that (a) each point of the set is the end of two and only two segments of the set, (b) the ends of each segment of the set are points of the set, (c) no two elements (*i.e.,* points or segments) of the set have a point in common, and finally (d) no proper subset of the set of points and segments satisfies (a), (b) and (c). It is a theorem of euclidean plane geometry that every simple polygon in a plane π is the planar boundary of a unique connected region of finite extent which is contained in a. The planar boundary of a set of points in a plane and a connected region in a plane are the two-dimensional analogues of the boundary of a solid and the interior of a solid respectively as defined above, circles of the plane replacing the spheres in the definitions referred to. Saying that a set of points is of finite extent means that it is contained in the interior of a sphere. The planar region thus determined by a simple plane polygon is called a polygonal region.

A finite set of points, segments and polygonal regions is called a *polyhedron,* if and only if (a) every segment of the set is a side of the boundaries of two and only two polygonal regions of the set, and every side of the boundary of a polygonal region of the set is a segment of the set, (b) every point of the set is an end of at least one segment of the set, and the ends of any segment of the set are points of the set, (c) if P is any point of the set, the set a of all polygonal regions of the set whose boundaries have P as a vertex form a cycle, *i.e.,* every segment of the set which has P as an end is a side of the boundaries of two polygonal regions of the set σ and no proper subset of σ has that property, (d) no two elements (*i.e.,* points, segments or polygonal regions) of the set have a point in common, and (e) there is no proper subset of the set of points, segments, and polygonal regions which satisfies (a), (b), (c) and (d). By omitting some of the conditions of this definition, more general configurations which are also called polyhedra are defined thereby, and the set just defined is called a simple or an ordinary polyhedron. Just so there are polygons which are not simple and which are defined by less restrictive definitions than that given above. In what follows, the words polygon and polyhedron signify respectively, simple polygon and simple polyhedron. Despite the qualifying term simple, the class of simple polyhedra has a most interesting and important theory which still leaves much to be done.

Non-metrical Properties. — That every polyhedron is the boundary of a unique solid of finite extent and also the boundary of a unique solid not of finite extent is a theorem of euclidean three-dimensional geometry which requires a proof of considerable length. This theorem is analogous to the theorem of euclidean two-dimensional geometry concerning the separation of a plane by a polygon contained in it; but at this point the spatial theory becomes much richer. Considering merely the internal connection of the elements of a polygon, one is very much like the other, but in the case of polyhedra that is not so. Besides polyhedra such as the tetrahedron, cube octahedron, etc., there are those which can be obtained by cutting one or more square holes out of the limited solid bounded by a cube, tetrahedron, etc. Between a polyhedron thus obtained and a cube or tetrahedron there is a fundamental difference. The diagram illustrates one of these polyhedra of more complicated structure. It consists of 16 vertices, 32 edges and 16 faces. In the case of a cube any polygon P consisting of vertices and edges of the cube separates the cube; *i.e.,* there is a pair of points (and, of course, many pairs) of the cube, which do not belong to any polygonal line which is made up of points of the cube and which contains no points of the polygon P. (It should be emphasized that the terms cube, tetrahedron, octahedron, etc. are used here to denote polyhedra and not solids bounded by certain polyhedra.)



In the case of the polyhedron of the illustration the polygon ABCDA does not separate that polyhedron in the above sense; however, any pair of polygons contained in the polyhedron, *i.e.,* every vertex and every point of the sides of the polygon, are points which are either vertices or belong to edges and faces of the polyhedron, and having no points in common separates the polyhedron in the sense that a set S of polygons separates a polyhedron π if the polygons of S are contained in π and if there are two points of π such that any polygonal line which contains them and which is contained in π also contains a point of a polygon of S. For any polyhedron there exists a finite set T of polygons which have no points in common and such that the set Γ does not separate the polyhedron, while any set of non-intersecting polygons on the polyhedron, which contains more polygons than T, separates the polyhedron. The number of polygons in the set T is called the genus of the polyhedron. Thus it can be easily shown that the cube, tetrahedron, and the more common polyhedra are of genus zero, while the genus of the polyhedron of the above illustration is one. Speaking roughly, a polyhedron of genus p is not disconnected when it is cut along the circuits (polygons) of a certain set of p circuits, but it is disconnected when cut along any $p+1$ circuits.

A most important theorem may now be stated. If $v=$ the number of vertices, $e=$ the number of edges, and $f=$ the number of faces of a polyhedron of genus p, then $v-e+f=2-2p$. Thus in the case of the polyhedra of genus zero (such as the cube, octahedron, and icosahedron) $v-e+f=2$, while for the polyhedron illustrated above $v-e+f=0$. The number $v-e+f$ is called the clzaracteristic of the polyhedron. A remarkable fact in this connection is that, if two polyhedra have the same characteristic (or genus), then a subdivision of the elements of each exists so that the polyhedra thus derived are isomorphic; *i.e.,* any vertex, edge and face of one is paired respectively with a vertex, edge and face of the other such that a pair of elements of the first polyhedron which are incident corresponds to a pair of elements of the second polyhedron, which also are incident, and conversely. Thus, if a vertex A' and an edge a' of the second polyhedron are paired with the vertex A and the edge a of the first polyhedron respectively, and if A is an end of a, then A' is an end of a'; and similarly if a vertex and a face or an edge and a face are incident. The integer 2 minus the characteristic of a polyhedron is known as the *connectivity* number of the polyhedron and, as implied above, for a polyhedron in euclidean three-dimensional space it is either positive and even, or zero.

Classes of Polyhedra. — In the theory of polyhedra, considered merely as sets of objects, called vertices, edges and faces, which satisfy the relations of incidence and order of the definition of a polyhedron given above and which are not sets of points in any particular space, it is shown that there exists a polyhedron having any positive integer or zero as its connectivity number. In this theory two classes of polyhedra are distinguished. Any polyhedron of one of these classes has the property that there is at least one polygon on it which does not separate any region which is on the polyhedron and which contains the polygon. The term region is used here in a sense which, though analogous to, is a simple extension of, its meaning given above. All other polyhedra make up the other class. Polyhedra of the latter class are sometimes said to be *two-sided;* those of the former *one-sided.* The basis of this terminology is suggested above in reference to the separation of euclidean space by polyhedra. Only two-sided polyhedra exist in euclidean space and any two-sided polyhedron is isomorphic with a polyhedron in euclidean space. A generalized polyhedron *(see* below) in euclidean space may be one-sided.

The terms *non-orientable* and *orientable* are also applied to polyhedra of the former and latter classes respectively, because either of two senses can be defined on an orientable polyhedron just as in the case of the euclidean plane or sphere, while that is impossible in the case of so-called non-orientable polyhedra. In the general theory of polyhedra, also called *manifolds* (*q.v.*) in that context, the above equation relating v, e, f and p holds for all orientable polyhedra, while the equation $v-e+f=2-p$ is the corresponding equation for non-orientable polyhedra, the letters in both cases having analogous meanings. In the following, as in what preceded this digression, it is understood that the polyhedra are in euclidean three-dimensional space, and are therefore two-sided or orientable.

Classification of Polyhedra.— It is suggested immediately that polyhedra may be classified according to genus but then the question of a finer classification arises. The goal is the complete description of the classes so that any two polyhedra of the same class and no two of different classes are isomorphic. Each of the classes of such a classification shall be called a *type.* It is obvious that the polyhedra of the same class have the same genus, but that the converse is not true. It is also obvious that polyhedra which are not isomorphic may form the boundary of the same solid. No such exhaustive classification has ever been completed, not even for the class of all polyhedra of genus zero.

A most useful general method of thus classifying polyhedra is based on the problem of the determination of all types of polyhedra of $f+1$ faces or $v+1$ vertices, assuming that all the types of polyhedra of f faces or v vertices, respectively. are known. For example, any type of convex polyhedron (for definition *see* below) of $f+1$ faces can be obtained by cutting with a plane all the faces of a certain convex polyhedron of f faces, which are incident with the same vertex. In the case of the special convex polyhedra which Rave only vertices which are incident with three and only three edges, this process of "cutting off the corners" results in a polyhedron of the same speciality and gives a comparatively complete result. If $\psi(f)$ denotes the number of types of convex polyhedra which have f faces and all of whose vertices are incident with exactly three edges, then $\psi(4)=1$, $\psi(5)=1$, $\psi(6)=2$, $\psi(7)=5$, $\psi(8)=14$, $\psi(9)=50$, and $\psi(10)=233$.

Very little, indeed, is known of the general behaviour of the function $\psi(f)$. If the polyhedra also satisfy the special condition that each polyhedron contains a face which is adjacent to all of the remaining faces, then a recursion formula for the value of $\psi(f)$ is known, but even in this very special case it is sufficiently complicated. A similar degree of completeness exists in the theory of the convex polyhedra, *i.e.,* the so-called duals of those just considered, *i.e.,* those which have only triangular faces. A polyhedron is said to be the dual *(see* DUALITY) or *reciprocal* of another if each vertex of the former is paired with a unique face of the second, so that thereby every face of the second is paired with just one vertex of the first, and if each edge of the first is paired with a unique edge of the second in a reciprocal way, and if a pair of incident elements of the second polyhedron corresponds to a pair of incident elements of the first.

Another general procedure in studying different types of polyhedra consists of making simple replacements of some of the elements of a polyhedron by new elements. For example, a face may be replaced by the two faces and the edge. which result from the division of the original face by a line which cuts its boundary in exactly two points, and different replacements are made according as the dividing line passes through no vertex, one vertex or two vertices incident with the face. For some such replacements the type of the polyhedron is not changed, while for others the type of the resulting polyhedron is different from but simply related to that of the original one. Many important theorems result from the consideration of such replacements of elements.

Regularly Connected and Convex Polyhedra.— In the case of certain special but important classes of polyhedra, the general ideas considered above lead to quite complete information about those classes. An important sub-class of polyhedra is that which consists of regularly connected polyhedra. A polyhedron is said to be *regularly connected* if every pair of vertices of the polyhedron which are incident with two of its faces are the ends of an edge of the polyhedron, which edge is also incident with those two faces. The type of a regularly connected polyhedron is completely determined by the incidence relations of its vertices and faces. Also, if the boundary of a face of a regularly connected polyhedron is removed the remaining set of vertices and edges is connected, but the converse, as is easily seen, is not true. It is interesting to note that the converse of the original statement with the phrase "regularly connected polyhedron" replaced by "polyhedron of genus zero," is true but not the modified statement. Finally there is the important special case of a regularly connected polyhedron of genus zero. Such a polyhedron will be said to be *convex-like,* because with regard only to incidence relations of its elements it does not differ from a convex polyhedron. The precise fact is given in the fundamental theorem that every convex-like polyhedron is of the same type as that of a certain convex polyhedron. As an important preliminary theorem here we have that every convex-like polyhedron is derivable from a tetrahedron by simple replacements of elements such as referred to above.

A convex polyhedron, already referred to several times, is defined in several equivalent ways. One definition requires that no line which is not in the plane of any face of the polyhedron contains more than two points of the elements of the polyhedron, and another is that, if α is any face of the polyhedron, then all of the elements of the polyhedron except a and the vertices and edges incident with a are on the same side of the plane which contains a. Again, a polyhedron which forms the boundary of a convex solid is a convex polyhedron. where by a *convex solid* is meant a solid which is such that, if two ends of a segment are points of the solid, then every point of the segment is a point of the solid. It is worth noting that these definitions require that a convex polyhedron be contained in a three-dimensional space, while the concept of a convex-like polyhedron is independent of any surrounding space.

Some further results of the foregoing will now be noted. If v, e and f respectively denote the number of vertices, of edges and of faces of a polyhedron then, since at least three edges are incident with each vertex and also with each face, $3v\leqq 2e$ and $3f\leqq 2e$; and if the polyhedron is of genus zero, then $v-e+f=2$. Conversely, it is proved that, if v, e and f are positive integers which satisfy these three conditions, the two inequalities and the equality, then there exists a polyhedron, in particular' a convex polyhedron, with v vertices, e edges and f faces. Further, it follows easily from the latter equality that every polyhedron of genus zero and, therefore, in particular every convex polyhedron (for it is shown easily that the genus of a convex polyhedron is zero) has at least one face that is bounded by a polygon and at least one vertex which is incident with 3, 4 or 5 edges. and has at least either one triangular face or one trilinear vertex, *i.e.,* a vertex incident with exactly three edges. Also, there exist polyhedra and, in particular, convex polyhedra having any number of edges, if that number is an integer greater than five and different from seven. There is no polyhedron having exactly seven edges.

Finally a fact that is remarkable (even in view of the greater richness of the theory of polyhedra in euclidean three-dimensional space as compared to the theory of polygons in a plane) is that there exist polyhedral solids evidently not convex. in euclidean three-dimensional space, which are not decomposable into a finite number of tetrahedral regions which have no points which are not on their boundaries in common, and whose vertices are vertices of the polyhedral solid. That an analogous decomposition of a polygonal region into triangular regions always exists is a theorem of euclidean plane geometry.

Metrical Properties of Polyhedra. — The preceding exposition has been concerned largely with non-metrical properties. In succeeding paragraphs metrical properties of polyhedra are also considered. These properties being based on the intuitive notions of size and shape were the chief objects of study in the very early development of the subject. The chief topics here are the congruence of polyhedra and the properties of polyhedra which have elements or groups of elements which are congruent respectively. Two configurations are said to be congruent in the narrow sense if, and only if, one can be transformed into the other by a rigid motion. Two configurations are said to be congruent in the broad sense if, and only if, one can be transformed into the other by a succession or product of a finite number of rigid motions and planar symmetries; *i.e.,* reflections in a plane. An equivalent set of definitions is the following: Two configurations are congruent in the broad sense if, and only if, the points of one are in one-one correspondence with the points of the other such that the distances between pairs of corresponding points are equal. If sense as well as distance is preserved by the correspondence, then and only then are the two configurations congruent in the narrow sense. The terms of these definitions have precise abstract meanings but in order to save space they are omitted here; their ordinary meanings should give a sufficient understanding.

An outstanding theorem on the congruence of polyhedra is that if two convex polyhedra are isomorphic such that corresponding faces are congruent, then the polyhedra are congruent in the broad sense. The theorem is obviously not true in the case of polyhedra which are not convex, and an interesting theory concerning the infinitesimal and finite deformations of non-convex polyhedra, which preserve length, presents itself.

Regular and Semi-regular Polyhedra. — The question of the congruence of polyhedra suggests the consideration of a single polyhedron whose elements satisfy certain relations of congruence. At the extreme of speciality there are the so-called regular polyhedra. Because of their very conspicuous regularity they are among the oldest objects of study in the theory of polyhedra. A polyhedron is a *regular* polyhedron if, and only if, the boundary of each face is a regular polygon which is congruent to the boundary of every other face and each polyhedral angle of the polyhedron is regular, *i.e.,* having congruent face angles and dihedral angles resp., and congruent to every other polyhedral angle of the polyhedron. There are exactly five types of regular polyhedra; further details of these are given in the table below. A generalization of the regular polyhedra are the *Archimedian* polyhedra; all the faces of such a polyhedron are bounded by regular polygons, not all congruent to each other, and all the polyhedral angles are convex and congruent to each other. There are thirteen types of such polyhedra besides the semi-regular prisms and prismoids.

A *prism* is a polyhedron of which two faces, called its bases, lie in parallel planes and each of the remaining faces is bounded by a parallelogram and is adjacent to each base. A prismoid is a polyhedron which also has two faces, its bases, which are in parallel planes, while each of its other faces is triangular and incident with a vertex of one base and a side of the other. If every face of a prism or prismoid is regular, *i.e.,* bounded by a regular polygon, and if the bases of the prismoid are congruent, then the prism or prismoid are said to be semi-regular. The Archimedian polyhedra and their reciprocals form the class of the so-called semi-regular polyhedra. The semi-regular polyhedra can be obtained by such simple operations as taking plane sections of and combining regular polyhedra, and by dualizing. For example, the cuboctahedron is obtained by cutting off the vertices of the cube or octahedron by planes passing through the midpoints of the edges; the icosidodecahedron by a similar treatment of the dodecahedron or icosahedron. The reciprocals of these two Archimedian polyhedra are respectively the rhombic-dodecahedron and the rhombic triacontahedron, which have in all twelve and thirty faces respectively, each face being a rhombus. For further details of semi-regular polyhedra, see table p. 945.

The idea of semi-regular polyhedra leads to the later generalization of the notion of regularity, which is contained in the idea of a polyhedron transformable into itself by a congruence transformation, in the broad sense, such that any polyhedral angle of the polyhedron is transformed thereby into any other. Reciprocally there is defined a polyhedron which is transformable into itself by a congruence transformation so that any face of the polyhedron is transformed into any other. Polyhedra of the former kind have a circumscribing sphere while those of the latter have an inscribed sphere. The mere requirement of the congruence of all of the polyhedral angles or of all of the faces of a polyhedron does not imply the existence of a circumscribing or an inscribed sphere respectively. Archimedian polyhedra are polyhedra of the former kind which have their faces bounded by regular polygons which are not all congruent to each other. A complete classification of the convex polyhedra satisfying this more general definition of regularity has been made, according to the kind of faces and the various relations of symmetry which are satisfied, and the number of distinctive types is finite. When the requirement of convexity is removed the complexity of the problem of classification is very great, and no classification of any satisfying degree of completeness has been made. In conformity with the present viewpoint a regular polyhedron may be defined as a polyhedron which is transformable into itself by a congruence transformation, in the broad sense, so that any vertex is transformed into any other vertex, any edge incident with the former vertex into any edge incident with the latter vertex, and any face incident with the former edge into any face incident with the latter edge.

The notion of symmetry furnishes another basis for the investigation of properties of regularity of polyhedra. It is a fundamental concept in the definition of an important class of polyhedral solids known as crystals. A configuration is called *symmetrical* if it admits of a congruence transformation, in the broad sense, into itself, which is not the identity. In this scheme of classification, two configurations are in the same class if the group of congruence transformations which transform one of the configurations into itself is the same as the group of congruence transformations which transform the other into itself.

A Crystal. — A crystal is a solid whose boundary is a polyhedron which has the following properties: In the first place its vertices, edges and faces are respectively on points, lines and planes of a rational space net. A rational space net is the set S of all points, lines and planes such that there are five points, P_1, P_2, P_3, P_4 and P_5, no four of which are in a plane, such as the vertices of a tetrahedron and a point interior thereto, with the property that if a denotes any element (point, line or plane) of *S,* then there exists a finite sequence of elements of S, P_1, P_2, P_3, P_4, P_5, α_1, α_2, a,,. . ., a,, α, such that the first five elements are the five points mentioned above and any other element of the sequence is uniquely determined by being common to or containing preceding elements of the sequence. Secondly, the polyhedron is transformed into itself by the transformations of a finite group of congruence transformations, in the broad sense, which transform a rational space net into itself. Such a group is known as a crystallographic group. There exist thirty-two crystallographic groups which thus determine the same number of classes of crystals.

Generalized Polyhedra. — At this point, perhaps, there should be mentioned a generalization of the notion of regular polyhedron, which is obtained by generalizing the idea of a polyhedron itself, although these generalized polyhedra are not the boundaries of unique solids. The boundary of a face of a polyhedron is, as stated early in this article, a simple plane polygon. A generalized *polygon* satisfies the conditions of the definition of a simple polygon, except that one which states that no elements of the polygon have a point in common. (One might generalize further by requiring an even number, not necessarily two, of sides inci-

Tables Giving Data cf Regular and Semi-regular Polylzedra

dent with each vertex.) *A regular generalized polygon* is defined accordingly; *e.g.,* any regular generalized polygon, sometimes called a *star polygon,* with n vertices is obtained by joining in order every k th vertex of a regular simple polygon of n vertices, where k is any integer between 1 and $n/2$.

In an analogous way the notion of a *generalized polyhedron* is defined; *i.e.,* by relinquishing the condition that two elements have no points in common. and at the same time allowing a face to be determined by a generalized plane polygon The generalized polygon is not the boundary of the face in the ordinary sense. For example, the sides of each pentagon which bounds a face of a regular dodecahedron when prolonged form a star pentagon, and all such star pentagons determine the faces of the small stellated dodecahedron. The latter generalized polyhedron is regular in a sense which is an obvious extension of the meaning of that term as applied to ordinary polyhedra. There are just four such *regular generalized polyhedra* and detailed data concerning them are given in an accompanying table. The other definitions involving the idea of regularity as applied to ordinary polyhedra evidently admit of like extension so as to apply to generalized polyhedra, and many interesting types of generalized polyhedra accordingly present themselves.

Explanation of Tables.—The symbols of the tables have the following meanings: f denotes the number of faces of the polyhedron, v the number of vertices, and e the number of edges; of the f faces m_1 are bounded by polygons of m sides, and m_2 of these m_1 faces are incident to each vertex. Similarly, in the case of the numbers n, n_1, n_2 and s, s_1, s_2. a is the number of times that the projection of the generalized polyhedron from its centre on to a sphere about that centre covers the sphere; a_1 and a„ are respectively the analogous numbers for a polygon which determines a face of the polyhedron, and for a polyhedral angle of the polyhedron; p is the genus of the polyhedron (the genus of all polyhedra in the first table is, of course, zero). Each polyhedron of a bracketed pair is dual to the other; the tetrahedron is self-dual.

GEOMETRIC SOLIDS IN GENERAL

The boundary of a solid may consist. of course, of several polyhedra; *e.g.,* a cube and one or more smaller cubes inside of the former. Some of these polyhedra may have points in common. The great diversity of such disconnected boundaries makes classifying them difficult; a rough classification is according to the number of pieces into which the boundary falls. As remarked earlier, the boundary of a solid may be a closed surface or consist of a number of such, or it may be a set of points of great irregularity. Solids with such irregular boundaries can be obtained by limiting processes in which certain constructions are repeated an infinite number of times.

The study of the general properties of solids of the class of solids whose boundaries are closed surfaces is made along lines suggested by the theory of polyhedral solids, a subclass of the former: for a closed surface can be transformed continuously into a polyhedron. This property may be taken as the defining property of a closed surface. The concept of genus carries over directly, when simple continuous curves are used in place of the polygonal lines and polygons of the definition of that term given above. Simple examples of closed surfaces are the sphere, ellipsoid, the surface of a cone, of a cylinder, and of an anchor ring, *i.e.,* a torus. With regard only to the primitive properties of continuity and connectivity, the first four closed surfaces are not different; the torus, however, is different from all of the other four. The genus of each of the first four is zero, that of the torus, one; it is impossible to transform continuously the torus into any of the others, but any one of the first four can be continuously transformed into any other. The similarity between the torus and the polyhedron illustrated above should be noted; the genus of each is unity and either is continuously transformable into the other. When projective or metric properties are regarded, distinctions between any two of the examples cited immediately appear. *(See* MATHEMATICAL MODELS.)

SOLID STATE PHYSICS. A solid may be defined as any body which possesses an innate tendency to return to its original form after forces have been applied to it and removed. This definition, as do most, possesses defects. Most prominent among these is the fact that the definition does not draw a sharp distinction between solids which undergo a slow permanent deformation, or creep, when they are loaded, and thixotropic liquids (*i.e.,* liquids which behave in a gelatinous fashion when small stresses are applied to them) which do not flow under small loads. The situation may be summarized best by saying that in nature there is not a sharp boundary line between those substances that we commonly think of as ideal solids and those we think of as ideal liquids.

The development of solid state physics is linked with the coniparatively recent adoption of the inductive method in science—the drawing of general principles from specific facts. in contrast to the deductive logic of the ancient philosophers, who began with generalizations and tried to fit these to the facts.

Even so great a pioneer of inductive science as Sir Isaac Newton did not believe it could go much beyond the deductive logic of Aristotle in explaining the structure of matter. In his *Opticks,* published in 1704, he wrote:

It seems probable to me that God in the beginning iormed Matter in solid, massy, hard, impenetrable, moveable Particles, of such Sizes and Figures, and with such other Properties, and in such Proportion to Space as most conduced to the End for which he formed them; and that these primitive Particles being Solids, are incomparably harder than any porous Bodies composed of them; even so very hard, as never to wear or break in Pieces; no ordinary Power being able to divide what God Himseli made one in the first Creation.

Gron-th of the various phases of solid state physics is summarized in the following section. The dominant factors in the tremendous expansion of the science in the 20th century were discovery of the structure of the atom and the industrial urgencies of the World Wars I and II.

This article is divided into the following sections:

I. Historical Development
II. Physical Properties of Solids
  1. Types of Solids
  2. Atomic Structure of Solids
  3. Chemical Composition oi Solids
  4. Principies Determining the Physical Form of Solids
  5. Elastic Properties of Soiids
  6. Plastic Properties of Solids
  7. Application of Quantum Mechanics to the Theory of Solids
III. Theoretical Methods of Treating Solids
  1. Atomic Approximation
  2. Free-Electron Approximation
  3. Treatment oi the Properties oi Solids
IV. Synthesis of Imperfections and Their Importance

I. HISTORICAL DEVELOPMENT

The physics of solids has gone. successively through a number of eras of development. each era being an essential steppingstone for the next stage of development.

Macroscopic Developments.—Starting in the 16th century a fundamental interest in natural crystals, mainly minerals, emerged along with other aspects of science. Many natural crystals show well-developed crystal faces and exhibit interesting optical or mechanical properties. Such substances were subject to systematic measurement and study with the relatively crude tools of the day. It was found that crystals often are anisotropic: that is. they exhibit different properties in different directions although they may be the same in two or more equivalent directions. By 1830 the cataloguing of the properties had revealed that all crystalline materials may be divided into 32 classes on the basis of symmetry. ranging from those which are completely anisotropic (*i.e.*, possess the same properties in no two directions) to those having the 48 symmetry elements corresponding to a cube. Correlated examination of the angles between crystal faces showed that such angles are accurately the same for a given mineral regardless of the source or the chance form of a given specimen (*see* CRYSTALLOGRAPHY). This type of study eventually reached its peak toward the end of the 19th century with the improvement of methods for making a wide variety of physical measurements on appropriately prepared specimens. The subject still has great interest since it provides information concerning the uses we may make of crystals; however. it is no longer the central field of research.

Lattice Theory.—Late in the 18th century and early in the 19th, interest arose in the origin of the remarkable regularity and symmetry propcrties of crystals. With the development of atomic theory it nas inevitably concluded that the macroscopic properties must reflect a highly ordrred arrangement of atoms or molecules. A Bravais. following earlier investigations, proposed that the molecules in crjstals are arranged in regular three-dimensional lattices, that is, all crystals possess translational symmetry in three directions. He showed that this hypothesis would explain the existence of the 32 symmetry types found in nature. The topic of lattice symmetry evolved slowly during the century but by 1890, W. Barlow, E. S. Federov and A. Schoenflies had demonstrated that 230 types of lattice symmetry (*i.e.,* 230 space groups) are possible. Unfortunately little was known about the actual arrangements of atoms in lattices although ingenious proposals were made for the simpler crystals, such as rock salt.

The subject of lattice theory came into its own in 1912 when Max von Laue and his colleagues demonstrated that the lattice spacing in typical crystals is exactly right to diffract X-rays in much the same manner that a finely ruled grating will diffract ordinary light. This discovery permitted both the development of X-ray (*see* SPECTROSCOPY, X-RAY) and the determination of the structures of many crystals. Within 10 years of von Laue's discovery the structures of many simple inorganic materials were known. During the 1920s the analysis was extended to more complex inorganic minerals. After 1930 a great advance was made in the study of organic crystals. In addition. X-ray techniques proved useful in studying imperfections in lattice structure through analysis of the deviations from ideal diffraction.

The use of X-rays was eventually supplemented by electron and neutron diffraction which provided rich additions to the harvest of material that grew with each passing year.

Electronic Properties of Ideal Crystals.—Soon after the discovery of the electron, near the end of the 19th century, great interest arose concerning the way in which electrons enter into matter. Much of this interest was focused on solids, as part of a broad investigation of the chemical and physical properties of substances. There were several attempts to develop detailed theories of particular types of solid. P. K. L. Drude and H. A. Lorentz presented a detailed theory of metals based on the notion that the valence electrons in good metals behave as a gas which is free to move under applied electric and magnetic fields. Similarly, E. Madelung and Max Born developed an electronic theory of ionic crystals which assumes that the substances are composed of regular arrays of the ions found in aqueous solutions. The theory of ionic crystals was particularly successful. By 1925 it had provided great insight into the nature of these substances. The theory of metals faced continuous difficulties. however, until the development of wave mechanics in the period between 1925 and 1928. Then rapid advances were made as a result of the application of quantum statistics and quantum mechanics (*see* QUANTUM MECHANICS: *Wave Mechanics).*

Studies of the behaviour of electrons in a potential field possessing lattice symmetry led to the development of the band theory of solids, which will be discussed below, and provided clarification of the striking differences between the ideal crystal types. In 1932 E. P. Wigner and F. Seitz discovered a practical method lor developing wave functions for simple solids. This method was extended by J. C. Slater, N. F. Mott, C. Herring and J. H. Van Vleck during the subsequent decade. By 1940 one had a fairly detailed semiquantitative picture of the behaviour of electrons in the four types of ideal solids. This subject advanced in many detailed ways after 1940.

Imperfection-Determined Properties.—During the period of clarification of the electronic propcrties of ideal crystals a new phase of study was opened. that concerned with the properties determined by imperfections in the ideal structure or arrangement. This topic developed slowly before 1940 but matured rapidly in the late 1940s. It was a well co-ordinated discipline by 1950. Just prior to World War I. K. Baedeker pointed out that the materials later known as impurity semiconductors owe their electrical properties to imperfections. namely, foreign atoms. This discovery can probably be regarded as the initial step in the evolution of the subject. In 1927 J. Frenkel demonstrated that the electrolytic conductivity of ionic crystals must be associated with mobile charged lattice imperfections. The proposed models for such imperfections was amplified in 1930 by W. Schottky and C. Wagner.

By 1934 E. Orowan and G. I. Taylor had proposed models of imperfections, termed dislocations, which explained the plastic properties of ductile crystals. Thus the full importance of understanding the nature and properties of imperfections in crystals was appreciated by 1940. The subject was not quite ripe at that time, however. for reduction to a few relatively broad principles. Such clarification came only after World War II. For a more detailed presentation of our understanding of imperfections in crystals see *Synthesis of Imperfections and Their Importance* below.

Surface Properties. — The latest phase in the development of our understanding of solids is concerned with the physical properties of the surface. Chemists had been familiar with the importance of surfaces for many decades, principally through studies of catalysis (*q.v.*) and surface adsorption (*see* ADSORPTIOS). Similarly, experiments on the emission of electrons from metals and oxides during the period from 1920 to 1940 demonstrated that surface conditions have an important bearing on the ease with which electrons can pass through crystal boundaries. In 1932 I. Tamm pointed out that one could expect special electronic states to be associated with surfaces.

The subject of surface physics received great stimulus in 1947 when J. Bardeen proposed that the properties of contacts between metals and semiconductors depended upon the behaviour of electrons in surface energy levels. After that time the subject received increased attention both through theoretical study and by the development of special experimental techniques. Presumably it would grow rapidly into a major field of scientific investigation.

II. PHYSICAL PROPERTIES OF SOLIDS

1. Types of Solids. — There are two main classes of solids: crystalline and noncrystalline. The first type. which is most thoroughly understood, is an aggregate of crystals. As a result it possesses a very high degree of order in atomic arrangement. Practically all metals and minerals are of this type. Noncrystalline solids. which include glasses, plastics and gels, are those in which the atoms and molecules are not arranged in a definite lattice pattern.

Four distinct types of crystalline solid may be recognized: (1) metals and alloys; (2) salts (ionic crystals) ; (3) valence crystals; (4) molecular crystals. Metals and alloys are distinguished by their high electrical and thermal conductivity and "metallic lustre." (For information on particular metals and other classes of solids see articles under their names.) The conductivity of metals and alloys is known to he the result of the migration of free electrons. Salts may commonly be formed by precipitation from ionic solutions and may be viewed as aggregates of charged ions. They commonly possess an ionic conductivity that increases with increasing temperature. Valence crystals are hard. often brittle, materials such as diamond, silicon, germanium and silicon carbide. The more abrasive types have high melting points. Like salts, they tend to form in accordance with the rules of valence (*q.v.*) chemistry. The atomic arrangement in the simpler monatomic types, such as diamond, has the characteristic property that each atom is surrounded by a number of atoms equal to its valence. Unlike salts, they are not ionic conductors in the pure state and cannot be formed by aqueous precipitation. Molecular crystals are solids such as dry ice (the crystalline form of carbon dioxide [CO_2]), the solid forms of the rare gases and crystals of many organic compounds, which have a relatively high vapour pressure at ordinary temperatures. Their sublimation products, such as CO_2 in the case of dry ice, are usually stable molecules.

Many alloys, salts, valence crystals and molecular crystals which are good electrical insulators at low temperatures become electronic conductors at elevated temperatures. the conductivity increasing rapidly nith increasing temperature. The electronic conductivity is usually small compared with that of the good metals, such as copper, silver or gold, in which the electrical conductivity decreases rather than increases nith increasing temperature. Such materials are termed semiconductors. In general. the class cuts across the four divisions given above. Some solids. such as silicon, germanium and tellurium, show semiconducting properties even in the highly purified state; whereas others are semiconductors only when appropriate foreign additions are present or when their composition deviates from ideal combining proportions. The two types are commonly designated as intrinsic and impurity semiconductors. Cuprous oxide and zinc oxide are typical impurity semiconductors. Actually, the conductivity of most intrinsic semiconductors can be altered substantially by suitable additions of impurities. Although semiconducting solids had been of interest because of their ability to act as electrical rectifiers from about 1920, they received relatively tremendous attention, both during and after World War II. In particular. silicon and germanium. which were available in pure form only as chemists' curiosities prior to 1940, later became the basis for vast developments in the electronics industry. During World War II, they proved to be excellent materials for diode rectifiers in the range of radio frequencies used for radar. After the war they made possible the development of triode devices, of which the surface contact transistor (*q.v.*) invented by Bardeen and W. A. Brattain was the forerunner. Acute technological interest in these materials led to purification and fabrication on a scale previously unknown in the solid state. Basic research on such pure crystals, in turn. expanded our range of understanding of many properties of solids, particularly those governed by imperfections (see *Synthesis of Imperfections and Their Importance* below).

It should be emphasized that many crystalline solids belong midway between two of these classifications since they partake of the properties of two ideal types. For example, the silicates possess properties that resemble both those of salts and of valence crystals; and there are many alloys, such as Mg_3Sb_2, which possess compositions that resemble those of ionic crystals. It may be said that most crystalline materials partake of the properties of two of the ideal types.

The foregoing classification also can be applied to noncrystalline solids if a proper point of view is maintained. Most noncrystalline organic materials possess properties that are common to molecular and valence crystals. They frequently are composed of large molecules. between which there is a relatively weak cross linkage and an occasional strong valence bond. Most glasses are compounds which lie intermediate between the ideal valence and ionic types. It is noteworthy that both ideal metals (and alloys) and ionic substances always form crystalline solids.

2. Atomic Structure of Solids. — The differences between solids may be ascribed to two factors: the differences in the forces between the atoms of which they are composed and the differences in the manner in which the atoms are arranged. It is a general principle of atomic theory that a given pair of atoms attract one another when far apart and reuel one another at small separations. (*See* ATOM.) When expressed in terms of the energy of interaction. this principle is illustrated in fig. 1. If the energy of interaction is arbitrarily chosen to be zero at infinite separation, it is found to decrease as the atoms approach one another. pass through a minimum and then increase very rapidly as the atoms are brought very close together. The separation at which the minimum occurs is that for which the forces of attraction and repulsion are at equilibrium and represents the actual separation of atoms in the diatomic molecule. The depth of the minimum and the position at which it occurs is dependent upon the chemical species to which the atoms belong Thus, the minimum is shallow for two atoms of the rare-gas type and very deep for atoms which form strong chemical bonds. The depth of the minimum is a direct measure of the strength of the bond between atoms

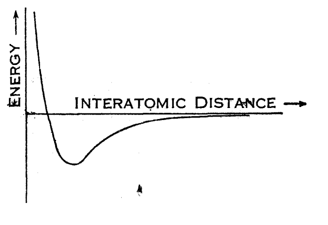

Fig. 1. — Variation of the energy of interaction of two atoms as a function of the interatomic spacing. The minimum of the curve represents the position of eauilibrium. The depth of the minimum provides a measure of the stability of the bond

The energy of interaction between a given pair of atoms usually is altered by the presence of other atoms. As a result. it is not possible in general to determine the cohesive forces in a solid by treating it as if it were composed of isolated pairs of atoms. In spite oi this it is very useful for qualitative work to regard each atom as if it were a definite spherical unit, with a fixed diameter, nhich attracts its neighhouring atoms until the spheres representing the boundaries of each come into contact. whereupon the sign of the forces is reversed. Extensive analysis of experimental observations shons that many of the properties of solids can be correlated with the use of this simple rigid sphere picture of the atoms. From the standpoint of the ultimate structure of the atom. its nucleus may be regarded as occupying a position at rhe centre of the sphere, whereas the electrons move in the volume about the nucleus.

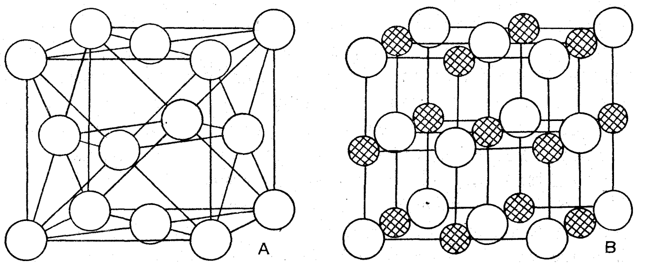

Fig. 2.—(A) The face-centred cubic lattice. About one-third of the metals possess this structure. (B) The sodium chloride lattice. One type of ion is designated by an open circle, the other by a full circle. Most of the alkali halides possess this structure, which is typical of ionic crystals

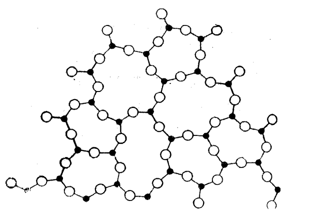
The distribution of atoms in solids may be determined with the use of X-rays. This science developed extensively after its start in 1913 and provided a large amount of exact information concerning the structure of all types of matter. The principal conclusions concerning solids that were obtained from it are the following:

a. Within each of the individual crystals or grains of which crystalline solids are composed, the atoms are arranged in a three-dimensional lattice. Typical three-dimensional lattices are shown in fig. 2. Fig. 2A shows the face-centred cubic lattice that is characteristic of many metals such as copper and nickel, whereas fig. 2B shows the lattice of sodium chloride. which is characteristic of most of the alkali halides.

b. Noncrystalline solids possess a lower degree of order of atomic arrangement than crystalline solids. In the most extreme case, which occurs in glasses (and in liquids), the immediate neighbours of a given atom are symmetrically disposed about it; however, relative to a given atom, this order does not extend beyond the first few sets of its neighbouring atoms. This difference between crystalline and noncrystalline solids is sometimes charactrrizrd by saying that the former possess both long-range and short-range order, whereas. the latter possess only short-range order. Fig. 3 shows the type of structure that is observed in the glasseous form of B_2O_3. Similarly, each silicon atom in silica glass is surrounded tetrahedrally by four oxygen atoms and each osygen atom possesses two silicon atoms as nearest neighbours. Yet, in both of these the total arrangement does not form a three-dimensional lattice as it does in crystalline quartz. The degree of order is frequently higher in fibrous materials than in glasses, for in such cases the long-chain molrcules of which the fibres are composed may be parallel to one another and linked together in such a way that there is an appreciable amount oi long-range order relative to the fibre-axis. Rubber and similar plastic substances or polymers frequently show a semicrystalline structure mhcn placed under tension.



W. H. ZACHARIASEN, JOUR. AMER. CHEM. SOC.

Fig. 3.—The two-dimensional network characteristic of boric oxide glass. The boron atoms are indicated by full circles, the oxygen atoms by open circles. It is to be* noted that the structure does not form a network with periodic or long-range symmetry

The diameter of a given atom may be found by determining the spacing between nearest atoms in the pure elemental substance. It is readily seen that the distance between the centres of such neighbouring pairs is equal to the atomic diameter. The accompanying table contains values of the atomic diameters of a number of elements that were determined in this way from X-ray data.

Diameters of a Number of Atoms and Ions

(Values expressed in units of 10^{-8} cm.)

Fl	0.75	Mg	3.20	W	2.73	Na^+	1.96
C	1.54	Zn	2.65	Pt	2.71	Mg^{+2}	1.56
Li	3.00	Al	2.86	F^-	2.66	Ca^{+2}	2.12
Na	3.67	Ti	2.89	Cl^-	3.62	Zn^{+2}	1.66
Cu	2.55	Sn	2.80	O^{-2}	2.64	Al^{+3}	1.14
Ag	2.88	Pb	3.48	S^{-2}	3.48	Fe^{+2}	1.66
Be	2.28	Fe	2.58	Li^+	1.; 6	Pb^{+2}	2.64

3. Chemical Composition of Solids.—Most solids which possess a low electrical conductivity, such as the saturated hydrocarbons and the oxides and chlorides of the simpler metals, conform to the usual rules of combining proportions that are summarized in elementary valence chemistry. Examples of this type are the alkali halides, magnesium oxide and the paraffins. This obedience to simple valence theory is reflected in the structure of these materials by the fact that their atoms are arranged in definite and simple ways. In crystalline materials each type of atom forms its own lattice and the complete lattice may he regarded as the result of combining these lattices. Similarly, in insulating noncrystalline solids, the short-range order exhibits a high degree of regularity and simplicity, as in the case of silica glass described above.

Metals, on the other hand, do not obey the usual rules of valence chemistry when they combine with one another. In the first place, they have a pronounced tendency to combine over wide ranges of composition; *e.g.*, copper will dissolve up to 30% of zinc without altering its face-centred cubic lattice structure. In the second place. they commonly form compounds the compositions of which bear little relation to the usual rules of combining proportions. Thus copper and zinc form compounds of approximate composition CuZn, Cu_5Zn_8 which have their own lattice structures.

W. Hume-Rothery and G. Hagg attempted to systematize the rules of combining proportions of metals for substitutional and interstitial alloys, respectively. Substitutional alloys have the property that as the composition is varied within the solubility limits of a given phase, atoms of one type are replaced by another. For example, atoms of copper are replaced by those of zinc as the amount of zinc in any given phase of brass is increased. Interstitial alloys differ from substitutional in that one type of atom is sufficiently small to fit into the interstices of the lattice formed by the other. Thus. only the fraction of occupied interstitial positions is altered as the composition of an interstitial alloy changes. Typical examples of interstitial alloys are those formed by dissolving carbon in iron or by dissolving hydrogen in palladium.

Hume-Rothery pointed out that substitutional alloys form for wide ranges of composition as long as the atomic diameters of the constituent elements do not differ by more than 15%. When the difference in diameter is more than this. few substitutional phases form and these possess very narrow solubility range. Moreover, he found that there is a very close relationship between the crystal structure of a substitutional alloy and the ratio of the number of valence electrons within it to the number of atoms. For example, the body-centred cubic lattice. which is characteristic of beta brass (CuZn), forms whenever the ratio of valence electrons to atoms is 1.;. In the case of beta brass, each zinc atom contributes two valence electrons and each copper atom contributes one, so that the ratio is $3:2=1.5$. The composition of the corresponding phase in the bronze (tin-copper) system has approximately the composition Cu_5Sn.

Hägg found that interstitial alloys form readily if two conditions are satisfied: if the reacting metals lie very close together in the electromotive series of elements and if the diameter of the smaller atom is less than 0.59 times the diameter of the larger. The only systems of alloys which satisfy these two conditions are those formed by combining the so-called metalloid atoms (hydrogen, boron, carbon and nitrogen) with the transition metals. such as those of the iron. platinum and palladium groups. In these systems the metalloid atoms fit into the interstices of the lattices formed by the transition metal atoms. Hagg also found that there is a close correlation between composition and structure among the interstitial metals.

It is interesting to note that two elements will not alloy well if the ratio of their diameters is larger than 0.59 or smaller than 0.85. When the ratio of diameters lies in this range the smaller atom is too large to fit into the interstices of the lattice formed by the larger, and too small to form an ideal substitutional alloy. Thus. this range constitutes something of a "no-man's land" for alloy formation. It should be added that the ratio is very near to the borderline limit of 0.59 for the iron-carbon system, Were the value somewhat larger it is entirely possible that we would have been denied the use of one of the most valuable of all alloy systems. that of steel.

The relatively feeble electronic conductivity of the intrinsic semiconductors indicates that they lie between the ideal metallic solids and the ideal insulators We shall see later (fig 6) that this transition between ideally insulating and ideally metallic solid can be given a clear picturization in terms of the energy levels of the valence electrons in solids. Practically all the impurity semiconductors also possess properties somewhat intermediate between insulators and metals Either they possess appreciable solubility for foreign atoms having appropriate size relations. or they are compounds ahich tend to form over an appreciable range of composition. Ferrous oxide (FeO), which is a typical semiconductor, frequently shows deviations from ideal combining proportions of the order of 1%. Similar deviations nere observed in zinc oxide, lead sulfide, selenide and telluride, cuprous oxide and even in specimens of the alkali halides that were transformed into semiconductors by being heated in the presence of alkali metal vapour. In such cases, the crystal lattice exhibits imperfections on an atomic scale which are distributed throughout the specimen (see *Synthesis of Imperfections and Their Importance* belou). Thus in iron oxide. some of the lattice sites that would be occupied by iron ions in the normal crystal are vacant. In zinc oxide, on the other hand. the deviation from ideal composition is associated with the presence of interstitial zinc atoms in the lattice of the oxide. Extensive experiments showed that the electronic conductivity of any one of these semiconductors increases as the deviation of the composition from the ideal value increases.

4. Principles Determining the Physical Form of Solids.— The lans of thermodynamics (*q.v.*) describe the manner in which the stable state of a system that is maintained at constant pressure is determined by the condition that the free energy

$$F=E+PV-TS \qquad (1)$$

be a minimum. Here E is the energy of the system, P is the external pressure, V is the volume, T is the temperature and S is the entropy. The variations in PT that normally occur when solids are maintained at atmospheric pressure are negligible. so that this term may be discarded. Thus. it usually is adequate for practical purposes to deal with the expression

$$F=E-TS. \qquad (2)$$

The term in TS vanishes at the absolute zero of temperature so that in this special case the equilibrium state is determined by the condition that E be a minimum. This is just the condition for the equilibrium of a mechanical system. Thus. the TS term in equation (2) has the nature of a correction factor which takes into account the influence of temperature fluctuations in altering the equilibrium state of a system from the value it would have at the absolute zero of temperature. As the temperature of a solid is raised. energy is absorbed and E grows larger. It can be shown that the entropy S, which measures the thermally induced disorder of the system, also increases. Thus the two terms on the right hand side of (2) compete with one another as the temperature is raised. the first desiring to increase and the second to decrease F. At low temperatures the atoms in solid systems tend to be in highly ordered arrangements for which E is small; whereas at high temperatures disordered states for which S is large are preferred. The tendency toward disorder as the temperature is raised may make itself felt in one or more of the following ways.

a. The atoms are set into oscillation about the positions of equilibrium at the absolute zero of temperature. This type of disordering is a universal characteristic of solids and starts as soon as the temperature is raised above absolute zero.

b. The system may decide to change irom one lattice structure to another in which the atoms have greater freedom of movement. This change is termed an allotropic transformation and is very common. For example, iron changes from the body-centred cubic to the face-centred cubic lattice at 903° C. Sulfur exhibits several different allotropic transformations which occur at successively higher temperatures.

c. Pairs of atorns of different types may interchange places, thereby disordering the lattice. This interchange is most commonly observed in alloys, for the net energy required to interchange two different atoms is smaller in these materials than in those in which the constituents are of widely different nature, as in salts. For example, at the absolute zero oi temperature the stable form of beta brass (CuZn) is a body-centred cubic structure in which one type oi atom occupies the body-centred positions and the other occupies the position at cube corners. As the temperature is raised, the different atoms at the two positions begin to change places until at 480° C. there is equal probability that a given position will be occupied by either type of atom. It is important to note that the basic lattice of the alloy remained unchanged in this type of transiormation. Only the relative likelihood oi finding a given type of atom at a given lattice site is altered as the temperature is raised.

d. In molecular crystals and in salts in which radicals appear, such as ammonium chloride, disordering may be introduced by the onset of rotation or libration oi the individual molecules or radicals. This type of disordering bears a close resemblance to that described in the preceding paragraph.

e. Disordering may result irom the migration of occasional atoms from normal positions in the lattice to interstitial position or to the suriace. In either of these events the lattice may be left with vacant lattice sites. In any given case of this type it can be shown that the number of disordered atoms, or lattice defects, per unit volume increases very rapidly with temperature, obeying the same law as the density of vapour above a liquid.

Experiments showed that diffusion (*q.v.*) and ionic conductivity in solids are intimately related to lattice defects of this type. It was shown that diffusion occurs in substitutional alloys because the vacancies produced in the lattice by the migration of atoms to the suriace are free to wander irom one lattice site to another. Their motion permits a shuffling of atoms within the lattice. Similarly, it was shown that the ionic conductivity of the alkali halides is related to the migration of vacancies in the lattice of both the halogen ions and alkali metals ions.

f. It is evident that changes from the solid to the liquid or gaseous state represent more extreme types of disordering than any of rhose mentioned above. Nevertheless, melting and sublimation End their origin in the same basic principles.

g. Metals contain iree electrons whose motion is responsible for the high thermal and electrical conductivity of the solids. The free electrons may contribute to the disorder of the solid by increasing their rate of motion. Ferromagnetism (*q.v.*) in iron, nickel and other metals and alloys originates in an ordered coupling of a fraction of the valence electrons. This order is disrupted at elevated temperatures and the ierromagnetism vanishes. For instance, it disappears at 780° C. in iron.

The onset of any given type of disorder increases the internal energy of the system and, as a result, requires the absorption of a corresponding amount of thermal energy. This absorhed energy makes itself evident either as the specific or latent heat necessary to raise the temperature. It frequently is possible to identify the nature of the disordering process by its contribution to the absorbed thermal energy. For example, the contribution to the specific heat that is associated with an increase in the amplitude of oscillation of the atoms as the temperature is raised varies as the third power of the temperature near the absolute zero of temperature and. attains a limiting value at high temperatures.

Allotropic changes, like melting, are accompanied by the appearance of a latent heat at the temperature where the phase change occurs. The observation of this latent heat is commonly used to detect allotropic changes.

The onset of order-disorder in alloys and of molecular rotation in molecular solids is usually distinguished by a very large increase in the specific heat of the solid over the temperature range neighbouring that at which the disordering. or rotation. becomes complete. In certain instances the transition is also marked by the appearance of a latent heat.

The disordering associated with changes in the state of the electrons present in the solid is also marked by thermal effects. For example. the free electrons in metals add a term to the specific heat which increases linearly with temperature. This term is particularly large in the transition metals such as iron and nickel. Similarly, the disappearance of ferromagnetism in iron at elevated temperatures is accompanied by the appearance of a peak in specific heat of the type observed during the disordering of alloys.

5. Elastic Properties of Solids.—As mentioned previously, each atom in a solid is normally at equilibrium under the action of the attractive and repulsive forces its neighbours exert upon it. The atoms take up new positions when external forces are applied to the solid, or in more technical terms the solid becomes strained. As long as the applied forces are sufficiently small, the atoms return to their original positions when the forces are relieved. A strain of this type is said to be elastic. The material is said to have been strained beyond its elastic limit if the strain is not reversible. The extent of the elastic range depends much upon the nature of the applied stresses, upon the material being stressed and upon its previous history. Most homogeneous materials are highly elastic when placed under hydrostatic pressure. In general, a tensile stress, a unidirectional compressive stress or a shearing stress is necessary for a deviation from elasticity.

Very large elastic strains were produced by hydrostatic pressure, particularly by P. W. Bridgman (*q.v.*), who employed pressures as high as 100.000 atmospheres. Changes in crystal structure may be produced by hydrostatic pressure. This pressure was used in 1953 to convert graphite into diamond. It is interesting to note that Bridgman discovered a variety of forms of ice which can exist at high pressures. most of which will sink rather than float in water.

For small pressures the relation between stress and strain is found to be linear for small stresses; however, quadratic and higher terms appear in the stress-strain relation at elevated pressures. If no phase change is induced by the pressure, the nonlinear terms usually have such sign as to imply that an ever-increasing increment of pressure is required to obtain a given increment of strain. This decrease in the compressibility of materials as the pressure increases is a consequence of the fact that the repulsive forces between atoms invariably increase with decreasing atomic separation. The linear relation between force and strain for small forces is valid only because the interatomic forces vary linearly for small displacements.

The force-strain relation is invariably linear within the elastic range whenever shearing stresses or tensile stresses are present, for in such cases the material either flows plastically or breaks before the absolute magnitude of the components of stress attain values as large as those employed in Bridgman's experiments. When a solid becomes strained under the action of applied forces, work is done upon it. The reversible component of this work represents a change in the free energy of the solid, and the elastic properties may readily be described in terms of the changes in free energy that accompany the atomic displacements associated with various strains. In most solids this change in free energy arises principally because of a change in E, the internal energy of the material; that is, the TS terms in equation (2 j above merely determine the relatively small amount by which the elastic constants at a finite temperature differ from those at the absolute zero. There are. however. notable exceptions to this rule. For example, the elastic properties of rubber are determined principally by the manner in which the entropy changes as the material is strained. The elastic constants of materials of this type are usually strongly dependent upon temperature.

***6.* Plastic Properties of Solids.**— Most noncrystalline solids, such as glasses. become brittle at low temperatures; that is, their elastic range is determined by the stresses at which they break. Many crystalline solids, however, most notably the metals. exhibit surprising ductility even near the absolute zero of temperature. This type of plastic flow was extensively examined in large single crystals and several important laws concerning it were discovered. These laws may be summarized as follows:

a. Crystals deiorm plastically as the result oi the displacement of one part of the crystal relative to another along a crystallographic plane. The planes are called slip planes (or glide planes) because one part of the crystal appears to slip relative to the other along it. The nature of the slip planes depends upon the particular material involved. For example, they are the octahedral planes of closest packing in the case of iace-centred cubic crystals and are the basal planes. which are normal to the hexagonal axis, in hexagonal crystals. There are three different types of slip planes in the body-centred cubic metals, such as alpha iron and tungsten. Under favourable conditions the displacement along a given plane is sufficiently great so that it is visihle either to the naked eye or under a low-powered microscope. In such cases the crystal gives the appearance of being composed of lamellae that become displaced relative to cine another much as the individual cards in a deck are displaced relative to one another when the deck is sheared. X-ray evidence indicates, however, that plastic flow occurs even within the lamellae that apparently move rigidly relative to one another. Thus, we may conclude that slip occurs extensively throughout the crystal even though the amount is much larger on certain preierred planes than on others.

b. The condition under which slip occurs along a given family of parallel slip planes is determined by the magnitude of the resolved shearing stress in these planes. In general, slip will occur in a given set of planes only if this shearing stress exceeds a critical value σ_c, which depends upon the previous history of the specimen and upon its purity. This limiting stress is called the critical shearing stress. It increases as the amount of plastic strain increases, a phenomenon reierred to as work-hardening. This property of solids is responsible for the fact that they become harder as they are deformed by mechanical action such as by drawing or rolling. The critical shearing stress may also be raised by the addition oi soluble impurities. It is by this type of alloying that metals such as copper, silver and gold can be made sufficiently hard for coinage. The values of the critical shearing stress for pure metals that have been annealed at elevated temperatures range between 1 and 100 kilograms per square centimetre; whereas values as high as 1.000 kg. per square centimetre are common for metals that have been work-hardened or alloyed.

c. There is a more or less well-defined temperature above which the effects of work-hardening may be removed by annealing in a reasonable time, such as half an hour. This temperature is called the resoftening temperature. In metals such as lead, zinc and tin it is near or below room temperature; however, it is well above room temperature for many useful metals. Resoftening probably occurs to some extent at any temperature above the absolute zero, although the rate is negligibly slow at temperatures below the resoitening temperature.

d. The critical shearing stress is slightly dependent upon temperature below the resoftening point; *e.g.*, the value for a specimen of very pure zinc was found to increase from 75 kg. per square centimetre to 140 kg. per square centimetre in going irom room temperature to 20° K. This means that metals retain a great deal of their ductility at low temperatures. Thus, the specimens of zinc bend under their own weight near the absolute zero of temperature.

A careful analysis of the origin of the high ductility of metals indicates it must be related to the presence of imperfections. For it can readily be shown that if two parts of an ideally perfect crystal were to be displaced relative to one another along a slip plane as rigid units. the stresses required mould be of the order of $\frac{1}{10}$ of Young's modulus (see ELASTICITY; MATERIALS, STRENGTH OF) ; that is, about 500,000 kg. per square centimetre. This is at least 1.000 times larger than the values normally observed in pure single crystals. It is interesting to note that hairlike microscopic crystals of the order of 0.0001 in. in diameter, which possess the theoretical strength, were produced by several methods. It is believed that such crystals may not contain the imperfections responsible for the ductility of most materials. Thus far such strong "whiskers'! constitute a scientific curiosity; however, they may prove to be the basis of practical developments. Two major conclusions were drawn from this analysis:

a. The planes of atoms on each side of a slip plane do not move relative to one another at once. Instead, the displacement must be propagated along the plane as a wave. Both Taylor and Orowan described imperfections which, if present in the crystal, could produce the observed results oi slip at the observed values of the critical shearing stress by moving across the slip plane. This type of imperfection is shown in fig. 4 and is called an edge dislocation. The manner in

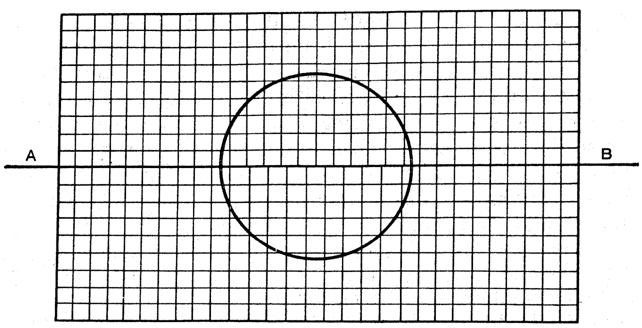


Fig. 4.—A dislocation. It is believed that this type of distortion pattern of the lattice plays an important role in plastic flow (see fig. 5). (After Orowan)

which it can produce slip is shown in fig. 5. It may be observed that there are two types of edge dislocation which produce the same effect by moving across the slip plane in opposite directions. They are called positive and negative edge dislocations. In 1938 J. M. Burgers demonstrated that other types of dislocations can play a role in plastic flow. It is known that a wide variety oi dislocations are possible.

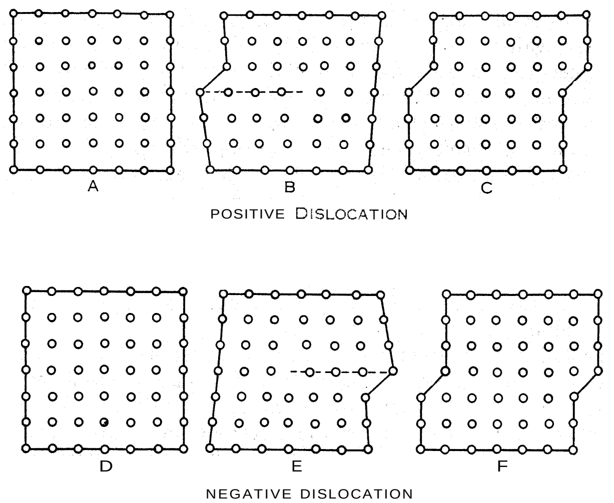

Fig. 5.—The manner in which motion of dislocations permits a crystal to flow without requiring that the slip planes move past one another simultaneously as rigid units. In the upper sequence the unit of plastic flow is produced as the result of the motion of a positive dislocation across the slip plane from left to right, whereas in the lower sequence the same unit of flow is produced by motion of a negative dislocation in the opposite direction. (After Taylor)

b. Although the stresses required to make dislocations move across the slip plane are as small as, if not smaller than, the observed values of the critical shearing stress, much larger local stresses are required to generate them in a perfect crystal. As a result, it is necessary to assume either that dislocations are produced during growth of the crystal or are generated at regions of the specimen where irregularities occur. Some of these irregularities could be regions of the specimen where tiny cracks or particles of foreign matter occur and where the applied stress is magnified by factors of the order of 100 or more. In addition, F. C. Frank and W. T. Read showed that appropriate arrays of dislocations may act to generate other dislocations in almost endless quantity. As of the mid-1950s it was not known to what extent the two types of imperfections act as the sources of the dislocations which produce plastic flow in typical materials. Probably each plays a role under appropriate circumstances.

It should be added that independent evidence for the presence of stress-raising cracks or foreign objects is provided by the observation that the rupture strength of crystals is usually much lower than would be the case if they were perfect. The weak regions used to explain the generation of dislocations are sufficient to account for the low values of the rupture strength.

The dependence of the hardness of a specimen of metal upon its previous mechanical treatment and upon its purity is readily interpreted in terms of the theory of dislocations on the basis of a principle first pointed out by Mott. If, in moving across a slip plane, a dislocatibn encounters a region of the specimen which had been strained irregularly and in which there are residual stresses which oppose the motion of the dislocation. the dislocation will not be able to proceed until the externally applied stresses become sufficiently large to reverse the sign of the stress in the regions opposing the motion. Thus, residual stresses will raise the critical shearing stress for plastic flow and harden the material. Various sources of residual stress are as follows:

a. Each dislocation is the centre of a stress field. As a result, pairs of dislocations interact with one another. Hence, as the concentration of dislocations in a specimen increases during continued plastic flow, they impede each other's motion because of the field of residual stresses they produce. This principle was made the subject of a theory of work-hardening by Taylor, who computed the relation between the increase in critical shearing stress and strain on the basis of the assumption that the positive and negative dislocations are produced in equal numbers, are arranged into a simple lattice and moved a distance of the order of one micron before becoming stuck.

b. Impurity atoms being more or less misfitted in the lattice produce stress fields which can impede the progress of dislocations and hence produce hardening. There appear to be two important ways in which the impurities or foreign atoms may affect hardening. (1) The misfit atoms are distributed more or less randomly through the lattice so that the dislocations encounter an increased resistance for motion whenever they move. The extra hardness determined by the amount of foreign material, in general, is more or less proportional to the addition. This hardness is produced by the simple alloying of metals (*e.g.,* by the addition of zinc or tin to copper). Usually the alloys retain ductility and related properties although they are less easy to deform than the pure metals. (2) The foreign atoms become attached to the dislocations and hence tend to lock them into position. This possibility was first pointed out by J. S. Koehler and A. H. Cottrell. In particular, Cottrell pointed out that the carbon atoms in plain carbon steels probably precipitate at dislocations. It is very difficult to initiate plastic flow when dislocations are locked in this way. However, the dislocations may move relatively freely once they are torn free from the locking atoms. Thus plastic flow can be continued with much lower stresses than those needed to initiate it. In other words, an alloy with locked dislocations exhibits an instability, the stress needed to initiate plastic flow being much higher than that needed to sustain it once started. Such behaviour is characteristic of steel and other alloys.

The pinning of dislocations by foreign atoms is particularly marked in valence crystals of diamond, silicon and germanium. In such cases it is necessary to hold the crystals at elevated temperatures before plastic flow can be initiated. The high temperature aids the dislocation in becoming free of the pinning atoms so that it can move relatively freely.

c. Newly formed crystals of a precipitated phase in a two-component alloy, such as small agglomerates of copper in a supersaturated solution of copper in aluminum, will distort the surrounding lattice because the average volume occupied by the atoms in the precipitate differs from that which they occupied when in solution. The residual stresses produced in this way are believed to explain the phenomenon of precipitation hardening by which copper is used to harden aluminum and beryllium to harden copper. They probably also explain the way in which martensite, a phase produced in steel by rapid quenching, hardens that alloy in normal quench-hardening.

7. Application of Quantum Mechanics to the Theory of Solids.—The most irnportant developments in the theory of solids during the years after 1930 were those arising from the application of quantum mechanics to the problem of determining the behaviour of the valence electrons. These developments permitted a much deeper understanding of the qualitative differences between the solids types than was possible before the discovery of the complete form of atomic dynamics. Moreover, they made it possible to calculate the properties of some of the simpler solids in a quantitative manner from first principles.

The mode of application of quantum mechanics to solids resembles closely the application to molecular systems in that the co-ordinates of the nuclei are treated as parameters when the wave functions for the electronic states are determined. This procedure is permissible because under ordinary conditions the electrons move so much faster than the heavier nuclei that the former may be regarded as if in a stationary state for each position of the nuclei even when the latter are in motion) as when executing thermal vibrations. This method of separating the electronic motion from the nuclear motion was first introduced by M. Born and J. R. Oppenheimer and can be shown to be accurate for most practical problems.

The complete wave function for the electrons in a solid is much too complicated to determine in a precise form. As a result the following simplifications are usually made in solving problems.

a. The electrons in the inner shells of an atom, which are not appreciably affected by changes in chemical binding, are treated as though part of the nucleus and their influence upon the valence electrons is taken into account by assuming that they merely contribute a static potential field which is centred about the nucleus.

b. In first approximation each valence electron is assumed to possess its own wave function. This approximation, which is known as the Hartree-Fock scheme, or the one-electron approximation, does not neglect the interaction betueen the valence electrons; however, its use is equivalent to assuming that the interaction between electrons can be taken into account by a field similar to that which is used to express the influence of the electrons in inner shells. It is easy to show that this approsimation is rather rough and that the results obtained from it are mainly of qualitative value. The principal advantage gained from its use is the fact that the motion of each electron can be described independently; that is. each electron can be assigned its own constants of motion. This procedure is always to be regarded as a first approximation to the correct one.

There are two ways in which the one-electron approximation is commonly used. The choice between the methods is made in each case on the basis of physical reasonableness. The two methods are:

Atomic Approximation.—In this scheme it is assumed that each electron is attached to a given nucleus or group of nuclei, much as if it were in an isolated atom or molecule. Thus, the entire solid has the aspect of an aggregate of atoms or molecules. Since the electrons are bound to definite nuclei, the solid described in this way is always an insulator; that is, the electrons are not free to move about the solid. This approximation is particularly good when one is describing the normal state of a rare-gas solid such as solid argon, a molecular solid such as solid methane or any molecular solid with a low boiling point, or an ionic crystal such as one of the alkali halides. In the last-named case, the units to which the electrons are bound are positive or negative ions rather than neutral atoms or molecules.

Free-Electron *Approximation*.—In this scheme it is assumed that each valence electron is free to wander throughout the lattice so that the wave function used to describe it has a finite amplitude throughout the specimen. In the simplest case this wave function has the same form as that for a free electron; however, the approximation is not restricted to this simple situation. At first sight it appears that a solid which is described with the use of free-electron functions must always be a metallic conductor, since the electrons are free to wander everywhere. Actually, this is not the case, for as we shall see below, the motion of the electrons is restricted by the Pauli exclusion principle; in certain cases this principle limits the electrons in such a way that they cannot conduct a current. It can be shown that the ground state of any insulator may be described with equal accuracy with the use of either the free-electron approximation or the atomic approximation. Thus, the free-electron approximation is of more general use than the atomic approximation in treating the normal states of solids.

Since the ground state of an insulating solid can always be approximated as well with the free-electron picture as with the atomic picture. whereas the ground state of metals can be described only with the first method, one may reasonably ask why the second should ever be used. The answer to this question lies in the fact that the excited states described by the two schemes differ in notable respects and that both types of excited state are observed in practice. Any neutral atom or molecule is characterized by the fact that it possesses a number of excited electronic states in which the electrons are bound to the nuclei. Similarly, a solid which is described with the atomic approximation may possess excited electronic states in which the excited electrons are bound to definite atoms or molecules so that the solid is not conducting. On the other hand, it can be shown (see Free-Electron Approxintation, below) that an excited state of a solid that is described with the use of the free-electron approximation is always conducting, even though the ground state represents an insulator. Thus, the atomic approximation can describe excited states that cannot be treated appropriately in the free-electron approximation. Since these nonconducting excited states have been observed in the alkali halide crystals, we may conclude that the atomic approximation is the more appropriate one to use in such cases.

To summarize. it may be said that the free-electron approximation can always be used as a first approximation when describing metals and the ground state of insulators. On the other hand, the atomic approximation is frequently better when the excited states of insulators are being described. It may be noted that the atomic approximation has sufficient flexibility to describe conducting excited states of insulators. These are the analogues of the ionized states of atoms and molecules. Neither of the one-electron approximations is perfect in any given case, since neither ever furnished an exact solution of the equations of the quantum mechanical equations of motion.

In spite of this defect. the one-electron schemes provide us with useful qualitative pictures of the behaviour of electrons in solids and give us a clear insight into many experimental facts which were not understood before the development of quantum mechanics. The difficult problem of modifying the approximations so as to give a more exact solution was solved only in a few simple cases in which special methods were used. More exact solutions were obtained in the case of the alkali halides, for which the atomic scheme is almost exact, and in the alkali metals, for which the free-electron approximation is almost correct. The development of high-speed. digital electronic computers after 1945 made it possible to apply the approximate methods of handling the theory more widely than was possible prior to World War II. The machines serve as labour-saving devices and reduce the drudgery of extensive calculations. (See COMPUTING MACHINES, ELECTRONIC; OFFICE MACHINES AND APPLIANCES.) We shall now survey the on -electron approximations more fully and illustrate their application to the important problems of the solid state.

III. THEORETICAL METHODS OF TREATING SOLIDS

1. Atomic Approximation. — In applying the atomic approximation to insulating solids we may employ most of the concepts which are gained from a study of the behaviour of isolated atoms and molecules. Most important of these are: (1) electrons move normally in orbits which are clustered into groups of nearly equal energy, called the electron shells, and (2) no two electrons can move in a given orbit unless they have opposite spin. The second fact is simply one form of statement of the Pauli exclusion principle (see also NUCLEUS; PERIODIC LAW; SPECTROSCOPY). which has universal applicability. This principle can also be expressed by saying that no two electrons can have the same one-electron wave function unless they possess opposite spin and in this form can be applied to the case in which the free-electron approximation is being employed.

As noted in the preceding section, a solid described by the atomic approximation is necessarily an insulator because the valence electrons are not free to roam about the specimen. In addition, it may remain an insulator when the electrons are excited to higher states of motion provided the orbits of the excited electrons are still bound to the atoms. The excited electrons will always become free if given sufficient energy for the same reason that atoms and molecules become ionized when excited sufficiently, viz., only a finite energy is required to remove any electron from an atomic system. If the specimen is excited by irradiation with light there may be certain ranges of frequency that are absorbed, but which do not make the crystal conducting. This is the case in which there are nonconducting excited states. On the other hand. as the energy of the light quanta increases sufficiently there will come a point at which the electrons are freed and the specimen becomes photoconducting. Most of the common insulating solids behave in the manner which is to be expected from this model. That is, they do not become conducting when irradiated with the longest wave lengths which are absorbed by the atoms of the bulk material.

The insulating solid may contain impurity atoms, a stoichiometric excess of one of the constituents or imperfections. In this case, the electrons attached to the foreign atoms, or those in the vicinity of the imperfections, will not be bound in the same way as the electrons of the bulk solid. They will. as a result, have their own characteristic excited states and ionization potentials. If these excited levels lie closer to the ground state than those of the bulk solid, the longest wave lengths of light absorbed by the specimen will be characteristic of the foreign atoms or imperfections. Hence, an impure crystal may become photoconducting as a result of its impurities. Most photoconducting solids that are used in practice are of this variety. If electrons may be freed from the atoms of an insulator by thermal fluctuations at ordinary temperatures the solid evidently is an intrinsic semiconductor. Similarly, if an otherwise ideal insulator contains foreign atoms which may be ionized thermally at normal temperatures the material is an impurity semiconductor.

2. Free-Electron Approximation. — Electrons moving in identical orbits on different atoms have the same energy in the atomic approximation. As a result, the energy level spectrum of the electrons resembles closely that for a gas. On the other hand, it is generally true that the electronic states have different energies in the free-electron approximation. We do not have sufficient space to enter into a detailed discussion of the free-electron wave functions and their energies; however, the pertinent facts map be summarized in the following manner.

a. The energy levels of the states of individual electrons may be grouped into bands which are nearly continuous. The separation of neighbouring levels in a band decreases with increasing size of the specimen and is so small in all practical cases that it cannot be resolved by any direct means of measurement.

b. The different bands of levels may be separated or may overlap, depending on the material being investigated (fig. 6, A and B). The principal factors that determine whether or not the bands overlap are: (1) the magnitude of the variation of the potential fields from position to position within the solid and (2) the crystal structure. In general, the larger the likelihood that the bands will be separated the larger the fluctuations in field intensity. It is more likely that the bands will be separated in a monatomic solid containing quadrivalent atoms, such as carbon, than in one containing alkali metal atoms, for the field electrostatic strength will be larger and will fluctuate more strongly in the first case. Similarly, it is more likely that the bands

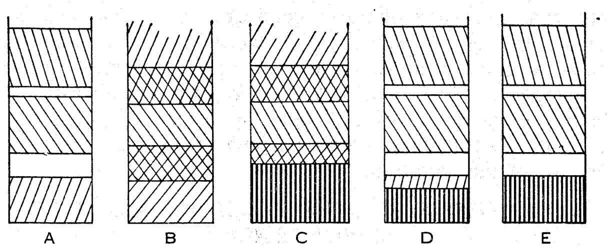

Fig. 6.—Energy levels of the electrons in solids and the manner in which they are occupied by electrons. The shaded area designates quasi-continuous bands of levels; the darkened area indicates occupied levels. (A) A situation in which the quasi-continuous bands of levels do not overlap. The gaps represent forbidden regions of energy. (B) A case in which the bands of levels overlap. (C) The manner in which the electrons fill the levels in a case in which the bands overlap. This case always represents a metal since the occupied levels border unoccupied levels infinitely closely. (D) A case in which the bands do not overlap and in which the uppermost occupied band is only partly filled with electrons. This situation represents a metal. It is unknown in practice. (E) Same as (D) except that the occupied region extends to the top of the highest occupied band. This solid is an insulator

will be separated in a salt containing strongly charged ions than in a monatomic solid in which each is neutral.

Although the spacing between levels in a band is very small, the actual magnitude is of practical importance because of the Pauli exclusion principle. A specimen solid of ordinary size contains of the order of 10^{23} atoms and hence has at least that number of valence electrons. Qnly two electrons at most may possess the same wave function and these must have opposite spin. Although the energy levels are degenerate (that is, more than one wave function is associated with each), the degeneracy is small so that only a few electrons may occupy any given level. As a result the electrons are distributed over a large number of levels, or over a large range of the spectrum. In the normal state of the solid the occupied levels will be those which lie as low as possible. Thus. all levels below a given point in the spectrum will be occupied as densely as possible. It is evident that the width of the occupied region depends upon the spacing of levels; hence, the importance of this spacing.

It can be readily shown that under normal conditions the electrons in the densely occupied portion of the spectrum are so paired that there is no net flow of current in spite of the fact that each electron is moving through the solid at a very rapid rate. In other words, for each electron moving in one direction in the solid there is another moving in the opposite direction with equal speed. If the bands of levels overlap, it follows that the uppermost occupied level of the energy spectrum is always very near to the lowest occupied level (fig. 6, C). Hence, when this type of solid is placed in even a very weak electrostatic field some of the electrons are excited from the occupied to the unoccupied levels, statistical balance between motions of electrons is upset and an electrical current flows. This situation is evidently characteristic of a metal. We may conclude that any solid in which the top of the occupied region is very close to unoccupied levels is a metal. This situation evidently will always obtain when the bands overlap. It will also obtain if the bands do not overlap and if the top of the occupied band does not extend to the upper edge of the highest band occupied (fig. 6, D).

If, however, the bands do not overlap and if the occupied range extends to the top of a band (fig. 6, E), the solid will not be a metal. For in this case the statistical balance between electrons can be disturbed only if the externally applied electrostatic field is so large that electrons can be stimulated from the highest occupied band to the lowest unoccupied one. The field usually required to do this is of the order of 1,000,000 volts per centimetre. Thus, in the free-electron approximation, an insulator is described by the situation shown in fig. 6, E in which the occupied region is separated from the unoccupied one by a large margin.

If the spacing between the highest filled band and the lowest empty band is sufficiently small in the case corresponding to fig. 6, E, electrons may be thermally excited from the lower to the upper band. A solid of this type will be a semiconductor even when pure and having ideal stoichiometric composition. That is, it will be an intrinsic semiconductor. Intrinsic semiconductivity of this type has been found in germanium, silicon and diamond. One can determine the width of the gap from the dependence of electronic conductivity upon temperature in such cases.

It should be emphasized that the crystal gains conductivity for two reasons when an electron is removed from a filled band and transferred to an empty band (see fig. 7): (1) it contains an unimpeded electron in the empty band and (2) the electrons in the filled band are no longer completely impeded, for one electron is absent. The filled band from which an electron is removed is said to contain a hole. It is conventional to describe the conductivity associated with the absent electron in terms of the presence of the hole, much as one gives individuality to a bubble or void in an otherwise filled container of liquid. The hole behaves as a positively charged particle, complementary to the electron, since it is derived by subtraction of an electron from an otherwise neutral system. It is possible to show that the hole behaves as a positive charge in the presence of both electric and magnetic fields.

Considerable success was achieved in determining the arrangements of bands and the manner in which they are occupied for a large number of simple solids. Reasonably accurate diagrams of the bands are available for many relatively simple metals and salts and for valence crystals such as diamond, silicon and germanium.

Van Vleck and H. Brooks developed a method for relating the behaviour of the electrons in simple solids to the behaviour in the free atom without solving the equations of quantum mechanics directly. This method is successful in treating the cohesive properties of a number of simple solids, particularly the metals. In a sense, the procedure enables one to relate the properties of the solid to easily measured properties of the free atoms without resorting to all the complexities of solving the basic equations of the theory.

3. Treatment of the Properties of Solids.—The solution of the equations of quantum mechanics obtained by use of the methods described in the previous sections were used to correlate many of the properties of solids. The following are the most important of these.

Cohesion.—The cohesive energy of a solid may be expressed in terms of the energy required to remove an atom from the surface to infinity; that is, the heat of sublimation. This quantity can be computed once the energies of the electrons are known. The one-electron approximations usually are not sufficiently good to give accurate values of the cohesive energy so that better approximations must be found. Such calculations were made of a number of simple solids, such as the alkali metals and the alkali halides, and the agreement obtained with experiment leaves little doubt that quantum mechanics can give reliable answers to problems involving the bonding of solid matter. The foregoing methods were much more widely used to obtain estimates of the relative magnitudes of the cohesive energies of different solids. H. Jones succeeded in giving a satisfactory interpretation of the Hume-Rothery rules (see Chemical *Composition* of Solids, above) with the use of the band approximation and thereby explained the importance attached to the electron-atom ratio in substitutional alloys. The same procedure mas used to explain the comparatively great stability of the metals containing partly filled d and *f* shells.

Electrical Conductivity.—Solids may conduct electricity because they contain either mobile ions or free electrons. In the first case, the quantity determining the conductivity is the probability that a given ion will become sufficiently free, as a result of thermal fluctuations, to jump from one equilibrium position to another. This process was examined in detail for a number of simple salts and as a result. many aspects of the subject became fully understood.

One of the greatest successes incurred in the application of quantum mechanics to solids was the understanding of the nature of electronic conduction in metals and semiconductors. The theory provided a much deeper insight into the nature of the current carriers in these solids and the manner in which they move. It became known that metals would possess an infinite electrical conductivity if all of the atoms were at complete rest and the lattice were perfect. The conductivity is finite only because the free electrons which are accelerated by the applied field are deflected from their course by imperfections in the lattice. Most important of these in a pure material are those caused by the thermal vibrations of the lattice. However, foreign atoms play an important role in raising the resistivity in impure metals and in alloys.

It is apparent that the free electrons in a metal attempt to avoid one another because of the repulsive forces originating in their identical negative charge. As a result. a free-electron gas does not behave quite the same as a perfect gas of neutral atoms. Cnder certain circumstances the electrons undergo highly co-operative motion. This co-operative behaviour is normally treated in the plasma theory of electron behaviour. first developed systematically for solids by D. Bohm and D. Pines.

The phenomenon of superconductivity. which is observed in some metals at very low temperatures. excited interest after it was first discovered by K. Onnes in 1911. A number of metals, such as lead and tin, abruptly lose all their resistivity on being cooled below some temperature near the absolute zero. The onset of superconductivity is accompanied by a marked change in magnetic properties. In effect the superconductor attempts to expel the lines of magnetic force from the metal or to become an ideal diamagnetic. Stimulated by the observation that the transition temperature at which superconductivity occurs depends upon the composition of isotropic masses present in the specimen. H. Frohlich and Rardeen proposed that the conduction electrons became interlocked with the lattice vibrational waves in the superconducting state in such a manner that the metal behaves as an insulator in which the gap between bands is exceedingly small. This approach has been developed by L. Cooper, T. Schrieffer and J. Bardeen into a very promising semiquantitative theory of the phenomenon.

A typical specimen of a ferromagnetic metal, such as iron, is not homogeneously magnetized but can be divided into blocks or domains which are magnetized in different directions. It can be shown that the energy of the system is lower in the absence of an externally applied magnetic field if domains are present. L. Neél demonstrated that the observed patterns of domains can be explained on relatively elementary principles regarding the interaction of one part of a magnetized specimen with another. much as one can discuss the stable orientations of simple bar magnets.

For many years magnetic iron oxide, magnetite (Fe_3O_4), a ferromagnetic insulator, was regarded merely as an interesting curiosity. During World War II, J. L. Snoek developed a number of similar oxides which proved to have useful magnetic properties. Such ferrites found service in many high-frequency applications because the eddy current losses are small.

One aspect of magnetism which received considerable attention after the war is that associated with the changes in absorption of high-frequency radio waves which occur when materials are placed in magnetic fields. The energy of the nuclei and the electrons will depend upon their orientation relative to the magnetic field if they have a resultant magnetic moment; that is, if they behave as tiny magnets. Nuclei of odd mass number and unpaired valence electrons usually have a magnetic moment. Radio waves of an appropriate frequency can induce changes in the orientation of the electrons or nuclei and thereby lose energy to the solid. Studies of such magnetic resonance furnished a great deal of information concerning the properties of solids and other systems. (See also ELECTRICITY., CONDUCTION OF).

Magnetic Properties.—The quantum theory was widely used with outstanding success in the exploration of the magnetic properties of solids. It served to give a clear-cut explanation of the origin of the differences between diamagnetic. paramagnetic and ferromagnetic substances. Moreover, it made possible the development of detailed pictures of the properties of materials in each of these categories. Most prominent among these were: the theory of the paramagnetism (*q.v.*) of simple metals developed by W. Pauli; the theory of ferromagnetism developed by W. Heisenberg, F. Bloch and a number of other investigators: the treatment of the paramagnetic salts by Van Vleck; and the investigation of the strongly diamagnetic metals, such as antimony and bismuth, by Mott and Jones.

Optical Properties.—As in the preceding cases, the application of quantum mechanics offered a good explanation of many of the optical properties of solids which were previously mysterious. Perhaps the greatest advance was made in the treatment of metals. For example, the free-electron theory gives a straightforward explanation of the colour of gold and copper and of alloys such as brass. and nhy the alkali metals become transparent in the ultraviolet part of the spectrum.

IV. SYNTHESIS OF IMPERFECTIONS AND THEIR IMPORTANCE

In the preceding sections it was seen that imperfections play an exceedingly important role in determining some of the most interesting and useful properties of crystals. Among these are the electronic conductivity of semiconductors, the electrolytic conductivity of salts and the plastic properties of all ductile materials. There was ample appreciation of the importance of imperfections prior to 1940; however, one might have supposed at that time that an essentially unlimited number of imperfections were possible and that new imperfections would be introduced almost indefinitely to describe the various properties of solids. Actually. the number required is relatively small and a substantial part of the seeming complexity of imperfection-determined properties arises through the circumstance that a small number may play an intricate role by the combination of individual behaviour and complex interactions.

The principal imperfections appear to be the following.

Lattice Vibrations (**Phonons**).—Since the atoms in crystals interact with forces that obey Hooke's law (see ELASTICITY; MATERIALS. STRENGTH OF) to a first approximation. they can be made to vibrate. Such vibrations are stimulated by heating the crystal; *i.e.*, raising its energy. The simplest mode of vibration is obtained by allowing a sound wave of fixed frequency and direction of motion to pass through the crystal. Vibrational waves of this type can exhibit particle properties, for their energies are limited to discrete values. much as are the energies of light waves or light quanta. As a result the vibrational waves are frequently termed phonons. by analogy with the term photons employed for light waves.

If there is a random group of vibrational waves, as when obtained by heating the solid. the waves may interfere with one another both constructively and destructively. Thus the phonons may impart a large amount of energy to a single atom when the constructive interference is appropriate. Such an event corresponds to a large thermal fluctuation, which may be sufficient to eject an atom from a normal position in the lattice or cause a similar change.

Free Electrons and **Holes** in Insulators.—As mentioned. the ideal insulating solid is one in which an uppermost filled band is separated from an empty one by an appreciable energy gap. Such an insulator becomes conducting if free electrons are introduced into the empty band and free holes are introduced into the filled band (see fig. 7). The conductivity depends upon the number of free electrons and holes and the ease with which each moves. It is clear that free electrons or free holes in an otherwise perfect insulator can be looked upon as a type of imperfection. A free electron in an insulator behaves in much the same way as a free electron in a vacuum. However, as was seen previously, a free hole behaves as a positively charged particle, originating in the dearth of an electron.

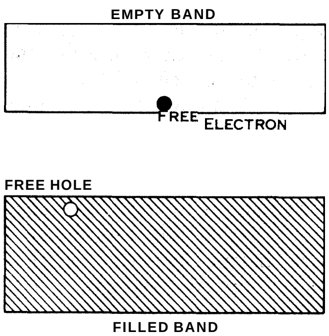

Fig. 7.—Schematic diagram showing a free electron in the otherwise empty conduction band and a free hole in the otherwise filled valence band. Both the electron and the hole may contribute to the conductivity of the insulator. An electron–hole pair may be produced by exciting an electron from the filled to the empty band. The hole and electron have an electrostatic attraction for one another and may form a bound (exciton) state, analogous to the bound state of the electron and proton in the hydrogen atom

Excitons.—A hole and an electron in a given insulator have opposite charges and, as a result, attract one another in accordance with the Coulomb law (see ELECTRICITY). Just as an electron and a proton in a hydrogen atom have bound states in which the two particles rotate about a common centre. an electron and a hole can form a bound state in which they move about as a closely coupled unit. This unit carries no charge because the two opposite charges compensate. It can, however, transport energy from one part of the crystal to another. In place of regarding the exciton as formed by the coupling of a free electron and a free hole, one can view it as generated by the excitation of the insulating crystal to an excited electronic state. similar to the discrete states of an atom which lie below the ionization limit. The coupled electron–hole pair is commonly termed an exciton. It is relatively difficult to detect, except by indirect means, because it is uncharged and cannot be deflected easily by electric or magnetic fields. Excitons were detected, however, in salts such as the alkali halides and cuprous oxide. They play probably an important role in many photochemical processes involving solids. This is particularly true in cases in which energy associated with incident light is absorbed in the interior of a crystal and plays eventually a role in a chemical reaction at the surface. In such cases the energy may be transferred from the interior, where the light was absorbed, to the surface by means of excitons.

Vacancies and Interstitial Atoms. — Thermal fluctuations can disorder a lattice at sufficiently high temperatures. Atoms may be driven from normal lattice sites' into interstitial positions, thereby producing vacant lattice sites or vacancies and interstitial atoms. Such imperfections can, either in unison or independently, contribute to the transport of atoms from one region of the solid to another; *e.g.*, one of the atoms in a normal site neighbouring a vacancy may jump into the vacancy and thereby gain a freedom of motion which it would not have if the vacancy were absent. It is evident that the vacancy is somewhat the counterpart of a hole in a filled band of electronic states. In the same way, an interstitial atom may push a neighbouring normal atom into another interstitial place and replace it at the normal site. Thus interstitial atoms may also impart freedom of motion to the typical atoms of a lattice. The migration of thermally induced vacancies and interstitial atoms is responsible for diffusion and electrolytic conductivity in most solids.

Vacancies and interstitial atoms can be produced pairwise by bombarding a lattice with fast particles such as protons, neutrons and electrons produced by high-voltage accelerators. The defects may also be produced by radioactive disintegrations of atoms within the lattice. Such changes in the lattice are conventionally referred to as the results of radiation damage. Studies of such damage and its recovery give exceedingly valuable information on the behaviour of interstitial atoms and vacancies in typical solids.

Foreign Atoms. — Foreign atoms may modify the properties of crystals in many ways. As was seen, atoms which have loosely bound electrons or holes may transform an insulator into an impurity semiconductor. Similarly. appropriate foreign ions in ionic crystals may be accompanied by vacant lattice sites or interstitial atoms which are attached relatively loosely and mhich become free at normal temperatures and thereby increase both electrolytic conductivity and diffusion. For instance, divalent ions such as Ca^{+2} replace two Na^{+} ions when dissolved in NaCl. The calcium ion occupies one site but the other is vacant and may become mobile. Similarly. S^{-2} can be dissolved in silver chloride by substituting for Cl^{-}. The ion is acco'mpanied by an interstitial Ag^{+} ion in an interstitial site.

Extra electrons associated with foreign atoms in insulating solids usually absorb and emit their own characteristic frequencies of light. Thus, such foreign atoms may absorb or emit radiation and render the crystal fluorescent. It is also possible for the crystal to possess intrinsic fluorescence; that is, to absorb and emit light even when pure.

Dislocations. — The dislocation is the most intricate of the imperfections in the lattice. We saw previously that it was first introduced in order to explain plastic flow in ductile solids. However, it has many other properties. Dislocations of the type shown in fig. 4 may act as relatively easy sources or sinks for vacancies or interstitial atoms. Such imperfections can be produced by thermal fluctuations at dislocations in the interior with the same ease as at the crystal surface.

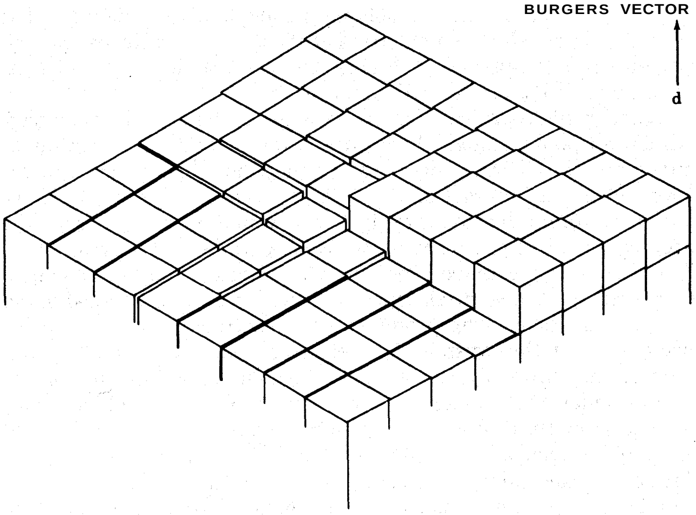

Fig. 8.— Schematicdrawing of the region where a screw dislocation breaks through the surface of a crystal (after F. C. Frank). As on a spiral staircase, one can pass continuously from one crystallographic plane normal to the dislocation to the next by passing around the dislocation. The ridge or step associated with the terminus of the dislocation on the surface may act as a region of catalytic activity or as one for nucleation of growth or solution of the crystal

Another dislocation introduced by Burgers in 1939, termed a screw dislocation, can terminate at a ridge on the surface as shown in fig. 8. The name is derived from the fact that the crystallographic planes which would normally be at right angles to the axis of the screw dislocation wind about the dislocation line similar to the surface of a screw. The ridge (Burgers vector) shown in fig. 8 remains, even if the crystal grows or dissolves by the addition or subtraction of atoms to or from the ridge. An imperfect surface region of this type. produced by an intersection of a screw dislocation at the surface, is an ideal catalyst for the growth of the crystal by deposition of atoms from solution or from the vapour. This characteristic property of the screw dislocation was pointed out by W K. Burton, N. Cabrera and Frank. in 1949. It led to a new understanding of the mechanism of crystal growth from solution or vapour when the degree of supersaturation is low.

The regions where dislocations break through to the surface can be detected by etching the surface with appropriate reagents. The point of emergence becomes the centre of an etch pit. Studies of such etch pits give much valuable information concerning the properties of dislocations.

Interaction of **Imperfections.**—Many of the most interesting properties of crystals are the result of the interaction of two or more imperfections. Lattice waves or phonons may interact with electrons and holes and affect the current flowing through a crystal. Similarly, impurity atoms of an appropriate type may capture free electrons or holes produced by light or other means of excitation and prevent them from contributing to the current. When edge dislocations are forced to move, as during plastic flow, it appears that they leave a trail of vacant lattice sites which can enhance diffusion and other atomic migrational processes in crystals.

Dislocations, particularly those present after plastic flow, which are someuhat irregular, can capture free electrons and holes.

Negative ion vacancies in salts, which are positively charged, may capture free electrons and produce what can be regarded as new imperfections. These neutral units are termed F-centres. They alter the colour and many other properties of the specimens containing them. They may be introduced in controlled amounts by heating an alkali halide crystal, such as sodium chloride, in alkali metal vapour. An excess of metal is absorbed by the crystal but actually appears in such a form that some of the halogen ions are replaced by electrons. Extensive investigations of the alkali halides containing F-centres by R. W. Pohl and his colleagues made the topic an almost self-sustaining field of science. The vacant lattice sites which are necessary for F-centres can be produced in a number of ways; *e.g.*, by plastic flow or by irradiation with ultraviolet light or X-rays.

When a photographic film is exposed to light. a latent image which can be developed chemically is formed within the grains of silver bromide. The process of forming the latent image appears to involve the interaction of a large number of imperfections. The first comprehensive physical theory of the process from the atomic point was put forward by R. W. Gurney and Mott in 1938. The theory was extended somewhat after that time but remained unaltered in its essential aspects. Gurney and Mott postulated that the incident light produces free electrons and holes which wander about the crystal. The electrons become trapped at imperfections, probably dislocations, although possibly at foreign atoms under the proper circumstances. The trapped electrons attract interstitial silver ions which are produced thermally and are mobile even at room temperature. Clusters of silver atoms formed by the union of electrons and interstitial ions in this way constitute the latent image. Such specks of silver may catalyze the transformation of the entire grain into free silver when a developer is present. The deposition of silver atoms at dislocations in silver bromide was demonstrated by J. W. Mitchell. S. Amelinckx demonstrated in a similar way that F-centres in the alkali halides will precipitate along dislocations if the crystals containing F-centres are held at a temperature where the formation of colloids is favoured.

SOLIHULL, a municipal borough in Warwickshire, Eng.. 8 mi. S.E. of Birmingham, became a separate division of the parliamentary county of Warwick in 1948. Pop. (1961) 96,010. Area 31.5 sq.mi. Though mainly a residential area for Birmingham. Solihull has motor car and light industries.

The parish church of St. Alphege, with its 13th-century chancel. is the most important old building. Solihull hall (14th century), Grimshaw hall (16th century) and Old Berry hall (partly moated) are timber framed. Packwood house (15th century) is owned by the National trust and has a unique yew garden. Solihull school was in existence in 1560.

The borough of Solihull, constituted in 1954, includes, besides the central area of Solihull. Shirley, Olton and Sheldon.

SOLIKAMSK, a town in Perm *oblast* in the Russian Sdviet Federated Socialist Republic of the U.S.S.R., stands on the small Usolka river, 7 mi. above its confluence with the Kama. Pop. (1959) 82,000. The town, probably'the first Russian settlement in the Urals, was founded in the early 15th century as a salt-mining centre and it has remained so to the present. Its deposits of potassium salts are among the world's largest. The important chemical industry based on them produces fertilizers, chlorides, bromide, sulfides and industrial alcohol. The magnesium works are the largest in the U.S.S.R. A railway and highway join the town to Berezniki on the Kama.

In 1959 the satellite town of Borovsk was merged with Solikamsk. (R. A. F.)

SOLIMAN: *see* SULEIMAN I; SULEIMAN II.

SOLINGEN, a town in North Rhine-Westphalia, Ger., on a height above the Wupper, 13 mi. E. of Diisseldorf, and 20 mi. N.E. of Cologne. The population in 1959 (est.) was 168,455.

Sword blades have been made there since the early middle ages, and tradition affirms that the art was introduced during the Crusades by smiths from Damascus.

Solingen is one of the chief seats of the German iron and steel industry, its specialty consisting in all kinds of cutlery, knives, razors; scissors, files, steel frames and the like, produced in enormous quantities. Other metalwares are also manufactured. These articles are largely made by the workmen at their own homes and supplied to the depots of the large dealers.

Solingen received its municipal charter in 1374.

SOLIPSISM (Lat. *solus,* "alone," *ipse,* "self"), in philosophy, a term originally applied to moral egoism (*q.v.*) but now used in an epistemological sense to denote the extreme form of subjective idealism which denies that the human mind has any valid ground for believing in the existence of anything but itself. F. H. Bradley, in his *Appearance and Reality,* characterized the solipsistic view as follows: "I cannot transcend experience, and experience is *my* experience. From this it follows that nothing beyond myself exists; for what is experience is its (the self's) states." Presented as a solution of the problem of explaining our knowledge of the external world (see KNOWLEDGE, THEORY OF), it is generally regarded as a *reductio ad absurdum. See* further IDEALISM; and compare PHENOMENALISM.

SOLÍS, JUAN DÍAZ DE (1470?–1516), Spanish navigator and one of the early explorers to enter the Rio de la Plata estuary. As a pilot major of Spain he led an expedition which left San Lúcar de Barrameda, Spain, on Oct. 8, 1515, in three ships. After touching the coast of modern Brazil around Cape São Roque, he sailed down the east coast of South America and in Jan. 1516 reached the Rio de la Plata (River Platej which he called Mar Dulce. He entered the estuary and named the first island he found Martin Garcia after one of his sailors who had died. Sailing partly up the Uruguay river, he landed with eight men on the left bank, in modern Uruguay, inhabited at the time by the Charrúa Indians, who attacked his party while they were taking possession of the land for Spain. All but one were killed and eaten by the Indians in sight of the remaining crewmen on the ships. Francisco del Puerto, the sole survivor, was made prisoner, and later gave valuable information about the area to Sebastián Cabot when he arrived in the region in 1526.

The ships sailed back to Spain, but one was wrecked off the island of Santa Catarina near the south coast of Brazil, and 11 of the crew saved themselves by swimming ashore. Survivors of this group were rescued by Sebastián Cabot and told him of great wealth in the interior of South America. Cabot, as a result, sailed south, entered the Rio de la Plata and ascended the Paraná river looking for the kingdom of silver. After 1948 Argentine historians accepted the contention of their colleague (Roberto Levillier) that Amerigo Vespucci and not Solís discovered the Rio de la Plata, as early as 1502. (F. L. HN.)

SOLITAIRE, the name given to certain American birds of the thrush family (Turdidae) and to an extinct flightless bird. The present-day solitaires (*Myadestes* and *Cichlopsis* speciesj are noteworthy songsters. The best known is Townsend's solitaire (M. *townsendi),* found in the Rockies from Alaska to northern Mexico; it is a slim gray bird

AMBLER - NATIONAL AUDUBON SOCIETY

TOWNSEND'S SOLITAIRE (MYADESTES TOWNSENDI) OF WESTERN NORTH AMERICA with a white eye-ring, white sides of the tail and a buffy wing patch.

The extinct solitaire (*Pezophaps solitaria*), which formerly lived on the island of Rodriguez, was exterminated, along with the closely related dodos, by man and introduced animals (see also DODO).

SOLITAIRE is the preferred name in the United States for all games of patience, or card games that may be played by one person. There are more solitaires than all other card games together, and solitaire is the most widely played of all forms of cards.

Most games are played with one or two 52-card packs. the cards ranking king (high), queen, jack, 10, 9, 8. 7, 6, 5. 4. 3, 2, ace. Sometimes the sequence is continuous, the ace ranking next to the king. Many solitaire games are known by a variety of names; even the game probably played by most players, Klondike, is more often miscalled Canfield. properly the name of a quite different game. The following terms describe features common to most games:

1. The *layout.*—The array of cards as first dealt on the table, comprising all cards that do not remain in the hand.
2. The *tableau.*—A distinctive arrangement into which the cards that may be "worked" are first dealt.
3. The *foundations.*—Usually all the cards of a designated rank, upon which other cards are built in sequence.
4. The stock.—A special pile of cards that is part of the layout in some games.
5. *The* Itand.—Any remainder of the pack not used in the layout.
6. The talon.—A waste or discard pile into which are placed those cards turned up from the hand that cannot be immediately built upon the tableau or foundations.
7. Available Cards. — Those cards of the tableau, stock, etc., that are subject to transfer to other parts of the layout. In most games, certain cards of the tableau are not available until uncovered by the transfer of cards above them.
8. A space.—An empty place in the tableau created when all the cards of one pile have been transferred elsewhere.
9. Rows.—Lines of cards across the table horizontally.
10. Columns.—Lines of cards extending vertically away from the player.

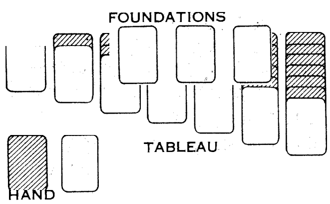

FIG. 1.—LAYOUT OF CARDS FOR KLONDIKE

A few of the popular forms of solitaire are here described.

Klondike.—One pack is used and a tableau dealt of seven columns in a row, with one card in the column at the far left, two in the next, three in the third, etc., the column at the far right containing seven cards. Only the topmost card in each column is turned face up. The foundations are aces, which are put in a row above the tableau as soon as they become available. Each foundation must be built up in the same suit in sequence to the king (*i.e.*, ace, deuce, trey, etc.). A card placed in a foundation may not thereafter be moved.

On the uppermost card of any tableau pile may be placed a card of next lower rank and opposite colour. When transferring cards within the tableau, all the face-up cards on any tableau pile must be moved as a unit onto a card of next higher rank and opposite colour to the highest card of the unit. If the highest card of the unit is a king, it may be moved only into a space, and a space may be filled only by a king (or a unit built upon a king). The lowest card of a unit may be removed and played in proper sequence upon a foundation pile.

Whenever a transfer leaves a face-down card uncovered, this card is turned up and becomes available.

The hand is turned one card at a time and is run through once only. A card not added to the foundation or the tableau is placed face up on the talon. Top card of the talon is always available.

Game is won if all cards can be built upon the foundations.

Double **Klondike.**—Many solitaires can be played by two, but Klondike is by far the favourite for this purpose and is the game referred to as double solitaire. Each player deals his own layout with his own deck. Neither may build on the other's tableau; but foundation piles are common property. Turn to play alternates, ending when a player lays a card on his waste pile. Play continues until one player has built all his cards on the foundations or until neither can make a further play. It is not compulsory to play a card to the centre; strategy may dictate withholding a play that would help the opponent get rid of a great number of cards.

In a blocked game, winner is determined by counting the cards each has played to the foundations.

Canfield. — From a single pack, a stock of 13 cards is counted out and the pile turned face up, with only the top card visible. The next four cards are dealt face up in a row to the right of the stock, forming the tableau. The next card is placed face up above the tableau to start the foundation row. Other cards of the same rank as this starter are placed in the foundation row as soon as available. Foundation piles are built in continuous ascending sequence in the same suit. (Thus, with ♡Q turned as the starter, other queens are played to the centre as soon as available. After the king has been added, the next card in sequence is the ace, then the 2. 3, etc.)

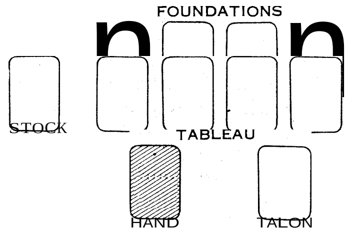

FIG. 2. — CANFIELD

Tableau columns are built in downward sequence and alternate colour, black on red, red on black. The king plays on the ace unless either rank is the foundation starter. Piles may be combined when the touching cards are of correct sequence and colour. Customarily, the entire column must be moved as a unit but some play that the available card may be individually shifted; *i.e.*, a column of ♡ 8, ♤ 7, ◇ 6 may be placed as a unit upon the ♤ 9 or ♧ 9, or the ◇ 6 may be shifted separately onto ♧ 7 if available. after which ♤ 7 may be placed on ◇ 8.

The hand is turned up in packets of three cards at a time, each packet being placed face up on the talon. The top card only of the talon or stock is available; the card immediately below becomes available when the top card is played. A space must be filled by the top card of the stock, but when the stock is exhausted the player may use any available card of the talon.

After the hand is run through once, the talon is turned over and, without shuffling, is run through again, continuing as often as plays can be made. Game is won if all cards are played onto the foundations.

Others. — The wide variety of solitaire games offers simple layout and count-out pastimes suitable for children, such as clock and accordion, as well as games that are a challenge to skill, such as calculation. Few who know how to play cards of any kind do not know at least one kind of solitaire.

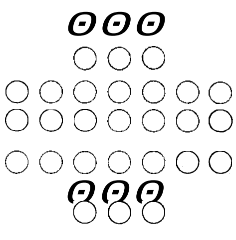

FIG. 3.—ARRANGEMENT OF HOLES FOR ...SION PEGBOARD GAME

Pegboard Game. — Solitaire also is the name of a pegboard game or solo puzzle, similar to a game the American Indians played with arrows stuck into the ground. In one version, the board is pierced with 33 holes arranged in a pattern of three vertical and three horizontal rows intersecting to form a cross. Pegs are set in all but one hole. One peg at a time is jumped over another and into a vacant hole, the peg thus jumped being removed from the board as in checkers. Jumps must be horizontal or vertical. never diagonal; the object of the basic puzzle is to remove from the board all but a single peg.

To make the game even more difficult, one variation calls for the last peg to be left in the centre hole.

See Morehead and G. Mott-Smith, Complete Book of Solitaire and *Patience* Ganzes (1949). (R. L. FY.)

SOLNA, an industrial suburb 4 mi. N.W. of Stockholm, Swed. Pop. (1960) 50,864. It is an ancient settlement and antedates Stockholm, having historic buildings including an 11th-century church and old palaces and manors. Ulriksdal palace on Lake Edsviken is the royal residence for part of the year; the Haga palace on Lake Brunnsviken, is the crown prince's residence; and the Karlberg palace is now the Royal Military school.

There are also a Nobel institute for scientific research, an institute for the blind and the Karolinska hospital with a medical school. Sports facilities include a racecourse and football stadium. Its expanding industrial development includes printing works and electronic industries. It is also a centre of the Swedish film industry. (L. E. MA.)

SOLO (BENGAWAN), a river (*Kali*) in East Java. Indonesia, and the longest river (335 mi.) of Java. Its headwaters are on the slope of the Lawu volcano and the southern limestone range (Gunungkidul). Flowing through several small basins the river enters the densely populated Surakarta plain near Wonogiri. Several tributaries join it in this volcano-bordered plain. North of Surakarta (or Solo) the river gradually bends eastward round the central limestone range (Gunungkendeng). Its longest tributary, the Madiun, joins the Solo at Ngawi, where it begins its 20 mi. breakthrough of the Gunungkendeng and emerges into the region called the Solo valley. There the river has little gradient and meanders through a lowland 10 mi. wide and 80 mi. long between the Gunungkendeng and the northern limestone ridges in the district of Bodjonegoro.

A project to use the Solo river for large-scale irrigation was never completed. The delta is very marshy and used for fish ponds. In order to reduce silting of the strait between Madura and Java (the northern approach to the port of Surabaja) the main mouth of the Solo was diverted to the north, away from the strait.

In the dry season much of the river bed is dry; in the wet season (November–April) the average volume (in the Solo valley) is 440 cu.m., the maximum 2,800 cu.m.

The Solo is navigable for river *prahus* (fishing boats) from Ngawi downstream. Sea-going *prahus* in the wet season can reach Tjepu. (J. O. M. B.)

SOLOGNE, a region of France extending over portions of the *départements* of Loiret. Loir-et-Cher and Cher. Area 1,800 sq.mi. Its boundaries are, on the north the Loire, on the south the Cher, on the east the districts of Sancerre and Berry. The Sologne is watered by the Cosson and the Beuvron, tributaries of the Loire, and the Sauldre, an affluent of the Cher. The impermeable mixture of sand and clay has given rise to numberless pools and marshes; portions were being drained largely by Huguenots, when persecution scattered them and the work was delayed until Napoleon III led the way in the reclamation of swamps and the planting of pines and other trees. These changes much improved the climate of the district. Arable farming and stock raising flourish in the Sologne, but there is little manufacturing activity, the cloth manufacture of Romorantin being the chief industry. Game is abundant, and the region owes much of its revived prosperity to the creation of large sporting estates.

SOLOGUB, FEDOR (pen name of FEDOR KUZMICH TETERNIKOV) (1863–1927); Russian man of letters, was born on Feb. 17, 1863 in St. Petersburg, the son of a tailor. On the latter's death, his mother became a domestic servant and the son was brought up by her employers. He studied at the Teachers' institute in St. Petersburg and was a schoolmaster for 25 years, retiring in 1907. He died on Dec. 6, 1927.

In 1897 Sologub published his first volume of poetry and also some short stories. He is considered the greatest figure of the Symbolists in prose and poetry. His best novel is *The Little Demon* (1907), in which he has created a universal type of evil in the central figure, the schoolmaster, Peredonov. He also wrote several plays.

His other works include *The Sorcery of Death* (a series composed of *The Created Legend, Drops of Blood, Queen Ortruda,* and *Smoke and Ashes*). *The Little Demon, The Created Legend, The Old House and Other Tales* have been translated into English.

SOLOLÁ, a department in the central highlands of Guatemala, and location of the beautiful Lake Atitlán. Area 410 sq.mi., of which 53 sq.mi. are covered by the water of the lake, pop. (1950) 82,921; (1957 est.) 95,308. The lake and town of Atitlan (*q.v.*), a favourite tourist area, occupy a valley dammed by volcanic ash at an altitude of about 4,500 ft. On the borders of the lake are three cone-shaped volcanoes, Atitlin, Tolimán and San Pedro. The Maya Indians, who make up the greater part of the population, grow maize, wheat and beans. On the southern shore of the lake there are plantations of coffee. Much land in the department is used for the feeding of beef cattle and hogs. The lake is used also for fishing. The department is served by the Inter-American highway which passes through Sololá on the way from Guatemala City to Quezaltenango.

Sololá, the departmental capital (pop. [1960 est.] 4,231) is near the northern shores of the lake, about 45 mi. W.N.W. of Guatemala City. It is 6,900 ft. above sea level. It is a colourful market centre for the Indian farmers of the highlands who come to buy or sell cotton and woolen textiles and foods. (P. E. J.)

SOLOMON, son of David, succeeded his father on the throne of Israel *c.* 974 and reigned to c. 937 B.C. In the story of David's intrigue with Bathsheba Solomon is the second child of the union, born after David had made her his wife, and after the death of the illegitimate child. But in the lists of David's children he seems to be the fifth child of the union. a discrepancy indicative of the uncertainty attaching to much of his history.

The name Solomon may mean peaceful; according to I Chron. xxii, 6–19, David was directed by Yahweh so to name his son as symbolizing the "peace and quietness" which, in contrast to the turbulence of his own reign, should be the characteristics of Solomon's. A variant reading in II Sam. xii, 24, however, states that Bathsheba herself chose the name. The following verse says that the prophet Nathan gave to the child the name Jedidiah, "beloved of Yahweh," the first element in which is from a root akin to David. This name is found nowhere else.

The Accession.—In contrast to the summary notices given in the books of Kings to the beginning of a new reign the circumstances of Solomon's accession are related with very full detail. To call Solomon not the true heir to the throne is mistaken, for in the case of a monarchy such as that of Israel there was no rule that the king's eldest son was his legitimate successor; the king might nominate any one of his sons to take his place: yet it is probable that Solomon had not been regarded as the son most likely to succeed David. The eldest son, Amnon, had been slain by Absalom, the third son, who was himself killed in an abortive revolt against his father. Of the intermediate son, Chileab, nothing is known.

When David was evidently on the point of death his son Adonijah, who "was born after Absalom," set to work to ensure for himself the right of succession. Like Absalom he was a man of fine appearance and seemingly popular. He appears also to have been a favourite with his father (I Kings i, 6). 'He surrounded himself with a royal bodyguard and enlisted the aid of the two foremost men in David's court, the warrior Joab and the priest Abiathar. At a feast he prepared he seems to have received support from the men of Judah and most of the king's sons, but his deliberate exclusion of the prophet Nathan, the warrior Benaiah, the "mighty men," and Solomon, from the invitation would suggest that the succession had already been the subject of intrigue, and that there was a pro-Solomon party.

At Nathan's instigation Bathsheba reminded the feeble old king of an oath he had sworn to make Solomon his successor, which story the prophet came in and confirmed. Whether this mas really the case or not—on one view of the narrative it would seem that David in his weakness was persuaded that he had made such a promise—the king immediately caused Nathan, Benaiah and Zadok the priest to proclaim Solomon. This action met with approval on the part of the citizens, and Adonijah's party collapsed without a struggle, he himself seeking asylum at the altar, and being sentenced to confinement in his own house.

Subsequently Joab was killed by Benaiah and Abiathar replaced by Zadok, at Solomon's command, Adonijah having been previously slain for preferring a request that Abishag, the damsel who had cherished David in his last days, should be given to him as wife. This would, according to oriental ideas, have been equivalent to claiming the succession, and it is indeed difficult to believe the story that Adonijah made such a request through Bathsheba. It is possible that this narrative, and also the instruction given by David to Solomon that Joab should be slain, are invented to palliate the ruthlessness with which Solomon removed from his path those who had challenged his position.

The King. — The general impression which the biblical narratives seek to convey is that Solomon's reign was most prosperous and peaceful, and this impression has substantial evidence in its favour. The fact that his reign endured for 40 years shows that he must have consolidated the kingdom, though he had no love for military adventure and made no attempt to enlarge its borders. Rather he sought to make his position secure by allying himself with his neighbours. Early in his reign he ensured the friendship of Egypt by espousing the pharaoh's daughter. This alliance brought about also a further gain, for the pharaoh, who had attacked and reduced the important Canaanite fortress Gezer, handed it over to Solomon as a dowry for his daughter, and Solomon rebuilt it. Perhaps even more advantageous was the extension of the alliance which David had earlier concluded with Hiram of Tyre. This afforded Solomon security on his northern frontier, and enabled him to use freely the Mediterranean. The erection of high places near Jerusalem for the worship of the deities of Zidon, Moab and Ammon is indicative of friendly relations with those peoples. That he was able to use a port at the head of the Gulf of Aqaba (I Kings ix, 26) for commerce with Ophir implies that Solomon controlled Edomite territory on the southeast.

The commercial activity of Solomon seems to have been extensive. His imports were on a scale so lavish that he is said to have made silver as common as stones, cedars as sycamores, in Jerusalem. In partnership with Hiram of Tyre he maintained a fleet of ocean-going ships trading at regular intervals to Mediterranean ports, bringing "gold, silver, ivory, apes and peacocks" (I Kings x, *22)*. In his trading ventures down the Gulf of Aqaba he was assisted by skilled Tyrian navigators supplied by Hiram (I Kings ix, 27–28). This passage was evidently misunderstood by the chronicler, who took it to mean that Hiram supplied the ships (II Chron. viii, 18). Ophir, the land to which these vessels ventured is not identified with certainty, but may be southern Arabia. Solomon brought Israel for the first time fully into the current of oriental commerce and civilization, and during his reign Jerusalem, at any rate, was a city of wealth and luxury.

The Builder. — The long and peaceful reign of Solomon permitted him to indulge his passion for building, and his activities completely transformed his capital city, Jerusalem. David had built a palace there, being furnished with artificers and material by Hiram. This was, however, not regarded by Solomon as sufficiently splendid, and he spent 13 years in constructing a magnificent royal dwelling. He built also a temple, the details of which occupy a disproportionate space in the records, for it was, after all, in the nature of an appanage to the palace, and took little more than half the time devoted to the latter. Like his father, he relied largely upon Hiram for material and artisans. He also built and fortified numerous cities which were used as barracks, arsenals and storehouses.

In order to obtain supplies for his grandiose schemes he divided the land into 12 districts, seemingly independent of the old tribal divisions. upon which levies were made in rotation. Forced labour was exacted from the Canaanites. But though the boast is made that the Israelites were not treated as bond servants, the exactions made from them for the upkeep of the court and harem, and the expenses of building, must have reduced many of the people to a condition hard to distinguish from slavery. However splendid the court and capital may have been, the state of the ordinary folk must have been far from hayyy. and in the lavish expenditure of Solomon may be found a prime cause of the discontent which led under his successor to division of the kingdom.

Factors of Unrest.—Nor was the political situation quite as easy as the picture in Kings might lead us to suppose. The exact interpretation of I Kings ix. 12–14 is uncertain, but evidently Solomon was compelled to part with territory in the north to placate Hiram. An Edomite, Hadad, who had escaped the ruthless slaughter of Edomites by Joab under David, took refuge at the Egyptian court. where he attained a considerable position. He returned to his 'native country after the death of Joab, and evidently was a thorn in Solomon's side. Rezon, an Aramean, too, established himself in Damascus; and was "an adversary to Israel all the days of Solomon." And, though the attempt of the able Jeroboam at revolt was crushed by the king, he had established a sufficient personal ascendancy to gain the allegiance of the northern tribes after Solomon's death. Undoubtedly the shadows have been toned down in the Old Testament records of Solomon's reign. This does not, however, prevent us from recognizing that he was, with all his limitations, an able ruler. Though very little of the wisdom which is attributed to him in the Old Testament is correctly assigned, it is extremely unlikely that the attribution would have been made had not the facts of his rulership provided a basis for the picture of Solomon the Wise.

Religion. — Solomon was a sincere worshiper of Yahweh, more cultured but less passionate in his devotion than David. His erection of altars to foreign deities for the sake of his foreign wives, and even his participation in the rites connected with them, would not be in his eyes apostasy. These things were of the political rather than the religious sphere. But in the eyes of later puritans they were departures from orthodoxy. So we have the curious double picture of Solomon as on the one hand a most pious benefactor to the national religion in his building of the temple and care for its ceremonial — though even here the doubt insinuates itself as to whether he did not consider to some extent the prestige which was reflected on himself; on the other hand as an apostate, who when his obituary notice is written (I Kings xi, 43) receives no glowing testimonial, and about whom it is said that he "went not fully after Yahweh, as did David his father" (I Kings xi, 6). Yet even the passage which contains this censure shows that the other side of the picture was not forgotten, because it represents with more charity than truth the participation of Solomon in the rites of foreign altars as a lapse of his old age. (W. L. W.)

SOLOMON, ODES OF, is a collection of *42* short pseudepigraphical hymns resembling the canonical Psalms in their general nature. They are characterized by a spirit of adoration; only exceptionally do they touch some theological theme, and then the religious lyric tends to veil it, wrapping it in mystical speech. But not everything fades away from our sight: the centre of salvation is not the cross but God's self-humiliation (as in Phil. ii); virginity is a prerequisite for perfection, and the congregation is envisaged as a mystical union.

Until 1908, when a Syriac manuscript containing both the Odes and the Psalms of Solomon was discovered, they were known only from fragments: a citation of one ode (xix, 6) in Lactantius' *Divinae Institutiones* (early 4th century A.D.); and five odes (i, v, vi, xxii, xxv) in the *Pistis* Sophia, a 3rd–4th-century Gnostic work in Coptic. One ode (xi) in Greek has subsequently come to light in a 3rd-century papyrus.

The question of provenance has been much discussed. The idea that the odes stem from Gnosticism is untenable; dualism is lacking and there is nothing else in them that indicates a Gnostic background. Nor are there any reasons for postulating a Montanist origin. These texts reflect the oriental Christianity of the 2nd century and are not unorthodox. Greek has been regarded as their original language, but their content — an amalgam of covenant consciousness, baptismal imagery and Encratism — indicates that their home must be sought in Mesopotamia. There seems to be an echo of the history of Edessa, the home of Syriac literature, and the style and rhythm savour of a Syriac original, which shines through even in the Greek version. Syriac provenance also would explain some affinities with the Thanksgiving Psalms found at Oumran (*see* DEAD SEA SCROLLS).

SOLOMON, PSALMS OF, a collection of 18 pseudepigraphical psalms extant in Greek and Syriac versions. The ascription to Solomon, which probably goes back to the editor who first put them into their present form, makes them analogous to the canonical psalter ascribed to David. The poet (or poets) who composed the Psalms of Solomon seems not to have thought of ascribing them to Solomon, for they contain not even an allusive reference to him. It makes little difference whether more than one author is concerned, for the psalms all come from the same period and milieu and share the same religious and political views. The most that can be said is that the three great political psalms (ii, viii and xvii) were written by one and the same author, a man of poetic vigour and imagination.

The Hebrew original of the Psalms of Solomon is not extant, but the Syriac translation as well as the Greek seems to have been made directly from it. This is indicated by a number of passages in which the Greek is incomprehensible because the Hebrew it translated must have been corrupt, whereas the Syriac reveals the correct reading in the Hebrew. (The reverse situation also occurs.) Only occasionally did the Syriac translator correct himself by reference to the Greek version.

The Psalms of Solomon were clearly composed in Palestine, and some certainly originated in Jerusalem. This accounts for the important role which Jerusalem plays in them. The three political psalms can be dated fairly exactly because they make a clear reference to Pompey the Great. Thus most of xvii was composed shortly before Pompey entered Jerusalem in 63 B.C., though verses 11–14 are a later addition which refer back to this event and date from after 61 B.C. In ii, 26 ff. there is a reference to the death of Pompey in 48 B.C. As all the psalms belong to the same period, the collection can be dated to between 80 and 40 B.C.

The importance of the Psalms of Solomon lies chiefly in their vivid and contemporary presentation of the political and religious thought of the "pious of Israel" (*i.e.,* the Pharisees) in the last century B.C. The author of the psalms was certainly a Pharisee. Psalm xvii is particularly interesting for its detailed description of the eschatological messianic king and the political and religious expectations of his reign. This is the conception of the Messiah still current among the Jews during Jesus' lifetime; as the Gospels show. it lies behind the reaction of the common people to Jesus' teaching, the opposition of the Pharisees, high priest and scribes, and the hopes and expectations of the disciples.

SOLOMON, SONG OF (or SONG OF SONGS; in the Douai version of the Bible, CANTICLE OF CANTICLES, from *Canticum Canticorum* in the Vulgate; derived from the title in the Hebrew Bible. SHIR HASHIRIM), a book of the Old Testament, one of the Megilloth, or "Rolls," the others being Ruth, Lamentations, Ecclesiastes and Esther. The Megilloth are read in the synagogue at certain festivals, the Song of Solomon being used at Passover, which celebrates the Exodus from Egypt. The reasons for this are not entirely clear, but the fact that spring is referred to in ii, 11 ff. and vi, 11 (Passover being also celebrated in spring), and the allegorical interpretation of the book as referring to God's love for Israel and the events of the Exodus, especially the Covenant at Mt. Sinai, should be considered in this connection.

Contents. — There is no coherent story in the book. It consists of a series of love poems in which a man and a woman speak alternately. A number of songs describe systematically the beauty and excellence of the beloved (called by a modern Arabic term wasf, "description"): iv, 1–7; v, 10–16; vi, 4–7; vii, 1–6. There is reference to the bride's seeking for her beloved: i, 7 ff.; iii, 1–5; v, 6–8. There is a description of a festive procession: iii, 6–11. And there are dialogues between the two partners: *e.g.,* i, 9–ii, 7, etc.

Author. — The Hebrew title of the book mentions King Solomon as its author, but several considerations make this improbable. Solomon is referred to in the third person; the language of the book seems to reflect a much later epoch (*e.g.,* there are Persian and perhaps even Greek loanwords); and the city of Tirzah is referred to (vi, 4) in such a context as to make it probable that it is the capital of the northern kingdom of Israel (9th century B.C.). This, alongside the fact that the language contains some archaic elements, seems to suggest that an older text has been revised at a later epoch. The author of the book remains unknown.

Interpretation. — The Song of Solomon has been interpreted in many different ways of which four, described below, are important.

Allegorical. — The allegorical interpretation takes the book as an allegory of God's love for Israel or of Christ's love for the church. This type is represented by the Jewish Targum (the free Aramaic rendering given in the synagogue when Hebrew was no longer understood), which makes it refer to the lawgiving on Mt. Sinai, the history of Israel and the coming of the Messiah. In the Christian Church this interpretation is maintained by the early Fathers, by the Eastern Churches and by many modern Roman Catholic scholars. In medieval mysticism the Song of Songs was applied to the love between Christ and the human soul, and Bernard of Clairvaux gave a famous exposition of it to that effect. The earliest traces of an allegorical interpretation seem to be Rev. iii, 20 (which may reflect S. of Sol. v, 2) and II Esd, v, 23–26 (1st century A.D.).

Dramatic. — The dramatic interpretation is based on the fact that a considerable part of the book is clearly in dialogue form. According to this view, the heroine of the book is a peasant maiden in Solomon's harem. who longs for her shepherd lover and utters her feelings to the ladies of the court; they lead her on to describe her lover and to tell how she came to be carried off by Solomon. Finally her constancy secures her release, and the curtain falls on the sentiment of true affection in viii, 6, 7. This theory is attractive in certain respects, but in view of the absence of drama in the Semitic literatures it is not very probable. Moreover, any progress of action from first to last is difficult to prove. Most advocates of the theory find it necessary to rearrange the sequence of the sections considerably in order to get a coherent story, which seriously weakens their case.

Literal. — The so-called literal interpretation considers the book to be a collection of secular love songs without any religious implications. This theory was introduced in modern research by J. G. Wetzstein, who during the 19th century was Prussian consul at Damascus and whose observations of the wedding customs of Syrian peasants led him to believe that the biblical book is substantially a collection of songs originally sung at such festivities. During the first seven days after the wedding the man and his young wife play the part of king and queen. A threshing board is erected on the threshing floor as a throne, and after the royal couple have taken their seats a dance in their honour begins. The accompanying song to a great extent consists of wasf, *i.e.,* a description of the physical perfections and the ornaments of both. Wetzstein's contribution, which was originally published in the *Zeitschrift für* Ethnologie in 1873, was reprinted by F. J. Delitzsch in an appendix to his Commentary, and his theory was accepted by K. Budde (1898) and by many other scholars.

The songs edited by Wetzstein, and folk songs from Palestine later published. indeed show a striking similarity in language and imagery with the Song of Songs—*e.g.,* apart from the wasf, the description of the bride as a garden (iv, 12; vi, 2, 3) and many other details. This theory would also account for the reference to Solomon in the Song of Songs: it would be another way of saying that the bridegroom is playing the role of a king. However, the very fact that the young couple in Syria are celebrated as king and queen calls for an explanation. Another difficulty arises from the fact that almost throughout the Song of Solomon it is the bride and not the bridegroom who takes the initiative, which would be inconceivable in an ordinary Syrian or Palestinian wedding. This has given rise to a fourth theory.

Cultic-Mythological. — The cultic-mythological interpretation is based on the fact that the poems of the Song of Songs are strongly reminiscent of the songs connected with the Sumerian rite of the sacred marriage. This ceremony, an element of the fertility cult of ancient Mesopotamia, most frequently implies the consummation of a ritual marriage between the king and a goddess, represented perhaps by a temple prostitute or priestess, the king playing the role of the fertility god Tammuz. Description songs (wasf), the goddess's search for the god and several other typical motifs and expressions occur here for the first time in history, much earlier than the Song of Songs and the modern Arabic folk songs.

The cultic interpretation was inaugurated by Erbt in 1906 and further elaborated by a number of scholars. It implies that rites similar to the Sumerian ones were practised in ancient Canaan—this is to some extent substantiated by the Ras Shamra texts, dating from the 14th century B.C.—and that these practices were in some way or other taken over by Israel. It is known at least that this was the case during the reign of King Manasseh (II Kings xxi). But it is difficult to explain how a collection of more or less pagan cult songs was introduced into the Hebrew canon of Holy Scriptures. One suggested explanation assumes that these songs were used for centuries in popular celebrations in springtime until their original meaning was forgotten, and then were adopted because of the allegorical interpretation which was given to them partly because their performance happened to coincide with the celebration of the Exodus at Passover.

This theory has the advantage over all the others: it accounts for the dialogue form; it is "literal" in that it understands the text as it is without looking for hidden implications; and it even provides a certain basis for an allegorical interpretation, if it may be assumed that the sacred marriage forms the background of the prophetic description of the relationship between Yahweh and Israel as a marriage (Jer. ii, 2; Isa. liv, 4 ff.; lxii, 4 ff.).

The cultic interpretation is accepted by an increasing number of writers, especially since the discovery and publication of many new parallels in Sumerian texts. The main reason for rejecting it is the difficulty of explaining the book's presence in the canon on these premises. The only alternative is the interpretation as secular love songs, the similarity with Sumerian cult poems being accounted for by the assumption that they are dependent on a common tradition of love songs. Some Egyptian collections of love songs, which also offer some parallels to the Song of Solomon, seem to be of a more secular character, although many of them are thought to have originated in the cult of the love goddess Hathor.

BIBLIOGRAPHY.—A good survey of the different interpretations is given by H. H. Rowley in his collection of essays *The Servant of the Lord* (1952). For commentaries, *see* T. J. Meek in *The Interpreter's Bible* (1956); *H.* Ringgren in *Das Alte Testament deutsch* (1958). For folk songs, *see* St. H. Stephan, *Modern Palestinian Parallels to the Song of Songs* (1923; also in *Journal of the Palestine-Oriental Society*, vol. ii, 1923); S. Linder and H. Ringgren, *Palästinische Volksgesange*, 1–2 (1952–55). (H. RI.)

SOLOMON ISLANDS, a chain of islands in the Melanesian area of the southwestern Pacific, which extends in a northwest-southeast direction for almost 900 mi. between latitudes 5° and 11° S.. and longitudes 154° 40' and 162" 30' E. The group includes the Santa Cruz Islands, about 300 mi. to the east of the southernmost Solomons, and the Lord Howe (Ontong Java) Islands. The northernmost islands, Buka and Bougainville, are administered by Australia as part of the trust territory of New Guinea (*q.v.*); the remaining islands—including Guadalcanal, San Cristóbal, Malaita, Santa Isabel, Choiseul, New Georgia, Santa Cruz. Lord Howe, Reef and Duff groups and Mitre Island—form a British protectorate. The area of the Australian-administered islands is about 4,100 sq.mi. and that of the British protectorate about 11,500 sq.mi.

The group contains a number of low coral atolls, but the larger islands are all volcanic and rugged. Heights of more than 8,000 ft. are reached on Bougainville and Guadalcanal. Geologically the islands form a continuation of the volcanic arc to the east of New Ireland.

Bougainville (*q.v.*) is the largest of the group. South of Bougainville the islands are arranged in two parallel chains, the western including Vella Lavella, Kolombangara, New Georgia and Guadalcanal, and the eastern, Choiseul Island, Santa Isabel Island and Malaita. The two chains converge on the southernmost island, San Cristóbal.

The climate is equatorial, with constant heat, high humidity and no dry season. Rainfall on most of the islands exceeds 100 in. a year. The vegetation is a heavy forest and, as in most island groups, the animal life is restricted.

The islands were discovered in 1568 by the Spaniard Alvaro de Mendaña, who tried to establish a colony in 1595. The expedition, which failed miserably, is the subject of a novel by Robert Graves (see Bibliography). Only toward the end of the 18th century was European knowledge of the group completed, by the voyages (1766–92) of Philip Carteret, Count Louis Antoine de Bougainville, John Shortland, Antoine Raymond Joseph de Bruni d'Entrecasteaux and others. The British protectorate was established over the southern islands in 1893, after a century of European contact with generally unfortunate results.

A German protectorate over the northern Solomons was declared about 1885, but in 1899 all except Buka and Bougainville were transferred to Great Britain in return for recognition of German claims in western Samoa. The German islands were occupied by Australian troops in 1914, and after 1920 the two northern islands were administered by Australia. In 1942 the Japanese advance into the Pacific swept the Solomons where its further progress was checked. The fighting in the following three years was among the bitterest in the Pacific, particularly the long struggle on Guadalcanal (see WORLD WAR II: The War in the Pacific).

The total population of the Solomons is about 180,000, of whom 124,076 (1959 census) live in the British protectorate. The most populous island is Malaita, with (1957 est.) 47,000 inhabitants. The larger islands are almost entirely populated by Melanesians, but there has been much racial admixture and there is a great variety of physical types and linguistic groups. Ten separate languages are spoken on Bougainville. A few Polynesians are found on the atolls.

There are only two towns, Kieta on the east coast of Bougainville, and Honiara, administrative capital of the protectorate, on the north coast of Guadalcanal.

In 1960 a new constitution was brought into operation for the protectorate. The legislative council, presided over by the high commissioner for the western Pacific, has an official majority. The executive council is divided equally between official and unofficial members.

Primary education is mostly provided at subsidized mission schools, and there are a secondary boarding school and a training college for teachers and carpenters. There is a central hospital at Honiara, besides a leprosarium at Tetere, and district, rural and mission hospitals.

Copra is the mainstay of the economy of the Solomons, and is produced by both native growers and European estates, the latter mainly on Guadalcanal, the Russell Islands, San Cristóbal Island and Santa Isabel Island. Great damage was done to the coconut plantations during World War II, and even by 1960 only about two-thirds of the prewar area of 64,000 ac. were productive. No new estate plantings of coconuts had taken place, although there had been a small increase in native copra production from Santa Isabel Island and Malaita. There had, however, been a marked improvement in the quality of copra produced, following the granting of a premium for the better grades by the copra board, which is the sole purchaser of copra in the islands.

The administration had endeavoured to introduce cacao as an alternative cash crop; it was taken up by some native growers on Malaita, and a little is produced by Europeans in the western Solomons.

Only two other commercial activities have more than a local importance: the Kieta area of Bougainville produces a little gold, and the islands of Guadalcanal and Vanikoro support a lumbering industry that makes a small contribution to the export trade. About four-fifths of the exports by value, however, are accounted for by copra.

See PACIFIC ISLANDS; *see* also references under "Solomon Islands" in the Index volume.

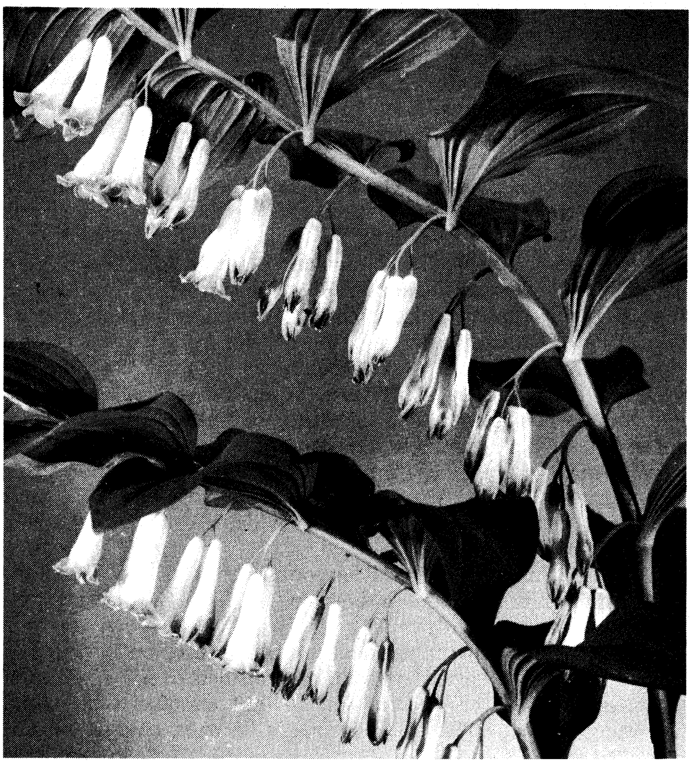
SOLOMON'S-SEAL, the common name for perennial herbs of the genus *Polygonatum,* of the lily family (Liliaceae), comprising about 30 species native to north temperate regions. The plant springs from a fleshy, creeping rootstock on which the scars of the previous year's shoots leave curious seallike marks—hence the common name. Two species occur in eastern North America and three are found in Great Britain.

The single erect or arching stem, one to eight feet high, bears



ROCHE

SOLOMON'S-SEAL (POLYGONATUM)

ovate or lance-shaped, sharp-pointed, sessile leaves in the axils of which appear narrow greenish, whitish or pinkish bell-shaped flowers, on slender, drooping stalks, followed by globular, pulpy, usually bluish berries.

In the United States various species of *Smilacina,* a closely allied genus. are called false Solomon's-seal.

SOLOMOS, DIONYSIOS, COUNT (1798–1857), was the first poet of modern Greece to show the capabilities of its spoken language (the *dimotiki*) when inspired by wide culture and a first-rate lyrical fancy. Born in Zante, he was educated in Italy (1808–18), at Venice, Cremona and Padua, after which he returned to Zante. His earliest poems were written in Italian but in 1822 he finally determined to write in the spoken tongue of Greece. His noble *Hymn to Liberty,* in 158 four-line stanzas, was composed in May 1823, and his poem on the death of Lord Byron in 1824–25.

The unfinished *Lambros,* a romantic poem of the revolutionary times written in ottava rima (*q.v.*), was begun in 1826. To this period (1823–28) belong also some shorter lyrical pieces and some satires, of which the most notable is I *Gynaika tis Zakynthos* ("The Woman of Zante"), a long sketch written mostly in poetical prose. In 1828 he migrated to Corfu, where he remained until his death.

His lyrical exuberance was curbed by a growing preoccupation with German theories of dramatic form and by an inhibiting dissatisfaction with the as yet meagre resources of his chosen linguistic medium. These impediments, together with a disastrous family quarrel (1833–38), explain why his major poems of this period remain fragmentary.

Nonetheless, *O Kritikos* ("The Cretan," 1833), the second and third sketches of *Oi Eleftheroi Poliorkimenoi* ("The Free Besieged") of Missolonghi (before and after 1844), and *O Porphyras* ("The Shark," 1849) exhibit, even in their fragments, a sense of rhythm, a "curious felicity" and a melody of cadence not found in his *juvenilia.*

Jenkins, *Dionysius Solomds* (1940); P. Michalopoulos, *Dionysios Solomos* (in Greek) (1931); M. Sigouros, O *Solomos* (in Greek) (1958). (R. J. H. J.)

SOLON, Athenian statesman, the son of Execestides of the family of Codrus, was born about 638 B.C. The prodigality of his father made it necessary for Solon to maintain himself by trade. especially abroad. In his youth he became well known as the author of amatory poems and later of patriotic and didactic verse. Hence his inclusion among the Seven Sages.

Solon's first public service was the recovery of Salamis from the Megarians. A law had been passed forbidding any reference to the loss of the island; Solon solved the difficulty by feigning madness, and reciting an inflammatory poem in the agora. It appears that Solon was appointed to recover the "fair island" and that he succeeded in expelling the Megarians. Sparta finally arbitrated in favour of the Athenians (c. 596). About a year later Solon seems to have moved a decree before the Amphictyons declaring war on Cirrha. At this period the distress in Attica and the accumulating discontent of the poorer classes, for whom Draco's code had proved inadequate, reached its height. Solon was summoned by all classes unanimously to discover a remedy.

Under the legal title of Archon, Solon received unlimited powers nhich he exercised in economic and constitutional reforms *(see* below). These reforms met with considerable opposition, and Solon left Athens for ten years. After visiting Egypt, he went to Cyprus, where Philocyprus, king of Aepea, received him with honour.

Herodotus (v, 113) says that Philocyprus, on the advice of Solon, built himself a new town called, after his guest, Soli.

The story that Solon visited Croesus in Lydia, and made to him the famous remark—"Call no man happy till he is dead"—is unfortunately discredited by the fact that Croesus seems to have become king nearly 30 years after Solon's legislation, whereas the story must be dated within ten years of it. Subsequently Solon returned to Athens. to find civil strife renewed, and shortly afterward his friend Peisistratus made himself tyrant.

About 558 B c. Solon died and, according to the story in Diogenes Latrtius i, 62 (but *see* Plutarch's *Solon,* 32), his ashes were scattered around the island of Salamis.

If the story is true, it shows that he was regarded as the oecist of Salamis.

Reforms.—The date of Solon's archonship has been usually fixed at 594 B.C. (Ol. 46, 3), a date given by Diog. Laert. (i, 62) on the evidence of the Rhodian Sosicrates (fl. 200–128 B.C.; *see* Clinton. *Fast. Hell.* ii, 298, and Busolt, 2nd ed., ii, 259). The date 594 is confirmed by statements in the Aristotelian *Constitution of Athens* (ch. 14). For various reasons the dates 592, 591 and even 590 have been suggested by various historians *(see* the concluding paragraph of this article).

The historical evidence for the Solonian reforms has always been unsatisfactory. There is strong reason to conclude that in the 5th and 4th centuries there was no general tradition as to details. In settling differences there is no appeal to tradition, and this though there occur radical and insoluble contradictions. Thus the *Constitution of Athens* (ch. vi) says that the Seisachtheia ("shaking off of burdens") consisted in a cancelling of all debts public and private, nhereas Androtion, an elder contemporary, denies this specifically, and says that it consisted in the reduction of the rate of interest and the debasement of the coinage. The *Constitution* denies the existence of any connection between the coinage reform and the relief of debtors. The absence of tradition is further confirmed by the fact that the Constitution always appeals for corroboration to Solon's Poems. Of the Laws it is probable that in the 4th century, though some dealing with agrarian distress were in existence, those embodying the Seisachtheia were not, and few if any of the purely constitutional laws remained. The main source of the account in the Constitution is, therefore, the Poems of Solon, from which numerous quotations are made (see chs. 5–12).

The reforms of Solon may be divided under three heads—economic, constitutional and miscellaneous. They were necessary owing mainly to the tyrannical attitude of the rich to the poorer classes. Of these many had become slaves in lieu of payment of rent and loans, and thus the land had fallen gradually into the hands of capitalists. It was necessary to readjust the economic balance and to provide against the evil of aristocratic and capitalist predominance.

A. Economic Reforms.—Solon's economic reforms consisted of the Seisachtheia and certain commercial laws (*e.g.,* prevention of export trade except in olive oil, Plut. Solon 24). By far the most important of these was the law encouraging trade and manufactures (Plut. Solon, 22) which laid the foundation of the future commercial greatness of Athens. Even within a century from the time of its making the trade of Athens with Sicily increased, as is shown by archaeological discovery in that island, to such an extent that, though negligible in quantity at the beginning of the century, it almost rivalled that of Corinth at the end of it. (See Grundy, *Thucydides* and the History of his Age, p. 66 ff.). Among all the problems connected with the Seisachtheia, it is clear (1) that Solon abolished the old Attic law of debt which permitted loans on the security of the debtor's person; (2) that he restored to freedom those who had been enslaved for debt; (3) that he refused the demand for the division of the land (*γῆς ἀναδασμός*). As to the cancelling of all debts (*χρεῶν ἀποκοπή*) there is some controversy; Gilbert and Busolt maintain that all debts were cancelled; strong reasons may, however, be advanced against it, amongst others, that the Greek, unlike the Roman revolutionary, though ready to deal freely with the property of others, did not seek to remedy financial difficulties by abolishing debts. It is possible that the statement in the *Constitution* is a hypothesis to explain the restoration of the slaves to freedom. Further, Solon seems to have regulated the accumulation of land (cf. in Rome the legislation of Tiberius Gracchus) and the rate of interest; and to have simplified commerce by replacing the Pheidonian standard by the Euboic, which was in use among the Ionian traders, in commerce with whom he foresaw thai prosperity lay. It is impossible here to enter into the details of the controversy in connection with Solon's land reforms; it must suffice to give the bare outlines of the dispute. There is no question that (1) the distressed class whom Solon sought to relieve were the *Hektemoroi*, and that (2) the achievement on which he prided himself was the removal of the ὅροι or stones which were seen everywhere in Attica, and were symbolic of the slavery of the soil. Almost all writers say that these ὅροι were mortgage-pillars: that they were originally boundary stones and that when land was mortgaged the terms of the agreement were carved on the stones, as evidence. Now, firstly, though such mortgage-pillars existed in the time of Demosthenes, none are found earlier than the year 400 B.C., nor is there any reference before that year to this special sense of the word. If then these stones which Solon removed were mortgage-pillars, it is strange that none should have been found till 200 years later. Secondly, it is highly improbable that the terms on which land was then cultivated admitted of mortgaging at all. The Hektemoroi who, according to the Constitution, paid the sixth part of their produce as rent,[1] were not freeholders but tenants, and therefore, could not mortgage their land at all. From this it follows that when Solon said he had "removed the stones" he referred to the fatal accumulation of land by landowners. The tenants failed to pay rent, were enslaved, and the "boundary stone" of the landowner was moved forward to include their land. Thus the removal of the *ὅροι* was a measure against the accumulation of land in the form of enclosures (*τεμένη*), and fits in with the statement at the end of chapter iv. of the Constitution, "the land was in the hands of a few." It should be noted (1) that from this releasing of the land it follows that Solon's law against lending on the security of the person must have been retrospective (*i.e.,* in order to provide a sufficient number of freeholders for the land released); and (2) that it is one of the most remarkable facts in Athenian economic history that when at the end of the Peloponnesian War a proposal was brought forward to limit the franchise to freeholders, it was found that only 5,000 failed to satisfy this requirement. It is noteworthy that the Hektemoroi disappear from history after Solon's time. This looks as if they had been converted into freeholders. Antiquity ever tended to regard the cultivation of land as the best title to its possession, a development of an earlier idea that property in respect to land did not reside in the land itself but in the crop grown on it. The Diacrii of the time of Peisistratus are quite a different class.

[1] Others say they were: (1) labourers who received one-sixth of the produce as wages; (2) tenants who paid five-sixths as rent and kept one-sixth, or (3) tenants who paid one-sixth as rent and kept five-sixths. As to (3) it is said such tenants could not have been in real distress, and as to (1) and (2) it is said that such a position would have meant starvation from the first.

B. Constitutional Reform.—It is on this part of his work that Solon's claim to be considered a great statesman is founded. By his new constitution, he laid the foundations of the Athenian democracy and paved the way for its later developments. It should be noted in the first place that the following account is written on the assumption that the Draconian constitution described in chapter iv. of the Constitution of *Athens* had never existed (see DRACO). In some respects that alleged constitution is more democratic than Solon's. This, coupled with the fact that Solon is always spoken of as the founder of democracy, is one of the strongest reasons for rejecting the Draconian constitution. It will be seen that Solon's state was by no means a perfected democracy, but was in some respects rather a moderate oligarchy in which political privilege was graduated by possession of land. To Solon are generally ascribed the four classes—Pentacosiomedimni, Hippeis, Zeugitae and Thetes. Of these the first consisted of those whose land produced as many measures (medinzni) of corn and as many measures (*metretae*) of oil and wine as together amounted to 500 measures. The Hippeis (the horsemen, *i.e.,* those who could provide a war-horse for the service of the state) were rated at over 300 and under 500 *medimni;* the third class (those who tilled their land with a yoke of oxen) at 200 medimni and the Thetes below 200 medimni. The Zeugites, probably served as heavy-armed soldiers, and the Thetes were the sailors of the state. It is likely that the Zeugites were mainly Hektemoroi (see above) whom Solon converted into freeholders. Whether Solon invented these classes is uncertain, but it seems clear that he first put them into definite relation with the political organism. The Thetes (who included probably the servants of the Eupatridae, now secured as freemen), the fishermen of the Paralia (or sea-coast), and the artisans (cerameis) of Athens for the first time received political existence by their admission to the sovereign assembly of the Ecclesia (*q.v.*). Of these classes the first alone retained the right of holding the offices of archon and treasurer; other offices were, however, opened to the second and third classes (*sc.* the Poletae, the Eleven and the Colacretae; see Cleisthenes [1]). It is of the utmost importance to observe that the office of Strategus (*q.v.*) is not mentioned in connection with Solon's reform. It is often said that Solon used his classification as the basis of a sliding scale of taxation. Against this, it is known that Peisistratus, whose faction was essentially the poorer classes, established a uniform 5% tax, and it is highly unlikely that he would have reversed an existing arrangement which was particularly favourable to his friends. The admission of the Thetes to the Ecclesia was an important step in the direction of democracy (for the powers which Solon gave to the Ecclesia, see ECCLESIA). But the greatest reform of Solon was undoubtedly the institution of the Heliaea (or courts of justice). The jury was appointed by lot from all the citizens (including the Thetes), and thus the same people elected the magistrates in the Ecclesia and subsequently tried them in the Heliaea. Hence Solon transferred the sovereign power from the areopagus and the magistrates to the citizens as a whole. Further, as the archons, at the expiry of their year of office, passed into the areopagus, the people exercised control over the personnel of that body also (see AREOPAGUS). In spite of the alleged Draconian constitution, alluded to above, it is still very generally held that Solon invented the Boulē or Council of Four Hundred, 100 from each of the old tribes. The importance of this body as an advisory committee of the Ecclesia, and the functions of the Prytaneis are explained under BOULĒ. It is sufficient here to point out that, according to Plutarch's *Solon,* (ch. 19) the state henceforth rested on two councils "as on anchors" and that the large powers exercised by the Cleisthenean Boulē were not exercised by the Solonian. From this and the articles AREOPAGUS, BOULĒ, ECCLESIA and GREEK LAW, it will be seen that Solon contrived an absolutely organic constitution of a "mixed" type, which had in it the seeds of the great democratic growth which reached its maturity under Pericles. It should be added here, in reference to the election of magistrates under Solon's constitution, that there is discrepancy between the Politics and the *Constitution;* the latter says that Solon gave to the Thetes nothing but a share in the Ecclesia and the courts of justice, and that the magistrates were elected by a combination of selection and lot (κληρωτοὶ ἐκ προκρίτων), whereas the *Politics* says that Solon gave them only the power to elect the magistrates and try them at the end of their year. It seems likely for other reasons that the former scheme should be assigned to the years after Marathon, and therefore, that the account in the *Politics* is correct (but see ARCHON).

C. Miscellaneous.—The miscellaneous laws of Solon are interesting primarily as throwing light upon the social condition of Athens at the time (see Evelyn Abbot, History *of Greece,* i xiii §18). In the matter of trade it has been said that he favoured one export only, that of olive oil, in which Athens was peculiarly rich; further he encouraged the settlement of aliens (*metoikoi*) engaged in commerce, and compelled fathers to teach their sons a useful trade under penalty of losing all right to support in old age. The influence of women Solon regarded as most pernicious. Wealthy wives he forbade; no bride might bring more than three changes of raiment and a little light furniture to the house; all brothels and gymnasia were put under stringent state-control (*see* PROSTITUTION). Solon also regulated intestate succession, the marriage of heiresses, adoption, the use and sinking of wells, bee-farming, the planting of olives and figs, the cutting down of olive trees, the calendar. Further, he ordained that each citizen must show how he obtained his living (Herod. ii 177) and must, under penalty of losing the franchise, adhere to one or other party in a sedition (for these laws *see* Plutarch's *Solon,* chs. 20–24).

The laws were inscribed on Kyrbeis or tablets framed in wood which could be swung round (hence also called *axones*). The boulē as a body swore to observe the laws, and each archon undertook to set up a life-size golden statue at Delphi if he should be convicted of transgressing them.

Solon appears to have supplemented his enactments by a law that they should remain in force for 100 years, and according to another account that his laws, though not the best, should stand unchanged for ten years (Plut. Solon, 25; *Herod.* i. 29). Yet according to the *Constitution* of *Athens* (chs. 11–13) (without which the period from Solon to Peisistratus was a blank), when Solon went abroad in 593 (?) the city was disturbed, and in the fifth year dissension became so acute that no archon was elected (for the chronological problem, see J. E. Sandys, *Constitution* of *Athens,* ch. 13, note); again four years later the same *anarchia* (*i.e.,* no archon elected) occurred. Then four years later the archon Damasias (582?) continued in office illegally for two years and two months. The office of the archon was then put into commission of ten: five from the Eupatrids, three from the Agroeci and two from the Demiurgi, and for 20 years the state was in a condition of strife. Thus we see that 12 years of strife (owing to Solon's financial reforms) ended in the reversal of Solon's classification by assessment. We are, therefore, driven to conclude that the practical value of his laws was due to the strong and enlightened government of Peisistratus, whose tyranny put an end to the quarrels between the Shore, the Upland and the Plain, and the *stasis* of rich and poor.

See editions with notes of *Constitution of Athens* (*q.v.*); histories of Greece later than 1891 (*e g.,* Busolt, Eduard Meyer, etc.). *See* also Gilliard, *Quelques reformes de Solon* (1907); Cavaignac, in *Revue de Philol.,* 1908. *All* works anterior to the publication of the *Constitution* are so far out of date, but reference should be made to the work of Grote. (J. M. M.; X.)

SOLOR and **ALOR** ISLANDS, a group of islands between Flores and Timor, an eastward extension of Flores, one of the Lesser Sunda islands, in the Netherlands Indies. They are from west to east Solor, Adunara (both small), Lomblen, Pantar and Alor (the largest).

Alor, divided from Timor by Ombai passage, 17 mi. wide, is very mountainous (Mt. Kolana in the east, is 6,000 ft. and Mt. Muna, in the southwest, is 4,680 ft., both old volcanoes), and is much broken up by steep ravines, with only one plateau, and some small coastal plains. It is mostly covered with low trees and *alang alang* grass. The coast is mostly rocky, with few indentations, but on the west coast, Kaiabahi bay, 10 mi. long and nearly a mile wide, divides a northwestern promontory from the rest of the island, with which it is connected by a very low alluvial isthmus about $2\frac{1}{2}$ mi. wide. Pantar is high (Mt. Laki in the south is 4,450 ft.), with a rugged coast; Lomblen has mountains in the north and south (Mt. Kedang in the northeast is 4.979 ft. and Mt. Lamahero in the south is 3,350 ft.), one of which, Lobetola (5.400 ft.), is an active volcano; Adunara has a volcano, Ili Buleng (5,446 ft.), in the southeast and a plateau, ringed with hills, reaching 3,000 ft.; Solor is hilly also. All the islands are attached: administratively, to the residency of Timor and dependencies. Alor has a population (1930) of 51,423, resembling the natives of Timor, a warlike race of strong physique, suspicious of strangers. fond of hunting and fishing (bow and arrow the chief weapon) and leaving agriculture to the women and children, but direct Dutch rule is curbing the warlike spirit. Villages, in the hills, are in well-nigh inaccessible positions, with strong bamboo fences, the houses being on piles, and solidly built; houses on the coast are better built. Most of the people are pagans (some Mohammedans live in the northwest), the mountain folk being divided into tribes, worshipping animals (snakes and crocodiles), observing *pomali* (Tabu), growing rice, maize, tobacco, fruit and vegetables, and keeping pigs. Clothing, except at places along the coast, is very primitive. The coastal folk weave sarongs. Many tongues are spoken, differing greatly.

Pantar has about 8,000 people, in the northern part of the island; pagans. tall and strongly-built, with Mohammedans on the coast. Conditions of life, etc., resemble those of Alor, but Pantar is poor, and the people often emigrate to Timor. Houses and villages are scattered and unfenced. As in Alor, many languages are spoken, one an Alorese. The population of the Solor islands is estimated at 35,000, the people being Malayo-Papuan (Wallace terms them "of dark Papuan type"), with dark skin, curly hair and strong frame. Agriculture and fishing are practised; many coco-nut trees are found on Lomblen and Adunara; the Lomblen folk weave sarongs and build boats, and all three islands have smiths. Horses, buffaloes and chickens are kept. In coastal villages houses are on the steep hillside, almost overhanging the water. Inland villages are larger and grouped about a square, in which stands a large tree, and sometimes a round platform, where feasts are celebrated. Under European influence the defensive method of village- and house-planning tended to disappear, house's being built on flat ground. Each village has its barns and *pomali* house. Stone-carved seats for graves are known, also stone offering-places. The Adunara people prize very greatly elephants' teeth, imported, in earlier days, from Further India. Marriage is by dowry, the woman having no freedom of choice, and young girls are so highly prized that kidnapping is known on Lomblen and Adunara. The standard of married morality is high. In one part of Lomblen, some time after burial, the head is dug up and preserved in a shed. The languages spoken vary considerably from those of Alor. There is communication with Dilly, in Portuguese Timor, and with Flores and Macassar.

A Portuguese claim to Larantuka, in East Flores, and the Solor islands, led the Dutch, in 1757, when there mas a fear lest the Portuguese should cede Larantuka to the French, to send an agent to Solor to acquire the island for the Dutch East India company, but Portuguese claims to both Solor and Adunara were not given up until 1848, when a Dutch agent was sent to Lawajong, in Solor, to recruit labour, and the treaty between Holland and Portugal by which Larantuka, Solor, Adunara, Alor and Pantar were surrendered was not ratified until 1859, though Dutch garrisons were placed in Larantuka and Lawajong in 1851. Disturbances at Lawajong in 1889 compelled the Dutch official there to withdraw to Larantuka, and in 1909 armed intervention in Solor became necessary, after which Solor, Adunara and Lomblen were formed into a subdivision and included in the province of the civil governor of East Flores.

The island group fell to the Japanese during World War II.

(E. E. L.; X.)

SOLOTHURN (Fr. *Soleure*), a canton in northwest Switzerland; the total area is 305.5 sq mi., of which about 97% is reckoned as productive. This is higher than for any other Swiss canton. Solothurn has a most irregular shape, dependent on the fact that the canton consists of territories won at different dates by the town from which it takes its name. It includes an area of plain along the Aar valley projecting into Canton Berne, with the Bucheggberg in the southwest between the Aar and Emme, a right-bank tributary joining the larger river near the town of Solothurn. Farther downstream, a part of the Aar valley belongs to Berne, but Solothurn resumes possession somewhat later and here the Aar receives the Wigger on the right bank at Aarburg, and the Dunneran from the Jura on the left bank at Olten. This section of the canton may be described as the foot of the Jura. The Hasenmatt (4751 ft.) is the highest point of the Weissenstein section of the main Jura range which runs through the country north of the capital. Across this range, Solothurn stretches in a broad belt to the north where, at various points, it shares with Berne the river Birs, a tributary flowing into the Rhine near Basle. Beyond the Birs, are two separated districts belonging to the canton: Hofstetten, including the famous pilgrimage centre Mariastein, and Kleinlützel. The north part of the canton and its detached fragments touch the cantons of Berne and Basleland. Highroad and railway communications are excellent. Olten is a great railway junction where the direct lines from the St. Gotthard via Lucerne, from Geneva, from Zürich, and from Basle all unite. Formerly various districts were in the dioceses of Lausanne, Basle and Constance, but since 1814 they have all ranked as part of the diocese of Basle, with the town of Solothurn as the site of the bishop's palace. In 1930 the population was 144,198 and in 1941 was 154,872, all but a few of whom were German-speaking. Roughly two-thirds of the inhabitants are Catholics, the rest practically all Protestant. The capital is Solothurn (15,432 pop. in 1941), and the only other fairly large town is Olten (15,282), both on the Aar. Between Solothurn and the small industrial town of Grenchen, to the west-southwest, lies the village of Selzach, noted for its annual passion-play.

Till about 1850 the cantonal activities were mainly agricultural and pastoral, and though these are still important, yet its density of population (502.3 per sq.mi. in 1939, against 263.4 for Switzerland as a whole), is largely dependent on the variety of its manufactures, e.g., watches, jewellery, shoes, cotton, motor parts and cement, particularly around Solothurn and Grenchen.

Soleure is divided into ten administrative districts with 132 communes. The cantonal Constitution dates from 1887, but was substantially revised in 1895. The *Kantonsrat*, or legislative assembly, is now elected according to the principles of proportional representation. The 146 deputies are chosen on the basis of one member for each 1 000 of the total resident population. The *Regierungsrat* or executive consists of five members. Both groups hold office for four years, but any 4,000 citizens can demand a popular vote on Abberufung, or recall, to decide as to whether the existing members shall continue to sit or not. In addition, the "obligatory referendum" and the "initiative" exist. By the former, since 1869, all laws and financial resolutions passed by the *Kantonsrat* must be approved by a popular vote. By the latter, since 1869, 2,000 electors can compel the legislative assembly to consider any legislative proposal. Further, since 1856, the demand of 3,000 electors is sufficient to necessitate a popular vote as to the advisability of effecting some constitutional change. The two members of the federal *Ständerat* and the seven members of the federal Nationalrat (according to the census of 1941) are also chosen by a popular vote.

SOLOTHURN (Fr. *Soleure*), the capital of the Swiss canton of that name, an ancient little town, situated on the river Aar. In 1941 it had 15,432 inhabitants. almost all German-speaking, with a small Catholic majority. A 16th-century rhyme claims for the town of Solothurn the fame of being the oldest place in "Celtis" save Trier. Certainly its name, "Salodurum," is found in Roman inscriptions and the remains of the Roman "castrum" still exist. Its position as commanding the approach to the Rhine from the south-west has led to its being more than once strongly fortified. The mediaeval town grew up round the house of secular canons founded in the 10th century in honour of St. Ursus and St. Victor by Queen Bertha, the wife of Rudolph II., king of Burgundy. The prior and canons had many rights over the town; but in 1218 it became a free imperial city, and in 1252 shook off the jurisdiction of the canons and took them under its protection. In 1295 we find it allied with Bern, and this connection is the key to its later history. In the 14th century the government of the town fell into the hands of the gilds, whose members practically filled all the public offices. Through Bern, Solothurn was drawn into association with the Swiss Confederation. An attempt to surprise it in 1382, made by the Habsburgs, was foiled, and resulted in the admittance of Solothurn in 1385 into the Swabian League and in its sharing in the Sempach War. It was included in the Sempach ordinance of 1393 and in the great treaty of 1394 by which the Habsburgs renounced their claims to all territories within the Confederation. In 1411 Solothurn sought in vain to be admitted into the Confederation, a privilege only granted to it in 1481 at the diet of Stans. It was also in the 15th century that by purchase or conquest the town acquired the main part of the territories forming the present canton. In 1529 the majority of the "communes" went over to the reformed faith, and men were sent to fight on Zwingli's side at Kappel (1531); but in 1533 the old faith regained its sway, and in 1586 Solothurn was a member of the Golden, or Borromean, League. Solothurn was the usual residence of the French ambassador from 1530 to 1797. From 1681 onwards, it had an aristocratic form of government; but this was finally broken down in 1831, Solothurn in 1832 joining the league to guarantee the maintenance of the new cantonal constitutions. Though distinctly a Roman Catholic canton, it did not join the "Sonderbund," and voted in favour of the federal constitutions of 1848 and 1874.

The position of Solothurn at the foot of the Jura and close to the navigable portion of the Aar has always made it a meeting-point of various routes. Six railway lines now branch thence. Its chief building is the minster of SS. Ursus and Victor, which dates from the 18th century, though it stands on the site of a far older edifice. Since 1828 it has been the cathedral church of the bishop of Basel. The ancient clock tower and the older portions of the town-hall date still further back. The early 17th century arsenal contains the finest collection of armour and old weapons in Switzerland, while the modern museum houses a splendid collection of fossils from the Jura, rocks collected by F. J. Hugi (1796–1855), a native of Soleure, and a Madonna by the younger Holbein. The building now used as the cantonal school was the residence of the French ambassadors to the Swiss confederation from 1530 to 1797. There are some fine 16th century fountains in the town, which in its older portions still keeps much of its mediaeval aspect, though in the modern suburbs and in the neighbouring villages there is a certain amount of industrial activity (watch-making, motor manufactures, etc.). One mile N. of the town is the Hermitage of St. Verena, in a striking rock gorge, above which rises the Weissenstein ridge.

See K. Meisterhaus, *Kurze Entwicklungsgeschichte der Stadt Solothurn* (1895)

SOLOVIEV, SERGEI MIKHAILOVICH (1820–1879), Russian historian. was born in Moscow on May 17, 1820. and died on Oct. 16, 1879. From 1842–44 he travelled in Europe as tutor in Count Stroganov's family. He wrote treatises on *The Relations between Novgorod arid the Grand Princes* (1845). and on the *History of the Relations among the Russian Princes and the House of Rurik* (1847), and was appointed professor of history at and later rector of the university of Moscow. His *History of Russia* (29 vols.; Moscow, 1851–79), was the first complete scientific treatment of Russian history. from its origins up to 1774, since Karamzin's *History of the Russian State* (1818–29). Other works by him are *Historical Letters* (1858) ; *History of the Fall of Poland* (1863) ; and *The Political and Diplomatic History of Alexander I.* (1877).

SOLOVIEV, VLADIMIR SERGEVICH (1853–1900), Russian idealistic philosopher, critic and poet, son of the historian, Sergei Soloviev (*q v.*), was born in Moscow on Jan. 16, 1853, and died at Uzkoe, near Moscow, on July 31, 1900. Vladimir studied theology at the University of Moscow, publishing in 1875 his Ph D. thesis on *The Crisis of Western Philosophy.* After visiting England and Egypt, where he studied eastern philosophical ideas. he returned to Russia and was appointed reader in philosophy at Moscow university in 1877. But his outspoken criticism of the government cut short his career as a lecturer; a speech against capital punishment lost him his readership at Moscow, and he nas soon removed from the minor professorship at St. Petersburg (now Leningrad) to which he was next appointed. The rest of his life nas devoted chiefly to writing. The chief tenet of Soloviev's theology, the union of eastern and western beliefs in a universal church, led him to take up a pro-Roman attitude for a time and in 1889 he published in French *La Russie et l'Église Universelle* (3rd ed.. 1922). He upheld the Christian ideal of universal brotherhood as opposed to Slavophilism. Philosophically he laid stress on the spirituality of all being, the idea of absolute one-ness, and the evolution of the God-man. His best known works are a *History of Materialism* (1894); *History of Ethics* (1896–98); *The Justification of the Good* (1898; Eng. trans. in Constable's Russian Library, 1915); *War, Progress, and the End of History, including a short story of the Anti-Christ* (1900; Eng. trans. 1915, with biographical notice by Dr. Hagberg Wright). *See* also *War and Christianity from the Russian Poznt of View,* three conversations, translated 1915, with an introduction by Stephen Graham. For a brief account of Soloviev's philosophy *see* L. M. Lopatin, *The Philosophy of Vladimir Soloviev* (1916).

SOLSTICE, in astronomy either of the two points at which the sun reaches its greatest declination north or south (Lat. *solstitium,* from *sol,* sun, and *sistere,* to stand still). Each solstice is upon the ecliptic midway between the equinoxes, and therefore 90° from each. The term is also applied to the time at which the sun reaches the point thus defined (about June 21 and Dec. 21).

SOLUNTUM (Gr. Σολόεις or Σολοῦς), an ancient town of Sicily, one of the three chief Phoenician settlements in the island, situated on the north coast, 10 mi. E. of Panormus (Palermo), 600 ft. above sea level, on the southeast side of Mt. Catalfano (1,225 ft.), in a naturally strong situation, and commanding a fine view. It was a Carthaginian possession until the First Punic War, when, after the fall of Panormus, it opened its gates to the Romans. Excavations have brought to light considerable remains of the ancient town, belonging entirely to the Roman period.

SOLUTIONS.— The concept of a liquid solution is familiar to everyone. Sugar and salt dissolve in water to form solutions, alcohol mixes with water in all proportions to form solutions and sea water is a solution containing a high concentration of salt and relatively small amounts of other substances. The general subject includes morc than liquid solutions, and a rigorous definition is required to fix its limits and its terminology.

Definitions.— A phase is a homogeneous portion of a system with definite physical boundaries. Thus, water can exist in three phases: ice, liquid and vapour. In general, a phase which contains two or morc substances (components) is a solution. Consequently, mixtures of gases; gases, liquids or solids dissolved in liquids; and solids in solids are solutions. This discussion will be restricted to liquid solutions containing two components. It is customary but somewhat arbitrary to regard one of the two components of a binary mixture as being dissolved in the other. The substance which dissolves is called the solute and the dissolving medium the solvent.

Composition.— The formula weight of a substance is the unit most suitable for expressing the composition of a solution. This is the quantity of substance which contains the number of molecules equal to the number of atoms contained in 16 g. of oxygen. (*See* AVOGADRO'S CONSTANT.) This quantity is called the gram-molecular weight of the component. Depending on the experiment and the kind of system to be investigated, different composition scales have been employed. If a solution contains n_1 and n_2 formula weights of the first and second components, respectively, the composition may be expressed by: $N_1=\frac{n_1}{n_1+n_2}$; $N_2=\frac{n_2}{n_1+n_2}$ whereby N_1 and N_2 are denoted the mol fractions of the first and second components. Another practical scale is the "molal," in which concentrations (molalities) are given by the number of formula weights of dissolved substance (solute) in 1,000 g. of solvent. Frequently, it is more convenient to employ a volume concentration scale. The "molar" concentration is the formula weight of a component in one litre of solution and the "normal" concentration, so useful to analytical chemists, is given in gram equivalents of solute per litre of solution. For expressing the properties of solutions containing large molecules, the volume fraction has proved the most useful. The total volume, V, is given by the expression $V=n_1v_1+n_2v_2$, where v_1 and v_2 are the volumes per formula weights of the two components in the solution so that n_1v_1 and n_2v_2 are their actual volumes. Their volume fractions become $\frac{n_1v_1}{n_1v_1+n_2v_2}$ and $\frac{n_2v_2}{n_1v_1+n_2v_2}$ –

General Classification of Properties.—The properties of solutions fall into two groups: (1) those of systems which are in equilibrium (static); (2) those of systems in which disturbances cause relative motion of parts of the solution (dynamic). The first group can be treated by the exact methods of thermodynamics where specially defined "reversible" processes are considered. The second group comprises the class of irreversible processes among which are the flow of the solution as a whole (viscous flow), the movement of one component into the other (diffusion) or the movement of parts of the solution under the influence of an electrical field (electrical conductance).

The properties of solutions which conduct the electric current depend upon the presence of electrically charged particles, or "ions." Although the presence of ions was suspected by R. Clausius (1857), it was not until 1887 that S. Arrhenius recognized that ions are present in considerable quantities in many solutions of acids, bases and salts. Thereafter it was found convenient to consider solutions from two points of view, *nonelectrolytic* and *electrolytic.* Nonelectrolytic solutions comprise a large class of mixtures containing substances which have a high resistance to the flow of electricity, such as alcohol-water, carbon tetrachloride-benzene, etc. Their properties are determined by the individual characteristics of their molecules and molecular interaction. Electrolytic solutions may contain both electrically charged atoms and neutral molecules so that they possess certain electrical properties.

THERMODYNAMIC PROPERTIES

The thermodynamic properties are universal for all liquid solutions, and the application of the methods of thermodynamics effects a simplification in an otherwise extremely complicated situation. J. H. van't Hoff (1887) was the first to apply thermodynamics to solutions systematically, but his treatment lacked the generality which could have been achieved if he had employed the thermodynamic system devclopcd by J. W. Gibbs (1875–78).

Solubility.— When a solute is brought into contact with a liquid at a given temperature and pressure, it will dissolve and its concentration in the resulting solution will increase if it is soluble in the liquid. When no more solid dissolves and a state of equilibrium is reached, the solution is saturated with the solute. The concentration of the solute in this saturated solution is its solubility. Other procedures may yield saturated solutions, but care must be exercized in establishing a stable state of equilibrium and avoiding the unstable state of supersaturation in which the solute concentration is greater than its solubility. It is important to note that the process of solution is one of transference whereby the solute passes from its pure state into the solution. If the solute is a solid the reverse process of crystallization is also a transfer process whereby this component leaves the solution and appears in the solid state. The thermodynamics of solutions is concerned with such transfer processes, of a very specially defined nature: "thermodynamically reversible processes." (See THERMODYNAMICS.) Thus, consider a solid in equilibrium with its solution and imagine a process whereby a gram molecule passes from the solid state into a sufficiently large (infinite) amount of solution without producing a change in the solubility concentration. Every stage in such a process would be infinitesimally close to state of equilibrium rnd the entire process would be a reversible one in the thermodynamic sense.

Osmotic Pressure.—Abbé J. A. Nollet (1748) reported that when an animal bladder was filled with alcohol and immersed in water, water entered the bladder and caused a considerable distension. M. Traube (1867) first produced artificial membranes of cupric ferrocyanide which permitted the passage of one of the components of a solution and not the other. The first quantitative determinations of osmotic pressure were made by W. Pfeffer (1877) Pfeffer's apparatus (fig. 1) consists of a porous cup. P, in the interior of whose walls is deposited a membrane of cupric ferrocyanide This membrane allows the passage of water but does not permit the passage of the solute, cane sugar. The cell containing the solution, S, is immersed in water in the vessel, W. The water enters through the membrane into the solution and exerts a pressure which causes the mercury to rise in the outer limb of the manometer, M. After equilibrium is reached, the osmotic pressure is measured by the difference, h, in heights of the mercury in the two limbs of the manometer.

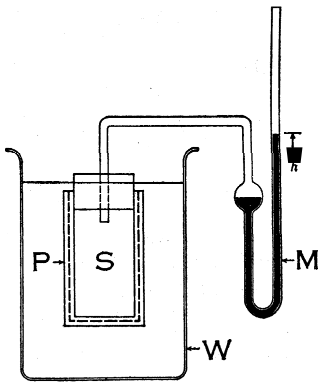


FIG 1—APPARATUS FOR THE DETERMINATION OF OSMOTIC PRESSURE

Pfeffer obtained the first numerical data indicating how the osmotic pressure varies with the temperature and concentration of solute and it was van't Hoff who pointed out that the mathematical relation between the osmotic pressure, concentration and temperature of dilute solutions has exactly the same form as the ideal gas laws (see CHEMISTRY: Physical *Chemistry*). More exact measurements of the osmotic pressures of cane sugar and some salt solutions, performed by H. N. Morse and J. C. W. Frazer (1902–12) in the United States and the earl of Berkeley and E. G. J. Hartley (1906–09) in England, confirmed these observations.

The process of osmosis consists in a transfer of the solvent from the solvent to the solution and is similar in principle to the phenomenon of solubility in which the solute is transferred. Therefore, we can imagine the reversible transfer of one mol of solvent from solvent to solution or vice versa under the condition that the system is in equilibrium, or differs from equilibrium by an infinitesimal amount only.

Vapour Pressure.—When a liquid is placed in a closed evacuated vessel at a given temperature, it evaporates until the vapour acquires a definite equilibrium pressure, which is termed the vapour pressure of the liquid. If an external pressure greater than the vapour pressure is applied to this vapour, it will condense to form liquid. Thus, evaporation or condensation is a transfer process subject to thermodynamic treatment.

If a substance which possesses no appreciable vapour pressure is dissolved in a liquid, the resulting solution is found to have a lower vapour pressure than the solvent. Although A. Wüllner (1858–60) observed that this lowering was proportional to the amount of dissolved substance, the formulation of general law of the lowering of the vapour pressure should be accredited to François Marie Raoult (1886). Thus, if p_1° is the vapour pressure of the solvent and p_1 that of a solution containing a nonvolatile solute, the relative lowering of the vapour pressure is proportional to the mol fraction of the solute, N_2. Thus: $\frac{p_1^\circ - p_1}{p_1^\circ} = N_2$. Now, since the sum of the mol fractions of the two components is unity, $N_2 = 1 - N_1$, where N_1 is the mol fraction of the solvent, and Raoult's law becomes $1 - \frac{p_1}{p_1^\circ} = 1 - N_1$, or $p_1 = p_1^\circ N_1$. This law is fundamental to the whole science of liquid solutions. A solution which conforms to this law at all values of the concentrations is called "ideal." Most solutions are not ideal, but for all solutions the prediction of this law agrees more and more closely with experiment as the concentration of the sclute decreases, or when the mol fraction of the solvent approaches unity.

Elevation of the Boiling Point.—The vapour pressure of a liquid increases with the temperature and when it exceeds the external pressure on the liquid it boils. The boiling point is defined as the temperature of the liquid when it boils at atmospheric pressure (1 atm. = 760 mm. of mercury). Since the addition of a nonvolatile solute to a solvent lowers its vapour pressure, a higher temperature is required to cause the solution to boil, and the difference between the boiling points of the solution and of the pure solvent, denoted by the elevation of the boiling point, is always positive. Since in dilute solution equal mol fractions of different nonvolatile solutes produce the same relative lowering of the vapour pressure, they always produce the same rise in boiling point, and this rise per mol of solute is a characteristic property of the solvent.

If T_b° is the boiling point of the pure solvent and T_b that of the solution of molality, m, the observed rise in boiling point is $(T_b - T_b^\circ)$. The observed rise per mol in 1,000 g. of solvent is $\frac{(T_b - T_b^\circ)}{m}$. The limiting value of this quantity as m approaches zero is called the molal boiling point elevation, ΔT_b. From the laws of thermodynamics, van't Hoff showed that ΔT_b is given by $\Delta T_b = \frac{M_1 R T_b^2}{1{,}000\, L_v}$, where M_1 is the molecular weight of the solvent, L_v the latent heat of vaporization of one mcl of solvent, and R the gas constant (R=1.9865 cal. per mol degree). For water **at** the boiling point, L_v is 9,710 cal. per mol whence

$$\Delta T_b = \frac{18.016 \times 1.9865 \times (373.16)^2}{1{,}000 \times 9{,}710} = 0.512^\circ.$$

For ethyl alcohol and acetic acid at their boiling points, 78.3° C. and 118.3° C., ΔT_b is 1.214° and 3.15° C., respectively, and other liquids possess molal boiling point elevations of the same order of magnitude.

Lowering of the Freezing Point.—The temperature at which a liquid exists in equilibrium with its solid phase is its freezing point. If a liquid containing a small amount of a solute is cooled, the solvent will freeze out and the freezing point of the solution will be the temperature at nhich this solid exists in equilibrium with the solution. The addition of a solute to a solvent always causes a lowering of the freezing point and, like the elevation of the boiling point, this lowering is characteristic of the solvent and depends on the number of mols of the dissolved substance. For dilute solutions, the lowering, ΔT_f, per mol of solute in 1,000 g. of solvent was shown by van't Hoff to be given by $\Delta T_f = \frac{M_1 R T_f^2}{1{,}000\, L_f}$, where M_1 is the molecular weight of the solvent, T_f the temperature of the freezing point, R the gas constant and L_f the molecular latent heat of melting of the solvent. The values of the molal lowering of the freezing point for water at 0° C. and acetic acid at its freezing point (16.6° C.) are 1.858° and 3.73' C., respectively.

Electromotive Force of Galvanic **Cells.**—The processes of osmosis, vaporization, boiling and freezing result in transferring solvent, whereas the solution process transfers the solute. Another very important method for transferring solute applicable in electrical conducting systems is obtained by the use of galvanic cells, the theory of which was developed by Gibbs and H. von Helmholtz in 1878. Such a cell which among others has proved of great value in the study of solutions may be represented by

$$\overset{-}{\mathrm{Pt}}-\mathrm{H_2}|\mathrm{HCl}(m_1)|\mathrm{AgCl}-\overset{+}{\mathrm{Ag}};\ \mathbf{E}_1,$$

where a platinized platinum electrode over which hydrogen gas passes ($Pt-H_2$) and a silver chloride-silver electrode ($AgCl-Ag$) are immersed in hydrochloric acid of molal concentration m_1[$HCl(m_1)$]. This system spontaneously generates an electric current. The electromotive force, $\mathbf{E}_1$, can be measured with very high precision. The electrical work obtained from a cell is associated with definite chemical changes which take place in the cell and for scientific purposes it is essential to know just what these changes are. In this case, the chemical reaction taking place is simply the reduction of silver chloride by hydrogen gas to form silver and hydrochloric acid at concentration m_1 according to the equation

$$\tfrac{1}{2}\mathrm{H_2}+\mathrm{AgCl}=\mathrm{Ag}+\mathrm{HCl}(m_1);\ \mathbf{E}_1.$$

For thermodynamic purposes, this cell must be reversible and therefore its electromotive force must be determined when the system is in equilibrium, or, in other words, when no current is flowing. Such a measurement can be effected by a potentiometer circuit in which the electromotive force of the cell is balanced against an external electromotive force. If the electromotive force of a cell containing the acid at another concentration, m_2, is measured, then the cell reaction is

$$\tfrac{1}{2}\mathrm{H_2}+\mathrm{AgCl}=\mathrm{Ag}+\mathrm{HCl}(m_2);\ \mathbf{E}_2,$$

where $\mathbf{E}_2$ is the corresponding electromotive force. Since in the first and second of these reactions everything is identical with the exception of the hydrochloric acid concentrations, subtraction of the second equation from the first yields

$$\mathrm{HCl}(m_2)=\mathrm{HCl}(m_1);\ (\mathbf{E}_1-\mathbf{E}_2),$$

and the difference ($\mathbf{E}_1-\mathbf{E}_2$) corresponds simply to the work involved in the reversible transfer of hydrochloric acid at concentration m_2, from the second to the first solution, nhere its concentration is m_1.

Thermodynamic Generalization.— These considerations show that all the processes just described have one common element, the reversible transfer of one of the components from pure solid or liquid to the solution or vice versa, or from a solution of one concentration to a solution of another concentration. This permits thermodynamics to effect the great simplification that all these measurements may be employed to determine one thermodynamic quantity, which mill be found to be the change in chemical potential of a component. Without thermodynamics all such properties and the various methods used to investigate them would have to be treated independently. The thermodynamics of solutions is thus resolved into the science of evaluating the chemical potentials and related quantities as functions of the component concentrations, the nature of the solvent media, the external pressure, the temperature and any other variables of importance.

To understand fully the properties of the chemical potential, a brief exposition of the general theory is required. It was shown by Gibbs that the energy, E, of a phase of c components may be expressed as a function of the pressure, P, the volume, V, the temperature, T, the number of mols of each of the components, n_1, 122, ... n_c, and other variables such as surface area, electric charge, etc. Including only those variables which are essential for the moment, the energy is expressed by

$$E=f(p,\ V,\ T,\ n_1,\ n_2,\ \ldots\ n_c)+E^\circ. \tag{1}$$

The energy is not an absolute quantity but is measured relatively to some standard value, E°. From the equation of state which relates one of the variables of a phase to the others, it is always possible to eliminate one variable. The first law of thermodynamics requires that the increase in energy of a system at constant composition is equal to the heat absorbed by the system plus the work done upon it. In differential form, the first law may be written

$$dE=dQ-PdV+dW, \tag{2}$$

where dQ is the heat absorbed, PdV is the work done by the system against pressure and dW symbolizes any additional work terms which for simplicity will not be required for this development. The second law of thermodynamics requires that the entropy change, dS, must equal the reversible heat change divided by the absolute temperature, or

$$dS=\frac{dQ}{T}. \tag{3}$$

By differentiation of equation (1) and introduction of these expressions for the two laws, it is found that, for reversible processes,

$$dE=TdS-PdV+\mu_1dn_1+\mu_2dn_2+\ldots\mu_cdn_c, \tag{4}$$

where μ_1, μ_2, ... μ_c are substituted for the partial differential coefficients, $\frac{\partial E}{\partial n_1}, \frac{\partial E}{\partial n_2}, \ldots \frac{\partial E}{\partial n_c}$. These are the chemical potentials first introduced by Gibbs.

Since for practical purposes other variables than the entropy and volume are more suitable, the thermodynamic functions H, A and F, denoting the heat content, the work content and free energy, have been introduced by means of their definitional equations

$$H=E+PV, \tag{5}$$
$$A=E-TS, \tag{6}$$
$$F=E-TS+PV. \tag{7}$$

The general equations for their differentials are

$$dH=Tds+VdP+\mu_1dn_1+\ldots\mu_cdn_c, \tag{8}$$
$$dA=-SdT-PdV+\mu_1dn_1+\ldots\mu_cdn_c, \tag{9}$$
$$dF=-SdT+VdP+\mu_1dn_1+\ldots\mu_cdn_c, \tag{10}$$

in which

$$\begin{aligned}\mu_1=\left.\frac{\partial E}{\partial n_1}\right]_{S,\ V,\ n_2\ldots n_c} &= \left.\frac{\partial H}{\partial n_1}\right]_{S,\ P,\ n_2\ldots n_c}\\ =\left.\frac{\partial A}{\partial n_1}\right]_{V,\ T,\ n_2\ldots n_c} &= \left.\frac{\partial F}{\partial n_1}\right]_{P,\ T,\ n_2\ldots n_c}\end{aligned} \tag{11}$$

Similar relations can be written for μ_2, μ_3, ... μ_c.

Consideration of these differential coefficients clearly indicates their relation to the transfer processes which have been described. Each one of these coefficients represents a change in the respective quantities per mol of the component; for example, $\frac{\Delta F}{\Delta n_i}$ as An, approaches zero, all other indicated variables remaining constant. It is implied that the composition of the phase is constant. Consequently, the chemical potential is associated with a transfer process of a component into or out of a phase. It is thus easy to see that the removal of a component from a solution at one concentration and its introduction into a solution of another concentration is associated with a differencein two values of the chemical potential of this component. Indeed, this type of reversible transfer corresponds to the galvanic cell process described in the last section.

Gibbs deduced from the relations given by equations (10) and (11) applied to a system composed of p phases that at equilibrium at constant pressure and temperature the chemical potential of each of the components was the same in all phases. In symbolic form, this condition is given by

$$\begin{aligned}\mu_1'&=\mu_1''=\ \ldots\ \mu_1^p,\\ \mu_2'&=\mu_2''=\ \ldots\ \mu_2^p,\\ &\ldots\ldots\ldots\ldots\\ \mu_c'&=\mu_c''=\ \ldots\ \mu_c^p,\end{aligned} \tag{12}$$

where μ_1', μ_1'', ... μ_1^p represent the chemical potentials of the first component, μ_2', μ_2'', ... μ_2^p those of the second component, etc., in each of the p phases, respectively. This equality of the chemical potentials is the basis for the theoretical study of transfer processes involved in freezing and boiling, solubility and vapour pressure measurements. For, imagine a process of three steps whereby water initially at its freezing point is transferred to a solution containing a solute. (1) One mol of water is frozen reversibly at 0°. During this process the system is in equilibrium so that its chemical potential is the same in water as in ice and the change in this quantity is zero. (2) Cool the ice to the temperature of the freezing point of the solution. This step involves a change in the chemical potential of the ice. (3) Melt the ice reversibly at this temperature. No change in chemical potential occurs. Thus, a measurement of the change in chemical potential for the second step will determine its change for the entire process. Similar considerations are involved in transfer of the solute or solvent by boiling, evaporation, osmosis, solubility or galvanic cell transfer.

There remains one further very important consideration deduced by Gibbs. At constant pressure and temperature, equation (10) becomes

$$dF=\mu_1 dn_1+\mu_2 dn_2+\ldots\mu_c dn_c. \qquad (13)$$

Since this equation is homogeneous and of the first degree in the extensive variables, n_1, n_2, ... n,, it can be integrated to give

$$F=\mu_1 n_1+\mu_2 n_2+.\quad \mu_c n_c \qquad (14)$$

which upon complete differentiation and recombination with equation (13) yields

$$n_1 d\mu_1+n_2 d\mu_2+\ldots n_c d\mu_c=0.$$

This relation although applicable to a phase of any number of components is particularly useful for the computation of the properties of a two component solution. In this case,

$$n_1 d\mu_1=-n_2 d\mu_2, \qquad (16)$$

which immediately yields the integrals

$$\int d\mu_1=-\int\frac{n_2}{n_1}d\mu_2;\ \int d\mu_2=-\int\frac{n_1}{n_2}\partial\mu_1. \qquad (17)$$

If the change in chemical potential of one component in a two-component solution can be measured, the chemical potential of the other component may be calculated. Therefore, all the above processes in which transfer of one or the other component occurs can be used to determine the chemical potential of either component.

SOLUTIONS OF NONELECTROLYTES AND ELECTROLYTES

Cane sugar in water does not conduct electric current and causes a lowering of the freezing point per mol of solute in 1,000 g. of solvent of 1.858° C. A dilute solution of salt conducts electricity and possesses a molecular lowering of twice this amount. These differences in behaviour are typical of solutions of nonelectrolytes and electrolytes, respectively, and led to the generalization by van't Hoff (1887) that all substances which produced such abnormally large lowerings of the freezing point or elevations of boiling point were electrically conducting. As a measurement of this abnormality, van't Hoff introduced the factor i which for sodium chloride is nearly 2. Arrhenius (1887) interpreted this fact to indicate that one mol of salt dissolved in water yields twice as many molecules as a solution of one mol of cane sugar, and is dissociated in water according to the scheme: $NaCl \rightarrow Na^+ + Cl^-$, where Na+ and Cl^- represent the sodium and chloride ions. Electrolytes of higher valences such as barium chloride, lanthanum chloride and lanthanum sulphate were thought to dissociate according to: $BaCl_2 \rightarrow Ba^{++}+2Cl^-$; $LaCl_3 \rightarrow La^{+++}+3Cl^-$; and $La_2(SO_4)_3 \rightarrow 2La^{+++}+3SO_4^{--}$, respectively, and their values of the van't Hoff i derived from data in very dilute solutions will approach 3, 4 and 5, respectively, if their solutions are sufficiently dilute. Electrolytes are classified according to their valence types and in the following sections salts like NaCl, $BaCl_2$, $LaCl_3$, $La_2(SO_4)_3$, etc., will be designated 1–1, 2–1, 3–1, 3–2, etc., electrolytes, respectively.

The experimental knowledge of the thermodynamic properties of electrolytic solutions since 1900 have been investigated principally by A. A. Noyes, G. N. Lewis, H. S. Harned, V. K. LaMer, D. A. MacInnes, G. Scatchard, T. F. Young, F. T. Gucker, Jr., O. Redlich and others in the United States, N. Bjerrum, J. N. Brönsted and E. Güntelberg in Denmark, E. Lange in Germany and R. A. Robinson in New Zealand. The thermodynamics of nonelectrolytic solutions has been developed largely by J. H. Hildebrand (1911), G. Scatchard and S. E. Wood.

Solutions of Nonelectrolytes.—The Ideal *Solution.*—For a solution containing a nonvolatile solute, Raoult's law is $p_1=p_1^\circ N_1$ which equates the vapour pressure of the volatile component over the solution with the vapour pressure of this pure component, p_1°, times its mol fraction. For solutions containing two volatile components miscible in all proportions, Raoult's law may be generalized to give $p_1=p_1^\circ N_1$ and $p_2=p_2^\circ N_2$ for the first and second component, respectively. These relations are illustrated by fig. 2, where the graphs of p_1 and p_2 versus N_1 and N_2 appear as straight lines. If the vapours of both components obey Dalton's law that the total pressure (p_1+p_2) is the sum of the partial pressures in the mixture of gases, then this latter quantity is also a straight line as shown in the figure. Conformity of actual vapour pressures with the requirement of Raoult's law has been used as a criterion of an ideal solution. A few combinations of liquids agree closely with this law of perfect mixtures but the properties of a great many solutions vary from this law to a lesser or greater degree. The more nearly alike the molecules of the two components are in all their properties (structure, size, shape, etc.), the closer will their mixture conform to the law. As a corollary, deviations from the law become very important because they are a measure of the various interactions between different kinds of unlike molecules.

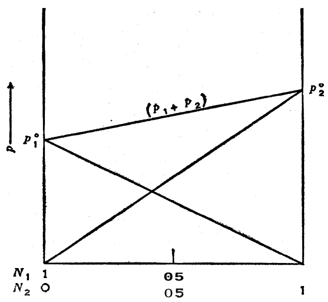

FIG. 2—ILLUSTRATING RAOULT'S LAW FOR THE VAPOUR PRESSURE OF IDEAL MIXTURES

Solutions *Which* Are Not Ideal.—The behaviours of two mixtures which exhibit negative and positive deviations from Raoult's law, taken from the partial vapour pressure measurements of J. von Zawidski (1900), are shown in fig. 3 and 4. Fig. 3 illustrates the negative deviations indicated by the occurrence of the solid curves below the dashed straight lines for chloroform-acetone mixtures, while positive deviations appear in fig. 4 for carbon disulphide-methylal solutions. More nearly ideal solutions, such as propylene bromide-ethylene bromide mixtures, composed of molecules show the ideal behaviour represented by the dotted lines. Many mixtures exhibit much larger deviations than those illustrated by these figures and in some cases such as pyridine-water both positive and negative deviations occur.

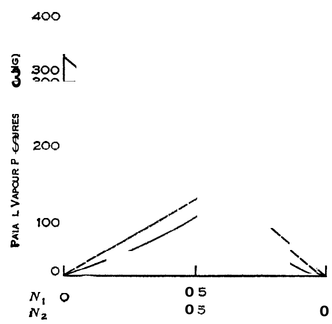

FIG. 3—PARTIAL VAPOUR PRESSURES OF CHLOROFORM-ACETONE MIXTURES AT 35 17° C. N_1=MOL FRACTION OF CHLOROFORM; N_2=MOL FRACTION OF ACETONE. (DATA OF J. VON ZAWIDSKI)

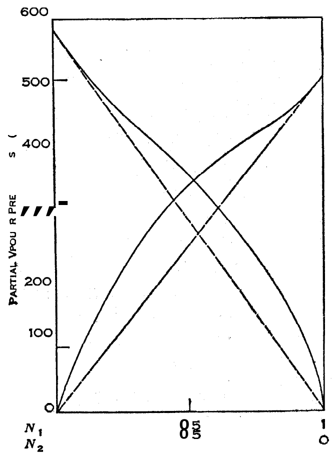

FIG. 4—PARTIAL VAPOUR PRESSURES OF CARBON DISULPHIDE-METHYLAL MIXTURES AT 35.17° C. N_1=MOL FRACTION OF CARBON DISULPHIDE; N_2=MOL FRACTION OF METHYLAL. (DATA OF J. VON ZAWIDSKI)

The departures from the ideal law of gases which occur at high pressures were successfully interpreted by J. D. van der Waals (1890) by assuming attractive forces or "internal pressures" between the molecules as well as short-range repulsive forces resulting from the fact that the molecules have volumes. In liquids, these forces are very much larger than in gases because the distances between the molecules are smaller, so that in all cases, molecular force interactions will play a role. On the other hand, in a mixture containing molecules A and B, the possibility of formation of chemical compounds, A_2, B_2, AB or higher complexes cannot be excluded.

F. Dolezalek (1906), by employing the law of mass action, was able to show that compound formation can account for both positive and negative deviations from Raoult's law. When the two components react with each other to form AB, negative deviations are to be expected according to this theory, and when associated molecules A_2 and B_2 and AB are present, positive deviations occur. The fact that the formation of these compounds affects the moi fractions of the components is the reason for these behaviours. The properties of systems such as those shown in fig. 3 and 4 can be computed by this theory. In most cases, no direct proof of the existence of such compounds has been observed and the theory of Dolezalek has yielded to the more general one based on attractive forces which will now be described.

In a liquid the molecules have a thermal random motion which tends to cause them to escape and this tendency is balanced by forces of attraction which tend to prevent the molecules from leaving the liquid state. The vapour pressure depends on both these factors. In a liquid mixture in which both molecules have identical forces of attraction, replacement of a molecule of A by B will cause no effect which will lead to a departure from Raoult's law, but if the force of attraction of A for B is greater or less than A for A and B for B, deviations may be expected to occur.

Hildebrand (1916) suggested the use of internal pressures as a means of interpreting the properties of liquid mixtures. He computed extended tables of the relative internal pressures of liquids. He showed that when both molecules in a binary mixture had the same individual internal pressures, their vapour pressure conformed to Raoult's law and that deviations of increasing magnitude occurred when the differences in internal pressures increased.

The modern attempts to develop a quantitative theory of the effects of attractive forces, which followed the work of J. J. van Laar (1928), W. Heitler (1928) and H. Menke (1932), have been based on the conclusion of F. London (1930) that the forces between molecules is given by the law $\frac{-k}{r^6}+\frac{k'}{r^{12}}$. where k and k' are specific attractive and repulsive force constants. and r is the distance between the molecules. The forces of attraction and repulsion are inversely as the 6th power and 12th power of the distance, respectively. From such considerations Hildebrand (1929) and Scatchard (1931) have deduced equations which include both this factor and also the effect caused by the difference in volumes (repulsion force effect) occupied by each of the two components. These equations contain three constants which correspond to the forces of attraction of molecules A for A, B for B and A for B, respectively, and have been reasonably successful in describing the behaviour of mixtures of "nonpolar" molecules. These molecules possess internal electrical symmetry. Molecules which are electrically unsymmetrical contain permanent dipoles and are called "polar." Substances containing them are characterized by higher dielectric constants than nonpolar compounds. The permanent dipole moment defined by P. Debye (1929) is a measure of polarity which varies from o in molecules like benzene to 4.2×10^{-18} electrostatic units for nitrobenzene. Polarity was recognized by Hildebrand to be an important factor in determining the effects of specific interactions and orientation of the different kinds of molecules upon the properties of two component liquid systems.

Very large deviations from Raoult's law occur in solutions containing large molecules, such as linear polymers (see POLYMERIZATION) and proteins (see PROTEINS). In these solutions, the volumes and shapes of the molecules, in addition to the intermolecular forces, are predominating factors.

Solutions of Electrolytes.— The fact that solutions of acids, bases and salts conduct the current led R. Clausius (1857) to conclude that relatively small numbers of charged particles must be present in these solutions. The Arrhenius theory (1887) assumed that in many solutions the molecule of solute is dissociated to a large extent into two, three, four or more ions. This conception is fundamentally correct but its early application failed to establish to what extent electrolytes are dissociated and to estimate correctly the effects of the electrical forces between these charged ions. One very important generalization was made simultaneously by W. Nernst and J. J. Thomson (1893) that, since the electrostatic field between charged particles was less in a medium of high than low dielectric constant, D, dissociation would depend on this factor. Since water has a dielectric constant of 78.5 at 25° C., high dissociation occurs in this solvent but very low dissociation and low electric conductance is to be expected in media such as benzene of dielectric constant of the order 2. Qualitatively, this rule is universally valid.

Properties of Ionic Solutions.— *Thermodynamic Properties.* —It can be shown by the application of thermodynamics that, at constant pressure and temperature, the chemical potential, μ_1, of a volatile solvent in a binary solution is related to the chemical potential of the pure solvent, μ_1°, by the equation

$$\mu_1=\mathrm{k}Tln\frac{p_1}{p_1^\circ}+\mu_1^\circ, \tag{18}$$

where k is the gas constant per molecule. If as before we define an ideal solution as one which obeys Raoult's law, $p_1=p_1^\circ N_1$, then

$$\mu_1=\mathrm{k}TlnN_1+\mu_1^\circ \tag{19}$$

is the expression for the ideal behaviour of the solvent. A similar equation may be obtained for the other component. If equation (16) be divided by (n_1+n_2), the mol fractions N_1 and N_2 are introduced so

$$d\mu_2=-\frac{N_1}{N_2}\,d\mu_1. \tag{20}$$

If the value of μ_1 given by equation (19) is introduced and if N_1 be replaced by $1-N_2$, then equation (20) reduces to

$$d\mu_2=\mathrm{k}TdlnN_2, \tag{21}$$

which upon integration becomes

$$\mu_2=\mathrm{k}TlnN_2+\mu_2^\circ, \tag{22}$$

exactly analogous to equation (19).

Relations (19) and (22) define the behaviours of the components of an ideal solution and approach exact validity only as the concentrations of the components approach zero. In order to express the thermodynamic properties of real solutions, G. N. Lewis (1907) introduced a function, a, which he denoted the "activity." For any component, the activity may be defined by the equation

$$\mu=kTlna+\mu^\circ, \tag{23}$$

which can be rewritten in the form

$$\mu=\mathrm{k}TlnNf+\mu^\circ. \tag{24}$$

In this equation, f, the rational activity coefficient, is a pure number which measures the deviation of the chemical potential of a real solution from ideality. The chemical potential of the reference state, μ°, is a function of pressure and temperature but not of concentration.

If the solute component is an electrolyte, it is necessary to take into account the dissociation of the molecule. For an electrolyte of the simplest type which dissociates into one equivalent of cation and one equivalent of anion according to: $CA\rightarrow C^++A^-$, a mean activity $a_\pm$ may be defined by

$$a=a_+a_-=a_\pm^2, \tag{25}$$

where a+ and a_- are the conventional activities of the ionic constituents. Then, equations (23) and (24) become

$$\mu=2kTlna_\pm+\mu^\circ \tag{26}$$

$$\mu=2kTlnN_\pm f_\pm+\mu^\circ, \tag{27}$$

where $N_\pm$ and $f_\pm$ are the mean mol fraction and mean activity coefficient, respectively. Similar equations which involve complicated algebraic expressions for these mean quantities are required for electrolytes which dissociate into more than two ions. The standard chemical potential, μ°, is defined in such a way that $f_\pm$ equals unity as $N_\pm$ approaches zero so that-the ideal law for infinitely dilute solutions becomes simply

$$\mu=2kTlnN_\pm+\mu^\circ, \tag{28}$$

which is similar in form to equations (19) and (22).

The characteristic behaviour of the activity coefficient both in water and in media of lower dielectric constant is illustrated in fig. 5, in which log $f_\pm$ of hydrochloric acid is plotted against the square root of the molar concentration. The five curves refer to pure water and 20%, 45%, 70% and 82% dioxane in water solutions with dielectric constants of approximately 80, 60, 40, 20 and 10, respectively. If the law represented by equation (28) were valid, then $\log f_{\pm}$ would be zero for all values of c. Increasingly wide deviations from this condition are to be noticed as the dielectric constant decreases, and these departures, measured by the decrease in $\log f_{\pm}$, are large even in the dilute solutions. This behaviour is typical of electrolytes which are highly dissociated in water. Further, the three top curves approach the dashed straight lines from above as the square root of the concentration approaches zero. The two bottom curves approach this condition from below.

These facts can be generalized into a limiting law,

$$\log f_{\pm} = -\alpha\sqrt{c}, \quad (29)$$

where a is a constant. Thus, for an electrolyte $\log f_{\pm}$ approaches proportionality to the square root of the concentration as this latter quantity approaches zero.

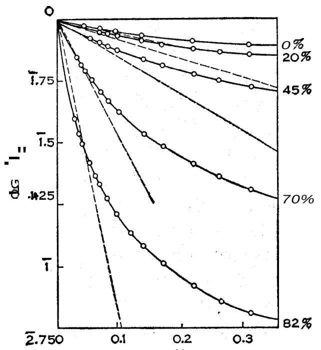

FIG 5—LOGARITHM OF THE ACTIVITY COEFFICIENT OF HYDROCHLORIC ACID IN DIOXANE-WATER MIXTURES AT 25° C THE STRAIGHT LINES (DASHED) REPRESENT THE LIMITING LAW. THE FIGURES ON THE RIGHT GIVE THE WEIGHT PERCENTAGES OF DIOXANE IN THE MIXTURES. (DATA OF H. S. HARNED *et al.*)

Irreversible Processes *and* Dynamic *Properties*.—Three ways in which the ions of an electrolytic solution can move are subject to quantitative computation. Under the influence of an electrical field, the cations move in one direction and anions in the opposite direction and the result is a phenomenon of electrical conduction. Second, when an electrolyte flows freely into a solvent, both ions move with equal velocities in the same direction and diffusion occurs. Third, the motion of the solution as a whole is determined by its viscosity.

Conduction. —The conductance of a solution is equal to the sum of the cationic and anionic currents under a potential gradient of one volt (see ELECTROLYSIS). It is customary to employ the equivalent conductance, A, which is defined as the conductance of a solution containing a gram equivalent of electrolyte between electrodes one centimeter apart. In fig. 6, the values of Λ at 25° for hydrochloric acid in water and in water-dioxane mixtures of the same composition as those in fig. 5 are plotted against the square root of the acid concentration. This series of graphs illustrates the behaviour of many solutions of acids, bases and salts in media of high and low dielectric constants. As in fig. 5. the three top curves approach the straight lines tangentially from above as the concentration approaches zero. The two bottom curves approach the straight lines from below and reach coincidence with them only at extremely dilute solutions. At $c=0$, Λ equals the limiting conductance, $\Lambda°$. This latter quantity. unlike the values of $\log f_{\pm}$, differs for each electrolyte and each solvent medium, and therefore the limiting law, represented by the straight lines, is expressed by

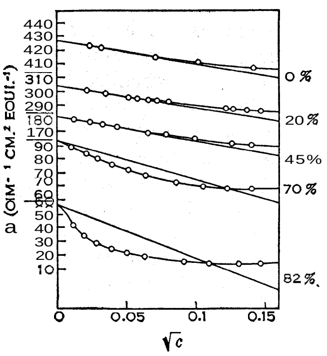

FIG. 6— MOLECULAR CONDUCTANCE OF HYDROCHLORIC ACID IN DIOXANE-WATER MIXTURES AT 25° C THE STRAIGHT LINES REPRESENT THE LIMITING ONSAGER CONDUCTANCE EQUATION. THE FIGURES ON THE RIGHT GIVE THE WEIGHT PERCENTAGES OF DIOXANE IN THE MIXTURES. (DATA OF B. B. OWEN AND G. W. WATERS)

$$\Lambda°-\Lambda=\beta\sqrt{c}. \quad (30)$$

This law was found empirically by F. Kohlrausch (1900) to be valid for many electrolytes from measurements of conductances in media of high dielectric constant. Rohlrausch also found that the limiting values of the individual ionic conductances are additive, or that $\Lambda°=\lambda_1°+\lambda_2°$. Thus, under the influence of the electric field, the ions migrate independently with different velocities and, as the concentration decreases, their properties become additive.

Diffusion.—When an electrolyte is allowed to diffuse freely in a solvent, both positive and negative ions move with the same velocity. If this were not so, a solution would become electrostatically charged by simple diffusion. The electrostatic forces between the positive and negative ions prevent this. The diffusion coefficient, $\mathscr{D}$, is a measure of the rate of diffusion and has a characteristic value for each electrolyte in a given medium. It possesses a limiting value, $\mathscr{D}_0$, at zero concentration of electrolyte which can be calculated from the limiting ionic conductances by an equation first derived by Nernst (1588). As the concentration of electrolyte approaches zero, $\mathscr{D}$, like the equivalent conductance, approaches a limit according to the law

$$\mathscr{D}_0-\mathscr{D}=\gamma\sqrt{c}, \quad (31)$$

where γ is a constant. Thus, $\mathscr{D}$ reaches a limiting value when c equals 0.

Viscosity.—The coefficient of viscosity is a measure of the rate of flow of a fluid and may be determined from measurements of the relative rates of flow through capillary tubes. In dilute solutions of electrolytes the viscosity, η, of the solution is a linear function of the square root of the solute concentration. Thus,

$$\eta_0-\eta=-\delta\sqrt{c}, \quad (32)$$

where η_0 is the viscosity of the solvent and δ is a constant.

To summarize these considerations, it can be stated that the logarithm of the activity coefficient, $\log f_{\pm}$, which is involved in all the thermodynamic properties, the conductance, A, the diffusion coefficient, $\mathscr{D}$, and the viscosity, η, for electrolytic solutions at constant temperature and pressure approach their limiting values according to the same formal law of variation with the concentration of dissolved substance. It will now be shown how the modern theory of electrolytes succeeds in interpreting this common property in terms of the operation of electrostatic forces.

Theory of Dilute Electrolytic Solutions.—The quantitative theory of electrolytes in contradistinction to that of nonelectrolytes depends on two factors: (1) To a first approximation, the properties of electrolytic solutions may be derived by additions of contributions by the individual ions. Deviations from additivity increase slowly with the ionic concentrations. (2) The law of force between the electrically charged ions is known.

The early theory of S. Arrhenius did not include an estimate of the effect of the electrostatic forces and attempted to account for the deviations from the ideal law for the chemical potential (equation [28]) and the variation in the equivalent conductance with concentration by assuming the presence of fewer ions because of incomplete ionization of the electrolyte. Because of the extent of additivity of the properties of electrolytes in dilute solution, this idea was questioned by W. Sutherland (1902), A. A. Noyes (1904) and others who suggested that many electrolytes in water are completely dissociated. If this is true, then the deviations from ideality must be caused by interactions among the ions and between the ions and the solvent. The importance of electrostatic forces was recognized by Laar (1894) and unsuccessful attempts were made to compute their effects by P. Hertz (1912) and J. C. Ghosh (1918). S. R. Milner (1912) successfully analyzed the problem and obtained a square root law for the variation of $\log f_{\pm}$ but his mathematical treatment was involved and did not give an entirely satisfactory solution. P. Debye and E. Huckel (1923) were able to solve the problem for the thermodynamic properties and Debye's fundamental conceptions were soon extended by L. Onsager (1927) and H. Falkenhagen (1928), who are responsible for the interionic attraction theories of conductance, diffusion and viscosity.

In an electrolytic solution the ions have a random distribution because of thermal agitation, but this randomness is restricted somewhat by the attractive and repulsive forces between the ions. These coulombic forces obey the inverse square law

$$\mathscr{F}=e_ie_j/Dr^2, \quad (33)$$

where $\mathscr{F}$ is the force between ions of charges e_i and e_j, r their distance apart and D the dielectric constant of the medium.

The net effect of the thermal and electrostatic factors was shown by P. Debye to produce a condition in which on the average each ion is surrounded by an atmosphere of ions of opposite charge. The presence of this "ionic atmosphere" is a result of the tendency of unlike charges to attract and like charges to repulse one another. Debye's theory makes possible the calculation of the electrical potential due to the ion and its atmosphere, the electrical potential due to the atmosphere alone, the work of charging an ion in the field of this potential and finally the chemical potential and the logarithm of the activity coefficient, $\log f_{\pm}$. Taking into account the actual sizes of the ions, or, more particularly, the mean distance of approach of both positive and negative ions, Debye obtained the equation

$$\log f_{\pm} = \frac{-\alpha\sqrt{\ }}{(1+A\sqrt{c})}, \tag{34}$$

where at constant temperature and pressure α is a constant calculable from the magnitudes of the charges on the ions, the dielectric constant, the gas constant per molecule and Avogadro's number. The parameter, A, is a function of the distance of approach of the ions, the dielectric constant and the temperature. As the concentration of the electrolyte c approaches zero, the denominator approaches unity so that this equation equals the limiting equation (29), $\log f_{\pm} = -\alpha\sqrt{c}$, at infinite dilution. The straight lines in fig. 5 represent this theoretical limiting law from which it is apparent that agreement is approached as the concentration approaches zero. Thus, in dilute solutions, the effect of coulombic forces is sufficient to account for the variation of the quantity $\log f_{\pm}$.

Fig. 6 shows that the equivalent conductance decreases with concentration of the electrolyte, so that, if the electrolyte is completely dissociated, the difference $\Lambda^\circ - \Lambda$ must be accounted for by the action of the electrostatic forces. This means that the mobilities (velocities under a gradient one volt per centimeter) of the ions must decrease with increasing concentration. On the basis of Debye's theory, two factors contribute to this retardation. The first, computed by Debpe, is caused by "electrophoresis," whereby, as the ion moves in the electrical field, its oppositely charged atmosphere and associated solvent must move in a direction opposite to that of the ion. Thus, the ion is moving in a counterflow of medium like a swimmer against a current and obviously its migration is retarded. The second factor which retards the motion of the ions is a hydrodynamic effect first computed by L. Onsager (1927). When an ion is moving in a low electrical field, it is migrating within an atmosphere which has a charge of opposite sign to that of the ion. As a result, the ion will have to drag an oppositely charged atmosphere with it, an effect which will retard its velocity. Onsager's limiting equation may be written

$$\Lambda^\circ - \Lambda = (\alpha^*\Lambda^\circ + \beta^*)\sqrt{c}, \tag{35}$$

in which α^* is a theoretical quantity depending on the temperature, the dielectric constant and the ionic charges. β^* can be computed from these quantities and the viscosity of the solution. The first coefficient, $\alpha^*\Lambda^\circ$, is a result of the hydrodynamic effect and the second, β^*, of electrophoresis. At a given temperature and in a given medium $(\alpha^*\Lambda^\circ + \beta^*)$ is a constant so that this equation is formally in agreement with Kohlrausch's empirical equation (30). Comparison of Onsager's equation with experiment is shown in fig. 6 in which the theoretical requirement is represented by the straight lines. Exact confirmation is obtained with the experiments in media of high dielectric constants represented by the three top curves. The two bottom curves which approach the limiting slopes from below are characteristic of incomplete ionization of an electrolyte. Later, it will be shown that this Nernst-Thomson dielectric constant effect is universal.

Further confirmation of the correctness of the fundamental postulates of this interionic force theory may be found in the effects produced by high electrical fields upon the conductance of electrolytes, a phenomenon discovered by M. Wien (1927) and investigated by Wien and his colleagues. In high fields, the ions can acquire a velocity great enough to draw them out of their atmospheres, in which case the hydrodynamic effect is obliterated acd the conductance of the solution is increased. This conclusion is in theoretical agreement with the observed results. The conductance of an electrolytic solution becomes greater in fields of higher frequency. Debye and Falkenhagen developed a theory of this frequency effect which is in accord with experimental knowledge.

The interionic attraction theory of electrolytic diffusion has been developed by Onsager and R. M. Fuoss with the result that their limiting equation agrees in form with equation (31). Experimental determinations of the diffusion coefficient of very dilute potassium chloride solutions obtained by H. S. Harned and R. L. Nuttall (1947) are in close agreement with the theory. Since in diffusion both positive and negative ions move with equal velocities. the hydrodynamic effect is found to disappear, but an electrophoretic factor is present which depends on the forces between the ions and the solvent molecules, as the solvent moves in a reverse direction to the ions. This effect is not so large as that caused by the gradient of the chemical potential of the electrolyte.

The interionic attraction theory was also extended by Falkenhagen to account for the increase in viscosity of the solvent produced by the addition of ions. He succeeded in deducing a theoretical expression for the constant, δ, in equation (32) and his theory mas confirmed for dilute aqueous solutions of many electrolytes of various valence types of G. Jones, M. Dole and colleagues (1927–40).

Electrolytic **Dissociation and Ionic Association.**—There are two ways in which ions may combine. Because of the electrostatic forces. they can form unchanged ion pairs, charged triple ions. uncharged quadruple ions and ion clusters of still higher order. Second, the positive and negative ions can combine more closely to form undissociated molecules with covalent chemical bonds. Such molecules, of which acetic acid and ammonium hydroxide are examples, are ionized to a small extent in media of high dielectric constants and are known as weak electrolytes According to the rule of Nernst and Thomson, the tendency to form both ion pairs, etc., and undissociated molecules will be greater the lower the dielectric constant of the medium, and qualitatively this prediction is universally valid. This behaviour is illustrated by the lower graphs in both fig. 5 and 6 which approach the limiting laws from below. In the 45% dioxane-water mixtures ($D \sim 40$), the theoretical result for Λ is approached from below but the effectis hardly noticeable. In the 70% mixtures ($D \sim 20$) and the 82% mixtures ($D \sim 10$), this effect is much more pronounced. This decrease in conductance below the limiting law for a completely dissociated electrolyte is to be explained by the removal of the ions as effectively charged carriers of electricity to form ion pairs. Similar behaviour is to be observed for the log $f_{\pm}$ in fig. 5, although the effects are less pronounced. Extended studies of the conductances of various electrolytes in nonaqueous solvents were carried out by P. Walden and after 1915 by C. A. Kraus and co-workers.

A quantitative theory of ion-pair formation was developed by N. Bjerrum (1926). By considering the distribution of ions under the influence of their electrostatic forces, he showed that the probability of ion-pair formation is very small until the distance apart of the positive and negative ions reaches a certain value, q, and that at distances less than this the probability of such combination increases very rapidly. If the ionic sizes are great enough so that the sum of their radii is greater than q, they cannot approach each other closely enough to pair, but if this sum is less than q, ion-pair formation occurs. In water, q depends on the valences of the ions and equals approximately 3.5 A and 7.0 A for sodium and barium chlorides, respectively. It also depends on the dielectric constant and becomes larger as this quantity decreases. The equation derived b~ Bjerrum may be written

$$K^{-1} = \frac{B}{D^3}Q(b), \tag{36}$$

where K is a constant, characteristic of ion-pair dissociation; B is a function of the charges carried by the ions, Avogadro's number, Boltzmann's constant and the temperature, and $Q(b)$ is a complicated function of these quantities as well as the sum of the ionic radii If the dissociation of the ion pair is represented by $[C^+A^-] \rightleftarrows C^+ + A^-$, then the ionization constant, K, is defined by

$$K=\frac{c_+c_-}{c_\pm}\Big]_{c\to 0} \tag{37}$$

where c_+, c_- and $c_\pm$ are the concentrations of the species denoted by subscripts. It is to be noted that K is the limiting value of the right member of this equation as c approaches zero. Since K^{-1}, the association constant, varies inversely as the cube of the dielectric constant, it increases extremely rapidly as the dielectric constant decreases. $Q(b)$ also decreases in a similar manner.

Bjerruin's theory received confirmation from the experiments of Kraus and Fuoss, who measured K of tetraisoamylammonium nitrate in water and in dioxane-water mixtures. In water, this salt is completely ionized since the sum of its ionic radii is of the order of six angstroms. The enormous extent of the variation of its ionization constant is shown in fig. 7, in which log K is plotted against log D. The curve is derived from theory and the circles represent the observed results. Fuoss developed the theory to account for triple- and quadruple-ion clusters and obtained satisfactory agreement by experiment.

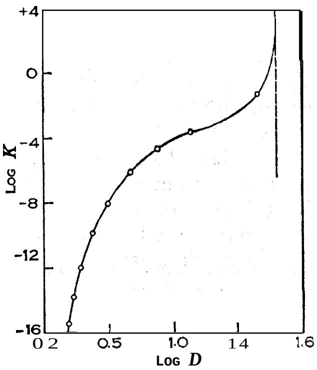

FIG. 7— ION-PAIRDISSOCIATION AS A FUNCTION OF THE DIELECTRIC CONSTANT. TETRAISOAMYLAMMONIUM NITRATE IN DIOXANE-WATER MIXTURES AT 25° C. (DATA OF R. M. FUOSS AND C. A. KRAUS)

The general situation is too complicated to be explained by this relatively simple action of electrostatic forces. Although studies of Raman spectra and of other properties indicate that many electrolytes in water are completely dissociated at all concentrations, there are a great many that are not. Silver nitrate and thallous chloride are examples of 1–1 salts which are not completely ionized. The 2–1 salts show various degrees of dissociation. Whereas calcium chloride and zinc iodide are highly dissociated, cadmium chloride dissociates to a much smaller extent and cadmium iodide and mercuric chloride are weak electrolytes. In these cases the dissociation occurs in stages:

$CdI_2 \rightleftarrows CdI^+ + I^-$; $CdI^+ \rightleftarrows Cd^{++} + I^-$

and it is probable that the cadmium and iodine are joined by a covalent bond; *i.e.*, that CdI^+ is not a loose electrostatically bound ibn pair.

Weak Electrolytes.— Only a few acids and bases, such as hydrochloric acid and sodium hydroxide, are strong in water, but there is a very large number which form a class of weak electrolytes. Most of these are organic acids, bases and ampholytes and their relative strengths vary greatly. The extent of dissociation is measured by the thermodynamic constant of equilibrium between the undissociated molecule and the ions, represented by the reaction: $CA \rightleftarrows C^+ + A^-$. This constant is given by the equation

$$K=\frac{a_C a_A}{a_{CA}}=\frac{\gamma_C\gamma_A m_C m_A}{\gamma_{CA} m_{CA}}, \tag{38}$$

valid at constant temperature. In this equation a, γ and m denote the activities, the activity coefficients and the concentrations in mols per 1000 gs. solvent of the undissociated molecule, the cation and the anion, as denoted by subscripts. It is to be noted that in this equation the molar concentrations have been employed and not the mol fractions. This procedure conforms with the customary method of expressing ionization constants. When the concentration of electrolyte is zero, this equation assumes the same form as equation (37) since by definition the activity coefficient function becomes unity.

Some precise values of K_A for a few acids and water are given in the table. These illustrate how widely this quantity varies with the nature of the electrolyte. Thus, the ionization constant of chloroacetic acid is of the order of 10^{11} times that of water and 10^7 times that of boric acid. It is to be noted that the ionization constant of acetic acid becomes less as the dielectric constant of the medium (water-dioxane) decreases, a phenomenon exhibited by all electrolytes.

Ionization Constants at 25° C.

Acids	Medium	D	K_A*
Chloroacetic	Water	78.54	1.379×10^{-3}
Formic	"	"	1.772×10^{-4}
Acetic	"	"	1.754×10^{-5}
	Water—20% dioxane	60.8	5.11×10^{-6}
	Water—45% "	38.5	4.93×10^{-7}
	Water—70% "	17.7	4.78×10^{-9}
	Water—82% "	9.5	7.24×10^{-11}
Boric	Water	78.54	5.79×10^{-10}
Water	"	"	1.008×10^{-14}

*Concentrations are in mols per 1,000 g. water.

As first pointed out by Brönsted (1920), a property common to all weak electrolytes may be deduced from equation (38). In dilute solution, the activity coefficient of a neutral molecule, CA, changes little when the ion concentration is increased by the addition of neutral salt. On the other hand, the activity coefficients of the ions decrease rapidly as shown by fig. j. Consequently, the quantity $\gamma_C\gamma_A/\gamma_{CA}$ decreases in dilute solutions, and since K is constant, $m_C m_A/m_{CA}$ must increase. Extensive determinations of the ionization of water and some weak electrolytes in various salt solutions were made by Hained *et al.* from cells without liquid junction, and optical measurements of the same effect were carried out by H. von Halban which confirm the universality of this phenomenon.

Ampholytes, or molecules which in solution possess both acid and basic properties, form a class of solutions whose properties depend to a considerable extent upon their unique electrical nature. Of these the most important are the amino acids whose neutral molecules, as suggested by Bjerrum (1923), are amphions (zwitter ions) which carry both a positive and negative charge. If such dipolar molecules be denoted by $Z^\pm$, their acid and basic equilibria can be represented by

$$ZH^+ \rightleftarrows Z^\pm + H^+$$
$$ZOH^- \rightleftarrows Z^\pm + OH^-$$

The ionization constants of ZH^+ (K_A) and ZOH^- (K_B) are of the same order of magnitude as those of other weak acids and bases. For example, K_A and K_B for glycine at 25° are 4.47×10^{-3} and 6.04×10^{-5}, respectively.

In order of complexity, the ampholytes include the simple amino acids, the peptides, hetaines, phospholipids and finally the proteins. Because of the presence of many amino groups, a protein molecule carries a very large number of charges and its properties are conditioned to a great extent by the presence of many dipolar groups in the molecule. They have high permanent dipole moments and their solutions possess very high dielectric constants. Similar enhanced effects occur with many of their other properties (*see* PROTEINS).

Hydrolysis.— Hydrolysis is chemical change brought about by the action of water and may be represented by the chemical reaction, $RX + H_2O \rightleftarrows ROH + HX$. If in aqueous solution, RX is a completely dissociated electrolyte, hydrolysis occurs to a considerable extent when either the hydroxide, ROH, or the acid, HX, are weak electrolytes. Thus, when ROH is a weak hydroxide $R^+ + H_2O \rightleftarrows ROH + H^+$ the solution is acidic, and when HX is a weak acid, $X^- + H_2O \rightleftarrows HX + OH^-$ and the solution is basic. The equilibriums represented by these equations can be computed from the equilibrium constants of the weak electrolytes. For example, sodium acetate in water may be represented by the equation $Ac^- + HOH \rightleftarrows HAc + OH^-$. This equation may be obtained by subtracting the equation for the ionization of acetic acid, $HAc \rightleftarrows H^+ + Ac^-$, from that representing the ionization of water, $HOH \rightleftarrows H^+ + OH^-$. Therefore, the equilibrium constant K of the hydrolytic reaction is given by the ratio of the ionization constant of water to that of acetic acid. Thus, at 25° C. (*see* table)

$$K=\frac{a_{HAc}a_{OH}}{a_{Ac}a_{H_2O}}=\frac{a_H a_{OH}}{a_{H_2O}}\ \frac{a_{HAc}}{a_H a_{Ac}}=\frac{1.008\times10^{-14}}{1.754\times10^{-5}}=5.75\times10^{-10} \tag{40}$$

where a_{HAc}, a, etc., are the activities of the species denoted by the subscripts.

Concentrated Solutions of Strong Electrolytes.—In concentrated solutions, electrolytes show wide variations in their properties. This is illustrated in fig. 8, where graphs of $\log f_\pm$ versus $\sqrt{c}$ for a number of 1–1 electrolytes at 25° C. are drawn. The lower curve represents the limiting law, $\log f_\pm = -0.509\sqrt{c}$, and the curve designated (å = 4) is the plot of equation (34). The parameter A as computed from a value of mean distance of approach å of four angstroms, an approximate value for many strong 1–1 electrolytes in water. All these results approach the curve (å = 4) as the concentration decreases, but it is apparent that only in very dilute solutions ($\sqrt{c}<0.01$) do they approach the predictions of the limiting law. In concentrated solutions, the individual effects become large. The electrolytes whose graphs lie above the curve (å = 4) have minima and curve upward to greater or lesser extents in the very concentrated solutions. Since these graphs lie above the theoretical curve, the electrolytes are probably completely dissociated. Caesium chloride solutions begin to exhibit evidence of ion-pair association, and thallous acetate and silver nitrate are most probably incompletely dissociated electrolytes.

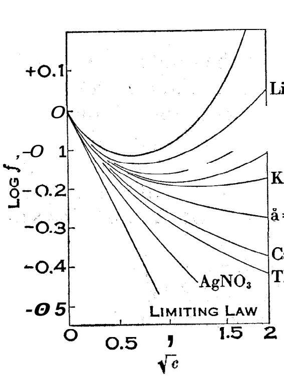

FIG. 8— ACTIVITYCOEFFICIENTS OF SOME 1-1 ELECTROLYTES (DATA OF R. A. ROBINSON)

The interpretation of the nature of these concentrated solutions is very difficult and no general theory exists for computing their properties The effects caused by the interactions of the ions with the solvent water molecules, which are not the predominating ones in very dilute solutions, become increasingly large in concentrated solutions. In addition to these ionic hydration effects, a change in dielectric constant of the medium occurs with change in composition of the solution. This latter effect has not been measured nor has it been estimated with any degree of accuracy. These considerations as applied to 1–1 electrolytes, let alone the more complicated behaviour of higher valence electrolytes, are sufficient to show that a detailed interpretation of the individual behaviour of electrolytes in concentrated solutions is accompanied with the greatest difficulties.

Solutions of Large Molecules and Suspensions.— The foregoing discussion was restricted from its beginning to the properties of binary solutions in a "homogeneous" phase. It is to be observed, however, that every species of molecule with its individual mass, size, shape and force field retains its identity and therefore, microscopically, a solution containing two or more kinds of molecules is heterogeneous. In all the solutions described above, the molecules are too small for direct observation by any instrument now available. The diameters of the molecules in these so-called homogeneous solutions are roughly of the order of ten angstroms in diameter and their molecules possess molecular weights relative to the oxygen molecule ($O_2^{16}=32.0000$) of 20 to 500 or somewhat higher. Now, solutions of synthetic polymers, of proteins with molecular weights in the neighbourhood of 100,000 and viruses with molecular weights of the order 10,000,000 to 2,000,000,000 are important examples of systems containing large molecules. Virus molecules of diameters of 230 A have been observed directly by the electron microscope, an instrument with a linear magnifying power of 100,000. Systems containing even larger particles which to the eye are homogeneous but whose heterogeneity may be observed by means of the ultramicroscope are known as disperse systems and have been classed under the general title of colloids.

The science of solutions containing large molecules requires the extension of the methods of thermodynamics and hydrodynamics to the statics and dynamics of these systems, with proper allowance for their sizes, shapes and the large number of charges on their ions (*see* POLYMERIZATION; PROTEINS; VIRUSES). Considerable progress is being made in this domain as well as in the field of colloidal solutions where modifications caused by surface action become important (*see* COLLOID).

BIBLIOGRAPHY.—Textbooks and treatises on physical chemistry contain treatments of the properties and theories of solutions. Nonelectrolytic solutions are discussed in detail by J. H. Hildebrand, *Solubility,* American Chemical Society Monograph No. 17 (1950). The theory of electrolytic solutions is described by H. Falkenhagen, *Electrolytes,* Eng. trans. by R. P. Bell (Oxford, 1934). A comprehensive treatment of the theory and properties of electrolytes is to be found in H. S. Harned and B. B. Owen, *The Physical Chemistry of Electrolytic Solutions,* American Chemical Society Monograph No. 95 (1950). An excellent short presentation of the theory of the thermodynamic properties of electrolytes by E. A. Guggenheim is given in chap. ix of R. H. Fowler and E. A. Guggenheim, *Statistical Thermodynamics* (1940). The theory and properties of protein solutions are comprehensively discussed in E. J. Cohn and J. T. Edsall, *Proteins, Amino Acids and Peptides as Ions and Dipolar Ions,* American Chemical Society Monograph No. 90 (1943). (H. S. HD.)

SOLVAY, ERNEST (1838–1922), Belgian industrial chemist and social reformer, who developed an important process for making alkali commonly known as the ammonia-soda process, was born at Rebecq on April 16, 1838. The son of a salt refiner, he attended school in Malonne and later worked for his father at Rebecq. Solvay read books on elementary chemistry and physics and in 1860 became an assistant to an uncle who was head of a small gasworks at Schaerbeek.

In 1863 Solvay developed his process for the production of soda ash, which is considered one of the most important 19th-century advances in industrial chemistry, and founded Solvay and company, with headquarters at Couillet. After initial difficulties, the daily production was 1,500 kg. by 1866. Replacing the old Leblanc "black-ash" process, Solvay's process was widely utilized in many countries. (*See* also CHEMICAL INDUSTRY and ALKALI MANUFACTURE.)

Solvay became wealthy and contributed to various philanthropies and research organizations. In 1894 he established in Brussels the Institut des Sciences Sociales, which became the Institut de Sociologie in 1901.

Solvay opposed the amassing of "unearned" inherited wealth and proposed a system of social accounting which would replace money. His works include *Science contre religion* (1879); *Du rôle de l'électricité dans les phénomènes de la vie animale* (1894); *Le comptabilisme socia* (1897); *L'Energétique considérée comme principe d'orientation rationnelle pour la sociologie* (1904); and *Questions d'énergétiques sociales* (1910).

Solvay died at Brussels on May 26, 1922.

SOLWAY FIRTH, an inlet of the Irish sea between England and Scotland. Bordering it are Wigtownshire, Kirkcudbrightshire and Dumfriesshire in Scotland and Cumberland in England. The outer portion is really a gulf at whose head is the shallow joint estuary of the Nith, Lochar, Annan, Esk, Eden, Wampool and Waver. Between St. Bees head and Abbey head it is 22 mi. wide and it stretches some 35 mi. northeastward from that line. The waters of the firth are generally shallow (under 10 fm.). Wide stretches of sand are exposed at low tide, particularly on the Scottish side. and the estuarine section is choked by shifting sandbanks. Craft of fair size can reach Silloth, on the English side, without difficulty.

A viaduct. $1\frac{1}{2}$ mi. long, carries the railway across the head of the estuary almost on the line of an ancient ford from Bowness to Annan. The firth was also fordable at two higher points. That across the Esk estuary, the *sulwathe* (*i.e.,* "muddy ford") gave its name to the firth. The tide runs quickly in the estuary and periodically gives rise to a bore. The normal tidal range is about 2j ft. (T. HER.)

SOMA, in Vedic India personified the *Asclepias acida,* whose sap, fermented. is an intoxicant. As a Bacchuslike god Soma is lauded in 114 hymns of the *Rig-ceda* IX and as a co-equal of Indra, Agni and Rudra in other Books. Its uses. like its name (*Haoma* in the *Avesta*), go back to Iranian times, and it was prized both in India and Iran as a medicine conducive to longevity.

The celestial variety, distinct from that of earth, was drunk by the gods, and incited Indra to establish the universe. In the post-Vedic Epics Soma is the Moon, who wanes when drunk by gods but is replenished by the Sun.

SOMALILAND, so named from the Somali inhabitants. descended from Arab immigrants from the 7th century onward, is the Horn of Africa, bounded by the Gulf of Aden on the north, the Indian ocean on the southeast, and an ill-defined line on the west, running from the south end of the Red sea to the Tana river in Kenya. To the west of Somaliland lie Eritrea, Ethiopia proper and the Boran area of Kenya toward Lake Rudolf. The area is roughly triangular, approximately between long. 41° and 51° 25′ E., and between lat. 12° N. and 1° 40′ S. About 600 mi. along the Gulf of Aden and 1,000 mi. along the Indian ocean, the triangle is completed by about 900 mi. of irregular inland boundary to give a total area of about 425,000 sq.mi., of which 120,000 sq.mi. are in Ethiopian-controlled Somaliland (Ogaden) and 50,000 sq.mi. in the northern frontier district of Kenya. The remainder is split up between French Somaliland and the Somali Republic (est. July 1, 1960; area 246,201 sq.mi.), comprising the former British Somaliland Protectorate and Italian Somalia, which are described below.

The total population of the British, French and Italian parts of Somaliland was estimated in 1958 at more than 2,000,000, including 25,000 Danakils in French Somaliland; and local pockets of Galla, Negroes (especially along the fertile river valleys), Arab and Indian traders. and European traders and government officials. The Ethiopian Ogaden province probably accounted for 600,000 Somalis and 200,000 Galla and other Africans, while Kenya had about 50,000 Somalis north and east of the Tana river.

PHYSICAL GEOGRAPHY

Geology.—The metamorphic basement, probably Archaean, with some later less metamorphosed Inda Ad series, crops out along the scarps facing the Gulf of Aden. Both are intruded by Younger Granite and pegmatites, while the older basement is much granitized. Some mineralization is probably associated with the Younger Granite.

The basement is upwarped again in the upper Juba area, but over most of the territory it is covered with sediments dipping usually to the south-southwest. Karroo sandstones of Trias or Lias Age! and Jurassic shales and limestones, locally kerogenous, occur in some faulted basins. These or the basement are covered, over most of the territory, by terrestrial Cretaceous sandstones with some shales. but in the northeast by marine Cretaceous limestones. In the south both Jurassic and Cretaceous include lagoonal evaporite deposits.

Above the Cretaceous a Paleocene or Lower Eocene marine transgression laid down limestones over most of the country, including the main feature-forming rock. A regression of the sea eastward resulted in huge deposits of Eocene evaporites followed by a further incursion to form Middle Eocene limestones in the eastern areas.

The country was then uplifted, and much faulted, especially in east-west and northwest-southeast lines. In the Lower Miocene a minor transgression formed a limestone fringe a little inland from the present shore line. capped locally along the Gulf of Aden lowlands by Plio-Pleistocene basalt flows, with some rhyolites. In French Somaliland these cover all other rocks except two small exposures of Jurassic and Cretaceous, and the later Pleistocene and Recent reefs. evaporites and gravels.

There are sand dunes along much of the coasts, but the greater part of the country is covered by Recent sandy clays or calcareous or gypseous rock.

Physiography. — From the Gulf of Aden coast line the land rises rapidly to the main watershed range between Guardafui in the east. with mountains up to 4.000 ft. high near the coast, to the Harar plateau in the west about 7,000 to 8.000 ft. There are some passes in this range. but often steep cliffs facing north. with some stretches of permanent water in the drainage north to the Gulf of Aden. There in the highlands are the highest rainfall and the pleasantest climatic conditions South of the watershed are low foothills soon dying out into gently undulating waterless plains, sloping south to the Indian ocean. Inland in the Ogaden and Kenya is some higher ground whence come the permanently flowing Webi Shebeli. Juba and Tana rivers.

Climate. — Rainfall varies from about 20 in. annually in the highlands (with local freak records up to 50 in.), to less than 3 in. on the coast, though in the northeast and on parts of the Indian ocean coast, where hills or dunes are near the shore, a narrow coastal belt may have more than 1j in. Rainfall is snoradic.

Temperatures vary from occasional frost in the mountains to maxima of about 116° F. in the shade on the coast. Owing to the generally dry climate, diurnal variation of temperature is about 10° on the coast to 20° F. in the hills. Much of the country has poor soil, tending as a result of rapid evaporation of rainfall to become caked with lime or other salts. The irregular heavy storms tend to cause excessive erosion wherever the natural balance of vegetational cover is disturbed, as in locally overgrazed areas or in neglected agricultural clearings.

NATURAL RESOURCES

Vegetation. — In the mountains over about 5,000 ft. are relict juniper and box forests. with some acacias. euphorbias and gums, stretching in a broken line from their Ethiopian highland habitat in the west to northeastern Somali Republic.

The plateau is dominated by open savannah of acacias (especially *A. etbaicu, A. bussei, A. spirocarpa* and *A. mellifera*), and *Commiphora* shrubs and grasses, though in the gypseous areas the stone-croplike *Suaeda, Limonium,* etc., are dominant and valuable salt grazing. There are also large areas of open treeless grassy plains, and in the nongypseous areas reddish anthills, up to 23 ft. high, dominate wide tracts both in the bush and on the plains.

In the lowlands similar vegetation to that of the plateau persists, though with more bare soil, stunted trees and stunted shrubs, especially *Indigofera,* replacing much of the grass. Along the coast are more *Suaedas,* and rarely mangroves. *Acacia spirocarpa* seems to be ubiquitous at any altitude in any soil. The acacias are popularly referred to as camel-thorn. Along the southern rivers are giant acacias, doum palms and other vegetation of the wet tropics along the narrow flood plains and along the equatorial coast

Animal Life. — Mosquitoes. sand flies, houseflies, ticks, scorpions and locusts are temporary seasonal pests, usually in limited areas. except for the mosquitoes near permanent water Termites are important soil makers except on gypsum. Snakes are well distributed but do little harm, and there are crocodiles in the southern rivers. There are a few fresh-water fish inland, as well as in the big rivers, and important shark. tunny and kingfish, especially in the Gulf of Aden. Birds include several kinds of bustard, guinea fowl and other game birds, wild ostrich, vultures, secretary birds, eagles, hawks and the ubiquitous lesser raven. Wart hogs are common within range of water, giraffe occur near the equator. and there are a dozen or so species of antelope including greater and lesser koodoo, oryx and many gazelles, among which are the rare beira and Clarke's gazelle. Hartebeeste now occur only in the south. Wild asses are restricted to a few local herds, and there are zebras in the south. Elephants and some hippopotamuses occur along the Webi Shebeli, Juba and Tana rivers. By mid-20th century rhinoceros were limited to the equatorial region. Common small mammals are hyrax, hare, porcupine, rat, jerboa. ground squirrel, badger, mongoose and some stoat and ant bear. Jackals and striped and spotted hyenas are well distributed, and there are black-eared fox. Wildcat, lynx, cheetah and lion are common, but the leopard is becoming rarer. Bats live in wells and caves, and tribes of baboons range near any water supply, while there are tree monkeys in the west and south.

(J. A. Ht.)

POPULATION

The Somali belong to the Hamitic race which includes among its northeast African members the Beja, the Afar or Danakil, the Agaw of Ethiopia, the Galla, and the Sidama peoples. They are probably the most recent of the Hamitic migrants from southern Arabia. According to their traditions. heavily coloured by an ultra-Moslem bias, at various times between the 7th and 16th centuries AD. Arabs (many fleeing from persecution) landed on the northern Somali coast, and by intermarriage with the Galla who then lived there produced the Somali nation. Except for the fact that the Galla did once live in northern Somaliland, the general trend of this account is unlikely for both historical and anthropological reasons, for the arrival of the first of the Somali in Africa must antedate Islam by a considerable time; and the Somali language so far from being a hybrid derived from Galla (as has been suggested) is a separate but related language, phonetically perhaps the most difficult of all the Hamitic languages. In the 20th century a Somali named Usman devised an alphabet for writing the language. which at first was known as Usmaniya, but is now generally called Somalia Writing by the Somali. There is a large body of oral literature, including alliterative poetry. The name Somali first occurs in'the form *Sumule* in a praise song of Yeshaq I of Abyssinia (1412–27); the meaning is obscure, but it may be derived from the Arabic words *zu mal,* "possessors of wealth"

The Somali are pastoralists owning camels and sheep, with cattle and horses where suitable. The camel is a source of both nourishment and transport; it also forms the basis of wealth, and is thus of the highest value. Cattle are kept in parts of the Somali Republic, especially by the Habar Awal in the west, and in parts of southern Somali, the chief cattle onners there being some of the Ogaden tribes, and the Harti and Jiddu. Horses are owned by the Dulbahante. Warsangeli, Habar Awal, and some of the Ogaden tribes. Agriculture is practised in western Somali Republic; on the "high plateau" round Isha Baidoa; and sporadically in the country between the middle Webi Shebeli and the Juba. A primitive plow drawn by two oxen is used in places Water is one of the dominating factors in Somaliland, much of nhich is a barren region of stunted thorn trees, aloes, dry watercourses and rocky hills. Tribal rights over water and grazing are of vital importance and are strictly regulated; and recognized seasonal stock routes have become established to grazing grounds which are in many cases outside the normal tribal area.

The Somali comprise more than a hundred tribes divided into six groupings or "confederacies" called Is'haq, Dir, Darod. Hawiya, Digil, and Rahanwein. These are classed in three major divisions: a northern, comprising Dir, Is'haq and Darod; the Hawiya and associated tribes; and the Sab, comprising Rahanwein and Digil. The word *sab,* "people," acquired a pejorative significance, for it nas also applied by the northerners to certain pariah groups living among the Somali: so to counteract this association with inferior (and therefore "unclean") peoples an ancestor called Sab was invented. A Somali tribe, *qabil,* is divided into clans, *qolo;* subclans or family groups, *jilib* (literally "joint"); and families, *rer;* the last is a political unit under the control of one of its elders. The *jilib* is the group of people who combine to pay and receive blood money, and is thus an important unit among an excitable people who are quick to kill, and assess compensation for homicide at 100 camels for a man and 50 for a woman. In some tribes there is no chief, and the maintenance of law and order rests with the family elders. In other tribes there is a chief, whose title varies; the terms sultan, *garad, ugas, boqor, islan,* and *waber* are recorded. An important element in Somali life is the custom of *magan* (*shegat* in the south): whereby an individual or group can arrange for protection from another group, receiving the full rights of the new group and in return accepting all the customary obligations.

The Somali have produced at least two outstanding leaders, the soldier Ahmed ibn Ibrahim el-Ghazi, called Grañ ("left-handed") by the Abyssinians, who ravaged Abyssinia in the 16th century; and Mohammed Abdallah Hasan, "the mad mullah." who dominated the Somali during the first 20 years of the 20th century (see *British Somaliland Protectorate: History* below).

Somali material culture is poor. The typical house is no more than a tent of matting placed over an arched framework of long sticks fixed in holes in the ground; these are taken down and carried on camels when the owners move. The spear is the main weapon, sometimes with a single or double blood course (a longitudinal channel in the blade); the shield, made of hide, is circular, with a central boss. Swords are also used.

In religion the Somali are Moslems of the Shafi' sect of Sunni (orthodox). Though inclined to be fanatical, their religious fervour varies with distance from the coast and contact with external Islam. The more remote and backward Somali are little more than nominal Moslems. and itinerant preachers called *wadad* (mullah) go about keeping Islam alive. There are also religious fraternities called *tariya.* The Somali are somewhat lax in their observance of the rules of Islam. Their women, for example, do not veil; many pray but three times a day; and in some places there are survivals of pre-Islamic pagan festivals. The mosque is not the centre of Somali Islam; instead there is a form of worship at the graves of local holy men.

The tribal groupings of the Somali are:

1. *Is'haq* confederacy: the Eidagale, Habar Awal, Habar Ja'alo or Tol Ja'alo and Habar Yunis.

2. *Dir* confederacy: the Isa, Gadabursi and Biyemal.

3. *Darod* confederacy, divided into three groups: (1) those of the Ogaden, which run through central and south Somalia (there is no Ogaden tribe); (2) those of the Majertein or Mijertein in northeastern Somalia (there is no Majertein tribe); (3) a third group comprising some nine scattered main tribes. Tribes of the Ogaden include the Aulyehan, Bahgiri, Makahil, Makhabul, Mahamud Zubeir. Malingur, Rer Adan Khair, Rer Ali Nasar, Rer Dalal, Rer Hamadin; the Rer Ugas Guled, Rer Ugas Ilmi, Rer Ugas Koshin, Rer Ugas Nur, and Rer Warfa which form a group on both sides of the Fafan river; and the Talamuge. Tribes of the Majertein include the Ali Jibril, Ali Suleiman, the Oman Mahamud, in whose area are the smaller tribes of Aurtable and Lelkase, the Rer Bi'dyahan, Siwakhron, Usman Mahamud and Wabeneiye. Other Darod tribes are the Abaskul, Bartireh, Dashishe, Dulbahante, Gelimeis, Harti, Kaptanle, the Marehan in two divisions, and the Warsangeli.

4. *Hawiya* confederacy: in two main geographical groups, an eastern to the east of the Webi Shebeli, and a western in Kenya between Wajir and the Ganale Doria. The Hawiya include the Abgal, Abgal Waaisle, Daud Abgal, Eli Omar Abgal, and Matan Abgal in central Somalia; the Ajuran (western group), the Auramale in two divisions, the Badi Ado, Habar Gidir Air, Habar Gidir Saad, Habar Gidir Suleiman, Jijele, Karanle, Mobilen, Murosada in two divisions, and the Wanjel. Tribes associated with the Hawiya include the Awadle, Digodia (western group), Galjal in three divisions, Gare (western group) and the Huber.

5. *Digil* confederacy: the Dabare, Gerirkhe, Gurre, Jiddu, Tunni, Tunni Tore and Tunni Doi.

6. *Rakanwein* confederacy: most of the tribes of this confederacy live in an area extending east of the Juba for about 140 mi. inland from the coast, and for about 120 mi. to the north and to the south of Isha Baidoa. They include the Begedi. Diso, Eimit, Elai, Gamale, Geledi, Gelidle, Harau, Harian, Helledi, Jilible, Jihron. Komal, Leisan, Lowai, Maalin Wein. Yalalle and Yantar.

There is a number of outcast or pariah groups scattered throughout Somaliland and living in subjection to and under the protection of the Somali. The three chief groups are the *Tomal* or blacksmiths. who are also magicians; the *Midgan* or hunters, who are also traders. metalworkers and physicians; and the *Yibir* or leatherworkers. who also provide charms and whose women perform the operation of clitoridectomy on the Somali girls. Among the Hawiya there are also pariah groups of *Madaral* (tanners) and *Dardo* (weavers). These peoples (who are called collectively *Bon* by the Hawiya) are not Somali, and may be related to the hunting peoples in Ethiopia known as Watta. (G. W. B. H.)

EXPLORATION

The Somali coast is believed to be the land of Punt of the 15th-century B.C. Egyptians, and was probably known to all the middle eastern empires of Assyria, Persia. Greece and Rome. British Indian army officers began to explore the interior in 1848, when C. J. Cruttenden. Lieutenant (later Sir Richard) Burton and J. H. Speke first landed there. Burton made a journey to Harar in disguise in 1854. F. L. James and his brother, with G. P. V. Aylmer and E. Lort-Phillips, H. G. C. and E. J. E. Swayne, and A. Donaldson Smith, an American, continued exploration in the latter part of the 19th century from the Gulf of Aden, penetrating as far as the Indian ocean. Lake Rudolf and the Tana river. Meanwhile two Italians, Luigi Robecchi-Bricchetti and Vittorio Bbttego, explored westward from the Indian ocean, and Georges Révoil, a Frenchman, in the northeast.

Many hundreds of soldiers, administrators, traders, scientists and others have continued the exploration since then, and most of the area is covered by air photography. Much has also been mapped geologically, but many areas each of several hundred square miles or so between motorable tracks, remain practically unknown. except to the local nomads who graze those particular localities.

SOMALI REPUBLIC

British Somaliland Protectorate.— This former protectorate, along the African shore of the Gulf of Aden between long. 42" 40' and 49° E., and lat. 8° and 11° 25' N., was bordered to the northwest by French Somaliland, to the southwest and south by Ethiopia (mostly by the Somali Ogaden province), and to the southeast and east by the former Italian Somalia with which it united in 1960 to form the Somali Republic. Roughly 400 mi. along the coast from east to west, the area of the former protectorate extends inland about 80 mi. in the west to 200 mi. farther east, and covers an area of about 68,000 sq.mi.

Physically the country can be divided into three parts: coastal lowlands with some hills up to 3,000 ft. above sea level; the main watershed mountains rising abruptly from the coastal lowlands to between 4,000 and 8,000 ft. (Surud Ad near Erigavo is 7,900 ft.); and the plateau sloping gently southward from 4,000 to 2,500 ft. The southern part of this plateau is the valuable Haud grazing area which straddles the Ethiopian Ogaden boundary.

From the main watershed short, dry river beds, with some permanently flowing reaches, drain north to the Gulf of Aden. South of the watershed most of the drainage is collected in the three west-southwest flowing valleys: the Daror in the northeast, the Nogal diagonally across the centre of the plateau and the dry Bokh in the south. The Nogal flows mostly below the surface till the Somalia boundary at Geroweh, and into the Indian ocean. The Daror has a subsurface flow, but the Bokh, which disappears into the Mudugh area of Somalia, appears to have dried up, despite the rainfall flowing into it.

The northeast monsoon blows from October to March when the sun is south of Somali, and the unpleasant hot dusty southwest monsoon from May until September. There are hot calm periods between the monsoons. The main rains are from April to June, and short rains in October and November. In the higher parts of the plateau rain is usual in July and August (August is the wettest month of the year in Hargeisa), and in the northeast in

January or December. The rainfall cannot be relied upon except over a period of years. Ten to 20 in. of rainfall above 4,000 ft. altitude, with freak local rainfalls of over 40 in. In the lower country the average rainfall is nil to 10 in. Much runs off or is evaporated, and the greater part of the country is semidesert to dry savannah. Maximum average monthly temperatures are from 87° to 108° F. with absolute maxima on the coast up to 115° in the shade. Minimum temperatures are 32° in the mountains to 70° on the coast. There is always a diurnal range of 10° and usually 20°.

The People.—Apart from about 200 Europeans, mostly government servants, a few hundred Indian officials or traders, and 1,000 or more Arabians, the population (1957) was estimated to be 650,000 Moslem Somalis. Of these about 100,000 were Dir (Isa and Gadabursi), 420,000 Is'haq, and 120,000 Darod.

Some Somalis are educated in Roman Catholic missions in Aden or Jibuti, and some in Egypt, the Sudan or Syria. There are local Koranic schools and from 1944 an expanding government educational program provided primary and secondary schools, scholarships abroad and some girls' schools.

Excellent government hospitals were established at district headquarters, and a main one at Hargeisa with modern equipment and nursing staff. Tick fever is practically unknown since new insecticides destroyed the carriers, and wet-tropic diseases, such as typhoid and amoebic dysentery, are rare.

Berbera (pop., 1956, est., 7,500), the old capital, is the only good natural harbour on the African coast between Jibuti and Mombasa, but needs dredging and lacks modern port facilities. Zeila is a poor shallow harbour, overshadowed by Jibuti, and there are open roadstead ports at Bulhar, Karin, Onkhor, Shalau, Heis, Mait, Las Khoreh and Elayu. Inland on the plateau, Hargeisa (pop., 1956 est., 45,000) was the capital of the protectorate, and Borama, Burao, Erigavo and Las Anod were district headquarters.

History.—This coast was known in Egypt at least 1,500 years B.C., and traces of Persian culture still remain in Zeila. In the 7th century Arabs conquered Zeila and later Harar. The main Moslem Arab invasion, by infiltration, conquest and absorption of the Galla inhabitants, began on the Makhir coast in the northeast during the 13th century, the resulting Somali people spreading over the Horn of Africa from there. In the 16th century, Galla from Abyssinia drove the Arabs in the Zeila area back to the coast, where for a few years Zeila, as well as Berbera, were occupied by the Portuguese. Before the end of the century a further immigration of Arabs landed near Zeila to found the Dir tribes, Isa and Gadabursi, as well as other Dir tribes which spread south to mingle inamicably with the Is'haq and Darod waves from the northeast. Anchorage and trading agreements were made by British sea captains in 1827 and 1840, Aden having been annexed in 1839.

With the opening of the Suez canal in 1869 there was renewed European interest in the area, but in 1874 khedivial troops under Turkish sovereignty occupied the coast and Harar. With the mahdi's Sudan rebellion in 1882 these troops began to withdraw, and a British consul from Aden (then under the India office) came to Berbera, Bulhar and Zeila, in 1884. The Turks then withdrew to Suez, and in the next few years treaties were made by the British with the tribes. Germans and Russians visited the coast during this period. In 1888 a protectorate was declared, and accord reached with the French at Obok. The consuls, with a platoon of troops, kept the peace near the coast. In 1898 the foreign office took over from the India office. In 1894 boundaries were agreed with Italy and in 1897 with Ethiopia.

From 1900 until 1920 the "mad mullah," Mohammed Abdallah Hasan, of the Ogaden, fought the British, retiring into Italian- or Ethiopian-controlled territory when worsted by military expeditions. During a lull in this war in 1905 the colonial office took over control of the protectorate and in 1906 the Anglo-Franco-Italian agreement defined spheres of influence in the whole area of the Somalilands.

Another lull in the "mad mullah" wars in 1910 resulted in a British withdrawal to the coast for reasons of economy. They armed the friendly tribes, which promptly started to fight each other. The mullah's raids increased, and in 1913 Richard Corfield, commandant of the camel constabulary, was killed with much of his force. In 1914 the British reoccupied part of the interior, but the defeat of the mullah was postponed until after World War I. In 1920, the mullah was finally beaten, but once again escaped, and died of influenza in Ethiopia in 1921.

Thereafter followed a period of peaceful administration by colonial administrative officers, though in 1922 a district commissioner was shot during a riot over proposed direct taxation.

In 1936 the Italians had conquered Ethiopia. Their frontier patrols interfered with seasonal nomadic movements of graziers. In 1940, during World War II, British troops withdrew. The Italians occupied the protectorate until they in turn were driven out in March 1941 by the British. A military government, with a core of colonial service officers, took over the protectorate. In Aug. 1944 the Somaliland camel corps mutinied without bloodshed and was disbanded, to be replaced later by the Somaliland scouts. From 1945–56 there were intertribal feuds and battles at intervals, some of them serious, and in 1945 antilocust-control riots.

In Nov. 1948, the colonial office again took over from the war office, and in Feb. 1955 the Haud grazing areas, which had been administered by the British government since 1941, were returned to Ethiopian control. The protectorate gained its independence on June 26, 1960, and joined Italian Somalia on July 1 to form the Somali Republic.

Administration.—The protectorate was administered by a governor at Hargeisa, with six district commissioners. The chief secretary, secretariat and most departmental headquarters were at Hargeisa. An indigenous advisory council in 1957 became a legislative council, with increasing powers as Somalis were beginning to take over senior administrative posts. There was a colonial force, the Somaliland scouts, a police force, and an irregular force of Illalos controlled by district commissioners. A judge of the high court, district courts, kadi's (Moslem law) courts and subordinate (Somali) courts were established.

On July 1, 1960, the legislative assemblies of the former protectorate and Italian Somalia met in joint session to elect a provisional president as chief of state. A premier was designated to form a government, and work on a constitution was begun.

Economy.—The most important industry is stock herding. In 1955 there were estimated to be 1,200,000 camels, 2,355,000 black-headed fat-tailed sheep, 1,645,000 goats, 223,100 humped zebu cattle, 5,100 donkeys and 650 horses with the British protected tribes. The camel, last to survive in a drought, is the mainstay of the local economy providing transport, meat, milk and hides. Sheep and goats provide meat, milk and ghee (clarified butter), and are the most important export for meat and for the world-prized Berbera sheepskin. Cattle and donkeys are limited to better-watered or agricultural areas. Erosion is locally serious where overstocking due to maldistribution upsets the balance of vegetative cover suitable to the climate.

Agriculture is confined to about 5% of the country, millet and some maize being grown in rain gardens above 4,000 ft., or in flood gardens in inland deltas. There are also some vegetable gardens irrigated from permanent streams or wells, and some government experimental date gardens near the coast. Gums (frankincense, myrrh, gum arabic) are collected from wild trees for export. Guano from Mait island is all exported to Arabia. The growing of *Catha* edulis, chewed as a drug, is forbidden.

There are some areas declared forest reserves, and some timber is obtained from relict forests of Juniperus procera. Conocarpus *lancifolia* is exported for dhow building, and some plantations were developed near the coast in the 1950s. In the internal economy Acacia bussei is the most important tree.

Small quantities of beryl, columbite and cassiterite have been exported, while rutile, mica, galena, samarskite and monazite are known to occur. There are three known oil seepages, and exploration for mineral oil was carried out after mid-century. Apart from possible oil, the only potentially valuable mineral is the large reserves of gypsum and anhydrite, millions of tons of which outcrop within 10 mi. of Berbera harbour.

Currency, in East African shillings, was valued at 20 to the pound sterling. There is a weekly steamer service between Aden and Berbera, and from October to April a monthly ship from Great Britain. There are well-distributed landing grounds, and good air-fields at Hargeisa and Berbera, which are linked by the all-weather Berbera-Harar road. Wireless telegraphy is available at all district headquarters. From Hargeisa are the main roads through Mogadishu to Nairobi, and to Jibuti.

In 1955 revenue was £701,417 and expenditure £1,197,004, the balance made up by Great Britain. Import duty produced about £465,000 and export duty £90.000 of the revenue. The only direct tax was a business profits tax. The main imports are cloth, rice, sugar, tea, dates. millet, gasoline and cigarettes in that order. a third from India, a quarter from Great Britain and a third from countries outside the commonnealth. Exports, in order of value, are sheep. sheep and goat skins. goats, cattle, gums, camels and hides. Most commodities were transshipped at Aden, severely taxing the economy of the former protectorate. Considerable transit trade, mostly taxed 1.5%, is especially to Ethiopia and parts of Somalia.

Italian Somaliland.—Former Somalia, the easternmost strip of Africa, bounded by the Gulf of Aden, round Guardafui to the Indian ocean, southwest to Dicks Head on the Kenya border, then north to hfandera on the Kenya-Ethiopia border. east-northeast and northeast bordering Ethiopia and former British Somaliland, and finally north to Bender Ziada on the Gulf of Aden, lies between lat. 12° N. and 1° 40' S, and long. 41° and 51" 25' E., including the most easterly point of Africa. Ras Hafun.

The capital of the trust territory, Mogadishu (Mogadiscio), became the capital of the Somali Republic; other important towns include Kismayu (Chisimaio), Brava, Merca, Obbia, Eil and Bender Beila on the Indian ocean. Bender Cassim on the Gulf of Aden, and Galkayu. Bardera, Lugh Ferrandi. Isha Baidoa and Villagio Duca degli Abbruzzi in the interior. Its area is 178.201 sq.mi.

The land rises rapidly from the Gulf of Aden to the Al Maskat hills about 4,000 ft., thence sloping southward through plateau lands to low-lying semidesert. relieved by the well-watered flood plains of the Webi Shebeli and Juba in the southwest and south. Little of the country is over 2,000 ft. above sea level. and to the south of 8° N most is less than 1.000 ft.

Short river beds, with some permanent water, flow north from the Al Maskat, and to the south the Daror and Nogal, with some flowing reaches, drain east to the Indian ocean South of the Nogal most of the rainfall goes underground in semidesert gypsum country. The Webi Shebeli from the Ethiopian highlands flows southeast irom Belet Wein to near Mogadishu, where it turns southwest behind the coastal sand dunes in which it is lost. The Juba, also permanent water, crosses Somalia from Bardera to the Indian ocean just north of Kismayu.

In the north (the Mijertein), the climate is similar to that of iormer British Somaliland, with rainfall of 3 to 6 in. on the coast, to 10 in. or more in the Al Maskat. The northeast monsoon blows from October to March, and the stronger southwest monsoon irom May to September, with calm periods between. Most of the rainfall is during the southwest monsoon, except around Guardafui where local winter rainfall is important. Average minimum temperatures fall to 70° F. on the coast, and perhaps 40° in the Al Maskat. Average maxima are 100° on the coast to 90° in the highlands. South, nearer the equator, is a different climatic region, though records are scarce. At Mogadishu average annual rainiall is about 15 in., the southwest monsoon from July to September and the northeast from December to March.

The People.—In 1953 the estimated population was 1,263,584, including about 30,000 Arabs, 1,000 Indians, and 4,916 Italians and 124 other Europeans. There are, however, many Negroid and half-Negroid tribes especially along the big rivers and south of Kismayu. All the Somalis are Sunni Moslems.

Apart from Moslem schools, Catholic missions and orphanages date from about 1900. The medical department expanded rapidly after 1941 and qualified Somalis began to replace Italian doctors.

History.—The first Hamitic invaders were forebears of the non-Moslem Galla. The second invasion in the 13th century was of Moslem Arabs through the Makhir coast of British Somaliland. Later the Darod tribes spread southward to the Tana river. The Hawiya, starting near Jibuti, spread south and east to central Somalia. The Galla, converted to Islam, were mostly driven west to Ethiopia or south, though the "outcast" tribes, Midgan, Tumal and Yibir, probably originate irom Galla ioreiathers.

In 1507 Brava was sacked by the Portuguese Tristan da Cunha, and by the end of the 19th century the imam of Oman, from Zanzibar, controlled the east African coast irom Mogadishu to Mozambique. Italy made trade treaties irom 1889 and in 1892 leased the Benadir coast ports of southern Somalia from the sultan of Zanzibar, finally buying them in 1895 for 3,800,000 lire. In 1895 Vittorio Bbttego founded the station at Lugh on the upper Juba, and agreements with other European powers and Ethiopia were made, in 1897, 1906 and 1907. The hinterland of the Benadir coast in agreement with Ethiopia was undefined.

Meanwhile the "mad mullah" of the Ogaden tried to drive the British into the sea from 1900 until his death in 1921. The Italians made some halfhearted attempts at settling this quarrel, as the mullah used to retire to the Mudugh, inland oi Illig and Obbia, and was getting arms and supplies through the Somalia coast. In 1919 Britain ceded Kismayu and the Jubaland to Italy, and in 1920 Belet \Vein was occupied.

After the defeat by the British of the mullah, the Italians started to occupy the Mijertein in the northeast and brought it under control between 1925 and 1927. They then followed and encouraged the westward migration of the tribes, setting up posts as iar inland as Walwal, where in 1934 they attacked Ethiopian troops with the Anglo-Ethiopian boundary commission, and then annexed all Ethiopia in 1935–36. Money was poured into Somalia and Ethiopia for development and to build up military power. In Aug. 1940, during World War II, the British were driven from British Somaliland by the Italians. Late in Jan. 1941 the British began to invade Somalia from Kenya, captured Mogadishu a month later, and by the end of April had swept on to the Ethiopian highlands leaving Somalia and British Somaliland occupied.

Somalia was administered by a skeleton staff of military political officers, and agriculture, industry, education and medical services improved, while the country continued to be administered according to Italian and sheriat (Islamic) law. Italy, as trustee of the United Nations, took over the administration of Somalia again on April 1, 1950, after which the training and education oi Somalis ior self-government a decade later progressed rapidly. The Somali Republic, formed by the union of British Somaliland and Italian Somalia, was proclaimed on July 1, 1960.

Administration.—The trusteeship government was on the colonial pattern with an elected legislative assembly and provincial and district administrators outside the capital. Most of these were Somali. There was universal suffrage, and principal parties in the assembly were the republican Somali Youth league, the Hisbia Dighil Mirifle (in favour of conservative tribal responsibility and increased education), and the Partito Democratico Somalo consisting mostly oi townsmen.

Economy.—About 70% of the population live by herding stock, which in 1957 was estimated at 1,156,000 camels, 1,200,000 cattle, 2,000,000 sheep, 2,135,000 goats and 20,000 donkeys. Average stock per head of population is slightly lower than that for former British Somaliland, and proportion of cattle to camels higher.

In Mijerteinia are some small irrigated date gardens and some maize, millet and vegetable flood gardens locally. In the south the valleys of the Webi Shebeli and Juba, and the dune lands of the Benadir coast, produce millet, sesame, maize, cotton, bananas, sugar and some rice and dates. Some higher inland areas such as Isha Baadoa have enough rainiall to produce millet and maize. These agricultural areas are of considerable economic value.

Kismayu is a poor natural harbour, and Mogadishu a fair artificial one, the other ports being mere roadsteads. Good main roads built by the Italians were added to during British military occupation. Most of the agricultural .produce is absorbed locally, but bananas, sugar and sometimes millet are exported, as are ghee, hides, skins and gums and tunny irom the Mijertein, salt from Hafun and some dressed leather from Brava.

Under UN trusteeship there was only 8% direct taxation, the rest of revenue being derived by indirect taxation. In 1953 the annual expenditure amounted to 99,956,000 somalos (20 somalos = $2.80 = £1), including 58,332,000 somalos contributed by Italy.

FRENCH SOMALILAND

French Somaliland, or Côte française des Somalis, lies on the African coast where the Red sea meets the Gulf of Aden, between lat. 10° 55' and 12° 43' N., and long. 41° 38' and 43° 25' E. It is bounded to the north and the west by Ethiopia, and to the south by the Somali Republic. The ports of Obok and Tajura are on the north side of the Gulf of Tajura, and Jibuti (Fr. Djibouti), the capital, on the south. The area is 8,996 sq.mi. in extent, and consists of very broken country with mountains up to 6,630 ft. (Musa Ali), separated by a series of rifts some of which contain salt lakes below sea level.

The drainage flows partly eastward to the coast and partly inland to the lakes, but few streams flow above the surface except after rain. At Jibuti, irom October to March the northeast monsoon brings temperatures of 75° to 85° F., with an average rainfall, mostly between October and December, of 3.76 in. April and September are calm, hot and humid, and irom May to August the southwest monsoon blows with average temperatures of 85° to 99° F., often reaching 113° or more in July. The southwest monsoon is complicated by dust-laden khamsin winds from the northwest, and average rainiall is 0.9 in. between April and September.

The People.—Outside Jibuti most of the people are transhumant stock herders, many passing through the country from British Somaliland to Ethiopia and back, seasonally. In 1954 the population was estimated at 63,734, including 28,000 Somalis of the "black" Isa tribe, 25,000 Danakils, 6,000 Arabs on the coast and 3,132 Europeans, two-thirds of them French. The people are Moslems, but there are Roman Catholic schools at Jibuti and Ali Sabieh, as well as secular government schools, a hospital in Jibuti, dispensaries in other centres and a hygiene department. Population of Jibuti (1954 est.) was 31,000.

History.— The original Galla population, conquered by Ethiopia in the 14th century, were invaded from Arabia by the forbears of the Danakil, who fought the Ethiopians until 1530 when their leader Mohammed Grañ died. A further wave of Arab invasion south of the Gulf of Tajura gave rise to the Isa Somali there, and for a short time in the 16th century Portuguese occupied the coast. In 1839, a French naval lieutenant, obtained a concession at Amphala, and in 1840 the British took the Moucha islands in the Gulf of Tajura. Rochet d'Héricourt got a concession of Tajura and made a treaty with the king of Shoa in 1842. In 1858 Henri Lambert, French consul in Aden, made further approaches, and by 1862 Danakil chiefs made a commercial treaty ior the area between Doumeira and Tajura, and the French purchased Obok ior 50,000 ir. This area was occupied in 1881, the Italians occupied Assab to the north in 1882, and an Egyptian agent in Zeila ceded Sagallo to the French. In 1884, the French commandant of the territory signed treaties with the Danakil sultans of Tajura and Gobad, and in 1885 with the Isa Somalis. After some squabbling with Great Britain, and a feint at occupying Sagallo by the Russians, accord was reached and the Franco-British frontier settled in 1888, the French withdrawing their claim to Dongarita (between Zeila and Bulhar), and the British giving up the Moucha islands.

In 1892 the capital was moved from Obok to Jibuti, and plans for a railway to Addis Ababa made in 1896. The Ethiopian boundary was agreed in 1897 and the Eritrean frontier in 1900–01. By 1902 the railway reached Diredawa, and in 1915 Addis, whereupon the territory prospered, exports in 1916 being valued at 51,000,000 fr. as against 39,000,000 ir. worth of imports. Lej Yasu, Moslem former king of Ethiopia, led a Somali rebellion in 1917–18, but was quelled.

In 1940 the territory joined the Vichy French government thereby exposing the British flank and withdrawing the only Allied air support. The British evacuated Somaliland and on their return blockaded Jibuti from 1941 until 1943, when it joined the Free French and again entered the war against Germany, Italy and Japan.

Administration.— After initial periods as a number of trading posts, and more direct rule on the coast after 1890, the country was administered by a governor aided by a local legislative council, partly elected and partly nominated.

In 1957 a new system of government was introduced. A territorial assembly, elected by universal suffrage, thereafter elected an executive council composed of a vice-president and ministers, the governor remaining president. The country was also represented in the metropolitan French parliament and in the assembly oi the French Union.

Economy.— Domestic stock, which forms the livelihood of most of the indigenous population, consisted in 1955 of about 40,000 camels, 40,000 cattle, 200,000 goats and 100,000 sheep and about 1,500 donkeys.

Apart from stock herding, and the production of meat, milk, ghee, hides and skins, the wealth of the country depends on the iree port of Jibuti, and the railway to Addis Ababa. Salt by evaporation of sea water and from Lake Assal is exported. The port of Jibuti has six deep-water quays (10–30 ft.), and is well equipped. The airport has a 2.400 m. runway, and the railway after 60 mi. in French Somaliland continues ior 430 mi. more to Addis Ababa, carrying up to 750,000 metric tons of traffic a year. About 3,500,000 tons gross of shipping use the port annually, exporting salt, coffee, grain, hides and skins, and importing oil and coal for fueling and to provide electric power. In 1949, Jibuti became a iree port, and the Jibuti franc, valued at 1.63 metropolitan francs, was created as freely convertible currency. Exports exceeded imports till 1952 since when adverse trade balances were probably due to the capital development and competitive development of Massawa by the Ethiopians. There was little direct taxation escept 15% on consumer goods.

SOMBART, WERNER (1863–1941), German economist, author of a widely read history of capitalism, was born at Ermsleben in the Harz on Jan. 19, 1863. He was appointed professor at the University of Berlin in 1917. Sombart's chief work, *Der Moderne Kapitalismus*, first appeared in 1902, and was enlarged and amended in the second edition of 1916. His history of capitalism was brought to a close with the publication of *Hochkapitalismus* in 1928. In Sombart's view the capitalist organization was created by a spirit that generated in the late middle ages; it combines economic rationality with the exclusive direction of economic activity toward maximizing money profits. The most controversial aspect of his study is the role he assigns the Jews as the chief creators of capitalism. He divided the development of capitalism into three stages: early capitalism, from about the 15th to the middle of the 18th century; high capitalism, 1760 to 1914; and late capitalism, the period of disintegration, which began at the close of World War I. In his early career he was a convinced Marxist. Later he rejected Marxism as a program of social reform, but he never ceased to consider himself as Marx's heir in the "scientific!' study of capitalism. His *Deutscher Sozialismus* (1934) is generally considered an apology for German Naziism.

Sombart died on May 19, 1941. (A. L. Hs.)

SOMBOR, a town of Vojvodina, Yugos. Pop. (1953) 26,637. It is in a fertile plain and is a centre of corn and cattle trade.

SOMERS, JOHN SOMERS (or Sommers), **Baron** (1651–1716), English lord chancellor, was born on March 4, 1651, near Worcester, the eldest son of John Somers, an attorney, and of Catherine Ceaverne of Shropshire. Educated at Worcester and at Trinity college, Oxford, he studied law under Sir Francis Winnington, and soon became intimate with the leaders of the country party, especially with Essex, William Russell, and Algernon Sidney, but never entered into their plans so far as to commit himself beyond recall. He was reputed to have written the *Just and Modest Vindication of the Two Last Parliaments*, in answer to Charles II's declaration of his reasons for dissolving them. This, however, was by Sidney, though probably Somers was responsible for the final draft. As counsel for the sheriffs Pilkington and Shute before the court of King's Bench, and junior counsel in the trial of the seven bishops, Somers won a reputation which was further enhanced by the part which he took in the secret councils which preceded the revolution. Elected to the Convention parliament, he was appointed one of the managers for the Commons in the conferences between the houses, and was further distinguished by being made chairman of the committee which drew up the Declaration of Right.

In May 1689 Somers was made solicitor-general and knighted, and he now became William III's confidential adviser. In the controversy which arose between the houses on the question of the legality of the decision of the court of King's Bench regarding Titus Oates, and of the action of the Lords in sustaining this decision, Somers was again the leading manager for the Commons, and has left a clear and interesting account of the debates. He was appointed chairman of the select committee of the House of Commons on the Corporation Bill (1690), by which those corporations which had surrendered their charters to the Crown during the last two reigns were restored to their rights. On March 23, 1693, the great seal having meanwhile been in commission, Somers was appointed lord-keeper and a privy councillor. Somers now became the most prominent member of the Junto, the small council which comprised the chief members of the Whig party. When William left in May 1695 to take command of the army in the Netherlands, Somers was made one of the seven lords-justices to whom the administration of the kingdom during his absence was entrusted; and he was instrumental in bringing about a reconciliation between William and the princess Anne.

In April 1697 Somers became lord chancellor, and was created a peer by the title of Baron Somers of Evesham. Somers had been free from attack at the hands of political opponents; but his connection in 1699 with Captain William Kidd, to the cost of whose expedition Somers had given £1,000, afforded an opportunity for a vote of censure, in the House of Commons which was rejected by 199 to 131. The attack was renewed shortly on the ground of his having accepted grants of Crown property to the amount of £1,600 a year, but was again defeated. On the subject of the Irish forfeitures a third attack was made in 1700, a motion being brought forward to request the king to remove Somers from his counsels; but this again was rejected by a large majority. In consequence, however, of the incessant agitation Somers was finally compelled to resign. In 1701 he was impeached by the Commons for his share in the negotiations relating to the Partition Treaty in 1698, and defended himself most ably before the house, answering the charges seriatim. The impeachment was voted and sent up to the Lords, but was there dismissed. On the death of the king Somers retired into private life, but he actively opposed the Occasional Conformity Bill (1702), and in 1706 was one of the managers of the union with Scotland. In the same year he carried a bill regulating and improving the proceedings of the law courts. He was made president of the council in 1708 upon the return of the Whigs to power, and retained the office until their downfall in 1710. He was also president of the Royal Society from 1699–1704. He died on April 26, 1716. Somers wrote *The History of the Succession of the Crown of England,* as well as several poems and pamphlets

For a contemporary character of Somers Addison's paper in the *Freeholder* for the 14th of May 1716 should be referred to; and there is in Macaulay's History (iv. 53) an eloquent tribute to his character and comprehensive learning. A catalogue of his publications will be found in Walpole's Royal and *Noble Authors.*

SOMERSET, EARLS AND DUKES OF. In the 11th century Somerset and Dorset were under the jurisdiction of one sheriff, and for a considerable period titles derived from each of these shires were borne by the same person. (See DORSET, EARLS, MARQUESSES AND DUKES OF.)

The earldom of Somerset in the Beaufort family dated from 1397, in which year it was granted by Richard II. to JOHN BEAUFORT (*c.* 1373–1410), the eldest of the three illegitimate, but afterwards legitimated, sons of John of Gaunt, duke of Lancaster, by Catherine, wife of Sir Hugh Swynford, and daughter of Sir Payne Roelt. He was followed in the earldom successively by his three sons: Henry, who died unmarried in 1418; John (1404–1444), who in 1443 was created earl of Kendal and duke of Somerset, both of which titles became extinct at his death; and Edmund, who was created earl of Dorset in 1441, marquess of Dorset in 1443, and duke of Somerset in 1448 (*See* SOMERSET, EDMUND BEAUFORT, DUKE OF.) On the execution of Edmund's son Henry, 5th earl and 2nd duke of Somerset, by the Yorkists in 1464, his titles were forfeited by act of parliament; but his brother Edmund was from that date styled duke of Somerset by the Lancastrian party till his death in May 1471, when the house of Beaufort became extinct (See BEAUFORT) The title. conjoined with the dukedom of Richmond, was, however, borne by Henry Fitzroy, illegitimate son of Henry VIII., from 1525 till his death without heirs in 1536.

EDWARD SEYMOUR, duke of Somerset (*q.v.*), known as the Protector, was the first of the line of dukes to which the holder of the title at the present day belongs, having been created Viscount Beauchamp of Hache, Co. Somerset, in 1536; earl of Hertford in 1537; and in 1547 Baron Seymour and duke of Somerset. His honours, which were entailed on the issue of his second in priority to that of his first marriage, being forfeited by attainder in 1552, Robert Carr became earl of Somerset (q v) in 1613, but died without male issue in 1645, when his title became extinct. A curious incident in the history of this title was the grant by Charles I. in 1644 of a commission to Edward Somerset, son of Henry, 1st marquess of Worcester, empowering him to fill up certain blank patents of peerage with a promise of the title of duke of Somerset for himself. After the Restoration this instrument was cancelled in consequence of a resolution of the House of Lords declaring it to be "in prejudice to the peers"; and the grantee, who had meantime succeeded to the marquessate of Worcester, surrendered his claim to the dukedom of Somerset in Sept. 1660. In the same month the dukedom of Somerset and barony of Seymour were restored to WILLIAM SEYMOUR (1588–1660), great-grandson of the I'rotector, who in 1621 inherited the titles of earl of Hertford and Baron Beauchamp which had been granted to his grandfather Edward Seymour in 1559, and who, in 1640, had himself been created marquis of Hertford. He died in Nov. 1660, a few weeks after his restoration to the dukedom, and was succeeded by his grandson William, 3rd duke of Somerset (c. 1651–1671). As the latter died unmarried, the Ssmerset title devolved on John Seymour (c. 1628–1675), the 2nd duke's fifth and youngest son, at whose death without issue in 1675 the marquessate of Hertford became extinct; his cousin Francis Seymour (1658–1678) becoming jth duke of Somerset.

CHARLES SEYMOUR, 6th duke of Somerset (1662–1748), who succeeded his brother Francis, the 5th duke, was educated at Trinity college, Cambridge; and in 1682 he married Elizabeth, daughter of Joceline Percy, earl of Northumberland, who brought him immense estates, including Alnwick castle, Petworth, Syon House and Northumberland House in London. (See NORTHUMBERLAND, EARLS AND DUKES OF.) In 1683 Somerset received an appointment in the king's household, and two years later a colonelcy of dragoons; but at the revolution he bore arms for the prince of Orange. He became a great favourite with Queen Anne, receiving the post of master of the horse in 1702. He made friends with the Tories, and succeeded in retaining the queen's confidence, while his wife replaced the duchess of Marlborough as mistress of the robes in 1711. In the memorable crisis when Anne was at the point of death, Somerset acted with Argyll, Shrewsbury and other Whig nobles who. by insisting on their right to be present in the privy council, secured the Hanoverian succession to the Crown. Dismissed from his office of master of the horse in 1716, he retired into private life, and died at Petworth on Dec. 2, 1748. At the death of his son ALGERNON (1684–1750), 7th duke, without male issue, the earldom of Hertford, and the baronies of Beauchamp and of Seymour of Trowbridge became extinct; and the dukedom of Somerset, together with the barony of Seymour, devolved on a distant cousin, Sir Edward Seymour, 6th baronet of Berry Pomeroy, Devonshire. (*See* SEYMOUR or ST. MAUR.)

The Seymours of Berry Pomeroy were the elder branch of the family, being descended from the protector Somerset by his first marriage, the issue of which had been excluded from succession to the titles and estates until after the failure of the issue of his second marriage. (*See* above.) SIR EDWARD SEYMOUR (1695–1757), who thus became 8th duke of Somerset, was grandson of Sir Edmund Seymour, Speaker of the House of Commons in the reign of Charles II. EDWARD ADOLPHUS, 12th duke (1804–1885), held various offices in Lord Melbourne's administration from 1835 to 1841; was a member of Lord John Russell's cabinet in 1851; and first lord of the admiralty from 1859 to 1866. In 1863 he was created Earl St. Maur of Berry Pomeroy. He married (1830) Jane Georgiana, youngest of the three celebrated daughters of Thomas Sheridan, who was the "Queen of Beauty" at the famous Eglinton Tournament in 1839. The duke was the author of *Christian Theology and Modern Scepticism* (1872), and *Monarchy and Democracy* (1880). At his death the family titles, except the earldom of St. Maur, which became extinct, devolved on his two brothers successively.

See SEYMOUR OR ST. MAUR.

SOMERSET, EDMUND BEAUFORT, DUKE OF (c. 1404–1455), was the younger son of John, earl of Somerset, and grandson of John of Gaunt, duke of Lancaster He was taken prisoner at Baugé in 1421 during his first campaign, and did not return to England till 1431. He was then styled earl of Mortain, and in 1432 was one of the envoys to the council of Basel. In 1436 he served at the relief of Calais, two years later he commanded with some success in Maine, and in 1440 recovered Harfleur. Next year he was made earl, and in 1443 marquess of Dorset. In 1444 on the death of his elder brother he became duke of Somerset. As head of the Beaufort party he was the rival of Richard of York, whom in 1447 he superseded as lieutenant of France. Me lacked statesmanship, and as a general could do nothing to stop French successes. The loss of Rouen and Normandy during the next four years was precipitated by his incompetence. and his failure made him a special object of Yorkist censure. The fall of Suffolk left Somerset the chief of the king's ministers. and the Commons in vain petitioned for his removal in January 1451. In spite of York's active hostility he maintained his position till Henry's illness brought his rival the protectorate in March 1454. For a pear he was kept a prisoner in the Tower "without any lawful process." On the king's recovery he was honourably discharged. and restored to his office as captain of Calais. Mistrust of Somerset was York's excuse for taking up arms. The rivalry of the tno leaders was ended by the defeat of the Lancastrians and death of Somerset at St. Albans on May 22, 1455.

For further information *see* Sir James Ramsay, *Lancaster and York* (Oxford, 1892); C. Oman, *Political History of England, 1377–1485* (1906), with authorities there cited. (C. L. K.)

SOMERSET, EDWARD SEYMOUR, 1ST DUKE OF (*c.* 1500–1552), was protector of England in the reign of Edward VI. Born about 1j00, he was the eldest surviving son of Sir John Seymour (d. 1536) of Wolf hall, Wiltshire. The Seymours claimed descent from a companion of William the Conqueror, who took his name from St. Maur-sur-Loire in Touraine; and the protector's mother was descended from Edward III. Edward was page of honour to Mary Tudor at her marriage mith Louis XII in 1514, served in the duke of Suffolk's campaign in France in 1523 and accompanied Cardinal Wolsey on his embassy to France in 1527. Henry VIII, to whom he became (1530) squire of the body, married his sister Jane in 1536. and Edward was created Viscount Beauchamp. and. after the birth of Edward VI. earl of Hertford.

In 1541, during Henry's absence in the north, Hertford, Thomas Cranmer and Baron Audley had the chief management of affairs in London; in Sept. 1542 Hertford was appointed warden of the Scottish marches, and in December lord high admiral. a post which he almost immediately relinquished in favour of John Dudley, Viscount Lisle. later earl of Warwick and duke of Northumberland (*q.v.*). In Feb. 1544 Hertford was made lieutenant general in the north and instructed to punish the Scots for their repudiation of the treaty of marriage between Prince Edward and the infanr Mary Queen of Scots. He landed at Leith in May, captured and pillaged Edinburgh. and returned a month later. He then served at Boulogne, returning to Scotland in Sept. 1545 to avenge the Scottish victory at Xncrum moor. In March 1546 he was sent to Boulogne to supersede Henry Howard, earl of Surrey (*q.v.*); and from October to the end of Henry's reign he 1%-asin attendance on the king, engaged in that unrecorded struggle for predominance which was to determine the complexion of the government during the coming minority. Personal, political and religious rivalry separated him and Lisle from the Howards, and Surrey's attempt to secure the predominance of his family led to his own execution and his father's imprisonment.

Their overthrow had barely been accomplished when Henry VIII died. He had had no statutory power to appoint a protector, but in the council of regency which he nominated, Hertford and Lisle enjoyed a decisive preponderance; and the council determined to follow precedent and appoint a protector. They chose Hertford (now duke of Somerset), and he quickly emancipated himself from the trammels originally imposed on him; he was king in everything but name. He used his authority to divest the government of the apparatus of absolution perfected by Thomas Cromwell. In his first parliament, which met in Nov. 1547, he procured the repeal of all the heresy laws and nearly all the treason laws passed since Edward III. In foreign affairs, also, he at first adopted a more liberal policy. He had protested against his instruction in 1544, and now dropped the claim to suzerainty over Scotland which Henry VIII had revived. He sought to win over the Scots by promises of autonomy, free trade and equal privileges with England. But Scottish sentiment, backed by Roman Catholic influence and by French intrigues, money and men. proved too strong for Somerset's amiable invitations. The Scots turned a deaf ear to his persuasions ; the protector led another army into Scotland in Sept. 1547 and won the battle of Pinkie (Sept. 10).

Somerset apparently thought that the religious question could be settled. by public discussion and throughout 1547 and 1548 England went as it pleased so far as church services were concerned. All sorts of experiments were tried and the country was involved in a grand theological debate. in which Protestant refugees from abroad hastened to join. The result convinced the protector that the government must prescribe one uniform order which all should be persuaded or constrained to obey; but the first Book of Common Prayer, which was imposed by the first Act of Uniformity in 1549, was a studious compromise between the new and the old learning. very different from the Protestantism of the second book imposed in 1552 after Somerset had been removed. The Catholic risings in the west in 1549 added to Somerset's difficulties. but were not the cause of his fall. The factious and treasonable conduct of his brother 'Thomas Seymour (*q.v.*), lord high admiral, in whose execution (March 20. 1549) he weakly acquiesced. also impaired his authority. But the main cause of his ruin was the divergence between him and the majority of the council over the questions of constitutional liberty and enclosures of the commons. His efforts to check enclosures were foiled, and the popular revolts which resulted from their failure weakened his position. He was divided in mind between his sympathy with the rebels and his duty to maintain law and order. France seized the opportunity to declare war on Aug. 8; and the outlying forts in the Roulonnais fell into their hands, while the Scots captured Haddington.

These misfortunes gave a handle to Somerset's enemies. Warwick combined on the same temporary platform Catholics who resented the Book of Common Prayer. Protestants who thought Somerset's mildness paltering with God's truth and the wealthy classes as a whole. In September he concerted measures with the former lord chancellor R'riothrsley; and in October, after a vain effort to rouse the masses in his favour, Somerset was deprived of the protectorate and sent to the Tower. But the hostile coalition broke up as soon as it had to frame a constructive policy. Warwick jockeyed the Catholics out of the council and prepared to advance along Protestant lines. He could hardly combine proscription of the Catholics with that of Somerset. and the duke was released in Feb. 1550. For a time the rivals seemed to agree. and Warwick's son married Somerset's daughter. But growing discontent with Warwick made Somerset too dangerous. In Oct. 1551, after Warwick had been created duke of Northumberland. Somerset was sent to the Tower on an exaggerated charge of treason, which broke down at his trial. He was. however. as a sort of compromise, condemned on a charge of felony for having sought to effect a change of government. Few expected that the sentence would be carried out, and apparently Northumberland found it necessary to forge an instruction from Edward VI to that effect. Somerset was executed on Jan. 22, 1552, dying mith exemplary patience and fortitude.

See A. F. Pollard, *England Under Protector Somerset* (London, 1900), also his article in the *Dictioaary of National Biography* and vol. vi of *Political History of England* (London, 1910). (A. F. Po.; R. B. WM.)

SOMERSET, ISABELLA CAROLINE (LADY HENRY SOMERSET) (1851–1921), English philanthropist, was born in London on Aug. 3, 1851, the eldest daughter and coheiress of the 3rd and last Earl Somers. She married in 1873 Lord Henry Somerset. son of the 8th duke of Beaufort. from whom sbe later separated. She was long president of the Nationai British Women's Temperance association. In 1894 she founded the *Woman's Signal* in the interests of women's work, becoming its editor. She died in London on March 12, 1921.

See Kathleen Fitzpatrick, *Lady Henry Somerset; a Memoir* (1923).

SOMERSET, ROBERT CARR (or KER), EARL OF (c. 1590–1645), Scottish politician, youngest son of Sir Thomas Ker of Ferniehurst by his second wife, Janet, sister of Sir Walter Scott of Buccleuch. He may have accompanied James I as page to England, but his early history is obscure. In Dec. 1607 he was knighted and made a gentleman of the bedchamber and thereafter rose rapidly in royal favour. Entirely devoid of all high intellectual qualities. Carr was endowed with good looks. excellent spirits and considerable personal accomplishments. These advantages were sufficient for James. In 1609 the king conferred on Carr Sir

Walter Raleigh's forfeited manor of Sherborne. Carr's influence was already such that in 1610–11 he persuaded the king to dissolve his first parliament. which had shown signs of attacking the Scottish favourites. On March 2j, 1611, he was created Viscount Rochester, and subsequently a privy councilor (April 1612), and on Lord Salisbury's death in 1612 he began in July to act as the king's secretary. On Nov. 3, 1613, he was advanced to the earldom of Somerset, in December was appointed treasurer of Scotland, and in 1614 lord chamberlain. Somerset fell from favour in 161j, when the circumstances of the murder of Sir Thomas Overbury in 1613 were disclosed, and he and his wife. who had secured a divorce from the earl of Essex to marry him, were implicated. For this story *see* SIR THOMAS OVERBURY. Possibly Somerset was no more than an accessory after the event. He was pardoned in 1624, and from that time disappears from history. He died in July 1645.

See the article *by* S. R. Gardiner in the *Dictionary of National Biography,* with authorities there cited; G. E. Cokayne, *Complete Peerage,* xii (London, 1953). (R. B. WM)

SOMERSET, a southwestern county of England. bounded north by the Bristol channel, the Avon river and Gloucestershire, east by Wiltshire, south and west by Dorset and Devon. The geographical area is 1.613 sq.mi. with a population (1951) of 551,453.

Physical Features.— The county consists of a basin surrounded on three sides by hills and limited on the fourth by the sea. The northern hills are the Mendips, composed of Carboniferous Limestone, stretching from Nunney to the sea and appearing again in the islands of Steep Holm and Flat Holm, which link the structure of Somerset with that of south Wales. The summit of the Mendips is a long tableland between 500 and 1,000 ft. in height, but rising in the west to just over the latter figure. To the north they die away gently, as a number of low hills. toward the Avon. There the Limestone is covered in places by Coal Measures, but most of the rocks are Triassic. Southward the Mendip hills drop steeply in an abrupt line broken by many coombes; *e.g.,* the gorge of Cheddar. The basin to the south is composed mainly of Triassic rocks, which, near the sea and along the valleys, are covered by recent alluvium. The basin is usually lower in its western than in its eastern part, which is known generally as Sedgemoor, but has different names in different parts. The large basin is subdivided into those of the Parrett and the Brue by the Polden hills, which run parallel to the Mendips from Lydford to Puriton. To the west of the Parrett rise the Quantock hills, which are outliers of the Devonian moorlands of Exmoor and the Brendon hills. These three hill groups consist almost entirely of Devonian rocks, and their highest points respectively are Will's Neck (1,261 ft.), Dunkery beacon (1,707 ft.) and Lype hill (1,391 ft.). Exmoor (*q.v.*) forest covers the western extremity of Somerset and a large tract of Devon adjoining it. From Crewkerne along the southern and eastern borders of the county as far as the Avon runs a more or less continuous line of low Jurassic hills, while around Chard in the south there is a fair extent of Cretaceous rocks.

History.— In early postglacial times the lowlands were morasses and the claylands forested, and so man, when he came to the district, settled on the open heights—the sterile old rocks of the west, the chalk of the south. the limestone of the Mendips and the oolites on the east—and the caves of Mendip have yielded valuable evidence of early prehistoric cultures. In the Mendips are the Cheddar caves and Wookey hole. Investigations indicated the existence of Mesolithic sites on the moors and in the western hills. Excavations of tumuli and hilltop earthworks produced evidence of occupation during the Bronze and early Iron Ages, but the most remarkable settlement of the pre-Roman period was that of the lake-village at Glastonbury (*q.v.*).

The Romans overran Somerset after the Claudian conquest of A.D. 43, and remains of the period of the Roman occupation are numerous, particularly between the Parrett and the Avon. Bath (Aquae Sulis), which was .probably a settlement in earlier times, became, on account of the medicinal properties of its waters, an important Roman centre where the Fosse way from Cirencester met another road from Silchester. The Fosse way was continued from Bath to near Seaton, Devon, and on it was a station at Ilchester *(Lendiniae?),* where it crossed the Yeo. Remains of about 50 Roman villas or related structures mere discovered in the county. Charterhouse in the Mendips was a centre of the Roman lead-mining industry. In the 6th century Somerset mas the debatable borderland between the Welsh and Saxons, the latter of whom pushed their way slowly westward. By 658 it had been conquered by the West Saxons as far as the Parrett, and there followed a struggle between the kingdoms of Wessex and Mercia, which led to the organization of the lands east of the Parrett as part of the kingdom of Wessex. About this time the monastery of Glastonbury was restored by Ine who completed the conquest of West Somerset. In the 7th century Somerset, as part of the kingdom of Wessex. was included in the diocese of Winchester. The new bishopric of Sherborne, founded in 705, contained the county until 909, when the see was divided into the dioceses of Salisbury, Exeter and Wells, the latter including the whole of Somerset. The diocese was divided into three archdeaconries. Disputes later between the chapters of Bath and Wells as to the election of the bishop led to a compromise in 1245, the election being by the chapters jointly, and the see being known as the bishopric of Bath and Wells.

King Alfred's victory in 878. folloued by the Peace of Wedmore, ended the incursions of the Danes for a time. but 100 years later they were again a great danger, and made frequent raids on the west coast of Somerset. At the Conquest Somerset nas divided into about 700 fiefs, held almost entirely by the Normans; the king's lands were of great extent and importance and the bishop of Winchester owned a vast property of which Taunton was the centre In the 11th century or a little later many Norman castles were built some of which have survived.

The chief families of the county in the middle ages were those of De Mohun, Malet, Revel, De Courcy. Montacute, Beauchamp and Beaufort, who bore the titles of earls or dukes of Somerset from 1396 to 1472. Eduard Seymour was made duke of Somerset in 1547, and in 1660 the title aas restored to the Seymour family, by whom it was still held in modern times. The marquess of Bath is the male representative of the Thynne family, which has long been settled in the county.

Somerset was too distant and isolated to take much share in the early baronial rebellions or the Wars of the Roses. and was really without political history until the end of the middle ages. The attempt of Perkin Warbeck in 1497 received some support, and in 1547 and 1549 there were rebellions against enclosures. Somerset took a considerable part in the Civil War. and with the exception of Taunton uas royalist. the strongholds being garrisoned and held for the king, but they all fell in 1645, and the county was subdued by the parliamentary forces. It nas the theatre of Monmouth's rebellion, and he was proclaimed king at Taunton in 1685. The battle of Sedgemoor on July 6 was followed in the autumn by the "bloody assizes" held by Judge George Jeffreys, in Taunton castle and at Wells.

The county was represented in the parliament of 1290; in 1295 it was represented by two knights, and 12 boroughs returned two burgesses each. It continued to return two members until 1832, when it was divided into Somerset East and Somerset West, each division returning two members. Two additional members were returned after 1867 for a third—the Mid-Somerset—division, until by the act of 1885 the whole county was divided into seven.

Antiquities.— In addition to the numerous prehistoric sites throughout the county, the remains of a unique Roman bathing station are to be seen at Bath. The county museum at Taunton exhibits the results of excavations in all parts of Somerset and particularly the mosaic pavement from the Roman villa at Low Ham.

Examples of medieval ecclesiastical architecture include the cathedral church of Wells, Bath abbey and the ruins of Glastonbury abbey, but Somerset's greatest wealth lies in its parish churches. Of these some have Norman and Early English features, but the most interesting especially for their magnificent towers, are those in the Perpendicular style. of nhich the outstanding examples are at Taunton, Glastonbury, Huish Episcopi, Leigh on Mendip and Kingsbury. Dunster castle, which dates from 1070, has been in the Luttrell family since 1376. Fine examples of domestic architecture of the medieval and Tudor periods are at Lytes Cary, Meare, Martock, Montacute, Barrington and Brympton; the imposing 18th-century architecture of Bath found echoes in simpler but attractive work in other towns in the county.

Agriculture, Industries and Communications. — Somerset has always been an agricultural county. Grain was grown and exported from the 11th to the end of the 18th century. Cider-making has been going on for centuries, and Cheddar gave its name to a famous cheese. Sheep farming was largely carried on after the period of enclosures and the woolen cloth trade flourished in Frome, Bath, Bridgwater, Taunton and many other towns from the 14th to the 19th century.

Somerset is the leading dairying county of England. Permanent grassland predominated in the mid-1950s (554,105 ac. in 1955), especially on the lower grounds, but there are areas where arable farming reaches a very high standard. Market gardening and fruitgrowing flourish in certain favourable districts. Stock raising is mainly concentrated on the hills, Exmoor, the Brendons and Quantocks being known for their calves raised for beef. Sheep breeding is similarly concentrated mainly in the west. On the flat moors of central Somerset more than 1,000 ac. are devoted to withy-growing for the manufacture of baskets, etc. The Forestry commission owned 7,611 ac. of land in Somerset and the National trust (1955) 15,892 ac.; Exmoor became a national park in 1954. Wild deer are still found on Exmoor and the Quantocks and a peculiar breed of ponies, hardy and small. Whitefish, shellfish, salmon and herring are caught in the Bristol channel and Bridgwater bay, part of which is protected for birds. Steep Holm is a native reserve containing rare birds and plants, notably the wild peony. Sharpham moor and Stert Island are also native reserves.

The chief mineral product is limestone from the Mendips. Peat is found in the Glastonbury area, clay (for brickmaking) near Bridgwater and fuller's earth near Bath. There is coal mining in the Radstock area.

Traditional manufactures include gloves at Yeovil and Wincanton, lace at Chard, linen at Crewkerne and silk at Taunton and Shepton Mallet. Many new industries were introduced—shoes at Street, shirts at Taunton, potash at Portishead and cellulose film at Bridgwater.

The holiday and tourist industry is economically important, not only at the seaside towns such as Weston-super-Mare, Burnham-on-Sea and Mir-head, but also inland at Cheddar, Wells, Taunton, on the Quantocks and on Exmoor.

Population and Administration. — The area of the administrative county is 1,603 sq.mi. with a population (1951) of 472,159. The municipal boroughs are Bath, a city and county borough (pop 1951, 79,294); Bridgwater (22,202); Chard (5,219); Taunton, the county town (33,620); Wells, a city (5,833); Weston-super-Mare (40,396); and Yeovil (23,337). There are 13 urban and 16 rural districts. Besides the county borough of Bath there are six parliamentary divisions, each returning one member; the county includes part of the parliamentary borough of Bristol.

SOMERVELL, BREHON BURKE (1892–1955), U.S. army officer, supply chief during World War II, was born in Little Rock, Ark., May 9, 1892. Graduating from the U.S. Military academy in 1914, he served overseas during and after World War I, winning decorations for combat bravery and administrative ability. During the 1920s Somervell was associated with Walker D. Hines in preparing plans for international use of the Rhine and the Danube, and in 1933–34 he participated in an economic survey of Turkey. Later he acted as federal Works Projects administrator in New York city (1936–40), chief of army construction (1940–41), assistant chief of staff for supply (1941–42) and commanding general of the army service forces (1942–46). He retired in May 1946 and died in Ocala, Fla., Feb. 13, 1955.

As army administrator for supply and service activities, Somervell was known for his energy and drive. He was both praised and criticized for getting work done quickly, at some extra cost and regardless of various interests involved. He held that war conditions demanded action, not extensive consultation and deliberation. Somervell was a strong advocate of military responsibility for the procurement and distribution of military supplies, and of a unified command within the army and the armed forces for handling military supply and service operations.

(J. D. MT.)

SOMERVILE, WILLIAM (1675–1742), English poet. A Warwickshire squire, he showed (in Samuel Johnson's words) "that it is practicable to be at once a skilful sportsman and a man of letters." *The Chase* (1735), a "georgic" in four books, offers sound advice on hunting and the breeding of hounds in blank verse with Miltonic rhythms which give way to a more staccato line at the excitement of a check in the hunt. *Hobbinol, or the Rural Games* (1740), a burlesque, and *Field* Sports (1742), both in blank verse, are less successful. (J. E. BT.)

SOMERVILLE, a city of Middlesex county, Mass., U.S.. on the Mystic river, is surrounded by Boston (Charlestown), Cambridge, Arlington and Medford. The last of the Mystic valley towns to separate from the early Charlestown colony, it was originally known as the Cow Commons and was entirely fenced in until 1685. In the city stands the Old Powder House, from which British Gen. Thomas Gage seized 250 half-barrels of gunpowder in 1774. In 1775 it became the magazine of the American forces besieging Boston. After the American Revolution brick-making grew to be an important industry and the opening of the Middlesex canal (1803) which passed through Somerville added to its desirability as an industrial site. It was incorporated as a town in 1842 and became a city in 1871.

The greatest growth in population and industrial activity occurred aiter 1900, when slaughtering and packing became the principal industries. By mid-20th century Somerville had become a working and middle-class residential suburb of Boston with substantial industrial development and importance as a distribution centre. Pop. (1960) 94.69'7; for comparative population figures *see* table in MASSACHUSETTS: *Population.* (L. G. BA.)

SOMERVILLE, a borough of north central New Jersey, U.S., on the Raritan river, is located 36 mi. S.W. of New York city; the seat of Somerset county. It is a retail-trade centre for a large area of farms, manufacturing plants and housing developments. First settled in the late 17th century by farmers, it became the county seat when the county was established in 1783. It mas incorporated as a town in 1863 and as a borough in 1909. In the 1750s Rev. John Frelinghuysen founded the first seminary of the Dutch Reformed Church in America. From these humble origins came Queen's college, chartered in 1766 and now Rutgers university. the state university of New Jersey *(see* NEW JERSEY: *Education);* and the New Brunswick Theological seminary. The Old Dutch parsonage, where Frelinghuysen lived, is open to the public, as is the Wallace house, used as headquarters by George Washington while his troops were quartered at Camp Middlebrook. The Duke estate, established in 1893 by James B. Duke, the tobacco magnate, is a research and exhibition centre for the New York Horticultural society. For comparative population figures *see* table in NEW JERSEY: *Population.* (E. R. D.)

SOMME, a *département* of France formed in 1790 of a large part of the province of Picardy (comprising Vermandois, Santerre, Amiénois, Ponthieu, Vimeu and Marquenterre) and a small portion of Artois. Pop. (1954) 464,153. Area, 2,424 sq.mi. It is bounded on the north by Pas-de-Calais, east by Aisne, south by Oise and southwest by Seine-Maritime, and its seacoast extends 28 mi. along the English channel. Two streams flowing into the channel — the Authie on the north and the Bresle on the southwest — bound it in these directions. The department is part of the chalk plateau of northwest France, cut by the English channel on the west with the result that it is seamed by well-marked valleys showing a succession of terraces which have become classical ground for the student of geology and of paleolithic man. On the plateau, which rises to about 700 ft. where it approaches the Pays de Bray in the southwest, there are large stretches of *limon,* a fine-grained, porous, fertile material. The Somme is a historic zone of defense of Paris, and the whole district east of Amiens bears the traces of much fighting during World Wars I and II. The river Somme has been made navigable by canalization of stretches. It also supplies considerable power. From Abbeville to the sea its canalized course can take ships of considerable size. From the mouth of the Authie to the Bay of the Somme the coast is lined with sand dunes about 2 mi. broad, behind which is the Marquenterre, a tract of 50,000 ac. reclaimed from the sea by dykes, and traversed by drainage canals. The Bay of the Somme, obstructed by dangerous sandbanks, contains the fishing ports of Le Crotoy, St. Valery, also the chief commercial port, and Le Hourdel. Next come the shingle banks, behind which the low fields of Cayeux (25,000 ac.) have been reclaimed; and then at the hamlet of Ault begin the chalk cliffs, which continue into Normandy. Near Amiens the Somme is joined by the Ancre, the Avre and the Selle. The Bresle is a small river south of the Somme, reaching the sea at Tréport.

The *département*, especially in the northeast, is one of the best cultivated in France. Beetroot for sugar is the staple crop of the Péronne *arrondissement;* cereals, chiefly wheat and barley, sugar beet, fodder and mangel-wurzels, oil plants, colza, flax, hemp and potatoes are grown throughout the *département*. Stock raising of all kinds is successful. The chief towns are Amiens (the capital), Abbeville, Montdidier, Péronne, Doullens, St. Riquier, Crécy and Ham. Albert (pop. [1954] 8,793) is a centre for machine construction; Villers-Bretonneux (3,326), a centre of hosiery manufacture; Corbie was once celebrated for its Benedictine abbey (founded in the 7th century) the church of which (16th–18th century) is still to be seen, though now ruined.

Folleville has a church (15th century) containing the Renaissance tomb of Raoul de Lannoy; Picquigny has the remains of a château of the 14th, 15th and 16th centuries, once one of the chief strongholds of Picardy; Rue has a 15th century chapel; and Tilloloy a Renaissance church.

SOMME, BATTLES OF THE, 1916. This series of battles, or, more strictly, succession of limited engagements, constituted the offensive campaign of the Franco-British armies in 1916. Into it was thrown the entire British effort of the year on the Western Front and such part of the French effort as was available after the exhausting strain of the long defensive "battle" at Verdun *(see* VERDUN, BATTLES *OF)*. The genesis of the Somme offensive is dealt with under WORLD WAR I.

The original intention had been that the French should play the larger part in the attack, but as they were drained of their strength at Verdun so did their share of the Somme plan evaporate. Eventually their front of attack on the Somme shrank from 25 miles to eight and their force from an intended 40 divisions to 16, of which only five assaulted on July 1. From now onward the British were to take up the major burden of the Western Front campaign, and this alone invests the attack of July 1, 1916 with a special significance. Yet the aims of the British commander-in-chief were not reduced in proportion to his resources. His intention was, in the first place, to break the German front between Maricourt and Serre. Secondly, to secure the high ground between Ginchy and Bapaume while the French seized its continuation past Sailly and Rancourt. Next, to wheel to the left and roll up the German flank as far as Arras, so widening the breach. With this aim all available troops, including the cavalry, would drive northwards from the line Bapaume-Miraumont while a converging attack was launched in co-operation against the German front south-west of Arras. Fourthly was to come a general advance towards Cambrai-Douai. If the Higher Command did not visualise quite so rapid a break-through as had been expected in 1915, the conception was of an advance immeasurably swifter and deeper than came about.

Topography. — To understand both the problem and course of the battle a brief description of the ground is necessary, for in few battles did topography have so far-reaching an influence and make so deep an impression on the minds of the combatants. Between Ham and Arras the river Somme runs first from south to north as far as Péronne and then bends sharply to the west, on its way to the sea. From Péronne a low range of hills runs somewhat to the north of west, forming the watershed between the Somme and the basins of the Scarpe and the Schelde. This ridge had fallen into German hands in Oct. 1914 in the course of the operations usually described as "the race to the sea" and the line in this quarter, indeed on the whole front from Arras southward to the Oise, had remained substantially unaltered during 1915, the chief change being that in July 1915 a British III. Army had been formed which relieved the French between the Ancre and the Somme. Subsequently a IV. Army was also formed, and early in 1916 the British had relieved the French X. Army on the Arras front, making their line continuous from Ypres southward. The right boundary between the British and French had varied considerably and in June 1916 was near Maricourt, about 3,000 yd. north of the Somme. Here the Allied line, which southward of this point ran north and south, turned sharply and following the lower slopes of the watershed already described ran west for another 7,000 yd. to make another sharp turn at Fricourt, whence it ran north to and beyond the Ancre, which pierces the ridge between Thiepval and Beaumont Hamel.

German Positions. — The German positions had become extremely formidable. Their defenders had been in undisturbed possession of the high ground for over a year and a half, and since the British had taken over this part of the front the previous autumn, the application of the usual British policy of aggressive trench-warfare had stirred the Germans to strengthen their defences, to develop artificially the advantage of nature. Woods and villages had become fortresses, two elaborate trench systems had been constructed about two to three miles apart, each containing several lines and connected up by intermediate lines or "switches" which greatly complicated the task of the attacker who should penetrate any part of the front. Deep "dug-outs," easy to construct in a chalk country, protected the trench garrisons against bombardment, broad belts of barbed wire obstructed the approaches, the lines bristled with well-placed and protected machine-guns, and every point of tactical importance had been specially fortified. The advantage of the ground for observation lay with the Germans. Masefield in his book "The Old Front Line" expressed the situation aptly: "Almost in every part of this old front our men had to go uphill to attack. . . . The enemy had the look-out posts, with the fine views over France and the scenes of domination. Our men were down below, with no view of anything but stronghold after stronghold, just up above, being made stronger daily."

For an attack on such positions the most elaborate preparations were necessary, both tactical and administrative. Roads and railways had to be made, vast dumps of ammunition and stores formed, gun positions selected and dug, bivouacking and encamping grounds prepared, the water supply expanded. It was not till the end of June that the offensive could be initiated; and it had been practically impossible to conceal from the Germans the scale and nature of the preparations or the intended extent of the attack. Surprise, difficult in face of such commanding positions, was the more difficult because the art of camouflage and of concealing preparation was still immature. Had not the vast preparations given it away, the fact that the bombardment lasted a week would in any case have announced all but the actual day of the attack.

Dispositions. — The British share of the attack was entrusted to Rawlinson's IV. Army of 17 divisions, of which only two, together with 3 cavalry divisions, were in army reserve. In addition a corps of three divisions and the headquarters of a reserve army — under Gough — were placed in the battle area under the hand of the commander-in-chief. Two divisions of the III. Army were to make a subsidiary attack near Gommecourt. The artillery concentration totalled 1,500 guns, averaging one gun to every 20 yards of front, a record at that time, although far eclipsed later. Rawlinson expressed doubts whether it was sufficient but his suggestion that the frontage should be reduced was not acceptable. The bombardment began on June 24, the attack being originally intended for June 29, but subsequently postponed until July 1. This involved not only spreading out the ammunition over a longer period, but a greater strain on the assaulting troops who, after being keyed up for the effort had to remain another 48 hours in cramped trenches, flooded by a torrential downpour, under the din of the bombardment and the enemy's retaliation.

I. THE FIRST STAGE

July 1, however, dawned dry and with the promise of broiling heat. At 7 A.M. the bombardment rose in intensity and at 7.30 A.M. the British infantry advanced in close-packed waves. These 1916 formations were designed to enable the assaulting infantry to swarm into the opposing trenches as soon as their own guns had lifted. But they exacted a heavier penalty in case of any interval or any insufficiency of the bombardment. And they cramped initiative and hindered the infantry taking sensible advantage of cover—for the infantry were taught to advance at a slow walk in strict alignment. Here the penalty was fully exacted by the stout-hearted and skilful German machine-gunners who, sheltering in dug-outs or shell-holes while the bombardment flattened their trenches, dragged out their weapons and opened fire directly it lifted.

Fricourt, on the right centre, was a turning point not only in the front but in the fortune of the day. All to the north was failure, with the heaviest British loss of any day in the war. On the British left the VIII. Corps attacked from Serre to Beaumont Hamel, but though its centre penetrated some way into the German lines north of Beaumont Hamel the flanks were checked and the central division was finally dislodged. Equal ill-success befell the X. Corps and the left division of the III. Corps to the south, in their attacks on the formidable defences of Thiepval and Ovillers. The right division (the 34th) pressed past La Boisselle to Contalmaison but was forced to fall back, its flank being enfiladed from Ovillers. The next corps, the XV., partially achieved its task of pinching out the bastion of Fricourt village and wood. On its north, next the 34th division, the 21st division gained and held a narrow salient, with both its flanks exposed until Fricourt fell next day. On the other side of Fricourt the 7th division and the XIII. corps (18th and 30th divisions) attacking in a northerly direction were all successful, taking Mametz and Montauban. Beyond them, again, the French astride the Somme fared brilliantly, reaching Hardecourt and Curlu north of the river, while south of it they actually penetrated to and captured six miles of the German second line. They took 6,000 prisoners at little cost.

The Germans had not expected a French attack and were less well prepared on the Fricourt-Montauban front than on the line running north from Fricourt, where both their positions and their fortifications were strongest. The success achieved by the British right and by the French went some way towards compensating for the disastrous failure elsewhere. The Germans could justly claim a victory, for with only six divisions available, and roughly a regiment holding each British division's sector of attack, they had yielded only 1,983 prisoners and a small tract of ground. Yet, although a military failure, July 1 had proved the moral quality of the new armies of Britain who, in making their heaviest sacrifice of the war, came through the ordeal with courage unshaken and fortitude established. These quondam civilians had borne a percentage of loss such as no professional army of the past had been deemed capable of suffering without being incapable of continued action. For five months more they were to continue.

For, on the morrow Haig, realizing the formidable nature of the frontage astride the Ancre, concentrated his attention on exploiting the success of the right—refusing to accede to Joffre's wish for a renewal of the attack on Thiepval. In the course of 10 days of hard fighting in which some six fresh divisions were thrown into the struggle, La Boisselle, Contalmaison and Mametz Wood were cleared and the line was advanced on a front of over six miles to within reach of the enemy's second system of defences on the southern crest of the main ridge.

Second Line of Defence Assaulted.—This system, less strong than that stormed on July 1, was formidable enough and the stubborn resistance of the Germans in their front system and intermediate lines had allowed large reserves of men and guns to be brought up and the defence to be reorganized. If Haig had been unduly ambitious and optimistic before July 14, he now perhaps tended to the other extreme. In contrast the IV. Army command held that in bold and rapid measures lay the only chance to forestall the building of freshly fortified systems in the rear. Rawlinson framed a plan to attack and break the second system on a four-mile front between Delville Wood and Bazentin-le-Petit Wood. His right was still three-quarters of a mile distant. If the obvious course was followed and an attack delivered only on the left, the prospects were barren. For the experience of 1915 had shown that an attack on a narrow frontage might gain an initial success, only to be "blown" out of the captured fragment of ground by the concentration of enemy gun-fire thus facilitated. Rawlinson proposed to cross the intervening and exposed area on the right under cover of darkness and then to attack along the whole frontage at dawn, preceded by a hurricane bombardment of only a few minutes duration.

In 1916 the ideas of a night advance and of such a brief bombardment were so unorthodox as to be a shock and appear a gamble to cautious opinion, especially as it would have to be carried out by troops of the new armies. The commander-in-chief preferred a more limited alternative but Rawlinson persisted, his confidence reinforced by that of the actual troop-leaders in their ability to carry out the night operation. He gained his way, but the debate caused a day's delay which had serious consequences. The attack was delivered by the 9th and 3rd divisions of the XIII. corps on the right and by the 7th and 21st divisions of the XV. corps on the left. Cavalry divisions were brought up close and placed under the two corps commanders.

The hazardous and difficult approach march on the right was successfully carried out and at 3.25 A.M. on July 14, five minutes after the barrage fell, the whole line advanced to the assault. Surprise was achieved, originality vindicated. The whole of the German second system was rapidly overrun. On the right the resistance soon hardened and the 9th division only fought its way with difficulty through Longueval and to the outskirts of Delville Wood. On the left, opportunity—and the open country—stretched out its arms. Soon after midday the German resistance was obviously disintegrating in front of High Wood, and an effort was made to exploit the opportunity. But delay occurred and not until after 6 P.M. did the 7th division move forward afresh, with two squadrons of cavalry working on their flank—the first mounted cavalry seen on a British battlefield since 1914. The second advance, however, was less vigorous than the first and although most of High Wood was cleared, the northern corner and the flanking trenches held out. Worst of all the 24 hours' postponement had enabled fresh German reserves to arrive on the battlefield and as their strength steadily swelled, the German hold tightened, the British relaxed. Late on July 15 the Wood was evacuated under pressure of counter-attacks, and two months were to pass before it was regained. On July 14 the British offensive came within reach of open country and within sight of a strategic decision; thenceforward it degenerated into a campaign of attrition. Two months of hard fighting followed during which the British were unable to make more than very gradual progress at disproportionate cost.

Progress was especially slow on the right, where Ginchy, Guillemont and Falfemont Farm formed a barrier against which many attacks were shattered even after Delville Wood had been won. It was important to extend on this side to get touch with the French who were gaining ground north of the Somme: High Wood in the centre, Pozières on the left, were equal obstacles, and behind Pozières were all the formidable defences of which Thiepval was the centre. Division after division was thrown into the fight, fought desperately, lost heavily and apparently achieved little, though Pozières was taken by the Australians before the end of July. The strain was at last beginning to tell heavily on the Germans: they checked the Allied progress but their resources in men, guns and ammunition were, by Ludendorff's admission, severely taxed and they had to relinquish entirely their attacks on Verdun.

II. THE SECOND AND THIRD STAGES

On Sept. 3 a renewed attack astride the Ancre by the V. Army, formed from troops taken out of Rawlinson's IV army and placed under Gough, was unsuccessful, but the IV army on the right at last mastered Guillemont and in the next few days added Falfemont Farm, Ginchy (Sept. 9), Leuze Wood and Bouleaux Wood to its gains, while the French made substantial progress north of the Somme and gained a big success south of it, taking 7,000 prisoners and storming three mi. of the old German front line as far as Chaulnes. These successes removed the main obstacles to the advance of the British centre, freeing it from the menace of being enfiladed.

Haig thereupon planned a big spring forward for Sept. 15, second only in scale and ambition to July 1. The attack was to pivot on the left wing—Gough's army. The object of the main blow, by Rawlinson's IV army, was to break through the Germans' original last line between Morval and Le Sars, in co-operation with a French thrust to the south between Combles and the Somme—"pinching out" Combles. If the opening success warranted the attempt the attack was to be extended on the left to seize Courcelette and Martinpuich. Eight divisions were deployed for the original attack, and two detailed for the "extension." A special feature was the employment for the first time of tanks (*q.v.*), the armoured cross-country machines which had been invented as an antidote to the defensive obstacle of machine guns and barbed wire. In disregard of the opinions of the tank's progenitors, and of their own expressed agreement with these opinions, the British higher command had decided to utilize such machines as were available, to redeem the fading prospects of the Somme offensive. When this decision was taken only 60 of the initial 150 machines had been transported to France. Forty-nine were actually employed, to work in tiny detachments of two or three machines—another breach of the principles laid down by Colonel Ernest Swinton. The rushed preparation combined with the mechanical defects of these early models to reduce the total so that only 32 reached the starting point. Of these, nine pushed ahead with the infantry, nine failed to catch the infantry but helped in clearing the captured ground, nine broke down and five were "ditched" in the craters of the battlefield. The first nine rendered useful aid, especially in capturing Flers, but the greater prize of a great surprise stroke thus lost was a heavy forfeit to pay for redeeming in a limited degree the failure of the Somme offensive.

The attack was launched at dawn on the 15th in a slight mist, and the XV corps in the centre made early and good progress, and by 10 A.M. its left division was beyond Flers. But on the right the XIV corps lost heavily and was held up long before it could reach Morval and Lesboeufs. The III corps, on the left, also fell short of its objectives, although its 47th division finally cleared the long-sought High Wood. On the extreme left the projected "extension" of the attack was carried out and both Martinpuich and Courcelette were taken. As a result of the day the crest of the ridge had been gained, except on the right, and with it the commanding observation which the Germans had so long enjoyed. A fresh attack on Sept. 25, swept over Morval, Lesboeufs and Gueudecourt and by joining up with the French who had again secured substantial successes both north and south of the Somme, compelled the Germans to evacuate Combles (Sept. 26).

Simultaneously with this success operations were resumed by the V army on the British left and Thiepval was at last taken (Sept. 26). This left the Germans with only the scantiest foothold on the main ridge. Thus by the beginning of October the enemy had been driven back to his last completed line of defenses, which ran from Sailly-Saillisel on the right, past Le Transloy and in front of Bapaume: he was busily engaged on fresh lines further in rear but as yet these were unready. On the other hand, these days had proved the continued strength of the German resistance, and the limited success held out little hope of a real breakthrough or its exploitation. The early onset of the autumn rains daily made this hope more slender. Continuous and heavy rain combined with the effects of the bombardments to make the ground a sea of mud, across which guns and transport could hardly be moved, and even lightly equipped men could only struggle slowly forward. Attacks under such conditions were terribly handicapped; that most of them failed was not remarkable, for when a trench was taken the difficulties of consolidating it were greater than ever. Eaucourt l-Abbaye (Oct. 3) and Le Sars (Oct. 7) were taken, though repeated attacks on the Butte de Warlencourt were foiled by the mud. Eventually the weather improved enough for a renewal of the attack on the left and the last important operation in the Somme offensive took the shape of an attack on Beaumont Hamel by seven divisions on Nov. 13. This proved successful on the right and centre, taking Beaumont Hamel itself, and Beaucourt-sur-Ancre with 7,000 prisoners. On the left, however, Serre again proved impregnable. Before the success could be expanded the return of bad weather again put a stop to active operations which were not resumed on any considerable scale until well after the New Year, just before the carefully planned German retreat to the Hindenburg line. The folly of the third phase was that having at last won the crest of the ridge and its commanding observation, the advantage was thrown away, without adequate prospect of compensation, by fighting a way down into the depression beyond. Thereby the British troops were doomed to spend the winter in flooded trenches, and the battles of the Somme closed in an atmosphere of disappointment and with such a drain on the British forces that the coincident strain on the defense was obscured. For the fighting sometimes known as the second battle of the Somme, *see* ST. QUENTIN, BATTLE OF, 1918.

SOMNAMBULISM or SLEEPWALKING, the condition under which people walk while asleep, apparently unconscious of external impressions, return to bed, and when they awake have no recollection of any of these occurrences. Sometimes the actions performed are of a complicated character and bear relation to the daily life of the sleeper. Frequently somnambulists have gone along dangerous paths, executing delicate movements with precision. Somnambulists may: (1) speak without acting, common in children and not usually considered somnambulistic; (2) act without speaking, the most common type; (3) act and speak, more exceptional and (4) act, speak and have the senses of touch, sight and hearing. The iourth class merges into hypnotism. It should never be forgotten that somnambulism may he an indication of some disorder requiring careful diagnosis and treatment so as to avoid more dangerous maladies. (*See* HYPNOTISM; PSYCHIATKY.)

SOMNATH (PATAN SOMNATH, SOMNATHA-PATAN), an ancient decayed city on the southern coast of Bombay, India, 103 mi. S. of Rajkot. There stood a famous temple of Siva as Soma-natha, "lord of the soma," a sacred intoxicating plant, and, by extension, "lord of the moon." The temple was sacked and its 9-ft. jeweled linga or phallic emblem broken down by Mahmud of Ghazni in A.D. 1025. The existing temple is fundamentally the second reconstruction of 1169, destroyed in the final Moslem invasions of the late 13th century. The last, sixth, rebuilding was in 1951, when Pres. Rajendra Prasad presided over the reinstallation of the Sivlinga or principal idol. PATAN (pop., 1951, 12,056), a port in Sorath district on the old city site, is now overshadowed by the adjacent port oi Veraval (40,378).

SOMNUS, Sleep, the son of Night and the twin brother of Death, with whom he dwells in the darkness of Hades. In Ovid the home of Sleep is placed in a dark grotto in the land of the Cimmerians, where he dwells surrounded by a band of Dreams.

See Homer, *Iliad*, xiv, 231 to xvi, 672; Hesiod, *Theog.*, 212, 758; Pausanias v, 18, 1.

SOMOV, KONSTANTIN ANDREEVICH (1869–1939), Russian decorative artist, the son of A. I. Somov, director of the Hermitage museum, was born in St. Petersburg on Nov. 18, 1869. He studied under the realist painter Ilya Repin at St. Petersburg Academy (of which he was elected academician in 1913) and in Paris, where he settled after the Revolution. He was a founder member of the group centred round Sergei Diaghilev's review *Mir Iskusstva* ("The World of Art," 1899; *see* DIAGHILEV, SERGEI PAVLOVICH), to which Alexandre Benois and Léon Bakst also contributed. Somov, at first an Impressionist. was later markedly influenced by Aubrey Beardsley and—in his paintings of rainbows, fireworks and Italian comedy scenes—by the French 18th-century painters of *fêtes galantes;* his portraiture (often in coloured crayon) owed something to Ingres. His illustrations included those for his own *Le Livre de la marquise* (1919); Goethe's *Journey in Italy;* and Antoine Prévost's *Manon Lescaut.* He also designed theatrical costumes. He died in Paris, May 6, 1939.

SONANCE: *see* VOICE.

SONATA, in music, originally a piece "played" as opposed to "cantata," a piece sung. By the time of Corelli the term had come to mean a group of instrumental movements. (A movement is a piece of music forming or starting as if to form, a complete musical design.) The sonatas of Corelli are classified as *sonata da chiesa* (church sonata) and *sonata da camera* (chamber sonata). Both kinds were usually for one or two violins with *continuo* bass (*see* CHAMBER MUSIC and INSTRUMENTATION). Handel, when a boy, wrote six for two oboes, and in later years several for flute, and also for one oboe.

The *sonata da chiesa* consists typically of a slow introduction, a loosely fugal allegro, a cantabile slow movement and a lively finale in melodic "binary" form (*see* SONATA FORMS). The *sonata da camera* consists mainly of dance-tunes (*see* SUITE). Bach, who uses neither title, keeps the two kinds unmixed in his six sonatas for violin alone, the first, third and fifth being *sonata da chiesa* and the others *partitas.* A fusion of the two styles persisted in Italian violin music almost to the end of the 18th century.

The sonatas of Domenico Scarlatti (*q.v.*) are small harpsichord pieces, of which the best known are extremely brilliant single movements in binary form. The complete collection of 545, published by Longo, shows that Scarlatti experimented audaciously in remote modulations; that he also wrote some orthodox violin sonatas; and that he sometimes followed a lively movement by a slow cantabile, as Paradies did in his sonatas. Clementi's early sonatas are at their best when they resemble a sober and heavy-handed Scarlatti in a first movement which maintains a uniform rush of rapid motion; and Mozart has left a fine example of the kind in the first movement of his F major violin sonata (K 377).

The main classical sense of the term indicates a work for not more than two instruments, containing at least two, and in the complete scheme, four well-contrasted movements, of which the first and last are on the same tonic, and the others in demonstrably related keys (*see* HARMONY); the forms being those dealt with in the following article. (D. F. T.)

SONATA FORMS, in music. The sonata forms (*see* SONATA above) cover the whole ground of instrumental music from C. P. E. Bach to the advent of Schumann's pianoforte lyrics and Liszt's symphonic poems, and are still living forms. Their rise made Gluck's reform of opera possible; for they represent a general change in the language of music which made it a truly dramatic medium. They comprise the largest and most central problems of pure music; and the outward forms must be studied in constant connection with instrumentation, harmony, melody, counterpoint and rhythm (*qq.v.*).

Elements of Form.—Two types of form are externally common to the true dramatic sonata style and the earlier melodic forms used in the suite (*q.v.*). The terms *binary* and *ternary* have been chosen for these; and, as we shall see, badly chosen. A binary melody falls into two portions, of which the first ends away from tonic, and the second ends on the tonic. *Barbara Allen,* quoted in the article MELODY, is an exquisite example on the smallest possible scale. A ternary melody, such as *The Bluebells of Scotland,* has a complete first clause, a second clause not as complete, and a third clause consisting of the first over again; a form conveniently symbolized as ABA.

No view of music can be correct that neglects the fact that it moves in time; though a composer may develop Mozart's capacity for seeing music spatially, *i.e.,* like a picture, all at once. Now, when do we know that a melody is going to be "ternary"? Obviously when its first clause has shown itself to be complete. If the sequel refuses to divide itself according to a "ternary" rule the ear is not going to reverse its judgments merely because we have chosen a bad term of classification. After the first clause, anything may happen. The rest of the tune may be no longer than the first clause. All that we can expect of it is that it will cover a wider ground than the first clause, even if in fewer notes or in less time. But this is not all. Every tune of several clauses lends itself to repeating its sections. Binary tunes repeat their two sections. Does a ternary tune repeat its three sections? Try the experiment on the very typical ternary theme of the variations in Beethoven's Kreutzer sonata. Play the first clause with its repeat and try repeating the second clause before returning to the first. You will hardly have the patience to finish the experiment. It will at once reveal that under the test of repeats our "ternary" melody is not ABA but A, BA.

Ex. 1

Andante

Thus while both these forms divide only into two repeatable portions the one named "binary" has an incomplete first part while the first part of the other is complete. Our pundits would make musical terminology less misleading if they would kindly find Greek or Latin names, not longer than the forms themselves, that should express "form-with-an-incomplete-first-part" on the one hand, and "form-with-a-complete-first-part" on the other. Clearly the distinction is that between higher organizations and lower, or sectional, forms. From the so-called binary form originates the sonata-form *par excellence,* that of the first movement of a sonata. From the so-called ternary form originate all those sectional forms of music that begin with a complete symmetrical melody, however many sections the form may eventually develop. Thus the "ternary" type underlies the *rondo* (*q.v.*).

The Sonata Style.—Sonata form represents a style that is evident in every bar from the outset, however its themes may be distributed. We are told that the binary form of a dance-movement in a suite has a polyphonic texture and a single theme; and that Philipp Emanuel Bach created the true sonata form by inventing the "second subject." Good teachers make sure that their pupils understand that the "subject" of a sonata is not a single theme, like the subject of a fugue; but in spite of all precautions a host of bad musical forms and crooked musical doctrines have grown up from the provincial fact that English musicians have fastened on the terms "first" and "second subject" instead of translating the excellent German terms *Hauptsatz* (principal member) and *Seitensatz* (subordinate member).

Some of Sebastian Bach's most typical gigues have at least two distinct themes, while more than one of Haydn's ripest sonata movements derive everything from their first themes. Accordingly we may illustrate the true distinction of style by examples which refute superficial doctrines.

These two examples are almost exactly the same length, yet

Haydn is beyond Bach's scope in the first eight bars. If Bach could have accepted so trite a theme as Haydn's. he would have postulated that it did not end with a bump: and bars 5–8 would have horrified him, for he would have supposed that a movement that began so vulgarly was condemned to continue in the same style. Bar 8, however, enters on matters that Bach had never known. In it the first bar of a new period overlaps with the last

Ex. 2. Bach. Gigue from 3rd Suite 'for Violoncello

bar of the old; and therewith we are plunged into a polyphony quite lively enough for Bach, and quite unpredictable in rhythm and key, its fourth bar overlapping with the answer in A minor, and the viola and violoncello entering in F major at intervals of two bars. Then, arising from bar 18, there are four bars on the dominant of F, with that merely jingling figure (c). We need not set limits to Bach's intelligence, and we may suppose that such a composition would have convinced him that here was no trivial divertissement, as he called the non-polyphonic sonatas that were becoming fashionable in 1745, but a new art with enormous possibilities.

Bars 23–26 transform the two notes of (a) into rich sustained harmonies. Then figure (b) bursts out in a new type of phrase, built up in 3-bar periods, which the ear need not trouble to recognize as such in the general bustle. The third of these periods abandons the figure and makes a melodious close into 5 bars of cadence on figure (b) with upper notes that merge into (c), nicely phrased. It is idle to say that all this has more than one theme, and worse than idle to deny that Bach's gigue has at least two distinct themes. that of the beginning, and that in bars 29–36. But Bach's relatively uniform texture will tolerate neither interruption nor irregularity of rhythm.

Haydn's exposition groups itself clearly into bars 1–8, the first group (*Hauptsatz*), asserting the tonic and overlapping with bars 8–22, which effect the transition (plus the sustained chords 23–26) to the second group (*Seitensatz*) in F major, bars 27–40, with its cadence-phrase (*Schlussgruppe*) in bars 36–40. These sections could not be more distinct uith any number of themes.

There are no rules whatever for the number or distribution of themes in sonata-form. When critics tell us that Rfendelssohn is weak "in second subjects, where the human element is required," they disqualify themselves by a terminology as useless as that of the friend who did not see where the painter was going to put his brown tree. Any generalized criticism of sonata themes is bound to be nonsense; for themes stand in endless variety of relation to the whole. They are details. which give pleasure in themselves as well as in their relation to the scheme. But it is foolish and vexatious to lay down rules as to what pleasure the details shall give. If you examine frescoes with a microscope or miniatures with a telescope you will not enjoy them; and if you expect Beethoven's "Harp" quartet to show you the purport of its first movement in its themes you might as well try to study foreign poetry through a traveller's phrase-book.

So much, then, for the vital element of drama in the sonata. Historically it originates wholly with Haydn and Mozart; and Philipp Emanuel Bach contributed to it nothing but a romantic rhetoric. His chief pride was in his invention of *Sonaten* mit *veränderten Reprisen;* that is to say sonatas in which the repeats were written out in full in order to control the fashion of altering and amplifying the ornaments on repetition Now, could anything more clearly betray a non-dramatic style? The survival of repeats in the most dramatic works of Beethoven and Brahms shows how powerfully an architectural symmetry can dominate a series of emotional tensions: but imagination boggles at the thought of using these repeats to display a new set of ornaments.

Haydn saw that the only place for C. P. E. Bach's device was in purely lyric slow movements. Even there he never had the patience to plod and pose (as C. P. E. Bach did to the bitter end) through a repetition of both parts. When his second part comes to recapitulate the second group it combines both versions. This form appears for the last time in history in one of Haydn's "London" symphonies, in the wonderful movement of which the theme is quoted in RHYTHM, Ex. 1. Though "binary" it is manifestly lyric, and could no more be applied to active movements than the Spenserian stanza could be applied to drama.

A more important step toward the true sonata style was made by Philipp Emanuel's less romantic brother. Johann Christian, who settled in London, founded the Bach and Abel Concerts, and had a great influence on the boy Mozart. J. C. Bach is the first composer to lay a dramatic emphasis on the transition between his first and his second group. In crude or deliberately formal examples this has been wittily described as "presenting arms" to the new key. Its point is not that there is any difficulty in apprehending the new key, but that the move into it is dramatic and not decorative. Whether the move be made with intellectual music or with common forms makes no difference. Beethoven preferred, in his most characteristic early works, to disguise it cleverly. In later works he acquired the grand formal breadth of Mozart's chamber-music in this transition.

First-movement Form.—The general scheme of the first-mo ement form or, par excellence, sonata form, is as follows. There is a first group in the tonic. followed by a transition to another key, where there is a second group that usually ends with a neat little cadence-theme. These groups constitute the exposition, which may be repeated. Then follows the development, the function of which is to put the previous materials into new

Ex. 3 Exposition in sonata style

lights, regrouping the figures into new types of phrase, modulating freely and settling, if at all, only in new keys. Eventually a return is made to the tonic, and so to the Recapitulation. This recapitulates the exposition, but it gives the second group in the tonic, and so completes the design. The development and recapitulation may be repeated; a coda may follow the recapitulations.

This account has required so many words that the illusion is apt to arise that it conveys more information than, say, the statement that the plan of a cathedral is cruciform and that the arms of the cross are called transepts, and so on. It gives us no means of distinguishing an ambling decorative movement by Boccherini from the first movement of a Beethoven symphony; and the description of the development is the only point which would rule out the sequel of our second example as a specimen of sonata-form. Haydn, Mozart and Beethoven differ widely in their handling of every part of the scheme.

The most regular form is to be found in Mozart, whose transitions are always broad and smooth. The effect of "presenting arms" is evident only in small or perfunctory works; and if it is found at all in larger works it is on such a scale and with such a purpose as Beethoven would give it. The second group contains at least one definite new theme and a number of cadence-phrases in various rhythms. The development is short, consisting of one broad sequential process that leads through a wide range of keys back to the tonic. Sometimes it contains an entirely new theme. Such an episode, which is generally placed at the beginning, by no means always indicates a lighter style and texture. It may be a relief from unusually concentrated figure-work in the exposition; and the developments of two of Mozart's most serious works (the C minor serenade for 8 wind instruments, better known as a string quintet, and the G minor pianoforte quartet) are episodic. The return to the tonic always has the effect of being accurately timed after a delightful period of anticipation.

The recapitulation is full and has' a deceptive appearance of regularity. In reality it is anything but mechanical. It has just that kind of difference by which stereoscopic pictures produce the effect of binocular vision. In the light of the recapitulation the listener finds that points that were superficial in the exposition have now become solid. The composer instinctively conceives his exposition in relation to the question "How will this sound when it returns?" The minimum change happens automatically with the transition to the second group, for this transition must no longer lead to the complementary key of the exposition. One quaint primitive device in the transition is that of making it not leave the tonic at all but simply come to a pause on (but not in) the dominant. This dominant is then taken literally as a key. In such a case the recapitulation need alter nothing; the second group merely follows in the tonic instead of in the dominant. Even this automatic device makes the recapitulation give a more solid impression than the exposition; for the pause on the dominant, treated paradoxically in the exposition, is now treated rationally.

We need not deny that formal devices are apt to become mechanical; but we have no right to, the a *priori* opinion that Mozart is writing unimaginatively every time that he decides that the most familiar course is the wittiest. It is much wiser to regard the most exact recapitulation as the extreme case of delicate balance, and even in the most exact the crucial detail will appear. Here is a case in a difference of a single bar, Mozart's string quartet in E flat (K. 428) has the following clause in the first theme:

In the recapitulation you have this—

The little comment of the second violin is expanded and made to turn the following "added 6th" chord into a momentarily solid supertonic key. Similar points make the recapitulation of the second group also stand out in higher relief. Most interesting of all are the ways in which Mozart in a minor movement translates the second group from the major into the minor mode. It is worth while trying the experiment of literal translation (not always an easy task) and then seeing what Mozart has done in such cases. For codas Mozart either finds a slight expansion in the recapitulation of his second group adequate, or else he adds a neat final paragraph. If the development contained an episode Mozart's coda may allude to it. In the finale of the so-called "Jupiter" symphony he uses the coda for his quintuple counterpoint on all the five themes of the movement. (See COUNTERPOINT.)

Haydn's practice in his later works differs from Mozart's in almost every particular. His second group often contains no new theme until the cadence-group at the end; his development is long and divisible into several stages, often including an illusory early return to the main theme in the tonic followed by a new excursion into remote regions; and as to recapitulation, the term is seldom applicable at all. The first theme, indeed, returns, but it is followed by a brilliant peroration full of new developments and giving the repose of recapitulation only in the fact that it remains firmly in the tonic. If after such a peroration Haydn chooses to end quietly and abruptly with his cadence-theme, the effect is witty. But it does not make him a formalist. He is a master not only of form but of spaciousness in the smallest possible compass. One main theme for both groups gives him more room for expansion than two; and instead of saying that his recapitulations are free we ought to say that he invented the most brilliant type of Beethoven's coda. And these features of his form are not, as has sometimes been alleged, primitive. They are only partially visible in quartets before Op. 50. Then they appear in full vigour, and Haydn's admiration for Mozart only confirms him in his independence.

Mozart's more symmetrical form is a function of two things, a more polyphonic style and a larger scale. We may sum up the relation between Mozart's form and Haydn's thus: that in Haydn we are aware of an expansive freedom which proves, on scrutiny, to have an all-pervading sense of proportion; while in Mozart we are aware of beautiful and symmetrical proportions which prove on scrutiny to be handled with an all-pervading freedom.

Beethoven combined the forms of Haydn and Mozart, writing on a scale large enough to contain Mozart's regular recapitulations together with Haydn's free perorations, and developing a tragic power all his own. Such new power was not to be obtained without a new technique. A pzssage from Haydn and one from Beethoven, may be chosen to show how Beethoven set to work. In the first movement of Haydn's A major quartet (op. 20, No.

6) the second group has been duly ushered in by a highly-organized transition Passage and has already started a new theme. This, however, comes to a pause on the dominant. and then we have the following modulating themes—Ex. 6. The harmonic colour of these keys is delightful, and their mutual relations are of direct importance. The passage is improvisatorial and ruminating. Its modulations are within the local range of its start in E minor, and its windings only confirm the drift towards E major. Without them the passage would lose its freedom: with wider modulations it would lose coherence.

Now take the opening of the second group in the first movement of Beethoven's sonata, Op. 2, no. 2. Here is its skeleton outline—

To analyse the enharmonic modulations and keys (including the unrelated ♭VI) of this passage is, in Kingsley's admirable parable, like making an exhaustive chemical analysis of a plum-pudding and omitting to ascertain that the cook had boiled it in a cloth. The gist of the matter is the steadily rising bass, with its accelerated later steps and the profound psychology of its pause for 8 bars (after the quotation) before plunging into the final codential steps G♯, A and B, in widely different octaves. This is one of the epoch-making passages in musical history. Its importance does not lie in its wonderful enharmonic modulations. These could not in themselves have achieved more than had been already achieved by C. P. E. Bach: for without the rising bass their purpose would be merely to astonish and not to construct. But with the rising bass and similar resources the whole art of tonality expands. This soon enabled Beethoven to choose remoter keys for his second group. (*See* HARMONY.)

Ex. 8 gives the outline of the first movement of Beethoven's "Eroica" symphony. Blank bars indicate the continuance of a harmony. They are often without theme, and are the lungs of the organism. Quaver-bars or other rhythmic indications above the line indicate the prevalent movement in accessory parts, whether contrapuntal or homophonic. Fine detail is not indicated, and short passages marked as repeated may be assumed to be rescored often beyond recognition. The outline, however, gives a comprehensive summary of the structure of this highly significant movement, and by means of it the reader will be enabled to apprehend, almost at a glance, the inexhaustible expansive and contractile power of Beethoven's phrase-rhythm. Nine conductors out of ten overlook the first theme of the second group entirely, but it is the one constant element in all Beethoven's dozens of sketches.

Freedom in a recognizable recapitulation can go no further than the marvellous modulations with which Beethoven transforms the first group; and anybody inclined to cavil at the exact recapitulation of no less than 100 bars comprising the transition and second group, may be surprised to learn that this is, by the clock precisely the same length as Isolde's Liebestod (*vide* RHYTHM) and that in the Liebestod Wagner exactly recapitulates, without transposition, the last movement of the love-duet in a previous act. Recapitulation is as inveterate in musical form as symmetry is in architecture; and nobody understood this better than the first and most uncompromising realist in the application of music to drama.

Other Movements.—A thorough understanding of the style and methods of first movements makes all the rest easy. As to slow movements, the first thing that must be realized is that if a theme conceived in an average quick tempo be played four times as slow it will take four times as long. Some composers, and even some teachers, do not seem to have learnt this remarkable fact. In the music of a master slowness means bigness. The first 16 bars of the slow movement of Beethoven's D minor sonata (Op. 31, no. 2) look like, and are, a single binary sentence closing into the 17th bar. But the all-seeing eye that takes this in at a glance many miss the important fact that that binary sentence takes a whole minute by the clock. Quavers at 96 is a very good metronome-tempo for this movement, and it gives exactly 16 of those bars to a minute. The metronome at 72 to a bar gives a good, moderate tempo for the finale. Now, see how far one minute takes us in the finale. The simple binary first sentence of the adagio takes as long as the two closely-printed pages from the beginning of the finale to the middle of its cadence-theme! Thus in the slow movement of Beethoven's fourth symphony (another case of 16 bars to the minute) the 15 bars beginning in E flat minor and dwelling in G flat (bars 50–64) are a very spacious development; and so are the 7 bars in the middle of the slow movement of the trio in D major, Op. 70, no. 1. Such passages are ample developments if they modulate widely and contain important changes of rhythm, instead of merely dwelling on the dominant before the return of the main theme as in the slow movement of the D minor sonata.

No wonder that in any movement slower than *andante* the full sonata form is unusual and of gigantic effect. The full-sized rondo-form (*see* RONDO) as in the case of the fourth symphony just mentioned, is still more voluminous in a slow tempo. Movements of more normal size may be in A, B, A form, or sonata-form without development (Mozart's favourite form); or may consist of a theme with five or six variations and a short coda. Haydn's form of variations on two alternating major and minor themes is sometimes used by him in slow movements, and sometimes (in small works) as the first movement or as finale. (*See* VARIATIONS.)

The finale is often in first-movement form, but will, in such cases, have a much simpler texture. The last part of a work that moves in time will always relieve the strain on the attention. Hence the large number and importance of rondo-finales; and hence the paradox that both Haydn and Beethoven found the fugue an excellent form for a finale. For the fugue, while continually stimulating and exercising the mind by means of details, makes no claim on the listener's memory over long stretches in a major composition.

The first movement, slow movement and finale have thus an unlimited dramatic scope. A purely lyric or dance movement added to such a scheme would in itself be dramatic by contrast, as a song may be a dramatic element in a play. This justifies the dance-form of the Mozart-Haydn minuet and trio, of which Beethoven accentuated the dance-character when he expanded it to the scherzo (*q.v.*). Haydn's very earliest minuets show an inveterate irregularity of rhythm which stamps them even sooner than his other movements, as dramatic. Mozart's minuets are smoother, but he can pack operas into them without bursting the bounds of melodic forms. The minuet of his E flat quartet, for example (K. 428), has five distinctly expressed themes; and its trio, which in contrast has only one theme, moves, however, in four distinct new keys.

The Sonata as a Whole.—The full scheme of a sonata consists, then, of these four movements, the minuet or scherzo being either second or third. Two movements, suitably contrasted, will make a sonata, even if (as in Beethoven's Op. 54) neither of them is in full first-movement form. But it is exceptional for a mature work to claim the title of sonata on merely lyric forms. And in

*The allusion is probably intentional as Beethoven had great difficulty with those introductory bars. At all events he found that their proper shape was that of final bars.

the case of quartets, the feeling of the classical masters is that when so many as four players are assembled it is a waste of opportunity to give them less than a four-movement work to play.

Why do the classical sonatas maintain this scheme of self-centred movements with no community of theme? The answer to this lies in the relation between their time-scale and their emotional content. In its early forms the sonata is a new kind of suite, complete in its contrasts. In its later developments the individual movements, while complete as designs, raise emotional issues which each movement is unable to satisfy without the others. The first movement of Beethoven's not inaptly named *Appassionata* sonata (Op. 57) whirls us through an immense tragedy in eight minutes. The movement is irrevocably completed; but our emotional reactions have not more than begun. We need the unutterable calm of the slow movement with its theme rooted to its tonic chord, and its simple and solemn variations in the ancient form of doubles. A foreign chord replaces that of its cadence; the vision is broken and the finale rushes headlong to the end of a tragic fate. The whole emotional scheme is perfect; but for one movement to take up the themes of another would be to tell a twice-told tale. Hence the classics, including Brahms, are not only cautious but cryptic in the few cases where they allow one movement to allude to another. The only occasion for clearness in such allusions is with introductions, which may well foreshadow the following movement, and, in the case of introductions to finales, may dramatically recall the past.

The emotional unity of the sonata is already significant in Mozart and Haydn. Their artistic hypotheses are those of comedy; and even so tragic a note as the last page of Haydn's F sharp minor quartet (Op. 50, no. 4) can be sounded only in the severe form of fugue. One of the most significant gestures in all the history of music is that of the introduction to the finale of Mozart's G minor quintet. The slow movement is one of the profoundest things possible before Beethoven. One is inclined to resent the notion that such music can have limitations. Being perfect it is infinite, and you cannot compare infinities. But you can be clear as to their elements; and the terms of its art forbid this pathetic music to handle tragic action. For tragedy, music needs such resources as are shown in Ex. 7, and these would shatter Mozart's aesthetic system. But after that slow movement even the finale of Mozart's own G minor symphony would sound peevish. So Mozart writes a solemn slow introduction which bids the art of music run away and play, for the rest is too sad for it. And so the bright rondo-finale is another story. Mozart would neither violate his aesthetic system nor anticipate Mendelssohn's naïve way of striking a religious note with a complete unconsciousness of its blasphemy.

The Sonata Since Beethoven. — The sonata-style belongs to the sonata time-scale and to the classical key-system. Music in the Wagnerian time-scale, or in "atonal" or other new harmonic systems, has no more to do with it than Greek prose. Nor do changes in the general outlines of the form mean much in themselves. The classical forms are, even externally, far more varied than those of later sonata-works; and the essentials of the sonata lie much deeper.

Schubert achieved wonderful things in his sonata works, but died before he had perfected his forms. His expositions digress into developments, his developments subside into long twice-repeated lyric episodes, and his recapitulations reveal that recapitulating is the very thing his expositions are not designed to bear. Nevertheless Schubert was on the high road towards genuine new forms.

What these forms were to be was best revealed by Brahms. It is fashionable to deny that Brahms invented new forms; and this is like Humpty-Dumpty's complaint that Alice's features were arranged so exactly like other people's that he could not be expected to recognize her. Forms must be studied in detail from phrase to phrase, and classified afterwards: not classified by guess-work and warped to fit the guess. Brahms has many new ways of phrasing and of developing themes (see MELODY, Ex. 11) ; and no two of his forms are alike. Least of all composers does he resemble Schumann, whom he was at first accused of imitating.

Schumann's sonata works show an interesting artificial system. His ideas were lyric and epigrammatic; and they shaped themselves squarely and with a Macaulayesque habit of antithesis. With this style he contrived to build important sonata works as one might construct a landscape in mosaic. He knew what he was doing, and the result is often delightful. In his D minor symphony he achieved a new continuity of form and theme, retaining the classical group of four main movements, but running them together without break and using transformations of the same themes in all four. Schumann's hard outlines and square rhythms have been copied without his wit in countless later sonata works, especially by those Russian composers who, led by Nicolas Rubinstein, danced upon his grave in derision of these very features.

Mendelssohn handled all sonata forms with an often dangerous facility but sometimes with genius. The opening of his D minor trio is the prototype of those innumerable allegros which are really andantes riding an ambling horse or running up a descending escalator.

The masterly scheme (there is only one) of Spohr is (as Schumann remarked) not so easy to imitate as it looks; but it is the prototype of most pseudo-classical works up to the present day; and many teachers believe it to be the only orthodox form. Against such teaching young artists do well to revolt, but why call it classical?

The quality most conspicuously absent in sonata-work since Brahms is movement. The fundamental mistake of Bruckner (*q.v.*) was in associating his Wagnerian style with sonata forms at all. Sibelius solves Bruckner's problem, and takes and leaves the sonata style as he pleases, and always with clear purpose, whether convincingly or not. Reger's meticulously regular forms are hard to accept as the really proper vessel for his strong chromatic brew; and as for imitating him, one might as well try to write a Meredith novel from one metaphor to the next. The art of movement is the crux of the sonata problem; and the classical solutions of it from Haydn to Brahms are the greatest things in pure music.

SONDRIO, a tonn of Lombardy, Italy. capital of the province of Sondrio, in the Valtellina, 1,140 ft. above sea level on the Adda river, 26 mi. E. of Lake Como and 82 mi. N E of Milan by rail. Pop (1951) 14.609 (commune). Sondrio has silkworks. Above the town to the north rise the snow-clad peaks of the Bernina group The railway goes on to Tirano 16 mi farther east. and thence over the Bernina pass into Snitzerland. while the Stelvio road crosses to Spondigna in the upper valley of the Adige (later called the Val Venosta)

SONE (SON). river of northeast central India. 46j mi long, and the chief tributary received by the Ganges from the south. The Sone flows through a deep valley from the Maikala range northwest as far as the Kaimur range. where it is deflected eastward and begins a slow course across the Gangetic plain It collects the drainage of the northern slopes of the Chota Nagpur highlands and enters the Ganges 10 mi. above Patna About 600,000 ac south of the main river between Benares and Patna are irrigated from a weir at Dehri. The scheme is mainly protective because water supplies are low in the spring. (T HER)

SONG is the joint art of words and music. two arts under emotional pressure coalescing into a third. The relation and balance of the two arts is a problem that has to be resolved anew in every song that is composed.

EARLY SONG

Little song survives from the ancient world, except insofar as elements from Jewish cantillation are to be found in plain song, which itself goes back beyond the time of Pope Gregory (590–604), and insofar as folk song. (*q.v.*) which has no history, everywhere preserves elements from its own past. From classical Greece six hymns and some fragments survive which have been deciphered from inscriptions and can be sung with confidence that they are correct. Troubadour song is an inheritance from the middle ages. Like ancient song, plain song and folk song, it is essentially monodic, *i.e.,* single-line melody with no prescribed instrumental accompaniment. In the art of the troubadours the pull of poetry and music against each other. which has to find its reconciliation in every song that is ever composed! is resolved *ab initio*, since the poet and the composer, and perhaps the singer, are one. The melodies are in the church modes in current use. with the Ionian, *i.e.,* our modern major, mode specially favoured, and are notated in the four-line stave used for plain song, of which they are indeed the secular equivalent. Over 300 poems with their melodies survive out of a corpus of 1,000 poems in the Provençal *langue* d'oc. The movement in which aristocratic .musician poets celebrated chivalric love started at the beginning of the 12th century. It spread to northern France where the language used was the *langue d'oïl, i.e.,* early French, and the practitioners of the art were called trouveres. Of their songs 800 survive. It is necessary to distinguish these courtly musicians from the goliards or wandering scholars who composed song, and spread songs in Latin — the *Carmina Burana* is the most famous collection — and from the wandering minstrels or *jongleurs* who practised their art in the market place rather than the castle.

The chief name among the troubadours is that of Bernart de Ventadour (d. 1195) ; among the trouveres, Adam de la Hale, who wrote the dramatic pastoral *Le Jeu de Robin et Marion* and also motets in the contemporary polyphonic style. The German equivalents of these aristocratic minstrels were the *Minnesänger* who flourished at a slightly later date. Of these the best known are the three borrowed by Richard Wagner for *Die Meistersinger* (*Meistersinger* incidentally were the bourgeois successors of the *Minnesänger*) and *Tannhaüser; i.e.,* Walter von der Vogelweide, Wolfram von Eschenbach and Tannhaiiser himself.

Folk song, the other monodic survival along with plain song into the modern world. bears the imprint of the community rather than of individual composition. Various theories have been propounded about its origin—communal composition (the brothers Grimm), individual creation orally transmitted through so many minds as to give it communal character (F. M. Böhme), clerical song come down in the world and become popular. But whatever its origin. its character is unmistakable and its best custodians are illiterate peasants. There are examples of degeneration and corruption occurring through oral transmission, but in general it works the other way, so that what are most typical of a community's songs are also its best specimens. Racial and national characteristics are discernible in the technical features of folk song. such as compass. favourite intervals, phrase lengths and accentuation (which naturally follows that of the language of the song). The 19th century saw a determined effort in all parts of Europe to collect and preserve such national folk song as survived, and the salvage was astonishingly alike in quantity and quality. The United States followed suit in the 20th century and added to the data for study the influence of the African Negro upon the various kinds of European music which immigrants had brought with them.

With the development of instrumental music in the middle ages the impulse to accompany songs made itself felt and has grown stronger with the passing of the centuries. The weak-toned lute. which was the first instrument to be used in the modern manner of an accompaniment. has been transformed into the thunderous symphony orchestra, and plain song and folk song have both submitted to accompaniment on a keyboard instrument.

The Lutanists.—At the close of the 16th century, when the lute was the popular musical instrument of the educated classes, the first really important body of song was produced. in Spain, Italy. France and England. At first it may be described as a small satellite detached from the large planet of the madrigal, which had for about a century held the field as the favourite diversion of musical amateurs. There is little doubt that the idea of solo song arose when in madrigal singing the parts of missing voices were taken by instruments. It is plain that if all the voices but one were missing. the effect of a solo song with instrumental accompaniment was realized. A still nearer approach to artistic solo song was reached when the singer sang his own part of a madrigal, playing the other parts himself, In John Dowland's *First Book of Songs or Airs* in four parts (1597), the principal vocal melody has an alternative accompaniment for three additional voices or the lute. Most English madrigals were published "for voices or viols."

In Italy Giulio Caccini published in 1602 his famous collection of songs for the lute (*Nuove Musiche*). He claimed in his preface to be the first to invent songs "for a single voice to the accompaniment of a single instrument." It is true that his friends in Rome, at whose houses these new compositions were performed, assured him that they had never heard the like before. and that his style exhibited possibilities for the expression of feeling that were excluded when the voice sang merely one part in a contrapuntal work. But about 30 years before Caccini lutanists in France had anticipated his innovation, and composed solo songs with lute accompaniments in which is ,evidenced the struggle, not always successful, to break away from polyphonic traditions. Adrien Le Roy's *Airs de Cour,* published in 1571, may be cited in proof of this statement (*see* Peter Warlock. *French Ayres* [1928]). Of these airs "Je suis amour" is somewhat in the declamatory recitative style of Caccini's *Nuove Musiche*. Generally speaking, it may be said of early French songs that they were longer in shaking off the influence of the past than the songs of the Italians, many tricks of expression, belonging to polyphonic times, surviving both in voice parts and accompaniments.

In England. about the end of the 16th century several volumes of songs to be sung with lute accompaniment made their appearance. It is worth observing that several were of earlier date than the "new music" of Caccini: they were an entirely English product. Some were songs or airs of four parts with tablature for the lute, so made that all the parts together or either of them separately could be sung to the lute, or orpharion; some were published only for a solo voice and lute. John Dowland (1563?–1626) who composed 88 songs. was undoubtedly the greatest of the large band of English lutanists. Even when, as in the first book of airs (1597), his songs could be sung ior four voices, they distinguished themselves from the madrigal by the special melodic interest given to the top part. He was thus really the creator of the modern art song. Though Il'illiam Byrd had (about 1583) composed "My Little Sweet Darling" and a few other songs with string accompaniment he did not, like Dowland, make the new type of song a special study. Dowland's fame. apart from the peculiar charm of his melodies, their expressive character, and their fitness to the words —a point which is characteristic of the work of the early lutanists — rests upon the important part he assigns to the lute. In many songs it contributes more to the expression than the vocal melody itself. Being himself not only a distinguished lutanist but a distinguished singer, he understood what it is that makes a song a joy to sing — as later Franz Schubert, also a singer, understood. It became in fact an art form. "Dowland was the first to specialize in this form and to develop it, and the art songs of Schubert, Robert Schumann and Johannes Brahms with pianoforte accompaniment are lineal descendants of Dowland's songs with lute accompaniment" (E. H. Fellowes). The following songs, "Can she excuse my Wrongs," "Sorrow Stay." "Flow my Tears," "Weep you no more sad Fountains," "In silent Night," "Fine Knacks for Ladies." and "Once Again," may be cited as supporting this statement.

Thomas Campion, Philip Rosseter and Robert Jones are, after

Dowland, the most individual composers in the same field Campion's "There is a Garden in her Face," "Shall I come if I swim?"; Rosseter's "If she forsake me," "When Laura smiles" and "Would you see my Mistress' Face": Jones's "Go to bed sweet Muse" and "Sneet Kate" are good examples of their work. Each of these composers wrote about 100 songs.

Italy.—Meanwhile Italian composers. in spite of the frottole, villote, villanelle. balletti and falalas (arrangements in vocal parts of popular melodies common in Italy and other countries in the last half of the 16th century) seem to have been unaffected in the new song movement by popular influences (we have practically no knowledge of the Italian folk song in mediaeval times); they went straight from the polyphonic to the recitative style (invented by Jacopo Peri and Caccini for their early experiments in opera) and advanced with extraordinary rapidity.

In opera and cantata melody was quickly added to relieve the monotony of recitative. and considerable advance in this direction was made by Pietro Cavalli and Marcantonio Cesti. Claudio Monteverdi, though a greater genius than either of them. was more concerned with dramatic expression than with melody for its own sake, but in the famous lament of Ariadne the two elements find their reconciliation in a passionate aria that, so great was its popularity, is found in three different forms. Giacomo Carissimi and Luigi Rossi in oratorio and cantata (a word which then merely described a piece that was sung. as sonata a piece that was played, consisting generally of alternate recitative and aria) brought the organization of melody to a high degree of elaboration, far beyond anything attempted by Cavalli or Cesti. In their hands the declamatory methods of Monteverdi were made subordinate to larger purposes of design. It was, moreover, inevitable in these early developments of musical style, in which melody played the leading part, that such sacrifices as were necessary in balancing the rival claims of expression and form should be in favour of the latter. rather than the former. But the formal perfection of melody was not the only problem which 17th-century Italian composers had to face. The whole question of instrumental accompaniment had to be worked out, the nature and capacities of instruments had to be explored, the reconciliation of the new art of harmony with the old art of counterpoint to be effected. It speaks volumes for the innate musical sense and technical skill of the early Italian composers that the initial stage of tentative effort passed so quickly, and that at the close of the 17th century we are conscious of breathing an atmosphere not of experimental work, but of mature art.

Alessandro Scarlatti (1659–1725) sums up the period for Italy. That much of his work is dry and uninspired is not surprising when the quantity of it is realized (he composed over 100 operas and 600 vocal cantatas) and also the unfavourable conditions under which operatic composers had to work, but the best of it is singularly noble in conception and perfect in design. The same is true of the best work of Giovanni Legrenzi. Francesco Durante, Leonardo Leo and Antonio Caldara, work which was of incalculable importance for the development of musical. and particularly of vocal art. Carissimi's "Vittoria," Scarlatti's "O cessate" and "Le Violette" are the most notable .survivors of a vast quantity of these 17th-century experiments in determining the relation of words to melody.

The almost universal preference of the Italians in the 17th and 18th centuries for the *da capo* aria involved some sacrifice on the dramatic and emotional side. This becomes clear at once if we think of an opera in which nearly all the songs end by repeating not only the melody of the opening part, but the words attached to it. It is this double repetition which from the point of view of dramatic propriety is the most disturbing. But composers mere too much occupied in exploring the formal possibilities of melody to establish a really intimate connection between music and text, a detailed interpretation of which lay outside their scheme of song. Much repetition of words was not felt as an absurdity so long as the music was broadly in accordance with the atmosphere or situation required.

Before Scarlatti's death in 1725 symptoms of decline had appeared. He was himself often compelled to sacrifice his finer instincts to the fashionable demand for vocal display. A race of singers, of whom the majority were virtuosi rather than artists. dominated the taste of the public, and forced composers to furnish opportunities in each role for a full display of their powers. The growth of virtuosity in all departments of music is a feature of 18th-century musical life. and singers, especially the male sopranos (castrati), were the most richly reuarded of all musicians, so highly was vocal display esteemed.

GERMAN SONG

Early Development. — Themusical genius of Germany. which has created for the world the highest forms as yet known of symphony. oratorio and opera! has also created the *Lied— the* term by which is most easily conveyed the modern conceptions of ideal song. Germany is. moreover, the only country in which the art of song in orderly and progressive development can be traced from the simple mediaeval *Volkslied* to the elaborate productions of Schubert. Schumann and Brahms. If Germany is united to the rest of Europe in its debt to Italy, still its final conception of song belongs to itself alone. And this conception has more profoundly influenced the rest of Europe than any Italian conception ever influenced Germany. The student, therefore. is more profitably employed in studying the phases of song development in Germany than in any other country.

It is not necessary to dwell, except in very general terms, upon German song of the 17th century. It can point to nothing corresponding with the *Airs de cour* of France. or the far more important songs of the English lutanists. The kind of literature necessary for such development was wanting and German art was too deeply affected by the spirit which produced the Reformation to develop freely in secular directions. Even in the domain of the *Volkslied* the sacred songs mere scarcely less numerous than the secular, quantities of secular airs being provided with sacred words in accordance with the spirit of the times. In the 17th century, the work of the Italian monodists was found eventually to stimulate German composers to make songs, but their interest at first lay more in opera and choral-instrumental works, in which solo songs appear. than in song as an independent branch of art. A good general view of such isolated songs as appeared can be obtained from Heinrich Reimann's collections *Das deutsche geistliche Lied* and *Dus deutsche Lied*. In spite of some stiffness and awkwardness, many of these exhibit a touching earnestness and sincerity which mark them as distinct from any work done elsewhere at the same time. On the other hand, they lack the certainty of touch, as well as the melodic and declamatory power, which make Henry Purcell in England stand out pre-eminently as the greatest song composer of the 17th century. But the formal aria established by Scarlatti was adopted by George Frederick Handel and bent to his own style and purposes (which were mainly religious) by Johann Sebastian Bach.

In considering the *Lied* it is necessary to distinguish between that more distinctly popular type of song, known as the *volkstümliches Lied,* in which the same melody served for all the stanzas of a poem (as in the *Volkslied* itself, on which the *volkstümliches Lied* was modelled!, and the *durchcomponiertes Lied,* or song "composed through," in which the music forms a running commentary on a poem. either without respect to its form, or varying the music in some stanzas or in all in accordance with their poetical significance. Generally speaking, the former aims at a wider audience than the latter, the appreciation of which involves some degree of culture and intelligence, inasmuch as it aims at interpreting more complex and difficult kinds of poetry. In the 18th century the simple *volkstümliches Lied* in strophic form was most in favour, and those who care to trace its history in the hands of popular composers such as J. A. Hiller, J. A. P. Schulz, J. F. Reichardt and K. F. Zelter, can easily do so by consulting Härtel's *Liederlexicon* (1867), one of a number of similar publications. Side by side with the outpouring of somewhat obvious and sentimental melodiousness which such volumes reveal, it must be remembered that the attention of greater men to instrumental composition, the growing power of composing for keyed instruments (which began to replace the lute in the middle of the 17th century) and the mechanical improvements through which spinet, clavichord and harpsichord were advancing toward the modern pianoforte. were preparing the way for the modern *Lied,* in which the pianoforte accompaniment was to play an increasingly important part. C. P. E. Bach (1714–1788) alone of his contemporaries gave serious attention to lyrical song. selecting the best poetry he could get. and aspiring to something beyond merely tuneful melody. The real outburst of song had to wait for the inspiration. which came with the poetry of Johann Goethe and Johann Schiller.

Haydn and Mozart.— It is unfortunate that Joseph Haydn (1732–1809) and Wolfgang Amadeus Mozart (1756–1791), endowed with all the gifts that make for beautiful song except that of literary discrimination. should have left so little of real value. There is. indeed. much to admire in some of Haydn's canzonets. of which "My Mother bids me bind my Hair" fully deserves its popularity. while Mozart's "Trennung," "Unglückliche Liebe," and "Komm' lieber Mai," are small treasures which we could not afford to lose. But in only two songs by Mozart, "Abendempfindung" and "Das Veilchen," is the goal to which the art was to advance clearly discerned and in the latter case perfectly attained. Both are *durchcomponiert,* in both the general spirit, as well as each isolated point of beauty in the verses is seized and portrayed with unerring insight. "Abendempfindung" is seriously marred by carelessness in accentuation (still worse examples may be seen in "An Chloe") and by annoying repetition of words, due to the development of the melody into a formal and effective climax, on instrumental, not vocal. lines. In "Das Veilchen," however. where Mozart touched a poem that was worthy of his genius, he produced a masterpiece — rightly regarded as the first perfect specimen of the *durchcomponiertes Lied.* Every incident in the flower's story is minutely followed. with a detailed pictorial and dramatic treatment (involving several changes of key. contrasts between major and minor. variations of rhythm and melody. declamatory or recitative passages), which was quite new to the art.

Beethoven. — With Ludwig van Beethoven (1770–1827), song was suddenly exalted to a place among the highest branches of composition. Taken in hand with the utmost seriousness by the greatest musician of the age and associated by him, for the most part. with lyrical poetry of a high order. it could at last raise its head and, freed from the conventional puerilities of the salon, look a larger world confidently in the face.

It cannot. however, be admitted that Beethoven was an ideal song composer. His genius moved more easily in the field of abstract music. The forms of poetry were to him rather a hindrance than a help. His tendency is to press into his melodies more meaning than the words n-ill bear. The very qualities, in fact. which make his instrumental melodies so inspiring, tell against his songs. Though his stronger critical instinct kept him, as a rule, from the false accentuation which marred some of the work of Haydn and Mozart. yet, like them, he could not free himself from the instrumentalist's point of view. at any rate in the larger song forms. The concluding melody of "Busslied" would be equally effective played as a violin solo, the same is true of the final movements of *Adelaïde* and of the otherwise noble cycle *An die ferne Geliebte* — movements in which the words have to adapt themselves as well as they can to the exigencies of thematic development and to submit to serious displacements and tiresome repetitions. In songs of a solemn or deeply emotional nature. Beethoven is at his best, as in that cycle, to sacred words of C. F. Gellert, of which "Die Ehre Gottes aus der Natur" stands as a lasting monument of simple but expressive grandeur, in "Trocknet nicht." "In questa tomba," "Partenza," in the first of four settings to Goethe's "Nur wer die Sehnsucht kennt," and more than all. in the cycle mentioned above, *An die ferne Geliebte.* We have left behind the pretty artificialities so dear to the 18th century, that play around fictitious shepherds and shepherdesses, and entered the field of deeper human feeling, with the surrounding influences upon it of nature and romance. The new spirit of the age. represented in German poetry by the lyrics of Gottfried Bürger, Johann Voss, Matthias Claudius and Ludwig Hölty, members of the famous Giittinger Hainbund. and more notably by those of Goethe and Schiller, communicates itself in Beethoven to song. It needs no large study of his songs to perceive that the accompaniment has assumed especially in the *Liederkreis,* an importance immeasurably greater than in the songs of any previous composer. It begins to take a real not a perfunctory, part in interpretation providing both a background and a commentary to the poet's verses

Schubert.—The pioneer nork of Schulz Reichardt and Zelter in the setting of Goethe's lyrics—for they did not confine their activities to popular songs — deserves mention as indicating the direction in which composers nere moving A word is also due J R Zumsteeg who in spite of the sometimes childish simplicity of his nork in the use which he made of modulation as a means of lyrical expression had some influence upon the greatest song writer of all ages, Franz Schubert (1797–1828).

Schubert's "Erlkonig" was written a few months before Beethoven's *Liederkreis,* "Gretchen am Spinnrade." about a year before the "Erlkonig." He was 18 when he composed the latter. in 1814. Lyrical song, divorced from all hindering elements and associations, whether of salon or theatre, was here at the threshold of his short career in almost full maturity and plenitude of power. It is sufficiently remarkable that a lad with so little education should have composed such music. It is more astonishing still that he should have penetrated with unerring insight into the innermost secrets of the best poetry. Two of the necessary qualifications for a great song composer were thus at last united. Schubert possessed the third — a knowledge of the human voice, partly intuitive, partly the result of his experience as a chorister. The beauty of his melodies is scarcely more striking than the gratefulness of their purely vocal qualities. The technique of singing had, indeed, been understood for nearly two centuries; but Schubert was the first to divine fully its emotional range, and to dissociate it in lyrical work from the traditions of the schools. From the beginning to the end of his career he never penned a note or a phrase merely because it was vocally effective. What he wrote for the voice to sing was there because for him the poetry could not have it otherwise. This was inherent in his method of working, in which he relied implicitly upon his musical inspiration for a response: usually instantaneous. to the inordinate receptivity of his mind to the impressions of poetry. To read through a poem was for him not only to seize its innermost significance and the salient points of its language and its form, but also to visualize the scheme by which both the whole and the parts could be translated and glorified through the medium of music. As the singer J. M. Vogl, the first of his profession to appreciate him. remarked, "He composed in a state of clairvoyance." It is consequently impossible to summarize in a short space the innovations he introduced: for new poems immediately suggested new types of song. His settings of Goethe's lyrics, that is, the best of 'them, differ as essentially from his settings of those of W. Müller in the cycles *Die schöne Müllerin* and *Die Winterreise,* as these, again, from the settings of the six poems of Heinrich Heine.

Hardly a single development in subsequent phases of the art (except those which eliminate the melodious element) is not foreshadowed in one or other of his songs (about 6j6 in number). Brahms, the greatest of his successors, said that there was something to be learned from every one of Schubert's songs. He was as perfectly at home in the *durchcomponiertes Lied* as in the simple strophic type, or the purely declamatory. "Der Wegweiser," "Haidenroslein," "Der Doppelganger" are familiar but supreme examples of each. Certain features may be selected for emphasis: first, his use of modulation as a means of emotional expression. "Du liebst mich nicht" traverses, in two pages, more keys than would serve most composers for a whole symphony — while the discords on the words "Die Sonne vermissen" and "Was blühen die Narcissen" give a piercingly thrilling effect which is quite modern. The modulations in "Wehmuth" illustrate the subtle atmospheric effects which he loved to produce by sudden contrasts between major and minor harmonies. More familiar instances occur in "Gute Nacht," "Die Rose" and "Rosamunde." Secondly must be noticed his inexhaustible fertility in devising forms of accompaniment which serve to illustrate the pictorial or emotional background of a poem: the galloping horses and the horn in "Die Post," the spinning wheel in "Gretchen," murmuring brooks in many songs from *Die schone Müllerin* and "Liebesbotschaft." the indications of an emotional mood in "Die Stadt" or "Litanei." Occasionally, it is true, the persistence of a particular figure or rhythm induces monotony. as in "Ave Maria" or "Normans Gesang," but generally Schubert had plenty of means at his command to prevent it, such as the presence of an appropriate subsidiary figure making its appearance at intervals, as in "Halt." "Der Einsame," or some enchanting ritornello, by which a phrase of the vocal melody is echoed in the accompaniment. as in "Liebesbotschaft," "An Sylvia." "Standchen" and "Fischerweise," or variations in the accompaniment to the different stanzas, as in "Im Friihling." Thirdly. the sudden entrance of declamatory passages, as in "Der Neugierige," "Am Feierabend." in .'Gretchen" at the famous "Ach, sein Kuss." Fourthly, the realistic touches, by which suggestions in a poem are incorporated into the accompaniment, such as the cock crowing in "Frühlingstraum," the convent bell in "Die junge Nonne," the nightingale's song in "Ganymed," or the falling tears in "Ihr Bild." Finally should be noted the rarity of slips in the matter of the just accentuation of syllables, and this is specially remarkable in a song writer who relies so much upon pure melody as Schubert; for to find and preserve a melodic outline which is felt as a true expression of a poem and yet does no violence to its text is far more difficult than to compose in the declamatory style. But nothing is difficult to Schubert. He is as successful in "Liebesbotschaft" as in "Prometheus."

Loewe, Weber and **Mendelssohn.**—Of his contemporaries, Carl Loewe *(1796–1869)* deserves mention for his singular success in overcoming the difficulties involved in setting long ballads to music. To preserve homogeneity in a form in which simple narration presents perpetually shifting changes of action, of picture, of mood, is a problem which Schubert himself only once triumphantly solved. Loewe's setting of "Der Erlkonig" is not outclassed even by Schubert's. He set scores of ballads of half a dozen European countries. and even some of oriental origin. "Edward" is the best known of a group of English and Scottish popular ballads which he set in Gottfried von Herder's translation. Carl Maria von Weber *(1786–1826)* contributed nothing of permanent value to song outside his operas, beyond a few strophic songs of a popular nature. He disqualified himself for higher work by that singular preference for rapid and trivial verse which so often led Haydn and Mozart astray.

The literary tastes of Felix Mendelssohn (1809–1847) took him often to the best poems but he made but little attempt to penetrate beyond their superficial and obvious import. His own lovable personality is far more clearly revealed in his songs than the spirit of his poets. Differences of literary style affected the style of his music less than that of any other distinguished composer. He attained his highest level in "Auf Flügeln des Gesanges," in the first of the two "Zuleika" songs and in "Nachtlied." It is noteworthy that there is no trace of Schubert's influence. Had he never lived Mendelssohn's songs would have been just the same. Hence, in spite of graceful and flowing melodies, simple in form and instinct with that polished taste and charm of manner which endeared both himself and his works to his own generation. his songs have exercised no permanent influence upon the art. Their immediate influence, it is true. was enormous. It is felt occasionally in Schumann, only too often in Robert Franz, and in the work of many composers of more or less distinction in many countries besides his own, such as Niels Gade. A. F. Lindblad, W. Sterndale Bennett and others who need not be specified.

Schumann.—Of far greater. importance is the work of Robert Schumann (1810–1856), whose polyphonic methods of technique and peculiarly epigrammatic style enabled him to treat complex phases of thought and feeling, which had hardly become prominent in Schubert's time, with extraordinary success. Both by temperament and by choice he identified himself with the so-called Romantic movement. a movement in which both poetry and music tended more and more to become a personal revelation rather than "a criticism of life." With Schubert, who was the very incarnation of romance, the note of universality, that abiding mark of the classical composers, is stronger than the impress of his own personality.

With Schumann the reverse is the case. If the Romantic movement gave a new impetus of vast importance both to music and literature, it had its weaker side in extremes of sensibility which were not always equivalent to strength of feeling. Mendelssohn's songs admittedly err on the side of sentimentality — Schumann, with Franz Liszt, Adolph Jensen, and Robert Franz, frequently betrays the same weakness. His best work appears in the settings of Heine's lyrics (especially the *Dichterliebe*), in the J. von Eichendorff *Liederkreis,* in Adelbert von Chamisso's *Frauenliebe und Leben,* and in a fair number of other songs, such as "Widmung," "Der Nussbaum." "Auftrage," and on the dramatic side in "Der Soldat." "Die Karten-legerin" and "Die beiden Grenadiere," all strong in feeling and full of poetic and imaginative qualities of a high order. He realized that the new poetry called for new methods of treatment. These Schumann, instinctively an experimenter, provided. First, he gave a closer attention to the minutiae of declamation than had hitherto been attempted, and herein syncopation and .suspension provide possibilities unsuspected even by Schubert (in whose work hardly a case of syncopation will be found in the voice part). Secondly, he increased the role of the pianoforte accompaniment — and in this he was helped on the one hand by novel methods of technique, of which himself and Frédéric Chopin were the chief originators. and on the other by his loving study of Bach, which imparted a polyphonic element which was new to modern song. In nearly all Schubert's songs, and in all Mendelssohn's, the melody allotted to the voice is an essential factor. In Schumann the role of interpreter often passes to the accompaniment, while the voice declaims the words, as in "Das ist ein Flöten und Geigen," or "Rosslein," but the notes in which it declaims them are musically important. Consistently with this attitude, he gave increased prominence to the opening and closing instrumental symphonies; these became in his hands no merely formal introductions or conclusions, but an integral part of the whole conception and fabric of the *Lied.* This may be illustrated by many numbers of the *Dichterliebe,* but most remarkable is its final page. in which the pianoforte, after the voice has stopped, sums up the whole cycle. A third point is his fondness for short, interrupted phrases (often repeated at different levels) in place of the developed Schubertian melodies; a practice which has been extended by later composers, but often, as in the case of Franz, without Schumann's tact. On many grounds, then, Schumann may be regarded as having widely extended the conception of the *Lied,* his example has indeed encouraged later composers to regard no lyric poetry as too subtle for musical treatment.

Liszt, Franz, **Jensen** and Cornelius. — A bold experimenter in song was Franz Liszt (1811–1886), whose wayward genius, with its irrepressible bent toward the theatrical and melodramatic, was not at home within the limits of a short lyric. It is true that there is sincerity of feeling, if not of the deepest kind, in "Es muss ein Wunderbares sein" and "Über allen Gipfeln," but concentrated emotion, which involves for its expression highly organized form, was alien to Liszt's genius. which is more truly represented in songs such as "Die Lorelei," "Kennst du das Land" or "Am Rhein," in which are presented a series of pictures loosely connected, giving the impression of clever extemporizations.

The admiration expressed by Liszt and Wagner for the songs of Robert Franz (1815–1892), and the cordial welcome extended by Schumann to those which first made their appearance, have led to an undue estimate of their importance in many quarters. They are characterized by great delicacy both of feeling and of workmanship, but the ingenuity of his counterpoint, which he owed to his intimate knowledge of Bach and Handel. cannot conceal the frequent poverty of inspiration in his melodic phrases, nor the absence of genuine constructive power. To build a song upon one or two phrases repeated at different levels and coloured by changing harmonies to suit the requirements of the poetic text (as in "Fur Musik" and "Du bist elend") is a dangerous substitute for the power to formulate large and expressive melodies. But it is the method which Franz frequently pursued. His songs are mostly short and in the strophic form, some alteration being reserved to give point to the last verse. His tricks of style and procedure quickly become familiar, but the sincerity of his aims, the idealistic and supersensitive purity of his mind (which banished as far as possible even the dramatic element from his lyrics), its receptiveness to the chaste, tender and refined elements in human character provide some compensation for the lack of the larger qualities of style and imagination. His best qualities are represented in the beautiful setting of Nikolaus Lenau's "Stille Sicherheit." Adolf Jensen (1837–1879) is another of the secondary German *Lieder* writers, much influenced by Schumann; he excelled in smaller songs of gay, tender and healthy sentiment. His song cycle *Gaudeamus* contains jovial student songs. Ballads by Sir Walter Scott and lyrics by Robert Burns were set by Jensen, who was himself both a singer and pianist.

A higher value than is usually conceded attaches to the songs of Peter Cornelius (1824–1874), a friend of Liszt and Wagner, but a follower of neither. Before he came under their influence he underwent a severe course of contrapuntal training so that his work, though essentially modern in spirit, has that stability of structure which makes for permanence. He was, moreover, an accomplished linguist, a brilliant essayist and a poet. That intimate fusion between poetry and music which, since Schubert, has been the ideal of German song is realized in an exceptional manner when, as with Cornelius, librettist and musician are one person. Finer declamation is rarely found than in his subtly imaginative "Auftrag," while for beauty of feeling, apart from technical excellencies of a high order, the *Weihnachtslieder,* the *Brautlieder* and much of the sacred cycle *Vater Unser* are hardly surpassed even by Schumann at his best, and point to Cornelius as one of the most beautiful and original spirits of the 19th century.

Brahms and Wolf.—The *Lieder* tradition of the 19th century culminates in the work of Brahms and Hugo Wolf, who adopted opposite solutions of the conflict of literary and musical values inherent in all song writing. Brahms is on the musical line but derives from Schubert; Wolf on the more literary that emerged in Schumann. The songs of Richard Strauss and Gustav Mahler show the tradition in a glorious decline.

The unerring sagacity of Johannes Brahms (1833–1897) discerned that the possibilities of song on the lines set by Schubert were far from being exhausted. A broad melodic outline was for him essential, also a strong contrapuntal bass. In form the majority of his songs are strophic and follow the orthodox ABA or AABA pattern (the letters standing for stanzas), the central portion (B) being so organized as to offer, with the least possible introduction of new material, a heightened contrast with the opening portion through changes of rhythm and tonality, and at the same time to justify itself by producing the mood in which the return to the opening portion is felt as a logical necessity. Chromatic effects in Brahms's scheme of melody are rarely introduced till the middle section, the opening being almost invariably diatonic. It must, however, be admitted that Brahms's formal perfection involves some awkward handling of words, as in the second stanza of "Feldeinsamkeit"; sometimes, as in numbers 3 and 4 of the *Magelone* romances, they are frankly sacrificed to that formal development of material which has already been criticized in the cases of Mozart and Beethoven.

No part of his songs deserves closer study than the few bars of instrumental prelude and conclusion, in them is enshrined the very essence of his conception of a poem. It may almost be said that, since Schumann set the example, the first and last word have passed from the voice to the instrument, from the singer to the accompanist, who is called upon to understand poetry as well as music. Mastery in close organization of form was allied in Brahms not only with the warmth and tenderness of romance but with the imagination and insight of an earnest thinker. Concentration of style and of thought are nowhere else in the history of the *Lied* combined on a plane so high as that which is reached, with all the perfection of melodic and harmonic beauty, in "Schwermuth," "Der Tod, das ist die kühle Nacht," "Mit vierzig Jahren," "Auf den Kirchhof," "O wüsst' ich doch den Weg zurück," and the *Vier ernste Gesänge,* which closed the list of his 197 songs. The alliance to song of so dangerous a companion as philosophy or at any rate of thoughts which are philosophical rather than lyrical, proved no obstacle to Brahms's equal success in the realm of romance. This side of his genius may be illustrated by numerous songs from the *Magelone* cycle (notably "Wie froh und frisch" and "Ruhe, Süssliebchen") and by many others such as "Liebestreu," "Die Mainacht," "Feldeinsamkeit," "Wie rafft' ich mich auf in der Nacht," "Minnelied," "Immer leiset wird mein Schlummer," "Lerchengesang," "Wie Melodien zieht es," "Geheimniss" and "Dein blaues Auge."

It has already been said that Brahms was a student of Schubert. If he had not Schubert's spontaneity of melody, he restored melody to its Schubertian place of supreme importance. In spite of all the tendencies of his age, he never shirked that supreme test of a composer, the power to originate and organize melody, though the long phrases, the wide skips and a certain uncompromising quality make his songs seem austere. But that Brahms is not difficult without reason, or elaborate when he might have been simple, may perhaps be assumed from the preference he felt for his slighter songs in the *Volkstümlich* form and style (*e.g.,* "Abschied," "Sonntag," "Vergebliches Ständchen" and "Wiegenlied"). He was strongly influenced by the *Volkslieder* of his country, the words of which he loved to repeat to himself, as they suggested ideas even for his instrumental compositions. His arrangements of *Volkslieder,* though not uniformly successful, mark an epoch in that field of work. Curiously enough, his love of folk songs did not involve the sense which distinguishes between the genuine and the sham. Of the 49 *Volkslieder* published without opus number in 1894 by far the greater number were imitations which are really quite easy to recognize as such. (*See* Max Friedländer, *Brahms's Lieder*). The value of his arrangements may be tested by comparing them with the small volume containing arrangements by Franz, which are ingeniously done but without inspiration, with those of W. Tappert, which are models of what such things ought not to be, and with the dull, uninviting work of A. Saran. Many of Hugo Reimann's arrangements, however, deserve recognition as both sympathetic and scholarly. One fact emerges from the study of folk song arrangements, in Germany and elsewhere—there are no general principles for success except that they must be done with love and not with a desire to "make something of" the folk song.

The songs of Hugo Wolf (1860–1903) are discussed in the article under his name. They represent the application of the principles of Wagnerian music drama to lyrical song, the piano performing and functions of Wagner's orchestra in illustrating, commenting and enlarging on the text, which is treated with the most scrupulous respect. His songs are therefore something quite new in the relations of the two arts, and he recognized the fact by publishing them as "songs for voice and piano" instead of "songs with piano accompaniment."

The above summary of German song, though necessarily incomplete and confined to the most conspicuous names, may yet provide some points of view from which the songs of other countries may be regarded, especially those in which German conceptions and German methods of technique have been dominant factors. Actual settings of German lyrics figure largely in the works of many non-German composers and can hardly be judged except by German standards. Anton Rubinstein, Peter Tchaikovsky and Edvard Grieg are cases in point, and at a later date Philip Jarnach (b. 1892 in France of Spanish parents).

Later German Lieder.—It remains now to conclude the survey of German song by touching on the work of a few prominent later composers, who may be regarded as having enlarged the scope of the *Lied* without entirely breaking with its past.

Hans Pfitzner (1869–1949), a composer who may be counted among the old romantics, enriched traditional form rather than created new ones. His songs are felt to be individual experiences, they are "original but not at the cost of music" (Oscar Bie), poetical and full of beauty. The charm of "Herbstlied," "Sie haben heut'Abend Gesellschaft," "So fällt ein Stern herunter," does not fade. Others worth quoting are "Das verlass'ne Mägdlein" and "Denk' es, O Seele," which may be compared with Hugo Wolf's settings of the same words, and "Du milchjunger Knabe," of which Brahms's setting is the best known.

Max Reger (1873–1916) composed 225 songs; they are worth exploring on account of the originality of his harmonies, and his extraordinary contrapuntal skill, which he used deliberately with more thought for expression than for beauty. Overweighted with much learning, they make no great appeal to the singer's instincts. With the exception of some of the *Wiegenlieder,* especially "Wiegenlied-Maria," some of the *Schlichte Weisen* (especially "Waldeinsamkeit") and a few of his later songs, such as "Volkslied," "Sterbendes Kind" and "Unvergessen," the bulk of his work in song is not likely to be remembered.

The songs of Richard Strauss (1864–1949) represent a new departure, new, that is to say, to the 19th century, to which the bulk of them belongs. He was, after Hugo Wolf, the most interesting of the modern composers who applied the principles of Wagner to song. Discarding in many cases accepted forms, he found freer play for his exceptional gifts in the matter of pictorial illustration and emotional colour. It is not surprising, therefore, that he originated no great melodies, or indeed, composed many purely melodic songs, apart from such exceptions as "Morgen" and "Du meines Herzens Kronelein," the melodies of which, if not highly organized. are graceful and appropriate. More often the phrase with which a song opens does not develop into a melody; we discover at once that the accompaniment with its rhythmical figure and changing harmonies is really in charge; and that the vocal phraseology, as the song proceeds, adapts itself to it. Though the plan is derived from Wagner, Strauss's music is both in style and feeling his own. "Ruhe, meine Seele," "Spatbot," "Traum durch die Dammerung," one of his most beautiful creations, "Gefunden" and "Schlechtes Wetter" exhibit his best qualities, among them his pouer of depicting a given mood or atmosphere and sustaining it to the end. For brilliance and effectiveness, both for voice and piano, the popular "Standchen" and "Heimliche Aufforderung" may be cited. It is noteworthy that Strauss's name is not associated, as in the case of most of the German song composers, with any particular poet. He composed no cycle unless the *Four Last Songs* with orchestral accompaniment are so regarded. Perhaps his songs came to him too easily. There is nowhere the burning intensity of Schubert or Wolf, and the feeling he had for the potentialities of the soprano voice only found its full expression in his operas.

In the songs of Gustav Mahler (1860–1911) we feel at once the presence of a tempestuous nature, tormented, restless, unsatisfied. He poured his heart into his songs. and his native land (Moravia) and the old German folk song were the inspiration of his music. What they meant to him is revealed in the series of vivid pictures, instinct with life. movement and colour, containing the four *Lieder emes fahrenden Gesellen* (originally for voice and orchestra) and in the three volumes of songs taken from *Des Knaben Wunderhorn* (a famouscollection of old German songs and ballads). They are essentially dramatic songs, even realistic, full of melody of the folk song type and provided with an accompaniment more orchestrally than pianistically conceived. The construction is apt to be loose and diffuse, with rough corners and purple passages; but they are original. alive, refreshing, worth knowing, in spite of blemishes, which are emphasized because they represent a danger to song; they bring it too close to the theatre. It should be added that the later songs composed by Mahler, after he had freed himself from operatic work. are quite different in style. They consist of five songs (not without interest) and the touching and deeply felt group of *Kindertotenlzeder*, the words of all being by Friedrich Ruckert.

There is a long list of composers who, like the above-named, are in touch with the old regime; many have written a number of attractive and well written songs, of which probably the best known are those of Felix Weingartner (1863–1942) and Erich Wolff (*e.g.,* "Du bist so jung." "Alle Dinge haben Sprache," and "Faden"). Those of Joseph Marx (1882–) are at least equally striking, and perhaps more original.

In the 20th century changes took place in the world of music quite as startling and revolutionary as those which, at the beginning of the 17th century. suddenly brought the days of vocal counterpoint and the modal system to an end and substituted harmony for melody as the basis of the "new music." Then, in its turn, the harmonic structure based on key relationship after three centuries of development, was shaken to its very base and the world talked once more of the "new music." Those who would study the "new music" in German song will find it in the later songs of Arnold Schonberg (1874–1951), in those of Anton von Webern (1883–1945), Ernst Krenek (1900–), and in Paul Hindemith's (1895–) *Die junge Magd* (for contralto with flute, clarinet and string quartet) and especially *Das Marienleben* (a cycle for soprano with pianoforte accompaniment). Schönberg's *Pierrot Lunaire* (1912) is a combination of verse and music, though it is not singing but *Sprachgesang.*

NORTHERN EUROPE

In the countries of Northern Europe, Denmark, Norway, Sweden and Finland, the *Lied* produced offshoots in nationally tinged songs, which were frequently provided with German words, to increase their potential appeal or because their composers had studied in Germany or were dependent on German publishers. The title of Niels Gade's *Neun Lieder in Volkston* is significant and Grieg's songs achieved as wide a popularity as his piano concerto. Jean Sibelius (1865–1957) wrote nearly 100 songs, of which the quality is variable, some having the popular touch of his slighter instrumental pieces. There is a classical side to him which produced better songs than these lesser essays in a more romantic vein. "The Tryst," "Jubal" and "A Song of Spring" are examples, and the visionary poetry of his friend A. V. Rydberg produced even stronger songs, such as "The War Song of Tyrtaeus" and "Autumn Evening," of which the original language is Swedish, as is the case with his two settings of Shakespeare. Sibelius's music however with its avoidance of anacrusis shows Finnish characteristics. Another Finnish composer whose reputation is built wholly on his 500 songs is Yrio Kilpinen, who set Finnish, Swedish and German words.

THE LATIN COUNTRIES

France. — The Latin countries have been but little subject to German influences. France especially has always found from age to age, and notably in modern times, solutions of its artistic problems which have proved of deep interest to those who live beyond its borders, they bear emphatically a French hallmark.

Allusion has already been made to the French as pioneers in establishing solo song to lute accompaniment, which there, as in Italy, originated in adaptations of polyphonic compositions. But in France from the first the main influence apart from opera has come from popular sources, the native folk song and the vaudeville, the ditties of country and town. In both that union of grace, simplicity and charm, characteristic of the French nation, tended to produce an art of dainty unpretentious attractiveness. It preserved these characteristics in spite of the artificial atmosphere of the French court, in which it mainly flourished up to the time of the Revolution. In spite, too, of the somewhat different influences derived from opera, the mania for which did not, as in Italy, kill the smaller branch of vocal music. Brunettes, musettes. minuets, vaudevilles, beorgerettes, pastourelles, as the songs were styled according to the nature of the poetry to which they were attached, may be found in Jean Baptiste Weckerlin's *Echos du temps passe,* 3 vol. (1855).

The melodious style of Charles Gounod (1818–1893), whose earlier songs are excellent. is felt as a real influence in the work of Jules Massenet, Benjamin Godard, Camille Saint-Saens. C. P. L. Delibes, Georges Bizet, Edouard Lalo, Cécile Chaminade, Reynaldo Hahn and others, but it yielded to tendencies which corresponded closely with those of the Impressionist movement in French literature and painting. The new movement owed much to the work and inspiration of Cesar Franck (whose contribution to song is small) but more to that of Gabriel Fauré (1845–1924). The style of this master was new and individual. His harmonic conceptions. at first considered strange and revolutionary, were soon justified by the subtle effects of mood which they enabled him to express. as. for example, in "Les Roses d'Ispahan," "Dans les ruines d'une abbaye." "Nell," "Le Secret," "Lydie" and "Les Berceaux." If much of his work in song may be regarded as experimental, this cannot be said of Henri Duparc (1848–1933) whose 1j songs rank among the treasures of French art. They are characterized by an individual warmth, both of feeling and colour. The quietly moving, subtly blending harmonies and the smooth but expressive melodic line, most grateful to sing, are of a kind which it is impossible to associate with any poetry or any language but that of France. When he is dramatic his work is brilliant but without forced effects or violent transitions. Franck was his master. Among Duparc's finest songs are "Extase," "La Vague et la cloche," "Phydyle," "Chanson triste," and "Soupir." To the same school belongs Ernest Chausson (1855–1899), whose songs are the expression of a refined and sensitive nature, remarkable for delicate beauty of detail and form, somewhat after the manner of Duparc but on a smaller scale; *e.g.*, "Le temps de lilas," "Les papillons," "Nanny," "La colibri." With these composers may be associated Pierre De Bréville (1861–1949), Guy Ropartz (1864–1955), composer of the well-known "Berceuse," and Deodat de Séverac (1873–1921).

The startling harmonic innovations of Claude Debussy (1862–1918) exercised a strong influence upon the music and the songs not only of France but of all Europe. He discovered a pathway which had not been trodden before, and explored it so thoroughly that little is left for other seekers within the limits he prescribed for himself. The delicacy and finish of his work, in which the smallest touch tells, is remarkable, as well as the skill with which the notes carrying the words are interwoven into the fabric of the music. The method is Wagner's but the style is Debussy's who makes it seem that it was made for the French language and no other. Only in the early songs and those in *L'Enfant prodigue* is his vocal line melodic. Debussy is certainly the greatest of the Impressionists. The following selection from his 48 songs exhibits the extent of his range and the variety of his style: "Je tremble en voyant son visage," "La Flute de Pan," "Recueillement.," "Clair de lune," "Fantoches," the songs in *Ariettes oubliées*, the three Villon Ballades and the terribly powerful "Noel des enfants qui n'ont plus de maisons," composed in 1915

Maurice Ravel (1875–1937) is a master of clear and effective delineation What he aimed at he achieved. Debussy suggests, Ravel defines, but his definitions are difficult both to play and to sing. His most characteristic songs are the sets *Shéhérazade* and the *Histoires naturelles*, the latter a series of brilliant pictures, full of elaborate and effective detail; of these "Le Paon," "Le Cygne" and "Le Martin-pêcheur" are the best known.

The next generation was for a time dominated by "Les Six," of whom Darius Milhaud (1892–), and Francis Poulenc (1899–) became song composers of serious intentions and achievements. Poulenc wrote a "Le bestiaire" on the times of Ravel's *Histozres naturelles* and many songs for the baritone. Pierre Bernac.

Italy and Spain.—Italy, absorbed in opera, did not contribute much that is likely to have permanent value to 19th-century song, but the finished work of Giovanni Sgambati (1841–1914) is worth knowing. He composed more than 40 songs, of which *Quattro melodie*, Op. 35, and the setting of the old Italian folk song "Separazione" may be cited as characteristic. Ottorino Respighi (1879–1936) studied with Nicolas Rimsky-Korsakov and Max Bruch, but his songs are individual—though not eccentric. Among them are "Nebbie," five charming "Canti all' antica," and the dainty "Stornellatrice." His pupil I. Pizzetti (1880–) in "I pastori," with its fine modal character, effective declamation and cross rhythms composed a remarkable song full of interest for both singer and pianist In Spain the "Trois Mélodies" and particularly the very striking arrangements of seven *Canciones populares* of Manuel de Falla (1876–1946) deserve special mention. Also a collection of 14 old Spanish airs of the 17th and 18th centuries arranged elaborately and with singular insight by Joaquin Nin. The composer includes in each volume a valuable introduction—in French as well as Spanish.

RUSSIA

Russian song deserves more attention than can be given to it here. Since Michael Glinka (1804–1857) released it from Italian influences, and by impregnating it with the spirit and the idiom of the folk song, made it, at least in his own work, national, it has steadily increased in importance. There is a fairly large store of good songs by Russian musicians, but they are only in part Russian, their general conception and to a large extent their technique being derived from the masters of the German *Lied*. They represent a hybrid art which, though full of interest, pales beside the entirely Russian work of one man of genius, Modeste Mussorgsky (1839–1881). Through him, in his songs as much as in his operas, it seems as if the very heart of the strange Russian people nere revealed. His style is sometimes undisciplined, his realistic painting sometimes crude—natural in an art where colour counts for more than line—but there the pictures stand, throbbing with life, memorable. Many a village tragedy is the subject of his song. Death himself appears, terrible but kind, but Mussorgsky can also sing, no one more tenderly, of the cradle and the nursery; there is humour and satire too Of the romantic sentiment, characteristic of Germany, there is no trace In the music of Europe he proved a potent Influence opening the doors of song to admit subjects hitherto thought impossible or unsuitable to set Of his 40 or 50 songs most are definitely melodious; in others the voice part approximates to the rise and fall of the voice in speech, an ideal of song writing nhich he consciously pursued; in all strong rhythm is an outstanding feature In his last years he composed the four *Dances of Death* and the cycle of six songs *No Sun*, ahich rank among the most intensely moving songs ever nritten, tragically sad, but full of beauty. Mussorgsky was one of the four whom Mily Balakirev drew together to form with himself a "nationalist" band of composers The others were Borodin, César Cui and Rimsky-Korsakov. Borodin's "Romance" and "The Sleeping Beauty," Cui's "Hungersong," Rimsky-Korsakov's famous "Song of India," "Believe me not" and Zuleika's song are all good. To this group of composers must be added the names of the more cosmopolitan Tchaikovsky, Sergei Rachmaninov, A. Grechaninov and A. Glazunov. Tchaikovsky's "Nur wer die Sehnsucht kennt" is probably the best of his numerous songs. "The Dreary Steppe" and "Slumber Reigns" are characteristic of Grechaninov Rachmaninov's "To the Children" and "The Harvest of Sorrow" are truly Russian, the one of rare tenderness and beauty, the other heavy with grief.

Nicholas Medtner (1880–1951), a Russian composer of German descent, is in his music both German and Russian. He composed songs in both languages, orthodox in form, but elaborate in texture, difficult to play and, at first, to understand but both on musical grounds and for their serious import well worth unravelling. They are the work of a forceful personality, not making experiments, though he wrote a sonata-vocalise and a suite-vocalise for voice and piano. Among his Russian songs may be cited "Whisp'-ring Nature faintly stirring," "O'er thee I bend," and "I have come to say, Good-morning" Op 24, "The Singer" and "The Muse" (Pushkin) Op. 29, "The Valse" and "To the Dreamer" (Pushkin) Op. 32, "Sleepless Nights" (Tutchevj and the Valse, Op 37; among his settings of Goethe, "Die Sprode," "Die Bekehrte" and "Einsamkeit"; of Nietzsche, "Verzweiflung"; of Eichendorff, "Winternacht," and of Chamisso, "Die Quelle" and "Frisch gesungen."

ENGLISH SONG

Successors of the Lutanists.—The beginnings of English song have already been alluded to in speaking of Dowland, Campion, Rosseter and Jones. The subsequent work of Henry Lawes, and his contemporaries William Lawes, Charles Coleman and John Wilson, was unpretentious and simple. Gems here and there, such as "Gather ye rosebuds" (W. Lawes) and others contained in two small volumes edited by A. Dolmetsch, are the student's reward for a good deal of uninspired and tentative work, in which the main object of composers was to "follow as closely as they could the rhythmical outlines of nonmusical speech: they listened to their poet lriends reciting their own verses and then tried to produce artificially exact imitations in musical notes," (Ernest Walker, *History of Music in England*), producing what was neither good melody nor good declamation. Such work, in spite of John Milton's sonnet to Henry Lawes, could only have a passing vogue, especially with Henry Purcell (1658?–1695) so near at hand to show the world the difference between talent and genius, between amateurish effort and the realized conceptions of a master of his craft. Songs like "Let the Dreadful Engines" and "Mad Bess of Bedlam" reach a level of dramatic intensity and declamatory power, which is not surpassed by the best work of contemporary Italian composers. "I attempt from love's sickness to fly" is so familiar in its quiet beauty. that we are apt to forget that melodies so perfectly proportioned were quite new to English art (though John Blow's "The Self-banished" deserves to stand side by side with it). Monteverdi's "Lament of Ariadne" already has been mentioned, and it is interesting to contrast its emotional force with the equally intense but more sublime pathos of Purcell's "Lament of Dido," in which song a ground bass is used throughout. The "Elegy on the Death of Mr. John Playford" (quoted in full by Walker in his history) exhibits the same feature and the same mastery of treatment. The "Morning Hymn" is scarcely less remarkable, and has likewise a ground bass. Purcell died, aged 37, in 1695; Bach and Handel were then but 10 years old. and Scarlatti, born in 1659, had still 30 years to live—facts of which the significance may be left to speak for itself.

It is among the ironies of musical history that so great a beginning was not followed up. There are echoes of Purcell, stronger ones still of Handel, in the generation that succeeded him, in William Croft, Maurice Greene and William Boyce; but they quickly died away. From the death of Purcell to the Victorian era there is no consistent development of artistic song that is worth recording in detail. Thomas Arne (1710–1778), it is true, composed many fine songs that deserve to be better known. Those which have survived are mostly of the melodious order, still acceptable for an air of freshness and gracefullness that marks them as his own, *e.g.,* "Where the Bee sucks," "Blow, blow thou winter wind" and "Lovely Phyllis." Song writers that followed him, H. R. Bishop, W. Shield. J. Hook, C. Dibdin, S. Storace, C. E. Horn and T. Linley (the elder), were all prolific melodists. who have each left a certain number of popular songs by which their names are remembered, and which are worth hearing occasionally, but there is little attempt to advance, in new directions, no hint that song could have any other mission than to gratify the public taste for tuneful melodies allied to whatever poetry—pastoral, bacchanalian, patriotic, or sentimental—lay readiest to hand A good song appeared now and then, but seldom of serious import.

The 19th-Century Revival.— Who can uonder at the delight with which England welcomed the songs of Mendelssohn? It was in his school of Leipzig that William Sterndale Bennett (1816–1875), the first serious composer of songs in England for nearly a century, received his training. His output and range are small, but the quality of his work is delicate and individual. "To Chloe in Sickness." "Dawn, Gentle Flower," "Gentle Zephyr," struck a note that was new in English song. But he gave to his country a new ideal. Arthur Sullivan (1842–1900), more original, more richly endowed than Bennett, was also trained at Leipzig. Though his reputation has suffered from songs which satisfied the public rather than his own ideals ("The Lost Chord" and "The Sailor's Grave") there are many which have real value, *e g.,* his settings of Shakespeare's lyrics ("O Mistress mine." "Orpheus with his lute." "Where the bee sucks"), of Tennyson's cycle *At the Window* (in which the influence of Schubert is clear), "Tears, idle tears" and "Swallow, Swallow, flying south." and of George Herbert's "Sweet day, so cool." in all of which the touch of genius is unmistakable. It is obvious from songs like these and from the occasional appearance of others, such as John Hatton's "To Xnthea." Charles Salaman's "I arise from dreams of thee," Frederick Clay's "Songs of Araby" and "The Sands of Dee." that new ideals were in the air. In their further realization the increasing familiarity of the musical public with the masterpieces of German song may be reckoned as an important factor.

In the early 1880s, when Hubert Parry (1848–1918) and Charles Villiers Stanford (18 j2–1924), who was also at Leipzig, appeared, it was seen that song was at last taking its proper place in musical art. Parry's early songs are delightfully fresh and melodious, "The Poet's Song," "On a day, alack the day," "Why does azure deck the sky?" The three stirring "Anacreontic" odes mark the transition to that individual style which made the appearance of "Prometheus Unbound" one of the landmarks in England's musical history. He composed about 150 songs in all, the bulk of which are in the 12 volumes of *English·Lyrics.* Breadth, dignity and sincerity, with a nobility of thought and feeling characteristic of the composer. mark the serious numbers, "Through the Ivory Gate," "When we two parted." "Armida's Garden." Equally characteristic are those in which he is boisterous or humorous as in "Crabbed Age and Youth," "The Laird of Cockpen," "Follow a Shadow"; or atmospheric, as in "Dirge in the Woods" and "4 Fairy Town"; or in light and happy vein. as in "Ye Little Birds," and the entirely charming "A Lover's Garland:" With all the good qualities of Parry's songs something is lacking in the majority of them, which may perhaps be described as that intimate lyric note in which heart and voice and instrument sing together. The melodic freshness of his early days grew less in the increasing awkwardness of his piano technique and. perhaps, in the determination at all costs to have his word declamation right. In this he was entirely successful. setting an example which has been of great value to English song.

Stanford composed about 150 songs. If the settings of the poems from George Eliot's *Spanish Gypsy,* Op. *I,* are placed beside the songs of *The Glens of Antrim*, probably the last he composed, it is seen at once that the harmony which adorns the melodies of the former is singularly rich, and that in the latter it is reduced to the barest minimum—and yet it suffices. This gives us the trend of Stanford's work in song—increasing mastery of his resources of technique through the severe principle of economy. not two notes where one will serve. If the expressive colour of "The Radiant Dark." is fine; the astonishing simplicity of "Spring" is perhaps the greater achievement. Between these poles in the long list of Stanford's songs every variety of colour and complexity will be found, but not unduly lavish display. In the work of no composer are the means more perfectly suited to the ends. Arresting songs could be cited in many styles. especially those in *An Irish Idyll* (Moira O'Neill). There, in six pieces of rarest beauty he has portrayed against a background of Irish wind, sky. mountain burn and loch, all that is most lovable and most deep in the Irish character, its wistfullness and its pathos, its sunshine and gloom, its seriousness and humour, with a poetical and imaginative power of a kind which is unique. In these will be seen the sureness and delicacy of his touch not only on the spirit of each song but on the exact words with which it is conveyed. Poetry and music are fused without sacrifice on either side; the unity is complete. in further illustration are the "Corsican Dirge," the remarkable ballads, "La Belle Dame sans Merci" and "The Pilgrimage to Kevlaar," also "Three Cavalier songs" (Browning). "A soft day," "The Pibroch," "The Chapel on the Hill," "Easter Snow," "The Monkey's Carol," "Grandeur," "Daddy-long-legs." No less masterly are his arrangements of Irish folk songs of which there are four volumes.

20th-Century Development.— In the next generation no one composer was so prolific of songs. Arthur Somervell (1863–1937) and Roger Quilter (1877–1953) will survive by virtue of their songs rather than their other work. Somervell produced a body of work characterized by sincere and tender feeling, instinct with a quiet beauty which is individual and charming. Larger qualities appear in the admirable cycle from Tennyson's *Maud,* in *A Shropshire Lad* and *Love in Springtime* (the last named containing the singularly beautiful "Young Love lies sleeping"). "The Shepherd's Cradle Song," "Once at the Angelus," "When I am dead, my dearest," and "Weep ye no more, sad Fountains," deserved to be remembered.' They are real songs. grateful to sing and without pretentiousness or pose. Somervell has arranged many folk songs. in *Songs of the Four Nations* and two volumes of *Welsh Folk-songs,* with notable skill, taste and sympathy.

Quilter's is a muse of charm and delicacy, his German training did not overlay his English sentiment though the sweetness of his harmony owes nothing to Purcell or folk song. Typical in its fragrance and lack of pretension is "Now sleeps the crimson petal" (Tennyson) and he found an affinity with Robert Herrick in his "Julia" songs. Two sets of Shakespearian and Elizabethan lyrics contain more robust examples of his essentially lyrical art.

John Ireland (1879–1962), also a song writer, has other titles to fame. notably his piano music. but his settings of Thomas Hardy and A. E. Housman and John Masefield sound a distinctive note and his "Sea Fever" achieved a well-deserved and enormous popularity. Ivor Gurney (1890–1937) and Peter Warlock (1893–1930), younger men of Ireland's generation, both died in their early maturity. Gurney, a pupil of Standford. set contemporary (Georgian) verse besides Elizabethan poems and was himself a poet in whom the identification of poet and composer thus recalled Campion. In Warlock, whose personality was a divided one. as was Schumann's, the robust songs are influenced by the Elizabethan poets and composers, the more reflective by Frederick Delius (1862–1934), who left about 40 songs to Danish. Norwegian. German, French and English texts. It is not surprising therefore that the general drift of the poem meant more to Gurney than either the claims of exact declamation or of sheer melodic beauty. Warlock was more careful in these matters, and he had a peculiar felicity in providing modern settings to mediaeval carols.

But already before World War I another composer of greater stature had begun to make his presence felt. The music of R. Vaughan Williams (1872–1958) was influenced at its formative stage by the rediscovery of English folk song with its modal melody and rhythmic freedom. An early song, "Linden Lea." is perhaps the only true *Volkstümliche* song in English music. In his youth Yaughan-Williams found inspiration in D. G. Rosetti, of whose sonnets he made settings from which one, "Silent Noon," is a masterpiece. Outgrowing Rosetti he turned to R. L. Stevenson and produced the open air *Songs of Travel* which first made him widely known. He went on to the mystical poets of the 17th century — the *Five Mystical Songs* of George Herbert contain the rapt "The Call" and the triumphant "Antiphon." Williams set Shakespeare intermittently all his long life — there are. for instance, two quite different versions of "Orpheus with his Lute." 30 years apart. Song writing became less during his main symphonic period, but "The Water Mill" is a sort of Theocritan idyll like nothing else in the long tradition of English solo song. His arrangements of folk songs for voice and piano, which run into scores in number. show an extraordinary integration of their communal and idiosyncratic elements. George Butterworth (1885–1916), who was killed in World War I. followed the path opened by Vaughan-Williams in basing his style on folk songs, making excellent settings of them and establishing his independence in a cycle of songs from *A Shropshire Lad*. Arnold Bax and Arthur Bliss both composed songs but only as a relaxation from work in the longer forms. Gerald Finzi of a still younger generation (1901–1956) derived something. though more indirectly. from folk song. He had an affinity with the mystical poets. and with Hardy; in his piano accompaniments he sometimes borrowed from Bach the methods of the figured chorale with fresh and subtle effect. Benjamin Britten (1913–), an enormously prolific composer who by the time he was 35 had composed in every form except Biblical oratorio, and had done more than anyone else to raise hopes for the rise of a British school of opera. reveals an imagination quicker to take fire from words than from purely musical sources. His contributions to the literature of English song are large. though in his youth he had a propensity to choose foreign and even outlandish words for setting. *Les Illuminations* is a cycle to words of Arthur Rimbaud with string orchestra. Another cycle with string orchestra plus a horn is *Serenade* (English words). *Seven Sonnets of Michelangelo, The Holy Sonnets* of John Donne, *A Charm of Lullabies*, and *Winter Words* (Thomas Hardy), are all song-sequences with piano and the individual song is not prominent in Britten's output. Even his settings of folk songs and realizations of Purcell are issued in groups, but he has experimented with two more extended forms of solo vocal music in two Canticles. The long tradition of English solo song going back to the "Agincourt Song" of the 15th century is still very much alive. (*See* also FOLK-SONG.)

SONG IN THE UNITED STATES

Even in the 17th century. colonial America imported and enjoyed song. Although the *Bay Psalm Book* (1640) acquired no printed tunes until the edition of 1690, and the absence of instrumental support made congregational singing a confused uproar, the Puritan frowning on secular music seems to have been largely official.

From the 1730s, concerts of vocal and instrumental music were presented in Boston, Charleston, S.C., New York, Philadelphia, and Williamsburg, Va. New York city heard Handel's *Messiah* two years earlier than did Germany. The Moravian community of Bethlehem. Pa., imported the symphonies and quartets of Haydn and Mozart. and before the century ended performed Haydn's *Creation* and *The Seasons*. Native composition was religious. the most original contributions being William Billings' "fuguing tunes," which later suggested exhilarating efforts by Henry Cowell. Negro singing impressed Thomas Jefferson in 1784, and mountaineers in the southeastern Appalachians preserved and transformed many traditional English ballads. Francis Hopkinson (1737–1791) and James Lyon (1735–1794) are usually reckoned the first secular composers.

At the beginning of the 19th century, English and German musicians dominated the scene — especially. James Hewitt, first of a long line of musicians, and Gottlieb Graupner, who helped to found the Boston Handel and Haydn society. He also appears to have sung "The Gay Negro Boy" to his own banjo accompaniment, perhaps initiating the trend toward Negro minstrelsy. But the native Lowell Mason (1792–1872) contributed largely to hymnology in the United States (for example. "Nearer, My God to Thee"), and founded the practice of musical instruction in the public schools, which was to become the most comprehensive musical effort in the United States. A few musical institutions destined to survive were established — including the Musical Fund society of Philadelphia (1820) and the Philharmonic Society of New York (1842,) — but the heart of the nation was won by such songs as "Rocked in the Cradle of the Deep." "Woodman, Spare That Tree," and highly sentimental effusions on mother love and disappointed affection.

The only national tune to sprout in United States' soil was the weedy but irrepressible "Yankee Doodle." of revolutionary days. But the Negro Minstrel Show, launched by Dan Emmett in 1843, speedily became. and remained until the end of the 19th century, the most popular entertainment, capturing English audiences as well. And it was Christy's minstrels which made the nation aware of its first authentic genius — Stephen Collins Foster (1826–1864). Foster's musical learning and experience were pitifully meagre. but his gift of melody was as genuine as that of Schubert, and the influence of his best songs on the taste of his countrymen is incalculable.

The European revolutions of 1848 drove many notable musicians to the United States. The Germania society, an orchestra of 25, showed New York city and Boston what finished orchestral performance might be. It disbanded after six years, but scattered its members over the country as excellent teachers. Jenny Lind —an unprecedented success under P. T. Barnum's management, although, as Mendelssohn said: "she sings bad music the best"— offered the nation a perfect example of the singer's art. Germans settled numerously in the Mississippi valley and founded in Cincinnati: St. Louis and Milwaukee strong choral societies which, combined with others in the North American Saengerbund, sponsored huge choral festivals offering valuable opportunities both to singers and composers. No lasting compositions were forthcoming. but the stature of musical art was revealed. largely through song, to a rapidly growing musical public. The Civil War impeded this revelation. It did produce some notable war songs — Emmett's inimitable "Dixie," "Johnny Comes Marching Home." etc.—and the burning question of slavery doubtless intensified the general interest in the Negro spiritual. the United States' truest folk music. But the seepage of German musical thought into the general consciousness gradually bred the soon widespread notion that study in Europe was essential to an American musical career. Both performers and composers underwent the often pedantic discipline of the German tonservatories. The composers were indeed taught to write. But they were also taught *what* to write, and as their ambition soared toward symphonic heights, their thought lost contact with life as lived in the United States.

Returning home, they discovered this disjunction. and often remedied it by founding music departments in colleges, in whose atmosphere their unconscious pedantry could breathe. The growing movement in the public schools was thus continued on the collegiate level—not without benefit. certainly, to the national taste? but also not without danger to its integrity. But. unless in pretentious choral works, song was regarded as a minor endeavour. Even by the best-trained of returning talents, feeble texts on trite themes were preferred to the endless riches of English lyrical poetry. But this indifference was not necessarily due to ignorance of that body of verse, or to insensitiveness to poetic appeal. Neither was it due to the supposed unsingableness of the English language. The German language is no more mellifluous than English; yet the German lyric literature has evoked the richest body of song. And it may be argued that the German lyrists, familiar with music and aware of its peculiar powers of expression, often anticipated the rounding out of their poetic image by the musician, and left it to him to create in tone that atmosphere of sound which was essential to the full embodiment of their poetic image. The English poets of the Romantic era (the song was a product of romanticism) lived in a society far less musical than the German, and anticipated nothing more from the musical composer than a possibly agreeable but (in their view, really superfluous) tonal decoration of their verse. Thus they not only introduced a variety of images quite impossible for the composer to complement in tone (it takes time to develop a musical image. whereas, for a poetic image, a single word may suffice), but contrived an onomatopoetic "atmosphere" so suggestive as to make needless any musical complement or amplification. It is thus quite possible that English lyric poetry is too complete in itself—is, in a sense, too good—to be set to music.

Thus neither J. K. Paine (1839–1906) nor his lesser contemporaries. W. W. Gilchrist. F. G. Gleason, and S. G. Pratt continued to be performed. The next generation. still confronted by growing but inexperienced audiences. also treated the song as a minor form. The salty G. W. Chadwick wrote more than 100 songs, of which only the "Ballad of Trees and the Master" remained impressive. Arthur Foote (1853–1937), without European training, had the vision of a cultured gentleman and within that field his insight was keen and his imagination sensitive. Horatio Parker (1863–1919) was more interested in choral than solo song; but in retrospect even *Hora novissima* seems perfunctory. Edward MacDowell (1861–1908) was at the turn of the 20th century the foremost U.S. composer. About a third of his work is in the song. He found many captivating melodies, but his texts (he wrote several himself) were often banal and his rhythms and repetitions distressingly inept. Mrs. H. H. A. Beach (1867–1944) won wide recognition as an instrumental composer. Three of her 150 songs—"Ah, Love, but a Day," "The Year's at the Spring," and "Ecstasy"—were general favourites. Ethelbert Nevin (1862–1901), whose "Rosary" was anathema to the learned but manna to the million, formed a kind of link between the lower and upper levels.

Opera, in America as in England: was always exotic; but the Metropolitan began in 1910, with Frederick Converse's one-act *Pipe of Desire,* to recognize native production. H. W. Parker's *Mona,* Walter Damrosch's *Cyrano,* and Deems Taylor's *King's Henchman* and *Peter Ibbetson* were largely in the European tradition. Howard Hanson's *Merry Mount* had a New England theme, couched in an idiom derived but often forcefully projected. The greatest operatic successes! however, were in the really native jazz—Louis Gruenburg's *Emperor Jones* and George Gershwin's *Porgy and Bess.* Both Reginald De Koven and Victor Herbert wrote grand operas, produced at the Metropolitan Opera house, but their lighter' pieces were true successes. Musical comedies or shows (the new names for light operas) such as those of Richard Rodgers and Oscar Hammerstein provided the bulk of popular song, but Gian-Carlo Menotti (*The Medium, The Consul,* etc.), Italian by birth but trained in the United States, bid fair to bridge the gap between the popular and the esoteric.

Learned opinion, under the influences just suggested, was inclined to avert a rather shocked gaze from the so-called "popular" music, much of which. being set to words, was undeniably a species of song. But one variety of this species, the Negro spiritual, possessed a vitality that gave rise to a considerable progeny. For not only did the spiritual, as a religious expression. arouse fine interpreters. both Negro and white, to serious effort. The Negro, not ashamed to enact with his own body his religious exaltation, spontaneously invented for its release new and compelling rhythms which American youth turned—quite without thought of their religious origin—to the purpose of secular enjoyment. The first result was the "ragtime" of the 1890s, which the learned of those days contemptuously dismissed as mere syncopation. Newer variants were given such names as "jazz." "swing," "boogie-woogie" (this latter an apparently unconscious adoption of the old passacaglia or "ground bass" principle), and "bebop": all with a deplorable deterioration in the texts, but all—with a similar deterioration in vocal tone—still often presented in the guise of song. Yet this music showed an ingenuity in arrangement and performance which many European composers recognized as America's only original contribution to musical thought, and which they frankly adapted to their own purposes.

Rhythmic interest predominated in this music. Melodic invention became rare. Only a few of the thousands of pieces that rose to prominence on the "hit-parades" proved to possess any enduring melodic interest; but the few that survived; *e.g.,* Hoagy Carmichael's "Star Dust" and Cole Porter's "Begin the Beguine," did possess that interest. And a considerable number of these hits borrowed their melodic lines from Chopin and other classic composers (in common parlance music came to be classified as "classic." "semiclassic" and "popular"). demonstrating once more the truth of Mozart's contention that melody is the essence of music. These melodies, however, were distorted by jazz-rhythmed accompaniments and by re-shaping them into the 4–4 time which was the only measure in which jazz musicians could think; and texts were provided uhich even the "torch singers" probably would have blushed to pronounce merely as words. Once established in popular favour, these pieces often were played as instrumental compositions purely to arouse, the dance-impulse being the evident objective of the performers.

The chief impediments to an early U.S. song literature—the rawness of the general public and the prevalence of European tradition—had been largely removed by the early 20th century. But another and perhaps a greater impediment then arose—a new musical idiom. Obscure rhythms, elusive melodic intervals, and "linear" counterpoint destructive of the old lahdmarks of tonality, yielded music performable on Instruments but difficult for average voices and confusing to average ears. (It should be noted that this idiom originated in Europe.) A new versification. also elusively measured, was likewise adopted by the poets. It cannot be denied that the new music made (but often by back-tracking toward older tradition) impressive headway and threw into high relief the flimsiness of much former conventional thinking. It seemed unfavourable, however, to a generally impressive treatment of the song.

The difficulty of the idiom, rather than indifference to the form, seemed to account for the considerable neglect of song by composers of the 1950s. Music appropriate to their verse was never anticipated by the English poets as it was by the 19th-century Germans. and that compatibility of word and tone uhich marks the masterpieces of a Hugo Wolf nas apparently harder to achieve in the existing than in the older idiom. The first of the "modernists" was Charles T. Griffes (1884–1920) who began with conventional settings, turned for a time to German texts (as did Charles Ives and others), then began to reveal the fertility of his genius—and died. Samuel Barber. at first a timid innovator, set Arnold's *Dover Beach* for voice and strings, and reached his summit with *Knoxville: Summer of 1915,* for soprano and orchestra. Besides a few ventures with surrealist verse, Barber did ten "Hermit Songs" to old Irish poems, and set three pieces from James Joyce's *Chamber Music*. Ross Lee Finney set that whole cycle, interestingly. Charles Ives (1874–1954), really the earliest and most daring of the modernists, was as provocative in song as in other fields, running the gamut from extreme simplicity to vocal conjectures almost impossible to sing, yet undeniably purposeful. Virgil Thomson, stimulated by Gertrude Stein, helped make that strange figure intelligible. Roger Sessions, Henry Cowell, Paul Creston, Aaron Copland, Douglas Moore. Paul Nordoff, Celius Doherty, Marc Blitzstein, Norman Dello Joio and a host of others contributed, in various manners, to the literature of the United States' song; but there was no aspirant to the eminence of a Hugo Wolf.

SONGBIRD. Besides the application to any bird that sings, the term songbird has a restricted, precise meaning in bird classification. The true songbirds comprise the 53 families of the suborder Passeres or Oscines, which includes most of the great group of perching birds called the Order Passeriformes. They are well represented by many common garden birds such as sparrows, warblers, thrushes and wrens.

General Description and Natural History.—These birds vary in size from tiny kinglets and sunbirds to comparatively large crows. They are land birds which live in a wide variety of situations, from open grassland to forest. While songbirds include some of our best songsters such as thrushes, some have harsh voices like crows, and some do little or no singing. Their main food includes insects, worms, seeds and fruit picked up from the ground or from among vegetation, depending on the species. However, some like the swallows are very capable flyers and catch insects on the wing. Others, as the dippers, seek their food underwater in streams; and shrikes may catch mice and small birds.

In many species the birds pair at nesting time. The nest is most often a cup-shaped structure. However, a hanging nest is made by some species and a tunnel excavated by others. The number of eggs may vary from one, in some tropical species, to as many as a dozen in some titmice. In colour the eggs range, depending on the species, from immaculate chalky white and light tints to deeper tones, and many are speckled and marked. The young hatch with a scant covering of down at most and in a blind, neariy helpless condition. They are cared for in the nest for a time and reach full size and are able to fly well a short time after leaving the nest. Many northern species migrate to a milder climate for the winter. The greatest number of species of songbirds is in the tropics, but they are also well represented in temperate zones. A few live in the arctic, but there are none in the antarctic.

Songbirds are distinguished from the other perching birds by certain anatomical characteristics, especially the more complicated vocal organ or syrinx (*see* below).

Bird Song.—Vocalization in birds includes a wide variety of calls besides the song proper and provides a means of social communication. Man is the only other animal that exceeds birds in the use of voice, and probably no other animals approach birds in this ability. Bird song is best considered the vocalization that is used in courtship and breeding, chiefly by the male, to advertise that he is ready to mate, to attract the female and perhaps stimulate her sexually, to keep the pair together and to inform rival males that he has established a territory from which they will be excluded. The male's calls are also part of a threat display that takes the place of actual combat in repelling intruding rivals. However, similar song is sometimes given spontaneously when there is no obvious use for it. Occasionally females sing, and especially in tropical species pairs may duet, again perhaps a method of reinforcing the bond between the pair. Often the song is delivered from a series of regularly used perches. Some species, especially those that live in grasslands, have flight songs.

In some birds other forms of sound-making have taken the place of vocalization in part at least, as in the woodpeckers which drum out a tattoo by pounding on a dead branch with their bill. Some grouse drum with their wings, others stamp their feet. The winnowing or bleating of the snipe in courtship flight is caused by air passing between the outer tail feathers; peacocks rattle their quills in courtship. (*See* COURTSHIP, ANIMAL.)

Song need not be pleasing to the human ears. The hooting of an owl; the monotonously repeated phrases of the North American whip-poor-will; the crazed repeated whistle of a Malayan cuckoo that has given it the name of the brain-fever bird; and the African tinker bird's repeated notes, which from their resemblance to hammering on metal, have given the bird its name—all must be called songs. While the best songsters are true songbirds, some birds of other groups have pleasing or musical utterances, like the quavering trill of the screech owl and the cheery whistle of the bobwhite quail.

Which birds are the best songsters is a question that is subjective in part. Although national pride and pleasant associations surely have an effect. there is general agreement on certain species. The nightingale of Europe (*Luscinia megarhynchos*), which is a small thrush, perhaps heads the list of famous songsters of literature. Its beautiful brilliant song, full of sweet trills, fluted notes and liquid phrases in surprising variety, is rich and loud. The melody is often enhanced by being delivered at night when all else is still. The European skylark of the poets (*Alaudia arvensis*) soars up, singing as it goes, until it is a mere speck in the sky where it alternately flutters and sails, pouring out its joyful and melodious song. Another outstanding songster is the European blackbird (*Turdus merula*), one of the thrushes.

In North America the mockingbird (*Mimus polyglottos*) is a wonderful performer with a rich, melodious, long-continued song. It consists of a great many phrases with notes repeated two or three times. Imitations of other birds are often incorporated into the mockingbird's song, and on moonlit nights the bird may sing almost until dawn. Among the finest songsters are the cardinal (*Richmondena cardinalis*), with its loud clear whistles in crescendo and accelerando; the hermit thrush (*Hylocichla guttata*), with silver bell-like quality to its serene song. Townsend's solitaire (*Myadestes townsendi*) is another thrush, whose superb song consists of clear, brilliant, ringing notes that rise and fall in pitch and volume as the bird warbles and trills.

In Australia the lyre birds, which are not true songbirds, have songs which are superlative in variety and intensity and have a dramatic quality. The pied butcherbird has a richly musical flutelike song. The brown honeyeater has a song remarkably like that of the European nightingale's, and divides his song into proper stanzas.

C. Hartshorne has elaborated the concept of bird song as music. He shows there is a measure of congruity between songbirds' feeling for sound patterns and ours. Birds have in unequal degree an actual musical ability and sensibility, and their song can be considered a primitive form of music, an evolutionary anticipation of human music. Of the approximately 9,000 species of birds perhaps only a third should be considered singing species. Of these perhaps 1,200 might be said to have fairly good songs and only 225 species, scattered over the world, have really outstanding songs. Of the outstanding songsters there are 26 in Europe, 21 in North America and about 20 in Australia. It is possible that there are more outstanding bird songs in the mountains of the tropics than elsewhere.

Music consists predominantly of tones rather than noises, *i.e.*, of relatively pure sounds of a single frequency or with natural harmonies instead of miscellaneous blends of frequencies. While birds produce both noises and tones, the latter are more conspicuous in the better songs. Flutelike notes are common in bird song, though often of higher pitch than flutes. There are truly chime or bell-like, guitarlike or even organlike tones in bird song.

Bird song tends to be high pitched (this is perhaps correlated with birds' high rate of metabolism) and their hearing range somewhat surpasses ours. Notes tend to be very short and arranged in some kind of pattern. It is true that some songs are repeated over and over with slight variation, but almost always there is a pause between songs. The birds may have a shorter attention span

and weaker memory than we have, and the monotony of certain of their songs is. therefore, heard by our ears rather than the bird's. It is significant, too, that the birds' songs which rate highest with us have a certain randomness, a quality of unpredictability. Thus the wood thrush (*Hylocichla mustelina*) has, say ten songs. which can follow one another in 90 combinations; the bird improvises scores of different contrasts in a few minutes' singing. According to Hartshorne there exists one radical inferiority in the best bird songs, when compared with human music. and that is their great simplicity in length, shonn by the brief time span of the motifs or musical units. The longest seems to be about ten seconds and only a few extend to six seconds. The average is probably less than three seconds. It is true that some birds have a repertoire that extends through a minute or two of uninterrupted singing, but these repertoires consist of discrete elements each lasting a few seconds at most. Other birds have a single song lasting a minute or longer, but this, like some insect songs, is a relatively patternless prolongation of a single sound, trill or buzz.

As well as having a primary biological function in the breeding season. when bird song reaches its height. some bird vocalizing appears to be secondarily a leisure activity or play. an effusive burst of song out of sheer joy. This is especially evident in such birds as the white-throated sparrow (*Zonotrichia albicollis*) nhich sings on migration, the many species which sing in the autumn; and such birds as the Carolina wren (*Thryothorus ludovicianus*), uhich may sing every day of the year. This off-season singing may be the species' song at its very best.

Bird song shows every elementary rhythmic effect: accelerando (field sparrow, *Spizella pusilla*). ritardando (yellow-billed cuckoo, *Coccyzus americanus*), crescendo (some thrushes), interval inversion, simple harmonic relations, retention of melody nith change in key and theme with variations. Bird song, according to Hartshorne, is always intelligible as simple music. The best singers are those with more variety and complexity in the use of elementary musical devices, and they seem to sing most.

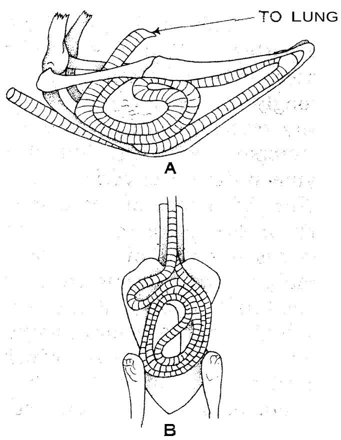
FIG. 2 — SYRINX OF SOME DUCKS HAS AN ENLARGED BONY CHAMBER
As found in (A) mallard, (B) pochard, (C) goosander, (D) steller's eider, (E) velvet scoter, (F) male and (G) female common scoter

Bird songs have been recorded in various ways. by musical notation by graphic notation, by fitting words to the song, by describing it in words and by capturing it on tape or phonograph disc. But a most useful way for analyzing and comparing bird song is the sound spectrograph which turns the song into a visual pattern recorded on paper. One of the important uses of this, by W. H. Thorpe of Cambridge university, was in a study demonstrating that in some birds the song is innate, while in others it is partly innate and partly learned from others of the same species. This learning takes place only in the early part of the bird's life.

Vocal Organs. — The syrinx, as the voice-producing structure or song box is called, is located at the point where the windpipe divides into two bronchial tubes to go to the lungs. (See fig. 1.)

The syrinx is an intricately constructed organ with a firm bony framework and filmlike vibrating internal membranes over which the air, during exhalation, passes rapidly, producing all the many utterances of the bird. A variable number of syringeal muscles and their controlling nerves adjust the tension on the membranes. The song box reaches its greatest complexity in the true songbirds. But it is not a complicated syrinx alone that determines singing ability for some true songbirds hardly sing at all.



FROM PYCRAFT HISTORY OF BIRDS (METHUEN)

FIG 3 —ELONGATED WINDPIPE
(A) Enclosed in the sternum of a crane and (B) elaborately coiled in a manucode, one of the birds of paradise

In certain ducks, especially in the males, the syrinx has an enlarged. bony chamber (see fig. 2). Honever. none of these birds have elaborate voices. though the male's voice may be different from that of the female. Sometimes the windpipe is elongated and elaborately coiled. In some cranes and swans this elongation is enclosed within the breast bone or sternum. In certain of the birds of paradise knonn as manucodes the elongated windpipe is coiled on the breast between the skin and the flesh (*see* fig. 3). Presumably this lengthening of the windpipe gives resonance to the voice.

SONNEBERG, a town of Germany, in the district of Suhl, situated in a narrow valley of the Thuringian forest. 13 mi by rail N E of Coburg. Pop. (1950) 30,182. It is famous for the manufacture of toys.

SONNET. Like most beginnings the genesis of the sonnet is somewhat obscure. On the whole the most probable account is that it sprang, as the result of endless experiments, from the popular short poems sung, in early medieval times. with or nithout refrain. to musical accompaniment. as the Idyl of Theocritus similarly arose from simple pastoral strains A very early specimen of the sonnet of a tolerably finished kind, is ascribed to Piero delle Vigne (d 1249). the famous chancellor of Frederick II. and this poem, alike by its Sicilian origin and by its formal elaboration, is sufficient to prove that a long period of experimenting must have preceded. Time is required both for the genre to have reached so far south and for the degree of finish shown by this poem to have been attained But nith every allowance for earlier talent we probably do little injustice if. in accord with the majority of critics. we call Guittone of Xrezzo (d 1294) the 'only begetter" of the sonnet as we know it It nas he nho firmly established its laws. From his time it was recognized that there must be an "octave," with rhymes (in an unusual notation), a. b, b. a;. a. b, b a and a "sestet." in which, while some variety is allowed the final couplet is excluded Betneen the octave and the sestet there is a distinct break and, as a rule, the first quatrain of the octave is though less strongly marked off from the second. More important still, in spite of a certain looseness of thought and roughness of style, Guittone established the unitary character of the sonnet.

It was the Guittonian sonnet which, in the hands of Dante and Petrarch, became—certain aberrations notwithstanding—the unquestioned model for later Italian writers. Especially as used by Petrarch, in his immortal Laura-poems, it set a standard which the greatest poets could hardly hope to overpass, and it was imitated bv such poets throughout the whole of western Europe.

The English Form.—Transplanted to England by Wyatt and Surrey (it is remarkable that it does not seem to have attracted Chaucer) the sonnet was made universally known by the very popular *Tottel's Miscellany* of 1557, and almost immediately captured the fancy of every poet, great, indifferent, or contemptible. In France, about the same time, it was cultivated with success by Desportes, de Baïf, Pierre de Brach, du Bellay, Ronsard and other writers, whose influence was very strongly felt in England—how strongly has been well shown by Sidney Lee. But in England, for many reasons (one, perhaps, being merely the scarcity of rhymes as compared with their abundance in the Romance languages), the rhyme-system was varied and simplified in endless ways.

For the names of the many sonneteers of this period any history of literature may be consulted. Most of them tried "sequences'—series of more or less connected sonnets; but while some individual poems are of surpassing beauty, few writers succeeded in composing more than two or three that deserve a place in a high-class anthology. Even Spenser was not wholly successful, though he adopted a form which might seem suited to his genius—the rhyme-system, a, b, a, b; b, c, b, c; c, d, c, d; c, c, which reminds us of the stanza of the Faerie Queene. Others came gradually to adopt uniformly the especially "English" scheme, a, b, a, b; c, d, c, d; e, f, e, f; g, g; a scheme in which it is immediately obvious that the three quatrains and the "clinching" couplet attain an epigrammatic effect foreign to that of the Petrarchan type.

Milton and Wordsworth.—By the date (1609) of the publication of the supreme examples of the Elizabethan type, Shakespeare's sonnets—which had indeed been probably written long before—the vogue of this style had worn itself out, and the 23 English and Italian sonnets of Milton show, as might be expected, a reversion to a stricter model. Though the poet of the "variously drawn-out" verse of Paradise *Lost* was bound to make no attempt to break the sense at the conclusion of the octave, yet in other respects he conforms (in the main) to the Petrarchan system, and is Italian enough to give us one "caudate" sonnet. Apart from questions of relative merit, the tone of these sonnets is thus altogether different from the Elizabethan. Since his time there have been few endeavours to revive the "English" style. Not that, till much later, the rigid rules were observed. Even the scholarly Gray, in his sonnet on the death of West, allows himself extreme licence; and Cowper's on Mrs. Unwin, beautiful as it is, ends with a couplet. Thus, as the merit of a sonnet is usually in proportion to its strictness, it is perhaps as well that it went out of fashion between 1740 (the date of Gray's sonnet) and 1789 (the date of those of Bowles). The importance of Bowles, again, consists hardly at all in intrinsic worth, but almost solely in the influence he exerted upon Coleridge and Wordsworth; nor are Coleridge's sonnets, few as they are, worth the trouble of reading. It is to Wordsworth that we owe the great and enduring popularity of the form, and possibly even the revived appreciation of Shakespeare's sonnets, which, as is well-known, Steevens refused to reprint on the ground that they were unreadable. Wordsworth, not merely by the surpassing beauty of 20 or 30 of his sonnets, but by his "sequences," is the modern founder of the genre. It is true that not many even of his sonnets are quite regular, and that it is not to the "Ecclesiastical Sketches" nor to the "Duddon" series that we look for his best work; but his perception that the form lends itself to the expression of connected thoughts inspired Rossetti in his House of Life, Mrs. Browning in her Sonnets *from* the Portuguese, and Meredith in his Modern Love, which, though not in the sonnet-form, has much of the character. Since Wordsworth there have never been lacking sonneteers, and at least some of their work has been of great excellence. It is noteworthy how often men not of the highest genius have found in the very constriction of the form "not bonds but wings," and have produced, by a flash of inspiration aided by labour, single sonnets not unworthy to be compared with the best even of Shakespeare's or of Milton's. While, as we saw, Coleridge failed, and while the genius of Shelley was cramped in the "narrow room" (he wrote but one good sonnet, and that not a true one), some great poets, like Keats, and others of a lower order, have moved in it with ease and have attained great heights.

The literature of the subject is large, and but a tithe of it can be mentioned here: for history and criticism Capell Lofft, Leigh Hunt, Mark Pattison (preface to Milton), Trench (preface to Wordsworth), Sidney Lee (Life of Shakespeare), Lentzner (down to Milton), Addington Symonds, Ashcroft Noble, Theodore Watts-Dunton and T. W. H. Crosland. Good and comprehensive selections also abound, many of them with critical and historical prefaces and notes. Of these we may choose Lofft, Hunt, William Sharp, Waddington, Hall Caine and Tomkinson. But as new sonnets are constantly being written so new selections are constantly being made. (E. E. K.)

SONNMO, SIDNEY BARON (1847–1922), Italian statesman and financier, was born at Florence on March 11, 1847. Entering the diplomatic service at an early age, he was appointed successively to the legations of Madrid, Vienna, Berlin and, Versailles, but in 1871 returned to Italy, to devote himself to political and social studies. On his own initiative he conducted exhaustive inquiries into the conditions of the Sicilian peasants and of the Tuscan *métayers*, and in 1877 published in co-operation with Signor Leopoldo Franchetti a masterly work on Sicily (La *Sicilia,* Florence, 1877). In 1878 he founded a weekly economic review, La Rassegna Settimanale, which four years later he converted into a political daily journal. Elected deputy in 1880, he distinguished himself by trenchant criticism of Magliani's finance, and upon the fall of Magliani was for some months, in 1889, under-secretary of State for the treasury. In view of the severe monetary crisis of 1893 he was entrusted by Crispi with the portfolio of finance (Dec. 1893), and by energetic measures he averted national bankruptcy, and placed Italian finance upon a sounder basis than at any time since the fall of the Right. Though averse from the policy of unlimited colonial expansion, he provided by a loan for the cost of the Abyssinian War in which the tactics of General Baratieri had involved the Crispi cabinet, but fell with Crispi after the disaster at Adowa (March 1896). Assuming then the leadership of the constitutional opposition, he combated the alliance between the Di Rudini cabinet and the subversive parties, criticized the financial schemes of the treasury minister, Luzzatti, and opposed the "democratic" finance of the first Pelloux administration as likely to endanger financial stability. After the modification of the Pelloux cabinet (May 1899) he became leader of the ministerial majority, and bore the brunt of the struggle against Socialist obstruction in connection with the Public Safety bill. Upon the formation of the Zanardelli cabinet (Feb. 1901) he once more became leader of the constitutional opposition, and in the autumn of the year founded a daily organ, *Il* Giornale *d'Italia,* the better to propagate moderate Liberal ideas. He was prime minister for a few months in 1906.

On Dec. 2, 1909, Sonnino formed his second ministry. But he did not enjoy the favour of the still Giolittian Chamber, and his cabinet was defeated over the new shipping bill. On March 21, 1910, he resigned.

In the autumn of 1914, he became foreign minister in the Salandra cabinet. He was still foreign minister, under Orlando's premiership, during the Peace Conference, which he attended as second Italian delegate from Jan. 18 to June 19, 1919 On the fall of the Orlando cabinet (June 19, 1919) Sonnino retired into private life. He died on Nov. 24, 1922.

SON OF MAN. In the Gospels Jesus often refers to himself as the Son of man in such a way that it becomes clear that this must have been a term that was well known and loaded with meaning before his time. There is no agreement, however, as to the origin of the idea and as to what extent these sayings of Jesus are to be considered as authentic.

In the Synoptic Gospels (Matthew. Mark, Luke) the sayings in which the term Son of man is used fall naturally into three categories:

1. Eschatological sayings in which the Son of man is depicted as the judge who is to come in glory with the clouds of heaven in order to judge the world (*e.g.,* Mark viii, 38, xiii, 26. xiv, 62; Matt. xxiv, 27. 37, 39. 44). In these sayings the Son of man is always referred to in the third person, and there is no clear indication that Jesus is identical with that eschatological figure. Only once (Luke xii, 8 ff.; *cf.* Mark viii, 38) is any relationship established between Jesus and the Son of man: "everyone who acknowledges me before men, the Son of man also will acknowledge before the angels of God."

2. Passages concerned with the suffering, death and resurrection of Jesus (*e.g.,* Mark viii. 31, ix, 31, x, 33 ti.): "the Son of man must suffer many things . . . and be killed, and after three days rise again."

3. A few sayings which refer to various aspects of the activity of Jesus: he "has authority on earth to forgive sins" (Mark ii. 10), he "is lord even of the sabbath" (Mark ii, 28), he is called "a friend of tax collectors and sinners" (Matt. xi, 19) and he is homeless, having "nowhere to lay his head" (Matt. viii, 20; Luke ix. 58).

There is no relation whatsoever among these groups.

The first question that should be asked concerning these passages is that of their authenticity. In some cases it can be observed that parallel passages use a simple "I" instead of the title Son of man. Thus Matt. x, 32 uses "I" to replace the "Son of man" of Mark viii, 38 and Luke xii, 8 ff.; Matthew introduces "Son of man" in xvi, 13, a saying where Mark has "I" (viii, 27). But in most cases tradition is firm on the use of the term. Few scholars question the authenticity of the group 1 sayings. As for group 2, it is necessary to remember that they presuppose the events of Easter and may express the faith of the early church although afterward put into the mouth of Jesus. Other scholars admit the possibility that Jesus uttered these words also, because he must have foreseen the outcome of his conflict with the Jewish authorities. The third group also presents some difficulties, but for the most part the attempts to question the authenticity have not been successful.

As far as the first group is concerned, the implications of the term are comparatively clear on the background of Jewish apocalyptic~. In Dan. vii, 13 there is a reference to "one like a son of man" who was given dominion so that all nations should serve him, and mention is made of a judgment of the evil; later in the same chapter this figure is interpreted as being "the saints of the Most High" (*i.e.,* ideal Israel). It is a matter of dispute whether "son of man" here means just "a man" in general, which would be in accordance with common Aramaic and Hebrew usage, or is already an eschatological term. In later apocalyptics the latter is definitely the case.

The book of Enoch uses the title son of man to denote an eschatological figure who is to come at the end of the present age to judge the world and establish the Kingdom of God. He is referred to as existing before the creation of the world and as being kept hidden with God until his appearance at the consummation of the age. Certain motifs connected with this figure seem to be influenced by the Iranian idea of the First Man, which is also reflected in certain (later) Gnostic speculations. It is a disturbing fact, however, that the son of man passages in the book of Enoch are all in the part of the book commonly referred to as the Similitudes, of which there remain no Greek fragments and which does not seem to be represented among the fragments from the Qumran caves. This suggests to some scholars that these passages may be later, perhaps Christian interpolations. However, II Esdras, which derives from the time immediately after the fall of Jerusalem in A.D. 70, testifies to the existence of the term in Jewish apocalyptics, and it would probably not have been introduced there after the title had been used by Jesus.

In the third group, one or two of the passages might be explained by assuming the meaning of "man" in general. or especially "mortal man," as is the case in a number of passages in Ezekiel, where the prophet is addressed as "son of man." Matt. xi, 19 is associated with the humble state of Jesus and may be connected with the suffering passages.

The idea of the suffering of the Son of man, represented by the second group of sayings. presents the most difficult problem. It is a matter of dispute whether or not the book of Enoch knew the idea of a suffering Son of man. There is no unambiguous evidence, and those scholars who find this idea represented reach their conclusion only on the basis of the fact that the Son of man has several features in common with the Servant of the Lord as described in Isaiah xl–lv (Deutero-Isaiah). But these common features are positive—his election, his function as a lawgiver and as a light to the nations and the hope of the holy ones, etc. The suffering of the Servant is not referred to in connection with the Son of man, and the contemporary Jewish method of biblical interpretation does not favour the assumption that the figure of the Servant was adopted in its totality; therefore, nothing warrants that the glory of the Son of man presupposes his suffering. The mention of "the blood of the righteous one" in Enoch xlvii, 1–4, immediately following a chapter dealing nith the glory of the son of man, is no conclusive evidence, and the text itself is not even certain.

Thus, if Jesus did really use the title "Son of man" in connection with his suffering, it would seem that it was he himself who made the combination of the Son of man of apocalyptics with the suffering Servant of Deutero-Isaiah. He may even not have known the book of Enoch but interpreted his mission in terms of Dan. vii, Isa. liii and perhaps also the suffering righteous of Wisdom ii–v.

It has also been suggested that the term might derive from Ps. viii, 4 and Ixxx, 17 where it is taken to refer to the king; since the messianic hope developed out of the idea of an ideal king, the term therefore from the beginning would have been a "messianic" title. Ps. viii, 4 is quoted in the New Testament as referring to Christ, but there is no evidence that Jesus applied these psalms to himself.

As a title of Christ the term "Son of man" seems to have lost currency rather soon. By far the most instances occur in the Synoptic Gospels. There are a few instances in the Gospel of John, referring to his pre-existence in heaven (iii, 13), his death (iii, 14, viii, 28, xii, 23, 34, etc.) and his function as a judge (v, 27). Paul does not use it. It seems probable that it mas introduced by Jesus himself, but that the early church found other titles more suitable to express its faith in Jesus as the saviour.

SONORA, a northwest state of Mexico. Pop. (1950) 510,607; (1956 est.) 623,622; area, 70,484 sq.mi. Sonora is bounded north by the United States, east by Chihuahua, south by Sinaloa and west by Lower California and the Gulf of Lower California. Until the 1940s Sonora was primarily a mining area, producing copper. gold and silver. Climatic conditions are generally arid to semiarid and irrigation is necessary to produce winter vegetables, cereals, cotton, tobacco and maize.

The state's population is clustered around Nogales (*q.v.*), at the border. Hermosillo the state capital, a neat and thriving air, highway and rail centre in the midst of a flourishing cotton district, Guaymas, a coastal deep-sea fishing resort, and Ciudad Obregón, in the heart of the Yaqui valley. The latter grew in the 1950s from a barren crossroads town to a booming city of 70,000, with modern architecture, airport and a large number of cotton-enriched farmers. Irrigation provided by the Alvaro Obregón dam (completed in 1952) on the Yaqui river made this expansion possible by supplying water to more than 500,000 ac. of desert land.

The area of Sonora was explored in the 1530s. and later became a famous colonial mining district. The small town of Alamos is a quaint reminder of this colonial past. In 1830 Sonora became a Mexican state, but the unruly Yaqui tribes were not finally subdued until the 20th century. The primitive Seris still follow their old way of life on the offshore island of Tiburón. The state derives its name (sonorous) from its deposits of grayish marble, which when struck emits bell-like sounds. (J. A. Cw.)

SONS OF LIBERTY, the name adopted by clubs of patriots that sprang into existence in Great Britain's North American colonies in opposition to the Stamp act passed by parliament in 1765. These radical, secret and loosely organized clubs, whose members were recruited mainly from the trading classes. served as headquarters for leaders who directed the mobs that resisted British efforts to collect taxes. Men of wealth and status often gave leadership to the clubs. The "Liberty Boys" terrorized stamp masters, burned stamps and mobbed supporters of alleged British tyranny. At times they gathered openly, held parades and dinners, sang liberty songs and stirred up popular sentiment against the British. A network of the societies covered all the colonies, but New York and Massachusetts supported the most spirited chapters. The New York Sons of Liberty appointed the first popular committee of correspondence, adopted the first nonimportation agreement, threatened those who used stamps and protected those who carried on business without stamps. The Sons of Liberty even attempted to create a military alliance of the northern colonies. The radical societies spread the spirit of resistance to British rule, marked the first effective intercolonial union and prepared the way for the later continental congresses and the American Revolution. (A. DE. C.)

SONSONATE, a department in western El Salvador established in 1855, bordering the Pacific ocean. Area 459 sq.mi. Pop. (1950) 120,327; (1955 est.) 141,801. The population is concentrated on southern mountain slopes, the hot coastal lowlands having few people. In the north, Izalco volcano, a black symmetrical cone without vegetation (altitude 6,184 ft.) and the most active in Central America, erupts at fairly regular intervals. The coastal lowlands produce 50% of the nation's balsam used in medicines. Sonsonate is important in the production of cheese, tobacco, coffee, sugar, pineapples and cotton.

Sonsonate city (pop. [1950] 17,949; [1956 est.] 20,736), the departmental capital, was founded in 1524. Interesting features are El Pilar Colonial church, old cathedral with 17 cupolas of all sizes, and nearby the San Antonio colonial shrine visited every year by thousands of pilgrims seeking cures. Sonsonate is 41 mi. W. of San Salvador by highway and 12 mi. by road and railway from Acajutla, an open roadstead port which handles about 20% of the country's foreign trade. (C. F. J.)

SOOCHOW (SU-CHOU, WU-HSIEN), a city in Kiangsu province, China, situated on the Yangtze delta, 36 mi. S. of the river, 55 mi. W. of Shanghai and close to the eastern lake shore of T'ai Hu. It probably dates from about 484 B.C., and like other old towns nearby was located upon onetime hilly coastal islands, which were later joined together by Yangtze silting plus man's diking and draining for at least 3,000 years. The scenic mass of lakes and canals, including the Grand canal, caused Europeans to name it the "Venice of China," while the Chinese esteemed its beautiful gardens and fair women. It was the capital of the Wu Kingdom in the 5th century B.C. The fertile rice and silk country created wealth which over the centuries was poured into the construction of more than 200 private gardens, many restored and maintained for public enjoyment. Water, fertile soil, a mild climate for vegetative growth, nearby eroded lake stone and leisure for scholarly study and aesthetic development raised gardening in Soochow to one of China's great arts. It was a place of official retirement, inspiration to poets and painters and a luxury handicraft centre for jade and ivory carving, silk weaving and embroidery. Under T'ai P'ing control (1860–63) Li Hsiu-ch'eng instituted numerous social and economic measures that, unlike T'ai P'ing programs elsewhere, won the support of the local people and foreshadowed many of the changes of the Chinese People's Republic. It was a treaty port in 1896 and was held by the Japanese (1937–45). In modern times, silk filatures. weaving mills and a sericulture institute were set up. It is the seat of South Kiangsu Technical college. The city is on the Shanghai-Nanking railway and has a spur line south to Chia-hsing, Chekiang, augmented by highways for local traffic; some of the city's streets were widened for motor traffic. Pop. (1953) 474,000. (TE. H.)

SOPHIA (1630–1714), electress of Hanover, 12th child of Frederick V, elector palatine of the Rhine, by his wife Elizabeth, a daughter of the English king James I, was born at The Hague on Oct. 14, 1630. Residing after 1649 at Heidelberg with her brother, the restored elector palatine, Charles Louis, she married in 1658 Ernest Augustus, who became elector of Brunswick-Liineburg (Hanover) in 1692. Her married life was not a happy one. Sophia became a widow in 1698, but before then her name had been mentioned in connection with the English throne. When considering the Bill of Rights in 1689 the house of commons refused to place her in the succession, and the matter rested until 1700 when the state of affairs in England was more serious. William III was ill and childless; William, duke of Gloucester, the only surviving child of the princess Anne, had just died. The electress was the nearest Protestant heir. Accordingly by the Act of Settlement of 1701 the English crown, in default of issue from either William or Anne, was settled upon "the most excellent princess Sophia. electress and duchess-dowager of Hanover" and "the heirs of her body, being Protestant." Sophia watched affairs in England during the reign of Anne with great interest, although her son, the elector George Louis, objected to any interference in that country, and Anne disliked all mention of her successor. An angry letter from Anne possibly hastened Sophia's death, which took place at Herrenhausen on June 8, 1714; less than two months later her son, George Louis, became king of Great Britain and Ireland as George I on the death of Anne.

Bodemann (1885, 1888) ; A. W. Ward, *The Electress Sophia and the Hanoverian Succession* (1909) ; O. Klopp, *Der Fall des Hauses Stuart* (1875–88) ; *Correspondance de Leibnitz avec l'électrice Sophie*, edited by O. Klopp (1864–75) ; R. S. Rait, *Five Stuart Princesses* (1902).

SOPHIA ALEKSEYEVNA (1657–1704), tsarevna and regent of Russia, was the third daughter of Tsar Alexius and Maria Miloslavskaya. Educated on semiecclesiastical lines by the learned monk of Kiev, Polotsky, she emancipated herself in a short time from the traditional tyranny of the *terem*, or women's quarters. Setting aside court etiquette, she had nursed her brother Tsar Theodore III in his last illness, and publicly appeared at his obsequies, though it was usual only for the widow of the deceased and his successor to the throne to attend that ceremony. Three days after little Peter, then in his fourth year, had been raised to the throne, she won over the *stryeltsy* (musketeers), who at her instigation burst into the Kreml, murdering everyone they met, including Artamon Matveyev, Peter's chief supporter, and Ivan Naryshkin, the brother of the tsaritsa-regent Natalia, Peter's mother (May 15–17, 1682). When the rebellion was over there was found to be no government. Everyone was panic-stricken and in hiding except Sophia, and to her, as the only visible representative of authority, the court naturally turned for orders. She paid off and pacified the *stryeltsy*, and secretly worked upon them to present (May 29) a petition to the council of state to the effect that her half brother Ivan should be declared senior tsar, while Peter was degraded into the junior tsar. This duumvirate was but a steppingstone to the ambition of Sophia, who thus became the actual ruler of Russia.

By Nov. 6, Sophia's triumph was complete. The conduct of foreign affairs she committed entirely to her paramour, Prince Vasily Golitsuin, while the crafty and experienced clerk of the council, Theodore Shaklovity, looked after domestic affairs and the treasury. Sophia's fondness for Golitsuin induced her to magnify his barely successful campaigns in the Crimea into brilliant triumphs which she richly rewarded, thus disgusting everyone who had the honour of the nation at heart. Most of the malcontents rested their hopes for the future on the young tsar Peter, who was the first to benefit by his sister's growing unpopularity. Sophia took council of Shaklovity, and it was agreed (1687) between them that the stryeltsy should be employed to dethrone Peter. The stryeltsy, hoaever, received the whole project so coldly that it had to be abandoned. A second conspiracy to seize him in his bed (Aug. 1689) was betrayed to Peter. and he fled to the fortress-monastery of Troitsa. All his friends rallied round him. including the bulk of the magnates, half the stryeltsy and all the foreign mercenaries.

From Aug. 12 to Sept. 7 Sophia endeavoured to set up a rival camp in the Kreml; however her professed adherents gradually left her. She was compelled to retire within the Novo-Dyevichy monastery, but without taking the veil.

Nine years later (1698), on suspicion of being concerned in the rebellion of the stryeltsy, she was shorn a nun and imprisoned for life.

See J. E. Zabyelin, *Domestic Conditions of the Russian Princes* (1895); *R.* N. Bain, *The First Romanovs* (1905).

SOPHIA DOROTHEA (1666–1726), nife of George Louis, elector of Hanover (George I of England), only child of George William, duke of Brunswick-Lüneburg-Celle by a Huguenot lady named Eleanore d'Olbreuze (1639–1722), was born on Sept. 15, 1666.

Sophia Dorothea was married. for dynastic reasons, to her cousin George Louis. son of Duke Ernest Augustus, who became elector of Hanover in 1692. This union was a very unhappy one. The electress Sophia hated her daughter-in-law. and this feeling was soon shared by the prince himself Cnder these circumstances Sophia Dorothea made the acquaintance of Count Philipp Christoph von Konigsmark (*q.v.*), who assisted her in one or tno futile attempts to escape from Hanover, and rightly or wrongly was regarded as her lover.

In 1694 the count was assassinated. and the princess was divorced and imprisoned at Xhlden remaining in captivity until her death on Nov 23, 1726 Sophia Dorothea is sometimes referred to as the 'princess of Xhlden." Her tno children were the English king. George II, and Sophia Dorothea. wife of Frederick William I and mother of Frederick the Great

SOPHISM, an unsound argument or fallacious proof especially one in which the fallacy is difficult to detect, or one which is put forward with deliberate intent to deceive. (Ao *C.*)

SOPHISTS, the name given by the Greeks about the middle of the 5th century B.C. to certain teachers of a superior grade who, distinguishing themselves from philosophers on the one hand and from artists and craftsmen on the other, claimed to prepare their pupils, not for any particular study or profession, but for civic life (**σοφιστής**, literally, man of wisdom). For nearly a hundred years the sophists held almost a monopoly of general or liberal education. Yet, within the limits of the profession, there was considerable diversity both of theory and of practice. Four principal varieties are distinguishable, and may be described as the sophistries of culture, of rhetoric, of politics and of "eristic," *i.e.*, disputation. Each of these predominated in its turn, though not to the exclusion of others, the sophistry of culture beginning about 447, and leading to the sophistry of eristic, and the sophistry of rhetoric taking root in central Greece about 427, and merging in the sophistry of politics. Further, since Socrates and the Socratics were educators, they too might be, and in general were, regarded as sophists; but, as they conceived truth—so far as it was attainable—rather than success in life, in the law court, in the assembly or in debate, to be the right end of intellectual effort, they were at variance with their rivals, and are commonly ranked by historians, not with the sophists, who confessedly despaired of knowledge, but with the philosophers, who, however unavailingly, continued to seek it. With the establishment of the great philosophical schools—first, of the Academy, next of the Lyceum—the philosophers took the place of the sophists as the educators of Greece.

The sophistical movement was then, primarily, an attempt to provide a general or liberal education which should supplement the customary instruction in reading, writing, gymnastics and music. But, as the sophists of the first period chose for their instruments grammar, style, literature and oratory, while those of the second and third developments were professed rhetoricians, sophistry exercised an important influence upon literature. Then again, as the movement, taking its rise in the philosophical agnosticism which grew out of the early physical systems, was itself persistently sceptical, sophistry may be regarded as an interlude in the history of philosophy. Finally, the practice of rhetoric and eristic, which presently became prominent in sophistical teaching, had, or at any rate seemed to have, a mischievous effect upon conduct; and the charge of seeking, whether in exposition or in debate, not truth but victory—which charge was impressively urged against the sophists by Plato—grew into an accusation of holding and teaching immoral and unsocial doctrines, and in our own day has been the subject of eager controversy.

Genesis **and** Development of Sophistry.—Sophistry arose out of a crisis in philosophy. The earlier Ionian physicists, Thales, Anaximander and Anaximenes, in their attempts to trace the Multiplicity of things to a single material element, had been troubled by no misgivings about the possibility of knowledge. But, when Heraclitus to the assumption of fire as the single material cause added the doctrine that all things are in perpetual flux, he found himself obliged to admit that. things cannot be known. Thus, though, in so far as he asserted his fundamental doctrine without doubt or qualification, he was a dogmatist, in all else he was a sceptic. Again, the Eleatic Parmenides, deriving from the theologian Xenophanes the distinction between ἐπιήστμη and δόξα, conceived that, whilst the One exists and is the object of knowledge, the Multiplicity of things becomes and is the object of opinion; but, when his successor Zeno provided the system with a logic, the consistent application of that logic resolved the fundamental doctrine into the single proposition "One is One," or, more exactly, into the single identity "One One." Thus Eleaticism, though professedly dogmatic, was inconsistent in its theory of the One and its attributes, and openly sceptical in regard to the world of nature. Lastly, the philosophers of the second physical succession—Empedocles, Anaxagoras, Leucippus—not directly attacking the great mystery of the One and the Many, but in virtue of a scientific instinct approaching it through the investigation of phenomena, were brought by their study of sensation to perceive and to proclaim the inadequacy of the organs of sense. Thus they too. despite their air of dogmatism, were in effect sceptics. In short, from different standpoints, the three philosophical successions had devised systems which were in reality sceptical, though they had none of them recognized the sceptical inference.

Towards the middle of the jth century, however, Protagoras of Abdera, taking account of the teaching of the first, and possibly of the second, of the physical successions, and Gorgias of Leontini, starting from the teaching of the metaphysical succession of Elea, drew that sceptical inference from which the philosophers had shrunk. If, argued Protagoras in a treatise entitled Truth, all things are in flux, so that sensation is subjective, it follows that "Man is the measure of all things, of what is, that it is, and of what is not, that is not"; in other words, there is no such thing as objective truth. Similarly, Gorgias, in a work On Nature, or on the Nonent, maintained (a) that nothing is, (b) that, if anything is, it cannot be known, (c) that, if anything is and can be known, it cannot be expressed in speech; and the summaries which have been preserved by Sextus Empiricus (*Adv.* Math. vii. 65-87) and by the author of the De Melisso, etc. (chs. 5, 6), show that, in defending these propositions, Gorgias availed himself of the arguments which Zeno had used to discredit the popular belief in the existence of the Many; in other words, that Gorgias turned the destructive logic of Zeno against the constructive ontology of Parmenides, thereby not only reducing Eleaticism to nothingness, but also, until such time as a better logic than that of Zeno should be provided, precluding all philosophical inquiry whatsoever. Thus, whereas the representatives of the three successions had continued to regard themselves as philosophers or seekers after truth, Protagoras and Gorgias, plainly acknowledging their defeat, withdrew from the ungrateful struggle.

Meagre as were the results which the earlier thinkers had obtained, the extinction of philosophy just at the time when the liberal arts became more technical and consequently less available as employments of leisure, threatened to leave a blank in Hellenic life. Accordingly Protagoras, while with the one hand he put away philosophy, with the other offered a substitute. Emphasizing the function of the teacher, which with the philosophers had been subordinate, and proclaiming the right end of intellectual endeavour to be, not "truth" (ἀλήθεια) or "wisdom" (σοφία), which was unattainable, but "virtue" or "excellence" (ἀρετή), he sought to communicate, not a theory of the universe, but an aptitude for civic life. "The lesson which I have to teach," Plato makes him say (Prot. 318 E), "is prudence or good counsel, both in respect of domestic matters that the man may manage his household aright, and in respect of public affairs, that he may be thoroughly qualified to take part, both by deed and by word, in the business of the state. In other words, I profess to make men good citizens." As instruments of education Protagoras used grammar, style, poetry and oratory. Thus, whereas hitherto the young Greek, having completed his elementary training in the schools of the γραμματιστής, the κιθαριστής, and the παιδοτρίβης, was left to prepare himself for his life's work as best he might, by philosophical speculation, by artistic practice, or otherwise, one who passed from the elementary schools to the lecture-room of Protagoras received from him a "higher education." The progsamme was exclusively literary, but for the moment it enabled Protagoras to satisfy the demand which he had discovered and evoked. Wherever he went, his lecture-room was crowded with admiring pupils, whose homage filled his purse and enhanced his reputation.

After Protagoras the most prominent of the literary sophists was Prodicus of Ceos. Establishing himself at Athens, he taught "virtue" or "excellence," in the sense attached to the word by Protagoras, partly by means of literary subjects, partly in discourses upon practical ethics. It is plain that Prodicus was an affected pedant; yet his simple conventional morality found favour, and Plato (Rep. 600 C) couples him with Protagoras in his testimony to the popularity of the sophists and their teaching.

At Athens, the centre of the intellectual life of Greece, there was soon to be found a host of sophists; some of them strangers, others citizens; some of them bred under Protagoras and Prodicus, others self-taught. In the teaching of the sophists of this younger generation two points are observable. First, their independence of philosophy and the arts being assured, though they continued to regard "civic excellence" as their aim, it was no longer necessary for them to make the assertion of its claims a principal element in their exposition. Secondly, for the sake of novelty they extended their range, including scientific and technical subjects, but handling them, and teaching their pupils to handle them. in a popular way. In this stage of sophistry then, the sophist, though not a specialist, trenched upon the provinces of specialists; and accordingly Plato (Prot. 318 E) makes Protagoras pointedly refer to sophists who, "when young men have made their escape from the arts, plunge them once more into technical study, and teach them such subjects as arithmetic, astronomy, geometry and music." The sophist of whom the Platonic Protagoras is here thinking was Hippias of Elis, who gave popular lectures, not only upon the four subjects just mentioned, but also upon grammar, mythology, family history, archaeology, Homerology and the education of youth. In this polymath we see at once the degradation of the sophistry of culture and the link which connects Protagoras and Prodicus with the eristics, who at a later period taught, not, like Hippias, all branches of learning, but a universally applicable method of disputation.

Meanwhile, Gorgias of Leontini, who, as has been seen, had studied and rejected the philosophy of western Greece, gave to sophistry a new direction by bringing to the mother country the technical study of rhetoric-especially forensic rhetoric (Plato, *Gorg.* 454 B; *cf.* Aristotle, *Rhet.* 1354, b 26)—which study had begun in Sicily with Corax and Tisias nearly forty years before. Gorgias was already advanced in years and rich in honours when, in 427, he visited Athens as the head of an embassy sent to solicit aid against Syracuse. Received with acclamation, he spent the rest of his long life in central Greece, winning applause by the display of his oratorical gifts and acquiring wealth by the teaching of rhetoric. There is no evidence to show that at any period of his life he called himself a sophist; and, as Plato (Gorg. 449 A) makes him describe himself as a ῥήτωρ, it is reasonable to suppose that he preferred that title. That he should do so was only natural, since his position as a teacher of rhetoric was already secure when Protagoras made his first appearance in the character of a sophist; and, as Protagoras, Prodicus and the rest of the sophists of culture offered a comprehensive education, of which oratory formed only a part, whilst Gorgias made no pretence of teaching "civic excellence" (Plato, *Meno,* 95 C), and found a substitute for philosophy, not in literature generally, but in the professional study of rhetoric alone, it would have been convenient if the distinction between sophistry and rhetoric had been maintained. But though, as will be seen hereafter, these two sorts of education were sometimes distinguished, Gorgias and those who succeeded him as teachers of rhetoric, such as Thrasymachus of Chalcedon and Polus of Agrigentum, were commonly called by the title which Protagoras had assumed and brought into familiar use.

Rhetorical sophistry, as taught by Gorgias with special reference to the requirements of the law courts, led by an easy transition to political sophistry. During the century which had elapsed since the expulsion of the Peisistratids and the establishment of the democracy, the Athenian constitution had developed with a rapidity which produced an oligarchical reaction, and the discussion of constitutional principles and precedents, always familiar to the citizen of Athens, was thus abnormally stimulated. The Peloponnesian War, too, not only added a deeper interest to ordinary questions of policy, but also caused the relations of dissentient parties, of allied and belligerent states, of citizens and aliens, of bond and free, of Greeks and barbarians, to be eagerly debated in the light of present experience. It was only natural then that some of those who professed to prepare young Athenians for public life should give to their teaching a distinctively political direction; and accordingly we find Isocrates recognizing teachers of politics, and discriminating them at once from those earlier sophists who gave popular instruction in the arts and from the contemporary eristics. To this class, that of the political sophists, may be assigned Lycophron, Alcidamas and Isocrates himself. For, though that celebrated personage would have liked to be called, not "sophist" but "political philosopher," and tried to fasten the name of "sophist" upon his opponents the Socratics, it is clear from his own statement that he was commonly ranked with the sophists, and that he had no claim, except on the score of superior popularity and success, to be dissociated from the other teachers of political rhetoric. It is true that he was not a political sophist of the vulgar type, that as a theorist he was honest and patriotic, and that, in addition to his fame as a teacher, he had a distinct reputation as a man of letters; but he was a professor of political rhetoric, and, as such, in the phraseology of the day, a sophist. He had already reached the height of his fame when Plato opened a rival school at the Academy, and pointedly attacked him in the Gorgias, the Phaedrus and the Republic. Thenceforward, there was a perpetual controversy between the rhetorician and the philosopher, and the struggle of educational systems continued until, in the next generation, the philosophers were left in possession of the field.

While the sophistry of rhetoric led to the sophistry of politics, the sophistry of culture led to the sophistry of disputation. It has been seen that the range of subjects recognized by Protagoras and Prodicus gradually extended itself, until Hippias professed himself a teacher of all branches of learning, including in his list subjects taught by artists and professional men, but handling them from a popular or non-professional point of view. The successors of the polymath claimed to possess and to communicate, not the knowledge of all branches of learning, but an aptitude for dealing with all subjects, which aptitude should make the knowledge of any subject superfluous. In other words, they cultivated skill in disputation. Now skill in disputation is plainly a valuable accomplishment; and, as the Aristotelian logic grew out of the regulated discussions of the eristics and their pupils, the disputant sophistry of the 4th century deserves more attention and more respect than it usually receives from historians of Greek thought. But when men set themselves to cultivate skill in disputation, regarding the matter discussed not as a serious issue, but as a thesis upon which to practise their powers of controversy, they learn to pursue, not truth, but victory; and, their criterion of excellence having been thus perverted, they presently prefer ingenious fallacy to solid reasoning and the applause of bystanders to the consciousness of honest effort. Indeed, the sophists generally had a special predisposition to error of this sort, not only because sophistry was from the beginning a substitute for the pursuit of truth, but also because the successful professor, travelling from city to city, or settling abroad, could take no part in public affairs, and thus was not at every step reminded of the importance of the "material" element of exposition and reasoning. Paradox, however, soon becomes stale, and fallacy wearisome. Hence, despite its original popularity, eristical sophistry could not hold its ground. The man of the world who had cultivated it in his youth regarded it in riper years as a foolish pedantry, or at best as a propaedeutic exercise; while the serious student, necessarily preferring that form of disputation which recognized truth as the end of this, as of other intellectual processes, betook himself to one or other of the philosophies of the revival.

In order to complete this sketch of the development of sophistry in the latter half of the 5th century and the earlier half of the 4th, it is necessary next to take account of Socrates and the Socratics. A foe to philosophy and a renegade from art, Socrates took his departure from the same point as Protagoras, and moved in the same direction, that of the education of youth. Finding in the cultivation of "virtue" or "excellence" a substitute for the pursuit of scientific truth, and in disputation the sole means by which "virtue" or "excellence" could be attained, he resembled at once the sophists of culture and the sophists of eristic. But, inasmuch as the "virtue" or "excellence" which he sought was that of the man rather than that of the official, while the disputation which he practised had for its aim, not victory, but the elimination of error, the differences which separated him from the sophists of culture and the sophists of eristic were only less considerable than the resemblances which he bore to both; and further, though his whole time and attention were bestowed upon the education of young Athenians, his theory of the relations of teacher and pupil differed from that of the recognized professors of education, inasmuch as the taking of fees seemed to him to entail a base surrender of the teacher's independence. The principal characteristics of Socrates's theory of education were accepted, *mutatis mutandis,* by the leading Socratics. With these resemblances to the contemporary professors of education, and with these differences, were Socrates and the Socratics sophists or not? To this question there is no simple answer, yes or no It is certain that Socrates's contemporaries regarded him as a sophist; and it was only reasonable that they should so regard him, because in opposition to the physicists of the past and the artists of the present he asserted the claims of higher education. But, though according to the phraseology of the time he was a sophist, he was not a typical sophist—his principle that, while scientific truth is unattainable by man, right opinion is the only basis of right action, clearly differentiating him from all the other professors of "virtue." Again, as the Socratics—Plato himself, when he established himself at the Academy, being no exception—were, like their master, educators rather than philosophers, and in their teaching laid especial stress upon discussion, they, too, were doubtless regarded as sophists, not by Isocrates only, but by their contemporaries in general; and it may be conjectured that the disputatious tendencies of the Megarian school made it all the more difficult for Plato and others to secure a proper appreciation of the difference between dialectic, or discussion with a view to the discovery of truth, and eristic, or discussion with a view to victory. Changing circumstances, however, carry with them changes in the meaning and application of words. Whereas, so long as philosophy was in abeyance Socrates and the Socratics were regarded as sophists of an abnormal sort, as soon as philosophy revived it was dimly perceived that, in so far as Socrates and the Socratics dissented from sophistry, they preserved the philosophical tradition. This being so, it was found convenient to revise the terminology of the past, and to include in the philosophical succession those who, though not philosophers, had cherished the sacred spark. As for Socrates, he ranked himself neither with the philosophers, who professed to know, nor with the sophists, who professed to teach; and, if he sometimes described himself as a *φιλόσοφος* he was careful to indicate that he pretended to no other knowledge than that of his own limitations.

It would seem then, (1) that popular nomenclature included under the term "sophist" all teachers—whether professors, or like Socrates, amateurs—who communicated, not artistic skill, nor philosophica! theory, but a general or liberal education; (2) that, of those who were commonly accounted sophists, some professed culture, some forensic rhetoric,-some political rhetoric, some eristic, some (*i.e.,* the Socratics) dialectic; (3) that the differences between the different groups of sophists were not inconsiderable, and that in particular the teaching of the rhetoricians was distinct in origin, and, in so far as its aim was success in a special walk of life, distinct in character, from the more general teaching of the sophists of culture, the eristics, and the dialecticians, while the teaching of the dialecticians was discriminated from that of the rest, in so far as the aim of the dialecticians was truth, or at least the bettering of opinion; and, consequently, (4) that, in awarding praise and blame to sophistry and its representatives, the distinctive characteristics of the groups above enumerated must be studiously kept in view.

Lapse of time and change of circumstances brought with them not merely changes in the subjects taught, but also changes in the popular estimate of sophistry and sophists. The first and most obvious sentiment which sophistry evoked was an enthusiastic and admiring interest. The sophist seemed to his youthful hearers to open a new field of intellectual activity and thereby to add a fresh zest to existence. But in proportion to the fascination which he exercised upon the young was the distrust which he inspired in their less pliable elders. Not only were they dismayed by the novelty of the sophistical teaching, but also they vaguely perceived that it was subversive of authority, of the authority of the parent over the child as well as of the authority of the state over the citizen. Of the two conflicting sentiments, the favour of the young, gaining as years passed away, naturally prevailed; sophistry ceased to be novel, and attendance in the lecture-rooms of the sophists came to be thought not less necessary for the youth than attendance in the elementary schools for the boy. The lively enthusiasm and the furious opposition which greeted Protagoras had now burnt themselves out, and before long the sophist was treated by the man of the world as a harmless, necessary pedagogue.

Relations of Sophistry to Education, Literature and Philosophy.—If then the sophists, from Protagoras to Isocrates, were before everything educators, it becomes necessary to inquire whether their labours marked or promoted an advance in educational theory and method. At the beginning of the 5th century B C. every young Greek of the better sort already received rudimentary instruction, not only in music and gymnastics, but also in reading and writing. Further, in the colonies, and especially the colonies of the West, philosophy and art had done something for higher education. Thus in Italy the Pythagorean school was, in the fullest sense of the term, an educational institution; and in Sicily the rhetorical teaching of Corax and Tisias was presumably educational in the same sense as the teaching of Gorgias. But in central Greece, where, at any rate down to the Persian Wars, politics, domestic and foreign, were all-engrossing, and left the citizen little leisure for self-cultivation, the need of a higher education had hardly made itself felt. The overthrow of the Persian invaders changed all this. Henceforward the best of Greek art, philosophy and literature gravitated to Athens, and with their concentration and consequent development came a general and growing demand for teaching. As has been seen, it was just at this period that philosophy and art ceased to be available for educational purposes, and accordingly the literary sophists were popular precisely because they offered advanced teaching which was neither philosophical nor artistic. Their recognition of the demand and their attempt to satisfy it are no small claims to distinction. That, whereas before the time of Protagoras there was little higher education in the colonies and less in central Greece, after his time attendance in the lecture-rooms of the sophists was the customary sequel to attendance in the elementary schools, is a fact which speaks for itself.

But this is not all The education provided by the sophists of culture had positive merits. When Protagoras included in his course, grammar, style, interpretation of the poets and oratory, supplementing his own continuous expositions by disputations in which he and his pupils took part, he showed a not inadequate appreciation of the requisites of a literary education; and it may be conjectured that his comprehensive programme, which Prodicus and others extended, had something to do with the development of that versatility which was the most notable element in the Athenian character.

There is less to be said for the teachers of rhetoric, politics and eristic, who, in limiting themselves each to a single subject—the rhetoricians proper or forensic rhetoricians to one branch of oratory, the politicians or political rhetoricians to another, and the eristics to disputation—ceased to be educators and became instructors. Nevertheless, rhetoric and disputation, though at the present day strangely neglected in English schools and universities, are, within their limits, valuable instruments; and, as specialization in teaching does not necessarily imply specialization in learning, many of those who attended the lectures and the classes of a rhetorician or an eristic sought and found other instruction elsewhere. It would seem then that even in its decline sophistry had its educational use. But in any case it may be claimed for its professors that in the course of a century they discovered and turned to account most of the instruments of literary education.

With these considerable merits, normal sophistry had one defect, its indifference to truth. Despairing of philosophy—that is to say, of physical science—the sophists were prepared to go all lengths in scepticism. Accordingly the epideictic sophists in exposition, and the argumentative sophists in debate, one and all, studied, not matter but style, not accuracy but effect, not proof but persuasion. In short, in their hostility to science they refused to handle literature in a scientific spirit. That this defect was serious was dimly apprehended even by those who frequented and admired the lectures of the earlier sophists; that it was fatal was clearly seen by Socrates, who, himself commonly regarded as a sophist, emphatically reprehended, not only the taking of fees, which was after all a mere incident. objectionable because it seemed to preclude independence of thought, but also the fundamental disregard of truth which infected every part and every phase of sophistical teaching. To these contemporary censures' the modern critic cannot refuse his assent.

To literature and to oratory the sophists rendered good service. Themselves of necessity stylists, because their professional success largely depended upon skilful and effective exposition, the sophists both of culture and of rhetoric were professedly teachers of the rules of grammar and the principles of written and spoken discourse. Thus, by example as well as by precept, they not only taught their hearers to value literary and oratorical excellence, but also took the lead in fashioning the style of their time. Their influence in these respects was weighty and important. Whereas, when sophistry began, prose composition was hardly practised in central Greece, the sophists were still the leaders in literature and oratory when Plato wrote the ***Republic,*** and they had hardly lost their position when Demosthenes delivered the ***Philippics.*** In fact, it is not too much to say that it was the sophists who provided those great masters with their consummate instrument, and it detracts but little from the merit of the makers if they were themselves unable to draw from it its finer tones.

The relation of sophistry to philosophy was throughout one of pronounced hostility. From the days of Protagoras, when this hostility was triumphant and contemptuous, to the days of Isocrates, when it was jealous and bitter, the sophists were declared and consistent sceptics. But, although Protagoras and Gorgias had examined the teaching of their predecessors so far as to satisfy themselves of its futility and to draw the sceptical inference, their study of the great problem of tlie day was preliminary to their sophistry rather than a part of it; and, as the overthrow of philosophy was complete and the attractions of sophistry were all-powerful, the question "What is knowledge?" ceased for a time to claim or to receive attention. There is, then, no such thing as a "sophistical theory of knowledge;)' Similarly, the recognition of a "sophistical ethic" is, to say the least, misleading. It may have been that the sophists' preference of seeming to reality, of success to truth, had a mischievous effect upon the morality of the time; but it is clear that they had no common theory of ethics, and there is no warrant for the assumption that a sophist, as such, specially interested himself in ethical questions. When Protagoras asserted "civic excellence" or "virtue" to be the end of education, he neither expressed nor implied a theory of morality. Prodicus in his platitudes reflected the customary morality of the time. Gorgias said plainly that he did not teach "virtue." If Hippias, Polus and Thrasymachus defied conventional morality, they did so independently of one another, and in this, as in other matters, they were disputants maintaining paradoxical theses, rather than thinkers announcing heretical convictions. The morality of Isocrates bore a certain resemblance to that of Socrates. In short, the attitude of the sophists towards inquiry in general precluded them, collectively and individually, from attachment to any particular theory. Yet among the so-called sophists there were two who had philosophical leanings, as appears in their willingness to be called by the title of philosopher. First, Socrates, whilst he conceived that the physicists had mistaken the field of inquiry, absolute truth being unattainable, maintained, as has been seen, that one opinion was better than another, and that consistency of opinion, resulting in consistency of action, was the end which the human intellect properly proposes to itself. Hence, though an agnostic, he was not unwilling to be called a philosopher, in so far as he pursued such truth as was attainable by man. Secondly, when sophistry had begun to fall into contempt, the political rhetorician Isocrates claimed for himself the time-honoured designation of philosopher, "herein," says Plato, "resembling some tinker, bald-pated and short of stature, who, having made money, knocks off his chains, goes to the bath, buys a new suit, and then takes advantage of the poverty and desolation of his master's daughter to urge upon her his odious addresses" (*Rep.* vi. 495 E). It will be seen, however, that neither Socrates nor Isocrates was philosopher in any strict sense of the word, the speculative aims of physicists and metaphysicians being foreign to the practical theories both of the one and of the other.

(H In.)

SOPHOCLES (497 or 495–406 B.C.), one of the three great Greek tragic poets, was born at Colonus, a village just outside Athens. The only ancient biography is a short anonymous account of unknown date, compiled from earlier biographies, and prefixed to most of the Sophoclean manuscripts—a mixture of bald fact, hypothesis and gossip. It can be supplemented from other ancient sources, but the result is meagre. All give a picture of a dignified, gracious and well-loved citizen who moved in good society and enjoyed the pleasures of life. His father, otherwise unknown, was Sophillus. perhaps a manufacturer of armour. He was wealthy and gave his son a good education: his master in music was Lamprus. the most distinguished musician of the day, and he is said to have studied tragedy (including no doubt musical composition and choreography) under Aeschylus. He was a beautiful boy, a good dancer, lyre player and wrestler. He was selected to lead a chorus of boys which performed a paean in celebration of the victory over the Persians at Salamis (480 B.C.). It is not known when he first competed in the dramatic festival; he gained his first victory in 468, defeating Aeschylus. This began a career of unparalleled success. An inscription of the 3rd century B.C credits him with 18 victories, the Suda lexicon (10th century A.D.) with 24, while the Life, citing a nriter of the 2nd century B.C., says that he won 20 first prizes, many second prizes and was never third. (The lowest of these figures may not have included victories won in the Lesser Dionysia.) Aeschylus won 13—but he died at the age of 68, and Sophocles nas still nriting at 90; Euripides won only three. Sophocles' most famous play Oedipus *Tyrannus* (Oedipzts Rex), brought him only the second prize: the prizes however were awarded not for single plays but for a tetralogy comprising three tragedies and one satyr play, and it may well be that the plays presented with the Oedipus were not first-rate. According to the Suda lexicon he wrote 123 plays—no unlikely number: it would correspond to about 30 trilogies in a productive career of 60 years, and in mere bulk would not much exceed Shakespeare's output. Of his minor poems nothing remains.

Unlike Euripides, he played a distinguished part in the public life of Athens. In 443–442 he was Hellenotamias (president of the board that collected the tribute from Athens' subject-allies in the Delian league; *q.v.*). In 440 he was elected one of the ten strategoi (military and naval commanders) in the war against the revolted Samians; his senior colleague was Pericles. The Argument to the *Antigone* attributed to the scholar Aristophanes of Byzantium says that Sophocles owed his election to the Impression created by the play. The statement can hardly have been more than a surmise; nevertheless it dates the Antigone. A story in Plutarch's Life of *Nicias* implies that Sophocles mas elected strategos a second time. The Life says that he served on embassies to foreign states, which is likely enough; also that he founded the Thiasos ton *Mouson* (which might be rendered "The Royal Society for Music and Literature," except that the patrons were the muses). Outliving Euripides (who was about 12 years his junior) by a fen months, he died just before the disastrous end of the Peloponnesian War. The Life of Euripides says: "Sophocles, hearing that Euripides nas dead, brought on his chorus and actors without their cronns. and himself put on mourning; and the people wept." Euripides had died at the court of Archelaus king of Macedon: Aeschylus also had died abroad (in 456 B.c.), in Sicily; it was gratefully remembered of Sophocles that he had remained in Athens. In 405 Aristophanes produced The Frogs, in which Aeschylus and Euripides contend for the throne of tragedy in Hades. with Sophocles sitting by, ready to take on Euripides if he should win (which he does not); Aeschylus himself had offered the throne to Sophocles, but he had declined it, "courteous in Hades, as he had been on earth."

WORKS

Of Sophocles' works, there remain seven complete tragedies, about 400 lines of a satyr play, the Ickneutai (*Ichneutae,* "The Investigators") discovered in Egypt in 1907 on a papyrus written in the second half of the 2nd century A.D. and several hundred fragments of plays now lost. The fragments vary in length from a single word, cited by a grammarian or a lexicographer, to passages of 12 or 15 verses. The seven complete plays derive from a selection made by a scholar unknown at a date unknown—perhaps in Alexandrian times, and perhaps for school use. All are works of Sophocles' maturity, though (apart from the Antigone, which must have been produced in 441 or 442) only one is dated by documentary evidence: the Philoctetes, 409 B C. Tradition, which there seems no good reason to disturb, makes *Oedipus Coloneus* a work of Sophocles' extreme old age; it is said to have been produced by his grandson. For dating the other plays we must depend on stylistic and metrical evidence—some of which is more hazardous with Sophocles than with, for example. Euripides. Sophocles' dramatic style was much more supple. and in some respects changes from minute to minute rather than from decade to decade. Contemporary allusions are also much rarer and more problematic than in. say, Euripides or Shakespeare. However, it is clear that the Ajax is the earliest of the seven; 447 ± 3 is a date that most scholars would accept. The Trachiniae was tentatively placed by R. C. Jebb between 420 and 410; later stylistic analysis places it much closer to the *Antigone*. For the remaining plays. Oedipus Rex and Electra, dates between 430 and 415 would be reasonable; the Electra seems to be the later of the two. The Ichneutae could be an early work, but the evidence available is not worth much.

Dramatic Style.—Ancient authorities credit Sophocles with dramatic innovations, most of them of minor importance. He invented *skenographia* (certainly not "scene painting." but probably some kind of device applied to the wall of the building at the back of the *orchestra*), and periactoi, which may have been revolving drums giving some indication of locale. The one major innovation—which, however, some authorities ascribe to Aeschylus—was the introduction of a third actor. It had always been permissible for the two actors to "double," but the addition of a third enabled the dramatist to increase the number of his characters, thereby making plot more fluid and situation more complex: Sophocles' finest scenes are those that involve the three actors at once, as for instance the messenger scene in the Electra (see below). Aeschylus in his later plays used the third actor to great effect, but in quite a different way, as when Cassandra is silent, though dramatically powerful, in the scene between Agamemnon and Clytemnestra. The differenceis that the typical Aeschylean plot is linear; the Sophoclean, complexive. In the Ovcsteia, for example. Agamemnon takes vengeance on Paris. Clytemnestra on Agamemnon and on Cassandra. and Aegisthus on Agamemnon; Orestes avenges his father upon Clytemnestra and Aegisthus, and then has to contend with the avenging spirits of his mother. In such a drama characters collide rather than struggle with each other; they destroy, and are destroyed, in accordance with cosmic, and evolving, conceptions of retribution. There is little personal interplay; the characters are impressive in size and power, and therefore are not drawn in detail. The typical Sophoclean tragic action is one that is seen, as it were, not through the telescope but by the natural vision, though a vision that is assisted, and controlled, by the pervasive presence of gods. The chief agent does something involving grave error; this affects others, each of whom reacts in his own way, and thereby. perhaps, causes the chief agent to take another step toward ruin—his own, and that of others as well. The characters do struggle with each other; therefore they must be drawn in more detail. Peripheral figures too become involved in the central issue; plot must be more complex—though Sophocles avoids anything like subplot or decorative additions; the economy and concentration shown by his plays are most remarkable. This more complexive tragedy demanded a third actor. Equally, those who were to suffer from the tragic error were none of them of the next generation; all were present at the time. Therefore Sophocles abandoned the spacious Aeschylean framework of the connected trilogy; all was comprised within the single play. From then on, with very rare exceptions, "trilogy" meant no more than three separate tragedies presented at the same festival.

The development of character and plot naturally increased the histrionic and decreased the lyrical element in drama. Counting by lines, slightly more than one-half of the *Agamemnon* is either sung or chanted; of the Antigone, less than one-third, though this play is by far the most lyrical of the seven. But the chorus is still integral. No one formula can sum up its functions. As Aristotle remarked, in Sophocles the chorus is "a fellow actor"; therefore it will often share the illusions of other actors in the piece. as it does for instance in the Arttigone and *Ajax,* where it takes, more or less, the point of view of Creon and Ajax respectively—that is. the wrong one. Sometimes it becomes the "ideal spectator," making philosophic comment (as in the solemn third ode of Oedipus Rex); sometimes it is a purely lyrical instrument, giving release from the tragic tension through the beauty of its dance and music.

Some of the odes, *e.g.,* the one just mentioned, or the second, third or sixth of the *Antigone,* place Sophocles in the front rank of Greek lyric poets. Of the music that he wrote nothing is known; about the choric dances this much can be inferred from their metres, that they must have been conceived in a very plastic fashion. As for the style of the spoken verse, it is reminiscent of Shakespeare's, responding directly to the dramatic needs of the moment; it is as far as possible from being a standard, uniform style, like Euripides'. It will be weighty or swift. intense or easy-going. highly-wrought or perfectly plain. It is no accident that Aristophanes. who parodied Euripides' and Aeschylus' style. left Sophocles' alone.

His Tragic Thought.—Sophocles has been universally admired for the sympathy and vividness with which he draws characters; especially notable are his tragic women: Electra, Antigone, Deianeira. Tecmessa and others. Also. few dramatists have been able to handle situation and plot with more power and certainty; the frequent references in the Poetics to *Oedipus* Rex show that Aristotle regarded this play as a masterpiece of construction, and few later critics have dissented. Further, he is unsurpassed in his moments of high tragic tension, and in his revealing use of tragic irony. In other respects there has been some tendency to compare him unfavourably with Aeschylus and Euripides: Sophocles. it has been said, was a supreme artist and no more: he grappled neither with religious problems like Aeschylus nor with intellectual and social ones like Euripides; he accepted the gods of Greek religion in a spirit of unreflecting orthodoxy. and contented himself with presenting human characters and human conflicts. Further, two of his plays. Ajax and *The Trachiniae,* have been adversely criticized in precisely that aspect of his art for which, elsewhere, he has been so much admired, namely in their structure: for though the Ajax seems to reach its natural conclusion in the suicide of the hero, the play continues with several scenes that concern the burial of his body; while in The *Trachiniae,* if Deianeira is the central character, she too kills herself two-thirds of the way through and is subsequently hardly mentioned, while if Heracles is taken to be the hero. he does not even appear until his wife is already dead, when he himself also is on the point of death. For the "lack of unity" in the Ajax several inorganic explanations have been offered, the most naïve of which is that Sophocles was running short of material; about The Trachiniae the worst that can be said is that he simply combined two personal tragedies into one play.

The source of these misconceptions is the same. Sophocles did not write tragedies of character about individuals, but tragic drama about Man and the Gods; the religious element in his plays is not orthodoxy, not something added, out of personal piety, to a humanistic drama already complete; it is his presentation of the way in ahich the universe works—and it is worthy of attention. This is the reason why his gods are so stern. sometimes baffling, rarely benevolent; and the reason why he does not criticize them is that there is not much point in grumbling at the universe. Further, he did not, like Aeschylus and Euripides, make statements about his religious ideas: his thought is made implicit in the structure of the plays, and if his most telling strokes are considered only as examples of theatrical virtuosity, naturally the thought disappears.

Electra.—Two scenes from the *Electra* illustrate the fusion of his thought with his art. It is easy to dismiss the messenger scene as being no more than a clever piece of stagecraft. Clytemnestra has been terrified by a dream portending that her son Orestes will return from exile to avenge his father upon her and her accomplice Aegisthus and to reverse their usurpation. She comes out from the palace; she offers prayer and sacrifice to Apollo that he will avert the omen of the dream, divert it upon her enemies (meaning Orestes and Electra her daughter). frustrate them and preserve for her nhat her murder and adultery have won. She has only just finished the sacred rite when there enters, unrecognized, Orestes' old servant with a story—prearranged by Orestes—that Orestes is dead: it is designed to throw Agamemnon's murderers off their guard. The story of his supposed death in a chariot race at Delphi is itself a brilliant narrative; the situation enhances it, for it is being told to the mother who finds her own deliverance through the death of her son, and to the sister who finds in it the ruin of all her life; the messenger's preoccupation is so to deceive Clytemnestra that he may be invited into the palace to make ready for Orestes' coming. But this is by no means all, for an audience that believed in Sophocles' gods—being in any case assured already, through the chorus, that Zeus will bring the avenger home to triumph. and that retribution follows crime—would see in the arrival of the messenger. directly after the blasphemous prayer, the god's devastating answer to it. So it is too with the coup de thkatre in which the play ends. Clytemnestra has summoned Aegisthus from the countryside to hear the glad news. He enters, arrogant, secure at last from any threat of vengeance. He orders those who have brought the body to bring it out and display it publicly. "Here lies one," he says, "struck down by the anger of the gods." He is right; he draws back the shroud. and finds himself looking at the face of his dead wife. Whereupon Orestes drives him in to die on the spot where he had murdered Agamemnon. So do the gods work; crime breeds its onn recoil.

It is the interfusion of divine and human action that gives to Sophocles' character drawing its deep significance. Electra is seen. for example, passing through the whole range of human emotion—from passionate love to cruel hatred, from numb despair to wild joy: the audience sees, in some detail. how her daily life with the murderers has entered like iron into her soul; she can live for nothing but vengeance and liberty. Orestes too, living on charity in exile, needs, and receives, no divine prompting: he asks Apollo not whether to do it but how to do it; however the god, though he approves. does not help. Sophocles is showing not that the gods from afar intervene to punish crime, but that the retribution comes in the natural order of things.

Alztigone and *Trachiniae.*—In the *Antigone* the prophet warns Creon that all the gods are angry at what he has done and that their Avengers are lying in wait for him. What the prophet threatens comes to pass. not through "divine intervention" but through the instinctive reactions against Creon of Xntigone, Haemon his son and Eurydice his wife. It is not the personal conflict between Antigone and Creon. great though it is, that is the deepest conflict in the play, but the conflict between Creon and the gods. He, for what he thought good reasons, ordained that the body of Antigone's traitor brother should not receive burial, the last tribute that humanity pays to humanity, but should be eaten by animals; Antigone rising in total rebellion, obeying all her instincts of love, loyalty and humanity, is indeed obeying "the unwritten and unchanging laws of the gods"; Creon is defying them, and they crush him. Individual characters and personal conflicts are in no way diminished or obscured by being set in this universal framework; on the contrary, they preserve to the full their own particular sharpness, and receive the added significance of being made universals.

The *Trachiniae* becomes unintelligible in structure only when we reduce it (perhaps under the influence of Aristotle) to personal dimensions Sophocles makes it quite clear what the scope of the play is. At the beginning, Heracles' patient and understanding wife is distracted with anxiety at the ominously long absence of her husband. Reassuring her, the chorus observes that in human life joy and sorrow alternate like day and night; they follow the same universal rhythm. Therefore, having known little but sorrow, she may now expect joy. Moreover, Heracles is a son of Zeus, and Zeus does not neglect his offspring. But at the end of the play. she is dead and he is dying—ravaged by the "shirt of Nessus" that she had innocently sent him, to charm back his love—and their son Hyllus cries out upon the cruelty of the gods. who have brought this to pass. But the play has made it clear why, in this case, the universal rhythm broke down: to get a young girl for his mistress, in utter disregard of his wife. Heracles has destroyed a city. killing all the men and enslaving the women. This hubris is followed by a second, when he sends the girl to live in Deianeira's house. Deianeira was certainly simple-minded in trusting to a supposed love charm given her by an enemy of Heracles; Sophocles' point however is that ignorance is an inescapable part of the human condition: later, he makes Hyllus curse his mother, in his ignorance, for a vindictive murderess, and then repent bitterly nhen he learns the truth. Life at its best is a precarious affair, but it was the reckless violence of Heracles, acting within this precarious framework, not the cruelty of the gods, that brought all down in ruin.

Ajax and Oedipus Rex.—The hero of the Ajax is like Shakespeare's *Coriolanus:* he is a magnificent fighting man, a great bulwark of the commonwealth, who yet ruins all through an insensate pride that drives him into treachery and crime, and so to suicide. If this were all, there would be no need of the final scenes; but in these, too. Sophocles draws attention to the human condition and the demands it makes. Twice already has the arrogance of Ajax affronted the gods; now, when the prize of valour has been adjudged not to himself but to his enemy Odysseus, his instant response is to murder the judges, his commanders. In this he is frustrated by Athena, who visits him with an attack of madness. so that he kills sheep instead. Athena—no gracious Madonna—points to the humiliated Ajax and invites Odysseus to exult over him: "You see how strong the gods are!" But he, unlike Menelaus later, will do no such thing: "I pity him in his ruin, for I see that Man is nothing but an empty shadow. Therefore" says Athena "shun pride; it is the prudent that the gods cherish." Nemesis comes to the great Ajax when he falls on his own sword: has lacked understanding of the way in which Man must live. also do the two kings, when they order that his body shall be g out to the animals—Menelaus, out of mean vindictiveness; memnon, to vindicate discipline. But this is no way in which ma should treat man. Once more it is Odysseus who shows understanding: no man, he says to Agamemnon, is always loyal and good; we must remember benefits and forget injuries. Any man may some time stand in need of forgiveness. Death is the common lot, and it must be respected. Agamemnon yields. but only as a favour to Odysseus, and Ajax's brother will not allow Odysseus to have any share in the funeral rite, fearing the anger of Ajax's spirit; so that Odysseus reluctantly departs. the only one in the play who understands the human condition and shows true reverence towards the gods.

In the *Oedipus Rex,* the most famous of the seven plays, the scene of discovery, between Oedipus and the two shepherds—only 86 verses long—is surely among the most tense in all dramatic literature. The play is sometimes described as a tragedy of blind, inexorable Fate before which human efforts. even human virtue, are of no avail. This interpretation, would, however, contradict the whole trend of Sophocles' work, and in particular the third ode in this play. Sophocles insists always on the necessity for reverence, purity, moderation—though, being a tragic poet, he never pretends that these virtues mill ensure security. One of the many tragic moments in the play is when Jocasta. jubilant before she learns the truth. proclaims that since life is random it is best to abandon principle and live from hand to mouth. The unifying thought in the play seems to be that since not even the greatest and most intelligent of us can control things, we should avoid the self-confidence that disregards religious restraints and leads straight to disaster.

Philoctetes and Oedipus Coloneus.—The *Philoctetes* concerns Neoptolemus the honourable but inexperienced son of Achilles who, on a clever plea of harsh political necessity, reluctantly undertakes a repulsive crime, only to find that it is much more repulsive than he had foreseen and also completely useless. The shifting relationship between him and his intended victim and Odysseus (who in this play is a plausible rogue) is presented with the utmost delicacy and vividness; also, in the background is the suggestion that the Greek commanders themselves, by their past inhumanity toward Philoctetes. have caused their present frustration, from which they are trying to escape by even worse inhumanity.

The last play. *Oedipus Coloneus,* is also the most imaginative, and is surpassed by none in the power and beauty of its poetry. Oedipus, now old, blind, an outcast, his very name a source of horror, is summoned by the god to his final resting place at Colonus, and becomes, in his death, a mysterious source of defense to the land that has given him refuge.

The Satyr Play.—The *Ichneutae* is based on two stories about the miraculous birth of the god Hermes: that the infant, growing to maturity in a few days, stole cattle from Apollo, baffling discovery by reversing the animals' hoof marks, and that he invented the lyre by fitting strings to a tortoise shell. In this incompletely recovered play the investigators are the chorus of Satyrs, who are looking for the cattle; they are amusingly dumbfounded at the sound of the new instrument. Enough of the play survives to give an impression of its style: it is a genial, uncomplicated travesty of the tragic manner; the antics of the chorus were apparently the chief source of fun. It escapes from the intensity of tragedy into a world in which myth is taken quite literally, for the sake of relaxation and amusement—a very suitable conclusion to a day in the theatre, most of which had been occupied by the strenuousness of three tragedies.

Bibliography.—On the manuscripts the standard work is A. Turyn, *Studies in the Manuscript Tradition of the Tragedies of Sophocles* (1952). The text of the seven plays was edited by R. C. Jebb (1897) and by A. C. Pearson, Oxford classical texts (1924). Of the commentaries, the best and fullest are those of R. C. Jebb, 7 vol. (1889–1914), each giving with the text an introduction, commentary and translation, supplemented by A. C. Pearson's three similar volumes on the fragments (1917). Jebb's translations, though archaic in style, are iaithful. The Budé text is edited, with introductions, by A. Dain, with French translation by P. Mazon (1950–). *Oedipus Tyrannus* has been edited by J. T. Sheppard with explanation and translation (1920). *See* also J. C. Kamerbeek, *Plays of Sophocles* (1953–1959).

SOPHRQN of Syracuse (fl. c. 430 B.C.), was the author of rhythmical prose mimes in the Doric dialect. Although the mimes survive mostly in fragments of only a few words, it can be seen from their titles, *e.g., The Tunny-fisher, The Sempstress,* etc., that they depicted scenes from daily life. One longer fragment deals with a magical ceremony. Plato thought highly of Sophron, who had some influence on Theocritus and also on Herodas.

For fragments *see* G. Kaibel (ed.), *Comicorum Graecorum fragmenta,* pp. 152–181 (1899); and for the longer fragment *see* D. L. Page (ed.), *Greek Literary Papyri,* "Loeb Series," 2nd ed., vol. 1, pp. 328–331 (1942). (E. A. B.)

SOPRANO (a variant of Ital. *sovrano,* supreme, sovereign), in music, the highest human voice, the term being often restricted to that range in the female voice, "treble" being used of a boy's voice. Male *soprani,* either natural or artificially produced, as formerly in the *castrati* of the papal choirs (*see* Eunuch), are also found.

SOPRON (German *Ödenburg*), a town of Gyor-Sopron, Hungary, on an important route from Transdanubia to Vienna through the so-called "Odenburg Gate" between the Leitha and Rosalien mountains. Through this gap German forms of culture penetrated and Sopron has in part the appearance of a west European town. The critical site has been continuously occupied since pre-Roman times, a Roman colony, *Scarabantia,* having existed there, and has a wealth of old buildings, notably the 13th-century Benedictine church, the 15th-century church of St. Michael in Gothic style and the 17th-century Dominican church. Pop. (1930) 35,895, about 50% German; (1957 est.) mun., 37,000.

SOPWITH, SIR THOMAS OCTAVE MURDOCH (1888–), British aircraft designer and well-known yachtsman. was born in London, Jan. 18, 1888. He taught himself to fly in 1910 and in that year won the de Forest prize for the longest flight to the continent. In 1912 he founded Sopwith Aviation Co., Ltd.. at Kingston-on-Thames and, flying a Blériot monoplane. won the first aerial Derby. In 1914 he designed and built the seaplane that won the Schneider trophy. During World War I his firm produced many military aircraft, including the "Pup," "Camel," "1½-strutter" and "triplane." Sopwith was chairman of the Society of British Aircraft Constructors, 1925–27. In 1935 he became chairman of the Hawker Siddeley Group, Ltd., which during World War II built the Hurricane fighter and the Lancaster bomber. They also built the first British jet aircraft, the Gloster E 28139, powered by the Whittle engine (see Whittle, SIR FRANK). Between the wars Sopwith raced such yachts as "Shamrock V" and "Endeavour II." (D. CR.)

SORACTE, a mountain in the province of Roma, Italy. It is a narrow, isolated limestone ridge, about 5 mi. S.E. of Civita Castellana, and $3\frac{1}{2}$ mi. in length. The highest summit is 2,267 ft. above sea level; just below is a monastery originally founded about 748 by Carloman, son of Charles Martel (the altar has fragments of sculptures of this period).

Owing to the isolated position of the mountain the view is magnificent, and Soracte is a conspicuous object in the landscape, being visible from Rome.

SORANUS (fl. 2nd century A.D.), Greek physician, born at Ephesus, lived during the reigns of Trajan and Hadrian. According to Suidas, he practised in Alexandria and subsequently in Rome. He was the chief representative of the school of physicians known as "methodists." Two treatises by him are extant: *On Fractures* (in J. L. Ideler. *Physici et medici minores,* i, 1841) and On *Midwifery and the Diseases of Women* (first printed in 1838, later by V. Rose in 1882, with a 6th-century Latin translation by Moschio). The uork of Soranus on midwifery was the source of many works on obstetrics; the book also contains a chapter on the care and feeding of infants. Of Soranus' most important work, *On Acute and Chronic Diseases,* only a few fragments in Greek remain, but there exists a complete 5th-century Latin translation by Caelius Aurelianus. The *Life of Hippocrates* (in the work cited, by Ideler) probably formed one of the collection of medical biographies by Soranus referred to by Suidas, and is valuable as the only authority for the life of the great physician, with the exception of articles in Suidas and Stephanus of Byzantium.

SORANUS, an underworld deity worshiped in antiquity on Mt. Soracte, in Etruria north of Rome. Traditionally the Hirpini (*q.v.*) got their name from the fact that once as they worshiped Soranus, wolves (*hirpi*) carried off the sacrificial entrails (Servius, *ad Aenezd,* xi. 785). As priests the *hirpi* (or *hirpini*) *Sorani* celebrated a rite in uhich they marched over burning coals barefooted (Pliny, *Natural Hzstory,* vii, 2, 19). Soranus mas identified with Dis and Apollo (*q.v.*) and had a female partner. Feronia. (R. B. LD.)

SORBONNE: *see* PARIS UNIVERSITY.

SORBS or LUSATIAN SERBS, a Slavonic-language-speaking people in eastern Germany. in Upper and Lower Lusatia (Lausitz), with the towns of Bautzen (Budysin) and Kottbuss (Chocebuz) respectively as their main cultural centres. They occupy roughly an area between Dresden in the west, the Polish frontier in the east. Czechoslovakia in the south and Liibben in the north. The Germans call them *Wenden* or *Sorben;* they call themselves *Srbi* (plural of *Srb*). There are about 150,000 Sorbs (1952 est.), *i.e.,* 20% of the present population in mixed German-Lusatian districts. They speak Lusatian, also known as Wendish and Sorbic, a west Slavonic language going through a process of consolidation and fusion of its two main forms, of which Lower Lusatian is nearer to Polish and Upper Lusatian to Czech. The religion of 90% is Lutheran.

See also LUSATIA.

See: E. Muka, *Slownik dolnjoserbskeje rěcy a jěje narecow* (1911–26), a vocabulary of Lower Lusatian language and its dialects; J. Jatzwauk, *Wendische (Sorbische) Bibliographie* (1952). (E. HL.)

SORBUS, a genus of the rose family consisting of ornamental woody plants, commonly known as mountain ash, grown for their attractive foliage, showy white flowers and handsome clustered unusually red fruit. By some authors the genus is treated as subgenus under *Pyrus*. *See* MOUNTAIN ASH. (J. M. BL.)

SORBY, HENRY CLIFTON (1826–1908), English pioneer petrographer and microscopist, was born at Woodbourne near Sheffield, on May 10, 1826. His first paper, on sulfur and phosphorus in agricultural crops. was published in 1847. An early paper dealing with the origin of valleys in Yorkshire was followed by others on the physical geography of geological periods, rock denudation and deposition and the formation of river terraces.

In 1849 Sorby began to prepare thin sections of rocks for study under the microscope, thus founding the science of petrography. In 1857 he proved that slaty cleavage was produced by lateral pressure which caused the rearrangement of particles in shaly rocks. His memoir "On the Microscopical Structure of Crystals," published in 1858 in the *Quarterly Journal of the Geological Soczety of London,* made a strong plea for the adoption of microscopic methods in geology and illustrated their value.

In 1865 Sorby announced a new type of spectrum microscope to be used in study of organic pigments, and especially in determination of minute bloodstains. He studied the metallography of iron and steel, concluding that the latter was a crystallized igneous rock, and did related aork of industrial value. His later geologic studies dealt with, among other subjects, the origin of limestones and other stratified rocks, and weathering. His publications in these various fields number 240. He died in Sheffield on March 9. 1908. (C. L. FE.; M. A. F.)
