The Nirmalas were not quite re-Hinduized but the general tendency of the Sikh laity was towards emergence into Brahmanism. Only the more ardent followers of Govind Singh preserved their distinctive tenets, dress, and protestant, anti-Brahmanical attitude. Thus ended the first phase of the Sikh revival. The second phase was greatly fostered if not initiated by the formstion of the Imperial Service troops. The Sikh recruits in the Phulkian states, south of the Sutlej, had often neglected to take the *pahul.* They were encouraged to do so by their British inspecting officers, and the military spirit of Sikhism was enhanced. With its revival came an awakened interest in other things. The Sikhs, even the stricter elements, had acquiesced in the decay of their religious institutions. In 1863 the British Government had by statute divested itself of all administrative control over religious endowments, but had provided no machinery to assume its functions. The SIKH orders had no written constitutions. Such an order as the Udāsi was in theory celibate. It proceeded to permit its members to marry, to found families of great respectability and influence, who were accepted as owners of the religious shrines and wealthy refectories, and administered them as private properties—on the Brahmanical model. But Brahmanism allows no lay interference with Brahman property.

Orders.—The humbler village fanes were equally appropriated by their incumbents, who naturally favoured the fatal principle **of** hereditary rights in them. The Kūka headship became a kind of dynasty. The Akalis alone retained celibacy, but even the Nirmalas failed to enforce it rigidly. But celibate or not, no order evolved any definite system of selecting its heads. The powers of the abbots, of the chapter and of the congregation were undefined. If, then, the glebe was alienated by a dissolute incumbent, or endowments mis-spent by incompetent abbots, the sole remedy for the laity was a suit in the courts, which begged the whole question of the layman's right to ask for relief by treating the priestly rights in the shrine as a matter of custom—of custom recently created by priestly malfeasance. Ignoring the fundamental doctrines of Sikhism in general and of its orders in particular, the courts proceeded to give legal recognition to the vested interests of the carnal heirs of spiritual offices in their benefices. This led to grave unrest among the Sikhs. Even the administration of the Khālsa college, founded under British auspices, had to be remodelled. The golden temple at Amritsar, being a purely religious foundation, was, however, beyond Government control. Internal dissensions made its problems difficult of solution. Its governing body had long been divided, one party permitting its walls to be adorned with Hindu mythological pictures, another condemning them as incompatible with Sikh monotheism. The Sikhs at a mass meeting accepted a provisional council, only in part nominated by Government, to draw up a scheme of management. But it failed to function. In 1920 the Mahātma Gandhi intervened, suggesting the appointment of the Shiromani Gurūdwāra Parbandhak committee for the management of shrines in general. This body proceeded at once to the high-handed seizure of places of worship, including the golden temple itself. It also reorganized the Akālis, recruiting them with lawless *jathas,* gangs of turbulent elements not all furnished by the Sikhs. It called on the Udāsi *mahant* or "abbot" of Gurū Nānak's birthplace, Nānkāna, to reform his institution. In defence of his property the Gurū enlisted Muslim mercenaries and so exacerbated Sikh feeling. A body of 130 Sikhs seized the sanctuary but were massacred to a man. Equally lawless seizures of shrines ensued. At Gurū kā Bāgh, the "Gurū's Garden," the Akālis captured the Gurūdwāra or fane of the Gurū, but the *mahant* held its house and lands. The committee took steps to seize some of the latter as appurtenant to the shrine, but the law was here successfully vindicated and no fewer than 5,000 Akalis arrested. In reprisal, the Akali order threw off a new and more militant offshoot in the Babbar ("lion") Akālis dedicated to the murder of village officials and others loyal to Government but in their isolation beyond its effectual protection. The tract between the Sutlej and Biās rivers was terrorized by Akāli and other lawless gangs, marked men being openly assassinated and property indiscriminately plundered Soldiery alone secured a semblance of order. Yet in 1923, when communal riots between Hindus and Muslims broke out at Amritsar the Akālis aided authority to maintain order. In 1924, however, the shrines committee espoused the cause of the misguided Maháràja of Nābha, who abdicated after levying private war on the sister Sikh state of Patiāla, and at Jaitoke a meeting of the new ruler's opponents had to be dispersed. The Akālis came to the rising, but their peaceful purpose was merely the perpetual recitation of the *Granth* for the restoration of the ex-Raja. Unfortunately they were reinforced by a huge mob which attacked the State forces. It was beaten off with a loss of 50 men, including 21 killed and only three or four Akālis fell. In 1925 the Sikh Gurūdwāra and Shrines bill became law. It set up legal machinery for the control of Sikh endowments, and if it is alleged to be unjust to the Sikh orders, it must be pleaded that the failure of those orders, even of the Udāsis, to organize their own self-discipline and protect the rights of the Sikh congregations made it a necessity The disruptions in the Udāsi order made it impossible to give legal embodiment to it or to anyone of its branches

SIKH WARS, two Indian campaigns fought between the Sikhs and the British, which resulted in the conquest and annexation of the Punjab (see Punjab).

FIRST SIKH WAR (1845–46)

The first Sikh War, or Sutlej campaign, was brought about by the insubordination of the Sikh army, which after the death of Ranjit Singh became uncontrollable and on Dec. 11, 1845, crossed the Sutlej, and virtually declared war upon the British. The British authorities had foreseen the outbreak, and had massed sufficient troops at Ferozepore, Ludhiana and Umballa to protect the frontier, but not to offer provocation. So complete were the preparations for advance that on the 12th, the day after the Sikhs crossed the Sutlej, Sir Hugh Gough, the commander-in-chief, marched 16m. with the Umballa force to Rajpura; on the 13th the governor-general, Sir Henry Hardinge, declared war, and by the 18th the whole army had marched 150m. to Moodkee, in order to protect Ferozepore from the Sikh attack. The Sikh army is referred to for brevity as "the Sikhs," but it was composed of Sikhs, Punjabi Muslims and Hindus, as are the present Sikh regiments of the Indian army. Gurkha, Hindostani and Afghan mercenaries were also found in the ranks.

Wearied with their long march, the British troops were enjoying a rest, when the news came in that the Sikhs were advancing to battle at four o'clock in the afternoon. The British had some 10,000 men, and the Sikhs are estimated by some authorities as low as 10,000 infantry with 2,000 cavalry and 22 guns. The battle opened with an artillery duel, in which the British guns, though inferior in weight, soon silenced the enemy, the 3rd Light Dragoons delivered a brilliant charge, and the infantry drove the enemy from position after position with great slaughter and the loss of seventeen guns. The victory was complete, but the fall of night prevented it from being followed up, and caused some of the native regiments to fire into each other in the confusion.

Ferozeshah.—After the battle of Moodkee Hardinge volunteered to serve as second in command under Gough, a step which caused some confusion in the ensuing battle. At 4 A M. on Dec. 21 the British advanced from Moodkee to attack the Sikh entrenched camp under the command of Lal Singh at Ferozeshah, orders having been sent to Sir John Littler, in command at Ferozepore, to join the main British force. At 11 A.M. the British were in front of the Sikh position, but Littler though on his way had not yet arrived. Gough wished to attack while there was plenty of daylight; but Hardinge re-asserted his civil authority as governor-general, and forbade the attack until the junction with Littler was effected. The army then marched on to meet Littler and the battle did not begin until between 3.30 and 4 P.M. The engagement opened with an artillery duel, in which the British failed to gain the mastery over the Sikhs, owing to the light weight of the British ordnance. The infantry, therefore, advanced to the attack; but the Sikh muskets were as good as the British, and fighting behind entrenchments they were a most formidable foe. Littler's attack was repulsed, the 62nd Regiment losing heavily in officers and men, while the sepoys failed to support the European regiments. But the Moodkee force, undaunted, stormed and captured the entrenchment. though the different brigades and regiments lost position and became mixed up together in the darkness. The army then passed the night on the Sikh position, while the Sikhs prowled round keeping up an incessant fire. In the morning the British found that they had captured seventy-three pieces of cannon and were masters of the whole field; but at that moment a fresh Sikh army, under Tej Singh, came up to the assistance of the scattered forces of Lal Singh. The British were exhausted with their sleepless night, the native troops were shaken, and a determined attack by this fresh army might have won the day; but Tej Singh, after a half-hearted attack, uhich was repulsed, marched away, whether from cowardice, incapacity or treason. and left the British masters of the position.

Aliwal.—After the battle of Ferozeshah the Sikhs retired behind the Sutlej, but early in January they again raided across the river near Ludhiana, and Sir Harry Smith was detached to protect that city. On Jan. 21 he was approaching Ludhiana when he found the Sikhs under Runjoor Singh in an entrenched position flanking his line of march at Budhowal. He passed on without fighting a general action, but suffered considerable loss in men and baggage. After receiving reinforcements Sir Harry again advanced from Ludhiana and attacked the Sikhs at Aliwal on Jan. 28. An attack upon the Sikh left near the village of Aliwal gave him the key of the position, and a brilliant charge by the 16th Lancers, which broke the Sikh square, completed their demoralization. The Sikhs fled in confusion, losing sixty-seven guns, and by this battle were expelled from the south side of the Sutlej.

Sobraon. — Ever since Ferozeshah Gough had been waiting to receive reinforcements, and on Feb. 7, his siege train arrived, while on the follo ing day Sir Harry Smith's force returned to camp. On Feb. 10 Gough attacked the Sikhs, who occupied a strong entrenched position in a bend of the Sutlej. After two hours cannonading, the infantry attack commenced at 9 A.M. The advance of the first brigade was not immediately successful but the second brigade following on carried the entrenchments. The cavalry then charged down the Sikh lines from right to left and completed the victory. The Sikhs, with the river behind them, suffered terrible carnage, and are computed to have lost 10,000 men and 67 guns. The British losses throughout the campaign were considerably heavier than was usual in Indian warfare; but this was partly due to the fact that the Sikhs were the best natural fighters in India, and partly to the lack of energy of the Hindostani sepoys. After the battle of Sobraon the British advanced to Lahore, where the treaty of Lahore was signed on March 11.

SECOND SIKH WAR—PUNJAB CAMPAIGN 1848–49

For two years after the battle of Sobraon the Punjab remained a British protectorate, with Sir Henry Lawrence as resident; but the Sikhs were unconvinced of their military inferiority, the Rani Jindan and her ministers were constantly intriguing to recover their power, and a further trial of strength was inevitable. The outbreak came at Multan, where on April 20, 1848, the troops of the Dewan Mulraj broke out and attacked two British officers, Mr. Vans Agnew and Lieutenant Anderson, eventually murdering them. On hearing of the incident, Lieut. Herbert Edwardes, who was Lawrence's assistant in the Derajat, advanced upon Multan with a force of levies drawn from the Pathan tribes of the frontier; but he was not strong enough to do more than keep the enemy in check until Multan was invested by a Bombay column under General Whish. In the meantime Edwardes wished for an immediate British advance upon Multan; but Lord Gough, as he had now become, decided on a cold season campaign, on the ground that, if the Sikh government at Lahore joined in the rising, the British would require all their available strength to suppress it. Multan was invested on Aug. 18 by Whish in conjunction with the Sikh general Shere Singh; but during the course of the siege Shere Singh deserted and joined the rebels, thus turning the rising into a national war. The siege of Multan was temporarily abandoned, but was resumed in November, when Gough's main advance had begun. and Mulraj surrendered on Jan. 22. In the meantime Gough had collected his army and stores, and on Nov. 9, crossed the Sutlej.

Chillianwalla.—On Nov. 22 there was a cavalry skirmish at Ramnagar, in which General Cureton and Colonel Havelock were killed. For a month after this Gough remained inactive, waiting to be reinforced by Whish from Multan; but at last he decided to advance without Whish, and fought the battle of Chillianwalla on Jan. 13, 1849. Gough had intended to encamp for the night; but the Sikh guns openipg fire revealed the fact that their army had advanced out of its intrenchments, and Gough decided to seize the opportunity and attack at once. An hour's artillery duel showed that the Sikhs had the advantage both in position and guns, and the infantry advance commenced at three o'clock in the afternoon. The battle resulted in great loss to the European regiments, the 24th losing all its officers in a few minutes, while the total loss in killed and wounded amounted to 2,338; but when darkness fell the British were in possession of the whole of the Sikh line. Gough subsequently retired to the village of Chillianwalla, and the Sikhs returned and carried off their guns. After the battle Gough received an ovation from his troops, but his losses were thought excessive by the public in England and the directors of the East India Company, and Sir Charles Napier was appointed to supersede him. Before, however, the latter had time to reach India, the crowning victory of Gujrat had been fought and won.

Gujrat.—After the fall of Multan Whish marched to join Gough, and the junction of the two armies was effected on Feb. 18. In the meantime the Sikhs had withdrawn from their strong intrenchments at Russool, owing to want of provisions, and marched to Gujrat, which Gough considered a favourable position for attacking them. By a series of short marches he prepared the way for his "last and best battle." In this engagement, for the first time in either of the Sikh wars, the British had the superiority in artillery, in addition to a picked force of 24,000 men. The battle began on the morning of Feb. 21 with two and a half hours' artillery fire, which was overwhelmingly in favour of the British. At 11.30 A.M. Gough ordered a general advance covered by the artillery; and an hour and a half later the British were in possession of the town of Gujrat, of the Sikh camp and of the enemy's artillery and baggage, and the cavalry were in full pursuit on both flanks. In this battle the British only lost 96 killed and 700 wounded, while the Sikh loss was enormous, in addition to 67 guns. This decisive victory ended the war. On March 12, the Sikh leaders surrendered at discretion, and the Punjab was annexed to British India.

SI KIANG: see HSI CHIANG.

SIKKIM, a princely state in the eastern Himalayas; a protectorate of India. Area 2.744 sq.mi. Capital. Gangtok. The country consists of part of the main chain of the Himalayas and of ranges projecting southward and gradually lessening in height.

On the west the Singalila range divides Sikkim from Nepal, the chief pass into which is Chiya Banjyany La (10.807 ft.). On the east the Chola range forms the boundary with Tibet. the chief passes being the Natu La (14.140 ft.) and Jelep La (14,890 ft.). Between these ranges the country is split up into mountain ridges and a succession of deep valleys, which in the south are only 1,000 ft. above sea level. The highest peaks are Kanchenjunga (28,168 ft.), Siniolchu or D2 (22,597 ft.), Kinchinjhau (22,700 ft.) and Chomo Yummo (22,403 ft.). The line of perpetual snow lies at about 17.000 ft. Between 12.000 and 15,000 ft. there are occasion~plateaus, with some small lakes, *e.g.*, at Changur, to which cattle are driven for grazing in the summer. Forests cover the mountain slopes from 9.000 to 12.000 ft. From 6.500 to 4,500 ft. the slopes have been brought under cultivation, crops of maize. millets and pulses being raised. At lower levels the slopes are terraced and rice is grown wherever irrigation is possible. Woolen cloth and cardamoms, oranges and apples are also produced, some fruit gardens being state maintained. The chief river is the Tista. which is formed by the confluence of the Lachen and Lachung in the north of Sikkim. The valleys drained by these two affluents are broader and more open than those in the south into which the steep sides of the mountains descend abruptly, forming narrow gorges.

Every variety of climate and vegetation, subtropical. temperate and arctic, is encountered. The rainfall is heavy, as the mountains are exposed to the moisture-laden monsoon winds blowing up from the Bay of Bengal, and averages 137 in. a year at Gangtok. The flora is exuberant and includes many species of rhododendron. Butterflies abound. Among mammals, the most interesting are the snow leopard, the cat-bear, the musk deer and two species of goat antelope.

The population numbers 137.725 (1951), of whom the majority are Nepalese. The other races are chiefly Bhotias of Tibetan extraction and Lepchas. The Lepchas, whose own name for themselves is Rongpa, *i.e.*, the people of the valleys or ravines, are believed to be the earliest inhabitants of Sikkim and to be of Indo-chinese origin. A peaceful simple people, they have been replaced at higher altitudes by the more industrious and pushing Nepalese, a hardy race of cultivators.

The Bhotias are mainly graziers, who make their homes at higher elevations.

Buddhism, the state religion, is professed by one-third of the inhabitants, chiefly the Bhotias and Lepchas, for most of the Nepalese are Hindus. There are a number of Buddhist monasteries picturesquely placed on the summits and shoulders of the hills. of which the most important is at Pemionchi. The Buddhism prevalent is oi the lamaistic type found in Tibet. There are no close clusters of houses that can be dignified with the name of village except around a few market places and in the Lachen and Lachung valleys.

History.—The ruling family is Tibetan and claims descent from one of the *gyalpos* or princelings of eastern Tibet. Their ancestors found their way to Lhasa and, in 1641, overcame the Lepcha chiefs of Sikkim. One of them established liis government and introduced Buddhist lamaism as a state religion. Till the end cf the 18th century Sikkim was practically a dependency of Tibet where its ruler was designated governor of Sikkim.

British relations with Sikkim began in 1816. when the Tarai or submontane portion of Sikkim {now in Darjeeling district), which had been occupied by the Nepalese, was restored to the raja by the treaty concluded at the end of the Nepalese War. In 1839 the site of Darjeeling was ceded to the British for use as a sanatorium. In 1849 the British resumed the whole of the Tarai and the outer hills, as punishment for repeated insults and injuries culminating in the imprisonment of Archihald Campbell, superintendent of Darjeeling, and Sir Joseph Hooker, when travelling in Sikkim. In 1861 a British force was required to impose a treaty defining good relations. The maharaja, however, refused to carry out his obligations and persisted in living in Tibet; his administration was neglected. his subjects oppressed and a force of Tibetan soldiers was allowed, and even encouraged. to build a fort in Sikkim territory. The government was forced in 1888 to send an expedition, which drove the Tibetans back over the Jelep pass. A convention was concluded with China in 1890, whereby the British protectorate over Sikkim was acknowledged and the boundary of the state defined; to this was added a supplemental agreement relating to trade and domestic matters, which was signed in 1893. A British political officer was appointed to assist the maharaja with a durbar or council composed of the chief civil officers and lamas. The maharaja refused to co-operate and tried to flee to Tibet through Nepal, where he mas stopped by the Nepalese and given over to the British. He then resided as a state prisoner near Kurseong in Darjeeling district and died in 1914 being succeeded by Tashi Namgyal.

When India attained independence in Aug. 1947 British paramountcy over Sikkim lapsed and under a standstill agreement the new dominion assumed control of the state's external affairs, communications and defense. In 1949 Maharaja Tashi Namgyal had to ask Indian help in restoring order: Indian troops were sent to Gangtok and an Indian civil servant was nominated as dewan or chief minister. A treaty of Dec. 5, 1950, formally provided for the protection of Sikkim by the Republic of India. In 1953 a state council of five elected and four nominated members was set up: two of the elected members assist the maharaja in the day-to-day administration of the state.

White, *Sikhim and Bhutan* (London, 1909); Earl of Ronaldshay, *Lands of the Thunderbolt* (London, 1923); J. Morris, *Living with Lepchas* (London, 1938).

SIKORSKY, IGOR IVAN (1889–), pioneer airplane designer and manufacturer. He was born in Kiev, Russia, May 25, 1889, and educated in Kiev, Petrograd and Paris. At an early age he turned his attention to aeronautics and in France and Germany studied the work of Blériot and Zeppelin (*qq.v.*). In 1909 he designed and built his first flying machine, a helicopter, but it was not successful and he turned to conventional fixed-wing airplanes. By 1911 he had produced five successful machines and become an accomplished pilot.

During the period 1913–17 Sikorsky designed. built and flew planes that were remarkable for their size and flying range. They were powered by four engines and were the precursors of the modern airiiners and large bombers.

In 1919 Sikorsky moved to the United States and became a citizen in 1928. He established an aircraft firm on Long Island that later became a division of United Aircraft corporation. His organization turned out a long series of land planes, seaplanes and amphibians that were used by the military services and commercial airlines.

In 1939, Sikorsky returned to his original interest in the helicopter, and produced the first successful direct-lift machine in the United States. He continued active development of this type until his retirement from United Aircraft corporation in May 1957. (S. P. J.)

SILAGE: *see* Ensilage.

SILAS, SAINT (*fl.* A.D. 50), early Christian prophet and missionary, was the companion of St. Paul (*q.v.*) on the second journey, when he took the place formerly held by Barnabas. The tour included southern Galatia, Troas, Philippi (where he was imprisoned). Thessalonike (Salonika) and Beroea. where Silas was left with Timothy, though he afterward rejoined Paul at Corinth.

He is in all probability the Silvanus (the abbreviation is similar to that of Prisca for Priscilla and Sopater for Sosipater) who is associated with Paul in the letters to the Thessalonians, mentioned again in II Cor. i. 19, and the bearer and amanuensis of I Peter (v, 12). It is possible, indeed. that he has an even closer connection with this letter, and some scholars are inclined to give him a prominent place among the writers of the New Testament. He was of Jewish birth and probably also a Roman citizen. St. Silas' feast day is July 13 in the west, July 30 in the east.

SILAY, a municipality of the province of Negros Occidental, Island of Negros, Philippine Islands, on the northwest coast, about 10 mi N. of Bacolod, the provincial capital. Pop. (1959 est.) 43,575.

SILCHESTER, a parish and village in Hampshire, England. 10 mi. S.W. of Reading. The parish contains the site of the Romano-British town of Calleva Atrebatum, excavated in 1864–78, 1890–1909, and 1938–39 (results published in *drchaeologia).* Soon after the Roman conquest Calleva became the cantonal capital of the Atrebates and the centre of a road system. The outer earthworks enclosed 230 ac.. the inner (about A.D. 160–170) 100 ac. The street plan divided Calleva into 37 *insulae* and there were a forum, basilica. public baths. several temples, a Christian church and an amphitheatre. (*See* Britain: *Roman.*) The main collection of antiquities from the site is in the Reading museum; the Calleva museum (opened 1951) illustrates the town's life. Pop. (1951) 421.

See G C Boon, *A New Guide to the Roman City Calleva Atrebatum at Silchester, Hampshire* (Reading, 1932).

SILENT TRADE: *see* Trade, Primitive.

SILENUS, in mythology, the son of Hermes (or Pan) and a nymph. The companion and nurse of Dionysus, he often appeared in art and in satyr plays in the god's train. He now and then emerged into cult, and a story. variously located in Asia Minor or Macedonia, showed King Midas as catching one (there were presumably many Silenuses, Silenoi, old satyrs) by making him drunk, and as being instructed by him on the woes of human life.

In art he generally appears as a little pot-bellied old man, with a snub nose and a bald head, riding on an ass and supported by satyrs; or he is depicted lying asleep on his mineskin, which he sometimes bestrides.

A more dignified type is the Vatican statue of Silenus carrying the infant Dionysus, and the marble group from the Villa Borghese in the Louvre.

SILESIA (Polish Slask, Czech Slezsko, German Schlesien). a region of central Europe, formerly a province of southwestern Poland.

The First Polish Period.—The name Silesia is derived according to German historians from that of the Silingae, a Vandal tribe; but this people migrated westward in the 3rd century, and by the 10th century the population of the country seems to have been exclusively Slavonic. The ownership of Silesia appears to have been disputed from early times between Poles and Czechs. In A.D. 1000 it was definitively attached ecclesiastically to Poland when a bishopric was founded in Wroclaw (Breslau) and attached to the Polish metropolitan see of Gniezno. The Bohemian dukes continued to claim political overlordship, but in 1054 the emperor Henry III, who had been called in to arbitrate, awarded the area to the Polish duke for payment by him to the Bohemians of an annual tribute.

King Boleslaw III of Poland established in his dominions the *senioratzcs* system under which every male member of the house of Piast received a portion of Polish territory. On his death in 1138 his eldest son, Wladyslaw, inherited Silesia with the *senioratus,* but was evicted from both by a younger brother. The emperor Frederick I restored Silesia to Wladyslaw's sons. It was then partitioned into the two duchies of Silesia (Slansco or Zlesia, later known as Lower, or northwestern Silesia) and Opole (Upper, or southeastern, Silesia), and as the Silesian Piasts proved extremely prolific, these were subdivided again in the course of following generations, until by the end of the 14th century there were no less than 18 Silesian principalities: Breslau (Wroclaw), Brieg (Brzeg). Glogau (Glogow), Jauer (Jawor), Liegnitz (Legnica), Miinsterberg (Ziembice), Oels (Olesnica), Schweidnitz (Swidnica) and Steinau (Scinawa) in Lower Silesia. and Beuthen (Bytom), Falkenberg (Niemodlin), Kosel (Kozle), Neisse (Nysa), Oppeln (Opole). Ratibor (Raciborz), Gross Strehlitz (Strzelce). Teschen (Cieszyn or Tesin) and Troppau (Opava) in Upper Silesia. All of these acknowledged a certain unity which was expressed in periodical meetings of the ruling princes, under the presidency of the senior Piast of the Silesian line.

In the meantime the ethnic composition of the population had been modified by the arrival of German settlers. The first of these coming from Flanders, arrived before the end of the 12th century, perhaps on the invitation of the Cistercian monks who played a large part in the development of the area. At the beginning of the 13th century, Henry the Bearded, duke of Silesia, colonized his principality extensively and systematically: he divided it into areas, in each of which he established a central town which he surrounded with a ring of villages with German settlers, mostly brought from western Germany. After the devastation of the country by the Tatar invasion of 1241, which although first checked at the battle of Liegnitz in Silesia, undid much of the early work, Henry's successors and his cousins resumed the work on the same system. Breslau was refounded as a German town, with Magdeburg law, and many other towns, similarly privileged, grew up. Even the countryside of Lower Silesia was then largely German. Forests were cleared, swamps drained and the land brought under cultivation. Both the mining and the weaving industries were developed and Breslau, which became a member of the Hanseatic league, and other towns became important trading centres, doing a large entrepdt trade between eastern and western Europe.

The Bohemian Period. — The petty Silesian princes often sought the help of the powerful kings of Bohemia against their own brothers and cousins, thus enabling those monarchs to revive their old claims to overlordship. In 1335 an arbitral award rendered by Charles Robert of Hungary assigned all Silesia to the Bohemian crown in return for the renunciation by the Bohemian king of his further claims to the Polish crown; this settlement was reaffirmed in 1338, 1356 and 1372. The change was, however, only one of overlordship; since the Piast princes remained hereditary rulers of their own principalities so long as their lines survived: only on the extinction of any line could the king of Bohemia take possession of the principality and assign it to a new *Landesfürst*. Although Bohemia was part of the empire, the Piast princes were left the status of *principes Poloniae.* (The Silesian princes became princes of the empire only under the emperor Rudolph II.)

Silesia belonged to the lands of the Bohemian crown, but not to Bohemia. On various occasions on which the will of its estates had to be consulted (chiefly on questions of succession) Silesia took a line different from Bohemia, although in practice usually identical with that of Moravia. In the Hussite disputes Silesia took the side of the emperor Sigismund against the Bohemian Hussites, whose aspirations it regarded as dangerous to the German national cause. It was in consequence heavily ravaged in the Hussite Wars of 1425–35, the German element suffering severely. Feeling in the country itself was divided, and when George of Podebrad ascended the throne of Bohemia in 1457, most of the Silesian princes recognized his suzerainty. The towns, however, led by Breslau, resisted, and because of this, the Hungarian king, Matthias Corvinus, was able to rule Silesia (with Moravia) from 1469 to 1490. Matthias introduced many reforms in Silesia, as in the rest of his dominions, establishing, *inter* nlia a regular diet, composed of representatives of the estates under the presidency of the prince-bishop of Breslau. On his death, Silesia reverted to the Bohemian crown, from whose weak holder, Vladislav, the estates exacted concessions which made them virtually independent.

The Habsburg **Period.**—On Dec. 5, 1526, the Silesian estates accepted without demur the succession of Ferdinand of Habsburg although the surviving Piast princes claimed that this could not affect their own rights, and one of them, Prince Ferdinand II of Liegnitz, concluded a *pactum mutuae successionis* of his own with the elector Joachim II of Brandenburg (1537). This had no immediate practical effect, and Silesia remained entirely under the Habsburgs, who progressively reduced its internal liberties, while tending to emphasize its independence of Bohemia.

The Reformation turned Silesia almost entirely Protestant, and consequently on the outbreak of the Thirty Years' War in 1618, it joined with Bohemia in its struggle against the Habsburgs. Like Bohemia, it suffered cruelly in the course of the long war, being repeatedly overrun by contending armies and plundered by lawless mercenary bands. Trade and industry were brought to a standstill and a high proportion of the population either lost their lives or emigrated. Even the physical damage was, houever, somewhat less severe than in Bohemia, and as a result of the intervention of Saxony, the Habsburgs were forced to renounce the complete enforcement of the Counter-Reformation in it. The peace of Westphalia (1648) provided that freedom of religion should prevail in parts of Silesia, and three Protestant churches were left to the population. At the peace of Altranstadt (1707) Charles XII of Sweden then forced Joseph I of Austria to restore to the Protestants 128 churches, with permission to build more. Silesia was again the most Protestant part of the emperor's Austrian dominions. Meanwhile it had been making an economic recovery which for some time was very slow: but the Austrian mercantilist reformers of the late 17th and early 18th centuries made the development of its mining and textile industries the cornerstone of their plans, and before long Silesia counted as the richest of all the Austrian provinces, while Breslau was now one of the largest and richest cities of the empire.

The Prussian Period. — It was chiefly its wealth that tempted Frederick II of Prussia to wrest it from Maria Theresa on her succession in 1740; his excuse was the old treaty of 1537, although his own great-grandfather had in 1686 renounced his claims under that treaty in return for the cession of the district of Swiebodzina (Schwiebus).

The wealth of Silesia caused Maria Theresa to resent and resist Frederick's aggression most bitterly: any concession, she declared, even the loss of the Netherlands, rather than cede one inch of Silesia. Under the treaty of Berlin of July 28, 1742, she was necertheless obliged to cede to Frederick all of Lower Silesia and Upper Silesia except the districts of Teschen, Troppau (Opava) and Jagerndorf (Krnov), and after the second Silesian War (1744–45) and the Seven Years' War (1756–63) had alike failed to reverse the decision of 1742, she reluctantly acquiesced in it The remnant of Austrian Silesia was united with Moravia until 1849, when it was made a separate crownland. Its history was purely provincial. Largely German as its wealthier classes were, they tended to take the anti-Czech side in politics. The Teschen area developed into one of the most important mining and industrial districts of the Austrian monarchy.

While Frederick's action in seizing the rest of Silesia had lacked any shadow of legal or moral justification, it had not been at all unwelcome to the German and Protestant Silesians, and it brought them many benefits. Frederick devoted much attention to his new acquisition, which was at first placed under a special *Landesminister.* The old estates were abolished, but a more efficient administration was introduced. Great attention was paid to the economic development. In 1807 the county of Glatz (Kladsko) was added to it, and the whole formally incorporated in Prussia as the Duchy of Silesia. In 181j this was further enlarged by the incorporation of Saxon Lusatia.

With the increasing importance of coal, in which Upper Silesia proved very rich, its economic development proceeded even more rapidly than beiore, until it became an industrial district second in Germany only to the Ruhr area. Lead and zinc, as well as coal and iron mere mined and utilized in factories on the spot. An important university was iounded in Breslau.

Lower Silesia was by this time purely German. In Upper Silesia, except for its western portions, the population was mixed. Most of the towns were almost entirely German, but many of the agricultural districts were Polish, and a fair proportion oi the miners and unskilled industrial workers were Poles, most oi them, indeed, nationally of a somewhat indeterminate type, speaking a dialect which was heavily interspersed with German words, and locally was described as *Wasserpolnisch.*

The Settlement of 1919–21.—In 1919 hoth Poles and Czechs laid claim to parts of Prussian Silesia, while conversely the Germans oi Austrian Silesia asked to be incorporated in Germany. Further, while the Czechs claimed the whole of Austrian Silesia, partly on grounds of historic right, Poland claimed Upper Silesia and part of Teschen Silesia as Polish by majority. Part of the district of Ratibor, with Hlucin, was transferred irom Germany to Czechoslovakia.

The Polish-Czech dispute was under consideration at the Paris peace conference when on Jan. 22, 1919, the Czechs iorcibly occupied Teschen. The powers ultimately on July 28, 1920, laid down a frontier which divided the area and the town itself. Czechoslovak Silesia was now incorporated in Moravia.

There remained the largest question of all: that between Germany and Poland. The Treaty of Versailles in its original iorm proposed to transfer the greater part of Upper Silesia (certain purely German districts being exempted) to Poland. In response to Germany's vigorous protests, this decision was modified, and article 88 of the final treaty provided that the population should declare by plebiscite whether it wished to belong to Germany or Poland. Pending the holding of the plebiscite, local authority in the plebiscite area (4,250 sq.mi.; pop., 1,942,000) was vested in an Inter-Allied commission, which arrived at Opole on Feb. 11, 1920. The troops at its disposal were too weak to keep impartial order even where they tried to do so, and there was serious fighting between Poles and Germans on several occasions, notably in Aug. 1920.

In the poll 706,820 votes were cast for Germany and 479,414 for Poland, practically all the towns voting for Germany. There was a Polish majority in the administrative districts of Rybnik, Pless (Pszczyna), Beuthen (Bytom), Kattowitz (Katowice), Tarnowitz (Tarnowskie Gory), Tost-Gleiwitz (Toszek-Gliwice) and Gross Strehlitz (Strzelce Opolskie).

The Inter-Allied commission proved unable to agree on the next step. The French wished to allot all southeastern Upper Silesia to the Poles, while the British and Italians wanted to leave the industrial district with the Germans. Protracted diplomatic negotiations led to no result. In May 1921 a rumour spread that the decision was going against Poland, whereupon the Polish plebiscite commissioner, Wojciech Korfanty, ordered an armed rising and took forcible possession of the area coveted by Poland. Much disorder occurred.

As the powers were still unable to agree on how the area should be partitioned, they eventually referred the problem to the council of the League of Nations, which on Oct. 12, 1921, awarded to Poland nearly three-quarters of the coal production and two-thirds of the steelworks.

The new frontier cut through a densely populated area which had grown up as an economic unit, and in order to guarantee economic continuity during the period of readjustment to the new conditions, the award recommended the conclusion of a convention establishing a special regime during that period. The convention was concluded on May 15, 1922. It fixed three transitional periods: one of six months, during which traffic across the frontier was almost free; another of three years (counting irom the date of the convention) when special, although smaller, concessions applied in each zone to the products of the other, while other concessions were to continue for 15 years, the total liietime oi the convention. These last included free importation into either country of the products of the coal mines of the other. During the whole 1; years railway and streetcar traffic operated under a special regime, all inhabitants regularly domiciled in either zone could obtain permits entitling them to cross the frontier without further formality, and the cultural and linguistic rights of minorities were guaranteed by most elaborate safeguards. A Mixed commission and an Arbitral tribunal had the duty of seeing these provisions (which in all occupied 606 articles, with a number of annexes) preserved.

The Mixed commission and the tribunal did their work extraordinarily well, but by the time the convention expired, Germany was out oi the League of Nations and Poland hostile to it. The convention was thereiore not renewed, the two countries announcing that they preferred to regulate their relationship bilaterally. The relationship was proioundly unhappy. since neither country was satisfied with the position: but the first changes in the frontier dispositions described above came at the expense of Czechoslovakia. As the result of the Munich conierence of Sept. 29, 1938, the greater part of Czech Silesia was ceded to Germany. Other portions went to Poland; during the months before Munich, Poland had again raised its never-forgotten claim on the Polish-inhabited parts of Czech Silesia. A few days aiter the Munich decision was announced, it occupied the areas claimed and secured the formal cession of them under an agreement signed on Nov. 1, 1938.

After World War 11.—After overrunning Poland in Sept. 1939 Germany reannexed Polish Upper Silesia. On Dec. 12, 1940, Silesia was once more divided into Lower Silesia (capital Breslau) and Upper Silesia (capital Kattowitz), the latter including parts of the Polish provinces of Kielce and Cracow. Much of the German war industry mas transferred there when the iactories of western Germany were put out of action by Allied bombing. Silesia was, however, itself overrun by the Russians at the end oi the war, and the Potsdam decision of Aug. 2, 1945, besides restoring the 1921 frontier, entrusted Poland with the administration of the whole oi German Silesia, Lower as well as Upper, as far as the Neisse (Nysa) river. The whole country was intensively Polonized, and its German inhabitants expelled. From June 1, 1950, Polish Silesia was divided in three provinces, Wroclaw, Opole and Katowice (Stalinogrod). Katowice included the Sosnowiec, Zawiercie and Czestochowa districts which beiore World War I1 had not been part of Silesia. The remnant of German Lower Silesia was incorporated in the land of Saxony. (C. A. M.)

SILHOUETTE, ÉTIENNE DE (1709–1767), controller-general of France. was born at Limoges on July 5, 1709. After travels in England. he established his reputation by his translations of Alexander Pope, Eliot Warburton and Henry Bolingbroke into French and by his writings on commerce and navigation. He then became, in succession, councilor to the *parlement* of Metz, chancellor to Louis, duke of Orléans, and royal commissioner to the Compagnie des Indes. On March 4. 1759, he mas made controller-general through the influence of the marquise de Pompadour. His reputed skill as a financier seemed to be confirmed by his immediate success in raising a loan of 72,000,000 livres, secured on the royal share of the excess profits of the farm of the indirect taxes. When. however. he announced his intention to restrict the expenditure of the royal household, to suspend for the duration of the war the exemption of municipal officeholders from the *taille,* to levy a third *vingtième* and to triple the poll tax on bachelors, opposition to his policy became general. These reforms were forced through against the resistance of the *parlements,* but the minister could not overcome the financiers' virtual boycott of his treasury operations and was compelled to resign on Nov. 23, 1759. Ridicule of him gave rise to the use of the term silhouette, first applied to a simplified design for men's pocketless clothing, in allusion to the sacrifices demanded by his fiscal exactions. He died on

Jan. 20, 1767, at Brie-sur-Marne. (A. GN.)

SILHOUETTE. The word silhouette commonly means a profile portrait cut out of black paper; but it is also used for any outline or sharp shadow of an object.

The earliest known pictorial art is that of paleolithic peoples, of several different eras, who made mural paintings and drawings in the limestone caves of France and Spain. Their art is distinguished by a brilliantly realistic representation that appears to have been first achieved by drawing the outline of the object's shadow, which was generally filled in with a flat colour. But representation by profile drawing persisted long after pictures and sculptures became conceptual rather than realistic (*e.g.*, the tomb paintings and relief sculpture of Egypt and the finely executed decorations on Greek and Etruscan pottery). The ancient Greeks knew how to draw the outline of a person's shadow cast by sunlight. Profile portraiture executed by using a candle or a lamp to throw the shadow on a wall or screen had become fairly common in Europe by the 17th century. Professional practitioners began to paint shadow portraits on any suitable material — plaster, wax, glass, vellum, paper — and to mount them, sometimes quite elaborately; and various mechanical devices were adopted to facilitate correct drawing. When paper became generally available the outline of the shadow was often cut out, and the cleverer practitioners learned to cut the portraits directly from life, besides making more elaborately composed pictures. In the 18th century the painted "shade" and the paper cut both became fashionable. After the coming of the daguerreotype and photography a few genuine artists, such as Phil May, sometimes made use of the painted shadow style in caricature; otherwise it can be said to have died out, except that the cut silhouette persisted.

The word silhouette was taken from the name of Étienne de Silhouette, the parsimonious finance minister of France in the middle of the 18th century, whose hobby was the cutting-out of paper portraits (the phrase "*à la Silhouette*," originally meant "on the cheap"). Silhouette's hobby was also that of later famous personages, including Johann von Goethe. Many connoisseur collectors in modern times look for both the painted and the cut silhouettes of the 18th and early 19th centuries, notably items by such artists as Francis Torond. A. Charles. John Miers, C. Rosenburg, Mrs. Brown, Auguste Edouart, T. Hamlet and Mrs. Beetham (nee Isabella Robinson).

In the middle of the 20th century there were still a few good silhouette cutters, but the underlying principles of the art lived then most vigorously in the cartoon film. (R. L. M.)

SILICA is a compound of the two most abundant elements of the earth's crust — oxygen and silicon — and it is the main constituent of more than 95% of the earth's rocks. Its resistance to change gives it special significance in the study of geology, and important applications in many chemical processes requiring a refractory (heat-resistant) substance. It occurs in a great variety of forms; the principal industrial sources are quartz sand and quartzite or sandstone rock.

Silica has the chemical formula SiO_2. By weight. it contains 46.75% of silicon and 53.25% of oxygen. It constitutes 59% of the mass of the solid crust of the earth, occurring both as free silica and in combination in the silicate minerals (*see* SILICON). The free silica found in rocks is almost universally crystalline quartz. Sea sand is quartz in the almost pure state.

Uses. — Buildings and roads consume the largest tonnage of silica, for sand is the ever-present constituent of portland cement concrete and lime mortar in construction work, and sandstone is one of the most permanent of building stones. The hardness of quartz becomes useful in the application of sand to the cutting, grinding and polishing of glass and stone, and in the consumption of a large tonnage of engine sand to prevent the slipping of driving wheels of a locomotive on a steel rail. The high melting point and low expansion coefficient of cristobalite make silica brick, usually manufactured from quartzite, one of the most useful of refractories, particularly in the steel industry. Another refractory use, consuming a large tonnage of sand, is in foundry molds. Low thermal conductivity adds to high melting point in making diatomaceous silica a popular refractory insulator for furnaces. Unusual insolubility in water and acids, together with negligible thermal expansion, gives vitreous silica a preferred place in chemical apparatus, both in the laboratory and in the plant.

As a chemical raw material, silica sand and rock enter into the manufacture of various products in which the silica, as such, largely disappears. to reappear in other combinations; these include glass. soluble silicates (water glass), ceramic products of various kinds, silicon carbide, ferrosilicon and silicones.

Pure silica is a chemical product as well as a raw material. When fused with an alkali. dissolved, precipitated. washed and partially dried, it is obtained in an amorphous. very finely divided form which has unusual absorptive properties for water vapour, gases and the minute impurities in certain liquids.

Principal Crystalline Forms. — Of the many forms of silica, the three principal crystalline forms are: quartz, tridymite and cristobalite. Quartz is the form that is stable, under atmospheric pressure. at all temperatures up to 867° C. Tridymite is the stable form from 867° C. to 1,470° C. Cristobalite is stable from 1,470° C. to its melting point at 1,723° C. (International Temperature Scale of 1948). The transformation of silica from one of these forms to another is sluggish, hence the two high-temperature forms can easily be preserved indefinitely at ordinary temperatures, while, conversely, quartz can be heated above 867" C. for hours or even for days and still remain either unchanged or only incompletely transformed into tridymite or cristobalite.

Three new crystalline forms of silica have been discovered since 1953: (1) coesite. which is stable only under high pressure and is the densest form of silica; (2) keatite, which is formed hydrothermally under high pressure and is possibly related to cristobalite in structure; and (3j a fibrous form not yet named by its discoverers, A. and A. Weiss, which is produced by the oxidation of silicon monoxide, SiO.

Each of the three principal forms exists in more than one polymorphous modification. depending upon the temperature. In contrast with the sluggish inversions mentioned above, these high- and low-temperature modifications are produced almost instantaneously when the inversion point is attained; only under very unusual circumstances is it possible to hold the high-temperature modification at a lower temperature than its normal range. These quick-changing modifications were formerly designated by Greek letters, such as alpha and beta. but because of confusion arising from differences in the convention as to which modification should be called alpha, it is clearer to refer to them by the words high and low, or upper and lower. They are so designated in the figure.

The high-low inversion of quartz is at 573° C. Tridymite has two such inversions, at 117° and 163° C. Cristobalite is peculiar among polymorphous substances in that its high-low inversion point changes through a range of temperature (200°–275° C.) according to the previous history of the cristobalite.

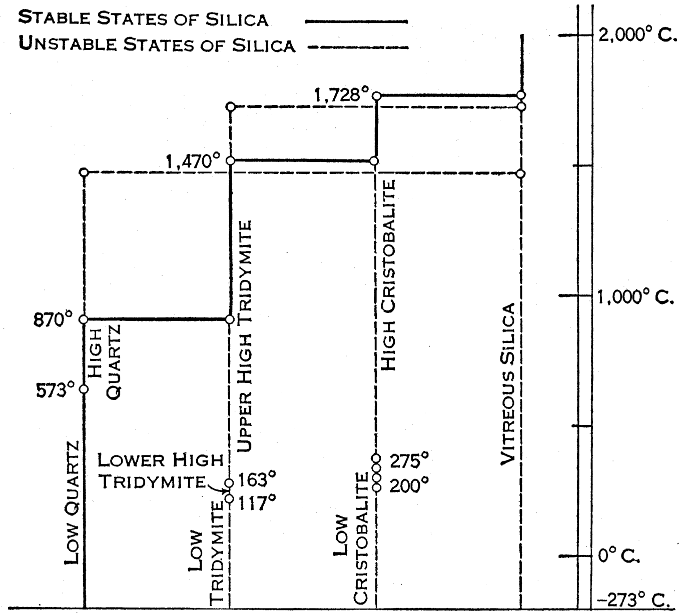
Imitating the sluggishness of the inversion between the principal crystalline forms. molten liquid silica when cooled below 1,723° C., crystallizes sluggishly and can therefore be easily cooled to an amorphous glass, called vitreous silica, fused quartz, or silica glass. (This property persists in the silicate glasses.) Vitreous silica is often incorrectly called quartz, but quartz is a crystalline substance of completely different properties. Upon long-continued heating at temperatures above 1,100° C. vitreous silica devitrifies slowly, usually with the production of white chalky cristobalite.

As the figure indicates, both quartz and tridymite can be melted at temperatures lower than the stable melting point of 1,723° C. but unless further heated to a temperature above 1,723° the fused silica so produced would gradually change over into cristobalite.

Silica is measurably volatile at temperatures above 1.600° C., but its vapour pressure is extremely small. The fluffy porous white deposits of silica often seen around electric furnaces usually are not due to direct distillation, but to reduction of SiO_2 by carbon monoxide and hydrogen to form volatile Si or SiO and gaseous SiH_4, which are subsequently reoxidized.

The Silica Minerals. — All of the three polymorphous crystalline forms mentioned above occur as natural minerals. and even the vitreous (glassy) form, though rare, has been found as a natural product. In combination with water in varying amounts up to about 12%, furthermore, silica occurs as the amorphous mineral opal. Finally, mixtures of hydrated and microcrystalline silica. over the whole range of possible proportions, occur in nature and can be grouped together as chalcedonic silica.

Cristobalite, the crystalline form stable at the highest temperature, always occurs as the low-temperature modification (see figure) but its external crystal form shows it to have grown



BY COURTESY OF AMERICAN IRON AND STEEL INSTITUTE

STABLE AND UNSTABLE STATES OF SILICA

at a temperature above the inversion range of 200°–275° C. Tridymite, likewise. occurs as the low modification, but its habit of growth in twinned hexagonal plates shows that it formed above 163° C. Both of these minerals are instances of Ostwald's rule, which states that a form of low or intermediate stability has a better chance of groning than the form that is most stable under the prevailing conditions.

Natural vitreous silica is called lechatelierite. It is the material constituting the peculiar tubes often found in sand. known as fulgurites, and produced by the intense local heating due to a stroke of lightning. It occurs in the meteor crater of Arizona, again a product of sudden and intense heating. An unexplained occurrence of lechatelierite is the scattered fragments found over a considerable area in the Libyan desert.

The foregoing (cristobalite, tridymite, lechatelierite) are relatively rare minerals. In extreme contrast is quartz, the world's second most abundant mineral (feldspar being first). It has received many names, differentiated according to external form, colour and visual effects caused by inclusions. Clear, colourless, well-crystallized quartz is often called rock crystal, and it received local names like "Herkimer diamond." It exhibits several types of twinning (see QUARTZ) and is frequently found as a pseudomorph of other minerals. The clear varieties which are coloured uniformly by various impurities include amethyst (purple, violet); sapphire quartz (indigo, blue); blue quartz; citrine and false topaz (yellow); rose quartz (pink and rose-red); smoky quartz and cairngorm stone (yellow to brown); and morion (deep brown). Inclusions of gas bubbles give rise to milky quartz; of red hematite, to ferruginous quartz; of needles of rutile (TiO_2) or tourmaline, to sagenitic quartz; of fine fibres and streaks of various composition. to cat's-eye and tigereye.

Like euhedral and massive quartz, the chalcedonic silica minerals have received a variety of names based upon visual characteristics. Because of their microfibrous structure, they all show a waxy lustre on a natural or a fractured surface. If visually homogeneous, nearly colourless and translucent, the mineral is chalcedony. Translucent green makes it chrysoprase, or prase if leek-green. Bright green due to chlorite inclusions produces plasma.

Other translucent varieties are bloodstone and heliotrope (green with red or yellow spots), carnelian (red or yellowish-red), and sard (brown). When banded instead of visually homogeneous, the mineral is agate, of which onyx and sardonyx are subvarieties characterized by banding in planes rather than curving surfaces. The less-prized, because opaque. varieties of chalcedonic silica are jasper, which is usually red, yellow or brown, and may even be green and bluish gray; flint. which is gray to black with conchoidal fracture; and chert. likewise gray to black with splintery conchoidal fracture.

Hydrated, apparently amorphous silica is usually given the name opal, of which the varieties used for gem cutting are characterized by iridescent colours. Hyalite is the colourless and transparent form of opal. Although opal shows no evidence of crystallinity under the microscope, the X-ray reveals it to have, at least in part, the internal structure of cristobalite. An interesting structural form of opaline silica is the material called diatomite, which consists of microscopic skeletons of fresh-water diatoms. Sponge spicules are also essentially opaline silica. (See DIATOMACEOUS EARTH.)

Physical Properties. — The density of the principal forms at 0° C. is: quartz 2.651, tridymite 2.26, cristobalite 2.32, vitreous silica 2.203.

The thermal expansion of the crystalline forms is greatly influenced by the high-low inversions, in that the expansion coefficient becomes steadily greater as a polymorphous inversion point. like that of quartz at 573° C.. is approached At the inversion point there is a sudden increase of volume in going over to the high-temperature modification, after which there is relatively little change with further rise in temperature. High quartz actually contracts a little with rising temperature. Vitreous silica has an expansion coefficient which is near zero at all temperatures. This property gives it a special industrial value, for it can be suddenly heated, or chilled from a bright red heat (as by plunging in water) without breaking.

The specific heat of the forms at 0° C. is: quartz 0.1664, cristobalite 0.170, vitreous 0.1657. The curves of specific heat against temperature have the usual form, rising from zero at the absolute zero of temperature, interrupted by a discontinuity at the high-low inversions, and approaching a value of about 0.28 at the melting point.

The thermal conductivity of vitreous silica is uniformly low at all temperatures, about 0.003 cal. per square centimetre per second, per degree centigrade per centimetre at 0° C. Quartz, in contrast, while in a class with vitreous silica at ordinary temperature. rapidly increases in conductivity as the temperature falls and at the temperature of liquid hydrogen conducts as well as some metals.

The forms of silica are both hard and strong. Quartz is standard substance no. 7 in the Mohs' scale of hardness. A tensile strength as high as 160,000 lb. per square inch has been observed in drawn fibres of vitreous silica, and fibres that will carry 100,000 lb. per square inch are easily made. The vitreous form is singularly free from elastic anomalies and is therefore prized for various physical instruments.

The forms of silica are diamagnetic, with a mass susceptibility of about -0.5 per gram. They are poor conductors of electricity; the resistivity of vitreous silica at 20° C. is about 10^{19} ohms per square centimetre per centimetre which makes it popular as an electrical insulator. It is especially valuable in such service because. unlike common glasses and many other substances, it does not condense a conducting layer of moisture upon its surface. (For other electrical properties, see the article on QUARTZ.)

Both quartz and vitreous silica are colourless and transparent in visible light, and are unusually transparent to ultraviolet light. This property makes the vitreous form valuable in windows for transmission of whole sunlight. and in lamps for transmitting ultraviolet from the mercury arc. At nave lengths longer than visible light, on the other hand, though more transparent than other glasses to most of the infrared spectrum, silica reflects like a metal in the vicinity of wave length 9 μ, and has considerable reflecting power also near 13 and 23 μ.

The useful optical properties peculiar to crystalline quartz, particularly rotatory power, are discussed in the article QUARTZ.

Chemical **Behaviour.**—In the laboratory, crystalline and vitreous silica are virtually insoluble in pure water and dissolve very slightly in water solutions of the common mineral acids. Silica is attacked (etched). however, by dilute alkaline solutions and by concentrated phosphoric acid. and is rapidly dissolved by a solution of hydrofluoric acid (HF). The only halogen that attacks it is fluorine.

A homogeneous liquid containing only water and a few per cent of silica is easily obtained by acidifying the water solution of an alkaline silicate and dialyzing out the electrolytes. This liquid proves to be a hydrosol. containing silica units of large molecular weight, and not a true solution. Much experimental work was done on these sols in the hope of proving them to be silicic acids analogous to sulfuric and phosphoric acids, but without success. The sol can be concentrated to a stage where it becomes a rigid and elastic gel, corresponding to the natural mineral opal. The percentage of water in such gels is controlled by the temperature and by the water vapour pressure in contact with the gel, as well as by its previous chemical and physical history.

As the temperature rises. silica becomes measurably soluble in water, and dontinues to in'crease in solubility, if the pressure is increased, even above the critical temperature of water, 374° C., where surface tension disappears and gas and liquid become continuous in properties. At the critical end point of the solution, which is less than one degree higher than the critical temperature of water, and at the pressure corresponding to coexistence of quartz, liquid and vapour, quartz is soluble to the extent of 0.023% by weight. Its maximum solubility under these equilibrium conditions is 0.075%, at 332° C. Above the critical point, at higher pressures, a concentration of more than 0.3% has been attained. Vitreous silica attains an apparent equilibrium with water at about twice the concentration of quartz.

Silica in all forms reacts at temperatures above 1,000° C. with all metallic oxides, also with many salts when in the presence of air and moisture, to form crystalline or liquid silicates.

SILICON is the second most abundant of the elements in the earth's crust, surpassed in quantity only by oxygen. It is found in measurable amount in practically every rock, in all natural waters, in the atmosphere (as siliceous dust), in many plants and in the skeletons, tissues and body fluids of some animals. Its presence in the sun and other stars is indicated by the spectroscope. It is never found in the free state, however, but always in combination—either with oxygen as silica (SiO_2), or with oxygen and aluminum, magnesium, calcium, sodium, potassium, iron and other elements in the numerous silicate materials which comprise rocks, soils and clays.

Prior to 1787 chemists had not differentiated silicon from its compound, silica, which they considered an element. In that year A. Lavoisier offered the speculation that silica was an oxide of an undiscovered element. In 1817 J. J. Berzelius found that the substance, free from oxygen, was present in cast iron; and six years later he established its existence as an element, although he was able to prepare it only in somewhat impure form. It was first obtained in reproducible crystalline form in 1854, when H. Sainte-Claire Deville crystallized it out of the alloy produced by electrolyzing a melt of mixed chlorides. The name silicon was derived from **silic-**, basal syllables of *silex,* Latin for "flint."

Silicon is chemical element no. 14 in the periodic system; symbol, Si. It is nonmetallic in character and has a chemical atomic weight of 28.09. Its isotopic composition, which has been found constant both in the earth's crust and in meteorites, is: Si^{28}, 92.28%; Si^{29}, 4.67%; Si^{30}, 3.05%. External electron arrangement: $1s^2\ 2s^2,\ 2p^6\ 3s^2,\ 3p^2$.

Forms.—Pure silicon crystallizes with isometric symmetry, and has the same structure as diamond. The distance between adjacent atoms is 2.3j A.

Amorphous silicon has been frequently described, especially by the earlier workers. Some of it was undoubtedly impure as a result of the method of preparation, and was mixed with silicides and silica. Even when fairly pure, the supposed amorphous element has been found to give the same X-ray pattern as the recognizably crystalline form.

Preparation and Physical Properties.—Silicon is best prepared by reaction of metals such as magnesium, aluminum and potassium with the halogen compounds of silicon. It can be purified by recrystallization from metallic solution, as in aluminum. the excess of solvent metal being removed with acid. Because of the difficulty of preparing the pure element, the recorded physical properties are not as reliable as those of more easily purified substances.

The physical properties of silicon are as follows:

Density (grams per cubic centimetre)	2.42
Coefficient of thermal expansion at 0° C.	7×10^{-6}
Melting point	1,420° C.
Boiling point	about 2,600° C.
Specific heat at 0° C., calories	0.174
Refractive index, $\lambda = 589\ m\mu$	4.24

Chemical **Behaviour** and Uses.—Silicon is attacked by oxygen and water vapour at a red heat and higher, but the coating of SiO_2 formed by the reaction protects the element. It is vigorously attacked by gaseous fluorine, chlorine and hydrofluoric acid. It is not acted upon by sulfuric acid, hydrochloric acid, nitric acid or aqueous ammonia at ordinary temperature. Many oxides are reduced by silicon at high temperatures with the formation of metal or silicide, and silica.

Silicon is used in industry principally as the alloy of iron and silicon called ferrosilicon. This may contain from 14% to 94% Si. It is used for deoxidizing common steels and for making special silicon steels.

Compounds.—Silicon stands next to carbon in the fourth group of the periodic system. By simple analogy, this fact leads to the expectation that silicon can form chain and ring compounds with hydrogen and the halides, as well as a complex system of hydrogen-oxygen compounds. This expectation is to some extent realized in the simpler chain formulas of silicon compounds, and even the names, suitably modified. of the carbon-hydrogen-oxygen compounds have been carried over into the silicon series. New compounds are constantly being added to the silicon series.

Silicon has four electrons in the outer or valence shell. These are capable of pairing with the valence electrons of other elements to give four covalent bonds. Silicon is therefore commonly classed as tetravalent. The electrons can also be transferred to the outer shell of a strongly electronegative element such as fluorine to form bonds of ionic type. The covalent bonds of silicon to oxygen are estimated to be about half ionic in character. In the compounds of carbon, on the other hand, ionic bonds are rare. Further, carbon never produces more than four covalent bonds, and in some compounds the number descends to three and two.

Another important factor in the formation of compounds besides the electron arrangement is the size of the atom, controlling the space available for close approach of other atoms. Silicon has a larger atom than carbon. The co-ordination number of the silicon atom in its compounds is in nearly all cases four. With some atoms, however, such as fluorine and (occasionally) oxygen, it can be six. It is never less than four in any known compound.

These differences in external atomic structure find expression in the following striking differences between the carbon and silicon compounds of similar formula: (1) The carbon compounds form self-contained independent molecules which maintain their separate existence even though vaporized, liquefied. dissolved and modified by substitution of atom for atom; the silicon compounds polymerize and pass over into solid crystalline or amorphous aggregates. or structures extending infinitely in one, two or three dimensions. (2) In a world where water is always present as vapour or liquid, the carbon-based molecules survive untouched, the silicon-based molecules hydrolyze and end as hydrated silica or as water-bearing micas and clay minerals. (3) The carbon series build up their complexities by conjunction of carbon atom to carbon atom, while the silicon series build up their complexities mainly through the intermediary of oxygen atoms. It is easy to see that. in a newly created world with prevailing temperatures of $-50°$ to $+100°$ C., carbon had within itself the possibility of an evolving life, while silicon was the possible parent mainly of cold rocks.

Hydrides.—Like carbon, silicon forms mith hydrogen a series of compounds containing a progressively smaller proportion of hydrogen. The first member is silane, SiH_4, and the series has been prepared as far as Si_6H_{14}. All can be made by action of an acid on a silicide. All are gases at atmospheric temperatures. There are no unsaturated hydrides corresponding to the ethylene, acetylene and benzene types of hydrocarbons.

Oxides.—There is evidence for the existence of a monoxide, SiO, but little information is available on its properties.

The dioxide. SiO_2, usually called silica, is one of the most extensively investigated and best-known of chemical substances. (See SILICA.)

Compounds With Hydrogen and Oxygen.—A number of such compounds, called by the generic name siloxanes. had been prepared and studied by mid-20th century, but they lack the stability and the variety of behaviour characteristic of the analogous organic acids, esters, etc.

Halogen Compounds.—Silicon tetrafluoride, SiF_4, is a gas formed by reaction of hydrofluoric acid, HF, on silica. It combines mith excess HF to form hydrogen silicofluoride, also called hydrofluosilicic acid or fluosilicic acid, H_2SiF_6, which is stable in water solution, giving the ion SiF_6^{--}. K_2SiF_6 is one of the few potassium salts that is difficultly soluble in water, making this acid useful in chemical analysis.

Silicon tetrachloride, $SiCl_4$, is a colourless liquid of boiling point 57° C. It reacts with water, either liquid or vapour, to form HCl and hydrated SiO_2. This reaction has been utilized, by including ammonia with the vapour, to produce a military protective dense white smoke consisting of particles of SiO_2 and NH_4Cl. As might be expected from the analogy with carbon, there are chlorides Si_2Cl_6, Si_3Cl_8 and others. Silicon tetrabromide is a colourless liquid boiling at 153° C. The tetraiodide is crystalline, melting at 121° C. and boiling at 290° C.

Numerous halogen derivatives of the silicon hydrides are possible, and many have been prepared and described. An example is silico-chloroform, $SiHCl_3$.

Carbide.—Silicon carbide. SiC, forms at electric furnace temperatures from reaction of carbon with silica. It exists in at least eight crystalline forms. It has become an important industrial abrasive and refractory, under trade names such as Carborundum and Crystolon. (See SILICON CARBIDE)

Organosilicon Compounds.—The introduction of silicon into carbon chains and rings—or, looked at from the other direction, the introduction of organic radicals into the simpler silicon compounds—opens an immense variety of possible structures, some hundreds of which have been prepared and described. None of these compounds has been identified as a natural product, though some may be taking part in the groath of silicon-bearing plant and animal tissues. Among the new compounds are the industrially important silicones (*q.v.*) which derive by polymerization from the general formula R_2SiO, in which R is an organic radical such as CH_3, C_6H_5 and the like. Another group of carbon-bearing compounds comprises the silicates, such as the industrially useful tetraethyl orthosilicate, $(C_2H_5)_4SiO_4$. The term organosilicon compound is restricted to those that contain at least one silicon-carbon bond.

Sulfide.—Silicon forms a colourless crystalline sulfide, SiS_2; its structure is that of an infinitely long chain of tetrahedra, SiS_4, which share opposite edges, the parallel chains themselves being held together by weak residual forces. It therefore differs from silicates of the chain type in that SiO_4 groups share corners but not edges (see below).

THE SILICATES

More than 95% of the earth's rocks contain silica as their principal component. Any such rock can be seen, either by direct inspection or by examination under the microscope, to be an aggregate of minerals, each homogeneous, usually crystalline, and usually transparent. In many rocks, one of these minerals is pure silica in the form of quartz. Most of the other rock minerals contain silica in combination; they are the silicate minerals.

Many of these minerals have been artificially duplicated, usually by high-temperature processes. New crystalline silicates, never found in nature. have also been produced by these same processes. Most of the silicates, both natural and artificial, are insoluble in water. A striking exception is the group of silicates of the alkali metals (lithium, sodium, potassium), which are obtainable as homogeneous water solutions containing silica in a wide range of proportions. These solutions can be concentrated to form glasses that still contain as much as 25% water. One such series, the sodium silicates. forms an important article of commerce, long known by the commercial name of water glass, no more commonly called silicate of soda.

By fusion with two or more oxides, commonly sodium oxide (Na_2O) and lime (CaO), both introduced as carbonate, silica forms the silicate glasses.

This extremely varied lot of substances, the silicate minerals, the synthetic silica compounds and the silicate glasses, are grouped by the chemist under the name silicates. As the name itself implies, the silicates were regarded throughout the 19th century and the first quarter of the 20th century as salts of certain silicic acids, in the same sense that sodium sulfate is a salt of sulfuric acid. The analogy was temporarily useful, even though it proved to be very difficult to produce a silicic acid resembling in any way the chemist's better-known acids. Pure silica proved to be extremely insoluble in pure water, and the homogeneous phases containing only silica and water, which are obtainable by various methods, were found to contain mostly colloidal or dispersed silica, with very little truly dissolved silica. The methods of organic chemistry failed completely to throw any light on the constitution of the silicates. and the field remained one for unrestrained speculation, uncheckable hypothesis and unproductive analogy.

The advent of the X-ray methods of studying the structure of crystalline and amorphous solids made possible a resumption of progress in the chemistry of the silicates. Systematic knowledge of silicate structure and constitution at mid-20th century was based largely on X-ray work particularly on the crystalline substances, the glasses and the clays. combined with the atomic-volume principle elucidated by V. M. Goldschmidt and others. It developed that the guiding unit is a group having the formula SiO_4. In all the silicates, as well as in pure silica, there are groups of four oxygen atoms arranged in space at the corners of a tetrahedron. There is usually a silicon atom at the centre of the tetrahedron, but it can be replaced here and there by aluminum (in most cases not to exceed one out of four silicon atoms), and rarely by beryllium. At the same time, an occasional tetrahedral corner will be found occupied not by an oxygen atom but by a fluorine atom or an OH pair (hydroxyl). The systematization of all the silicates is based upon the various ways in which it is possible to interconnect the silicon-oxygen tetrahedra. The chemically basic or electropositive elements, such as Li, Na, K, Mg Ca, Sr. Ba. Al (in part), Mn. Fe, fit into the openings between the tetrahedra in accordance with their atomic volume. The oxygen atom itself is larger than most of the silicate-forming atoms, which leads to the geometric possibility of fillable openings.

Silicate Structures.—Mineralogists and chemists are not in complete agreement as to the classification of the structures, but the main groupings are briefly characterized below, and some of the better-known examples are listed in parentheses. Some of the old names were still retained for lack of a more logical terminology.

Three-Dimensional Networks, or Silica Type.—All the tetrahedra share corners with other tetrahedra. The formulas contain the group SiO_2 or multiples thereof. The type includes silica itself; the feldspar group (orthoclase, plagioclase); the nephelite group; the cancrinite and sodalite groups in which certain electronegative units such as Cl, CO_3 and SO, are added to the structure; and the large zeolite family, with added molecules of H_2O as the principal structural characteristic.

Sheet Structures (Sometimes Called the *Disilicate* Type).—The tetrahedra are arranged in a plane, each being joined to other tetrahedra by three atoms in the plane. The type includes the aluminum disilicates (kaolin and other clay minerals); the nonaluminum member. talc; the analogous aluminum member, pyrophyllite; the chlorite family; and the micas (muscovite and biotite series).

Chain and Ring *Structures,* or *Metasilicate* Type.—These may be either chains or rings of tetrahedra, reminiscent in a way of the chain and ring structures of the chemistry of carbon. The chain structures, which are potentially infinite in length, include: single chain structures, containing SiO_3 or multiple thereof in the formula (pyroxene group, pyroxenoid family); double chains containing Si_4O_{11} in the formula (amphibole group); and other more complex chains. Ring structures include beryl and probably the tourmaline series.

Double Tetrahedral Structures, or *Pyrosilicate* Type.—Two tetrahedra share a single oxygen atom, giving formulas containing Si_2O_7. These silicates include the melilite group and the hemimorphite family.

Independent Tetrahedral Structures, or Orthosilicate *Type.*—There is no sharing of corners between tetrahedra, hence formulas contain the group SiO_4. The old formal derivation was from an imaginary silicic acid of the formula $Si(OH)_4$. These silicates include a varied assortment, such as the chrysolite group (olivine, forsterite, fayalite), garnet group and epidote group. Allied to these orthosilicates are some subsilicate minerals: in which not all the oxygen is in the independent tetrahedra (sillimanite, mullite).

Phase Equilibrium in *Silicate Systems.*—There is another approach to understanding the chemistry of the silicates which almost completely ignores the existence of atoms and proceeds on the thermodynamic basis of the Gibbs phase rule, determining experimentally the limits of stability of all the crystalline and liquid phases that can be produced synthetically. The work of the Geophysical laboratory of the Carnegie Institution of Washington, D.C., founded by A. L. Day in 1906, is the most extensive in this field. The method has the great advantage of proceeding from simple to complex systems and of covering the ground thoroughly as it goes, at least with respect to equilibriums readily attainable at high temperatures. It has the disadvantage of being faced with what might appear a numerically hopeless task. Hundreds and thousands of tests. short though they may be. are necessary for the complete survey of a system of three oxide components, and several such systems had been patiently completed by the 1950s, but no four-oxide system had been finished. Yet most silicate minerals contain at least five components and a great many contain ten. The total number of systems (unary, binary, ternary, etc.) that can be assembled from ten oxides is 1,023. Additional complications are: (1) the necessity, in systems containing the oxides of iron and manganese, of taking the metal and gaseous oxygen as the components. adding gaseous pressure as another variable; (2) the experimentally difficult problem of sealed high-pressure apparatus when water is one of the components. Nevertheless, the elucidation of the simpler systems had brought rich returns in such matters as the formulation of fundamental principles on the genesis of rocks, and the solving of industrial problems in ceramics.

Ten or more binary silicate systems are represented by reasonably satisfactory phase-equilibrium diagrams, together with six ternary systems (SiO_2 with the pairs Al_2O_3–CaO, Al_2O_3–MgO, CaO–MgO, CaO–K_2O, CaO–Na_2O, K_2O–Na_2O). Systems containing dissociable oxides are still fragmentary. Silicates of sodium and potassium with H_2O as a third component are fairly complete. Details will be found in articles on the individual metallic elements.

The Problem of Valence and Neutrality.— Implicit in both the atomic-structural approach and the phase-equilibrium approach to the study of the silicates is the chemist's basic assumption of the validity of Dalton's law of definite and multiple proportions. It is assumed, for instance, that the phases and the structures in a series of sodium aluminosilicates containing water can be correctly described in terms of the formulas SiO_2, Al_2O_3, Na_2O, and H_2O. But 20th-century chemistry. studying the metallic alloys and various inorganic systems containing solid solutions (*i.e.,* crystalline solutions), found that Dalton's rules are often only an approximation or a working limit, not an exact statement. In the system iron-oxygen, for example, there occurs one crystalline phase (wüstite) with a temperature range of stability from 560° to 1,424° C. and a range of composition from 23.10% to 25.60% oxygen, no point of which can be represented by a simple integral relation between the atoms; the composition FeO (22.27% oxygen) lies entirely outside the field and is nonexistent as a phase. The wüstite phase is a crystalline solution of oxygen in iron or iron in oxygen, whose composition depends upon the pressure and temperature. This relation will certainly carry over into the iron-bearing silicates.

Furthermore. it became apparent from study of the adsorptive and base-exchanging power of many substances that not only can there be ionization in liquid solutions but also in crystalline substances as well, with the possible production of structures into which ions and polar molecules can be introduced as a part of the systematic structure, to be released again under the proper chemical environment. The silicates with sheet structure include many such substances. (See ADSORPTION; VALENCE.)

Silicates in Industry.— The silicates are the foundation material for the widely various ceramic industries. In the United States the word ceramic is held to embrace not only industries based upon clay, which is the traditional usage, but any industry utilizing earthy raw materials (sand, clay, feldspar, magnesite) to manufacture a product with the help of a kiln or a furnace. The ceramic industries in the United States therefore include glass, vitreous enamels, portland cement and certain electric-furnace products (abrasives); as well as structural clay products (building brick, paving brick, tile), refractories, earthenware (pottery, sewer pipe) and whiteware (china. decorative porcelain, electrical porcelain). Soluble silicates have been mentioned above.

Another class of industrial silicates, the silicate slags, is closely allied to the metallurgical industries. In the production and refining of some metals. an active reagent is the nonmetallic liquid floating on the surface of the metal. collecting and removing the gangue of the ore and also reacting with constituents in the metal. The metallurgical slag produced in greatest tonnage is blast-furnace slag from the manufacture of crude iron. It consists essentially of silica. alumina and lime, with subordinate magnesia. Some of it is utilized as raw material for portland cement. Slag from the open-hearth furnace for making steel contains principaliy silica, lime and oxides of iron and manganese; in some localities it is high enough in phosphorus pentoxide to be utilized as fertilizer. Slags from the acid and basic Bessemer processes and from the smelting and refining of copper, lead and tin are siliceous in varying degree.

SILICON CARBIDE (CARBORUNDUM). Silicon carbide is a crystalline compound of metallic silicon and nonmetallic carbon which is of great technical and industrial importance. It was discovered accidentally by Edward G. Xcheson in 1891 while he was experimenting with the use of electrical energy for the production of artificial diamonds. Acheson was heating a mixture of clay and coke in an iron bowl with an ordinary arc light carbon in an attempt to convert the carbon to diamond. and found some bright hexagonal crystals attached to the carbon electrode. He thought that he had prepared a new compound of the carbon and the alumina (aluminum oxide) of the clay. Because the natural form of fused alumina has the mineral name of corundum (*q.v.*), he called the new compound carborundum. This name was originally protected as a trade name but in many places became synonymous with silicon carbide. In 1893 Xcheson was granted a U.S. patent covering his invention. About the same time Henri Moissan produced a similar compound from a mixture of quartz and carbon. However, in a publication of 1903 Moissan ascribed the original discovery to Acheson.

The significance of the discovery was immediately realized by Acheson, for he found that the crystals approximated the hardness of the diamond. His early product was offered for the polishing of gems, and sold at a price comparable with natural diamond dust. The new compound was found,to be attainable with cheap raw materials and with good yields so that it soon became of industrial importance as a manufactured abrasive of wide application.

Properties. — Silicon carbide, which has the chemical formula SiC, crystallizes in the hexagonal system. Five crystalline-type habits in the hexagonal system were isolated and described in the technical literature. The ordinary commercial product has crystals up to $\frac{1}{2}$ in. average dimensions in the hexagonal plane and thicknesses of up to $\frac{1}{4}$ in. in the other dimension. The crystals are usually found closely interlocked into a massive porous structure, but occasionally fully developed crystals are formed in voids of the furnace ingots. These are the spectacular large, shiny crystals which are often exhibited as typical silicon carbide. Pure silicon carbide is clear with a slight green tinge. The index of refraction is very high, 2.648 for the ordinary ray and 2.691 for the extraordinary ray. A slight amount of impurity will change the colour from light green to blue, gray and black. Typical impurities in the crystal are aluminum, magnesium, calcium, graphite and free silicon, all of which change the colour to black when present in amounts up to 0.5%. The crystal begins to oxidize when heated in air at around 1,000° C., forming a film of silica over the surface. This film produces iridescent and attractive colours when the proper film thickness is developed.

Some natural silicon carbide was found in the Canyon Diablo meteorite and bears the mineralogical name Moissanite after Henri Moissan.

A low-temperature form of silicon carbide (β-SiC) was discovered and isolated in 1926 by H. Ott. It has the same chemical composition but crystallizes in the cubic system and has properties different from the industrial product. The ordinary hexagonal variety of crystal has a hardness on the Mohs' scale of scratch hardness just above fused alumina or corundum and considerably below the hardness of the diamond. In 1891 silicon carbide was the hardest synthetic material which had ever been made. The discovery of boron carbide in 1929 took this distinction from silicon carbide.

Other properties of silicon carbide, in addition to its hardness, served to develop a large commercial market for it. The crystals are mechanically strong, have high thermal conductivity and desirable fracture characteristics which make them extremely useful in grinding wheels and in abrasive paper and cloth products. The high thermal conductivity, taken with the resistance to fluxing, fusion or oxidation of the material, makes it valuable in the manufacture of high-temperature bricks and other refractory products such as muffles, tubes and saggers. Silicon carbide also has unique electrical properties, including a high negative temperature coefficient of resistance. In the cold, silicon carbide might be classed as an insulator; as it is heated up to higher temperatures it becomes more conductive, so that at 2,000° C. it is as conductive as graphite. This places it in the class of semiconductors which have many special uses.

Industrial Production. — The total production of silicon carbide in the United States and Canada in the years following World War II was about 60,000 tons annually. Of this amount, roughly 60% was used for abrasives and 40% for refractories and other special uses. The total synthetic abrasive production of all types for the same period was about 350,000 tons annually, so that it is apparent that while silicon carbide was still an important abrasive material, it no longer represented the chief abrasive manufactured with electric power. This distinction had passed to fused alumina or corundum, which finds its chief use in the cutting and grinding of steel and other high tensile strength products. Silicon carbide is used mostly for the shaping of low tensile strength materials such as cast iron, bronze, glass and marble.

The commercial manufacture of silicon carbide is accomplished in much the same way throughout the world from the two basic raw materials, glass sand (pure SiO_2) and high-grade coke (low-ash petroleum or pitch coke). Most of the world production is localized in the Niagara district of the United States and Canada where electric power from Niagara falls is available for the large requirement of electrical energy needed in the production. About 4 to 5 kw.hr. are consumed for the production of each pound of silicon carbide. The other large producing areas in the world are in Norway and in Czechoslovakia.

At mid-20th century the electric furnaces used for the production of commercial silicon carbide were similar throughout the industry and were much the same as the original furnace described by Acheson in his original patent. A typical furnace is a large brick box ranging in size from 20 to 50 ft. in length and from 10 to 20 ft. in width and 10 ft. deep. The refractory brick box serves only as a container to hold the crude mixture which consists of ten parts of glass sand and six parts of high-grade coke. Some variable amount of wood sawdust is added to the mixture to change its thermal conductivity and gas permeability characteristics. This loose granular mix is piled into the box until it is half full, and a trench is cut lengthwise in the loose mixture. This trench is filled with coarse metallurgical coke particles which are in contact with large carbon electrodes at each end of the box. This granular core is used ordinarily as a starting resistance to bring up the centre zone of the mixture to the reactive temperature which is from 2,000° to 2,600° C. Because of the long resistor and the many contacts between the carbon particles, a high voltage (up to 500 v.) is needed for starting the furnace, but as soon as some reaction takes place and a sheath of silicon carbide forms around the outside of the central resistor, the conductivity of the resistor is increased. This increase proceeds during the course of the run so that the voltage continually must be adjusted downward. As the current goes up to as high as 40,000 amp. the voltage must be adjusted down to a low of 75 v. Furnaces normally require from 1,000 to 3.000 kw. of power input to produce the abrasive efficiently. Expensive electrical equipment is necessary to control these large blocks of power through the required operating range. Production stops long before the central developing ingot of silicon carbide approaches the walls of the brick container because there is no known refractory which can stand the high temperatures involved in this furnace operation. The product is made in an envelope of itself. The chemical reactions liberate great volumes of carbon monoxide; in fact 1.4 tons of carbon monoxide is produced for every ton of silicon carbide recovered. This gas permeates the loose mix and burns on the outside of the furnace, aiding somewhat in the reduction of heat losses from the container.

SILICONE, any one of a group of synthetic polymers (*see* POLYMERIZATION) composed of the elements silicon, carbon, hydrogen and oxygen. They are usually noted for ability to withstand comparatively high temperatures without decomposing.

Silicone polymers may take the form of oily liquids, resins or rubbery solids (elastomers), depending upon their chemical composition and the average size of the molecule. The commercial types of silicone resin and rubber are usually designed to have the greatest heat stability consistent with strength, adhesion and the other necessary physical properties, but some types are designed especially for fluidity or flexibility at very low temperatures or for some other special property such as solvent resistance. All types are quite inert chemically; they are indifferent to dilute acids and most reagents except strong alkalies and hydrofluoric acid, both of which are capable of destroying the basic structure of the polymer.

The name "silicone" was coined by F. S. Kipping of University college, Nottingham, Eng., to describe compounds of silicon which were analogous to the organic ketones (see KETONES). A silicone therefore designates a substance which has a composition corresponding to two organic groups or radicals bonded to a silicon atom which in turn is linked to oxygen; it might equally well be described as an organosilicon oxide. The analogy between silicones and ketones begins and ends with the empirical composition. however. for the two groups of compounds are very different structurally. The ketones have simple molecules corresponding to their elementary composition, whereas the silicones always have polymeric structures in which the unit of composition is repeated many times in a single molecule. A silicone polymer may therefore be pictured as a chain or network of alternate silicon and oxygen atoms bearing appropriate organic groups attached to the silicon atoms:

$$\begin{array}{ccccccc} & R & & R & & R & \\ & | & & | & & | & \\ - & Si & -O- & Si & -O- & Si & -O- \\ & | & & | & & | & \\ & R & & R & & R & \end{array}$$

The organic groups R modify what otherwise would be a purely inorganic siliccn oxide or silica glass, and provide the desired degree of flexibility. plasticity, or even fluidity. The kind of organic group and its size in relation to the silicon-oxygen framework thus has an important influence on the properties of the silicone polymer. In practice, the R groups are almost always methyl groups (CH_3-), but occasionally phenyl (C_6H_5-) or ethyl (C_2H_5-) groups.

Silicones usually are made by hydrolyzing the simpler organosilicon chlorides or ethers and condensing the products to polymeric form. The starting material is silica in the form of sand or quartzite, which by one of several methods is chemically combined with organic groups. In the Grignard method, silicon tetrachloride is prepared from the silica and is allowed to react with approximately two equivalents of organomagnesium chloride (Grignard reagent, *q.v.*) in an ether solvent to form a mixture of organosilicon chlorides from which the pure compounds are separated by distillation:

$$RMgCl + SiCl_4 = RSiCl_3 + MgCl_2$$
$$2RMgCl + SiCl_4 = R_2SiCl_2 + 2MgCl_2$$
$$3RMgCl + SiCl_4 = R_3SiCl + 3MgCl_2$$

In the direct method, elementary silicon is prepared by reduction of the silica and is caused to react directly with an organic chloride in the vapour phase and in the presence of a catalyst to form a mixture of organosilicon chlorides, from which the pure constituents again are distilled:

$$2RCl + Si = R_2SiCl_2, \text{ etc.}$$

In a third method, ethylene is absorbed by dichlorosilane made from silicon:

$$2HCl + Si = H_2SiCl_2$$
$$H_2SiCl_2 + 2C_2H_4 = (C_2H_5)_2SiCl_2$$

Pure organosilicon chlorides from any of these methods become the intermediates from which the silicone polymers are made.

Silicone resins are made by hydrolyzing a mixture of monosubstituted and disubstituted silicon chlorides, sometimes in a solvent. Reaction with the water replaces the chlorine nith hydroxyl groups, and the hydroxides intercondense to form a polymer:

$$R_2SiCl_2 + 2H_2O = R_2Si(OH)_2 + 2HCl$$

$$xR_2Si(OH)_2 = \left[\begin{array}{c} R \\ | \\ -Si-O- \\ | \\ R \end{array} \right]_x + xH_2O$$

Silicone resins prepared in this way usually are applied in the form of a solution or varnish. After the solution has been applied to the desired surface the solvent is evaporated and the resin is cured by heat, sometimes with the assistance of curing agents or catalysts. The final product has a molecular structure in which the chains of silicon and oxygen atoms are interconnected or cross-linked by extra atoms of oxygen on the monosubstituted silicon atoms, and is therefore comparatively insoluble and infusible. Such resins are useful as insulating and protective coatings, and some are serviceable at temperatures up to 600° C. for extended periods.

Silicone oils may be made by preparing linear polymers of dimethylsiloxane of a length corresponding to the desired viscosity and vapour pressure. In order to prevent further change of molecular weight through condensation, the chains are blocked by attaching unreactive groups to the ends. Such chain-blocked oils show little change of viscosity with temperature and so are useful at low temperatures as well as high. They do not oxidize or sludge as readily as do hydrocarbon oils, and they are suitable as dielectric media becsuse they have low electrical losses over a wide range of temperatures and frequencies.

Silicone elastomer is made by hydrolyzing pure dimethyldichlorosilane and extending the resulting linear polymers to very high molecular weight, so that the chains consist of thousands of dimethylsiloxane units. Such high polymers have elastic properties, and if they are milled with inorganic fillers and curing agents, the compounded material can be cured or vulcanized to a rubbery product.

Like silicone oil and resins, silicone rubber can be utilized at temperatures both above and below those permissible for the organic elastomers, both natural and synthetic.

Very thin films of silicone polymers also are formed *in situ* by reaction of the organosilicon chlorides with the adsorbed water on cellulose or glass, and the films so formed cause the surface to become highly water-repellent. Such a film is strongly bound and can be removed only by chemical action or by severe abrasion, but may readily be cleaned by alcohol or by solutions of wetting agents.

The process is useful wherever paper, cloth or glass is to be made water repellent.

SILICON STEEL. Invented by Sir Robert Hadfield in 1889, this alloy led to the perfection of what is termed low hysteresis steel, used in the manufacture of electrical apparatus. The term hysteresis is applied to the tendency of magnetic materials to remain in any magnetic state which already exists. This leads to loss of energy when this state is changed. Silicon steel is superior to iron itself in magnetic qualities, and improves with use. Therefore it makes an ideal core for electrical transformers. Silicon steel is made by heating steel containing $2\frac{1}{2}\%$ to 4% of silicon to a temperature of about 1,000° C. It is then cooled, reheated to about 800° C. and cooled again. See STEELS, ALLOY.

SILICOSIS is a chronic, fibrotic disease of the lung produced by prolonged inhalation of silica (SiO_2) dust. Several pneumonoconioses, or dust diseases of the lung, produce recognizabie changes in roentgenograms, but only three—silicosis, asbestosis and beryliosis—cause clinical symptoms.

Silica is widely distributed in nature, being found in sand, sandstone, granite, quartz and other rocks. The disease is strictly occupational and occurs in persons engaged in such trades as mining, metal polishing, glassmaking, grinding and stonecutting.

Disease is seldom produced with less than a two-year exposure to air containing at least 6,000,000 particles of silica per cubic foot. Only particles less than ten microns in diameter can reach the periphery of the lung and those particles between one and three microns are the most injurious.

The action of silica is not merely mechanical but physiochemical. Early lung changes are discrete, fine. uniformly distributed nodulations which later progress to fibrotic masses that involve both the lung tissue and the draining lymph nodes.

The chief symptom of the disease is shortness of breath. Later cough, tightness across the chest and weakness develop. Diagnosis depends upon typical roentgenogram findings plus a history of prolonged exposure to silica dust. Secondary infections of the lung are a common complication. Tuberculosis occurs in about 75% of the cases. is often severe in character and is frequently fatal.

Treatment of silicosis is largely preventive since there is no cure for the established lung changes. Treatment of the complications, however. is frequently very beneficial. *See* also PNEUMONOCONIOSIS. (W. R. BY.)

SILISTRA, a town in Bulgaria on a low-lying peninsula projecting into the Danube, is 81 mi. below Ruschuk. Pop. (1956) 20,491. The town was formerly a fortress of great strength, occupying the northeast corner of the famous quadrilateral (Ruschuk, Silistra. Shumen, Varna), but its fortifications were demolished in accordance with the Berlin treaty (1878). The principal trade is in cereals and the town also contains sawmills. It is surrounded by fine vineyards, some 30 kinds of grapes being cultivated, and tobacco is grown.

Apiculture is extensively practised and there are large market gardens in the neighbourhood. A considerable area is still covered with forest, to which the region owes its name of Deli Orman ("the wild wood").

Silistra, the Durostorum of the Romans, was one of the most important towns of Moesia Inferior and was successively the headquarters of the legio I (Italica) and the legio XI (Claudia). It was defended by the Bulgarian tsar Simeon against the Magyars and Greeks in 893. Thereafter it came successively under the control of Russia (967), Byzantium (971) and Turkey (1388). Briefly in the possession of the Walachian prince Mircea, it passed finally to Turkey in 1416. In 1810 the town was surrendered to the Russians who destroyed its fortifications before withdrawing. In 1828–29 the Russians again captured the town and held it until 1836. During the campaign of 1854 it was successfully defended against the Russians, but after being invested again in 1877 it was evacuated by the Turks. Silistra was assigned to Bulgaria in 1878, to Rumania in 1913 and to Bulgaria again in 1940

SILIUS ITALICUS (in full TIBERIUS CATIUS ASCONIUS SILIUS ITALICUS) (25 or 26–101), Latin epic poet, was the author of a long epic entitled *Punica,* an account in hexameter verse of the second war of the Romans against the Carthaginians (218–201 B.C.). Silius was an advocate of distinction in his early years, but he soon took to the public service and was consul in A.D. 68 (the year of Nero's death). His life thereafter is described by the younger Pliny in one of his letters: "he won repute by his proconsulship of Asia, and obliterated by the praiseworthy use he made of his leisure the stain he had incurred through his former exertions" (presumably as an assistant of Nero). "In dignity and contentment, avoiding power and therefore hostility, he outlived the Flavian dynasty, keeping to a private station after his governorship of Asia."

Silius was a rich man and able to indulge his tastes as a patron of literature and the arts. He so venerated both Virgil and Cicero that he bought for himself Virgil's tomb at Naples (which he restored) and Cicero's estate at Tusculum. In later life he imitated both, the former in writing epic, the latter in discussing philosophy with his friends, such as the poet Martial, Epictetus, who thought well of him as a philosopher, and Cornutus, the Stoic, who dedicated to him a commentary on Virgil. The Stoicism of Silius is not as marked in his epic as that of Lucan in his, but it is discernible, as one might expect, in a story of long and embittered warfare; and it was clearly to be seen in his life. for at the age of 75 he discovered that he was suffering from an incurable disease and starved himself to death.

The *Punica,* the only uork he is known to have committed to writing, is the longest epic in Latin literature, comprising over 12,000 lines. It deals with the second only of the Punic wars, though the story of Regulus (*q.v.*) appears in it as a digression. Silius draws heavily on the historian Livy for his material. For the most part he sticks well to his story and conscientiously describes all the six great battles of the war. The "details of slaughter" (as his translator J. D. Duff puts it) are often repulsive and the catalogues of armies monotonous. It is very imitative of Virgil's *Aeneid* both in its form and in its mythology. The gods take part, for example, and Juno frustrates the Romans just as she does the Trojans in the *Aeneid.* It lacks the poetry and the drama of Virgil, and the metre is monotonous and the style sometimes repetitive. The epic has indeed been harshly judged by its critics and has been rarely edited since the 18th century, but Silius can tell a story well and in simple language, far purer than the overdecorated style of other Latin poets of the Silver Age; and his accounts of military matters (*e.g.,* of the operations of siege engines) often bear the stamp of experience. His characters are mostly rather wooden, but his Hannibal is drawn with some dramatic skill and steals the place of hero from Scipio. Of the minor characters the best drawn are Fabius Cunctator, an evident copy of Lucan's Cato, and Paullus, the consul killed at Cannae.

The last three books show signs, as well they might, of fatigue; but posterity should be grateful for about half a dozen beautiful pieces of verse, mostly in dramatic scenes of war.

The poem was discovered in a manuscript in 1416 or 1417; from this manuscript, now lost. all existing manuscripts are derived. There were two *editiones principes* (1471). Other editions are by D. Heinsius (1600); J. C. T. Ernesti (1791); L. Bauer. "Teubner Series" (1890); J. D. Duff, with Eng. trans., "Loeb Series," 2 vol. (1934).

BIBLIOGRAPHY.—For his life the authorities are Pliny, *Epistles,* iii, 7; Tacitus, *Histories,* iii, 65; with frequent references in Martial.
(AN. K.)

SILK AND SERICULTURE. Silk is a fibrous substance produced by many insects. principally in the form of a cocoon or covering within which the creatures are enclosed and protected during the period of their principal transformations; the webs and nests, etc., formed by spiders are also of silk. But the fibres used for manufacturing purposes are exclusively produced by the mulberry silk-moth of China, *Bombyx mori,* and a few other moths closely allied to that insect.

History.—The silk industry originated in China; and according to native records it has existed there from a very remote period. The empress, known as the lady of Si-ling, wife of a famous emperor, Huang-ti (2640 B.C.), encouraged the cultivation of the mulberry tree, the rearing of the worms and the reeling of silk. This empress is said to have devoted herself personally to the care of silkworms, and she is by the Chinese credited with the invention of the loom. A voluminous ancient literature testifies to the antiquity and the importance of Chinese sericulture, and to the attention bestowed on it by royal and noble families. The Chinese guarded the secrets of their valuable art with vigilant jealousy; and there is no doubt that many centuries passed before the culture spread beyond the country of its origin. Through Korea a knowledge of the silkworm and its produce reached Japan, but not before the early part of the 3rd century. One of the most ancient books of Japanese history, the *Nihongi,* states that towards A.D. 300 some Koreans were sent from Japan to China to engage competent people to teach the arts of weaving and preparing silk goods. They brought with them four Chinese girls, who instructed the court and the people in the art of plain and figured weaving; and to the honour of these pioneer silk weavers a temple was erected in the province of Settsu. Great efforts were made to encourage the industry, which from that period grew into one of national importance. At a period probably a little later knowledge of the working of silk travelled westward, and the cultivation of the silkworm was established in India. According to a tradition the eggs of the insect and the seed of the mulberry tree were carried to India by a Chinese princess concealed in the lining of her head-dress. The fact that sericulture was in India first established in the valley of the Brahmaputra and in the tract lying between that river and the Ganges renders it probable that it was introduced overland from the Chinese empire. References in Sanskrit literature indicate however that a silk industry existed in India at about 1000 or possibly 4000 B.C. From the Ganges valley the silkworm was slowly carried westward and spread in Khotan, Persia and Central Asia.

Most critics recognize in the obscure word *d'wreseq* or *d'mesheq*, Amos iii. 12, a name of silk corresponding to the Arabic *dimaks*, late Greek μέταξα, English damask, and also follow the ancients in understanding *meshi*, Ezek. xvi. 10, 13, of "silken gauze." But the first notice of the silkworm in Western literature occurs in Aristotle, *Hist. anim.* v. 19 (1;), 11 (6), where he speaks of "a great worm which has horns and so differs from others. At its first metamorphosis it produces a caterpillar, then a bombylius and lastly a chrysalis—all these changes taking place within six months. From this animal women separate and reel off the cocoons and afterwards spin them. It is said that this was first spun in the island of Cos by Pamphile, daughter of Plates." Aristotle's vague knowledge of the worm may have been derived from information acquired by the Greeks with Alexander the Great; but long before this time raw silk must have begun to be imported at Cos, where it was woven into a gauzy tissue. the famous *Coa vestis*, which revealed rather than clothed the form.

Towards the beginning of the Christian era raw silk began to form an important and costly item among the prized products of the East which came to Rome. Allusions to silk and its source became common in classical literature; but, although these references show familiarity with the material. they are singularly vague and inaccurate as to its source; even Pliny knew nothing more about the silkworm than could be learned from Aristotle's description. The silken textures which at first found their way to Rome were necessarily of enormous cost, and their use by men was deemed a piece of effeminate luxury. From an anecdote of Aurelian, who neither used silk himself nor would allow his wife to possess a single silken garment, we learn that silk was worth its weight in gold. Notwithstanding its price and the restraints otherwise put on the use of silk the trade grew. Under Justinian a monopoly of the trade and manufacture was reserved to the emperor, and looms, worked by women, were set up within the imperial palace at Constantinople. Justinian also endeavoured, through the Christian prince of Abyssinia, to divert the trade from the Persian route along which silk was then brought into the east of Europe. In this he failed, but two Persian monks who had long resided in China, and there learned the whole art and mystery of silkworm rearing, arrived at Constantinople and imparted their knowledge to the emperor. By him they were induced to return to China and attempt to bring to Europe the material necessary for the cultivation of silk, which they effected by concealing the eggs of the silkworm in a hollow cane. From the precious contents of that bamboo tube, brought to Constantinople about the year 550, were produced all the races and varieties of silkworm which stocked and supplied the Western world for more than twelve hundred years.

The silkworm took kindly to its Western home and flourished, and the silken textures of Byzantium became famous. At a later period the conquering Saracens obtained a mastery over the trade, and by them it was spread both east and west—the textures becoming meantime impressed with the patterns and colours peculiar to that people. They established the trade in the thriving towns of Asia Minor, and they planted it as far west as Sicily, as Sicilian silks of the 12th century with Saracenic patterns still testify. Ordericus Vitalis, who died in the first half of the 12th century, mentions that the bishop of St. Evroul, in Normandy, brought with him from Apulia in southern Italy several large pieces of silk, out of the finest of which four copes were made for his cathedral chanters. The cultivation and manufacture spread northwards to Florence, Milan, Genoa and Venice—all towns which became famous for silken textures in mediaeval times. In 1480 silk weaving was begun under Louis XI at Tours, and in 1520 Francis I brought from Milan silkworm eggs, which were reared in the Rhone valley. About the beginning of the 17th century Olivier de Serres and Laffémas, somewhat against the will of Sully, obtained royal edicts favouring the growth of mulberry plantations and the cultivation of silk; but it cannot be said that these industries were firmly established before Colbert in the 17th century encouraged the planting of the mulberry by premiums, and otherwise stimulated local efforts.

Into England silk manufacture was introduced during the reign of Henry VI; but the first serious impulse to manufactures of that class was due to the immigration in 1585 of a large body of skilled Flemish weavers who fled from the Low Countries in consequence of the struggle with Spain then devastating their land. Precisely one hundred years later religious troubles gave the most effective impetus to the silk-trade of England, when the revocation of the Edict of Nantes sent simultaneously to Switzerland, Germany and England a vast body of the most skilled artisans of France. who planted in these countries silk-weaving colonies which are to this day the principal rivals of the French manufacturers. The bulk of the French Protestant weavers settled at Spitalfields, London—an incorporation of silk workers having been there formed in 1629. James I used many efforts to encourage the planting of the mulberry and the rearing of silkworms both at home and in the colonies. Up to the year 1718 England depended on the thrown silks of Europe for manufacturing purposes, but in that year Lombe of Derby, disguised as a common workman, and obtaining entrance as such into one of the Italian throwing mills, made drawings of the machinery used for this process. On his return, subsidized by the government, he built. and worked, on the banks of the Derwent, the first English throwing mill. In 1825 a public company was formed and incorporated under the name of the British. Irish and Colonial Silk Company, with a capital of £1,000,000, principally with the view of introducing sericulture into Ireland. but it was a complete failure, and the rearing of the silkworm cannot be said ever to have become a branch of British industry.

In 1522 Cortes appointed officials to introduce sericulture into New Spain (Mexico), and mulberry trees were then planted and eggs were brought from Spain. The Mexican adventure is mentioned by Acosta, but all trace of the culture had died out before the end of the century. In 1609 James I attempted to reinstate the silkworm on the American continent, but his first effort failed through shipwreck. An effort made in 1619 obtained greater success, and, the materials being present, the Virginian settlers were strongly urged to devote attention to the profitable industry of silk cultivation. Sericulture was enjoined under penalties by statute; it was encouraged by bounties and rewards; and its prosecution was stimulated by rhapsodical rhymes like the following:

> Where Wormes and Food doe naturally abound
> A gallant Silken Trade must there be found.
> Virginia excels the World in both—
> Envie nor malice can gaine say this troth!

Written instructions were sent to the colonists on the care of the worms, raising of trees and even an ingenious scheme for the creation of silkworms, from the putrefaction of a young calf. This description is given in a booklet published at London in 1620 with the title *Observations to be Followed, For the Making of Fit Roomes to Keepe Silk-wormes in: and For the Best Manner of Planting of Mulberry Trees, to feed them.* It concludes with the following exhortation:

"Meane while. with all speed make these timely and necessary prouisions aforesaid, for the ground-worke of the busines, as to plant store of the best Mulbery trees, in a good aire, in proper soyle, & fit distance, & dig store of holes in the ground betimes for the preparing of the earth, the better to plant the trees in: prouide also faire and fit middle lodgings for the Silk-wormes: for this delicate creature, which clothes Princes, and payes his charges so bountifully, cannot indure to bee lodged in bare and beggerly roomes, but in those that be large, sweet, neat. wel ayred and lightsome. It is a thing well knowne, that a few Silk-wormes, fed at large, and ease. make farre more silke than a greater number, pent in narrow and ill-fauoured roomes. No ill smels must come neere them, they must be kept sweet, and oft perfumed; therefore hauing such store of sweetwoods in Virginia as you haue there, you shall do well to make their roomes and tables of those woods: sweet sents being a thing most agreeable to them. Bee carefull to doe things curiously and thorowly well for them at the first, for your more plentifull and certaine gaine after: considering the charge to you is all one: and a thing once wel done, they say, is twice done, which will thereby also bring you twice double profit, with long continuance."

In the prospectus of Law's great *Compagnie des Indes Occidentales* the cultivation of silk occupies a place among the glowing attractions which allured so many to disaster. Onward till the period of the War of Independence bounties and other rewards for the rearing of worms and silk filature continued to be offered; and when the war broke out Benjamin Franklin and others were engaged in establishing a filature at Philadelphia. With the resumption of peaceful enterprise, the stimulus of bounties was again applied—first by Connecticut in 1783; and such efforts have been continued sporadically down almost to the present day. Bounties were offered by the State of California in 1865–1866, but the State law was soon repealed, and an attempt to obtain State encouragement again in 1872 was defeated. About 1838 a speculative mania for the cultivation of silk developed itself with remarkable severity in America. It was caused principally through the representations of Samuel Whitmarsh as to the suitability of the South Sea island mulberry (*Morus multicaulis*) for feeding silkworms; and so intense was the excitement that. plants and crops of all kinds were displaced to make room for plantations of M. *multicaulis*. In Pennsylvania as much as $300,000 changed hands for plants in one week and frequently the young trees were sold two and three times over within a few days at ever advancing prices. Plants of a year's growth reached the ridiculous price of $1 each at the height of the fever, which, however: did not last long, for in 1839 the speculation collapsed; the famous *M. multicaulis* was found to be no golden tree, and the costly plantations were uprooted.

Spasmodic efforts continued through the years but the next peak of interest came about following the tremendous increase in the use of silk after the World War. Raw silk values rose rapidly achieving the high price in the United States, the chief market, of $21.00 a pound in 1919 as contrasted with $3.64 in 1914. A new wave of interest in sericulture spread around the world. In the United States, intensive efforts were made in California to produce larger cocoons than those in the Orient and more frequent crops of cocoons than might be possible in a less favourable climate. The cocoons were raised and were of superior grade—but again the problem of reeling them into raw silk, on a commercial basis, proved the stumbling block of competition with the Orient. Some attempt was made to ship cocoons to Japan, but the commerce was not sufficiently developed to be successful on a wide scale. Other attempts in the United States were instigated by a promoter who not only sang the praises of meeting world competition on raw silk but also promised his clients special profits from producing a silk filament pre-coloured by injection of dyestuffs into the silkworm. Louisiana. Florida and Canada were the scenes of greatest activity among the buyers of the mulberry trees and the rainbow-hued silkworms. Newspaper accounts implied that fortunes were to be made and that, with the exception of the dyers who would find themselves without an occupation, the entire public would be grateful to the promoter. A year later, the investors were seeking buyers for their cocoons. None were found, and once more sericulture in the United States proved to be impractical.

In Persia, the venture assumed another role, that of acting as a substitute for the Persian poppy crop. The anti-narcotic division of the League of Kations pinned their hopes on the mulberry tree as a means of reducing the world output of opium. Persia, as one of the ancient homes of the silk industry, would have a natural aptitude for sericulture, it was thought, and the assistance of American silk manufacturers was sought in buying reeling machinery and employing skilled workers from France and Italy to teach the modern methods of raising and reeling silk. The Americans were already engaged in other fields and did not participate, but the industry was started. However. as in so many other cases, Persia found that producing the silk was only half the problem; the other half was the marketing of it. In 1939, Persian Government representatives presented to New York fabric dealers samples of plain and printed fabrics made in the factories of Iran (Persia) with the hope that the makers could share in the great dress market of the world but the exhibit, the type of fabrics and their styling, as well as the limited amount being made, did not result in any great show of interest on the part of potential buyers.

During this period, the American manufacturers returned to China, the original source of silk, and still the source of some of the strongest and best silk grown. The difficulty was the lack of modern methods of preparation for the user, the fabric manufacturer and the lack of standardization in the grades and quantities produced. To demonstrate the meaning of the modern requirements: the American silk industry subscribed a large sum of money to initiate the study of sericulture in three of the missionary colleges in China. Buildings were erected, land bought for mulberry orchards, modern laboratory equipment installed and courses of study established in the methods of raising and feeding worms so as to avoid disease and the consequent imperfect silk filament! in the proper sizing of the silk thread by efficient reeling, in the making of the size and type of skein required by high-speed modern looms, and in the conditioning and testing of the silk to determine its grade for the purchaser. It was thought by the Americans that the Chinese would be sufficiently interested to carry on the work when it had been demonstrated that the American market could be more equally shared with the Japanese if the methods were adopted. The Chinese, however, had found that they could sell their silk made in the accustomed manner to the European buyers who did not require the same high standard of efficiency as the Americans due to their less pressing high-wage problem and the use of older, slower looms. After a few years, the campaign was discontinued not only because of the results but also of the increasing domestic upheavals in China itself which resulted in disruption of many of the relationships so necessary to successful prosecution of the enterprise.

India was another experimental field. The Indian Government, especially at Mysore, evinced much interest in the educational work done by the Americans in providing the proper grade and adequate quantity of raw silk for the United States market. Similarly ambitious were officials in the Black sea area of Russia, in Greece, Spain and even South Africa but the American market continued to look mainly to China and Japan for its supplies and by 1936, United States Department of Commerce report on foreign commerce and navigation omits all mention of any of the smaller countries.

Raw silk can be profitably produced where there is not only low cost labour but labour working at low wages for long hours at a high degree of efficiency under modern conditions of factory organization, as evidenced in the success of the Japanese in capturing and maintaining the lion's share of the world markets.

The Silkworm.—The mulberry-feeding moth, *Bombyx mori*, which is the principal source of silk, belongs to the *Bombycidae*, a family of *Lepidoptera* in which are embraced some of the largest and most handsome moths. *B. mori* is itself an inconspicuous moth. of an ashy white colour, with a body in the case of the male not $\frac{1}{2}$in. in length. the female being a little longer and stouter. Its wings are short and weak; the fore pair are falcate, and the hind pair do not reach to the end of the body. The larva which is hairless. is of an ashy grey or cream colour, attains to a length of from 3 to $3\frac{1}{2}$in., and is slender in comparison with many of its allies. The second thoracic ring is humped, and there is a spine-like horn or protuberance at the tail. The common silkworm produces only one generation during the year where the seasons are defined: *e.g.*, Europe and the Near East; in Japan, the largest silk-producing country of the world, the race of silkworm is bivoltine, *i.e.*, reproduction takes place twice annually, while in parts of India and China reproduction is almost continuous and the races cultivated are called multivoltine; but the quality of the silk is in inverse ratio to the number of hatchings. The silkworm's natural food is the foliage of mulberry trees.

The silk glands or vessels consist of two long thick-walled sacs running along the sides of the body, which open by a common orifice—the spinneret or seripositor—on the under lip of the larva. As the larva approaches maturity these vessels become gorged with a clear viscous fluid, which, upon being exposed to the air immediately hardens to a solid mass. Advantage is taken of this peculiarity to prepare from fully developed larvae silkworm gut used for casting lines in rod-fishing. and for numerous other purposes where lightness, tenacity, flexibility and strength are essential. The larvae are killed and hardened by steeping some hours in strong acetic acid; the silk glands are then separated from the bodies, and the viscous fluid drawn out to the condition of a fine uniform line, which is stretched between pins at the extremity of a board. The board is then exposed to the sunlight till the lines dry and harden into the condition of gut. The preparation of gut is, however, merely an unimportant collateral manufacture. When the larva is fully mature, and ready to change into the pupa condition, it proceeds to spin its cocoon, in which operation it ejects from both glands simultaneously a continuous and reelable thread of 800 to 1,200yd. in length, moving its head around in regular order continuously for three days or thereabouts. The thread so ejected forms the cocoon, and consists of filaments seriposited from two separate glands. Two other glands, named after their discoverer the glands of Filippi, secrete a glutinous or resinous substance, which is believed to serve the double purpose of helping the thin viscous threads through the spinneret and causing the two filaments to adhere when brought into contact with the atmosphere.

Under the microscope cocoon silk presents the appearance of a somewhat flattened combination of twp filaments placed side by side, being on an average $\frac{1}{1,200}$ in. in thickness. The cocoons are white or yellow in colour, oviform in shape, and often with a constriction in the middle. According to race, etc.. they vary considerably in size and weight, but on an average they measure from an inch to an inch and a half in length. and from half an inch to an inch in diameter. They form hard, firm and compact shells with some straggling flossy filaments on the exterior, and the interior layers arc so closely and densely agglutinated as to constitute a parchment-like mass which resists all attempts at unwinding. The whole cocoon with its enclosed pupa weighs from 1 j grains for the smaller races to about 50 grains for the breeds which spin large cocoons. From 10 to 12 days after the completion of the cocoon the enclosed insect is ready to escape; it moistens one end of its self-made prison, thereby enabling itself to push aside the fibres and make an opening by which the perfect moth comes forth. The sexes almost immediately couple; the female in from four to six days lays her eggs, numbering 500 and upwards; and, with that the life cycle of the moth being complete, both sexes soon die.

SERICULTURE

The art of sericulture concerns itself with the rearing of silkworms under artificial or domesticated conditions: their feeding, the formation of cocoons, the securing of these before they are injured and pierced by the moths, and the maturing of a sufficient number of moths to supply eggs for the cultivation of the following year. The first essential is a stock of mulberry trees adequate to feed the worms in their larval stage. The leaves preferred in Europe are those of the white-fruited mulberry, *Morus alba,* but there are numerous other species which appear to be equally suitable. The soil in which the mulberry grows: and the age and condition of the trees, are important factors in the success of silkworm cultivation; and it has been too often proved that the mulberry will grow in situations where, from the nature of the leaf the trees put forth and from other circumstances, silkworms cannot be profitably reared. An elevated position with dry, friable, well-drained soil produces the best quality of leaves. Throughout the East the species of mulberry cultivated are numerous, but, as these trees have been grown for special purposes at least for three thousand years, they show the complex variations peculiar to most cultivated plants.

Incubation and Rearing of Worms. — The eggs of the silkworm, called "silk-seed" (Fr. *graines*), are hatched out at the period when the mulberry buds are breaking into leaf. The hatching is natural where the climate is uniformly hot, but in countries where the silkworm has been introduced. artificial heat has to be applied to thr eggs. In many parts this is done by the primitive fashion of imparting to the seed the necessary heat by contact with the human body, but this gives an irregular and unduly protracted hatching. Simple incubators are now in use which make incubation regular, and the eggs all hatch out tonether, which is a great advantage from the point of view of economical feeding later on. The eggs are very minute — ahout 100 weighing a grain; and a vast number of hatched worms may at first be kept in a small space; but as the worms grow and require more and more leaves, the caterpillars require quickly increasing and ample space. The seed is distributed in perforated boxes to rearers, as it requires air all through the period of preservation until the worms are hatched. The boxes are opened and the seed is evenly spread on trays which are placed into the incubator; the lamp of the incubator is lit and the temperature is brought to 6j° F. This is gradually increased daily by about 2° until it reaches 77°, at which temperature hatching takes place. The trays are withdrawn from the incubator and perforated paper or open-mesh gauze is spread over the minute worms; mulberry leaves, now young and very tender. are finely chopped and spread over the paper or gauze; the little norms wriggle up through the holes and begin feeding The temperature of the room in which they are placed should be maintained at 77°. In more progressive countries. a special rearing house (Fr *magnanerie*) is allocated to the rearing of silkuorms; it may he used for other purposes during the remainder of the year provided it is swept clean, disinfected and lime-washed ready for the reception of the worms. In more backward places. the dwelling of the peasant rearer is utilized, but the same scrupulous disinfection and cleanliness should be observed, though this is often neglected with unfortunate effects on the worms and the rearer The place set apart for rearing should be well ventilated but not necessarily well lit indeed, it should be capable of shading the worms from the direct rays of the sun, which are detrimental to them.

FIG I. — MULBERRY LEAVES, THE FAVOURITE FOOD OF SILKWORMS

Though there are many methods of keeping the worms during feeding, the best is probably to erect shelves about three feet wide in the centre of the room so that there is a walking space between them and the walls all round and gangways intersecting them These shelves are constructed by means of light scantling from the floor to the ceiling with crozs-pieces at intervals of two feet, the lowest being two feet above the floor. Over the frame-nork thus created is laid large-mesh wire netting which, in this way, provides a series of shelves each two feet high Paper is spread over the wire and the norms are placed on this; the worms increase in size with astonishing rapidity and they are given more and more space in conformity with their growth. No less remarkable is their groning voracity. After three or four days they are sufficiently grown to be able to consume whole young leaves, and from this time onwards their powers of consumption run parallel with the maturity of the mulberry. The feeding lasts about 42 days, but during that time the norm passes through four periods of sleep lasting 24 hours each; some races have only three periods of sleep. but these are rare During this sleeping period the skin of the worm cracks and when the creature wakes up it is able to shed the old skin and continue with the new one. The importance of the regularity of hatching out now becomes apparent. The worms hatched out on the same day all sleep at the same time, and during the sleep do not require nourishment If, however, the hatching out is irregular, sleeping and active hungry worms are mixed up, with the risk either of a waste of mulberry

leaf or of malnutrition of the active worms. Worms will not touch faded leaves; the latter must be green but very slightly wilted. The sleeping periods occur on the sixth, twelfth, eighteenth and twenty-sixth day after hatching. After the fourth sleep, the worms start their great and final feed. lasting for ten days during which period they consume about twenty times their own weight of leaves.

Laurent de l'Arbousset showed in 1905 that 1 oz. of seed of 30 grams producing 30,000 to 35,000 silkworms (30,000 may be depended upon to reach the cocoon stage) will give a harvest of 130 to 140lb. fresh cocoons and ultimate yield of about 12lb. raw silk properly reeled. The amount of nourishment required for this rearing is as follows:—hatching to first moult, about 9lb. of leaves of tender growth, equal to 40 to 45lb. ripe leaves; first to second moult, 24lb., representing 100lb. ripe leaves; second to third moult, 80lb., representing 240lb. ripe leaves; third to fourth moult, 236lb., representing 472lb. ripe leaves; fourth moult to mounting, 1,430lb., representing 1,540lb. ripe leaves, totalling to about one ton of ripe leaves for a complete rearing. The growth of the worms during their larval stage is stated by Count Dandolo to be as follows: the small, black, newly hatched worm weighs about one-hundredth of a grain, and is about one-twelfth of an inch long; when it has reached its full growth, the large white worm weighs about ten grains, and is more than three inches long. Or, in tabular form:

The **Cocoons.**—The worms show that they are ready to spin their cocoons by raising the forepart of the body and waving it slowly from side to side. Provision is now made for the structure on which they can spin. This consists of "bushes" of scrub-oak or other many-branched shrub which are placed vertically in the centre of the shelves on which the worms have hitherto spent their lives. Obedient to the dictates of nature, the worms, now replete with glutinous fibre, mount up into the bushes and proceed to spin the cocoons around themselves. If they are overcrowded there is the danger of two worms combining to spin one cocoon; this latter is practically useless for making silk as the combined threads are inextricably mixed up and the cocoon is incapable of being. reeled into fine silk. After eight days, the bushes are removed from the shelves and the cocoons are picked off them. The importance of an even incubation is again demonstrated here, for if the hatch-out were irregular some worms would be ready to spin before others and the rearer would run the risk of taking down the bushes before all the worms had completed their spinning, resulting in some cocoons of inferior quality. On the other hand, the rearer dare not wait more than eight days, otherwise the chrysalis would complete its transformation and change into a moth which, in emerging from the cocoon, would cut through the silk fibres and destroy it for reeling purposes and thus render it practically valueless.

With the exception of those selected for reproduction of eggs, the cocoons are now treated so as to preserve them intact for reeling. The chrysalis must be killed without damage to the cocoon. The worm spins the cocoon with one continuous thread in a manner forming the figure 8, therefore the cutting of the cocoon at one end to allow the moth to escape means the cutting of the one continuous thread into many thousands of short ones and naturally makes it impossible to unwind ("reeling silk" is only another way of saying "unwinding cocoons"). The method adopted for killing the chrysalides is that of suffocation. Leaving cocoons exposed to the hot sun will suffocate the chrysalides, but it also hardens the gum in the thread, making unwinding difficult and wasteful, and withdraws to a certain extent the colour from yellow cocoons. Another method is suffocation by steam. The cocoons are placed in shallow drawers in a cupboard which is constructed over a common washing copper. The bottoms of the drawers are constructed so as to allow of steam percolating through them. A fire is lit below the cauldron, which is filled with water, and steam is generated. The cocoons remain in the steam from eight to ten minutes and the chrysalis is suffocated. The cocoons are then spread lightly on canvas beds. sheltered from the sun, but where air can circulate freely. They remain on the beds from six weeks to two months, during which time they require to be turned over twice daily to prevent heating and the dead chrysalis gradually dries up without becoming putrid. In this method there is the risk of either keeping the cocoons in the steam too long and damaging the fibre, rendering the thread brittle, or not keeping them long enough so that the chrysalis, which has marvellous powers of recovery, will complete its metamorphosis and the moth will cut through after all. The safest and most practical method is suffocation by hot air. *Séchoirs,* or dryers, are constructed to take a large quantity of cocoons at one charge, and air is fanned through a steam-coiled chamber rendering it about 200° F. The hot air circulates by means of channels through the chambers containing the cocoons, and the chrysalis is suffocated and all moisture in it dried up in one process of twelve hours' duration. The cocoons are put into sacks and stored without fear of deterioration. Exposure to air and wind. which also means exposure to dust and dirt, is unnecessary, and the colour of the silk when the cocoons are reeled is richer. while the water used in the reeling keeps clean.

FIG. 4.— A SILKWORM. ALMOST FULL GROWN, FEEDING

Selection of Eggs for Reproduction.—The promiscuous production of eggs for the following crop by the rearers is strongly to be discouraged and in many countries it is absolutely prohibited, because of the great risk of propagating diseases to which the silkworm is prone. Reproduction, if a virile and healthy race of worm is to be preserved, must be under the supervision of experts. These experts choose rearers who are known to be extremely adept at cocoon-raising and give them specially selected eggs, each separate laying of nhich has been microscopically examined for the presence of disease. These eggs are known as "cellular seed." The experts pay periodical visits to the *magnanerie* during the rearing to examine the condition of the worms and take away any of doubtful appearance for microscopic examination. If the rearing is entirely successful and no trace of disease is found, the cocoons are taken to the "seed station," where they are examined. Ill-formed or imperfect cocoons are sent to be stifled and the selected ones are threaded together into long ropes and suspended from the ceiling to within a foot of the floor. In due course the moths emerge from the cocoons, mating takes place and the female is placed in a small linen bag, about 2in. square, which has been washed and disinfected; the mouth is tied up and these bags are strung together and suspended from the ceiling of another room. The female lays its eggs in the bag and dies. The males, after two or three matings, are destroyed. This part of the process is carried on until the cocoon crop is at an end. The ratio of reproduction is about 250 to 1, so the seed stations require about 1,000lb. of cocoons for seed for a crop of 25,000lb. of cocoons the next season.

FIG. 5.—A SILKWORM MOTH EMERGING FROM ITS COCOON (FRONT VIEW)

As soon as the mating is over, work is begun on the microscoping of the seed which has been laid. In the case of selection for cellular seed, each bag is emptied of its contents, the seed is washed in water to free it from the remains of the dead female and a few seeds are crushed and placed on a slide for examination. If the microscope tells no tale of disease, that particular laying is passed. If traces of disease are found, the bag and its contents are burned. In the case of seed not to be used for reproduction but only to be distributed for producing cocoons for silk, called industrial seed, each rearing is kept separate and the contents of all the bags of one rearing are emptied out together. This heap of seed is washed as before, is well mixed and half a dozen samples are taken, crushed and examined as before. If disease is detected, further samples are taken to determine the extent of it. If not more than 5% of disease is apparent, the rearing passes; if more, it is entirely destroyed. In this way all the eggs are gradually cleared through the microscoping room, a further washing takes place and, after the seed is dry, it is done up in small gauze bags in weights of 1 oz., $\frac{1}{2}$ oz. and $\frac{1}{4}$ oz. These, in turn, are placed in perforated cardbcard boxes and are ready for distribution to rearers the following season, the cellular seed being kept separate for selected rearers for a further cycle of reproduction.

FIG. 6.—SILKWORM MOTH EMERGING FROM ITS COCOON (SIDE VIEW)

The expert's task is not finished with the production of sound and healthy seed. He is also concerned with the cross-breeding of different varieties with a view to a higher yield of silk in the cocoons for reeling, to creating hardier races for different conditions of climate, to improving the cocoons of one part of the world by crossing the moths with those from another — an endless succession of problems for the propagation of sericulture in general.

DISEASES

That the silkworm is subject to many serious diseases is only to be expected of a creature which for upwards of 4,000 years has been propagated under purely artificial conditions, and these most frequently of a very insanitary nature, and where not the healthy life of the insect, but the amount of silk it could be made to yield, was the object of the cultivator. Among the most fatal and disastrous of these diseases with which the cultivator had long to grappie was "muscardine," a malady due to the development of a fungus, Botrytis *bassiana,* in the body of the caterpillar. The disease is peculiarly contagious and infectious, owing to the development of the fungus through the skin, whence spores are freed, which, coming in contact with healthy caterpillars, fasten on them and germinate inwards, giving off corpuscles within the body of the insect. Muscardine, however, has not been epidemic for many years.

The Pebrine Epidemic. — About the year 1853 anxious attention began to be given in France to the ravages of a disease among silkworms. This disease, which at a later period became known as *pebrine*—a name given to it by De Quatrefages, one of its many investigators — had first been noticed in France at Cavaillon in the valley of the Durance near Avignon. Pebrine manifests itself by dark spots in the skin of the larvae; the eggs do not hatch out, or hatch imperfectly; the worms are weak, stunted and unequal in growth, languid in movement, fastidious in feeding; many perish before coming to maturity; if they spin a cocoon it is soft and loose, and moths when developed are feeble and inactive. When sufficient vitality remains to produce a second generation it shows in increased intensity the feebleness of the preceding. The disease is thus hereditary, but in addition it is virulently infectious and contagious. From 1850 onwards French cultivators were compelled, in order to keep up their silk supply, to import graine from uninfected districts. The area of infection increased rapidly, and with that the demand for healthy graine correspondingly expanded, while the supply had to be drawn from increasingly remote and contracted regions. Partly supported by imported eggs. the production of silk in France was maintained. and in 1853 reached its maximum of 26,000,000 kilos of cocoons. valued at 117,000,000 francs. From that period, notwithstanding the importation at great cost of foreign graine, reaching in some years to 60,000 kilos, the production of silk fell off with startling rapidity: in 1856 it was not more than 7,500,000 kilos of cocoons; in 1861 and 1862 it fell as low as 5,800,000 kilos; and in 1865 it touched its lowest weight of about 4,000,000 kilos. In 1867 De Quatrefages estimated the loss suffered by France in the 13 years following 1853, from decreased production of silk and price paid to foreign cultivators for graine, to be not less than one milliard of francs. In the case of Italy, where the disease showed itself later but even more disastrously, affecting a much more extended industry, the loss in 10 years De Quatrefages stated at two milliards. A loss of £120,000,000 sterling within 13 years, falling on a limited area, and on one class within these two countries, constituted indeed a calamity on a national scale, calling for national effort to contend with its devastating action. The malady, moreover, spread eastward, and, although it was found to be less fatal in Oriental countries than in Europe, the sources of healthy graine became fewer and fewer, till only Japan was left as an uninfected source of European graine supply.

A scourge which so seriously menaced the very existence of the silkworm in the world necessarily attracted a great amount of attention. As early as 1849 Guérin Méneville observed in the blood of diseased silkworms certain vibratory corpuscles, but neither did he nor the Italian Filippi, who studied them later, connect them distinctly with the disease. The corpuscles were first accurately described by Cornalia, whence they are spoken of as the corpuscles of Cornalia. The French Academy charged De Quatrefages, Decaisne and Péligot with the study of the disease, and they issued two elaborate reports—*Études sur* les maladies *actuelles* des vers a soie (1859) and *Nouvelles Recherches sur* les maladies *actuelles* des vers *à* soie (1860); but the suggestions they were able to offer had not the effect of stopping the march of the disease. In 1865 Pasteur undertook a government commission for the investigation of the malady. Attention had been previously directed to the corpuscles of Cornalia. and it had been found. not only that they occurred in the blood, but that they gorged the whole tissues of the insect, and their presence in the eggs themselves could be microscopically demonstrated. Pasteur established (1) that the corpuscles are the special characteristic of the disease, and that these invariably manifest themselves, if not in earlier stages, then in the mature moths; (2) that the corpuscles are parasites, and not only the sign but the cause of the disease; and (3) that the disease manifests itself by heredity, by contagion with diseased worms, and by the eating of leaves on which corpuscles are spread. In this connection he established the very important practical conclusion that worms which contract the disease during their own life-cycle retain sufficient vitality to feed, develop and spin their cocoon, although the next generation is invariably infected and shows the disease in its most virulent and fatal form. This fact. however, enabled the cultivator to know with assurance whether the worms on which he bestowed his labour would yield him a harvest of silk. He had only to examine the bodies of the moths yielding his graine: if they were free from disease then a crop was sure; if they were infected the education would assuredly fail.

Pasteur brought out the fact that the malady had existed from remote periods and in many unsuspected localities. He found corpuscles in Japanese cocoons and in many specimens which had been preserved for lengthened periods in public collections. Thus he came to the conclusion that the malady had been inherent in many successive generations of the silkworm, and that the epidemic condition was only an exaggeration of a normal state brought about by the method of cultivation and production of graine pursued. The cure proposed by Pasteur was simply to take care that the stock whence graine was obtained should be healthy, and the offspring would then be healthy also. Small educations reared apart from the ordinary magnanerie, for the production of graine alone, were recommended. At intervals of five days after spinning their cocoons specimens were to be opened and the chrysalides examined microscopically for corpuscles. Should none have appeared till towards the period of transformation and escape of the moths, the eggs subsequently hatched out might be depended on to yield a fair crop of silk; should the moths prove perfectly free from corpuscles after depositing their eggs the next generation would certainly live well through the larval stage. For special treatment towards the regeneration of an infected race, the most robust worms were to be selected, and the moths issuing from the cocoons were to be coupled in numbered cells, where the female was to be confined till she deposited her eggs. The bodies of both male and female were to be examined for corpuscles, and the eggs of those found absolutely free from taint were preserved for similar "cellular" treatment in the following year. By this laborious and painstaking method it has been found possible to re-establish a healthy stock of valuable races from previously highly infected breeds. The rearing of worms in small educations under special supervision has been found to be a most effective means of combating pebrine. In the same way the rearing of worms for graine in the open air, and under natural conditions as far as possible, has proved equally valuable towards the development of a hardy, vigorous and untainted stock. The open-air education was originally proposed by Chavannes of Lausanne, and largely carried out in the canton of Vaud by Roland, who reared his worms on mulberry trees enclosed within "manchons" or cages of wire gauze and canvas. The insects appeared quickly to revert to natural conditions; the moths brought out in open air were strongly marked, lively and active, and eggs left on the trees stood the severity of the winter well, and hatched out successfully in the following season. Roland's experience demonstrated that not cold but heat is the agent which saps the constitution of the silkworm and makes it a ready prey to disease.

Other **Diseases.**—*Grasserie* is another form of disease incidental to the silkworm. It often appears before or after the first moult, but it is only after the fourth that it appears in a more developed form. The worm attacked presents the following symptoms: the skin is distended as if swollen, is rather thin and shiny, and the body of the worm seems to have increased, that is, it suffers from fatness, or is *engraissé*, hence its name. The disease is characterized by the decomposition of the blood; in fact it is really a form of dropsy. The blood loses its transparency and becomes milky, its volume increases so that the skin cannot hold it, and it escapes through the pores. This disease is more accidental than contagious and rarely takes very dangerous proportions. If the attack comes on a short time before maturity, the worms are able to spin a cocoon of a feeble character, but worms with this disease never change into chrysalides, but always die in the cocoon before transformation can take place. The causes which produce it are not well known, but it is generally attributable to currents of cold and damp air, to the use of wet leaves in feeding, and to sudden changes of temperature.

Another cause of serious loss to the rearers is occasioned by *flacherie,* a disease well known from the earliest times. Pasteur showed that the origin of the disease proceeded from microscopic organisms called ferments and vitrios. One has only to ferment a certain quantity of mulberry leaves, chop them up and squeeze them, and so obtain a liquid, to find in it millions of ferments and vitrios. It invariably occurs during the most active period of feeding, three or four days after the fourth moult up to the rising, and generally appears after a meal of coarse leaves, obtained from mulberries pruned the same year and growing in damp soil. It can also occur from the feeding of damp leaves, *e.g.,* leaves wetted by rain, to the worms or from leaves too freshly plucked and not allowed to wilt slightly. *Flacherie* is an intestinal disease of the cholera species and therefore contagious. The definite course is not occasioned so much from the ferments which exist in the leaves themselves, but from an arrest of the digestive process which allows the rapid multiplication of the former in the Intestines. Good ventilation is indispensable to allow the worm to give out by transpiration the great quantity of water that it absorbs with the leaf. If this exhalation is stopped or lessened the digestion in its turn is also stopped, the leaf remains longer than usual in the intestines, the microbes multiply, invading the whole body, and this brings about sudden death. The true remedies consist in the avoidance of the fermentation of the leaves by careless gathering, transport or packing, in proper hygienic care in ventilation and in maintaining a proper degree of dryness in the atmosphere in rainy weather, and in the use of quicklime to facilitate the transpiration of the silkworms.

WILD SILKS

The ravages of pebrine and other diseases had the effect of attracting prominent attention to the numerous other insects, allies of the mulberry silkworm, which spin serviceable cocoons. It had been previously pointed out by Captain Hutton, who devoted great attention to the silk question as it affects the East Indies, that at least six species of *Bombyx,* differing from *B. mori,* but also mulberry-feeding, are more or less domesticated in India. These include B. *textor,* the boropooloo of Bengal, a large species having one generation yearly and producing a soft flossy cocoon; the Chinese monthly worm, *B. sinensis,* having several generations, and making a small cocoon; and the Madrasi worm of Bengal (B. *croesi),* the Dassee or Desi worm of Bengal (*B. fortunatus)* and *B. arracanensis,* the Burmese worm—all of which yield several generations in the year and form reelable cocoons. Besides these there are many other mulberry-feeding *Bombycidae* in the East, principally belonging to the genera *Theophila* and *Ocinara,* the cocoons of which have not attracted cultivators. The moths yielding wild silks which have obtained most attention belong to the extensive and handsome family *Saturniidae.* The most important of the species at present (1940) is the Chinese tussur or tasar worm, *Antheraea pernyi,* which is an oak-feeding species, native of Mongolia, from which is derived the greater part of the so-called tussur silk imported into Europe. Closely allied to this is the Indian tussur moth, *Antheraea mylitta,* found throughout the whole of India feeding on the bher tree, *Zizyphus jujuba,* and also on many other plants. It yields a large compact cocoon of a silvery grey colour, which Sir Thomas Wardle of Leek, who devoted a great amount of attention to the wild-silk question, succeeded in reeling Next in promising qualities is the muga or moonga worm of Assam, *Antheraea assama,* a species to some extent domesticated in its native country.

The yama-mai worm of Japan, *Antheraea (Samia) yama-mai,* an oak-feeder, is a race of considerable importance in Japan, where it was said to be jealously guarded against foreigners. Its eggs were. first sent to Europe by Duchêne du Bellecourt, French consul-general in Japan in 1861; but early in March following they hatched out, when no leaves on which the larvae would feed were to be found. In April a single worm got oak-buds, on which it throve, and ultimately spun a cocoon whence a female moth issued, from which Guérin Méneville named and described the species. A further supply of eggs was secretly obtained by a Dutch physician Pompe van Meedervoort in 1863, and, as it was now known that the worm was an oak-feeder, and would thrive on the leaves of European oaks, great results were anticipated from the cultivation of the yama-mai. These expectations, however, for various reasons, have been disappointed. The moths hatch out at a period when oak leaves are not ready for their feeding, and the silk is by no means of a quality to compare with that of the common mulberry worm. The mezankoorie moth of the Assamese, *Antheraea mezankooria,* yields a valuable cocoon, as does also the Atlas moth, *Attacus atlas,* which has an omnivorous larva found throughout India, Ceylon, Burma, China and Java. The Cynthia moth, *Attacus cynthia,* is domesticated as a source of silk in certain provinces of China, where it feeds on the *Ailanthus glandulosa.* The eria or arrindi moth of Bengal and Assam, *Attacus ricini,* which feeds on the castor-oil plant, yields seven generations yearly, forming loose flossy orange-red and sometimes white cocoons. The ailanthus silkworm of Europe is a hybrid between *A. cynthia* and *A. ricini,* first obtained by Guérin Méneville, and now spread through many silk-growing regions. These are only a few of the moths from which silks of various usefulness can be produced; but none cf these presents qualities, saving perhaps cheapness alone, which can put them in competition with common silk.

A wild silk which has entered the market since the beginning of the 20th century is Anaphe. It-is found in West and East Africa. The worms combine to make large nests of cocoons with a strong outer protecting covering, tough as parchment. A peculiar and unpleasant quality of this species is the presence of hairs of a somewhat poisonous nature which bring out a rash on the skin when the nests are handled. Chemical treatment before handling has'eliminated this trouble, but progress with the utilization of this silk is slow. It first began to attract attention in Germany in 1913 but its experimental stage was held up until 1920. At first, the outer cover was thrown away and the internal cocoons were treated, but it has since been found that the outer cover is the more valuable and the internal cocoons hardly worth the trouble of working. Natives use the nests for the manufacture of their blankets but its economic usefulness in Europe has still to be proved. The systematic planting of the bush on which the Xnaphe worm feeds would also be indicated if there is to be a constant and cheaper supply of this material.

PHYSICAL AND CHEMICAL PROPERTIES OF SILK

Common cocoons *(Bombyx mori)* enclosing chrysalides weigh each from 0·4 to 2 grams, *i.e.,* there are from 300 to 600 to the pound, for small breeds. and 270 to 300 for large breeds. About one-sixth of this weight is silk and of that one-half can be reeled, the remainder which cannot be reeled consisting of surface floss or blaze and the husk of the chrysalis. It is therefore difficult to estimate the total length of thread produced by the silkworm or even that of the portion reeled. which varies in length and thickness according to the condition and robustness of the cocoon and may be joo metres in some breeds and in others 900 to 1,200 metres. It has been estimated that one pound of raw silk requires from 2,100 to 3.000 cocoons. Under favourable conditions 11 kilograms of fresh cocoons may give 1 kilogram of raw silk for commerce and about the same quantity of waste silk for spinning. The thread is usually thicker and stronger towards the middle of the reeled portion than at the extremities. The mean diameter of the cocoon thread or bave which is composed of two filaments of different specimens of mulberry silk was found at the Lyons laboratory to vary from 0·00180 to 0·0033cm.; the bave of wild silks from 0.0030 to 0·0070 centimetre. The denier or weight in grams of 9,000 metres of the bave of mulberry silk varies from 1.8 to 3.8. and that of the bave of the Anthers (wild silks) from 3 to 8 deniers.

The raw silk fibre *(see* FIBRES) consists essentially of two cores of *fibroin* cemented together and covered with *sericin* or silk albumen, besides small quantities of waxy and colouring matters. The ultimate filaments of fibroin, which constitute about 70 to 80% of drv. raw mulberry silk have in bulk, after removal of the gum, the characteristic soft white appearance and pearly lustre of pure silk. Under the microscope the filaments appear smooth and rod-like and. when examined by polarized light, show the colours given by doubly refracting substances; their cross-section is roughly triangular (maximum diameter, 0.0023 to 0·0014cm.; minimum diameter, 0·0018 to 0·0009cm.). The filaments have great tensile strength (3 to 5×10^9 dynes per sq.cm.) extending considerably before breaking, and show true elastic effects under limited stresses (Young's modulus, 0.4 to $0{\cdot}8 \times 10^{11}$ and rigidity, 0.2×10^{11} dynes per sq.cm. under ordinary conditions). In fact, silk is said to have almost the equivalent tensile strength of iron wire; that of the wire being 90,000lb. per sq.in. and that of silk 64,000. Its elasticity is also a remarkable characteristic. An elasticity of 20% means that the silk fibre can be stretched one-fifth of its original length and when released will return to its natural state. To the two properties of tensile strength and elasticity silk owes much of its excellence as a textile material, especially in the making of women's hosiery. The density of silk fibres is about 1·3, refractive index 1·5, and specific heat 0·3 calories per gram. The low electrical conductivity of fibroin. utilized in the employment of silk for electrical insulation, may cause a troublesome electrical excitation of the fibres during manufacturing processes in a dry atmosphere. Its thermal conductivity also is low. Under ordinary atmospheric conditions fibroin contains about 11% of its dry weight of hygroscopic moisture which may be removed by heating it at 105° C. It is insoluble but swells slightly in water, alcohol, benzene and other organic liquids.

Fibroin is an amphoteric colloid and belongs to the chemical class of proteins; the formula $C_{15}H_{23}N_5O_6$ sometimes assigned to it should be taken to be no more than an approximate expression of its elementary composition. The X-ray method of examination indicates the possible presence in fibroin of a crystalline constituent, and there is some chemical evidence that fibroin is chemically heterogenous. It dissolves in the cold in concentrated solutions of the mineral acids or of the caustic alkalies, and in an ammoniacal solution of copper oxide; from all these solutions it may be reprecipitated in a more or less altered form when the solution is neutralized. but, owing to more far-reaching changes, not after long standing. When heated, fibroin melts and burns giving a smell of burned feathers which serves to distinguish it from the vegetable fibres. including artificial silk. It may be distinguished from wool by its microscopical appearance and by chemical tests. The ultimate filaments of the wild silks are thicker and more ribbon-shaped than those of mulberry silk and exhibit longitudinal striations along which the filaments tend to split into fibrillae under any mechanical or chemical action; the fibroin of the wild silks possesses properties similar to those of mulberry fibroin but is more resistant to chemical action. Sericin, also a protein, is more active chemically than fibroin: from which it may be separated by the solvent action of hot water. best under pressure, or of acid or alkaline solutions. Its hot aqueous solution gelatinizes on cooling. Its elementary composition is similar to that of fibroin but it contains more oxygen; like fibroin it may be chemically heterogenous. The colouring matter of yellow silk is probably *carotene* or a related substance.

Silk has great power of absorption. Its brilliant colours are due to a greater capacity of absorption toward colouring matters in general than perhaps any other fibre. It also absorbs dyestuffs at much lower temperatures than does wool. So great are its powers of absorption that its weight can be increased as much as 30% in moisture without any change in appearance. In order to prevent fraud by shipping raw silk to which moisture was added by the seller to secure a greater return on the poundage sold. an international standard of 11% was established many years ago as the permissible limit of "regain" in moisture over the dry weight.

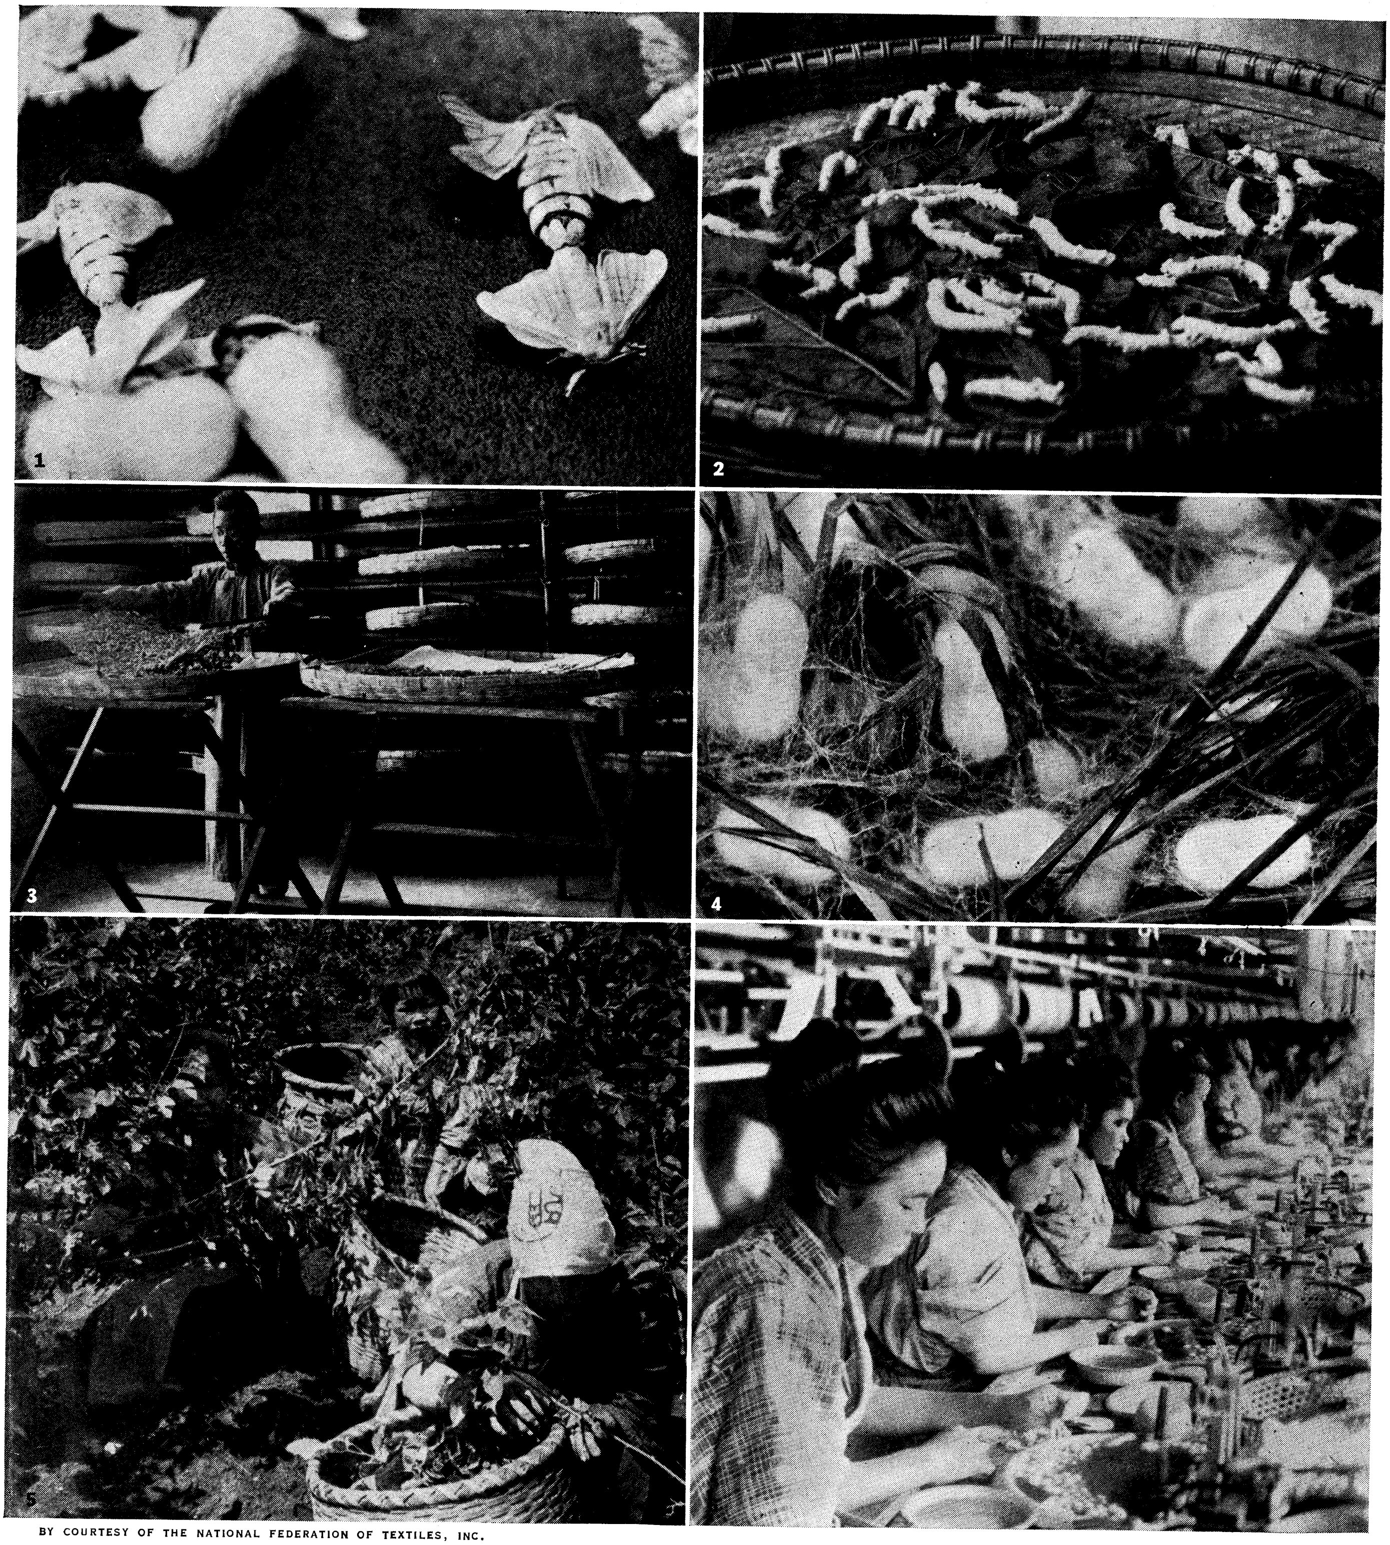
SILK MANUFACTURE. In discussing silk manufacture, it is necessary to distinguish between the preparation of the silk cocoons (the process called reeling) and the manufacture of productz made from the threads after reeling. Both are referred to as silk manufacture although the term popularly refers to the fabricated product. rather than to the thread or yarn, which is termed raw silk. Another exception is the waste or by-product of the cocoons which is shipped to the silk manufacturing countries for spinning into a special yarn termed spun silk. The process used resembles cotton or wool spinning methods rather than silk reeling. Raw silk is the commonest used form for industrial yarns.

Filature or **Reeling.**—When the cocoons have been gathered and the enclosed chrysalides stifled. they are sorted for reeling. Doubles (cocoon. made by two worms in conjunction). pierced cocoons and any from other causes rendered unreelable are put aside for spun silk. The object of reeling is to bring together the filaments from tno or more (generally five or six. but sometimes up to 20) cocoons, and to form them into the one continuous. uniform and regular strand (finer than human hair) which constitute.: the commercial raw silk. To do this, the natural gum of the cocoons which holds the filaments together is softened by boiling 10 to 12 min. The ends of the filaments are caught. and unnound and laid



CULTURE OF SILKWORMS

1. Breeding of the male and female silk moths
2. Full-grown silkworms feeding on mulberry leaves
3. Cleaning the feeding trays. Student at the University of Nanking using net type of lining on feeding tray, thus saving time and labour
4. Close-up view of silkworms spinning cocoons. The outside fibre Is removed and used as waste silk
5. Gathering mulberry leaves in a Japanese orchard. Only the tenderest and freshest leaves can be used
6. Modern silk reeling in a Japanese filature. The cocoons are placed in basins of hot water and the silk thread is wound up over the heads of the workers onto the reel in back of them. Size of the thread varies with the number of cocoon filaments run at ore time

together, so as to form a simple uniform rounded strand of ram silk. This extremely delicate reeling process is particularly suited to female labour. The establishment in which it is done is called a filature. and may contain 20 to 300 reeling basins.

A six-filament silk thread is scarcely visible. and yet can easily stand most strains imposed by the manufacturing process. A good silk stretches about one-third of its own length before breaking. During the reeling process. of course. breaks do occur continually, so the reeler must watch carefully and as soon as a break is detected supply a reserve thread which is kept ready. A break of one filament in a thread of six will be rectified by a first-class reeler within half a yard of thread. An unheeded break means a thin spot in the completed thread and shows as a ring or uneven shading in hosiery or fabric.

When the skeins of silk are removed from the reels. they are twisted and packed into small bundles called books. These books or hundles are packed to form a bale weighing about 133 lbs.

Silk Waste.—The term silk waste includes all kinds of unwindable raw silk which is unsuited to the throwing process. Before the introduction of machinery for spinning silk waste. the refuse from reeling and silk winding was nearly all destroyed as being useless. The exception was that which could be hand-combed and spun by means of the distaff and spinning wheel, a method which is still practised by some of the peasantry in India and other eastern countries.

Waste silk is supplied principally by the following sources: (1) The silkworm, when commencing to spin, emits a lustreless and uneven thread which is unreelable. (2) The extreme outside and inside layers of each cocoon are put aside as waste. (3) Pierced cocoons (those from which the moth has emerged). (4) During the reeling process the silk often breaks; and both in finding a true and reelable thread, and in joining the ends, there is unavoidable waste.

This waste silk, packed in bales of various sizes and weights, is a much-tangled mass of all lengths of fibre mixed with much foreign matter, such as ends of straws. twigs. leaves. worms and chrysalides. It is straightened out as fibres, with the aid of machinery, then joined to become the thread known as spun silk.

There are two distinct kinds of spun silk—one called schappe containing as much as 20% of the original silk gum "sericin" and the other spun silk which is entirely free of the gum.

The combings left after the processing of the spun silk fibres are called noils. They are used in spinning short fibres.

Growth of Industry and Uses of Spun Silk.—Spun silk is pure silk just as much as raw silk. Before the introduction of synthetic fibres such as nylon, the yarn was used widely for sewing thread. elastic webbing, lace, plush and for novelty yarns in combination with wool and rayon for use in men's clothing fabrics, upholstery materials, etc. During World War I millions of yards of cartridge bag cloth were woven of spun silk. Until the development of nylon and similar fibres only pure silk proved satisfactory for the bags, as it was necessary to have complete destruction occur when the gun was fired to avoid a backfire from burning ash when the next charge was inserted. To a large extent, rayon and spun rayon supplanted spun silk yarns in the making of plushes and velvets and by the latter 1950s there was only a limited market for the yarn.

Throwing.—Raw silk, being too fine and delicate for ordinary use. as received from the reeling machine undergoes a series of operations called throwing, the object of which is to twist and double it into more substantial yarn. It is as raw silk that the thread is shipped to the principal textile manufacturing countries—the United States. France, England and Italy.

The word throwing originated with the old Anglo-Saxon term *thrawan*, meaning "to twist." The man engaged in such work is known as a throwster and the product is termed thrown silk.

In the United States, throwing is a service performed chiefly by the commission throwster—one who will prepare for a fixed price per pound the raw silk sent him by the owner. Some throwsters buy the raw silk direct from the importers, throw it and sell the thrown silk to manufacturers of fabrics or hosiery. The silk is shipped on spools or cones, the latter for the hosiery trade. It also may be shipped as skeins. and prior to mid-20th century. silk fabrics were woven only from dyed yarn skeins. The development of crepe fabrics following World War I changed this practice, crepe yarns being dyed after woven into fabric. This can he understood by taking a tightly twisted piece of thread and attempting to make it lie straight. The resulting snarl demonstrates the necessity of winding crepe threads directly onto a spool or bobbin and waiting until the thread is woven into a fabric before it is dyed. This dyeing process is termed piece dye.

It is in the throwing process that raw silk shows itself different from other textiles. The thread. one continuous strand, does not need the combing and preparation required by the shorter fibres of cotton and wool. The only refining needed before weaving is that of producing different effects in the finished fabric by twisting the silk thread to varying degrees. In weaving some fabrics, no throwing is required.

In the crepes, however. silks are thrown and the types produced are organzine. crepe, tram and singles. Crepe is customarily spoken of as a separate type although technically it is organzine with a higher number of turns per inch: 40 to 80. Organzine is the result of doubling two or more threads, previously twisted as single threads and twisting them in the opposite direction 8 or 10 turns to the inch. This type of yarn is used chiefly for the warp or lengthwise thread. Tram, on the other hand, is used for the filling or crosswise thread and begins with the raw silk thread without doubling. Two or more threads are twisted together with a few turns per inch. Singles are the raw silk threads both twisted and untwisted. When twisted hard (hard twist). the yarn is used for making chiffons and other sheer fabrics.

Throwing, considered the least skilled operation in the manufacture of silk, employs chiefly women workers and is done in areas where a plentiful supply of relatively unskilled labour is available and power is cheap.

Raw silk is shipped to the throwing mill in the original bales. The bales are opened and the skeins are checked as to weight and quality and tagged with the name of the owner. The next step is soaking the skeins overnight in warm, oily (usually olive oil) soapsuds, to soften the natural gum. This done, the skeins are removed. dried and placed on reels or swifts. Then comes the winding process; that is, the silk is wound off the reels onto spools or bobbins about four or five inches long. The bobbins are wound with a rapid reciprocating motion, so as to lay the fibre in diagonal lines. In crepe weaves. the filling is made from alternating twists of hard-twist tram. The crepe effect is achieved by the contrary pull of the two tightly twisted threads. The weaver must know the direction in which the threads have been twisted—left or right. For easier identification, the throwster tints the threads a colour designated by his customer for the left and the right. These colours are known as fugitive tints as they must completely disappear in the boiling-off of the woven fabric before dyeing. If skeins are ordered, each is carefully divided into small sections by interlacing cotton threads to prevent tangling of the yarn in handling. Bobbins or cones are packed carefully and shipped in boxes or cases. Most thrown silk is shipped in this way rather than in skeins.

Weaving.—Silk looms are the same as those for other textiles; plain, box and Jacquard. In general, the plain looms weave the flat fabrics such as taffetas, linings, etc.; the box looms make the crepes and novelties; and the Jacquard loom is the intricate mechanism that weaves elaborate designs for damask, brocade and lamé. Silk looms have many contrivances to give smoothness to the weaving and regulate the tension on the fine threads. Ends and rough spots that would be relatively unimportant in cotton or wool weaving had to be eliminated in the silk weaving. For many years, the use of the hand loom in silk weaving was considered necessary.

This prejudice for the hand-made article was not unique to the silk industry however. It was paralleled in many other fields. Machine-made silks have resulted in a greater degree of perfection and lower cost, which in turn created an increased demand.

The weaves most closely identified with silk are taffeta, satin. chiffon and crepe. In the U.S., public acceptance of these weaves as synonymous with silk resulted in rulings by the Federal Trade commission that, regardless of the fact that originally the words were descriptive of a method of weaving or construction of weave. their use on anything but silk products must be accompanied by a qualifying description of the fibres substituted for silk. Technically, the words are applied to fabrics of any fibres as long as they are made in the method designated as taffeta. satin, etc.

Taffetas are the basic plain weaves. and comprised most of the silks of past generations. Satins were next in popularity. because the high lustre of silk was especially adaptable to the method of weaving that brings the filling thread on the surface of the material rather than the simple in-and-out movement of the taffeta. Crepes are woven either as the taffeta plain weave or in the satin effect. In many cases weaves are combined. Chiffons are transparent. thin. ephemeral: the origin of the name is a description—French. "rag". Following World War II crepe fabrics. because of the skilled labour required in handling the crepe yarns and by reason of style change, largely were replaced by a type of taffeta weave made of rough, coarser-sized ran. silk thread. simulating the oriental products known as Shantung, pongee and habutai. These fabrics. with their plain in-and-out weave, did not require throwing nor the smooth perfection needed for the finer crepes, satins. etc. Hahutai, originally a native Japanese iabric. was the most used silk fabric in the period after 1945 and was exported by Japan especially to the United States in large quantities for use in scarfs and other types of women's clothing. It was also exported unfinished. then printed. dyed and otherwise reprocessed in the importing countries, for clothing and shower curtains, umbrellas. raincoats, etc. Hahutai is also referred to (incorrectly) as momme silk because the commonly used Japanese designation of the weight of a fabric is its momme weight. Momme weight represents the weight in pounds of roo yd. of the fabric in the gray. One momme cloth equals 1.042 sq.yd. weighing .1323 oz.. or 1.00 sq.yd. weighing .1270 oz.. or 1.00 sq.yd. weighing .0079 lbs.. or 100.0 sq.yd. weighing .795 lbs.

Silk when woven from the undyed thread is referred to as raw goods or greige goods. The latter term comes from the term *grès* meaning "gum" and refers to the natural gum or coating of albuminous matter which is part of the filament spun from the cocoon and which is still a part of the thread before dyeing. The woven greige fabric has a lustreless, stiff and harsh appearance which would be unacceptable for most practical uses. One exception is bolting cloth. a unique type of silk fabric used primarily by millers in preparing fine flour. Coarser sizes are used in the process known as screen printing. Another use is as a filter for women's powder compacts. Originally, bolting cloth was made on hand looms in the cellars of mountain homes in the St. Gall and Appenzell sections of Switzerland where the humid air helped to keep the fine threads in place during the weaving operation. Although this remained true of some of the finer grades, there was a growing development in the manufacture of the fabric on power looms in the United States and France after 1940. Synthetic fibres (principally nylon) as well as silk. have been used for bolting cloth.

Other silk fabrics. when woven as raw goods, must be degummed or scoured before they are dyed and finished. These fabrics are termed piece dyed to differentiate from the yarn dyed which are dyed in the thread. In general all crepe fabrics and satins are piece dyed; taffetas may be either yarn or piece dyed. The process leaves a white. soft. flimsy fabric that has a pleasant touch but would be undesirable for general use in clothing. The degumming process is done as part of the dyeing and finishing operation and the process is also called boiling-off. The resultant liquid is a valuable adjunct in the dye bath as it contains a large amount of the natural sericin—it is known as boil-off liquor.

Degumming or Scouring Process.—Silk is usually boiled off in a solution of 30% of its own weight of neutral soap dissolved in sufficient pure water to give a 1% solution. If degummed in skeins. the hanks of ran silk hung on a wooden rod are immersed in this solution which is maintained at a temperature just below the boiling point. the hanks being turned around to expose all parts equally to the solvent action of the hot solution. If woven in the gum. the fabrics are immersed in the same type of solution. The temperature is about 95° C. After one hour the silk is removed and the water extracted before a second bath with half the quantity of soap. It is finally rinsed and dried in a hydroextractor. The amount of gum to be boiled off determines the strength of the soap solutions. but care has to be exercised not to overdo the scouring, whereby loss of strength. substance and lustre would result. The perfect scouring of silks removes from 20% to 27% of their weight, according to the character of the silk and the amount of soap or oil used in the working. Scouring renders all common silks. whether white or yellow in the raw, a brilliant pearly white. with a delicate soft, flossy texture. since the fibres which were agglutinated in reeling. being degummed. are separated from each other and show their individual tenuity in the yarn. Silks to be finished white are at this point bleached.

Knitting.—Silk is knitted into fabric and hosiery. Silk hosiery, from the time of Queen Elizabeth I of England. has typified a desirable luxury. but after World War I silk hosiery for women became a necessity coincident with the everyday use of silk fabrics for outer clothing and underwear. The strength of the silk fibre permitted the knitting of extremely thin or sheer fabric. where the shorter. weaker fibres such as cotton could produce only a heavy. thick iabric. Silk hosiery since 1941, has been largely supplanted by nylon but silk is still used to some extent in knitted silk fabrics commonly referred to as warp knitted (or glove silk) in which parallel yarns are arranged in two tiers on the knitting machine. There are two types of warp knitted silks—tricot and Milanese. Tricot, the more important, is characterized by fine vertical wales on the iace and crosswise ribs on the back. Its construction permits the making of designs such as stripes. Milanese is a fabric in which the threads are interknitted at every course in which the threads run diagonally. A fine rib on the face and a faint diagonal or diamond effect on the hack are characteristic. These fabrics are run resistant, but will develop holes where the thread breaks.

Dyeing, Printing and Finishing.—Silk has a special affinity for dyestuffs and finishing materials, and the handling of the fibre either as yarn or fabric has been the pride of dyers throughout the ages. In mediaeval Europe Florence. It.. was noted for its dyed silks. In France, the patronage of Louis XIV developed many new ways of dyeing silks and in 1630 reference was made in a French publication to the metallic weighting of silk. The finishing of silk fabrics to give them smoothness. lustre. stiffness and rustle was the subject of constant experimentation by the workmen of Italy. France and England. When the silk industry became established in the United States, many of the artisans from Europe brought their guild and family trade secrets with them. Although many formulas have been published for dyeing and finishing preparations. every dyer treasures his own method of handling silk. And that pride of individual artisanship still continues.

The process of weighting is primarily suitable for silk. but weighting of other fibres. notably rayon. has been attempted. Silk for centuries has been treated with sugar, salts of tin and lead; and iron to increase its weight and give the flimsy. soft pure silk the body and close texture that women for the past three centuries have always associated with "good" silk. To determine by laboratory research the effect of weighting on the silk fibre. groups both in the United States and in Europe compared weighted and unweighted samples and measured the tensile strength of silk fabrics periodically to learn to what degree the fabrics had lost strength. Contrary to the general impression. the amount of weighting did not of itself determine the tensile strength of silks. The manner in which the threads were woven. the ingredients used in weighting and the method followed in the weighting process were equally if not more significant.

These tests emphasized the mystery that surrounds the physical reaction of silk as it absorbs the minerals without outward change of appearance. Silk can absorb the liquids in its weighting bath to 300% oi its original u-eight without any noticeable change in its outward appearance. The solution does not coat the fibre, but is absorbed by it and is not removable except by laboratory treatment. For hundreds of years. the objective of the dyer was to develop his process to give the desired appearance to any fabric he handled. Rut weighting, or rather poor weighting, brought about a demand for satisfactory wear in fabrics as well as aesthetic appeal. Some fabrics were only usable nith heavy weighting. such as fabrics used in facing men's dress clothes. Contrarily, unweighted fabrics were found to be more popular for underwear.

The unweighted fabric is termed pure dye although the words are sometimes misunderstood by the layman. They have no reference to the quality of the dyestuffs but are probably a distortion of an expression intended to describe a finish as "pure dyestuff," *i.e.*, nothing but dyestuff, although the origin is not clearly established. The U.S. government edict, in 1938, demanded that where any weighting was present in the fabric, the percentage of weighting in proportion to the silk fibre content in the finished fabric must be so stated. Similar regulations were put into effect in France.

The process of weighting begins with the degummed fabric, which is placed in the weighting solution bath for several hours. It is then removed, washed and dried. Additional baths of this kind may be given and each time the threads gain weight. The length of time for the bath and the formula for the contents of the bath are, after many hundreds of years, still dependent largely on the skill and knowledge of the individual workman. After a further treatment of special solutions. the silk is dyed. During this process. one of the valuable adjuncts is the sericin or boil-off liquor which was saved aiter the degumming process. The gum solution gives added weight of a natural kind. The gum content of the silk is a cause of dissension as to the basis of expressing the amount of weighting in a fabric. The European method is based on "par weight" (the weight of the silk before degummingj. The European silk manufacturer considers that he may add weighting to the degummed silk up to the original weight. without technically weighting the silk. The percentage of weighting would be figured from the par weight not the degummed weight. The actual amount of weighting or foreign matter in the fabric would, therefore, be more than stated. In the United States, government regulations require that the percentage of weighting be expressed as the proportion of metallic weighting to the amount of actual silk fibre in the finished fabric: with no notice made of the original weight.

Printing of silk fabrics is done by the same general methods followed in other textiles. The most popular method is the roller printing done by engraved copper rollers, similar to book or magazine printing. Each colour in the design is a separate roller and in referring to designs, reference to the number of rollers is synonymous with the number of colours. Designs for roller printing run from one to four colours and can be application or discharge. In the first. the design is applied to the cloth; in the second. the design is made by chemically removing the background colour.

Screen printing is used for the prints of more than four colours and also for achieving a hand-printed effect that is in demand in more expensive printed iabrics. Instead of a roller for each colour. there is a screen for each colour. The process is slower than roller printing and is frequently used where a fewer number of yards of a given design is required.

Screen printing is especially preferred for silk fabrics. More brilliant colour effects are achieved and there is wider latitude in the type of design used. The chief advantage lies in the reduction of risk inherent in merchandising an article of fleeting style value such as printed fabrics. Roller printing requires the investment not only of the engraving and printing, but the minimum amount accepted by the printer for imprinting is 1.000 yd. Of that amount, at least half or all of it may be sold at less than cost if the design of the fabric does not gain buyer acceptance. In screen printing, as few as 10 yd. may be printed at one time.

To give the dyed and printed silk smoothness, dull lustre and suppleness. and to provide protection against certain characteristics of wear, such as creasing, perspiration, water-spotting. etc., the finishing of silk is an additional art in preparing the fabric for the market. The materials used include starches, dextrin, glue, gelatin, sulphonated oils, mineral oils, glycerine. resin and various organic chemical compounds used as softeners and penetrants. Not the least of these are perfumes or essential oils used at the final stage for eradicating any unpleasant odours remaining from the other materials. In addition to the oils and gums. the finishing treatment includes stretching. gassing, moiréing and framing. Fabrics must be made uniformly wide, wrinkles removed and fuzz burned off the surface. The natural strength and elasticity of silk provides ample opportunity for manipulation in producing desired effects.

Packaging. — Silk fabrics are prepared for the market as pieces of about 80 yd. each. They are rolled full width on paper tubes of about 2-in. diameter or folded in half of the width and reeled on flat cardboard reels about 14 × 24 in. The fabrics are carefully wrapped in tissue paper and a light cardboard outside wrapper.

SILK SCREEN PRINTING. Screen stencil printing is the modern form of what is probably the oldest of all printing processes. It is the logical development of the principle used by the Chinese and Japanese: who long ago learned to make very intricate stencils by gluing the cut design to a web of hair! thus making it possible to use isoiated elements which could not otherwise be held in place.

The screen stencil ordinarily used consists of bolting silk stretched over a wooden frame. On this silk is the design to be stencilled. This design may be produced by simply painting the areas which are to remain white with some substance, such as gum or shellac, which will make the silk impervious to the ink used. The stencil is placed in contact with the surface to be decorated and a puddle of ink is scraped from one end to the other by means of a rubber squeegee. This forces the ink, which resembles ordinary house paint, through the open areas of the stencil and it adheres to the surface beneath. The stencil is then lifted from the decorated surface and the ink allowed to dry, after which another colour may be applied from another stencil: and so on.

For special purposes. wire gauze or cotton fabrics may be substituted for the bolting silk, and a great number of ingenious methods have been devised for putting the design on the screen. Fine detail in the pattern generally makes it advisable to make the stencil photographically, by impregnating the screen with a light-sensitive material, such as dichromated glue or albumin, and exposing it to light under a tracing of the pattern. The image is developed by washing with water. which removes the coating from the open areas where it has not been light-hardened. Simple designs are often made by cementing patterns cut from paper. celluloid or metal, to the screen, a common method being to cut the design from shellac-coated paper and fasten it to the cloth by passing a hot iron over the two in contact.

As compared with other printing processes, screen stencil printing has the advantage of requiring relatively cheap equipment and little preliminary work. It is very economical for short runs of suitable subjects, and is widely used for show cards, posters, charts. etc. It permits printing on almost any surface: so it is used for decorating paper, cloth, glass. wood, celluloid, rubber, metal, linoleum and oilcloth. The inks used are usually oil paints, but may be water colours. dyes or lacquers, so that the process may be used to produce any effect from the most delicate of pastel shades to glossy, weatherproof colours. so heavy that they stand out in visible relief. Areas of relatively great size are easily stencilled: frames 50 by 60 in. are frequently used for textile printing. Finally, as the object to be decorated need not be limited in thickness or even perfectly flat. the process is much used for printing on objects such as toys, novelties, and machinery which could not be run through a printing press.

The limitations of the process lie in the fact that it is not suitable for reproducing subjects with fine detail and delicate gradations of tone, such as photographs for process colour work. It is unsuitable for reproducing very long runs because it is a relatively slow printing process and because the stencils are of limited durability.

SILL, ANNA PECK (1816–1889), U.S. educator, a pioneer in women's education in the United States who sought to bring the education of girls to the level of that for men, was born Aug. 9, 1816, at Burlington, N.Y. After attending the district school, she began to teach at a school near Albion, N.Y., and in 1837 entered Miss Phipps' Union seminary, where she shortly became a member of the faculty. There she remained until 1843, when she established a seminary for girls at Warsaw, N.Y.

After three years Miss Sill abandoned this project and went to teach at Cary Collegiate institute, Oakfield, N.Y. She was invited to Rockford, Ill., in 1849 to open a girls' seminary and was made principal of the school (Rockford Female seminary) in 1852. Thereafter she spent much of her time raising funds for the young institution. It expanded gradually until in 1887 it began to confer collegiate degrees. The name was changed to Rockford college in 1892.

Miss Sill had retired in 1884, but she remained with the institution as principal emerita and taught occasional classes. She died in Rockford on June 18, 1889.

SILL, EDWARD ROWLAND (1841–1887), U.S. author and educator, was born at Windsor, Conn., April 29, 1841. Although slight, Sill's poetry is notable for its reflection of the temper of his age: religious doubt, restlessness and the hopes of humanitarian idealism.

Orphaned in 1853, Sill lived with relatives at Cuyahoga Falls, O., and at Honesdale, Pa. He studied at Phillips Exeter academy and, although he found its academic formalism and Puritan atmosphere uncongenial, graduated at Yale in 1861. He then drifted through various jobs in California and made abortive attempts to study medicine and law. Returning to the east in 1866, he entered Harvard divinity school, but soon found himself restless in the confines of dogma and turned to newspaper work in New York which he also soon abandoned. He finally settled on teaching as his permanent career and was, successively, high-school principal and school superintendent in Cuyahoga Falls (1869–71), teacher and principal at Oakland, Calif., high school (1871–74) and teacher of English at the University of California (1874–82). Upon his resignation he returned to Ohio and devoted himself to writing, contributing frequently to the *Atlantic Monthly* and other periodicals.

Sill died in Cleveland, O., Feb. 27, 1887.

The Hermitage and Other Poems (1868) and *The Venus of Milo and Other Poems* (1883) were published in his lifetime. *The Prose of Edward Rowland Sill* (1900) and *The Poems* (1902) were collected posthumously.

See W. B. Parker, *Edward Rowland Sill: His Life and Work* (1915).

SILL (O. Eng. *syl,* Mid. E. *sylle, sille;* the word appears in Icel. *syll, svill,* Swed. *syll,* and Dan. *syld,* and in German, as *Schwelle;* Skeat refers to the Teutonic root *swal-*, "swell," the word meaning the rise or swell formed by a beam at a threshold; the Lat. *solea,* from which comes Fr. *seuil,* gives Eng. "sole," also sometimes used for "sill"), the horizontal base of a door or window frame. A technical distinction is made between the inner or wooden base of the window frame and the stone base on which it rests—the latter being called the sill of the window, and the former that of its frame. This term is not restricted to the bases of apertures; the lower horizontal part of a framed partition is called its sill. The term is sometimes incorrectly written "cill."

SILL. In geology, a tabular body of igneous rock formed by intrusion of magma (molten rock) along a structural break (bedding or foliation) in the earth. The tabular form and parallelism with surrounding structure are the diagnostic features. To many geologists there is another essential; injection must have occurred along relatively flat-lying breaks. The magma, therefore, displaced the adjacent rock vertically by lifting the roof. This mechanism is quite different from that involved in the formation of steep intrusive sheets (most dikes). In the latter, magma entered passively as the walls of the steep fractures were spread apart by horizontal movements.

It is believed that, as the injected magma comes into contact with the cooler adjacent rock, it becomes chilled and rapidly solidified to form a thin, dense selvage or layer along the sill roof and floor. Somewhat slower cooling of the more internal portions of the sill result in coarser textures. Margins of many sills show a streaked and banded appearance, believed to have been produced by liquid flow along the smooth sill roof and floor. Large crystals commonly show parallel arrangement of their long dimensions near sill boundaries. These are believed to have formed early and to have been turned into the lines and layers of flow parallel to sill contacts.

Some sills, after congealation, have been split open and injected by fresh magma. Such bodies are called multiple sills if the successive injections were of one kind of magma, and composite sills if different kinds of magma were involved.

Sills may range up to several thousand feet in thickness and may extend across country for hundreds of miles. They are commonly associated with dikes and larger intrusive bodies *(see* BATHOLITH; LACCOLITH; GEOLOGY). Most described sills are composed of diabase or dolerite and closely related rocks. Granitic, rhyolitic, dioritic, and andesitic sills are locally abundant; and the rocks comprising them commonly belong to the class known as porphyries *(see* PORPHYRY).

Some thick sills, such as the Palisades sill in New Jersey, furnish striking evidence that an essentially homogenous magma became differentiated during consolidation and yielded a diverse, layered series of rocks. In general, such sills show a dense chill zone at the top and bottom; and heavy rocks, near the base, grade upward to somewhat lighter rocks near the top. It seems clear that early developed heavy crystals (olivine and pyroxene) settled in the slowly congealing magma, whereas lighter minerals (feldspar) may have remained more or less stationary or possibly were buoyed upward.

The rocks immediately in contact with sills commonly appear to have been profoundly changed. This phenomenon, known as contact metamorphism, is believed to have been brought about largely by the heat of the intrusive magma. In the case of large sills, the metamorphic zone may extend a few hundred feet from the intrusive margin. Sedimentary rocks may show a baked or indurated and bleached appearance in contact with a sill roof or floor. Shale, for example, has commonly been reconstituted to a tough. brittle rock called hornfels, in which many new minerals (cordierite, feldspar, garnet, pyroxene, etc.) have formed. Blocks and fragments of the adjacent rock, accidentally caught up in the intrusive mass, may also show these metamorphic effects *(see* also METAMORPHISM).

See M. P. Billings, *Structural Geology* (1954); R. A. Daly, *Igneous Rocks and the Depths of the Earth* (1933). (C. A. CN.)

SILLANI, TOMASO (1888–), Italian author, was born March 25, 1888. at Otricoli. He contributed poetry and articles on political questions to Italian and foreign newspapers. One of the founders of the Pro-Italian Dalmatia association, he was active in supporting Italian claims to Adriatic and colonial expansion. Sillani founded (1918) and later directed the review *Rassegna Italiana.* Among his works are *Le Pastorali* (verse, 1912), *Il Perugino* (1914), *L'Alsazia e la Lorena* (1914), *La Dalmazia monumentale* (in collaboration with others, 1917), *Capisaldi* (2 vol., 1918), *La Libia in 20 anni di occupazione italiana* (1932), *La Vittoria dello spirito* (1925), *L'Italia e l'Oriente Medio ed Estremo* (1935), *Scritti sul Risorgimento di H. Nelson Gay* (1937).

In 1945 Sillani became founder and director of the Italian Study-Centre for International Reconciliation.

SILLANPÄÄ, FRANS EEMIL (1888–), Finnish author, was born in 1888, the son of a Finnish farmer. He began to write at an early age, studying in particular the lives of peasants in western Finland.

At first his novels were known only in Scandinavia, where they enjoyed a great popularity, but later they were translated into several European languages. The best known of the novels is *The Maid Silja.* Other of his publications include *Hurskas Kurjuus* ("Meek Heritage"), *Miehen tie* ("A Man's Way") and *Nuorena Nukkunut* ("Fallen Asleep While Young"). In 1939 he received the Nobel prize in literature. In December of that year, two weeks after Russia had begun the invasion of Finland. Sillanpaa crossed the Snedish border aith his seven children on his way to Stockholm to receive the award.

In addition to his novels of peasant life, he has published several collections of short stories and essays.

SILLERY, CHARLES ALEXIS BRULART, MARQUIS OF (Count of Genlis) (1737–1793). French soldier and politician, was born at Paris in 1737. In his youth he sailed for the West Indies for military sen-ice, but left his regiment to join the navy. He saw active service at sea in the Seven Tears' War (1756–63) and was captured by the English. Upon his release in 1762 he returned to France. married the countess of Genlis and became the confidential adviser of the duke of Chartres. In 1789 he became deputy to the states-general at Versailles and later to the National Convention, where he threw in his lot with the Girondists (*q.v.*). When the latter fell. Sillery was included in the proscription of May 1793. He was condemned to death and guillotined Oct. 31, 1793, at Paris.

SILLERY, CHARLES DOYNE (1807–1837), Irish poet, was born at Athlone, Ire., on March 2, 1807. His father was an Irish army officer.

After serving as a midshipman on a voyage to the far east, Sillery left the navy and in 1828 went to Edinburgh, Scot., where he died on May 16, 1837. His works include *Vallery, or the Citadel of the Lake*, 2 vol. (Edinburgh. 1829); *Eldred of Erin* (Edinburgh, 1833); *The Royal Marines and Other Poems* (London, 1833); and *The Exiles of Chamouni* (1834).

Religious books include *A Discourse on the Sufferings of Our Saviour* (1833); *An Essay on the Creation of the Universe* (1833); and *The Man of Sorrows*, which was published after his death.

SILLERY, NICOLAS BRULART DE (1544–1624), French diplomat and statesman, was born in 1544 at Sillery. In 1573 he became councillor at the parliament of Paris,.and in 1589 he was named ambassador to Switzerland, being appointed again to the latter post in 1593. In 1598 he negotiated for France the treaty of Vervins, which terminated the "war of deliverance from Spain."

He rose rapidly in the esteem of Henry IV, whose divorce from Marguerite de Valois, sister of Charles IX, Sillery had arranged in Rome. Henry named him chancellor of Navarre in 1605 and chancellor of France two years later. After Henry's assassination in 1610, he was kept in office by Marie de' Medici (whose marriage to Henry had also been negotiated by Sillery), but he lost influence and retired to the town of his birth, where he died in 1624.

SILEIMAN, BENJAMIN (1779–1864), U.S. chemist and geologist, was born on August 8, 1779, at Trumbull (then called North Stratford), Conn. Entering Yale college in 1792, he graduated in 1796, became tutor in 1799 and in 1802 was appointed professor of chemistry and mineralogy, a position which he retained till 1853, when by his own desire he retired as professor emeritus. Not only was he a popular and successful teacher of chemistry, mineralogy and geology in the college for half a century, but he also did much to improve and extend its educational resources, especially in regard to its mineralogical collections, the Trumbull Gallery of Pictures, the Medical institution and the Sheffield Scientific school.

Outside Yale he was well known as one of the few men who could hold the attention of a popular audience with a scientific lecture, and on account of his clear and interesting style, as well as of the unwonted splendour of his illustrative experiments, his services were in great request not only in the northern and eastern states but also in those of the south.

His original investigations were neither numerous nor important, and his name is best known to scientific men as the founder, and from 1818 to 1838 the sole editor, of the *American Jozirnal of Science and* Arts — often called *Silliman's Journal*—one of the foremost American scientific serials. In 1810 he published *A Journal of Travels in England, Holland and Scotland,* in which he described a visit to Europe undertaken in 1805 in preparation for the duties of his chair. He paid a second visit in 1851, of which he also issued an account, and among his other publications were *Elements of Chemistry* (1830), and editions of W. Henry's *Chemistry* with notes (1808), and of R. Bakewell's *Geology* (1827). He died at New Haven on Nov. 24. 1864.

His son, BENJAMIN SILLIMAN (1816–1885), chemist and mineralogist, was born at New Haven on Dec. 4, 1816. After graduating at Yale in 1837 he became assistant to his father, and in 1847 was appointed professor in the school of applied chemistry, which was largely due to his efforts and formed the nucleus of the subsequent Sheffield Scientific school. In 1849 he was appointed professor of medical chemistry and toxicology in the Medical college at Louisville, Ky., but relinquished that office in 1854 to succeed his father in the chair of chemistry at Yale. The duties of this professorship. so far as they related to the Academic college, he gave up in 1870, but he retained his connection with the Medical college till his death, which happened at New Haven on Jan. 14, 1885.

Much of his time, especially during the last 20 years of his life, was absorbed in making examinations of mines and preparing expert reports on technical processes of chemical manufacture; but he was also able to do a certain amount of original work, publishing papers on the chemistry of various minerals, on meteorites, on photography with the electric arc, the illuminating powers of gas. etc. A course of lectures given by him on agricultural chemistry in the winter of 1845–46 at New Orleans, La., is believed to have been the first of its kind in the United States.

In 1846 he published *First Principles of Chemistry* and in 1858 *First Principles of Physics or Natural Philosophy,* both of which had a large circulation. In 1853 he edited a large quarto illustrated volume, *The World of Science, Art and Industry,* which was followed in 1854 by *The Progress of Science and Mechanism.* In 1874, when the 100th anniversary of Joseph Priestley's preparation of oxygen was celebrated as the "Centennial of Chemistry" at Northumberland, Pa., where Priestley died, he delivered an historical address on "American Contributions to Chemistry," which contains a full list, with their works: of American chemists up to that date. From 1838 to 1845 he was associated with his father in the editorship of the *American Journal of Science,* and from 1845 to the end of his life his name appeared on the title page as one of the editors in chief.

SILLIMANITE, an aluminum sillicate mineral that. like the closely related aluminum silicates andalusite and kyanite (*q.v.*), may be used to form mullite, an important refractory material (*see* also MULLITE). It crystallizes in the orthorhombic system and has the composition $Al_2O_3.SiO_2$. It occurs in metamorphic rocks as long slender crystals and as rosettes. The hardness range is from 6 to 7 and specific gravity from 3.23 to 3.24. Its colour ranges from brown to gray to olive-green. In the laboratory it may be synthesized over a limited range of temperatures and pressures and is presumably so formed in nature. At pressures under approximately 3.000 atm.. in the temperature region of 600°-900° C., the stable phase of essentially the same composition is the mineral mullite. Sillimanite occurs at pressures from 3.000 to 12,000 atm. Above these pressures the mineral kyanite appears. At temperatures below approximately 600° C. the polymorph of sillimanite, andalusite. appears. It is an important geological mineral and serves both as an indicator of temperature and pressure of environment in which rocks containing it were formed. It is present in metamorphosed kaolin rich sediments. It was named after Benjamin Silliman (*q.v.*). (G. C. KY.)

SILLS, MILTON (1882–1930), U.S. actor, was born on Sept. 15, 1882, in Chicago, Ill. His parents, William Henry and Josephine Antoinette (Troost) Sills named him Milton George Gustavus, but he dropped his second and third names.

Graduated from The University of Chicago in 1903, he became a fellow in philosophy at the university, After his first appearance on the professional stage in a melodrama at New Palestine, O., in 1906, he toured the middle west. He played in Donald Robertson's Art theatre, Chicago, 1907–08, and later went to New York city, playing the leading man in *This Woman and This Man,* 1909. He also appeared in *A Happy Marriage,* by Clyde Fitch and managed by Charles Frohman. *The Servant in the House, The Fighting Hope, Diplomacy, The Governor's Lady, Mother, The Rack, The Law of the Land,* and *Just Married.*

In 1914 he appeared in the motion picture *The Pit,* based on a novel by Frank Norris. He had leading roles in *Behold My Wife, The Great Moment, Adam's Rib, The Barker, Burning Daylight, The Sea Hawk, Hard Boiled Haggerty, Paradise* and other motion pictures. He also was part author of *Men of Steel,* in which he appeared.

Sills was married to Gladys Edith Wynne of London, Eng., from whom he was divorced in 1925, and on Oct. 12, 1926, he was married to Doris Margaret Kenyon, an actress.

Sills died in Santa Monica, Calif., on Sept. 15, 1930.

SILO: *see* ENSILAGE.

SILONE, IGNAZIO (pseudonym of SECONDO TRANQUILLI) (1900–), Italian author whose novels reflect his belief in the need for social reform, was born at Pescina dei Marsi, Xbruzzi, on May 1, 1900. One of the founders of the Italian Communist party, he left the party in 1930 while in exile in Switzerland. Returning to Italy in 1944, he continued to influence Italian socialism, although without holding any important political office.

Silone's first novel. *Fontamara* (1930; Eng, trans., 1934), is a poignant description of poverty and Fascist oppression in an Abruzzi village. Its peasant hero. who struggles for freedom but dies in prison, believes that political and social regeneration will be accomplished by a Communist revolution. The hero of *Pane e vino* (1937; Eng. trans.! *Bread and Wine,* 1937) and *Il Seme sotto la Neve* (1940; Eng. trans., *The Seed Beneath the Snow,* 1943) has turned from Communism to a Christian belief in universal brotherhood.

In *Una Manciata* di *More* (1952; Eng. trans.! *A Handful of Blackberries,* 1954) Silone denounces Communism though still urging social reform and the development of the south of Italy, which is also the subject of *Il segreto di Luca* (1956).

See bibliography in *Fiera letteraria* (Aug. 14, 1955); an essay by Edmund Wilson in the *New Yorker* (Sept. 8, 1955). (F. DI.)

SILOTI, ALEKSANDR (ILYICH) (1863–1945). Russian-born pianist and conductor. who was a follower of Liszt. was born on Oct. 10. 1863. near Kharkov. He studied at Moscow under N. Rubinstein and Tchaikovsky. and from 1883 to 1886 at Weimar under Liszt, later founding the Liszt society at Leipzig. He first appeared as a pianist at Moscow in 1880, taught at the Moscow conservatory in 1887. and between 1890 and 1900 toured Europe and the United States. In 1901 he conducted the Moscow Philharmonic orchestra and subsequently divided his activities between conducting and piano playing. He published his reminiscences of Liszt in 1911.

Siloti settled in England in 1919. and in the United States in 1922, and from 1924 to 1942 taught at the Juilliard school of music. He died in New York on Dec. 8. 1945.

SILURES. These were a powerful and warlike tribe in ancient Britain. occupying approximately the counties of Monmouth. Brecon and Glamorgan. They made a fierce resistance to the Roman conquest about A.D. 48. but a legionary fortress (Isca Silurum, Caerleon) was planted in their midst and by A.D. 78 they were overcome.

Their town Venta Silurum (Caerwent, 6 mi. W. of Chepstow) became romanized. Its massive Roman walls survive, and excavations have revealed a town hall and market square. a temple, baths, amphitheatre. etc.

SILURIAN SYSTEM. This article is divided into several broad sections and subsections dealing with the Silurian system and period of geologic time. In addition to the cross references to related material given under the various headings of this article, for general background information *see* GEOLOGY: *Historical Geology;* PALAEOBOTANY; PALAEONTOLOGY. For additional information on the iorms of life referred to see separate articles on these iorms. as ECHINODERMA; FISHES; etc. *See* also Index references under "Silurian System" in vol. 24.

Following are the main divisions of this article:

I. The Silurian System and Period
  1. Physical Events and Features
  2. Climate and General Ecology
  3. Facies, Biogeography and Migration Routes
II. Silurian Life
  1. Characteristics and Evolution
  2. Invertebrates and Associated Fossils
  3. Fishes, Land Plants and Associated Fossils
III. Regional Summary
  1. Great Britain
  2. European Continent
  3. U.S.S.R.
  4. Asia
  5. Australia
  6. South America
  7. North Africa
  8. North America

I. THE SILURIAN SYSTEM AND PERIOD

Rocks of the Silurian system are those that were formed during the Silurian period. which is roughly the interval from 320,000,000 to 350,000,000 years ago. a middle division of the Paleozoic era (*q.v.*), as indicated on the accompanying geologic time chart. Many European geologists outside of England and the U.S.S.R. also include under the term Silurian the older rocks and the earlier time more generally called Ordovician. To them the Silurian as

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	1,000 Years
		CENOZOIC ERA	
Quaternary	Recent	Modern man	11
	Pleistocene	Early man	1,000
Tertiary	Pliocene	Large carnivores	
	Miocene	Whales, apes, grazing forms	
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plants	
	Paleocene	First placental mammals	70,000
		MESOZOIC ERA	
Cretaceous		Extinction of dinosaurs	130,000
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	160,000
Triassic		Appearance of dinosaurs	200,000
		PALEOZOIC ERA	
Permian		Reptiles developed, conifers abundant	235,000
Carboniferous			
Upper (Pennsylvanian)		First reptiles, coal forests	260,000
Lower (Mississippian)		Sharks abundant	285,000
Devonian		Amphibians appeared, fishes abundant	320,000
Silurian		Earliest land plants and animals	350,000
Ordovician		First primitive fishes	400,000
Cambrian		Marine invertebrates	500,000
		PRE-CAMBRIAN TIME	
		Few fossils	3,500,000–4,000,000

here defined is Upper (or Late) Silurian or Gotlandian.

Rocks of the Silurian system have yielded about 10% of U.S. iron, 20% of its salt and a little oil and gas. They also serve, especially where mainly limestone and dolumite, as host for many metallic mineral deposits, including important gold and tin ores in eastern Australia. And they are exploited industrially for cement. agricultural lime and building stone.

Silurian volcanoes dumped thousands of cubic miles of debris into linear subsiding zones and basins in eastern Australia and other regions, announcing related mountain building of this age. Contemporaneous deposits provide the earliest reasonably varied occurrences of fishes and land plants. Although both originated tens of millions of years before. neither is widely recorded until Devonian time. An aberrant vertebrate relative, *Monograptus,* the last surviving bladelike graptolite (*q.v.*), burst into a flowering of short-lived species whose flexible external skeletons are used to divide the Silurian marine deposits of the world into time-equivalent zones. Archaic reef-building corals and the brachiopods advanced less speedily but over broader fronts. The evidence of all these creatures, and the sediments, is interpreted to signify mild climates; not markedly zoned latitudinally, but with local, long-lasting. Late Silurian arid regions.

The responses of Silurian rocks to local conditions of erosion and weathering account for many of the world's distinctive landscapes. Undercutting of weak sedimentary layers beneath massive hliddle Silurian dolomites at the outlet of Lake Erie created and maintains Niagara falls. The picturesque glade country of Tennessee consists of isolated grassy areas on infertile shales surrounded by wooded areas on more calcareous shales or limestones of Middle Silurian Age. Beautiful Wenlock Edge in Shropshire is an east-dipping Middle Silurian limestone ridge, and much of Wales and the Lake district of England is underlain by Silurian rocks. The Swedish island of Gotland is the type site of the Gotlandian; picturesque Visby, its capital and ancient Hanseatic harbour, is built around a Silurian reef limestone.

Rocks are identified as Silurian (or a specific part of it) from comparison of their contained fossils with those of the type marine sequence in south Wales and Shropshire, or on relationship to or correlation with other rocks so dated. By definition, therefore, the Silurian includes all deposits formed during the same time as those in the type sequence, regardless of origin, location, or local relationships. The principal Silurian subdivisions for selected regions are outlined in the accompanying correlation table, emphasizing marine sequences as the basic local standards.

The Silurian is an enduring monument to British persistence. The Roman emperor Tiberius Claudius vowed (c. A.D. 43) to exterminate even the name of the warlike Silures of areas now in the Welsh borderland for their stubborn resistance under Caractacus (Caradoc). Beaten and dispersed by Julius Frontinus for Vespasian (A.D. 78), they were, in fact, almost forgotten until 1835, when Scotsman Sir Roderick Impey Murchison (*q.v.*), an old soldier himself, delighted in naming his new rock system for them. In his epochal The Silurian System (1839), Murchison reflects how:

In ancient days
The Roman legions and great Cesar found
Our fathers no mean foes, and Cressy plains
And Agincourt, deep tinged with blood, confess
What the Silures' vigour withstood
Could do in rigid fight.

He and his British successors have done a job worthy of their ancestors in unraveling the complicated rock succession of the type Silurian, subdividing it and establishing its graptolitic and shelly faunas as independent world-wide standards for correlation. In most of the rest of the world. however, the Silurian is one of the most neglected and thus most poorly known sequences—ironic contrast to the wide attention given to the lower part of Murchison's original Silurian, the Ordovician, which was not split off as an independent system until 1879.

1. Physical Events and Features.—Mountain-building deformation older than the oldest local Silurian deposits is indicated by Silurian overlap across folded Ordovician rocks in the Acadian region of east central North America (Taconic folding or orogeny) and eastern Australia (Benambian orogeny). Similar relationships indicate later deformation between Silurian and overlying Devonian in Australia (Bowning orogeny), in northwestern Europe (Caledonian orogeny) and apparently in the western U.S. Thus it is frequently said that the Silurian began and ended with important, if local, compressive movements of the earth's crust. Strong evidences of volcanism throughout the Silurian of eastern Australia, the Pacific border of North America and the Acadian region, however, and the thick sequences of coarse detrital sediments in Australia, south Scotland and the eastern Appalachian trough seem to imply continued crustal instability in the borderlands. As a consequence of such events, some seaways that were well defined during Ordovician time were strongly modified or abandoned in the Silurian, and new directions of marine invasion were found.

2. Climate and General Ecology.—Widespread reef formation by Silurian corals and stromatoporoids (hydrozoan relatives) couples with the evidence for high calcium metabolism furnished by laterally equivalent limestones and dolomites to imply extensive warm shallow seas in present continental areas and little latitudinal or seasonal temperature variation. Interference of mountainous tracts with prevailing winds, or other special meteorologic circumstances, created local arid conditions in the middle latitudes such as those under nhich the Silurian salt and gypsum deposits of New York state and the Michigan basin originated. If deposits which some interpret as glacial in southeastern Alaska, British Columbia and northern Norway prove to be both glacial and Silurian they would suggest mountains high enough to support valley glaciers.

Principal ecologic variations were presumably connected with physical and chemical changes due to increasing depth at sea or altitude on land. or special geographic configuration.

3. Facies, Biogeography and Migration Routes.—As those of all other geologic ages, Silurian rocks formed under differing local physical or chemical conditions, or with different sources of supply and biologic migration routes, take on a characteristic stamp, or facies, which may tell a great deal about their origin and ecology. Facies variations of rocks and accompanying fossil assemblages may be lateral (in space), vertical (in time) or both. Similar sedimentary facies that do not differ drastically in age, and some that do. are likely to contain similar fossils; and different facies of the same age ordinarily contain different assemblages of fossils. (See also FOSSIL.)

The stratigraphic correlation of unusual facies is worked out from field relations to deposits of known age. or is based on ubiquitous fossils of restricted time span. Species of graptolites, so characteristic of Silurian as well as Ordovician beds. have proved especially useful in indicating the probable contemporaneity of contrasting sedimentary facies. They are, in fact, such generally excellent index fossils, that they are logically interpreted as animals which actually floated at the surface of the water all or much of their lives instead of living somewhere below the surface like most planktonic species or floating only temporarily like the larval stages of so many aquatic organisms. This would explain their being buried, not only with the open-sea sediments of their normal living environment, but also in many different shallow water deposits, together with bottom-living shelly fossils. In eastern Australia, for example. species of *Monograptus* establish the Silurian age and particular stratigraphic level of the important early land plant *Baragwanathia* and associated paleobotanical remains.

Classification of Silurian biotal facies (faunas and floras) shows that they follow sedimentary facies that appear to be related to distance from land, depth of water and nature and amount of detritus brought to the sedimentary site. The usual Silurian deposits and faunas (plants are not numerically important) are divisible into three principal facies of marine sediments: (1) graptolitic shale and flaggy sandstone; (2) detrital limestone and calcareous shale with shelly faunas; (3) carbonate rocks (limestone and dolomite) with mainly coral and stromatoporoid faunas. To these three primary facies types must be added evaporite sequences (salt and gypsum) with highly restricted planktonic faunas in shaly interbeds, slabby argillaceous limestones that in part seem to represent special conditions of tide-flat sedimentation, Late Silurian continental (nonmarine) deposits with plants and fishes and the volcanic facies, which commonly grades to or alternates with graptolitic shale. The three principal facies are found in most regions with thick and extensive Silurian sections; the others represent special local conditions.

The wide dispersal of similar Silurian faunal facies implies good communication channels. Highly generalized possible connections at times of maximum marine expansion are suggested by the distribution map. The distinctive limestone and dolomite sequences of the western U.S. are very exceptional. They represent an extreme development of the carbonate facies, characterized by predominance of dolomite, with a sparse but widely distributed fauna of corals and large, thick-shelled pentameroid brachiopods. Thin graptolitic shales have been found only locally. The sea in which these deposits formed may have connected with the eastern North American seaways at its south end, although proof of this is lacking.

II. SILURIAN LIFE

1. Characteristics and Evolution.—The record of Silurian invertebrate life shows essentially an elaboration of Ordovician lineages (see ORDOVICIAN SYSTEM). It has. however, novel and distinctive features of its own, such as expansion of the corals and echinoderms, and a general substitution of the dominant groups of brachiopods. And it differs from the Devonian record in the types of corals and brachiopods present, the continued importance of graptolites and many less striking features. These differences, of course, are due partly to accidents of preservation and vagaries of collecting and recording.

Silurian plants and fishes are the oldest preserved, except for isolated occurrences of fish fragments in the Middle and Upper Ordovician of the North American Rocky mountains and Cambrian plants reported from eastern Siberia. Estonia and north India. This distribution pattern is apparently attributable to the rarity of preserved pre-Silurian terrestrial deposits.

The characteristics and evolution of Silurian or any other fossil

life are of interest not only from an aesthetic and scholarly point of view, but also because they provide the only practicable means of consistently telling fossil time. Radiogenic methods of absolute age determination do not yet suffice for general dating or correlation of the Paleozoic rocks. even though a very few apparently reliable dates are used to set. approximately, the hands of the paleontological clock in terms of years.

From the fossils also can be deduced much of the history, ecology and geography of ancient times, always in connection with the characteristics and positions of the rocks themselves. Ecologic deductions, for instance, are greatly aided by the tracks, trails and burrows made by different organisms. Indeed these are almost the only traces of life in some deposits, such as the Silurian of the eastern Appalachian trough.

2. Invertebrates and Associated Fossils.—In the Silurian, as with other fossiliferous rocks, the invertebrate and noncellular (or unicellular) organisms are the true indices of time, on the basis of which nearly all meaningful stratigraphic correlation with the standard marine sequence is founded. The form sequence of the monograptid graptolites illustrates well how such correlation may be accomplished either by relating stage of evolution to time or by the empirical knowledge of the ranges of specific morphologic types. Correlation, or paleoecological analysis. in practice, however, is usually made by analysis of the total biotal characteristics of the problem sample, considered in relation to lithology and sequence of the enclosing sediments. Ranges of selected index genera at the right side of the correlation table illustrate how Silurian fossiliferous sediments can be dated, using apparent terminal ranges of a variety of fossils.

The graptolites. despite their suggested close alliance to the vertebrates, are at best invertebrate chordates, and, in this sense, the most conspicuous and distinctive Silurian invertebrates. The monograptids are the evolutionary culmination of the simple sawbladelike forms of graptolites and appear to be exclusively Silurian—no Ordovician or Devonian report has ever been unequivocally substantiated.

Moreover, only a few species of two genera (Diplograptus and *Climacograptus*) of their Ordovician ancestors carried over into the Silurian. and these only into the lower part. The Silurian graptolite assemblage thus consists almost entirely of *Monograptus*, of short-lived derivative genera from it or older forms, and of occasional reticulate colonies such as persisted into the Devonian. The apparent time subdivision of Silurian rocks is based largely on short-ranged species of *Monograptus*—18 of the 26 graptolite zones in the type Silurian sequence are so characterized, and many of the same species floated around the world.

Corals and stromatoporoids are subordinate to the graptolites as Silurian time indicators but far ahead of them in range of evolutionary diversification. Compound corals particularly flourished, including the tabulates, which now reached their greatest expansion, and fasciculate tetracorals which did not attain their acme until the Devonian. Horn corals of simple types were more abundant and more complicated than Ordovician, less so than Devonian relatives. Stromatoporoids had also to await the Devonian for their climax, and no Silurian or other common Paleozoic coelenterate is anything like its modern relatives. Presumably however, they did have the same alternation of sessile and free-floating generations as typifies the living representatives of the phylum, which would account for wide distribution of identical species in favourable environments. Unlike the graptolites, which apparently could drift even after death, they are not found far from their place of life except as a result of unusual events.

Bryozoa are still about as common as they were in the Ordovician. with a slight dwindling of stony types and an increase of the more delicately ornamented tniglike cryptostomes. Locally they made small mounds at the bottom of the Silurian seas, as represented by the ball reefs of the Rochester shale in western New York state.

Among Silurian brachiopods, the globular, short-hinged and commonly large pentameroids were the most distinctive forms. Short-hinged spire-bearing brachiopods were essentially new, alhough there are common Ordovician forms. The wide-hinged spiriferoids began the expansion that was to flower in Devonian and Lower Carboniferous time.

The pelecypods continued to expand slowly from Ordovician beginnings, and the prosobranch gastropods became important fossils, in continuance of a long, progressive expansion to modem times. Among the cephalopods, ammonoid progenitors appeared and nautiloids dwindled. Some distinctive Ordovician groups of nautiloids were missing completely (*e.g.*, Endoceratida) and others died out during the Silurian (*e.g.*, Ascoceratida). As if to emphasize their decline, no important new nautiloid groups appeared.

Among the arthropods, trilobites continued their slow decline from a Cambrian maximum, and ostracods and merostomes both expanded slightly. Among the latter, eurypterids became much more common, while the aglaspids were missing; but xiphosurans ancestral to living *Limulus* are recorded. Ostracods are locally abundant and useful Silurian index arthropods. Trilobites, despite their general decline, showed an expansion of bizarre spiny types, perhaps as an adaptation to floating or camouflage, forced by increasing competition for the nutrient-rich bottom niches or predation. Allied developments may have caused the eurypterids to enter fresh water in later Silurian time, from which, according to one theory, they eventually chased the fishes. It is an old law of life that each time new or better offensive or competitive equipment or tactics are evolved compensation is made, or the hunted or competitive inferior perishes or takes exile.

Crinoids were the most successful Silurian echinoderms, enjoying their greatest recorded expansion of numbers and kinds. Unlike their commoner living relatives, these lilies of the sea were stalked forms; if they were equally colourful their colonies were the showy marine gardens of Silurian time. Cystoids were also common, and, although much more primitive, were similar in living habits and appearance to the crinoids. Other echinoderms were not important.

Noncellular invertebrates, or the Protista (Protophyta and Protozoa), are abundant in some Silurian deposits. Chitinous and agglutinated Foraminifera have been described from North America, the Baltic and England, and Radiolaria are occasionally reported, but little is known in detail of these Silurian records.

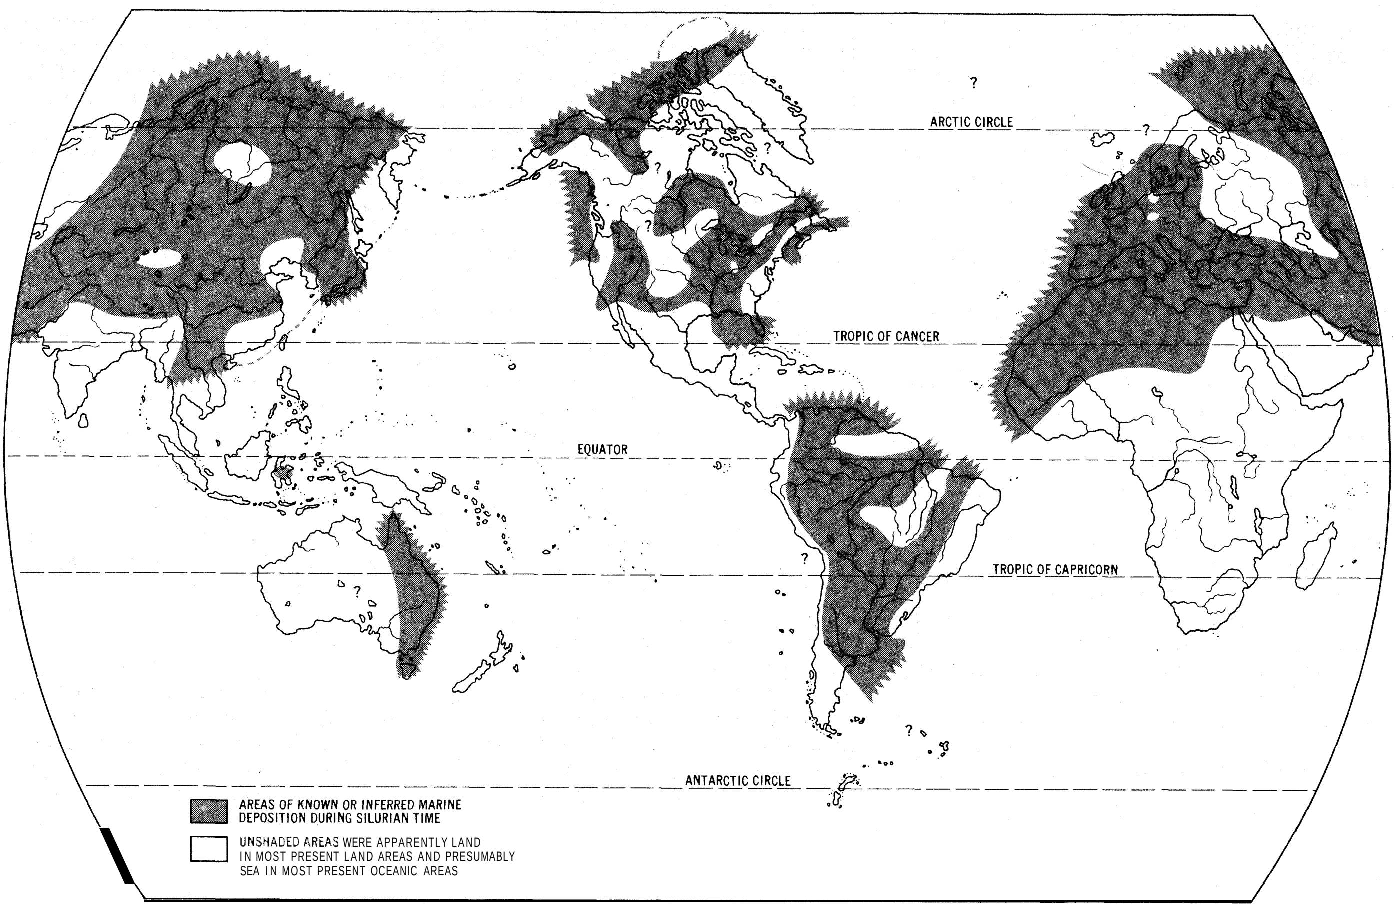
An important group of Silurian problematica is the Chitinozoa, consisting of minute, black, chitinous, vase-shaped to club- or ball-shaped organisms. Revelation of such tiny creatures or parts of creatures by chemical treatment of apparently unfossiliferous rocks sometimes permits the correlation of deposits whose position cannot be closely established by other methods.

3. Fishes, Land Plants and Associated Fossils.—Silurian occurrences of fish and plant fossils are more numerous and complete than in older rocks. They are, however, mostly, though not entirely, restricted to the upper part of the system and the fossils are not demonstrably more advanced than their predecessors. Conversely, they are greatly surpassed in number and variety by Devonian records. In the Late Silurian. in fact, the arthropods appeared to be making more headway than the vertebrates in colonizing the lands. The arachnids were represented by the scorpionid *Paleophonus*, from the Upper Silurian of both sides of the Atlantic. Millipedes are reported to occur in association with eurypterids (water-dwelling scorpionlike creatures) in Wales. Neither scorpion nor millipede was surely air breathing, but both were at least evolving in that direction. In the estuarine to questionably marine or fresh water deposits, where the early fishes are most commonly found, is also an abundance of eurypterid remains. Indeed the Silurian and Devonian saw the climax of this group, which comprised the greatest arthropod predators of all time, perhaps including principal foes of the early fishes, and possible ancestors of the arachnids.

The simple, externally armoured, mainly backboneless earliest fishes and the primitive early plant assemblages are discussed in a separate article on the Devonian system (*q.v.*).

III. REGIONAL SUMMARY

The distribution map shows where Silurian marine deposits of different ages might have been laid down on the present Iand areas. Naturally a map for any instant of the 30,000,000 years or so of



DISTRIBUTION OF SILURIAN SEAS AND LANDS

Silurian time would look very different from this highly generalized scheme, particularly if the Paleozoic geology of the ocean basins were known. Silurian nonmarine deposits and plutonic rocks are not well enough known to consider on a composite map of this scale. This map and the correlation table together give a general view of Silurian stratigraphy and paleogeography that supplements the condensed discussion of outcrop regions below.

1. Great Britain. — Silurian sediments of the type region in Wales and western England, and extending into southern Scotland, were deposited in a northeast-southwest trending subsiding area (the Caledonian geosyncline) and bordering shelf seas to the east. The basin or geosynclinal facies is characterized by graptolite-bearing slates and shales, flaggy and shaly silt stones. sandstones and mixed coarse detritus about 5,000 to 10,000 m. thick. This facies is typically developed in the Lake district of northwestern England. The shelf facies consists of shales (including mudstones), limestones and silt stones with a shelly fauna and a maximum thickness of perhaps 1.000 m. in typical development. It thins eastward to disappear toward the inferred Silurian seashore. Complete gradation in sedimentary facies, thickness and fauna occurs from shelf to basin along the margins of the subsiding trough, with some persistent zones of graptolitic shale that correlate between facies and record the history of down warping. The type area of south Wales and the Welsh borderland is happily intermediate between extreme developments of either shelf or basin facies. Northward, to the south of Scotland. the sediments suggest approach toward the northwest side of the geosyncline.

At many places in the Welsh borderland the oldest Silurian deposits in Britain are separated from underlying rocks by unconformity or abrupt upward reduction of volcanic components. Preceding crustal movements, of which the profuse Ordovician volcanicity is one indication. may have brought the southeastern part of the British subsiding area generally above water in the waning stages of the Ordovician. Subsidence. with sharply waning volcanism, was almost immediately renewed, however, and continued intermittently to near the end of the Silurian or beyond. Onset of the Caledonian orogeny forever reversed the process and made mountains where the sea had been, from Wales to Scandinavia.

Subdivisions of the British sequence are shown on the correlation table. The oldest interval, the Llandoverian (or Valentian, or May Hill), saw the sharpest distinctions between basin graptolitic shale facies and calcareous and in part sandy shelf facies. This distinction was less marked in the Wenlockian or middle division. when the importance of the calcareous facies was increased by growth of coral-stromatoporoid reefs and colonies on the shelf and spread of shelly fossils into the graptolitic shales. In Ludlovian or Upper Silurian time the distinction became progressively less marked. It finally disappeared in the last half of the Ludlovian (Aymestry) along with general faunal impoverishment and disappearance of the graptolites from Britain.

2. European Continent. — The same Caledonian depression in and along which were deposited the Silurian sediments of Britain, continued northeastward to Scandinavia, with a bordering shelf sea that locally extended as far eastward as Estonia. Best-known Scandinavian sequences are in southern Norway, southern Sweden and Gotland. That of south Sweden (Skåne) is a somewhat deformed but essentially complete basin succession of graptolitic shales with limestone interbeds increasing toward the top. This grades northwestward to the fine-textured and richly fossiliferous, but also structurally disturbed, intermediate to platform facies of limestones and shales north of Oslo. Southeastward it goes into the thin, calcareous. relatively flat lying shelf-facies of Gotland and Estonia. The Caledonian trough of pre-Silurian time thus seems now to have shifted its axis to the east and to have become a broad but not very deep embayment bulging northeastward into but not across Scandinavia. Later Caledonian deformation from a northwest direction folded the Norwegian sequence and that of south Sweden but did not noticeably affect Gotland or the eastern Baltic.

The Silurian section of Gotland, important because it comprises the type Gotlandian (synonym of Silurian as here used) is a thin but richly fossiliferous succession of limestones and calcareous shales. Many of the hills of Gotland are coral-stromatoporoid reefs, marvelously exposed for study. Despite its importance and fine shelly faunas, agreement has not been reached as to names, limits, or number of subdivisions for the Gotlandian section.

Between the Baltic and Brittany, the Silurian is represented by poorly developed and little understood shales, sandstones and limestones, commonly strongly metamorphosed and discontinuous. Only eastward in the Harz and Thiiringer uplifts does the section improve, with Bohemian aspects. The Armorican massif itself (Brittany) displays a basinal Silurian facies—500 m. or so of graptolitic black shales, with sandstone at the base.

In the Bohemian (or Czechoslovakian) massif around Prague is the famous Silurian sequence of Joachim Barrande and J. Perner; somewhat deformed by Caledonian as well as by later movements. This is prevailingly of graptolitic shales with at first inconspicuous limestone bands. The calcareous fraction increases toward the top until the whole sequence goes over to gray and black limestones, with both bedded and reef facies. Total thickness is somewhat under zoo m. A thin sandstone with land plants near the top is followed by shale and limestone with the last known uniaxial graptolites. This sequence represents a large span of Silurian time during which sediments presumably accumulated in a relatively shallow or slowly subsiding basin which connected through Brittany to the Caledonian seas. It also spilled over through the Montagne Noire of south central France and had connections to Elba, Sardinia, Spain, the eastern Bavarian Alps and the Balkans, where Silurian rocks generally resemble those of central Czechoslovakia.

3. **U.S.S.R.**—The so-called Tethyan seaway connected through the present site of the Alps, Mediterranean and the northern middle east to the Gralian trough and Siberia during parts of Silurian time. It left about 400 m. of richly fossiliferous marine Wenlockian and Ludlovian calcareous shales and limestones in Podolia, southwest Ukraine (formerly southeast Poland). The beds dip slightly westward along the walls of deeply entrenched streams beneath a cover of younger deposits, to disappear under Downtonian (basal Devonian) marine deposits and the Old Red Sandstone.

The north-south trending Uralian subsiding belt lay on the eastern side of the north European heartland and extended beyond Spitzbergen presumably to the north of Greenland and the northern islands of the Canadian Arctic archipelago. It developed independently, and its Wenlockian and Ludlovian shelly fauna is more like that of southeastern Alaska and northern California than to anything else well known. Presumably there was a direct connection across central Siberia and the Aleutian area at this time. Graptoliies occur in Llandoverian shales and sandstones of the Urals. The Silurian of the Altai mountains of south central Siberia consists of shales and limestones with grsptolites and corals, at places reefy.

4. Asia.—Limestones and sandstones with corals, brachiopods and graptolites are known from Spiti and Kashmir at the north of the Indian continent, and in the Shan states of Burma, where graptolites establish Early and Middle Silurian age. Total thickness may not exceed 300 m.

Connections are from the Tethyan or Mediterranean area to southwest China, where (in east and central Yunnan) there are about 1,000 m. of fossiliferous shales, sandstones and limestones of Llandoverian and Ludlovian age. Llandoverian deposits, in fact, occur widely in western and central China, but the Ludlovian is known only in the southwest, and the Wenlockian nowhere at all. The record in north China is obscure.

The Kitakami mountains of north Japan (north Honshu) reveal 200 to 300 m. of Middle and Upper Silurian limestones and slates, with corals and stromatoporoids in the limestones and radiolarians in slates near the series boundary. Silurian is also reported from central Honshu and the islands of Shikoku and Kyushu.

In Celebes is a Silurian outpost between Yunnan and eastern Australia, identified by the coral Halysites.

5. Australia.—The known Silurian of Australia is limited to the eastern coast and Tasmania. A thick (3,000 m.) conglomerate in the centre (Macdonnell ranges) has been tentatively referred to the Silurian for obscure reasons. but no fossils are known from it. Known Silurian sections consist dominantly of coarse clastic and volcanic deposits. Interbedded with these locally are graptolitic shales and limestones or calcareous shales with a shelly fauna. Northeast of Melbourne are 8,000 m. of clastic beds that may represent the whole of the Silurian. In the Yass district of New South Wales the section is only about 1,000 m. thick, but is famed for the rich and beautifully preserved fossils of its Yass beds and lower Hume limestones and shales.

Silurian crustal unrest, indicated by prolonged and widespread volcanic activity. culminated with compressive movements and deep-seated igneous intrusions locally termed the Bowning orogeny, and considered a phase of the more inclusive Caledonian orogeny. When the Devonian seas reinvaded eastern Australia their deposits frequently came to rest on the folded and erosionally truncated edges of Silurian rocks.

6. South America.—A compilation of South American paleogeographic data by Kenneth Caster shows broad invasion of that continent by the Silurian seas. The details, however, are little known and difficult to interpret, because Silurian was lumped with Ordovician in the reconnaissance studies that so long characterized South American geological exploration. Between South America and Antarctica, detrital and volcanic deposits at the base of the Cumberland bay series of South Georgia Island are questionably referred to the Silurian on doubtful fossil evidence.

7. North Africa.—Silurian deposits throughout north Africa are prevailingly in the basin facies. They imply a broad, open, but not very rapidly subsiding sea that connected freely with the Tethyan (Mediterranean) and north European seaways. In central Morocco the entire succession, save the top fraction, consists of graptolitic shales with characteristic species of most of the British stages. Altogether it is about 1,000 to 1,500 m. thick. This facies continues not only through the Great Atlas, where an axis of subsidence might be expected, but also southward, to the middle of the Sahara shield.

8. North America.—The Silurian rocks of North America are mainly the deposits of warm platform seas, which deepened in the eastern U.S. to form the Appalachian trough. Detrital sediments originating in eastern borderlands were largely restricted to this trough, and some (with fishes and eurypterids) along its eastern side may be nonmarine or very near shore. Leaving aside the Acadian deposits, with their European affinities, the gross form of the Appalachian succession is that of a wedge of sandstones, shales, carbonate rocks and some conglomerates from 300 to 2,000 m. thick—like a giant composite delta. By contrast, equivalent strata on the west side of the trough and the east flank of the Cincinnati arch are greatly reduced and are here already within the interior platform seas. Prevailing aridity over and adjacent to the Late Silurian seas from western New York state to southern Michigan led to the accumulation of commercial deposits of gypsum and salt in arms of the sea or intermittently connected salt basins. These evaporites are interbedded with green and red shales and grade eastward to coarser and partly red detritus. During parts of the Middle Silurian unusual (and uncertain) conditions led to deposition of the famous hematitic Clinton iron ores from New York to Alabama. The iron replaces formerly calcareous shell fragments and is deposited between them in stratigraphically limited zones of varying thickness. Graptolitic shales are also found in some of the Appalachian trough deposits, although not as common as in the good basin developments of Europe and north Africa.

Little mud or sand entered the Silurian seas west of the Cincinnati arch, and the sediments there were thin, almost entirely calcareous, and locally include reefs. Thus, sequences of limestone generally less than 300 m. thick are prevalent in the Mississippi valley. Limestone is also a common rock of the Silurian in central Canada, southwest of Hudson bay and in the Acadian region at the eastern apex of the continent; for instance, in eastern Quebec (Chaleur bay), northern Nova Scotia (Arisaig) and Anticosti Island. The interior limestones grade to dolomites in the shallower parts of the ancient seas, especially in the Great Lakes region.

The Silurian has restricted development in the eastern Great Plains and the subsurface of north central Texas, but richly fossiliferous limestones and shales are exposed in the Arbuckle mountains of southern Oklahoma.

Development in the Cordilleran region is almost restricted to the U.S., with an arm along the Mexican border to west Texas. There it is preponderantly dolomite, with limestone and shale subordinate and with identifiable fossils only locally. In the Eureka district of central Nevada the section is as much as 1,400 m. thick. The Pacific border deposits of California and Alaska are coarse, impure, detrital and volcanic sediments with occasional fossiliferous limestone lenses and with Siberian and Uralian faunal affinities. Those of the North American arctic seem to be mainly calcareous, dolomitic or shaly.

(P. E. Cd.)

SIEVA, ANTONIO JOSE DA (1705–1739), Portuguese dramatist, was born at Rio de Janeiro. Brazil, but went to Portugal with his parents at the age of eight. The parents belonged to a French family which had emigrated to escape the Inquisition. António was sent to study at Coimbra, and, while still a student. was arrested with his mother. Both were tortured, but António abjured his errors, and his mother figured as a penitent in an auto-da-f6. He completed his studies and joined his father in practice as an advocate at Lisbon. He married a cousin whose parents had been burned by the Inquisition, while she also had been exiled for her religion. On Oct. 5, 1739, husband and wife were imprisoned for "judaizing." having been denounced by the Inquisition. On Oct. 18 António was strangled, and his body burned in an auto-da-f6; on that same day one of his popular operettas was given at a Lisbon theatre.

His dramatic works, which were produced at the Bairro Alto theatre between 1733 and 1738, include the following comedies, all played by marionettes — D. Quixote (1733), *Esopaida* (1734), *Os Encantos* de Medea (1735), *Amphitrião* (May 1736), Labyrinth de Creta (November 1736), *Guerras* do Alecrim e *Mangerona* (carnival of 1737), As *Variedades* de Proteo (May 1737) and *Precipicio* de Faetonte (1735). Slight as these sketches are, they show considerable dramatic talent and an Aristophanic wit. The characters are well drawn and the dialogue full of comic strength, the scenes knit together and the plot skilfully worked out. Moreover Silva possessed a knowledge of stagecraft, and, if he had lived, he might have emancipated the drama in Portugal from its dependence on foreign writers; but the triple licence of the Palace, the Ordinary and the Inquisition, which a play required, crippled spontaneity and freedom. Even so, he showed some boldness in exposing types of the prevailing charlatanism and follies, though his liberty of speech is far less than that of Gil Vicente (*q.v.*). His comedies give a truthful and interesting picture of 18th century society, especially his best comedy, the Alecrim e *Mangerona,* in which he treats of the *fidalgo* pobre, a type fixed by Gil Vicente and Francisco Manoel de Mello (see MELO, FRANCISCO MANUEL DE).

BIBLIOGRAPHY.—His plays were published in the first two volumes of a collection entitled *Theatro comico portuguez,* which went through at least five editions in the 18th century, while the *Alecrim e Mangerona* appeared separately in some seven editions This comedy and the *D. Quixote* have been reprinted in a critical edition with a life of Silva by Dr. Mendes dos Remedios (1905). Ferdinand Denis, in his *Chejs-d'oeuvre du théâtre portugais* (pp. 365–496, 1823), prints liberal extracts, with a French translation, from the *Vida de D. Quixote.*

See Dr. Theophilo Braga, *Historia do theatro portuguez; a baixa comedia e a opera* (1871); F. Wolf, *Dom Antonio Jose' da Silva* (1860); Ernest David, *Les Opéras du juij Antonio Jose' da Silva, 1705–1739* (1880); Oliveira Lima, *Aspectos de litteratura colonial Braeileira* (1896); *Jewish Encyclopedia,* vol, xi. p. 341; G. A. Kohnt, "Bibliography of Works relating to Antonio José da Silva and Bibliography of Don Antonio's Compositions" in the *Publ. Am. Jew. Hist. Soc.* No. 4, p. 181; idem, "Martyrs of the Inquisition in South America," ib. p. 135; M. Grunwald, "José da Silva" in *Monatsschrift* (1880), xxix. p. 241.

SILVANUS (Lat. silva, wood), a deity or spirit of the woodland bordering on clearings. Thus he is partly wild and partly civilized, and reflects the experience of the earliest settlers in Italy; hence his later identification with foreign deities felt to be not wholly hostile. Accordingly Horace writes of the "horridi dumeta Silvani" (Odes, iii. 29) but he also calls him "tutor finium" (Epod., ii. 22) and Virgil "arvorum pecorisque deus" (Aen. viii. 600). A writer on land measurement (Script. *gromatici,* i. 302) tells us that each holding had three Silvani — domesticus (of the holding itself), agrestis (of the wilder pasture-land) and *orientalis* (of the boundaries). Although much worshipped, he never made his way into the towns, but is almost the only Roman deity who from first to last retained the same perfectly intelligible rustic character. His double nature as deity of woodland and cultivated land is seen well in the artistic representations of him; he carries a young tree in one hand, a pruning-hook in the other.

See Wissowa, *Gesammelte Abhandlungen* (1904, p. 78 foll.).

SILVER, a metal known from very early times, has long been used in the manufacture of articles of value such as coins, ornaments and jewelry because of its comparative scarcity, brilliant white colour and resistance to atmospheric oxidation. Apart from these uses, silver has a number of applications. most of which depend on its high thermal or electrical conductivity and corrosion resistance. Silver which has been hardened by elements such as copper or gold is used in electrical contacts. In electronic engineering conductors are sometimes coated with silver for radio-frequency currents. where the skin effect is important.

Silver apparatus is used to a limited extent in the chemical engineering industry, for example. in the manufacture of certain medicinal chemicals, in processing foodstuffs and beverages and in handling organic acids such as citric and lactic acids. Silver functions as a mild oxidation catalyst in the vapour phase oxidation of certain organic compounds such as the lower aliphatic alcohols.

The silvering of glass mirrors is an old-established industry and depends on the action of a chemical reducing agent such as invert sugar, Rochelle salt or formaldehyde on an ammoniacal silver solution. It is also possible to produce mirrors by evaporating silver on to a surface from an electrically heated filament in high vacuum. (See also Uses, below.)

Silver is uidely dispersed and sometimes occurs native, usually associated with copper and gold. The chief minerals are argentite (silver glance), Ag_2S, and chlorargyrite (horn silver), AgCl. There are also a number of complex sulfidic minerals such as stephanite (Ag_5SbS_4) and proustite (Ag_3AsS_3). Silver minerals are found with the ores of certain base metals, especially those of zinc, lead, copper and nickel, and considerable amounts are also derived from gold-silver ores.

Silver is present in sea water, though the concentration is minute and there appears to be no prospect of its economical recovery.

Physical Properties. — Silver, to which the symbol Ag is given, has an atomic number of 47 and an atomic weight of 107.88. The natural isotopes are Ag^{107} and Ag^{109} which are roughly equally abundant. Its chief radioactive isotopes are Ag^{108} (half life, 225 days), Ag^{110} (half life, 24 seconds) and Ag^{111} (half life, 7.5 days). The pure metal melts at 960.5° C. and boils at about z,000° C. In the molten state it dissolves oxygen (at the melting point about 20 vol. aye dissolved per volume of molten silver at one atmosphere pressure of oxygen). Most of this is evolved on solidification, a phenomenon which is known as the splitting of silver.

The metal has a face-centred cubic lattice (a = 4.0778 Å). The density is 10.49 at 15° C. but hard-drawn wire has a slightly lower value.

Silver is the most malleable and ductile of all metals except gold; one gram of pure metal can be drawn into a wire more than a mile long and it can be beaten into leaves of less than 0.00025 mm. thickness. The pure annealed metal has a Vickers pyramid hardness of 26: it is harder than gold but softer than copper. Pure silver is too soft for use as a coinage metal or in the manufacture of jewelry, and for these purposes it is generally alloyed with a small percentage of copper, which has no appreciable effect on its colour.

Silver has an excellent thermal conductivity. Taking it as 100 the relative values for other metals are:

Ag	Cu	Au	Zn	Sn	Fe	Pt	Pb	Bi
100	73.6	53.2	19.0	14.5	11.6	8.4	8.1	1.8

The electrical conductivity of silver is also slightly superior to that of copper. The resistivity at 20° C. is 1.59 microhm-cm. but this value is appreciably increased by cold working. The optical reflectivity of the freshly polished metal is about 98% for infrared light and 95% in the visible region of the spectrum. It decreases very rapidly in the ultraviolet below 3,500 Å and is only 10% at 3,200 A.

Chemical Properties.——Silver is more electropositive than copper but less so than gold. The standard electrode potential is − 0.7978 v. at 25° C. The metal does not react with moist or dry oxygen but is oxidized superficially by moist ozone. It is quickly tarnished by sulfur at room temperature and a surface film of silver sulfide is formed. A similar effect is obtained with hydrogen sulfide in presence of air or oxygen or with materials, such as vulcanized rubber, which can give free sulfur. Solutions of sulfides also blacken silver.

Fluorine, chlorine, bromine and iodine all react with silver at elevated temperatures but attack on the solid tends to be limited by protective halide films. Aqueous hydrofluoric acid and fluoride solutions do not attack silver appreciably but hydrochloric. hydrobromic and hydriodic acid react superficially. Silver dissolves readily in either strong or dilute nitric acid, forming silver nitrate ($AgNO_3$) and nitric oxide. Hot strong sulfuric acid dissolves the metal and forms silver sulfate (Ag_2SO_4) and sulfur dioxide. When the acid strength is less than 60% there is no action up to the boiling temperature except in presence of oxidizing substances.

In the absence of air fused alkali hydroxides have no action. It is also unaffected by fused alkali carbonates or cyanides though aqueous cyanide solutions in presence of oxygen form the argentocyanide ion.

Colloidal Silver. — In addition to the highly reactive forms of silver, sometimes called molecular silver, which are obtained as finely divided powders by precipitating the metal from its solutions with a reducing agent, or by reducing silver chloride with a metal such as iron or zinc in an acid solution, true colloids are readily obtained. Reducing agents commonly used in preparing colloidal silver are: formaldehyde, hydrazine salts and salts such as tartrates or citrates. Protective colloids are sometimes added. In addition good silver colloids are obtained by passing an arc between pure silver electrodes under water. The colour of the colloids may vary from lilac to red and is largely conditioned by the particle size. Red and yellow solutions contain the smallest and blue solutions the largest particles. Colloidal silver exhibits reducing properties and, in common with some other colloids, is able to catalyse the decomposition of hydrogen peroxide.

Chemically *Pure* Silver. — Silver of the highest purity is of special interest to the chemist because it was made and used in all the classical work on the determination of atomic weights. A procedure used by T. W. Richards and H. Wells in 1905 may still be quoted, though various other methods are now available. Silver nitrate is recrystallized, precipitated by hydrochloric acid and the resulting chloride thoroughly washed, and reduced to metal with pure invert sugar and caustic soda. The reduced silver is fused in a block of lime in the reducing flame of a blowpipe. The product is further purified electrolytically and again melted in a lime boat in an atmosphere of hydrogen. Silver of at least 99.999% has been obtained.

Compounds of Silver. — In the majority of silver compounds the element has a valence of one. These so-called argentous compounds include such familiar substances as silver chloride, bromide, iodide and nitrate. A few argentic compounds are known in which the element has a valence of two (see below).

Silver oxide (Ag_2O) is prepared as a dark brown precipitate by adding an excess of sodium hydroxide solution to a solution of silver nitrate. It is appreciably soluble in water (0.02 g. per litre at 25° C.) and this solution has an alkaline reaction and behaves as if it contained silver hydroxide. It will precipitate many insoluble metal hydroxides from solutions of their salts and absorbs carbon dioxide from the atmosphere to form silver carbonate. The oxide loses oxygen slowly at 250° C. and is rapidly decomposed to silver and oxygen at 350° C. In its reactions it behaves as a moderately strong oxidizing agent. The oxide dissolves in aqueous ammonia, probably forming the complex $[Ag.2NH_3]OH$. The solution, on exposure to air, forms a black precipitate of fulminating silver, which is dangerously explosive. Its composition is uncertain, but it may contain either the nitride Ag_3N, or the amide $AgNH_2$.

Halogen *Compounds*.—The halides of univalent silver, the most useful compounds of silver, are all well-known and stable compounds. Silver fluoride (AgF) differs from the chloride, bromide and iodide in that it is readily soluble in water (180 g. of AgF in 100 g. of water at 25° C.). It is obtained by dissolving silver carbonate in hydrofiuoric acid and evaporating the solution in vacuum. It forms several hydrates. The fluoride has a rock salt structure, in which it resembles silver chloride and bromide but differs from the iodide. The melting point is 435° C.: the fused salt decomposes slightly and contains a little free silver. A silver subfluoride with the formula Ag_2F is formed by the interaction of silver fiuoride and metallic silver at 50° C.–90° C., or in the cathodic reduction of silver fluoride. It is a solid with a bronze colour and a curious crystal lattice in which pairs of layers of silver ions alternate with single layers of fluoride ions. It is thus, in a sense, intermediate between a metal (silver) and an ionic crystal (silver fluoride), which is in keeping with the high electrical conductivity of the solid. Decomposition into silver and silver fluoride occurs above 100° C. or when the solid reacts with water.

Silver chloride (AgCl) is prepared by the addition of hydrochloric acid or a soluble chloride to a solution of a silver salt (*e.g.*, silver nitrate). It is formed as a curdy white precipitate which coagulates on heating or shaking. The salt may also be prepared by direct union of the elements as, for example, when chlorine is passed through molten silver. It melts at 455° C. It is found in nature as the mineral horn silver. The solubility in water at 25° C. is 1.91 mg. per litre. It is, however, much more soluble in concentrated hydrochloric acid and the solution is believed to contain the acid $HAgCl_2$. Silver chloride is also dissolved by solutions of soluble chlorides, the solubility being greater the greater the concentration of the dissolved salt. It is changed to silver sulfate by boiling with concentrated sulfuric acid and dissolves readily in dilute aqueous ammonia. The solution, which contains the complex cation $[Ag(NH_3)_2]^+$ yields silver chloride again on acidification with nitric acid. Silver chloride is soluble in alkali cyanide solutions and the solutions contain the complex anion $[Ag(CN)_2]^-$. On the addition of sodium thiosulfate solution to silver chloride, a solution is obtained which contains the complex anion $[Ag(S_2O_3)_2]^{3-}$. Silver bromide and iodide dissolve similarly and the formation of this complex is the reaction which occurs in the fixing of the emulsion of a photographic plate or film after first developing and washing it. The fixing removes all unchanged silver halide and so makes the emulsion insensitive to light. Silver chloride forms the compound $AgCl.3NH_3$ when it is treated with gaseous ammonia below 20° C. All the ammonia is driven off at 65° C. but there are several other ammoniates which are stable in the intermediate temperature range.

Silver bromide is found in nature as the mineral bromargyrite. It is formed by the action of bromine on silver or, as a curdy pale yellow precipitate, when hydrobromic acid or a soluble bromide is added to a solution of a silver salt. It melts at 434° C. The solubility in water is less than that of silver chloride (0.11 mg. per litre at 21° C.). It is only sparingly soluble in dilute ammonia solution, the solubility being less than that of silver chloride but greater than that of silver iodide. This difference may be used as a means of distinguishing between the three halides. The reactions of silver bromide with aqueous solutions of alkali cyanide and thiosulfate are similar to those of silver chloride. Ammoniates are also formed with gaseous ammonia.

Silver iodide is found native in the mineral iodoargyrite. It is prepared by methods exactly analogous to those for silver chloride and bromide, and is a yellow solid, which melts at 552° C. There are three crystalline modifications. which have wurtzite. zinc blende and cubic lattices respectively. The last of these is stable above 147° C. The solubility in water at 25° C. is only 0.0025 mg. per litre. The salt is soluble in a strong solution of potassium iodide. Other reactions are very similar to those of silver chloride and bromide.

When silver chloride, bromide or iodide is exposed to light the colour changes from white or yellow to pink. violet and finally to black. In this process halogen is lost and, with prolonged and intense irradiation, weight losses of up to about 10% may be recorded. It is not yet certain what is formed but it is thought to be either silver or a silver subhalide or both. When the silver halides are used in photography very much smaller exposures than those referred to above are involved; indeed they are such that no visible change occurs in the halide grains. Only when the emulsion is subsequently developed *i.e.,* submitted to the action of a chemical reducing agent, are those grains which have been exposed to light blackened because of the production of metallic silver (see PHOTOGRAPHY).

Other Compounds of Univalent Silver.—Silver nitrate ($AgNO_3$) is the chief silver compound which is of technical importance. It is made in large quantities by dissolving silver in nitric acid of density 1.25–1.30. It crystallizes in transparent plates which melt at 212° C, and can be cast. The solubility at 20° C. is 222 g. per 100 g. of water. It is moderately soluble in methyl and ethyl alcohols and, to a smaller extent. in various other organic solvents. When heated at about 320° C. silver nitrate loses oxygen and forms silver nitrite. At a red heat silver is formed.

The chief use of silver nitrate is as an intermediate in the preparation of silver halides for incorporation in photographic emulsions. When used for this purpose the technical salt must first be purified. In analytical chemistry aqueous solutions of silver nitrate are used in the volumetric determination of halides, cyanides and thiocyanates. as well as for the detection of reducing agents and of the cations of various acids which form insoluble silver salts. Silver nitrate has a causticizing action on the skin and produces a blackening because of the formation of silver. Cast sticks of silver nitrate are used in pharmacy under the name lunar caustic. A similar blackening is produced when the salt is in contact with other types of organic matter and, in aqueous solution, it has been used for marking linen. The free nitric acid tends, however, to destroy the fabric and it is preferable to use the silver salts of weaker organic acids.

Silver sulfide (Ag_2S) is found native in the mineral silver glance or argentite. It is also found associated with the sulfides of other metals (*e.g.,* with lead sulfide). The metal has a great affinity for sulfur and the sulfide may be made by the direct union of the elements or by the action of hydrogen sulfide on a solution of a silver salt. It is a black-brown solid which is insoluble in cold dilute mineral acids, though it dissolves in hot dilute nitric acid and also in alkali cyanide solutions.

Silver sulfate (Ag_2SO_4) is produced when the metal is dissolved in hot sulfuric acid, or by adding dilute sulfuric acid to a fairly strong solution of silver nitrate. It forms white rhombic prisms which are isomorphous with anhydrous sodium sulfate and are only sparingly soluble in water. The salt dissolves in aqueous ammonia, the solution yielding the complex salt $[Ag(NH_3)_2]_2SO_4$.

Silver selenide (Ag_2Se) is made by heating silver powder with selenium. It is a black crystalline material and a. semiconductor. Silver telluride (Ag_2Te) resembles the selenide and is prepared by a similar method. Both selenium and tellurium may occur with silver minerals and, if they find their way into the metal as trace impurities, they have a deleterious effect on its mechanical properties as well as on its usefulness as a catalyst.

Silver cyanide is obtained as a curdy white precipitate when a soluble cyanide is added to a silver salt solution. It is soluble in excess of cyanide solution and forms the complex anion $[Ag(CN)_2]^-$. This is important in electroplating. a process in which the object to be plated is made the cathode, the anode being a sheet of pure silver. The electrolyte is. as a rule, a solution containing the complex $K[Ag(CN)_2]$, the anion of which is dissociated to a slight extent into silver cations and cyanide anions. On electrolysis the former are deposited on the cathode to be plated and the latter react with the anode, causing fresh silver to pass into solution as the complex and so replenish the bath. Silver thiocyanate (AgCNS) is a very insoluble salt which is also insoluble in nitric acid. It is precipitated by the addition of ammonium thiocyanate solution to a silver nitrate solution. Silver azide (Ag_3N) is formed as a white precipitate when sodium azide is added to silver nitrate solution. It resembles silver chloride in many of its reactions, but is very explosive in the dry state and has been used as a detonator.

In addition to the silver salts already mentioned there are numerous others, among which are the phosphates, arsenates and chromates. which are insoluble and are used in testing qualitatively for the presence of these acid radicals in solution. The silver salts of many organic acids have been prepared and are of interest in that they yield silver when they are ignited in air and so may be used in determining the equivalent weight of the acid.

Silver also yields a large number of co-ordination compounds. A few of the more important, such as the complex cyanide and thiosulfate, have already been mentioned. In certain of these compounds the stability of the cation is increased by co-ordination. Thus, for example, co-ordination of the silver ion with ethylenethiocarbamide (etu) yields the complex chloride and bromide $[Ag(etu)_3]Cl$ and $[Ag(etu)_3]Br$, neither of which is darkened by light.

Bivalent Silver.—One of the few simple compounds of bivalent silver is argentic fluoride (AgF_2) which is a dark brown solid formed when fluorine reacts with argentous fluoride. It melts at 690° C. and is a ponerful oxidizing agent and also a good fluorinating agent. The other halides of bivalent silver are unknown. Anodic oxidation of silver or, alternatively, oxidation of an aqueous solution of silver nitrate with a persulfate gives a black compound of the empirical formula AgO which is very probably an oxide of bivalent silver.

There is some indication that anodic oxidation of silver may give a higher oxide, possibly Ag_2O_3. The stability of the argentic ion is much increased by co-ordination with various ligands. Thus, for example, although argentic persulfate is unknown, co-ordination of the metal with pyridine enables the relatively stable compound $[Ag(pyr)_4]S_2O_8$ to be prepared. It is isomorphous with the corresponding cupric compound. Other co-ordinating molecules which give similar products are o-phenanthroline and dipyridyl.

Alloys. — Silver alloys with most metals but few of the products have any practical value. Alloys with copper are harder, tougher and more fusible than silver and are used for coinage and jewelry. The proportion of silver in these alloys is stated in terms of fineness, which means parts of silver per 1,000 of the alloy. Sterling silver contains 92.5% of silver and 7.5% of another metal, usually copper; *i.e.*, has a fineness of 925. Gold and silver form a continuous series of solid solutions. Various alloys of gold. silver and copper are used in the jewelry trade and in dentistry. There are also several minor uses for these alloys (*e.g.*, in the manufacture of electrical contacts and for hard solders). Silver-zinc alloys are important because they form readily and provide the basis of the Parkes process for desilverizing lead. In dentistry a silver amalgam is used which is a mixture of mercury with a silver-tin alloy. It sets in the tooth cavity by the interaction of the components to form a ternary system of which mercury is a component. There are, however, other types of dental alloy. Lead and silver form a simple eutectic at 304° C. (2.5% silver).

There is also an important group of silver-bearing alloys which is used in soldering and brazing. Among these are various alloys based on the silver-copper-zinc and the silver-copper-phosphorus systems.

METALLURGY, MINING AND PRODUCTION, USES

History. — Early Roman records show that before the use of *argentum*, from which the chemical symbol Ag was derived, the word "Luna" and a crescent moon symbol were used for silver. The actual use of silver dates far back into antiquity; however, it is believed that gold and copper were the first metals to be worked by man. Silver ornaments and decorations have been found in the royal tombs dating back as far as 4000 B.C. In the Code of Menes, who is supposed to have reigned in Egypt about 3500 B.C., it was decreed that "one part of gold is equal to two and one-half parts of silver in value." This may have been the first gold standard. By 800 B.C. it is probable that both gold and silver were used as money in all countries between the Indus and the Nile. The Romans probably advanced the art and science of the metallurgy of silver further than any other race up to their time. The Romans had several large and important silver workings, using perhaps the first fire metallurgy (pyrometallurgy) to produce silver metal and then converting the metal into priceless silver ornaments.

According to Pliny in his *Historia naturalis*, "the ore was washed and sieved five times, fused with lead and then cupelled for pure silver." Cupellation is the process of oxidizing the lead to lead oxide, which is quite volatile at high temperatures. Several centuries later it was found that certain ores of gold and silver could be amalgamated by grinding in the presence of iron or copper salts, water and mercury. This method finally evolved into the Patio process. In the latter part of the 19th century, the cyanidation process was developed for the treatment of gold and silver ores. From about 1850 up to the middle of the 20th century approximately 70% of the world production of silver was derived as a by-product in the smelting and refining of copper, lead and zinc ores.

Occurrence. — Silver is widely distributed in nature, but the total amount present in the lithosphere (the solid part of the earth) and hydrosphere (the liquid part) is quite small when compared with other metals. For every 10,000,000 parts of iron, there are about 2 parts of silver found in the lithosphere. About 90% of the silver mined in the 20th century occurred in the native condition, either finely disseminated in other minerals, which is by far the most important, or as free silver. The term native silver means an alloy of silver and some other metals; gold is generally one of the metals. Free silver is native silver in a rather coarse form. Practically all sulfides of lead, copper and zinc contain some silver, and in general if the three different metal sulfides occur in the same ore: the largest per cent of the silver will be found in the lead sulfide (galena). These are called argentiferous ores. Argentiferous ores may contain amounts of silver from a trace to several thousand troy ounces per avoirdupois ton or about 10%. Ores containing silver mined from 1900 to 1955 averaged from about 3 to 30 oz. per ton. (See MINING, METAL.)

Unlike gold, silver tends to form many natural occurring minerals. Some of the most important silver minerals are: cerargyrite (silver chloride) and sylvanite (gold, silver telluride). This group, called secondary minerals? is generally found near the surface of the earth's crust. Another group is generally found deep in the earth's crust and includes argentite (silver sulfide), polybasite (silver antimony sulfide), proustite (silver arsenic sulfide), pyrargyrite (silver antimony sulfide), tetrahedrite (copper antimony sulfide) and tennantite (copper arsenic sulfide). In tetrahedrite and tennantite, part of the copper is usually replaced with silver. Pyrargyrite and proustite, because of their colour, are called ruby silver minerals, while tetrahedrite and tennantite, for the same reason, are called gray copper minerals.

Metallurgy. — Several methods are employed for the extraction of silver, or gold and silver from the ores. However, it must be realized that the majority of ores that contain silver also contain the base metals lead or copper or zinc or any combination of these three metals and are treated metallurgically mainly for the three. The silver they contain is removed as a by-product. Under certain economic conditions it may be more profitable to send such ores to a lead or copper smelter.

The amalgamation process consists of treating ores containing free silver and cerargyrite with water and mercury. The silver amalgams with the mercury and the cerargyrite reacts with the mercury to liberate silver, which amalgamates with the excess mercury. The amalgam is separated from the waste rock and then distilled in retorts. The mercury is condensed for further use and the silver is cast into bullion bars.

The cyanidation process is used mainly on ores in which gold is the main valuable constituent and silver a by-product. However, a large amount of the ore mined in blexico contains only silver as the main valuable constituent and is treated by the cyanidation process. In the cyanidation process the ore is generally pulverized and then leached with a basic dilute sodium cyanide water solution. The silver reacts with the sodium cyanide to form a water-soluble sodium silver cyanide. The resulting mixture is then filtered and the solids discarded. The solution containing the soluble silver is treated with metallic zinc dust, which causes the silver to precipitate from the solution. The metallic silver is filtered off, melted and cast into bullion bars.

Refining of crude silver bullion or gold-silver bullion may be carried out by a number of methods, the method used depending to a large extent on the purity and the amount of bullion to be refined. For bullions containing a large amount of impurities it may require smelting in a small furnace with lead oxide and other materials to form a slag (which can be sent to a lead smelter) and the lead bullion, which contains most of the gold and silver. The lead bullion is then cupeled. The resulting alloy, mainly gold and silver, is called doré. The high-purity doré can then be treated in the same manner as high-purity bullion obtained from cyanidation. The most important methods of treating high-purity gold and silver bullions are electrolysis and parting. In electrolysis the gold and silver bullions and dorés are used for the anode (positive pole). Silver and the more basic impurities are dissolved in a dilute nitrate water solution at the anode; gold remains unattacked and falls off the anode to the bottom of the electrolysis cell as the silver goes into solution. Pure silver is deposited at the cathode (negative pole), which is made of a thin sheet of pure silver. The resulting cathode silver is melted and cast into bars.

Parting, or wet method, is generally applicable to doré or very high-purity gold and silver bullion in which the silver to gold ratio must be higher than two parts of silver to one part of gold. If the ratio is not two to one or better, then silver must be added and the resulting alloy remelted. The doré or gold and silver bullion is placed into a bath of hot concentrated sulfuric or strong nitric acid and the silver is allowed to dissolve. The silver forms water-soluble sulfates or nitrates. The residue is filtered off and treated for its gold content. The clear solution containing the silver is treated with ferrous sulfate or copper or iron to precipitate the silver. The resulting precipitate is filtered off, washed, dried and melted down with flux to give a product that averages 99.5% silver or 995 fine of silver.

Uses.—Monetary use generally claims approximately 40% of the silver mined each year. This use to a large extent takes the form of stockpiling in government hoards. In the U.S. the largest part of the silver bars are stockpiled at West Point, N.Y. The U.S. silver dollar since 1834, the date of the last gold standard established by England, contains 0.773 + troy ounces of silver. The remaining part of the dollar is 10% copper. This 0.773 + oz. of silver in a U.S. dollar is based upon the ratio of 16 to 1; *i.e.,* when the gold standard was set in 1834, it required 16 oz. of silver to be equal in value to 1 oz. of gold. In 1834 the price fixed for gold was $20.67 + per ounce. At 16 to 1 ratio the value of silver is $1.292 +. Therefore, if a U.S. silver dollar contains 0.773 + oz. and the price of silver is $1.292 +, then the silver in a silver dollar is worth approximately $1; however, the price of silver was not fixed as in the case of gold but allowed to fluctuate on the world market as supply and demand dictated. The lowest yearly world price for silver after 1834 was $0.282 + per ounce in 1932 and the highest was $1.346 in 1934. This means that in 1932 the silver in a U.S. silver dollar was worth approximately $0.218 + and in 1834 approximately $1.041 +. The average yearly world market price for silver from 1834 to the mid-1950s was about $0.92 + per ounce. In 1933, to help restore prosperity the U.S. government fixed the price for newly mined silver in the U.S. at $0.646 + per ounce.

The average yearly world market price for silver in 1933 was $0.349 + per ounce. In 1934 the U.S. went off the gold standard established in 1834 and fixed the price of gold at $35 per ounce, but did not revaluate the silver coinage standard. In 1946 the U.S. government raised the price for domestic mined silver to $0.905 per ounce.

Use of the metal for silverware, ornaments, jewelry and other products consumes about 35% of all the silver mined in the world. An average teaspoon marked sterling (not less than 92.5% silver) will contain about 1 oz. of silver. Jewelry silver is an alloy containing 80% silver and 20% copper. Gold dental alloys contain about 75% gold, 10% silver, 10% copper and the remaining palladium, platinum and zinc. Dental amalgams are alloys of silver, tin and mercury. Yellow gold used in jewelry is composed of 53% gold, 25% silver and 22% copper (see Alloys, above).

The photography industry consumes about 15% of the silver mined in the world each year for making film and photographic plates. In this industry silver is used in the form of halides, such as silver bromide. Prior to World War II, manufacturers of airplanes and diesel locomotives began to use pure silver as a bearing material; such bearings have a seizure resistance of 1 compared with about 3 for babbit. After restriction on silver use was removed at the end of World War II, nearly all aircraft and diesel locomotives were equipped with pure silver main bearings. Each main bearing on a diesel locomotive will contain approximately 6 oz. of silver.

During World War II the U.S. government loaned nearly 1,000,000,000 oz. of silver to war plants for temporary nonconsumption uses, such as conductors of electricity. Silver has a relative electrical conductivity of 100 compared to about 95 for copper. Silver and its alloys are used extensively in the electrical industry, mainly because of its resistance to oxidation, for switches and contact points where arcing and wear is a problem. Silver coatings applied to ceramics, glass and mica are finding wide use in electronic devices. Electrical circuits, particularly for portable radios, may be made by stamping or printing a given electrical circuit on panels with silver ink. This modern method of making intricate electrical circuits has greatly reduced the consumption of metal conductors and labour required for soldering wire joints. Silver solders or silver brazing alloys have rather a low melting point and make strong joints that have high resistance to corrosion.

The catalytic properties of silver and its salts are used extensively to influence chemical reactions of ammonia for making fertilizers and other oxidation chemical reactions. Silver foil and plates are used for replacement of missing bone fragments because of its germicidal properties (see also *Medicinal* Uses, below). Certain silver compounds have fungicidal properties; a weak silver nitrate solution can be used to disinfect certain plants.

(S. L. S.)

Medicinal Uses.—Apart from silver nitrate, much of the silver which is used in medicine is in the colloidal form in association with proteins. The chief uses of silver compounds are as antiseptics, astringents and caustics. Silver ions in water have a germicidal action, even at very low concentration, and this has been utilized to a limited extept in water sterilization.

Applied externally, silver nitrate has a limited caustic action, destroying the superficial tissues and separating the part acted on as a slough. It may be employed to destroy warts. In granular lids and various forms of ophthalmia, solutions of silver nitrate are employed.

The nitrate is both astringent and stimulating as well as bactericidal and solutions of it have been used to paint indolent ulcers and in chronic pharyngitis or laryngitis.

External or internal medicinal administration of silver, except in large doses, causes no harmful systemic effects but continued exposure may produce a chronic form of silver poisoning which is known as argyria and in cases of which silver is deposited in the tissues. The most marked symptom is the dark slate-blue colour of the lips, cheeks, gums and, later, of the skin.

In large doses silver nitrate is a poison, causing violent abdominal pains, vomiting and diarrhea, with the development of gastroenteritis. The treatment consists in the use of solutions of common salt, followed by copious drafts of milk or white of egg and water, or soap in water, in order to dilute the poison and thus protect the mucous membranes of the esophagus and stomach.

(H. J. Es.)

Production.—Since about 1900, Mexico has been the leading producer of silver in the world, producing about 30%. The U.S. is second, producing about 25%, and Canada is third, producing about 15%.

The leading silver producing state in Mexico is Hidalgo, in which the world's largest silver mine, the Real de Monte y Pachuca, is located. In the U.S. Idaho leads; and in Canada, the province of British Columbia.

J. HORACE MCFARLAND CO.
LEAVES AND BLOSSOMS OF SILVER BELL (HALESIA CAROLINA)

SILVER BELL or SNOWDROP TREE, common names for three or four species of trees or large shrubs belonging to the genus Halesia of the storax family that are native to the southeastern United States. They produce rather large bright green, generally oblong and short-stalked leaves and showy white, slender-stalked, drooping bell-shaped flowers, appearing before or with the leaves and followed by light-brown winged fruits.

H. *carolina*, which reaches a height of 40 ft., is hardy as far north as Massachusetts, while H. diptera, usually a smaller plant but with larger flowers, is hardy to Philadelphia, Pa. H. *monti-*

cola, considered by some botanists as a variety of *H. carolina*, found in the mountains of North Carolina to Alabama, is the largest of all species, sometimes reaching a height of 90 ft. *H. carolina* and *H. diptera* can be cultivated rather easily in their natural range. (J. M. BL.)

SILVERBERRY (*Elaeagnus argentea*), a North American shrub of the oleaster family (Blaeagnaceae), found from Quebec to Hudson bay and British Columbia, south to Minnesota and Utah. It grows from 6 to 12 ft. high, with silvery-scurfy leaves and numerous fragrant flowers, pale yellow within and silvery without, borne in the leaf axils, and round-ovoid, olivelike silvery fruit, with a mealy edible fleshy portion enclosing a grooved nut.

SILVER CITY, a famous ghost town of Owyhee county in southwestern Idaho. U.S., was founded March 10, 1863, and quickly displaced adjacent Ruby City as the centre of the Owyhee mines. Exceptionally rich silver lodes in nearby War Eagle and Florida mountains took years to develop but were the subject of great excitement and bitter rivalry for control. The Poorman mine. although entangled in litigation. publicized the district particularly well; silver crystals from it won a special gold medal at the Paris exposition of 1866. In 1868 armed conflict among claim owners forced the governor to dispatch troops from Fort Boise to restore order. An important mining industry with a strong labour union movement had developed prior to financial collapse of the silver market accompanying the failure of the Bank of California on Aug. 26, 1875; by then Silver City had Idaho's earliest daily newspaper—the *Owyhee* Daily *Avalanche*—and sufficient stability to survive the economic panic. More efficient mining technology. extensive British investment and improved railway transportation near that remote mountain district (elevation over 6,000 ft.) brought a long revival after 1886. The gradual decline of mining activity led to loss of population and, in 1935, of the county seat. Silver City's peak population had been several thousand; in the 1960s it was less than 50. It can be reached by road from Nampa (44 mi.. part paved) or by gravel road (about 20 mi.) from the highway between Boise and Reno. Nev. There are a number of other ghost towns in the county. *See* also IDAHO: *History*. (M. D. B.)

SILVER CITY, a city of southwestern New Mexico. U.S., the seat of Grant county, is a mining and cattle centre located in the foothills on the southern edge of the Gila National forest, about 160 mi. N.W. of El Paso, Tex. The town dates from 1870. the date silver was discovered on the outskirts of Silver City; it was incorporated in 1878. Although the silver mines have been exhausted, other mining is still important in the area. The Chino Mines division of Kennecott Copper corporation at nearby Santa Rita is the district's largest industry and is one of the nation's largest open-pit copper mines. The combination of mining and ranching gives Silver City and its surrounding towns a western frontier atmosphere even in modern times. New Mexico Western college, a state-supported institution established in 1893, is located there.

The climate is cool in the summer but fairly mild during the winter. despite the altitude of approximately 6.000 ft. The nearby Gila forest provides recreation for the area and is the site of the Gila Cliff Dwellings National monument, established in 1907, an unspoiled relic of vanished Indian tribes. The city has a council-manager form of government in effect since 1957. For comparative population figures *see* table in NEW MEXICO: *Population*. (R. P. SA.)

SILVERFISH, a small active wingless insect, so called from the silvery glitter of the scales covering the body. It is less than half an inch long and is found in damp corners or among books and papers in houses. Although accredited with destroying paper and linen, it probably feeds only on farinaceous or saccharine substances. Scientifically it is *Lepisma saccharina* and belongs to the order Thysanura, subclass Apterygota (*q.v.*).

SILVERIUS, SAINT. pope from 536 to 537, was a legitimate son of Pope Hormisdas. born before his father entered the priesthood. He was consecrated successor to Agapetus I on June 8, 536, having been pressed on the Roman clergy by the Gothic king Theodahad. Six months afterward (Dec. 9) he was one of those who admitted Belisarius into the city.

Silverius opposed the restoration of the patriarch Anthimus, whom Agapetus had deposed, and thus brought upon himself the hatred of Theodora, who desired to see Vigilius made pope. He was deposed by Belisarius in March 537 on a charge of treasonable correspondence with the Goths, degraded to the rank of monk and sent to Lycia. Justinian, who entertained his complaint, sent him back to Rome, but Vigilius was ultimately able to banish his rival to Palmarola, where he died, probably about Dec. 537.

SILVERSMITHS' AND GOLDSMITHS' WORK. Personal ornaments, utensils, vases. decorative objects. etc.. made of silver or gold, with their various alloys, are known as silversmiths' and goldsmiths' work.

EGYPTIAN TO ROMAN

Gold, silver and their natural or artificial mixture called electrum or white gold, were worked in ancient Greece and Italy for personal ornaments, for vessels: arrows and weapons: for coinage, and for inlaid and plated decoration of baser metals.

Aegean lands were rich in precious metals. The largest of the Trojan treasures, the so-called Treasure of Priam, is a representative collection of jewels and plate. The gold ornaments were packed in a large silver cup. They consist of elaborate diadems or pectorals. bracelets. earrings or hair-rings and beads. The Trojan vases have bold and simple forms, mostly without ornament: but some are lightly fluted. Many are wrought from single sheets of metal. The characteristic handle is a heavy rolled loop soldered or rivetted to the body. Some silver flasks with inverted cup-covers have small shoulder-studs pierced vertically for hanging. Bases are sometimes round or pointed, sometimes fitted with separate collars. An odd shape in gold is an oval bowl or cup with a broad lip at each end and two large roll-handles in the middle. A plain spouted bowl of usual early Helladic shape in the Louvre is the typical specimen of goldsmith's work from pre-Mycenaean Greece. Silver seems to have been more plentiful in the Cyclades, but only a fen simple vessels, headbands, pins and rings survive.

Minoan and Mycenaean.—A profusion of gold jewellery was found in early Minoan burials at Mochlos, three silver dagger-blades come from a communal tomb at Kumasa, and silver seals and ornaments of the same age are not uncommon. An elegant silver cup from Gournia belongs to the next epoch (Middle Minoan I., *c.* 2000 B.C.). Minoan plate and jewellery are amply represented in the wealth of the mainland tombs at Mycenae and Vaphio.

The vases from Mycenae are made indifferently of silver, gold and bronze; but gold is generally reserved for drinking-cups, small phials and boxes; silver is used for jugs as well. Much of the funeral furniture is gold. It has been thought that the small gold discs, which Schliemann found in prodigious quantities (700 in one grave), were nailed on wooden coffins, but they may have been sewn on clothes. They are impressed with geometrical designs based on circular and spiral figures: stars and rosettes and natural forms such as leaves, butterflies and octopods. Models of shrines and other amulets are also made of gold. A splendid piece of plate is a silver counterpart of the black steatite libation-vase from Knossos in the form of a bull's head. with gold horns. a gold rosette on the forehead. gold-plated muzzle, ears and eyes. The gold is not laid on the silver, but on inserted copper strips. The gold cups from Mycenae are plain curved or carinated forms related to the silverware and pottery of Troy, and embossed conical vessels of the Minoan tradition. Some plain pieces have handles ending in animals' heads. The embossed ornament consists of vertical and horizontal bands of rosettes and spiral coils, floral, foliate, marine and animal figures.

Cretan and mainland tombs have produced many examples of weapons adorned with gold. Modest ornaments are gold caps on the rivets joining hilt and blade, but the whole hilt is often cased in gold. An example from Mycenae has a cylindrical grip of openwork gold flowers with lapis-lazuli in their petals and crystal filling between them; the guard is formed by similarly inlaid dragons. The most splendid Mycenaean blades are bronze inlaid with gold, electrum, silver and niello. Here again the work is done on inserted copper plates. This kind of flat inlay seems to have been originally Egyptian. It occurs on daggers from the tomb of Queen Aah-Hotep, which are contemporary with the Mycenaean (c. 1600 B.C.), and it is significant that two of the Mycenae designs have Egyptian subjects, though their style is purely Minoan. These are the scenes of cats hunting ducks among papyrus-clumps beside a river in which fish are swimming. Another blade bears Minoan warriors fighting lions, and lions chasing deer. A dagger from Thera has inlaid axe-heads; one from Argos, dolphins; and fragments from the Vaphio tomb show men swimming among flying-fish. These are masterpieces of Minoan craftsmailship; in the long decadence of the Mycenaean age there seems to have been no invention, and later pieces of goldsmith's work repeat conventional forms and ornaments.

Greek and Etruscan. — The period of transition from the Bronze to the Iron Age, when Aegean external relations were violently interrupted, was not favourable either to wealth or art, and the only considerable pieces of plate that have come from Greece are the embossed and engraved silver bowls made by Phoenicians. Most of them bear elaborate pictorial designs of Egyptian or Assyrian character, and are evidently foreign to Greece; but some simpler types, decorated with rows of animals in relief or wrought in the shape of conventional flower-bowls, can hardly be distinguished from the first Hellenic products. Early Greek work is rare. A severe and elegant silver bowl in the Metropolitan Museum, New York, represents the flower-type in its finest style. It is cast and chased, and probably belongs to the 5th century B C. Other pieces of the same age are simply moulded, and no special kind of decoration seems to have been developed for work in precious metals.

Silver vases and toilet instruments have been found beside the commoner bronze in Etruscan tombs. A chased powder-box of the 4th century is in the Metropolitan Museum, New York. The bronze reliefs of the archaic chariot in the same collection have their opulent counterparts in some hammered silver and electrum fragments in London, Munich and Perugia. The electrum details are attached with rivets.

Roman. — About the 4th century B.C. there was revived the fashion of ornamenting silver vessels with relief, and this type of work, elaborated in the Hellenistic age and particularly at Antioch and Alexandria, remained the usual mode of decoration until the end of the Roman empire. Various fabrics of moulded pottery correspond to the successive styles of metalware. A silver vase in the British Museum, bearing a frieze of chariots between floral bands, is nearly a reflex of an earthenware Calene bowl (3rd century B.C.) in the same collection. Pliny names Greek silversmiths whose work was valued highly at Rome, and laments the disappearance of the art in his own day. He must refer only to its quality, for Roman silverware has been abundantly preserved. Many rich hoards in modern collections were buried by design during the calamitous last centuries of the ancient world, and the most sumptuous, the Boscoreale treasure, was accidentally saved by the same volcanic catastrophe that destroyed Herculaneum and killed Pliny. This treasure (108 pieces) is mostly in the Louvre. A hardly inferior hoard (70 pieces) found at Hildesheim and now in the museum of Berlin, also belongs to the early empire. The acquisition and appreciation of silver plate was a sort of cult at Rome. Technical names for various kinds of reliefs were in common use (emblemata, *sigilla, crustae*), weights were recorded and compared and ostentatiously exaggerated. Large quantities of bullion came to Rome with the spoils of Greece and Asia in the 2nd century B.C., and Pliny says that even in republican times there were more than 150 silver dishes in the city of a hundredweight apiece. The Emperor Claudius had a slave who possessed a five-hundredweight dish. Weights of vessels are often marked on their bases.

Cups and jugs of Augustan style are usually covered with ornament in high relief. The subjects are very diverse: historical, mythological and mystic scenes, formal and naturalistic designs of flowers and foliage, graceful studies of animals and birds. Others have conventional fluting, petals or gadroons, Bacchic instruments and masks, embossed or engraved wreaths, gilt or inlaid with niello. Silver and niello inlay was commonly applied to bronze plates. A singular type of silver bowl (*patera clipeata*) has a central ornament in high relief or even in the round: portrait-busts are not uncommon in this place. In course of time the ornament was restricted, and later Roman plate is largely plain with narrow border-friezes, small central medallions, and handles embossed in low relief. One of the very few gold pieces that survive, a shallow bowl found at Rennes and now in the Bibliothèque Nationale of Paris, is exceedingly elaborate. It measures 25 centimetres across and weighs 1,315 grammes. The central medallion and its surrounding frieze contain scenes of a bibulous contest between Bacchus and Hercules; between these and the edge is a row of 16 gold coins each framed in a foliate wreath. The coins range from Hadrian to Caracalla. In the same collection are several examples of very large silver plates (*clipei* or *missoria*), in which the whole field is embossed with mythological or historical subjects. The largest (called the shield of Scipio) is 72 centimetres in diameter and weighs 10,300 grammes. Another bears the name of Gelimer, king of the Vandals and Alans (6th century). The "shield of Theodosius" at Madrid shows the emperor, seated between Valentinian and Arcadius among his guards, with an allegorical group in the exergue. The persistence of classical and even pagan subjects in early Christian work is well illustrated by the silver and gilt casket of Projecta, the centrepiece of the Esquiline treasure in the British Museum. It was a wedding-present; some of its many panels contain incidents in the marriage ceremony, others have groups of Venus and her attendants, and the lid bears the pious exhortation: *Secunde et Proiecta vivatis in Christo.*

Jewellery.—There is not the same break between prehistoric and classical jewellery as between other gold and silverwork and arts in general. It is true that certain types of ornament went out of fashion at various times and places, but the ancient jeweller's craft seems to have been rather cosmopolitan, and designs of common articles, earrings, bracelets and necklaces, were universal and persistent. The outstanding feature of ancient jewellery is its large display of figured surface, generally resulting in a tinsel fabric. The earliest specimens of Aegean jewels come from opposite ends of that region, Troy and Crete, and are contemporary (c. 2500 B.C.). The Trojan are the more elaborate but the elements are the same in both: thin wire in linked and plaited chains and coils, thin foil in petals and rosettes. The largest Trojan diadem or pectoral is made of 90 gold chains fringed with tiny scales and supporting foil-pendants. The simplest earrings are swelling hoops, simple or multiple or enriched with transverse bands. They are identical with archaic Greek types 2,000 years later. A more elaborate earring is a horizontal half-cylinder made of wire or plate with rosettes along its front upper edge and pendent discs below. This also reappears in the archaic period as the basket-earring of Etruria, doubtless an Ionian importation. Pinheads and bracelets are decorated with applied rosettes and spiral coils, and the pins are crowned with rows of little jugs. A plaited wire bracelet at Troy is reflected in a foil bracelet stamped with the same pattern at Mochlos in Crete.

This Early Minoan group contains many flower-headed pins, related on the one side to Trojan decorative rosettes, on the other to Sumerian hair ornaments. Granulation occurs on Trojan earrings, and was doubtless used at the same time in Crete, but very little jewellery has been found there, and earrings are scantily represented even in the wealth of the Mycenae shaft-graves. The swelling hoop was Mycenaean, and often had a pendent globule-cluster, which was ultimately enlarged into the semblance of a bull's head with granulated muzzle and coiled wire ears. The shaft-grave jewels are mostly diadems and hairpins, bracelets and pectorals, bead-necklaces and pendants, signet and finger-rings and plaques for decorating clothes. Thin plates cut and embossed in animal and floral forms served for all these ornaments. They are very seldom cast or wrought. Stone inlay is rare, but stone beads are often mounted in gold, and enamel is not uncommon. European and oriental (Phoenician) elements are combined in a treasure from Aegina, now in the British Museum, which belongs to the very end of the Mycenaean age, c. 1000 B.C. Its designs are mainly stylized openwork figures fringed with small pendants.

In the following period diadems, bracelets and earrings were decorated by the old processes of stamping, granulation and enamelling in the new Geometric style. Archaic Greek and Italian jewellery (700–500 B.C.) was almost wholly oriental in design, Egyptian and Assyrian models of Phoenician introduction being reinforced by rich Ionian and Lydian wares. New forms in Greece and Etruria were the coiled bracelets and earrings ending in heads of lions and bulls, pomegranate, lotus and palmette pendants, winged figures of sphinxes and sirens and masks of satyrs. But the technique was unchanged. Embossed plates are the basis of the work, stamped with separate punches or hammered into dies, and finished singly or joined back to back around a plsster core. Granulation was brought to an amazing fineness, particularly in Etruria. Patterns were precisely drawn in a field of minute grains, which were fused into globules and soldered to their background in one operation. In Greek 5th century work granulation is displaced by filigree, and enamel reappears. The style of this and the next century aims at elegance and delicacy. Necklaces consist of pendent flowers and tassels in a trellis of finely plaited ropes; flower-petals are variegated with enamel. Hoops of earrings are masked with filigreed rosettes and discs, and support elaborate pendants. Victories, Cupids and doves were favoured here by Hellenistic sentiment, and a strange but quite popular Graeco-Roman type was made with pendent vases. A change of fashion at this time, doubtless under oriental influence, introduced large coloured stones, at first garnets, in the centres of designs, and the new decorative principle became dominant in Roman jewellery. The stones are cut in simple shapes and grouped in rows by colour, blue, red, green, sapphire, garnet, plasma, with pearl borders. They are usually plain, but sometimes engraved as cameos or intaglios. In the closing period, from the 3rd century A.D., gold coins of contemporary and earlier emperors were also set like gems, and the goldsmith's skill was mainly exercised upon the borders and backgrounds. These bear arcaded patterns in chased relief and open-work, a bold and heavy style which, with colour-decoration, ousted the classical figure-work, and gave its character to the jewellery of mediaeval Europe.

EUROPEAN

During the first six centuries there existed two principal sources of production of early Christian silver vessels: the Hellenistic and the Persian. The designs consisted often of figure compositions. Antioch was an important centre for goldsmiths' work after the 4th century, and here was made, in the 4th or 5th century, the "Antioch" chalice, now privately owned in New York City. From the 10th century, church vessels, especially chalices, became more sumptuous and were occasionally enriched with enamel and gems. Among extant early silver is the Esquiline treasure, Hellenistic in character, and the Lampsacus treasure, both in the British Museum; and the sacred treasure of Luxor, 5th to 6th centuries, now at Cairo. In the Metropolitan Museum at New York is the 6th century treasure from Cyprus, probably part of the same "find" as the objects at Nicosia and in the British Museum.

Byzantine silver of the 6th century is often marked with stamps in the manner of modern plate. St. Mark's in Venice contains many precious examples of Byzantine goldsmiths' work, including the famous *pala* d'oro, fashioned in Constantinople in 976, and enlarged and modified later by Venetian and other goldsmiths. The monasteries of Mt. Athos are rich in early vessels.

Early goldsmiths' work of a sacred character comprises the 6th century gold cross of Justin II. and Sophia, in Sf. Peter's, Rome; three great altar-frontals; (a) that executed before 835 in S. Ambrogio, Milan; (b) that in Aix-la-Chapelle cathedral; (c, 1000); and (c) that in the Cluny museum, Paris. To these may be added the Codex *Aureus,* and the ciborium of the Emperor Arnoulf, both at Munich. Early figures of the Virgin are two of the 11th century (with later additions) in Essen cathedral and another by a goldsmith of Hildesheim. The celebrated treatise of c. 1100 by the monk Theophilus, of Essen, is of extraordinary interest in the history of metal working.

A highly-skilled school of metal workers and enamellers was established in the 12th and early 13th centuries on the Meuse, chief of whom was Nicholas of Verdun. By his pupil or follower, Hugo d'Oignies, are three authenticated works, including his masterpiece, the shrine of St. Eleutherius (1247) in Tournai cathedral (see *Burlington Magazine,* xxxv.; xxxix.). By Siegfroid, pupil of Nicholas of Verdun, is a superb chalice of c. 1230, in Borgå church, Finland. Of the same school was Godefroid de Claire, goldsmith and enameller, of Huy.

English ecclesiastical work suffered incredible destruction at the Reformation. Of the few English silver chalices one of the earliest is that of the 13th century in the British Museum. Patens are more common. Important works are William of Wykeham's crozier at Oxford, and a censer and incense boat of c. 1350 in the Victoria and Albert Museum.

The early examples of ecclesiastical work in France include the Gourdon gold chalice and paten of the 7th century; a 9th century casket and a 10th century statuette of St. Foy, at Conques; the cross of Laon, in the Louvre (c. 1200); an early 13th century ciborium in Sens cathedral; a cross of the same century in Amiens cathedral; the Virgin of the abbey of Roncevaux, 14th century; and the Virgin in the Louvre (1339).

The churches of Italy abound in sacred vessels, especially from the 14th century, the early works including the 12th century altar-frontal at Città di Castello; and the chalice of 1290 by Duccio of Siena. Famous among reliquaries is the bust of St. Agatha at Catania, by Giovanni Bartolo, of Siena (1376). But more celebrated is the great reliquary of Orvieto, containing the blood-stained corporal of the Bolsena miracle, by Ugolino da Siena (c. 1338). Crosses include that of S. Giovanni, Florence, 1459, important for its influence upon others. Two great altar-frontals are in the cathedral of Pistoia and in S. Giovanni at Florence. Upon the latter were employed several famous artists—Antonio Pollaiuolo, Michelozzo, Verrocchio and others. The Abruzzi's greatest goldsmith, Nicola da Guardiagreli, designed the altar-frontal of Teramo (1433–48). An example of the combination of niello, enamel and silver, is the celebrated pax by Maso Finiguerra at Florence (1452). The most celebrated work of Valerio Belli (1468–1546), carver of crystal and medallist, is the crystal casket of 1532 in the Pitti palace, Florence. Caradosso, famous as a goldsmith and medallist, was the maker of a gem-set golden tiara for Julius II., known from an old coloured drawing in the British Museum, with a drawing of the gold morse executed by Cellini for Clement VII.

The early goldsmiths' work of Spain was of considerable importance. The Cross of the Angels, made in Asturias in the time of Alfonso II., and the Cross of Victory (908), both at Oviedo, are well-known. Chalices and other sacred vessels of unsurpassed richness were made in the Gothic and Renaissance periods. Under the sway of three members of the Arfe family in the 16th century several cathedrals were enriched with costly custodias (monstrances), great tower-like structures peculiar to Spain.

Early chalices were of two types with or without two handles; both lasted until the 13th century, when the two-handled form would seem to have been no longer made. The goldsmiths of the Merovingian period (420–751) were highly skilled and produced great quantities of jewellery and plate. The Carolingian period (768–814) brought a new style into the West. It used figure subjects in relief and foliated ornament, adopted from the Christian East through Italy.

Spoons are among the earliest things in silver. The Romans and Anglo-Saxons had their spoons. The earliest extant English spoon is probably the celebrated anointing spoon of the late 12th or early 13th century, which was, however, re-fashioned in 1660. Early English spoons include the "Apostle" spoon, popular for 200 years from about 1450. Original sets of 13 are extremely rare, the first being dated 1536–37, and was acquired by the late J. Pierpont Morgan. Next in popularity was the seal-top spoon, made between *c.* 1510 and 1670. From about 1670 spoons in England became more common, and the patterns were copied by American silversmiths. Continental spoons are usually more ornate and are of many patterns from the 17th century. A typical German object in silver (and occasionally of gold) is a spoon, fork and toothpick combined, of the 16th and 17th centuries.

Forks of silver are rare until the 18th century. The earliest known English fork is dated 1632–33.

English Work.—In the early centuries, after the invasion of Britain, Anglo-Saxon ornamentation passed through three stages, in the use first of spiral decoration, secondly of animal ornament, and thirdly of animal ornament combined with the conventional interlacing patterns of Anglo-Saxon and Irish art, introduced in the 6th century, probably from the eastern Mediterranean. The art of the Kentish goldsmiths was particularly skilled, especially in the reign of Ethelbert (560–616). Notable examples are the famous Alfred jewel and the silver-gilt cup from Halton moor (British Museum). The beautiful Ormside bowl of copper and silver, 8th century, is also said to be Anglo-Saxon (York Museum).

Celtic craftsmen possessed an aptitude for borrowing ideas and implanting their own individuality upon them. Evidence of their skill in metal working is to be seen in their personal ornaments. The Celtic goldsmiths of Ireland in Christian times borrowed designs from the Anglo-Saxon craftsmen of Kent, but soon surpassed their Kentish masters in technical accomplishment, as may be observed in two masterpieces; the Ardagh chalice and the Tara brooch (9th and 10th centuries).

Not a vestige remains of the silver made in England during the Norman occupation. There is ample evidence of the superior merits of the English arts and crafts in mediaeval and Tudor times. The most common of English drinking vessels from *c.* 1200 to the 16th century was the mazer bowl. Two historic examples of drinking horns of the 14th century are at Oxford and Cambridge. Two unique English vessels are the Studley bowl, late 14th century, in the Victoria and Albert Museum, and the enamelled silver cup (1350–75) of the corporation of King's Lynn. England is still rich in cups, tankards and drinking vessels from the 16th century. Great standing salts were regarded with veneration, particularly in the reign of Elizabeth, when the decoration of plate was markedly under German influence. In the 16th century came the sumptuous rosewater ewers and basins.

The restoration of .Charles II. in 1660 was followed by the introduction of larger and more costly vessels and by ornate decoration. Soon after 1685 the French Huguenot refugees who fled to England after the revocation of the Edict of Nantes revolutionized the decoration of English plate. Much of the early 18th century English silver is distinguished for its austere simplicity and solidity. Louis XIV. ornament was also popular, and the influence of the French rococo was strong. In the comfortable 18th century many kinds of domestic vessels were introduced or became common. The influence of Robert Adam, architect and designer, is apparent in silver between 1770 and 1790, while a little later the classical spirit was conspicuous in the silver designed by John Flaxman, the sculptor, and others. Plate of English style was made at Dublin from the 17th century, and Scottish goldsmiths wrought excellent plate from the 16th century. Silver was made in the Channel Islands in the 17th century and probably earlier.

A gild of London goldsmiths existed as early as 1180, and in 1327 it was regularly incorporated. The mark of the leopard's head (lion's face) is first mentioned in 1300, followed in 1363 by the maker's mark. In 1478 and 1544 the date-letter and lion passant respectively were introduced. Between 1697 and 1719, the figure of Britannia and the lion's head erased were in use. From 1784 the sovereign's head was marked; it was discontinued in 1890. Silver was assayed in mediaeval and later times at Norwich, York, Chester, Newcastle and Exeter. The present assay offices are London, Chester, Birmingham and Sheffield.

France.—The development of the craft in France may be followed in some measure after the death of Louis XIV., though vast quantities of silver work were melted at the Revolution. Little remains of the work of Thomas Germain, a talented 18th century goldsmith, but several notable pieces by his son, François Thomas Germain, notably at Lisbon, have survived. For the more important of these the student must, however, repair to the old imperial and royal collections at Leningrad and Lisbon, which are unequalled in France itself.

The former contains notable objects by masters of the 18th century, by Claude Ballin the younger; François Thomas Germain; Paul Charvel and Louis Lenhendrick; Robert Joseph Auguste, a prolific goldsmith; Antoine Boullier; Edmé Pierre Balzac; and Claude Augustus Aubry. Two celebrated goldsmiths of the First Empire, Biennais and Odiot, are represented by notable specimens. Henri Auguste, a talented Paris goldsmith, fled to Jamaica and died there in 1816.

The écuelle is peculiar to France and became a common vessel in the 18th century. One delightful phase of French goldsmiths' work must be mentioned, namely, the exquisite gold and enamelled boxes of the 18th century.

One of the few surviving examples of early secular plate is the gold and enamelled cup (1380) of the kings of France, in the British museum, which is decorated with scenes from the life of St. Agnes, and is unparalleled elsewhere. The cup has undergone subsequent alterations in England and Spain.

One other important early French vessel is the covered beaker, made about the year 1462, now at Oriel college, Oxford. Of the few pieces of secular plate of the 16th century are the massive plain ewers with their dishes, the pair of cups and a wine bottle, all dating from 1581–82, from the chapel of the order of St. Esprit, and now in the Louvre. Here also are the unique and magnificent enamelled gold shield and morion of Charles IX of France (1560–74). The beautiful sardonyx and gold ewer in the old Imperial collection at Vienna, sent as a gift with Cellini's golden salt, from Charles IX to Ferdinand of Tirol, is believed to have been executed in Paris, as was the gold mounted sardonyx cup showing similar details, in the Louvre.

Italy.—Italy has great wealth in ecclesiastical goldsmiths' work but in secular silver it is singularly poor, many precious objects having been converted into bullion. One authentic work by Benvenuto Cellini alone can be mentioned: the celebrated gold salt at Vienna. French designs, especially Louis XVI styles, penetrated here as elsewhere, as in the "Turin" service at Leningrad and in the work of L. Valadini, of Rome.

Germany.—Domestic silver in Germany earlier than the second half of the 15th century is rare. In the prosperous cities of Augsburg and Nuernberg in the 16th century, the output of silver work was enormous. German Renaissance work is marked by exuberance of ornamental detail; much of it has been attributed to Italian goldsmiths, especially Benvenuto Cellini. One of the most precious German things of the period, attributed to Cellini, is the gold and enamelled Rospiglioso cup in the Altman collection in the Metropolitan museum, New York. The six members of the Jamnitzer family were prominent at Nuernberg between about 1535 and 1625.

English ornament of the Elizabethan and Jacobean periods was markedly influenced by German work. Every collection of German plate contains a preponderance of drinking vessels. A few cups of about 1590–1620 were made as "masterpieces," before admission to the gilds. Certain exclusively German cups are the giant cup (Riesenpokal), the double cups, the *Jungfrauenbecher* and the little ships. Other popular cups are those decorated with a large boss or lobe (buckeln), and the pineapple cup (*ananaspokal*), which was copied in London, in the reign of James I. The common gourd-shaped cup was also introduced into England. Certain fantastic cups were fashioned like birds and animals, figures and globes. Many are fitted with clockwork mechanism for propulsion along the table. Tankards were common from the 16th to the 18th century. The Baroque taste was strong, as was the rococo. Designs were executed for silversmiths by Albrecht Altdorfer (c. 1480–1538); Peter Flötner, whose *Kunstbuch* was published in 1549; Virgil Solis (1514–62); Hans Brosamer (fl. 1520–54); Bernard Zan ($. 1580–81); Hans Sibmacher (fl. 1555–95); Georg Wechter; and Paul Flindt; and the anonymous designers of the late 16th century.

Spain.—The early silversmiths' work of Spain shows many outside influences. In the second half of the 15th century artists came from Lombardy and South Germany and introduced new features in decoration. Spain is now singularly poor in early domestic silver. Some ornate shallow dishes were common in Spain and Portugal in the 16th century. For about 50 years from 1590, a small and characteristic ewer was made, mostly at Toledo. A common decoration of silver of the early 17th century are little enamelled plaques. Filigree work was popular in the 17th century. The Baroque taste prevailed in Spain and Portugal, as did the later French decoration. A notable atelier was founded in Madrid in 1778 by D. Antonio Martinez, who favoured severe classical designs.

Portugal.—In the reign of Emanuel I. (1495–1521) Portuguese work was infected by the national style in architecture, called Arte *Manuelina.* Of this style is the celebrated early 16th century gold and enamelled monstrance of Belem (in the National Museum at Lisbon), by the Lisbon goldsmith, Gil Vicente, from a design by Garcia de Rezende. Some 16th century silver and some 17th century basins are very elaborate. The influence of French decoration of the 18th century, superimposed on the national taste in decoration, is marked. English silver was copied by Portuguese silversmiths after the Methuen treaty of 1703 and in the early 19th century imitations of London marks were not infrequently stamped.

Holland.—Holland in the 17th century was rich in domestic silver. Many of the old gilds were provided with silver, some of which is in the Rijks Museum at Amsterdam. Adam van Vianen (c. 1555–1627) of Utrecht introduced a new decoration in silver which profoundly affected Dutch silversmiths' work for 50 years and spread to England and Germany. His brother, Paul, entered the service of the emperor Rudolph II. at Prague and there executed the superb ewer of jasper and gold, now at Vienna. Adam van Vianen, the younger, is chiefly known for his designs for silver (published 1892). Christian van Vianen visited England and made plate for Charles I. Next to the van Vianen family, the most prominent goldsmith of the 17th century was Johannes Lutma, the elder, of Amsterdam, a few of whose works are in the Rijks Museum.

Typical objects in silver are the wine-glass holder (bekersclzroef), the windmill cup (molenbeker) and the *brandewijnkom,* for brandy and raisins. "Still-life" pictures of the 17th century are interesting for the silver vessels they depict. Important silver was made in most of the other old towns of Holland in the 17th and 18th centuries. French taste of the 18th century in silver and furniture spread to Holland.

Scandinavia.—Denmark and Norway are noted for the great number of silver-mounted drinking horns of the 14th and 15th centuries. Distinctive beakers and tankards were common from the 16th century. The "peg" tankard of Denmark was made by English silversmiths, mostly at York, between about 1650 and 1690 The influence of French of the 18th century and the First Empire ornament on Danish and Norwegian domestic silver is manifest, as is also in a less degree that of English designs of the 18th century.

Domestic silver was extensively wrought in Sweden in the 17th century, much of it in the German taste. The beaker and the tankard were popular. Characteristic of Swedish silversmiths is the filigree work of about 1675–1725. In Sweden as in Norway, a charming old custom is commemorated by the silver bridal crowns, preserved in churches. French decoration prevailed here as elsewhere.

The Netherlands.—Flemish pictures and illuminated manuscripts afford a glimpse of the sumptuous vessels in daily use in Flanders, including the popular beaker. The only known work by Gerard Loyet is the famous gold reliquary (1466–67), in Liége cathedral. At Antwerp, the most important centre of the goldsmiths' art in Belgium in the 16th century, was made in 1558–59 the historic "Charles V." ewer and basin (in the Louvre). Excellent plate was executed in the French style in Belgium in the 18th century.

Russia.—As early as the 14th century, Russian workers under Greek influence began to cover the figures of icons with a plate (*riza*) of silver. The most conspicuous Russian silver domestic vessel in the 16th and 17th centuries is the drinking cup (bratina). Many are enriched with inscriptions in highly decorative Slavonic lettering called *Vyaz,* conveying a toast or sentiment or welcome. One of the most precious (at Vienna) is of solid gold, enriched with gems and enamel, and was the gift of the tsar Michael to Vladislaus IV. (1632–48), king of Poland. Another popular vessel from the 16th to the 18th centuries was the kovsh, used for dispensing drinks. One of gold is in the "Green Vaults" at Dresden. The third characteristic Russian vessel is the charka, a small cup, generally fitted with a single handle, for drinking strong liquors or for brandy. Many are wholly of precious metal, while others are of rock crystal, ivory, coral, and amber, cornelian and other semi-precious stones, mounted in gold and richly enamelled. One other vessel is the bowl of the 17th century, decorated with painted enamel.

Hungary.—Hungarian silver has certain individual features, and shows various external influences at different periods. A conspicuous feature of ecclesiastical work, especially on chalices, is the richly coloured enamel of the second half of the 16th century and the first half of the next century, introduced probably by Venetian goldsmiths. A prosperous school of goldsmiths was established at the Transylvanian town of Nagyszeben. An important phase of Hungarian goldsmiths' work are the garnitures de corsages for the national costumes from the 16th century. Highly important early mediaeval treasure has been found buried in Hungary of which the most important are the 23 gold objects from Nagy-Szent-Miklos, all in the Kunsthistorisches Museum, Vienna. Some authorities ascribe them to native craftsmen and others to Caucasian work of the 9th century.

Austria.—Several towns in Austria had their goldsmiths. Vienna claims Wenzel Jamnitzer (later of Nuremberg) as one of its most celebrated goldsmiths. An earlier worker was Wolfgang Zulinger, of Wiener Neustadt, the supposed maker of the "Matthias Corvinus" cup of the 15th century, in the Rathaus there. This great cup is covered with the familiar lobes or bosses of German cups. Erhard Efferdinger of Vienna is identified by his imposing Gothic monstrance, 1524, in the church at Schattau in Moravia. Later came the well known Marx Kornblum (d. 1591).

In the 18th century the goldsmiths flourished in Vienna and were markedly under French influence. Anton Matthias Domanek (1713–79) was prominent and was the maker of the gold toilet service for Maria Theresa, at Vienna. Another was Ignaz Joseph Wiirth, a member of a flourishing family. An exponent of the Louis XVI. and "First Empire" styles was Ignaz Krautauer.

Poland.—Ecclesiastical vessels are the oldest relics of the goldsmiths' art in Poland. The many-sided artist, Wit Stoss (Stwosz), of Cracow, provided designs for goldsmiths at the end of the 15th century, among whom was his brother, Maciej (Matthew). Several Italian craftsmen emigrated to Poland during the early Renaissance, including Gian Jacopo Caraglio, designer, engraver, goldsmith, enameller and gem-cutter to the Polish court, 1539–60. German goldsmiths were also employed at this time. Later in the century several French goldsmiths were attracted thither. Characteristic of Poland from mediaeval times are the silver belts to be seen in early Polish portraits and the elaborate silver harness for horses.

Other European Work.—Bohemian goldsmiths were much employed in the 15th and 16th centuries in the execution of ecclesiastical vessels. Rudolph II. (1552–1612) attracted talented goldsmiths to his court at Prague, among them the Dutchman, Paul van Vianen.

Prague was a centre for the fashioning of domestic vessels of great beauty from rock crystal, jasper, lapis-lazuli and other

EARLY AND RECENT EXAMPLES OF SILVERSMITHS' AND GOLDSMITHS' HANDIWORK

1. Bimaran gold reliquary set with rubies (100 B.C.–A.D. 100)
2. Chinese silver tazza-shaped cups ornamented with floral scrolls and birds on granulated ground (8th–9th cent.)
3. Persian gold armlet (5th–4th cent. B.C.)
4. Aztec gold ornaments (about A.D. 1500)
5. Peruvian gold objects (about A.D. 1500)
6. Greek silver dish (6th cent. A.D.)
7. Sassanian silver dish with Persian bird and dragon design (3rd–6th cent.)
8. Gold fan, in the Temple of the Tooth Relic, Kandy, Ceylon, probably 18th cent.
9. Nineteenth century Punjab silver jug.
10. Eighteenth century gold tray, in the Temple of the Tooth Relic, Kandy, Ceylon
11. Eighteenth century Indian silver enamelled hookah base

ETRUSCAN, GREEK, HELLENISTIC AND ROMAN ORNAMENTS DATING FROM 6TH CENTURY B.C. TO A.D. 400

Greek buckle, in upper left, and beneath it an earring of gold decorated with enamel and stones of about 400 B.C.

In upper centre an Etruscan silver and gold relief with electrum plating, from Perugia. Said to be Ionic work of the 6th century B.C.

Beneath third jewel in the necklace, a Hellenistic earring of about 200 B.C. In lower centre is the front panel of the lid of Projecta's bridal casket; early Christian All other objects are Roman—necklace, earrings, beads and pendants, A.D. 100 to 400

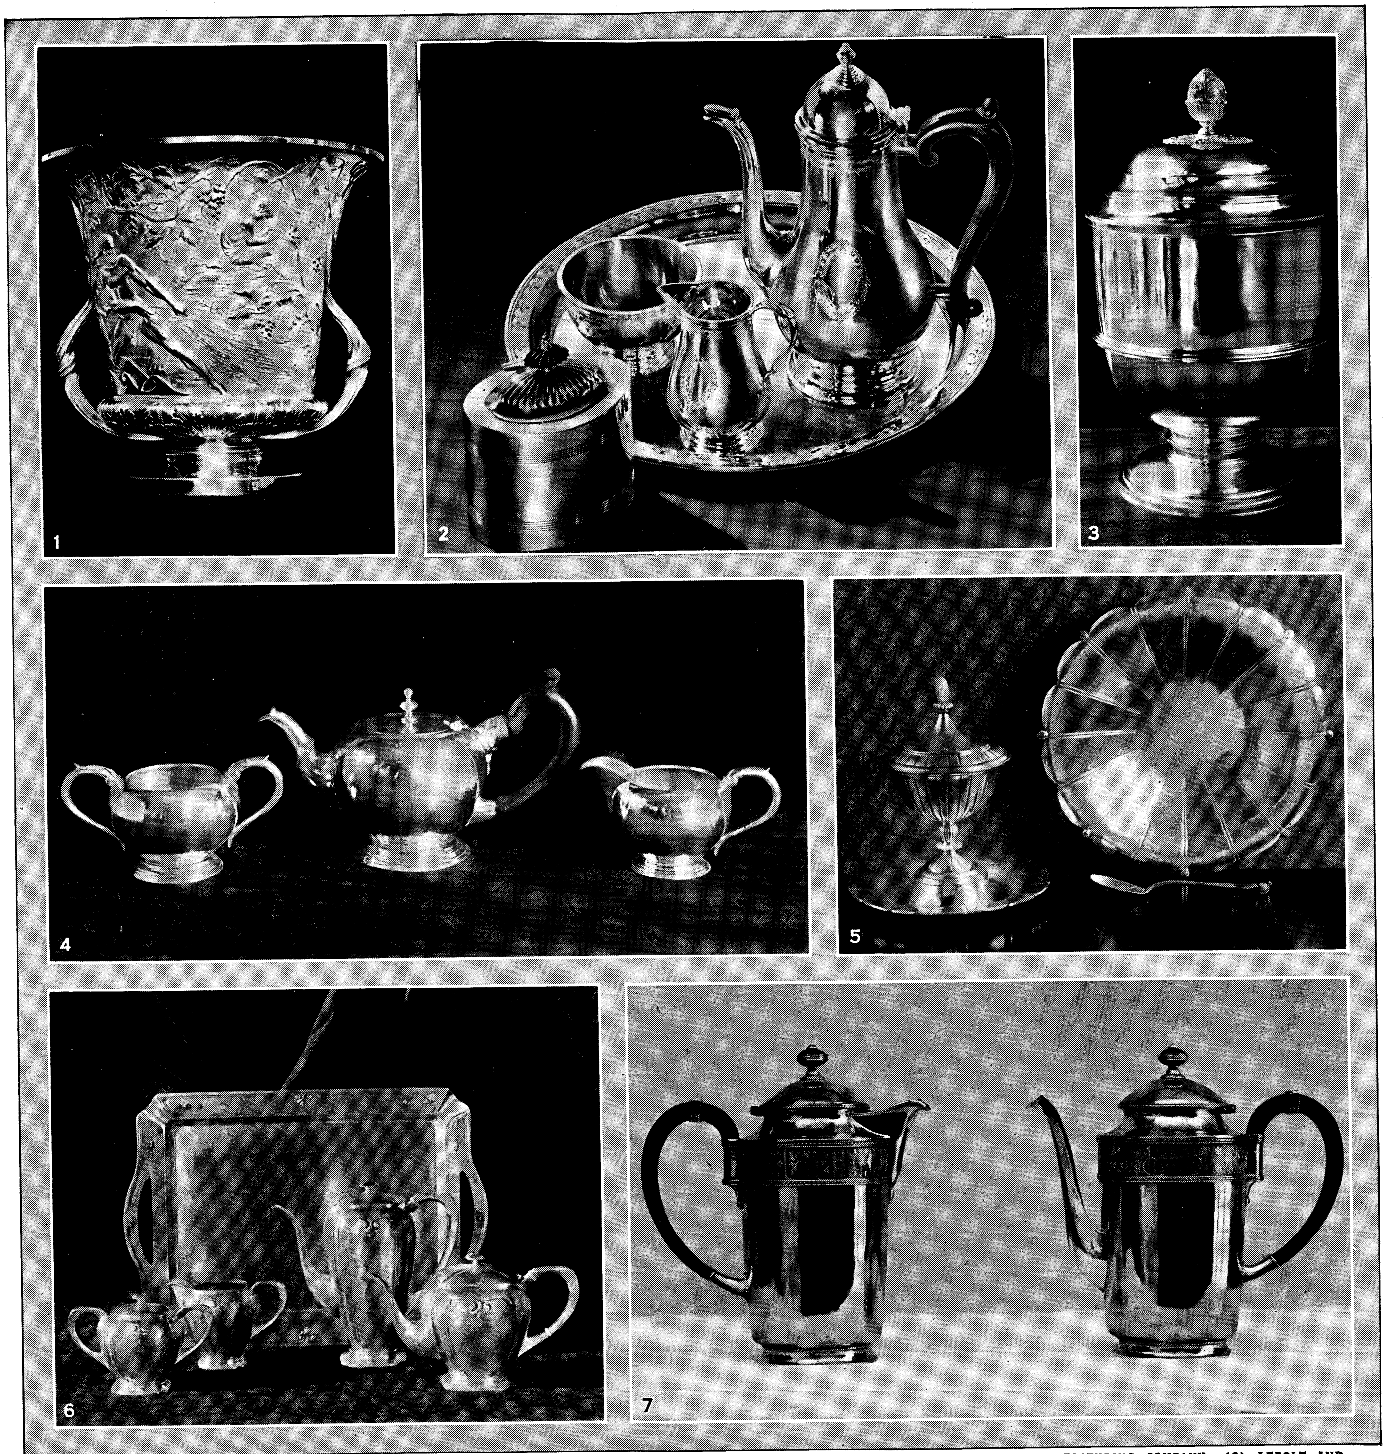
MEDIAEVAL SILVER AND GOLDSMITH'S WORK

1. Foundress' Cup. Silver gilt, dated 1440. Stem, bowl and cover ornamented with branches. 2. Bowes Cup, dated 1554. Note two different methods of employing crystal — in the bowl and stem. Enamel used in the coat of arms. Shows influence of South German craftsmen. 3. Jasper and gold ewer made for Emperor Rudolph II., by Paul van Vianen, a Dutch goldsmith, in 1608. 4. An English salt cellar dated 1592–3. Cover is raised above the receptacle for salt. Elaborately chased and enamelled. 5. A steeple cup of silver gilt, dated 1627–8. This type of cup believed to be an original conception of English craftsmen. 6. Silver gilt ewer with elaborate design, Antwerp, 1558–9. In the Louvre. 7. English cup, made 1350–75. Decorated with enamel figures. Believed to be one of the earliest of its type now in existence. 8. A Dutch silver ewer. Made in 1610 by Adam van Vianen. 9. Silver cup by Sanderson and Hull of Boston, Massachusetts. Bought in 1674 with legacy of Capt. Thomas Willett. Inscribed "Capt. Willett's donation to ye Ch. of Rehoboth, 1674." 10. "Banquet of the Gods," gold on lapis-lazuli slab, 16th century. Jacob Cornelisz Cobaert. 11. Silver spoon with figure of a bishop on the handle. Believed to be work of a German craftsman of the 17th or 18th century

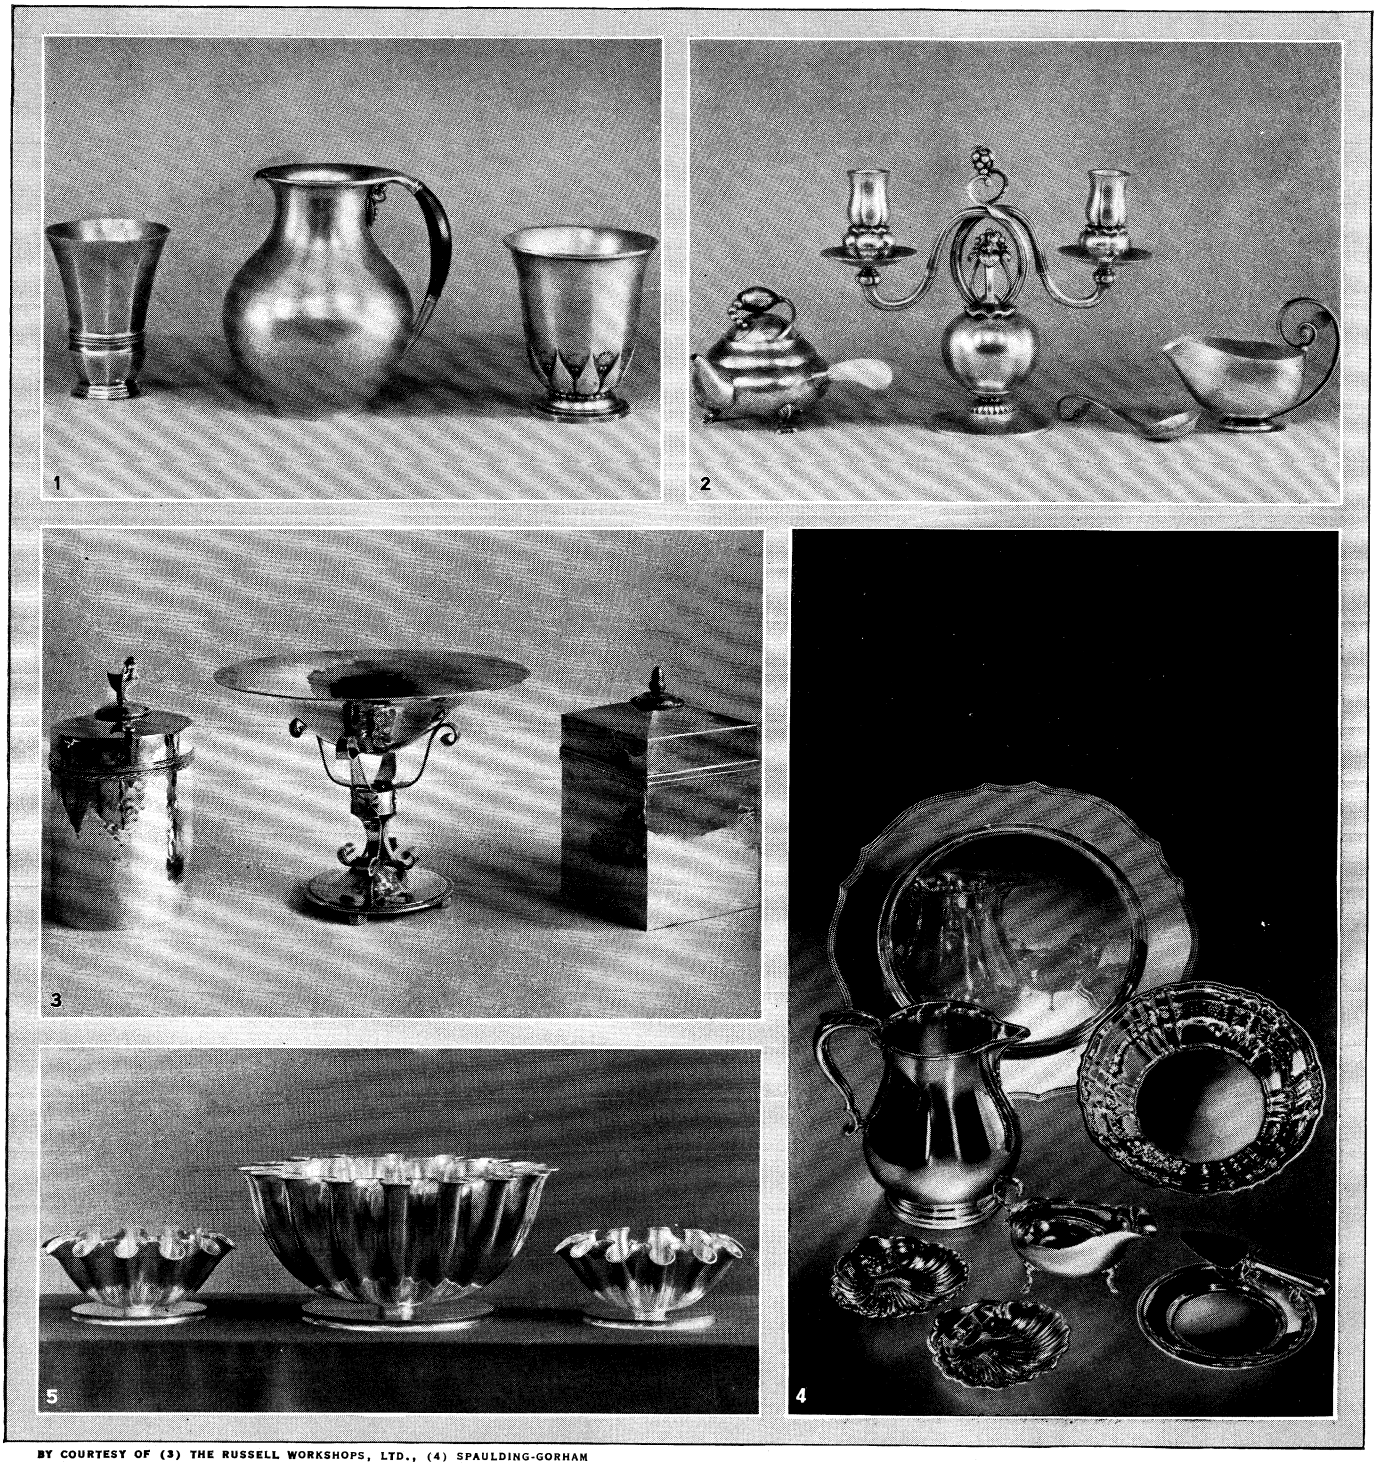
SILVERSMITHS' AND GOLDSMITHS' WORK



BY COURTESY OF (1) HIS MAJESTY KING GEORGE THE FIFTH, (2) SPAULDING-GORHAM, (3, 4) GEORGE C. GEBELEIN, (5) THE GORHAM MANUFACTURING COMPANY, (6) LEBOLT AND COMPANY, (7) BERNARD CUZNER

EXAMPLES OF SILVERSMITHS' WORK

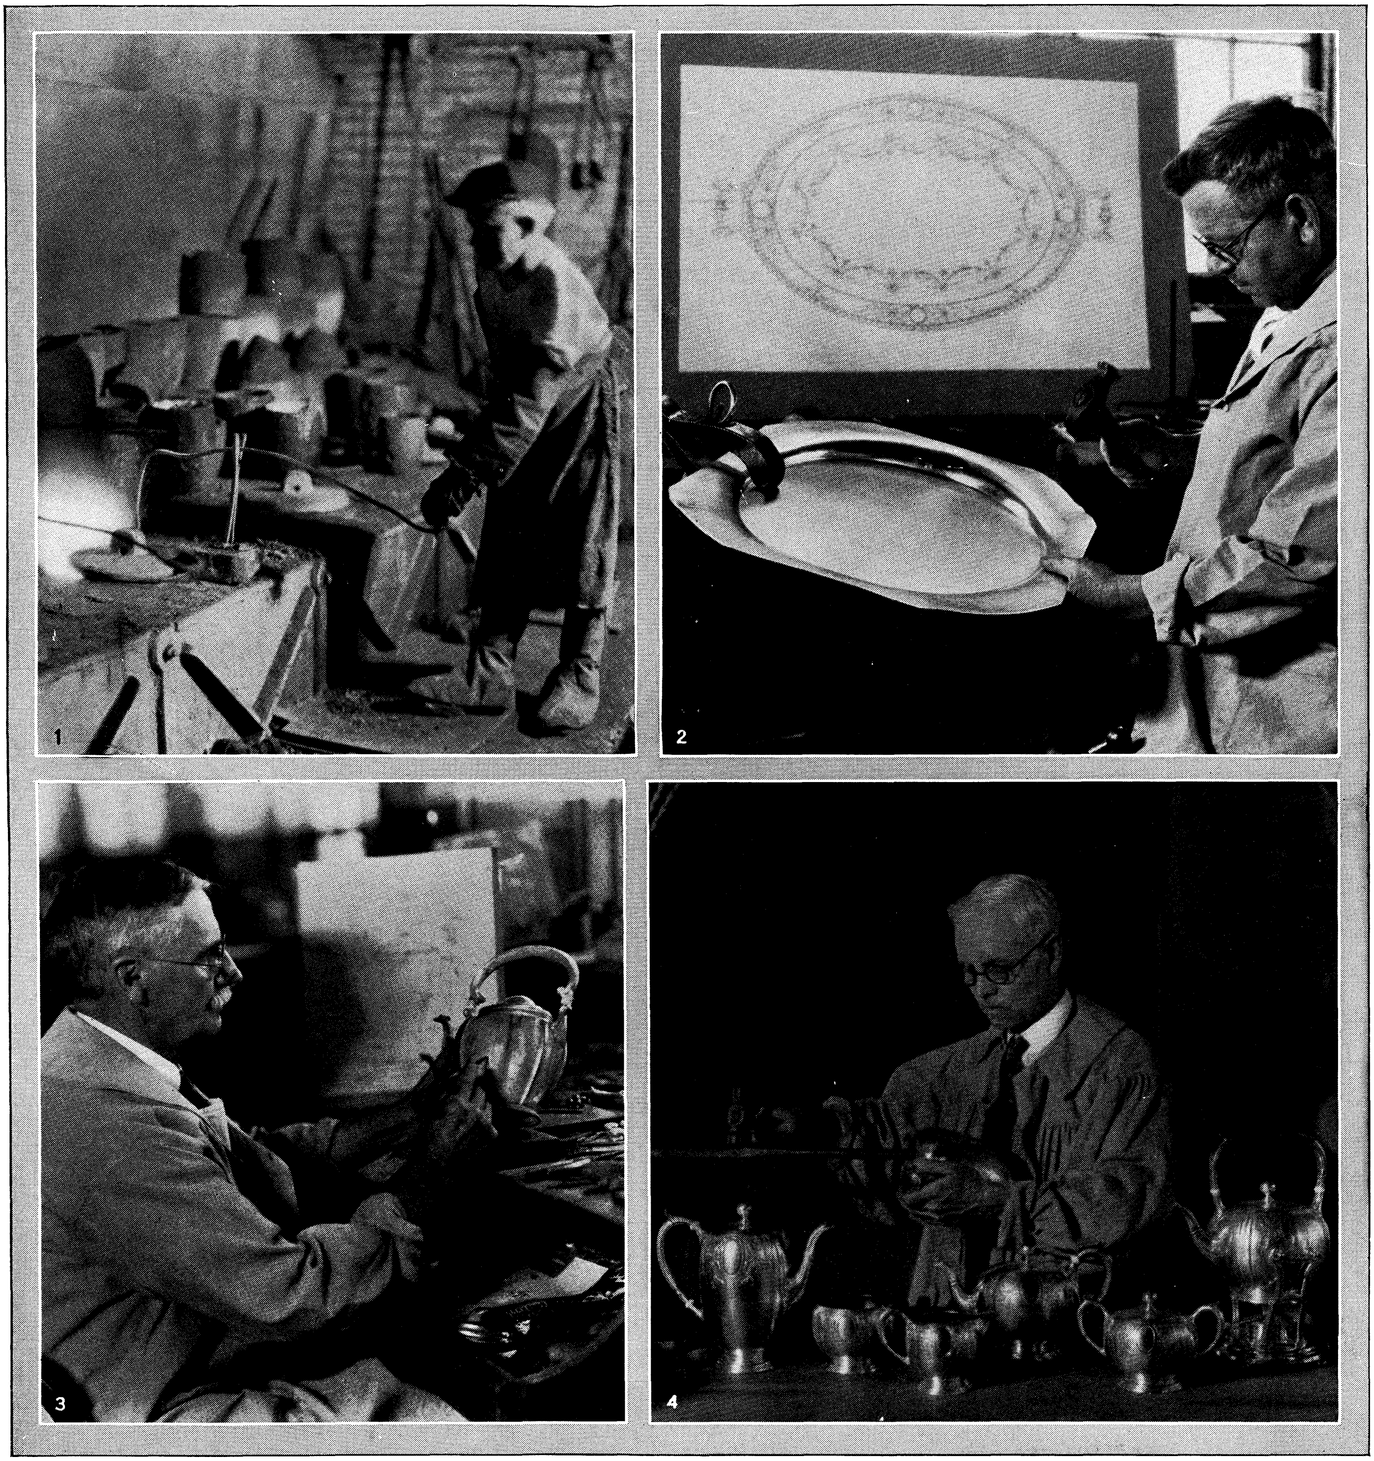
1. Silver-gilt cup designed by John Flaxman, 1812, and made by Paul Storr
2. Antique reproduction of a George I after-dinner coffee service and tea caddie used as cigarette jar
3. Sterling silver Guild cup, English and continental adaption
4. Reproduction in sterling silver of an early American teapot, sugar bowl and cream pitcher
5. Silver service of modern design ornamented with ivory or lapis-lazuli balls
6. Hand chased tea service
7. Hot water jug and coffee pot of silver with chased decorations and fibre handles and knobs



BY COURTESY OF (3) THE RUSSELL WORKSHOPS, LTD., (4) SPAULDING-GORHAM

MODERN DESIGNS IN SILVER AND OTHER METALS

1. A pitcher and two cups by Georg Jensen
2. Teapot, candelabrum, ladle and jar, the work of Georg Jensen
3. Left: Brass biscuit box with silver-plated interior. Right: Biscuit box in gilding metal, with silver-plated interior. Centre: Copper fruit dish. Group designed and made by Gordon Russell, Broadway, Worcestershire
4. Modern American sterling silverware inspired by creations of 18th century silversmiths
5. Silver bonbonnières made by A. Michelsen (Danish)



BY COURTESY OF THE GORHAM MANUFACTURING COMPANY

PROCESSES IN WORKING SILVER AND GOLD

1. Heating and alloying the silver in an American plant. The silver is placed in a crucible, mixed with other metals in the proper proportions, and melted in the furnace

2. Shaping a sheet of sterling silver. The design to be worked into the silver tray is seen on the wall in the background

3. Skilled worker in silverware plant drawing the design on a teapot preparatory to working

3. Silver chaser using the snarling iron. A snarling iron has a long beak and is used in making raised work on silverware. The worker is holding one end of the snarling iron in a vise and striking the shank with a hammer. It makes its impression on the rebound from the inside

PLATE VIII

SILVERSMITHS' AND GOLDSMITHS' WORK

BY COURTESY OF THE GORHAM MANUFACTURING COMPANY

DIFFERENT PROCESSES OF SILVER WORK

1. Skilled workman engraving with a gravec elaborate design on a silver tray. 2. Soldering the top on a silver candlestick. 3. Erik Magnussen, noted European designer, hand-chasing a sterling silver vase. A new and modern motif is expressed in his work. 4. Stamping the Hall Mark on a finished piece of silverware. The Hall Mark is used to identify the maker of the piece and the date, and to attest to the purity of the silver

semi-precious stones.

Swiss silver in form and decoration not unexpectedly was under the domination mainly of Germany. Zürich was an important centre of the goldsmiths' art. It was here that Rudolph Wyssenbach issued in 1549 his very rare pattern-book of arabesques for silversmiths. Many other Swiss towns had flourishing goldsmiths.

Silver is known to have been wrought for several centuries at Reval and Riga. Hans Ryssenberch, the elder, of Reval, was the maker of an important monstrance in 1474, now in the Hermitage museum at Leningrad. Here also was probably mounted (1551) the rare horn-shaped cup of Islamic glass, perhaps of the 14th century, also in the Hermitage. In Finland there were goldsmiths from mediaeval times.

In the monastery at Putna in Bukovina, founded shortly after 1465, are important treasures of the 15th and 16th centuries, which reveal a glimpse of art and culture in the Balkans. The Petrossa treasure of gold (found near Petrossa in Wallachia) probably made in the Balkans in the 4th or 5th century A.D., consisted originally of 22 vessels, including an elegant ewer.

NORTH AND SOUTH AMERICA

The history of silver in America begins actually with Robert Sanderson (1608–93), a London silversmith settled in Boston. John Hull (1624–83) became his partner. An example of their work is the plain cup in Newman Congregational church East Providence, R.I., bought with the bequest in 1674 of Capt. Thomas Willett the first mayor of New York city. More than 150 names of silversmiths had been recorded at Boston before 1800. Colonial silver is dependent for its undoubted charm on the simplicity of its lines and graceful forms, copied for the most part in New England from contemporary English silver before 1775. Paul Revere of Boston achieved prominence for his work not because of superior technical merit but as the hero of Longfellow's poem. From the end of the 17th century the wealthy merchants of Boston acquired silver, especially tankards and porringers. The last-named vessel, not to be confused with the English vessel of this name, became common in silver and pewter in every well-ordered household. Besides Boston, there were other places in New England where silver was made, chief among them being Newport, R.I. Silversmiths settled in New York soon after the settlement by the Dutch, and much of their work is identifiable by the decoration. Important work was made at Philadelphia late in the 17th and early in the 18th centuries.

Silversmiths were working in Quebec in Canada soon after the French conquest. In the 18th century excellent work was executed by François Ranvoyze (b. 1739) and later by Laurent Amyot.

The high skill of the metal-workers of old Mexico is well known. In the American Museum of Natural History at New York (Heye Foundation) is a precious collection of gold ornaments, including a wonderful eagle's head (*quauhtli*), conferred upon certain warriors for valour in warfare. Highly skilled also were the craftsmen of Peru. The natives had little to learn from the Spanish craftsmen but new models and patterns. Silver plates and dishes for the tables of Spanish officials were hammered out by the hundred and many delightful pieces still survive in Peru and Bolivia. Stirrups, spurs and horse trappings are also common. Silver was more accessible than tin or iron to the South Americans and since alloys were not understood, it was used in pure form. One common object found in various parts of ancient America, notably Mexico, Costa Rica, Panama, Colombia, Ecuador and Peru, is the golden breast-plate in the form of a disc. The Keith collection in New York of gold work from Costa Rica and Panama is unsurpassed, and contains many beautiful amulets.

Soon after the Spanish conquest, goldsmiths from Spain emigrated to Mexico, though most of their early works have perished. Churches were richly furnished with sacred vessels, but many of these were imported from Spain. Several names of goldsmiths of the 16th, 17th and 18th centuries are recorded.

ORIENTAL WORK

The goldsmiths of the famous Achaemenid period in Persia were in an advanced state of culture, as witness the Oxus treasure of the 5th and 4th centuries B.C., in the British Museum, which with the Susa find (in the Louvre) alone presents a comprehensive group of goldsmiths' work of ancient Persia. In the same museum is some important silver of the later Sassanian dynasty. Persian silversmiths in more recent times have shown by many fine examples that they have retained their skill.

Ancient China was poor in gold. Of the T'ang dynasty (618–906), when the progress of the arts was most marked, but little goldsmiths' work has survived; it includes 15 silver vessels in the British Museum. In the great collection of Chinese art of George Eumorfopoulos are two pieces of exquisite gold jewellery: a hair-pin and an ornament, of about the 9th century A.D., and of the 9th to 11th century A.D. respectively. Two little silver cups are of the 8th or 9th century A.D. A rare little gold plate, chased with flowers and foliage, is of about the 12th century A.D.

Earlier than either of these are the superbly wrought gold pommel of a dagger or staffhead and the silver bowl chased with characteristic Chinese fret work, both of the Ch'in dynasty 255 to 207 B.C.

The goldsmith's craft in India is of ancient origin. Highly important is the Bīmarān gold reliquary, set with rubies (British Museum), attributed to the beginning of, or a little earlier than, the Christian era. In the British Museum are a silver dish of the 3rd or 4th century A.D., decorated with a bacchanalian scene representing perhaps Kuvera, king of the Yakshas, treated in Indian style; and a silver bowl of the 7th century from northern India, embellished with medallions in low relief. Delhi was famous for its craftsmen, especially in the time of Akbar the Great, Jahāngīr, and Shah Jehan. The Indian museum at South Kensington contains a rosewater sprinkler of chased gold, enriched with champlevé enamels, probably made for Shah Jehan. vessels and Ornaments of jade, inlaid with gold and gems, are a distinct and delicate branch of art, practised at Delhi in the 17th century. A graceful vase of this kind, set with emeralds and rubies, was brought from India by the great Lord Clive with other notable specimens of Indian goldsmiths' work.

A characteristic Indian ewer, with and without a cover, in silver, copper and brass, has been used from early times for the ceremonial ratification of gifts by pouring water, and for domestic purposes. Decorated trays of silver and brass are used for offerings and for conveying gifts, but more especially for flowers to be offered in temples, as may be seen in many of the old Sīgiri paintings.

Enamelling has deservedly attained a great reputation in northern India. Enamellers from Lahore were brought by Man Singh to Jaipur in the 16th century and enamel was extensively employed in the 17th and 18th centuries here and elsewhere in gold and silver work. The craftsmen of the Punjab were renowned for their skill and Lucknow was long celebrated for its metal work, as was Chanda. At Kutch and Gujarat (Bombay Presidency) were clever goldsmiths. The metal work of the Sinhalese is of special excellence. Siamese goldsmiths executed excellent work in the 18th and 19th centuries and Turkish craftsmen have not been without skill.

In consequence of the prohibition of the use of gold and silver in ceremonial worship, there are no vessels or ornaments in these precious metals in religious use in Burma, Similarly, the use of gold or silver vessels for domestic purposes was denied to all but those of royal blood. The India museum at South Kensington contains part of the Burmese regalia of gold, and other relics. Some fine work executed at Tibet in the 17th and 18th centuries is in the Indian museum at South Kensington.

(E. A. J.)

SILVER SPRINGS, one of the largest limestone springs in the world, is located in Marion county, Fla., 6 mi. E. of Ocala. The average flow of the springs is about 530,000,000 gal. per day and more than 480 tons of minerals are carried off in solution each 24 hours. The water maintains a constant temperature of 72" F. The source of the main spring is a cavern 65 ft. long and 12 ft. high. Most of the water discharged from the more than 100 springs in the group is from the abundant rainfall of north central Florida, which passes through the porous surface soil and sand of the region and enters the limestone lying immediately beneath. This filtration causes the extreme clearness of the spring water.

Silver springs is the source of Silver river, a 7-mi.-long navigable stream which eventually reaches the Atlantic ocean via the Oklawaha and St. Johns rivers.

There are more than 30 varieties of fish, as well as turtles and shellfish in Silver springs. Remains of mastodons, manatees and extinct elephants have also been found in the springs or in the Silver river.

Swimming facilities, glass-bottomed boat rides, cruises on the Silver river, religious exhibits, a zoo and a snake farm are provided for visitors. Thousands of tourists visit the springs each year. Because of the clarity of the water, Silver springs is a favourite location for motion-picture companies that wish to film underwater scenes.

The explorer Hernando de Soto was probably the first European to see Silver springs when he camped at Ocali, an Indian village near the springs, in 1539. The Indian name for Silver springs is *Sua-ille-oka,* which means "sun-glinting water." (J. E. Jo.)

SILVER TREE (*Leucadendron argenteum*), a South African tree, the leaves of which are covered with fine silky hairs, and are used for painting on. The tree has been nearly exterminated. There are about 70 species of the genus *Leucadendron* (family Proteaceae) all South African.

SILVESTER, or SYLVESTER, the name of three popes and an antipope.

SILVESTER I, pope from 314 to 335, succeeded Melchiades in Jan. 314. The story of his having baptized Constantine the Great is fictitious. as contemporary evidence shows that the emperor received this rite near Nicomedia at the hands of Eusebius. bishop of that city; and the *Donation of Constantine* (*q.v.*) has long been known to be spurious.

An important event of this pontificate was the council of Nicaea in 325, to which Silvester sent legates. Silvester died in Dec. 33j and is commemorated on Dec. 31.

SILVESTER II (Gerbert), pope from 999 to 1003, was born in the county of Xuvergne. Educated in the abbey of St. Géraud at Aurillac in Xuvergne under the abbots Gerald and Raymund. he was taken beyond the Pyrenees in 967 by Borel, count of Barcelona. who entrusted his further education to Atto, bishop of Vich (Ausona). Accompanying these two patrons to Rome in 970–971, Gerbert was presented to the emperor Otto I, to whom he admitted his skill in the quadrivium while deploring his comparative ignorance of logic. About 972, he went to Reims to study under Archbishop Adalbero, under whom he seems to have lectured for many years. having among his pupils Robert. the future king of France, and the chronicler Richer. His growing fame roused the envy of Otric of Saxony. who, suspecting him of error in his classification of the sciences, accused him of this before the emperor Otto II. By Otto's command the two rivals then had a disputation at Ravenna. which is said to have lasted a whole day (about Christmas, 980).

Otto subsequently gave Gerbert the abbey of Bobbio (982 or early 983), but Gerbert found such difficulty in collecting his dues that he returned to Reims in 984 to resume service under Adalbero. The latter involved him in his intrigues against the last Carolingian kings of France.

Adalbero died in Jan. 989, having, according to Gerbert. designated him his successor as archbishop. The appointment, however, was given instead to Arnulf, an illegitimate son of the late king Lothair. Arnulf took an oath of fealty to Hugh Capet, who had taken the place of Lothair's son Louis V as king of France, and Gerbert was persuaded to remain with him. Then, in the late summer or autumn of 989. Reims was taken by Lothair's brother Charles of Lorraine, now the head of the Carolingian house. Gerbert, falling into Charles's hands, continued for a time to serve under Xrnulf, who had gone over to his uncle's side. He was able, however, to return to the Capetian allegiance before the treachery of Xdalberon-Xscelin of Laon put both Charles and Xrnulf at the mercy of Hugh Capet (March 991). At the synod of St. Basle, near Reims, Xrnulf was degraded from the archbishopric and Gerbert, in recognition of his services, appointed his successor (June 991).

The vigour and the activity of Gerbert as a metropolitan made thernselves felt as far away as Tours: Orléans and Paris. But meanwhile Arnulf's friends were active! and Pope John XV objected to the summary deposition of Xrnulf. Gerbert had to appear before a papal legate at Mouzon in 995 and went himself to Rome to put his case before the new pope, Gregory V, in 996 (he was present at Otto III's coronation). Finally, in 997, after Gregory's synod of Pavia had suspended all the bishops concerned in the proceedings of St. Basle. Gerbert despaired of his archbishopric and left France for the court of his former pupil the young emperor Otto III.

Otto welcomed him as an old supporter of the imperial family as well as a great scholar and quickly procured his appointment to the archbishopric of Ravenna (about April 998). The death of Gregory V during the following year enabled the emperor to do even better for his protégé, by sponsoring his elevation to the papacy.

Gerbert was consecrated as Silvester II on April 2, 999. It is he who is generally credited with having encouraged the splendid vision of a restored empire that then began to fill Otto's mind.

In ecclesiastical administration Silvester was by no means inactive. He confirmed his old rival Arnulf in the see of Reims (999), rebuked Adalberon-Ascelin of Laon for his crimes (1000) and settled the dispute between Willigis archbishop of Mainz and Bernward bishop of Hildesheim (1001). Of more lasting importance was the erection of Gniezno to metropolitan status in a Polish Church independent of the German hierarchy (1000). The genuineness of the letter to St. Stephen of Hungary. accepting his kingdom as a fief of the Holy See, is contested. Silvester's plans for the advancement of the church and empire together were halted by Otto III's death on Jan. 23, 1002. Little more than a year later. on May 12. 1003, the pope himself died. He was buried in the church of St. John Lateran.

Besides being the most distinguished statesman. Gerbert was also the most accomplished scholar of his age. Richer has left a detailed account of his system of teaching at Reims. So far as the trivium is concerned; his textbooks were Victorinus' translation of Porphyry's *Isagoge,* Aristotle's *Categories* and Cicero's *Topics* with the commentaries of Boethius. From dialectics he urged his pupils to the study of rhetoric; but, recognizing the necessity of a large vocabulary. he accustomed them to read Virgil. Statius. Terence, Juvenal, Horace, Persius and Lucan. More remarkable still were his methods of teaching the quadrivium. To assist his lectures on astronomy he constructed elaborate globes of the terrestrial and celestial spheres, on which the course of the planets was marked. For facilitating arithmetical and perhaps geometrical processes he constructed an abacus with 27 divisions and a thousand counters of horn. A younger contemporary speaks of his having made a wonderful clock or sundial at Magdeburg. It is known from his letters that Gerbert was accustomed to exchange his globes for manuscripts of those classical authors that his own library did not contain.

More extraordinary still was his knowledge of music—an accomplishment which seems to have been his earliest recommendation to Otto I. Gerbert's letters contain more than one allusion to organs which he seems to have constructed. and William of Malmesbury preserved an account of a wonderful musical instrument still to be seen in his days at Reims. The same historian says that Gerbert borrowed from the Saracens the abacus with ciphers (*sc.*, for numerals from one to nine, instead of mere units, but without the zero).

Perhaps Gerbert's chief claim to the remembrance of posterity is to be found in the care and expense with which he gathered together manuscripts of the classical writers. His love for literature was a passion. In the turmoil of his later life he looked back with regret to his student days, and "for all his troubles philosophy was his only cure." Everywhere (Rome, Trier, Montier-en-Der, Gerona and Barcelona) he had friends or agents to procure copies of the great Latin writers for Bobbio or for Reims. To the abbot of Tours he writes that he is "labouring assiduously to form a library." and "throughout Italy, Germany and Lorraine [Belgica] is spending vast sums of money in the acquisition of mss." It is noteworthy, however, that Gerbert never wrote for a copy of one of the Christian fathers, his aim being, seemingly, to preserve the fragments of a fast-perishing secular Latin literature.

So remarkable a character as that of Gerbert left its mark on the age, and fables not unlike those later accumulated around Faust soon began to cluster round his name. Toward the end of the 11th century Cardinal Benno, the opponent of Hildebrand, is said to have made Gerbert the first of a long line of magician popes. William of Malmesbury adds a love adventure at Córdova, a compact with the devil, the story of a speaking statue that foretold Gerbert's death at Jerusalem — a prophecy fulfilled, somewhat as in the case of Henry IV of England, by his dying in the Jerusalem church of Rome — and that imaginative story of the statue with the legend "Strike here" which found its way into the *Gesta Romanorum.*

Bibliography.—Collections of Gerbert's works were edited by *A.* Olleris, *Oeuvres de Gerbert, pape sous le nom de Sylvestre II* (Paris, 1867); by J. Havet, *Lettres de Gerbert* (Paris, 1889); and by N. Boubnov, *Gerberti opera mathematica* (Berlin, 1899).

Picavet, *Gerbert, un pape philosophe* (Paris, 1897); I. Eichenbrun, "Gerbert (Silvester II) als Personlichkeit," in *Beitruge sur Kulturgeschichte des Mittelalters und der Renaissance,* vol. xxxv (Leipzig, 1928); J. Leflon, *Gerbert, humanisme et chrétienté au X^e^ siècle* (Abbaye de Saint-Wandrille, 1946); P. E. Schramm, *Studien zur Geschichte des Kaisers Otto III* (Heidelberg, 1923).

Silvester III (John), bishop of Sabina, became pope on Jan. 20, 1045, after the Romans had driven out Benedict IX; but he resigned the papacy on March 10, 1045. Retiring to his old bishopric, he recognized Gregory VI as pope. The synod of Sutri (Dec. 1046), under the presidency of the emperor Henry III, formally passed sentence of deposition on him, as is shown by the documents issued in his capacity as bishop of Sabina during 1046.

Silvester IV (Maginulf), antipope from 1105 to 1111, a man of dubious antecedents. was elected in opposition to Paschal II by the dissident nobles under Werner. margrave of Ancona. on Nov. 18. 1105. Though Paschal's troops expelled him from Rome the next day, his supporters continued to give trouble during the following year; and the emperor Henry V accorded him some recognition. When Paschal and Henry came to terms, however, the antipope's pretensions were dismissed (April 1111).

SILVESTRINES (Sylvestrines), an order of monks under the Benedictine rule, founded 1231 by St. Silvester Gozzolini, who in 1231 built a monastery at Montefano. The rule was the Benedictine, but as regards poverty in external things, far stricter than the Benedictine.

The order was approved in 1247 by Innocent IV, and at Silvester's death in 1267 there were 11 Silvestrine monasteries. At a later date there were 56, mostly in Umbria, Tuscany and the March of Ancona. In 1941 there were 75 Silvestrine monasteries and 8 monks houses.

See Max Heimbucher, *Orden* u. *Kongregationen* (1907), i, § 30; Wetzer and Welte, *Kirchenlexicon* (ed. 2); and the *Catholic Encyclopaedia,* art. "Sylvestrines."

SILVICULTURE is the technical branch of forestry *(see* Forests and Forestry) which is concerned with the establishment and maintenance of the forest.

See Arboriculture.

SIMALUR (Simeulue), the northernmost island of the chain off the west coast of Sumatra, Indonesia. It is about 61 miles long, and is hilly, the coasts being rocky and reef-bound.

Sinabang, on a bay in the southeast, is the capital and port, where vessels of the Royal Packet Navigation company ordinarily call, giving connection with Tapa Tuan, on the Sumatran mainland; there is also a cable between Simalur and Singkep, in Achin, Sumatra.

Other small places on the coast are Sibigo and Sigule; they are connected by a road. The Banyak Islands, nearly 70 in number, lie southeast of Simalur. They are prolific in coconut palms and form a port of call for copra. Simalur was occupied by the Japanese in World War II.

SIMANCAS, a town of Spain, in the province of Valladolid; 8 mi. S.W. of Valladolid, on the road to Zamora and the right bank of the Pisuerga river. Pop. (1950) 1,423 (mun.). Simancas is a town of great antiquity, the Roman Septimanca, with a citadel dating from the Moorish occupation in the 9th century. In 934 it was the scene of a battle between the Moors and Christians.

The citadel is now the Archivo General del Reino, to which the national archives of Spain were removed by order of Philip II in 1563. Their transference thither was first suggested to Charles V by Cardinal Ximenes or Cisneros (d. 1517).

The extensive alterations were made by three celebrated 16th-century architects, Juan de Herrera, Alonso Berruguete and Juan Gomez de Mora; the arrangement of the papers was entrusted to Diego de Ayala. They include important private as well as state papers. The archives of the Indies were transferred in 1784 to the Lonja of Seville.

SIMAROUBACEAE, the quassia *(q.v.)* family. shrubs or trees, many of which yield a bitter principle. About 32 genera are recognized, with about 200 species, chiefly in the tropics of both hemispheres. *Quassia amara* and *Aeschrion excelsum,* both natives of tropical America, are used in the practice of medicine and as a tonic, and locally species of *Brucea, Samadera, Simarouba, Harrisonia, Castela* and others are considered to have medicinal properties. Several members of the family produce useful timber, and a few are cultivated as ornamentals, mostly in warm regions. The Chinese tree of heaven, widely naturalized in Europe and in the United States, is *Ailanthus (q.v.) altissima.*

(E. D. Ml.)

SIMBIRSK: *see* Ulianovsk.

SIMCOE, JOHN GRAVES (1752–1806), British soldier and first lieutenant governor of Upper Canada (1791–96), was born at Cotterstock, Northamptonshire, Eng., on Feb. 25, 1752. As commander of a Loyalist corps, the queen's rangers, he served nith distinction during the American Revolution. Although well-to-do after his marriage in 1782. he found no satisfactory career in England

As lieutenant governor he proved an energetic administrator and. although seldom moderate in his language about the United States, he acted discreetly in the border crisis of 1794. His enthusiasm for the new Canadian colony and for aristocratic government in it quickly waned. the more so as he greatly disliked the governor in chief. Lord Dorchester. Given sick leave in 1796, he nevertheless agreed to go as governor and commander in chief to St. Domingue (Haiti), half-conquered by the British from the French. In seven months he reformed its administration and waged a successful campaign, but returned to England and resigned his colonial appointments. He was unable to get more active service, but was given command of the Western district with headquarters in Exeter (1799--1806). Then a new British government made him commander in chief in India. Diverted on a diplomatic mission to Lisbon, Spain, he fell ill and returned to die at Exeter, Oct. 26, 1806.

(S. R. M.)

SIMEON, SAINT, the New Theologian (949–1022), Byzantine abbot and mystic whose works had a formative influence on Orthodox spirituality, was born in Paphlagonia, of an aristocratic family, and came to Constantinople as a young boy. He insisted on entering the monastery of Studios (977). but differences with the abbot resulted in his migration to the neighbouring house of St. Mamas in the same year. There he became abbot (980) and imposed strict discipline. His vigorous cult of his spiritual father, Simeon the Studite, and other reasons brought him into conflict with the patriarch and he was exiled to the Asian shore of the Bosphorus (1009). There he built up the monastery of St. Marina near Chrysopolis (Scutari) and, though eventually reconciled to the patriarch. refused to return to the capital. He was a well-known and popular figure and was called the Younger or the New Theologian. perhaps to distinguish him from the two other "theologians" par excellence in the Orthodox Church—John the Evangelist and Gregory of Kazianzus. Some of his works have been translated into modern Greek, Russian and Latin; much has not been published in the original Greek.

His numerous writings fall into three main groups: sermons, the *capita,* and the "hymns of the divine loves." One group of the sermons. the catecheses, originally preached to the monks of St. Mamas, were later drastically revised and combined with other writings of Simeon to provide a compilation suitable for a wider public. Both his sermons and his hymns are illuminated by his own personal experience, and his underlying theme is the means, particularly obedience and tears, whereby through grace union with God may be attained in this life. His emphasis was often Christo-centric, though the climax of his mystical experiences was the indwelling of the Trinity revealed as divine light. His contribution is highly individual; he provides a link between earlier mystics. as John Climacus, and later Byzantine spirituality.

SIMEON, CHARLES (1759–1836), evangelical leader in the Church of England. was born at Reading on Sept. 24, 1759, and educated at Eton and Ring's college. Cambridge. where he was a fellow from 1782 (vice-provost, 1790–92). He came under the influence of Henry and John Venn and in 1782 was presented to the living of Trinity church. Cambridge. where he remained until his death. He was at first unpopular with his parishioners who had wanted the curate. John Hammond. in his place and his services were noisily interrupted. But his pastoral care. especially in sickness and in the famine of 1788, and his quiet. peaceable nature. slowly won the regard of the town and the university. and he became widely known as an evangelical leader who was yet a convinced member of the Church of England and lover of its liturgy and discipline.

He was concerned for missionary work, especially in India, and persuaded his best pupils to the venture, above all his curate. Henry Martyn; he helped to found the Church Missionary society (1799) and assisted the newly founded (1804) British and Foreign Bible society and the Society for Promoting Christianity Among the Jews; he gave to the support of missions from his own pocket. including part of the payment for his *Horae Homileticae,* discourses on the Bible published in 21 vol. in 1832–33. Following the example of Henry Thornton. in order to ensure the continuity of evangelical teaching. he administered the Simeon trust (founded 1816) to purchase the right to appoint clergymen to livings. He died on Kov. 13, 1836. and is buried in the chapel of King's college.

Simeon was a representative of the evangelical tradition at its best. and his influence upon the university left an indelible mark on religious life at Cambridge.

Smyth, *Simeon and Church Order* (1940); *Charles Simeon (1759–1836)*, ed. by A. Pollard and M. Henncll (1959). (W. O. C.)

SIMEON, in the Old Testament, the name of a tribe of Israel, named after the second son of Jacob by Leah (Gen. xxix. 33). According to Gen. xxxiv, the brothers Simeon and Levi massacred the males of Shechem to avenge the violation of their sister Dinah ("judgment") by Shechem the son of Hamor. Jacob disavowed the act, and on his deathbed solemnly cursed their ferocity, condemning the two to be divided in Jacob and scattered in Israel (xlix, 5–7). Subsequently the priestly Levites are found distributed throughout Israel without portion or inheritance (Deut. xviii, 1, Josh. xiii, 14).

On the other hand. Simeon is reckoned among the northern tribes in II Chron. xv, 9, xxxiv, 6, but is elsewhere assigned a district in southern Palestine. the cities of which are otherwise ascribed to Judah (*cf.* Josh. xix. 1–9 with xv. 26–32). An interpolation in I Chron. iv, 31 states that Judah was their seat in David's time. but there is no support ior this in other records (*see* I Sam. xxvii, xxxj. In fact. Simeon is not mentioned in the "blessing of Moses" (Deut. xxxiii. *see* S. R. Driver, *Deut.*, p. 397 ff.) or in the stories of the "judges"; and notwithstanding references to it in the chronicler's history of the monarchy. it is not named in the earlier books of Samuel and Kings. But is Gen. xxxiv to be taken literally? Shechem is the famous holy city, Hamor a well-known native family, Jacob talks of himself as being "few in number," and the deeds of Simcon and Levi are those of communities, not of individuals. What historical facts are thus represented, and how they are to be brought into line with the early history of Israel. are problems which have defied solution (*see* J. Skinner. *Genesis,* p. 421 ff.). It is conjectured that Dinah represents a clan or group (*see* TWELVE TRIBES OF ISRAEL) which settled in Shechem and was exposed to danger (*e.g.,* oppression or absorption); the tribes Simeon and Levi intervened on its behalf. the ensuing massacre was avenged by the Canaanites and the two were broken up. These events are supposed to belong to an early stage in the invasion of Palestine by the Israelites (15th–13th century B.C.), perhaps to a preliminary settlement by the "sons" of Leah (Reuben, Simeon. Levi and Judah), previous to the entrance of the "son" of Rachel. Joseph, the "father" of Ephraim and Manasseh.

In the New Testament, (1) the seer who recognized the infant Jesus as the Redeemer; (2) an alternate form of Simon.

SIMEON (or SYMEON) **OF DURHAM** (d. after 1129), English chronicler! embraced the monastic life before the year 1053 in the monastery of Jarrow; but only made his profession at a later date, after he had removed with the rest of his community to Durham.

He composed his *Historia ecclesiae Dunelmensis,* extending to the year 1096, at some date between 1104 and 1108. The original manuscript is at Durham in the library of Bishop Cosin. There are two continuations. both anonymous. The first carries the history from 1096 to the death of Ranulf Flambard (1129); the second extends from 1133 to 1144.

A Cambridge manuscript contains a third continuation covering the years 1141–54. About 1129 Simeon undertook to write a *Historia regum Anglorum tit Dacorum.* This begins at the point where the *Ecclesiastical History of Bede* ends. The section dealing with the years 1119–29 is. however, an independent and practically contemporaneous narrative.

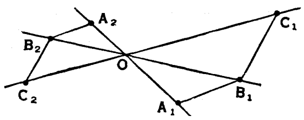
The most complete modern edition of his works is that of Thomas Arnold, "Rolls Series." 2 vol. *(1882–8.5).* Simeon's works have been translated by J. Stevenson in his *Church Historians of England,* vol. iii, part ii (1855).

SIMEON STYLITES, ST. (390–459), the first and most famous of the Pillar-hermits (Gr. *stylos,* "pillar"), n-as born in N. Syria. After having been expelled from a monastery for his excessive austerities. at thirty years of age he built a pillar six feet high on which he took up his abode. He made new pillars higher and higher. till after ren years he reached the height of sixty feet. On this pillar he lived for thirty years without ever descending. A railing ran round the capital of the pillar, and a ladder enabled his disciples to take him the necessaries of life. From his pillar he preached and exercised a great influence, converting numbers of heathen and taking part in ecclesiastical politics. The facts would seem incredible mere they not vouched for by Theodoret, who knew him personally *(Historia religiosa,* c. *26).* Moreover, Simeon had many imitators, well authenticated pillar-hermits being met with till the 16th century.

The standard work on the subject: is *Les Stytites* (1895), *by H.* Delehaye, the Bollandist; for a summary *see* the article "Saulenheilige," in Herzog's *Realencyklopadie* (ed. 3). *On* Simeon *see* Th. Nöldeke's *Sketches from Eastern History* (1892), p. 210, the *Dictionary* of *Christian Biography* and *The Catholic Encyclopaedia.*

SIMFEROPOL, the administrative centre of the Crimean *oblast,* situated on the northern slopes of the Chatyr-dagh mountains in 44° 58' N., 34° 3' E. on the Salgar river. Simferopol grew rapidly after the railway linking it with the main Russian net was constructed. Pop. (1959) 189,000. The small fortress of Napoli erected by the ruler of Taurida about 100 B.C. existed near the town until the end of the 3rd century. Later it was a Tatar settlement Ak-mechet (Sultan Serai), the residence of the chief military commander of the khan. It was captured and burned by the Russians in 1736 After the conquest of the Crimea by the Russians in 1784, it received its present name.

SIMILAR FIGURES. Geometric figures are said to be *similar* if they have the same shape but not necessarily the same size; *e.g.,* any two squares are similar; if they are of the same size, they are *congruent,* or *identically equal,* but they are still similar. Any two circles are similar, but not any two ellipses, for ellipses may have different shapes *(see* ELLIPSE). Solids may also be similar, as in the case of cubes or of spheres. Similarity of figures is the basis of trigonometry *(q.v.)* and of indirect measures in general. Speaking more precisely, two systems of points, $A_1, B_1, C_1, \ldots$ and $A_2, B_2, C_2, \cdots$ are said to be similar when they can be so placed that all lines A_1A_2, B_1B_2, $C_1C_2, \ldots$, joining corresponding points form a pencil whose vertex. O, divides each line into segments having a constant ratio r. In the figure here shown, the constant ratio is 2/3. Two figures are said to be similar when their systems of points are similar. The point O is called the *centre* of *similitude.* If $r=1$, the figures are said to he *symmetric with respect to the centre O (see* SYMMETRY).



SIMILAR FIGURES

SIMLA, a municipal town and district in the Ambala division of Punjab, India. The area was used as a rest area for troops after the Gurkha War, 181j–16. The first English house was built there in 1819. The town was from 1840 to 1939 the summer residence of the viceroy and the staff of the Indian and the Punjab governments. After the outbreak of World War II, the essential government departments remained in Delhi and those of lesser importance in Simla. From 1947 until 1953 (when it was moved to Chandigarh) it mas the headquarters of the (East) Punjab government and later the seat of the government of the adjacent state of Himachal Pradesh. It is 53 mi. N.E. of Ambala. with which it is connected by rail (metre-gauge from Kalka, 2j mi. below Simla). Between Kalka and Simla there are 103 tunnels. Mean temperature: 39° F. (Jan.) to 67° F. (July). Annual rainfall is 63 in.; snow often falls in winter. Pop. (1951) 46.150.

The mountains about Simla (southern outliers of the central chain of the east Himalaya) are forested with deodar; rhododendrons clothe the slopes up to the limit of perpetual snow. Simla occupies a spur of the lower Himalaya, running east and west for about 6 mi The ridge culminates at the east in the eminence of Jakko, where residences are most numerous; the old viceregal lodge stands on Observatory hill (7.050 ft.). The east of the town is known as Chota [Little] Simla and the west as Boileauganj. The situation is one of great beauty; and the residential parts lie at elevations between 6,600 and 8,000 ft. above sea level. To the north, a beautiful wooded spur, branching from the main ridge, is known as Elysium. Three miles west is the cantonment of Jutogh. The minor health resorts of Kasauli, Sabathu, Dagshai and Solan lie a distance to the south. In Solan are the headquarters of the federal university of the Punjab, founded in 1947. Simla has become the permanent headquarters of many official establishments.

The two chief medical institutions are the Ripon and Walker hospitals. In Simla are tuo undergraduate colleges and a women's training college attached to Punjab university.

SIMLA DISTRICT (8 sq.mi.) comprises only the town. Before 1948 it covered 80 sq.mi. around the town.

The former SIMLA HILL STATES AGENCY (4,960 sqmi) consisted of Bashahr, Jubbal, Keonthal, Nalagarh and 23 other states contrclled from Simla. Control was transferred to the resident for the Punjab states, at Lahore, in 1921.

SIMMEL, GEORG (1858–1918), German philosopher and sociologist whose fame as an original scholar rests on several lengthy and brilliantly written essays on sociological methodology and analysis, although during the last decade of his life he devoted himself mainly to metaphysics and aesthetics. He became well known to U.S. sociologists, in part because of the translations and commentaries on his works by A. W. Small. Simmel was born in Berlin, March 1, 1858, and was appointed a lecturer in philosophy at Berlin university in 1885. where he remained until called to the chair of philosophy at Strasbourg university in 1914. He died there on Sept. 28, 1918. Simmel is noted for his analytical study of the forms of social interaction. He sought to isolate the general forms or recurrent regularities of social interaction from the specific content of association in concrete types of activity, such as political, economic and aesthetic. Hence, his sociological writings were abstract rather than realistically descriptive of life.

In his studies of social interaction Simmel gave special attention to the problem of authority and obedience. His methodological contributions did much to clarify the scope of sociology, to give it greater precision, and to establish it as a basic social science in Germany. Simmel made one important effort to apply his abstract principles to the interpretation of social behaviour in a specific field. economics. in his essay *The Philosophy* of *Money.* He stressed the role of a money economy in specializing social activity and depersonalizing individual and social relationships, a concept later developed more fully by Werner Sombart in his famous work on capitalism. Simmel's writings on the philosophy of history, ethics, religion and art are also important.

SIMMONS, EDWARD EMERSON (1852–1931), U.S. artist. one of the original members of the Ten American Painters, was born at Concord. Mass., on Oct. 27, 1852. He graduated from Harvard college in 1874, and was a pupil of Jules Joseph Lefebvre and Gustave Boulanger in Paris, where he took a gold medal. Simmons was awarded the prize by the Municipal Art Society of New York for a mural decorative scheme, carried out for the criminal courts building. Later he decorated the Waldorf-Astoria in New York city, the Library of Congress, the state capitol at St. Paul. Minn., and other public and private buildings. He was elected to the National Institute of Arts and Letters. Simmons died on Nov. 17, 1931.

SIMMS, WILLIAM GILMORE (1806–1870), U.S. regional novelist, was born in Charleston, S.C., April 17, 1806.

Edgar Allen Poe stated in 1844 that Simms had "more vigor, more imagination, more movement and more general capacity than all our novelists (save Cooper) combined." A 20th-century critic J. B. Hubbell, stated that, Simms "rather than Poe is the central figure of the literature of the Old South. He knew personally most of the southern writers of the time, and he more than any other man stimulated them to write and to publish. But he was a national as well as a sectional figure, and he was the most important literary link between North and South." (J. B. Hubbell, *The South in American Literature,* p. 572, Duke University Press, 1954.) Of Simms' 82 volumes, his historical novels are most important. His field of fiction is the frontier of the lower south—Spanish explorations of the 16th century, the settlement of South Carolina in the 17th, the revolution in South Carolina in the 18th and southwestward migration in the 19th, preserving for the social historian an authentic and salty cast of woodsmen, Indians, Negro slaves, partisan fighters, outlaws, adventurers, loyalists, shyster lawyers, land speculators, gamblers, half-breeds and typical ladies and gentlemen of what to Simms was an heroic age.

Motherless at two, Simms was reared by his grandmother, while his Scotch-Irish father fought in the Creek wars and under Jackson at New Orleans. Simms lived a vicariously adventurous childhood through his father, while absorbing history through his storytelling grandmother who had lived through the Revolution. He attended public schools four years. Upon entering the College of Charlestori at the age of ten he knew enough French, Latin, German and Spanish to dabble in translations. At the age of 12 he completed the study of materia medica, and leaving college became a druggist's apprentice. He began publishing poetry in Charleston papers at 16, edited a magazine and published a volume of poetry at 19, married at 20 and was admitted to the bar at 21.

Simms was a prodigious worker, whether at Woodlands plantation in winter, Charleston in summer or on yearly publishing trips north. As state legislator and magazine and newspaper editor (the *Charleston City Gazette*), he became embroiled in political and literary quarrels. From Charleston and the south he nevertheless received lifelong praise approaching adulation; from the north, wide audience and eminent literary friendships. Though he was shadowed by the defeat of the Confederacy, the death of his second wife, poverty and the destruction of his home and library by Gen. William T. Sherman's stragglers, the five volumes of his published letters attest a gallant figure, the richness of whose performance was too long underestimated by literary historians. He died on June 11, 1870 in Charleston.

Simms' chief fault was writing too much, too carelessly and with too frequent use of stock devices; he was at his best the master of a racy and masculine English prose style. His gift as a charming teller of tales in the oral tradition, and the care of an antiquarian in preparing historical materials, triumph over hasty composition, whether in *Vasconselos* (1853) in a 16th-century setting; *The Yemassee* (1835) in a colonial setting; his revolutionary series—*The Partisan* (1835), *Mellichampe* (1836), *The Kinsmen* (1841), *Katherine Walton* (1851), *Woodcraft* (1854), *The Forayers* (1855), *Eutaw* (1856); the best of his border romances—*Richard Hurdis* (1838) and *Border Beagles* (1840); his short story collection *The Wigwam and the Cabin* (1845); or in his *History of South Carolina* (1840). Of his 19 volumes of poetry the collected *Poems* (1853) deserve mention. Most popular of his biographies were *The Life of Francis Marion* (1844) and *The Life of Chevalier Bayard* (1847). His literary criticism is represented in *Views and Reviews of American Literature* (1845).

SIMNEL, LAMBERT (fl. 1477–1534), English impostor, was probably the son of a tradesman at Oxford. About 10 years old in 1487, he was described as a handsome youth of intelligence and good manners. In 1486, the year following the accession of Henry VII, rumours were spread by the Torkists that the two sons of Edward IV, who had been murdered in the Tower of London, were still alive. A young Oxford priest, Richard Symonds, decided to put forward the boy Simnel as one of these princes and provided him with a suitable education. Meanwhile a report had gained currency that the young earl of Warwick, son of Edward IV's brother George, duke of Clarence, had died in the Tower and Symonds decided that the impersonation of Warwick would be more effective. The Yorkists had many adherents in Ireland, and thither Lambert Simnel was taken by Symonds early in 1487. He gained the support of the earl of Kildare, the archbishop of Dublin, the lord chancellor and a powerful following, and was crowned as King Edward VI in the cathedral in Dublin on May 24, 1487.

Messages asking for help were sent to Margaret, duchess of Burgundy, sister of Edward IV, to Sir Thomas Broughton and other Yorkist leaders.

On Feb. 2, 1487, Henry VII held a council at Sheen to concert measures for dealing with the conspiracy. Elizabeth Woodville, widow of Edward IV, was imprisoned in the convent of Bermondsey; and the real earl of Warwick was shown in public in the streets of London. John de la Pole, earl of Lincoln, himself a nephew of Edward IV, had probably connived at the Simnel impersonation. He fled to Flanders, where he joined Lord Lovell, who had headed an unsuccessiul Yorkist rising in 1486, and in May 1487 the two lords proceeded to Dublin, where they landed a few days before the coronation of Lambert Simnel. They were accompanied by 2,000 German soldiers under Martin Schwarz, procured by Margaret of Burgundy to support the enterprise, Margaret having recognized Simnel as her nephew. This force, together with some ill-armed Irish levies commanded by Sir Thomas Fitzgerald, landed in Lancashire on June 4. King Henry immediately marched to Nottingham, where his army was strengthened by the addition of 6,000 men. Making for the fortress of Newark, Lincoln and Sir Thomas Broughton, accompanied by Simnel, attacked the royal army near Stoke-on- rent on June 16, 1487. After a fierce and stubborn struggle the Royalists were completely victorious, though they left 2,000 men on the field; Lincoln, Schwarz and Fitzgerald with 4,000 of their followers were killed, and Lovell and Broughton disappeared. The priest Symonds and Simnel were taken prisoners. Henry VII, recognizing that Lambert Simnel had been a tool in Yorkist hands, took him into his own service as a scullion. He was later promoted to be royal falconer, and is said to have afterward become a servant in the household of Sir Thomas Lovell. He was still living in the year 1534.

See Francis Bacon, *History of Henry VII*, notes by J. R. Lumby (1876); James Gairdner, *Henry VII* (1889); J. D. Mackie, *The Earlier Tudors* (1951).

SIMOCATTES, THEOPHYLACT (or THEOPHYLACTUS; Gr. THEOPHYLAKTOS SIMOKATTES) (fl. 6th–7th century A.D.), Byzantine writer whose history is a valuable source for the reign of Maurice (582–602). He was an Egyptian, who after legal training held office at Constantinople under Heraclius (610–641). His history, for which he had access to official sources of information, shows keen awareness of the Greek tradition of historiography, for he was acquainted with the work of Herodotus and Diodorus as well as later historians including near contemporaries. He also wrote a work on natural history (*Quaestiones naturales*) and a number of literary exercises in epistolary form.

His *Historia* was edited by C. de Boor in the "Teubner Series" (1887) and I. Bekker in the Bonn corpus (1834). Other works edited include *Quaestiones naturales*, ed. by J. L. Ideler, *Physici et medici graeci minores*, vol. i, pp. 168–183 (1841), and. together with the *Epistulae*, by J. F. Boissonade (1635); *Epistulae* ed. by R. Hercher, *Epistolographi Graeci*, pp. 763–787 (1873).

See K. Krumbacher, *Geschichte der byzantinischen Litteratur*, pp. 247–251, 2nd ed. (1897); G. Moravcsik, *Byzantinoturcica*, vol. 1, pp. 544–548, 2nd ed. (1958). (J. M. Hy.)

SIMON, SAINT, one of the 12 apostles, always mentioned in the last of the three groups of four names in the apostle lists (Mark iii. 18; Matt. x, 3; Luke vi, 15; Acts i, 13). In Mark and Matthew he bears the surname *Kananaios*, or the Cananaian, often wrongly interpreted as meaning "from Cana" or "from Canaan." It is in fact the Greek transliteration of an Aramaic word *qan'anaya*, meaning "the Zealot," which is precisely the title given him by Luke both in his Gospel and in Acts. Whether he was one of the group of Zealots (the Jewish nationalistic party prior to A.D. 70) cannot be answered for lack of evidence. Nothing further is known about him from the New Testament. He is said to have preached the Gospel in Egypt and then joined St. Judas (Jude Thaddeus) in Persia, where both were martyred (according to the apocryphal Passion of Simon and Jude). Oct. 28 is the feast of SS. Simon and Jude. (J. A. Fi.)

SIMON, SIR JOHN (1816–1904), English surgeon and sanitary reformer, was born in London on Oct. 10, 1816. He was the son of Louis Michael Simon, for many years a leading member of the London Srock exchange. Simon was educated at a preparatory school in Pentonville, spent seven years at Charles Parr Burney's school in Greenwich and then ten months with a German priest in Rhenish Prussia.

He began the study of medicine on Oct. 1, 1833, when he was a few days short of the age of 17. He was an apprentice of Joseph Henry Green, surgeon at St. Thomas's who was well known for his friendship with Samuel Taylor Coleridge, whose literary executor Green became. He became a demonstrator of anatomy and in 1840 was appointed assistant surgeon to King's College hospital. In the autumn of 1847 he was made surgeon and lecturer on pathology at his old school, St. Thomas's, where, with progressive changes, he continued to remain an officer.

In the spring of 1844 he gained the first Astley Cooper prize by a physiological essay on the thymus gland, and the following year was elected F.R.S. Simon published many clinical surgical lectures of the greatest importance. and contributed an article on "Inflammation" to Holmes's *System of Surgery* which has become a classic of its kind. It was, however, on his appointment in 1848 as medical officer of health to the City of London, and afterward to the government, that his great abilities in sanitary science found full scope. Simon can claim priority over Edward Cock in the operation of perineal puncture of the urethra in cases of retention from stricture. He died on July 23, 1904.

SIMON, JOHN ALLSEBROOK SIMON, 1ST VISCOUNT (1873–1954), British lawyer and politician, who was leader of the Liberal National party (*see* LIBERAL PARTY) from 1930 until 1940, was born in Manchester on Feb. 28, 1873. Educated at Fettes college, Edinburgh, and Wadham college, Oxford, he became a fellow of All Souls in 1897 and was called to the bar in 1899. He took silk in 1908. In 1906 he entered parliament as a Liberal, becoming solicitor general in 1910 (in which year he was also knighted) and attorney general in 1913. In 1915 he chose a political rather than legal career when he refused the lord chancellorship to become home secretary, a post which he resigned a year later in opposition to conscription. A follower of H. H. Asquith, he lost his seat in 1918, but was re-elected in 1922. As chairman of the commission which examined the working of the 1919 Government of India act, he visited India during 1927–30, and while there announced his resignation from the bar, where he had been making more than £50,000 a year.

Simon became foreign secretary in the national government of 1931; many thought his advocacy of disarmament unrealistic in the face of Japanese aggression in Manchuria and the growing territorial ambition of Germany and Italy. As home secretary, 1935–37, he introduced much-needed factory legislation. He became chancellor of the exchequer in 1937. He shared Neville Chamberlain's downfall in 1940 and accepted a viscountcy and the lord chancellorship, a position in which his legal acumen and lucidity made him outstanding. After the fall of the coalition government in 1945 he remained active in the house of lords. He died in London on Jan. 11, 1954.

SIMON, JULES FRANÇOIS (1814–1896), French statesman and philosopher, was born at Lorient on Dec. 27, 1814. His father was a linen-draper from Lorraine, who abjured Protestantism before his second marriage (of which Jules Simon was the son) with a Catholic Breton. The family name was Suisse, which Simon dropped in favour of his third prenomen. At the École Normale in Paris he came in contact with Victor Cousin, who sent him to Caen and then to Versailles to teach philosophy. He helped Cousin, without receiving any recognition, in his translations from Plato, and in 1839 became his deputy in the chair of philosophy at the Sorbonne, with the meagre salary of 83 francs per month. He also lectured on the history of philosophy at the École Normale. At this period he edited the works of Malebranche (2 vols., 1842), of Descartes (1842), Bossuet (1842) and of Arnauld (1843), and in 1844–1845 appeared the two volumes of his *Histoire de l'école d'Alexandrie.* He became a regular contributor to the *Revue des deux mondes,* and in 1847, with Amédée Jacques and Émile Saisset, founded the *Libertk de penser,* with the intention of throwing off the yoke of Cousin, but he retired when Jacques allowed the insertion of an article advocating the principles of collectivism. In 1848 he represented the Côtes-du-Nord in the National Assembly, and in 1849 entered the Council of State, but was retired on account of his republican opinions. After the *coup d'état,* which was followed by his dismissal from his professorship, he used his leisure in writing *Le Devoir* (1853), which was translated into modern Greek and Swedish, *La Religion naturelle* (1856, Eng. trans., 1887), *La Liberté de conscience* (1857), *La Liberté politique* (1859), *La Liberté civile* (1859), *L'Ouvrière* (1861), *L'École* (1864), *Le Travail* (1866), *L'Ouvrier de huit ans* (1867) and others. In 1863 he was returned to the Corps Législatif for the 8th *circonscription* of the Seine, and supported "les Cinq" in their opposition to the government.

He became minister of instruction in the government of National Defence on Sept. 5, 1870. After the capitulation of Paris in January 1871 he was sent down to Bordeaux to prevent the resistance of Gambetta to the peace. But at Bordeaux Gambetta, who had issued a proclamation excluding from the elections officials under the Empire, was all powerful. He affected to dispute Jules Simon's credentials, and issued orders for his arrest. Meanwhile Simon had found means of communication with Paris, and on Feb. 6, was reinforced by Eugène Pelletan, E. Arago and Garnier-Pagès. Gambetta resigned, and the ministry of the Interior, though nominally given to Arago to avoid the appearance of a personal issue, was really in Simon's hands. Defeated in the department of the Seine, he sat for the Marne in the National Assembly, and resumed the portfolio of education in the first cabinet of M. Thiers's presidency. He retained office until a week before the fall of Thiers in 1873.

Simon was regarded by the monarchical Right as one of the most dangerous obstacles in the way of a restoration, which he did as much as any man (except perhaps the comte de Chambord himself) to prevent, but by the extreme Left he was distrusted for his moderate views, and Gambetta never forgave his victory at Bordeaux. In 1875 he became a member of the French Academy and a life senator, and in 1876, on the resignation of M. Dufaure, was summoned to form a cabinet. He replaced antirepublican functionaries in the civil service by republicans, and held his own until May 3, 1877, when he adopted a motion carried by a large majority in the Chamber inviting the cabinet to use all means for the repression of clerical agitation. Marshal MacMahon then practically demanded his resignation. This act of the president, known as the "Seize Mai," drove him finally from office. He justified his action in submitting instead of appealing to the Chamber by his fear of providing an opportunity for a *coup d'état* on the part of the marshal.

The rejection (1880) of article 7 of Ferry's Education Act, by which the profession of teaching would have been forbidden to members of non-authorized congregations, was due to Simon's intervention. He was in fact the chief of the Left Centre opposed to the radicalism of Jules Grévy and Gambetta. He was director of the *Gaulois* from 1879 to 1881, and his influence in the country among moderate republicans was retained by his articles in the *Matin* from 1882 onwards, in the *Journal des Débats,* which he joined in 1886, and in the *Temps* from 1890.

He left accounts of some of the events in which he had participated in *Souvenirs du 4 septembre* (1874), *Le Gouvernement de M. Thiers* (2 vols., 1878), in *Me'moires des autres* (1889), *Nouveaux me'moires des autres* (1891) and Les *Derniers me'moires des autres* (1897), while his sketch of *Victor Cousin* (1887) was a further contribution to contemporary history. For his personal history the *Premiers me'moires* (1900) and *Le Soir de ma journée* (1902), edited by his son Gustave Simon, may be supplemented by Léon Séché's *Figures bretonnes, Jules Simon, sa vie, son oeuvre* (new ed., 1898), and G. Picot, *Jules Simon: notice historique . . .* (1897); also by many references to periodical literature and collected essays in Hugo P. Thieme's *Guide bibliographique de la litt. franç. de 1800 à 1906* (1907).

SIMON, RICHARD (1638–1712), French biblical critic, born at Dieppe on May 13, 1638, was educated by the Fathers of the Oratory at Dieppe and at the university of Paris. Simon entered the priesthood in 1670, and the same year wrote a pamphlet in defence of the Jews of Metz, who had been accused of having murdered a Christian child. About this time began his controversies with the Port Royalists and with the Benedictines, and his enemies sought to drive him from Paris. He was engaged at the time in superintending the printing of his *Histoire critique du Vieux Testament,* which was to be dedicated to Louis XIV.

The proof sheets were held up pending the return of the king from Flanders, and fell into the hands of the Port Royalists, who had in hand a translation into French of the Prolegomena to *Walton's Polyglott.* Simon now announced his intention of publishing an annotated edition of the Prolegomena, and actually added to the *Critical History* a translation of the last four chapters of that work, which had formed no part of his original plan. Simon's announcement prevented the appearance of the projected translation, but his enemies found the desired opportunity in the alleged heterodoxy of some of the views expressed by Simon. A decree of the council of state was obtained, and the whole impression, consisting of 1,300 copies, was seized by the police and destroyed. Simon was expelled by the Oratorians from their fellowship, and retired in 1679 to his curacy of Bolleville, Normandy. Finally the *Critical History* appeared, with Simon's name on the title page, in the year 168j, from the press of Reenier Leers in Rotterdam. Simon died at Dieppe on April 11, 1712.

The remaining works of Simon were: *Histoire critique du texte du Nouveau Testament* (1689), *Histoire critique des versions du Nouveau Testament* (1690); *Histoire critique des principaux commentateurs du Nouveau Testament* (1693), and his *Nouvelles Observations sur le texte et les versions du Nouveau Testament* (1695).

The principal authorities for the life of Simon are the life or "éloge" by his grand-nephew De la Martinière in vol. i. of the *Lettres choisies* (4 vols., 1730); *Richard Simon et son Vieux Testament,* by A. Bernus (Lausanne, 1869); H. Margival, *Essai sur Richard Simon et la critique biblique au XVIIe siècle* (1900). For the bibliography, *see,* in addition to the various editions of Simon's works, *A.* Rernus, *Notice bibliographique sur Richard Simon* (Basel, 1882).

SIMON, THOMAS (c. 1623–1665), English medalist, who designed coins, medals and seals for the Commonwealth and Restoration governments. was born, according to Vertue, in Uorkshire about 1623. He studied engraving under Nicholas Briot, and about 163j received a post in connection with the mint. In 1645 he was appointed by the parliament joint chief engraver along with Edward Wade. and. having executed the great seal of the Commonwealth and dies for the coinage, he was proinoted to chief engraver to the mint and seals. He produced several fine portrait medals of Cromwell, one of which is copied from a miniature by Cooper. After the Restoration he was appointed engraver of the king's seals. In the course of his contest with his rival. John Roettiers in 1662, Simon produced his celebrated design for a crown piece of Charles II. on the margin of which he engraved a petition to the king. This is usually considered his masterpiece. He died of the plague in London in June 1665.

A volume of *The Medals, Coins, Great Seals and Other Works of Thomas Simon, Engraved and Described by George Vertue,* was published in 1753.

SIMON BEN YOHAI (2nd century A.D.), a Galilean Rabbi, one of the most eminent disciples of Akiba Ben Joseph (*q.v.*). His master was executed by Hadrian, and Simon's anti-Roman sentiments led to his own condemnation by Varus c. A.D. 161 (according to Graetz). He escaped this doom and dwelt for some years in a cavern. Emerging from concealment. Simon settled in Tiberias and in other Galilean cities. He acquired a reputation as a worker of miracles, and on this ground was sent to Rome as an envoy. To Simon were attributed the important legal homilies called *Sifre* and *Mekhilta (see* MIDRASH), and the *Zohar*, the Bible of the Cabala (*q.v.*). This latter ascription is altogether unfounded, the real author being Moses de Leon (*q.v.*).

The fullest account of Simon's teachings is to be found in W. Bacher's *Agada der Tannaiten,* ii. pp. 70–149.

SIMONDS, FRANK HERBERT (1878–1936), American writer, was born in Concord, Massachusetts, April 5 1878. He graduated from Harvard University in 1900, after having seen active service in the war with Spain. He became a reporter on the New York *Tribune* in 1901, and was with the Washington bureau of that paper in 1903, and its Albany correspondent in 1904–05. He was Albany correspondent for the New York *Evening Post* in 1906–08, became an editorial writer for the *Sun* in 1908, was editor of the New York *Evening Sun* in 1913–14, and from 1915 to 1918 was associate editor of the New York *Tribune.* During the World War his brilliant articles in the American *Review of Reviews,* analysing the military and political situation from month to month, brought him a wide reputation. After the Armistice he continued to contribute articles on international politics to this review (of which he became foreign editor in 1914), to other periodicals, and to a newspaper syndicate. His books include *They Shall Not Pass* (1916), an account of Verdun; *History of the World War* (1917–20); and *How Europe Made Peace without America* (1927).

SIMONIDES (or SEMONIDES) **OF AMORGOS,** Greek iambic poet, flourished in the middle of the 7th century B.C. He was a native of Samos, and derived his surname from having founded a colony in the neighbouring island of Amorgos. According to Suïdas, besides two books of iambics, he wrote elegies, one of them a poem on the early history of the Samians. The elegy included in the fragments (85) of Simonides of Ceos is more probably by Simonides of Amorgos. We possess about thirty fragments of his iambic poems, written in clear and vigorous Ionic, satiric in type, but less personal than Archilochus. His largest fragment is an elaborate comparison of various types of women with various animals.

See Fragments in *T.* Bergk, *Poëtae lyrici Graeci;* separate editions by F. T. Welcker (1835), and especially by P. Malusa (1900), with exhaustive introduction, bibliography and commentary.

SIMONIDES OF CEOS (*c.* 556–469 B.C.), Greek lyric poet, was born at Iulis in the island of Ceos. During his youth he taught poetry and music in his native island, and composed paeans for the festivals of Apollo. Later he went to live at Athens, at the court of Hipparchus, the patron of literature. After the murder of Hipparchus (514), Simonides withdrew to Thessaly, where he enjoyed the patronage of the Scopadae and Aleuadae (two celebrated Thessalian families). Apparently some disaster overtook the Scopadae, which resulted in the extinction of the family. After the battle of Marathon Simonides returned to Athens, but soon left for Sicily at the invitation of Hieron, at whose court he spent the rest of his life.

His reputation as a man of learning is shown by the tradition that he introduced the distinction between the long and short vowels (ε, η, ο, ω), afterwards adopted in the Ionic alphabet which came into general use during the archonship of Eucleides (403). He was also the inventor of a system of mnemonics (Quintilian xi. 2, 11). So unbounded was his popularity that he was a power even in the political world; we are told that he reconciled Theron and Hieron on the eve of a battle between their opposing armies. He was the intimate friend of Themistocles and Pausanias the Spartan, and his poems on the war of liberation against Persia no doubt gave a powerful impulse to the national patriotism. For his poems he could command almost any price: later writers, from Aristophanes onwards, accuse him of avarice, probably not without some reason.

Of his poetry we possess two or three short elegies (Fr. 85 seems from its style and versification to belong to Simonides of Amorgos, or at least not to be the work of our poet), several epigrams and about ninety fragments of lyric poetry. The epigrams written in the usual dialect of elegy, Ionic with an epic colouring, were intended partly for public and partly for private monuments. There is strength and sublimity in the former, with a simplicity that is almost statuesque, and a complete mastery over the rhythm and forms of elegiac expression. Those on the heroes of Marathon and Thermopylae are the most celebrated. In the private epigrams there is more warmth of colour and feeling, but few of them rest on any better authority than that of the Palatine anthology. One interesting and undoubtedly genuine epigram of this class is upon Archedice, the daughter of Hippias the Peisistratid, who, "albeit her father and husband and brother and children were all princes, was not lifted up in soul to pride." The lyric fragments vary much in character and length: one is from a poem on Artemisium, celebrating those who fell at Thermopylae, with which he gained the victory over Aeschylus; another is an ode in honour of Scopas (commented on in Plato, *Protagoras,* 339 b); the rest are from odes on victors in the games, hyporchemes, dirges, hymns to the gods and other varieties. The poem on Thermopylae breathes a lofty national pride; the others are full of pathos and feeling, combined with a genial worldliness. "It is hard," he says (Fr. 5), "to become a truly good man, perfect as a square in hands and feet and mind, fashioned without blame. Whosoever is bad, and not too wicked, knowing justice, the benefactor of cities, is a sound man. I for one will find no fault with him, for the race of fools is infinite." His most celebrated fragment is a dirge, in which Danae, adrift with the infant Perseus on the sea in a dark and stormy night, takes comfort from the peaceful slumber of her babe. Simonides here illustrates his own saying that "poetry is vocal painting, as painting is silent poetry."

Of the many English translations of this poem, one of the best is that by J. A. Symonds in *Studies on the Greek Poets.* Fragments in T. Bergk, *Poetae lyrici Graeci;* standard edition by F. G. Schneidewin (1835) and of the *Danaë* alone by H L. Ahrens (1853). Other authorities are given in the exhaustive treatise of E. Cesati, *Simonide di Ceo* (1882); *see* also W. Schroter, *De Simonidis Cei melici sermone* (1906).

SIMON MAGUS. One of the most ancient and interesting rivals of early Gentile Christianity was the sect of the Simonians. Its founder was a skilful magician who had established himself in the city of Samaria just prior to its evangelization and had captivated the populace by his sorcery, so that he was generally known as "the power of God which is called great." His ascendancy was broken by the arrival in Samaria of Philip (Acts 8.5; the interpretation of this story depends somewhat on the view taken of the sources of Acts), whose novel cures and teaching attracted many converts to Christianity and ultimately won over Simon himself who was baptized with the rest. It is probable that Simon's conversion was due less to a change of heart than to a misunderstanding that baptism and the apostle's cures were evidence of a magic superior to his own, the art of which he might hope to acquire as Philip's disciple. Proof that he had carried over the mentality of his old profession into his new religion was not slow in forthcoming. When Philip was reinforced by Peter and John who supplemented baptism by the gift of the Spirit through the laying on of hands, Simon asked that he might be taught to perform this rite and to obtain power to dispense the Holy Spirit and he offered the Apostles a fee for their instruction. Peter, perceiving how slight an impression Christianity had made upon the magician's mind, rebuked him severely and pointed out that, as he had no right understanding of Christianity, he could not share in its benefits. Simon accepted the reproof and begged Peter to pray for his forgiveness.

We hear no more of Simon in Acts and might have assumed that his repentance was enduring and that he had been absorbed into the mass of Samarian Christians, if we did not have later references to him and fragments of a sectarian literature in which he figures as a god and which show that he must have withdrawn from Christianity and initiated a movement of his own in which Christian and Pagan elements were freely and curiously combined. From these later sources (Justin Martyr, Irenaeus, Epiphanius and Hippolytus), it appears that Simon's birthplace was Gitta, that he journeyed to Rome where he had some success in gaining followers under Claudius, that he was generally accompanied by a Phoenician woman named Helen, who had formerly been a prostitute but whom he associated with his own claims for divine honours, that he had a number of disciples of whom the most important were Menander and Saturninus and that he met his end through a foolish attempt to reproduce the resurrection of Jesus by allowing himself to be buried alive in the mistaken supposition that he would be able to rise again on the third day. Justin has a story that a statue was set up in Simon's honour on the Tiber with the inscription, *Simoni Deo Sancto,* but this is probably an error, as a statue answering to Justin's description and inscribed, *Semoni Sancto Deo Fidio Sacrum Sex Pompeius, S P. F. Col. Mussianus Quinqennalis Decur Bzdentalis Donum Dedit,* was unearthed on the Tiber in modern times. Semo was a local, perhaps Sabine, deity and had nothing to do with Simon, but the mistake was not an impossible one for Justin or his source to have made.

On the development of Simonian theology we are better informed than on the external history of the sect. Just what was implied in the view, current in Samaria in Simon's pre-Christian days, that he was "the power of God which is called great" is obscure and it is only a possibility that the god whose power he was thought to be was Jehovah. Evidence that he was influenced by Judaism apart from Christianity is wholly lacking. The recurrence of the phrase, "power of God," or its equivalent, in all the later accounts suggests a certain continuity and it seems probable that, even before his conversion, he advanced a theology similar to that described by Irenaeus (Adv. *haer.* 1.16.1 Harvey) but lacking the elements borrowed later from Christianity and that after his withdrawal from the church he revised this system into a parallel and rival of Christianity.

Apart from Justin's meagre statement that Simon was worshipped as the supreme God and Helen regarded as the "primary notion" emanating from him, our first satisfactory account of Simonian theology is given by Irenaeus, whose assumption that he is describing Simon's own teaching is erroneous, for he is evidently drawing from a later source in which reflections from contemporary christological speculation are unmistakable. In this system Simon is identified with the supreme God, the Father and most exalted Power from whom, before the creation of the world, a female principle emanated. This principle was his first notion through whom it occurred to him to create angels and archangels. Knowing the Father's mind, she issued from him to execute his will and made the angels and powers who, in turn, fashioned the visible world. These inferior beings were ignorant of the Father's existence but were jealous of their mother and, unwilling to be thought the offspring of another, detained her on the earth and forced her through a series of degrading incarnations. She appears in history as Helen of Troy and later as Simon's companion, Helen of Tyre, whom he came to save and who, in Simonian exegesis, is identical with the lost sheep of the parable. To rescue her and to bring salvation to men the supreme Power became incarnate and descended to earth where the angels were quarrelling for ascendancy. He came in human form, though in fact he was no man, and played the Passion in Judaea, though his sufferings were only apparent. He appears among the Jews as the Son, but also descended in Samaria as the Father and among the Gentiles as the Holy Spirit. The advent of this hitherto unknown god abrogated the precepts of the Prophets whose utterances had been inspired by the angels and designed to enslave man and obscure the truth that salvation comes not through good works but through the grace of Simon and hope in Helen and him.

The interesting features in this otherwise rather commonplace myth are the curiously Sabellian-like Trinitarian doctrine, the Iocetic theory of incarnation, and the doctrine of justification by faith or rather by hope—all of which appear to have been transferred bodily from Christianity and adapted to Simon's theology. The meaning of the Father's appearance in Samaria is obscure, but may refer to the Samaritan temple at Gerizim. It is also impossible to make out the relative importance of Jesus and Simon in the system. The Simonians evidently believed that the same divine principle was incarnate in both, but the reference to the Passion shows that they could not have confused the two historical figures. Further clarity cannot be expected as Irenaeus was not sufficiently interested or well informed to describe the doctrine of salvation in detail.

More remote from the original stock is a system preserved in a document quoted at length by Hippolytus and entitled "the Great Pronouncement" (apophasis megale). Here fragmentary survivals of the original Simonian myth serve only to cloak a philosophic system allied to Stoicism. Elaborate metaphor and fanciful exegesis do much to obscure the meaning and the affinities with other known Simonian systems are very slight. The substitution of an innate saving principle in human nature for a personal saviour is reminiscent of Saturninus, but the underlying ideas are more philosophical and myth serves only as a symbol, not as a naïve statement of fact. Still more tenuous is the connection between Irenaeus' account and a system of theology attributed to Simon in the Clementines, but this problem can be satisfactorily treated only after further research on the text and sources of that literature have been made.

Both Irenaeus and Hippolytus inform us of the liturgical practices of the Simonians. Apart from magic of various kinds, worship was paid to Simon and Helen before statues of Zeus and Athena It was, however, customary not to mention their names but to use the titles "Lord" and "Mistress" (kyrios, kyria). Anyone violating this convention was detected as an outsider and expelled from the mysteries. (R. P. C.)

SIMON OF ST. QUENTIN (*fl.* 1247), Dominican mission-traveller and diplomatist, accompanied, and wrote the history of the Dominican embassy under Friar Ascelin or Anselm, which Pope Innocent IV. sent in 1247 to the Mongols of Armenia and Persia. Large sections of Simon's history have been preserved in Vincent of Beauvais's *Speculum* historiale, where 19 chapters are expressly said to be ex *libello* fratris *Simonis,* or entitled frater Simon. The embassy proceeded to the camp of Baiju or Bachu Noyan (*i.e.,* "General" Baiju, Noyan signifying a commander of 10,000) at *Sitiens* in Armenia, lying between the Aras river and Lake Gokcha, 59 days' journey from Acre. The papal letters were translated into Persian, and thence into Mongol, and so presented to Baiju; but the Tatars were irritated by the haughtiness of the Dominicans. The Frankish visitors were treated with contempt: for nine weeks all answer to their letters was refused. Thrice Baiju even ordered their death. At last, on July 25, 1247, they were dismissed with the *Noyan's* reply, dated July 20, which complained of the high words of the Latin envoys, and commanded the pope to come in person and submit to the Master of all the Earth (the Mongol emperor). The mission thus ended in complete failure.

See Vincent of Beauvais, Speculum historiale, book xxxii. (sometimes quoted as xxxi.), chaps. 26–29, 32, 34, 40–52 (*cf.* pp. 453 A-454 B in the Venice edition of 1591); besides these, several other chapters of the Spec. *hist.* probably contain material derived from Simon, *e.g.,* bk. xsxi. (otherwise xxx.), chaps. 3, 4, 7, 8, 13, 32; and bk. xxx. (otherwise xxix.), chaps. 69, 71, 74–75, 78, 80. See also d'Ohsson, *Histoire des Mongols,* ii. 200–201, 221–233; iii. 79 (edition of 1852); Fontana, Monumenta Domtnicana, p. 52 (Rome, 1675); Luke Wadding, Annales *Minorum,* iii. 116–118; E. P. d'Avezac's Introduction to Carpini, pp. 404–405, 433–434, 464–465, of vol. iv. of the Paris Geog. Soc.'s *Recueil de Voyages,* etc. (Paris, 1839); W. W. Rockhill, *Rubruck,* pp. xxiv.–xxv. (London, Hakluyt Soc., 1900); C. R. Beazley, *Dawn of Modern Geography,* ii. 277, and *Carpini and Rubruquis,* 269–270.

SIMON'S TOWN, a town and naval base in South Africa, used by the British admiralty under agreement with the South African government, 22½ mi. from Cape Town. A tidal basin of 26 ac.. with a depth of 30 ft. at L.W.O.S.T. was completed in 1910. South of this, in a reclaimed area, are the dockyards. Simon's Town dates from the close of the 17th century and is named after Simon van der Stel, governor of the Cape. 1679–99. Pop. (1951) 7,776 of whom 3.374 were Europeans. On the south side is a popular seaside resort. An industrial area has been laid out and there is a large fish oil refinery.

SIMONY, an offence, defined below, against the law of the church. The name is taken from Simon Magus (*q.v.*). In the canon law the word bears a more extended meaning than in English law. "Simony according to the canonists," says Ayliffe in his Parergon, "is defined to be a deliberate act or a premeditated will and desire of selling such things as are spiritual, or of anything annexed unto spirituals, by giving something of a temporal nature for the purchase thereof; or in other terms it is defined to be a commutation of a thing spiritual or annexed unto spirituals by giving something that is temporal." In the Corpus *juris canonici* the Decretum (pt. ii. cause i. quest. 3) and the Decretals (bk. v. tit. 3) deal with the subject. The offender whether *simoniacus* (one who had bought his orders) or *simoniace promotus* (one who had bought his promotion), was liable to deprivation of his benefice and deposition from orders if a secular priest,—to confinement in a stricter monastery if a regular. No distinction seems to have been drawn between the sale of an immediate and of a revers'ionary interest. The innocent *simoniace promotus* was, apart from dispensation, liable to the same penalties as though he were guilty. Certain matters were simoniacal by the canon law which would not be so regarded in English law, *e.g.,* the sale of tithes, the taking of a fee for confession, absolution, marriage or burial, the concealment of one in mortal sin or the reconcilement of an impenitent for the sake of gain, and the doing homage for spiritualities. So grave was the crime of simony considered that even infamous persons could accuse of it. English provincial and legatine constitutions continually assailed simony.

For the purposes of English law simony is defined by Blackstone as the corrupt presentation of any person to an ecclesiastical benefice for money, gift or reward. The offence is one of purely ecclesiastical cognizance, and not punishable by the criminal law. The penalty is forfeiture by the offender of any advantage from the simoniacal transaction, of his patronage by the patron, of his benefice by the presentee; and now by the Benefices Act 1892, a person guilty of simony is guilty of an offence for which he may be proceeded against under the Clergy Discipline Act 1892. An innocent clerk is under no disability, as he might be by the canon law. Simony may be committed in three ways—in promotion to orders, in presentation to a benefice, and in resignation of a benefice. The common law (with which the canon law is incorporated, as far as it is not contrary to the common or statute law or the prerogative of the Crown) has been considerably modified by statute. Where no statute applies to the case, the doctrines of the canon law may still be of authority. Both Edward VI. and Elizabeth promulgated statutes against simony.

The general result of the law before the Benefices Act 1898, as gathered from statutes and decisions, may be stated as follows: (1) it was not simony for a layman or spiritual person not purchasing for himself to purchase, while the church was full, an advowson or next presentation, however immediate the prospect of a vacancy; (2) it was not simony for a spiritual person to purchase for himself a life or any greater estate in an advowson, and to present himself thereto; (3) it was not simony to exchange benefices under an agreement that no payment was to be made for dilapidations on either side; (4) it was not simony to make certain assignments of patronage under the Church Building and New Parishes Acts; (5) it was simony for any person to purchase the next presentation while the church was vacant; (6) it was simony for a spiritual person to purchase for himself the next presentation, though the church be full; (7) it was simony for any person to purchase the next presentation, or in the case of purchase of an advowson the next presentation by the purchaser would be simoniacal if there was any arrangement for causing a vacancy to be made; (8) it was simony for the purchaser of an advowson while the church was vacant to present on the next presentation; (9) it was simony to exchange otherwise than simpliciter; no compensation in money might be made to the person receiving the less valuable benefice. The law on the subject of simony was long regarded as unsatisfactory by the authorities of the church. In 1879 a royal commission reported on the law and existing practice as to the sale, exchange and resignation of benefices. Many endeavours were made in parliament to give effect to the recommendations of the commission, but it was not until 1898 that any important change was made in the law. The Benefices Act of that year absolutely invalidated any transfer of a right of patronage unless (a) it is registered in the diocesan registry, (b) unless more than 12 months have elapsed since the last institution or admission to the benefice, and (c) unless "it transfers the whole interest of the transieror in the right" with certain reservations; in other words, the Act abolished the sale of next presentations, but it expressly reserved from its operation (a) a transmission on marriage, death or bankruptcy or otherwise by operation of law, or (b) a transfer on the appointment of a new trustee where no beneficial interest passes. It also substituted another form of declaration for that required under the Clerical Subscription Act 1865, and this form has been again amended by the measure of 1923 (*infra*). It abolished the sale by auction of an advowson in gross, and empowered a bishop to refuse to institute or admit a presentee to a benefice on a number of specified grounds: among others, on the ground of possible corrupt presentation through a year not having elapsed since the last transfer of the right of patronage, and constituted a new court to hear appeals against a bishop's refusal to institute. This court consists of a judge of the Supreme Court, who shall decide all questions of law and of fact, and of the archbishop, who gives judgment. The Benefices Act 1892 has non been amended in many details by the Benefices Act 1898 Amendment Rfeasure 1923 and the Benefices Rules 1926.

In Scotland sirnony is an offence both by civil and ecclesiastical law. The rules are generally those of the canon law. There are few decisions of Scottish courts on the subject. By the Act of 1584, c. 5. ministers, readers and others guilty of simony provided to benefices were to be deprived. An Act of Assembly of 1753 declares pactions simoniacal nhereby a minister or probationer before presentation and as a means of obtaining it bargains not to raise a process of augmentation of stipend or demand reparation or enlargement of his manse or glebe after induction.

In the United States, there is no recognition of simony in the courts.

SIMOOM: *see* WIND.

SIMPLICIUS, SAINT (d. 483). pope from 468 to 483. was born at Tivoli. During his pontificate the western empire was overthrown, and Italy passed into the hands of the barbarian king Odoacer (476). In the east. the usurpation of the empire by Basiliscus (475–476), who supported the Rfonophysites, gave rise to many ecclesiastical troubles. The emperor Zeno, having procured the removal of Basiliscus, endeavoured to compound with the Monophysite party; and Acacius. bishop of Constantinople. nho had previously been on the pope's side in defense of the council of Chalcedon, abandoned Simplicius and subscribed to the Henoticon. the conciliatory document promulgated in 482 by the emperor.

Simplicius died on March 2, or perhaps March 10, 483. He is commemorated on hfarch 2.

SIMPLICIUS (6th century A.D.), Greek philosopher, a native of Cilicia, was a pupil of Damascius at Athens and of Ammonius at Alexandria ; his work displays the influence of both these schools of Neoplatoriism (*q.v.*). The school of philosophy at Athens having been disendowed and its teaching forbidden (529). Damascius, Simplicius, Priscianus and four others resolved in 531 or 532 to seek refuge with Chosroes, king of Persia, but within two years they returned to Greece.

After his return Simplicius wrote commentaries on Aristotle's *De coelo, Physica, De anima* and *Categoriae,* which, with a commentary on the *Enchiridion* of Epictetus. have survived. These contain many valuable fragments of the older philosophers as well as of his immediate predecessors. One of his general principles is that Xristotle is in harmony with Plato, being opposed only to a superficial understanding of his words. (D. J. A.)

SIMPLON PASS, Alpine pass and tunnel. Not known early save as a purely local route, the Simplon pass rose into importance when Napoleon caused the carriage road to be built across it between 1800 and 1807. The Simplon tunnel was opened in 1906. The pass proper starts from Brig in the upper Rhône valley. $90\frac{1}{2}$ mi. by rail from Lausanne. From Brig it is about 14 mi. to the pass (6,592 ft.), close to which is the hospice (first mentioned in 1235) in charge of Austin canons from the Great St. Bernard. The road descends past the Swiss village of Simplon, and passes through the wonderful rock defile of Gondo before entering Italy above Iselle (28 mi. from Brigj. There the road joins the railway line through the tunnel, which is $12\frac{1}{4}$ mi. in length, and 2,313 ft. high, being thus both the longest and the lowest tunnel through the Alps.

From Iselle it is about 11 miles by rail to Domo d'Ossola, whence the Toce or Tosa valley is followed to the Lago Maggiore (23 miles).

SIMPSON, SIR JAMES YOUNG (1811–1870), Scottish obstetrician. whose fame rests principally upon his pioneer work in the introduction of anesthesia into midwifery practice, was born at Bathgate. Linlithgowshire, Scot.. on June 7. 1811. He was sent at the age of 14 to Edinburgh university and obtained his M.D. degree in 1832. He was elected senior president of the Royal Medical society of Edinburgh in 1835 and in 1837–38 acted as deputy for John Thonison, professor of pathology. In 1840 he was appointed to the chair of midwifery in the university. When news of the first trials of ether reached Scotland in 1846, Simpson immediately realized its potential value and tried it in obstetric practice. In March 1847 he advocated its use in a paper read before the Royal Medical society. He continued. however. to make systematic search for more efficient anesthetics, carrying out many self-experiments with his assistants, and on Nov. 4. 1847, he discovered the anesthetic properties of chloroform. He published a full account of chloroform (1847) in which he stressed its advantages over ether and strongly advocated its use in surgical operations and in obstetric practice.

The use of chloroform for the relief of pain in childbirth mas violently opposed both on medical and on theological grounds. but Simpson's uncompromising advocacy and, finally. the administration of chloroform to Queen Victoria at the birth of Prince Leopold in 1853. silenced all opposition.

Apart from his great work on anesthesia, Simpson made contributions of permanent value to many departments of obstetrics and gynecology. His principal writings are *Obstetric Memoirs and Contributions* (2 vol., 1855–56); *Selected Obstetrical and Gynaecological Works* (1871) ; *Anaesthesia, Hospitalism, Homoeopathy, etc.* (1871) ; *Clinical Lectures on the Diseases of Women* (1872). He was also greatly interested in archaeology and in the history of medicine; two volumes of his *Archaeological Essays* were published in 1873. He was appointed one of the queen's physicians, for Scotland in 1847 and in 1866 was created a baronet. He died on May 6. 1870, in London.

See John Duns, *Memoir of Sir J. Y. Simpson, Bart.* (1873) ; E. B. Simpson, *Sir James Young Simpson* (1896) ; H. L. Gordon. *Sir James Young Simpson and Chloroform* (1897). (W. J. BP.)

SIMPSON, MATTHEW (1811–1884), U.S. bishop of the Methodist Episcopal Church. was born in Cadiz, O., on June 21, 1811. Largely self-educated, he began to practise medicine in 1833, but the same year was licensed as a preacher of the Methodist Episcopal Church. In 1837 he was appointed professor of natural science in Allegheny college, Meadville; and was from 1839 until 1848 president of the newly established Indiana Xsbury (later De Pauw) university. Greencastle, Ind. He was editor of the *Western Christian Advocate,* which he made a strong temperance and anti-slavery organ, from 1848 to 1852, and was elected a bishop in May 1852. Simpson died on June 18. 1884. in Philadelphia.

He published *A Hundred Years of Methodism* (1876) and *Lectures on Preaching* (1879), and edited a *Cyclopedia of Methodism* (1878). *A* volume of his *Sermons* (1885) was edited by G. R. Crooks.

See his *Life by G. R.* Crooks (1890) ; E. M. Wood, *The Peerless Orator* (1909).

SIMROCK, KARL JOSEPH (1802–1876), German poet and man of letters, was born on Aug. 28. 1802. at Bonn, where his father was a music publisher. He studied law at Bonn and Berlin, and in 1823 entered the Prussian civil service: from which he was expelled in 1830 for writing a poem in praise of the French July revolution. He became lecturer and eventually (1850) professor at Bonn, where he died on July 18. 1876. Simrock established his reputation by his excellent modern rendering of the *Nibelungenlied* (1827), of the poems of Walther von der Vogelweide (1833), and other Old High German poems.

Of his republications the most popular and the most valuable were the *Deutsche I'olksbucher,* of which 55 were printed between 1839 and 1867. His best contribution to scholarship was his *Handbuch der deutschen Mythologie* (1853–55). Simrock took a high place among students of Shakespeare by his *Quellen des Shakespeare in Novellen, Märchen und Sagen* (1831); and afterward he translated Shakespeare's poems and a considerable number of his dramas. His *Ausgewählte Tt'erke* were published by G. Klee (12 vol., 1907).

See N. Hocker, *Karl Simrock, sein Leben und seine Werke* (1877).

SIMS, WILLIAM SOWDEN (1858–1936), U.S. naval officer! was born of American parents at Port Hope, Ont.. on Oct. 15, 1858, moving in childhood to Pennsylvania. He graduated from the U.S. Naval academy in 1880, and for eight years served on board various ships in the North Atlantic. During 1889–93 he was with the nautical school ship "Saratoga." was transferred to the Pacific station and later to the China station. From 1897 to 1900 he was naval attaché to the U.S. embassy at Paris and at St.

Petersburg (Leningrad), but in 1900 he returned to the Pacific station.

Convinced of the inadequacy of U.S. methods of target practice, he pressed his views upon the government, and in the end was enabled to arrange for a gunnery test and prove his claims. This resulted in his being made inspector of target practice in the bureau of navigation, where he served seven years (1902–09). In 1907 he was made commander and appointed naval aide to Pres. Theodore Roosevelt. and in 1909 he became commander of the battleship "Minnesota."

During a visit of the Atlantic fleet to England in 1910, Commander Sims caused a stir at a dinner at the Guildhall, London, where he said: "Speaking for myself, I believe that if the time ever comes when the British empire is menaced by an external enemy you may count upon every man, every drop of blood, every ship and every dollar of your kindred across the sea." A semi-official protest against this utterance was made at Washington by the German government, but the incident ended in a severe reprimand from the president of the United States.

In 1911 Sims was promoted captain and for two years was a member of the class of the Naval War college, Newport, R.I. During 1913–15 he was in command of the Atlantic torpedo flotilla and in 1916 in command of the battleship "Nevada." In 1917 he returned to Newport as president of the Naval War college. When the United States entered World War I in April 1917 he was chosen to command U.S. naval forces in European waters. In January he had been promoted rear admiral and in May he was given the temporary rank of vice-admiral.

On the conclusion of the war he relinquished command of the fleet and resumed his position as president of the Naval War college. In 1920 he made a formal report to the U.S. navy department, charging it with serious errors in the conduct of naval operations during the war.

He published The Victory *at* Sea (1920). He died in Boston, Mass., on Sept. 28, 1936.

SIN is the name given to moral evil, when regarded from the point of view of religion, as distinguished from that of civic law or that of ethics. The Christian's ideal is to do all things as unto the Lord; and he looks upon his shortcomings as offences against a divinely given law or as grieving the Holy Spirit. But if this aspect of sin, or the religious associations with which moral evil is tinged, be of high significance for religious life, the nature of sin as moral evil correlated with responsibility and guilt, is fundamentally a question for ethics and psychology. That "sin is lawlessness," even when the law transgressed is regarded as divine, is a description which needs amplification, in order to fulfil the requirements of theological doctrine.

Of the several conditions of accountable moral conduct, the one just indicated may be treated first; the forthcomingness of a law, of which sin is transgression; or of a mark, of which sin is the missing. Moral law is a social acquisition; and knowledge of it is socially mediated, not innate to the individual. It is only when we begin to find certain kinds of behaviour expected of us, as what we owe, and become spectators of our conduct from the point of view from which others see us, that conscience emerges in us. It is not inborn, like instinct; nor does the soul possess it, before embodiment. We are born non-moral, not sinners. Further, St. Paul's teaching, that where no law is, sin cannot be imputed, needs to be supplemented. This brings us to the second condition of the possibility of sin. In order that an individual be accountable, it is not enough that there is moral law forthcoming, whether primitive customs or unconditional standards of Christian ethic; he must be aware of them as binding on himself, and must be in a position to perceive his act to be a shortcoming at the time of its occurrence. This reference to time is also essential. For instance, a heathen who may be blameless as to such law as he knows, is no sinner against Christian law that, as yet, he cannot know; and if he become a Christian and learn a higher ethic, he cannot then rightly accuse himself of guilt, in that, in his heathen past, he left undone what, had he been a Christian he should have done. The conduct of the infant that knows no law, or that of the adult heathen who obeys some law but knows not the highest, cannot even from the Christian standpoint, be deemed sinners. Else we should have to attribute sin to snakes and volcanoes. For the only relevant difference between the moral and the non-moral agent, is that the former can, and the latter cannot, be aware of law having dominion over it. We cannot assert sin to be non-compliance with moral law, as distinct from known moral law, without destroying the ethical significance of sin. All sin is imperfection; not all imperfection is sin. Thus it follows that there cannot be one absolute standard of perfection, to fall short of which, in any conditions and at any stage of moral enlightenment, convicts of sin. The only relevant standard is comparable to a sliding scale: it is what, to the all-seeing eye of God, is the highest that a given agent can recognize, at the time of his activity that is in question. Hence the wisdom of the counsel; "then at the balance let's be mute." Development is incompatible with perfection; the Christian, of ali men, cannot say it is incompatible with sinlessness.

Turning now from the moral law and knowledge thereof to the acts and conduct to which ethical standards are applicable, we may consider the remaining conditions of what, in the strict sense, is to be called sin. Conscience and moral status, it has been said, are not innate; they are socially acquired, as human experience evolves from its earliest stages. But certain instincts and impulsive or appetitive tendencies are undoubtedly inherited. That is to say that in the body, with which an individual subject or soul becomes associated, are already ingrained aptitudes, etc., transmitted and fixed by heredity, which evoke specific reactions and responses from the soul, with its actual and potential faculties and capacities. Such appetites, instincts, strivings, etc. are involuntary, because, as yet, will or volition is not in existence. They are necessary and inevitable; the embodied soul is not responsible for them, and had no part in moulding them. They are also, from the biologist's point of view, natural or normal; not the outcome of derangement. Some of them, at least, are essential to the health and life of both individual and race. Theology must affirm that they belong to man, as it has pleased God to make him, *i.e.*, through evolutionary process. Lastly they are not only non-moral, in that they are involuntary and prior to conscience, but also neutral, in respect of what shall eventually be made out of them by the moralized person. They are the basis of virtues as well as of vices. In themselves, therefore, these propensities, or tendencies of the stock, are not sinful; no natural passion is base-born or condemnable. They are, however, the primary stuff out of which sinful conduct is shaped. But it is the will that shapes, not the stuff that is shaped, which alone calls for moral evaluation. They can no more be wicked than can alcohol or prussic acid. For the fact that they are strongly entrenched in us at birth, we are not responsible. Nor are we responsible, for the fact that they continue to assert themselves clamorously, after will and conscience have been acquired, and without respect for moral considerations; though it is thus that arise most of the "manifold temptations that death alone can cure." Temptation, however, is not sin; nor is temptability a sign of sinfulness—it is a condition of morality. But before these ethical and psychological reflections suggested themselves with the urgency they now possess, it was usual, and indeed natural, to call such inborn propensities sinful. Hence the expressions "inherited sin" and "original sin." Theologians who have framed and taught the doctrine of original sin have generally, though not universally, been willing to allow that original sin is not sin proper, and that, unlike actual sin, it is not a matter of moral responsibility and guilt. It is now generally admitted to be "sin" in but a figurative sense. Some would urge that retention of the old name "original sin" is no longer expedient, because ministering to confusion and inconsistency. What is "original" in the sense of innate or thrust upon us willy-nilly, cannot strictly be called sin. The root of sin is not a sinful root. For the fourth condition of the possibility of sinful activity is volition, and indeed intention. There must be capacity to choose between higher and lower ends, as has been recognized throughout the history of the doctrine of sin. Consequently, if there be in us, as some authorities have maintained, a moral taint that cleaves to us at our birth; some tendency, the origin of which must be beyond the conscious exercise of our freedom of will; an abiding root of sin, which a man finds present in himself when his moral consciousness awakes; it must be brought by the soul itself, and have been contracted voluntarily in a life previous to the soul's embodiment. This speculative view has found supporters here and there down the ages; but we have no knowledge as to such life, and certainly, if the soul possessed such moral volition before embodiment, it must somehow have become dispossessed of it on entering into this life, because psychology can trace the development of volition and conscience which, at birth, are absent This suggestion, like all other forms of doctrine of a fall, whether of the race collectively or of each soul singly, has doubtless been cherished because it has seemed difficult to many minds to account otherwise for the prevalence — often assumed to be strictly universal — of sinfulness throughout mankind; also. perhaps, because it seems to explain the emergence of moral evil in God's good world. But, as for the former of these motivations, it is enough to know that the race has solidarity in respect, not of ready-made sin, but of the non-moral appetites, etc. which prompt the will to evil choice As for the latter of them. any kind of fall such as is invoked to account for racial sinfulness, would seem only to put the difficulty further back, not to eliminate it. Evil must have entered into the human world somehow and at some time, whether in Adam, or in Satan, or in each soul in a previous life; and that presents just the same difficulty as does the origination of sin in each man in this life. Indeed, in the case of the theory that sin originated in a previous life, the difficulty would seem to be increased. For had we all been in the same case as Milton's Satan, to account for all sinning without exception, each being the Adam of his own soul, and that before embodinicnt, is hardly possible; whereas our bodily nature supplies the motives which make our sinfulness explicable enough, however condemnable it be. On the other hand, the traditional doctrine that we all owe our sinfulness to the sin of the first parent of the race, either offends our moral consciousness and sense of responsibility or else confounds sinfulness with the non-moral "material" out of which our will makes sin.

Sin has, so far, been dealt with only in its elemental aspects and its earliest stages It is, in fact, there that we encounter the controversial issues, and the features of the problem that present most difficulty and most interest for theology. The more advanced and complex stages present no further disputable issues. But it should be observed that from the dawn of volition. of thought or ideation. and of morality, our blind springs of action cease to be blind. When imbued with volitional response, they become desires, and eventually personal attitudes. Actions engender habits; emotions establish sentiments; and so on We soon discover that appetites, the satisfaction of which yields pleasure, can be stimulated, in order to be enjoyed Hunger may be voluntarily transformed into gluttony, sensibility into voluptuousness; and as knowledge and experience widen the lengths to which "making provision for the flesh" can be carried. become indefinitely extended. But it is not necessary to follow further the development of the intricacy of the moral life of man; the essentials for a sound psychology of sin are manifested, and can be most clearly studied, in the primary moral situations to which attention has here been almost exclusively directed

LITERATURE —For a critical account oi the main theories and treatment from the standpoint of sin-consciousness, see W. E. Orchard, *Modern Theories* of *Sin* (1909). For a discussion of sin on the lines indicated above, see F. R. Tennant, *The Concept of Sin* (1912).

(F. R. T.)

SIN, the name of the moon-god in Sumerian, derived from *zu-en,* usually written *en-zu,* "lord of wisdom" He became one of the principal deities of the (Semitic) Babylonian pantheon, and only in the period of the later West Semitic occupation (22nd–18th centuries) is found any trace of the pure Semitic cult of the moon god, when the title *'ammu, ḫammu* "uncle" appears As god of the new moon he has the title *šeš-ki,* "brother of the earth," pronounced by the Semites *Nannar>Nanna.* The chief seats of his worship were Ur in the South and Harran in northern Assyria, hut the cult at an early period spread to other centres, and temples to the moon-god are found in all the large cities of Babylonia and Assyria. During the period (*c.* 2399–2282 B C.) that Ur exercised a large measure of supremacy over the Euphrates valley, Sin was naturally regarded as the head of the pantheon. It is to this period that we must trace such designations of the god as "father of the gods," "chief of the gods," "creator of all things," and the like. The development of astrological science culminating in a calendar and in a system of interpretation of the movements and occurrences in the starry heavens would be an important factor in maintaining the position of Sin in the pantheon. The name of Sin's chief sanctuary at Ur was E-gish-shir. gal. "house of the great light"; that at Harran was known as E-khul-khul, "house of joys." On seal-cylinders he is rcprrsented as an old man with flowing beard. with the crescent as his symbol. In the astral-theological system he is represented by the number 30, and the planet Venus as his daughter by the number 1 j. The number 30 stands obviously in connection with the thirty days as the average extent of his course until he stands again in conjunction with the sun. The "wisdom" personified by the moon-god is likewise an expression of the science of astrology in which the observation of the moon's phases is so important a factor. The tendency to centralize the powers of the universe leads to the establishment of the doctrine of a triad consisting of Sin, Shamash and Ishtar (q *v.*), personifying the moon, sun and Venus.

Nabunidus, the last king of Babylonia, inaugurated a movement to elevate the cult of Sin to the supreme place in religion, a movement clearly based upon astrological and astronomical theory that the triad, moon. sun and Venus are the controlling forces of divine providence. There is no doubt but that the emphasis placed upon moon worship by Sargon of Agade is due to his Semitic connection; in Arabia and throughout the Semitic races of Western Asia the moon god was from the beginning the most important deity. The consort of Sin was Ningal, to whom a special temple was built at Cr, and her cult was widely known in Syria where her name appears as Nikal. The cult of the Babylonian Sin seems to have been particularly favoured by the Assyrian colony in Cappadocia in the 21st–19th centuries, and among the Hittites of Anatolia and Syria.

SINAI, the name given to the triangular peninsula lying between Egypt, Israel, and Saudi Arabia, with the Mediterranean forming its northern boundary, the Suez canal and Gulf of Suez on the west, and the Gulf of Aqaba to the southeast. Sinai is usually regarded geographically as part of Asia, but poiitically is a governorate of the United Arab Republic (Egypt). Area 23.200 sq.mi. ,Pop. (1960) 126.000.

The oldest rocks and the highest mountains in Sinai are to be found in the southern third of the peninsula, an extension of the Red sea mountains of the African mainland. These form a complex of Pre-Cambrian crystalline rocks: gneisses and schists into which were intruded masses of igneous plutonic rocks with varied igneous dikes veining the whole great complex. They form high, rugged mountains predominantly red in colour, from which the Red sea takes its name. In the west, basaltic lava flows, probably of Miocene age, rest upon the old rocks. Along the Gulf of Suez coast a narrow plain of recent rocks separates the mountains from the sea except just south of the Wadi Feiran where for 20 mi. abrupt cliffs of red granite rise from the shore. All along the shore of the Gulf of Aqaba the Sinai mountains rise in a precipitous wall. North of the well-watered Wadi Feiran outcrops of red (Nubian) sandstone terminate the ancient core of the peninsula. Against them to the north in a series of dissected scarps successively younger strata outcrop, mainly of limestone of Cretaceous and Eocene age. The gravel-covered central part of the limestone plateau, known as the wilderness of el Tih ("the wandering") averages 3.000 ft.: its highest part, the Egma plateau in the south, attains 5,335 ft. To the north the land slopes down to the Mediterranean, its surface broken by inlier of older rocks creating marked limestone and sandstone hill masses, principally Yelleg (3,570 ft.). Hellal (2,900 ft.), both of middle Cretaceous series, and Maghara (2.400 ft.) of Jurassic age. Near the Mediterranean shore line is a broad tract of sand dunes, some over 300 ft. high. This northern shore line, fringed with salt marsh, is sinking. In the west this is compensated for locally by the eastward drift of Nile sediment.

The granite peaks in the south, the highest mountains in the governorate of Sinai, include Katharina (8,651 ft.), Um Shomer (8.482 ft.), El Thebt (7,997 ft.) and Musa or Mt. Sinai (7.495 ft.). The area is difficult of access: deep, rocky gorges hem in the maze of sharp ridges and gaunt peaks. This mountainous area experiences a few inches of rain each year, mostly in irregular, heavy downpours, insufficient for agriculture, but sustaining springs and wells, and in a few bordering wadis small streams flow and nourish oases, such as at Feiran. The greater part of the scanty drainage of the northern two-thirds of the peninsula is ultimately to the Wadi al Arish which, rising in the Egma plateau, eventually reaches the Mediterranean. For most of the year the plateau is waterless except for a few permanent springs, as at Nakhl.

The Wadi al Arish rarely carries water to the sea, but water is obtained from wells dug in its bed. Underground water is also tapped by wells in the hollows between dunes along the northern coast where. four or five feet down, a foot or so of fresh water rests on salt.

The railway between Palestine and Egypt was inoperative to some extent after 1948. The main paved road runs from Ismailia to Abu Aweiqila, where it forks, one branch going north to Gaza and the other to El Auja. The old pilgrim route, still in use, runs from Suez via Nakhl, Al Thamed and Aqaba to Medina and Mecca. Most of the country is not suitable for wheeled vehicles but it is possible to pass along the wadi beds when these are not in flood.

In general the climate is healthful but liable to sudden changes in temperature. In the mountain regions the nights are usually cold, but over most of the peninsula the heat of summer is intense. The rainy period from mid-October to mid-April often results in serious floods In a normal year there is sufficient rainfall to support scrub and tamarisk bushes and even a few poor crops. Vegetation consists mainly of tamarisk and camel's-thorn, with date palms at al Arish, Feiran, and al Tor. Agriculture is practised only in limited areas. A dam was recently built in the Wadi al Arish.

Animals are rare. They include ibex, gazelle, sand fox, leopard, wildcat, jackal, hare, hedgehog and mole. Falcons and eagles are indigenous, and in addition there are the seasonal migrants such as quail, partridge and grouse, which are shot for food as are the ibex and gazelle.

Sinai is sparsely populated by Bedu tribes, which are divided into two main groups. In the south the most numerous are the Sawalihah; in the north, the Terabin. The estimated Bedu population amounted in 1948 to about 17,000. The people of the coastal area are an admixture, and after 1948 there was a great influx of refugees encamped in the Gaza strip. A small group, the Jebeliyeh, situated round St. Catherine's monastery, are said to be the direct descendants of Bosnian and Wallachian serfs settled there by Justinian as guards for the monastery and forcibly converted to Islam at the time of the Arab invasion. A few retained their Christianity, the last descendant dying in 1750. The majority of the sedentary population lives near the north coast, especially at al Arish. the administrative centre (pop. [1947] 10,791) and at Kantara Sharq (East) on the eastern side of the Suez canal—pop. (1947) 13,384.

History. — The name Sinai is thought to be derived from the Akkadian moon-god Sin. Mt. Sinai is famous as the scene of the giving of the law to Moses and the entering of the Israelites into a covenant with the Lord, but there is considerable doubt as to which of the mountains of Sinai was the relevant site. Mt. Serbal was originally so accepted. with the result that the city of Paran was built at its foot and in time became a cathedral city and a bishopric; but the claims of Mt. Sinai were later preferred, and on this mountain was built St. Catherine's monastery.

In the Wadi al Arish, at al Kossaima, Bir Hassaneh and Nakhl, implements of Acheulo-Levalloisian type were discovered, and it is therefore thought that paleolithic man was present in north, central and southwestern Sinai. Neolithic and Chalcolithic remains were found on the Ismailia-Bir Hassaneh track. Stone circles, rectangular stone ruins and circular tombs, all of uncertain date, occur in the Wadi Solaf and in many other regions of the peninsula. The ancient Egyptians mined turquoise and copper in the mountains, in the Wadi Maghara and in the Feiran oasis; their inscriptions date from the 1st dynasty. At Serabit al Khadim, Sir W. M. Flinders Petrie found a temple dedicated to Hathor. It was used by the mine workers and contained records and inscriptions of many of the Middle and New Kingdom rulers. The last Egyptian king to make recorded offerings at this place was Rameses V of the 20th dynasty.

The Serabit inscriptions collected by Petrie and published by A. H. Gardiner and E. T. Peet may be the earliest alphabetic script, but the matter is still undecided. The passage of the Israelites through Sinai and the route and date of the Exodus are still matters for argument. At Sheikh Zuwaid in the north of Sinai there is an Egyptian frontier fortress dating at least from the time of the 18th dynasty, and it is likely that there was a chain of these fortresses extending along the northern coastal route. There is evidence from the texts and from surface finds that the Egyptians held all this region at the time when they were effectively controlling Palestine and Syria. After the decline of the Egyptian empire, Nabataeans from Petra controlled the trade routes of the Wadi 'Araba and the peninsula during the first two centuries B.C., until they were defeated by the Romans in A.D. 106. The region then became the Arabian province of the Roman empire and a capital was established at Bosra.

During the early Christian period Sinai became the home of many hermits, particularly in the southern mountain region where natural springs made habitation possible.

The building of the monastery of St. Catherine dates from AD. 530 when Justinian I, after complaints of robber incursions from the monks who had settled there, fortified the traditional site of the burning bush observed by Moses on the lower slopes of Mt. Sinai. This provided a centre for the scattered communities of Christians, and was spared by the invading Moslems; to conciliate the latter, the monks, according to tradition, erected the small mosque that stands within the malls. The monastery was a pilgrimage centre during the middle ages. It still retains much of its original appearance and has had an unbroken history since the 6th century. The original gray granite walls (280 x 250 ft.) still stand, and so does the church dedicated to the Virgin Mary, which was built at the same time. In the apse is a mosaic of the Transfiguration, probably also dating from this period, though it has been restored. The monastery's greatest treasures are its icons, some of nhich are prior to the 8th century, and its manuscripts. These, housed in the library built in 1945, are mainly in Greek and Arabic. In 1949–50 most of these manuscripts were microfilmed by the American Foundation for the Study of Man, acting on behalf of the Library of Congress and with the assistance of the University of Alexandria.

The most important manuscript now in the monastery is the Codex Syriacus, a Syriac text of the Gospels written about 400. The Codex Sinaiticus, now in the British museum, is a Greek manuscript of the Bible dating to the 4th century.

After 1517 Sinai formed part of the Ottoman empire and the country was administered by an official from Constantinople. When Egypt became independent of Turkey, conditions in Sinai deteriorated and traveling became difficult. Order was not restored until 1831, when Ibrahim Pasha, son of Mohammed Ali, advanced through Sinai and defeated the Turks at Acre. At the Treaty of London in 1840 Egypt was nominally restored to Turkish rule, and remained in this position until the outbreak of war in 1914. In October of that year Turkish forces seized al Arish, and in 1915 and 1916 they advanced to the Suez canal, but were driven off. In Jan. 1917 the battle of Rafah in northern Sinai marked the final advance through the country of the British army. At the end of World War I Sinai was returned to Egypt and has since been administered by that country. After 1948 the Sinai-Israeli border was the scene of frequent frontier incidents. In 1956 the Israeli army advanced through Sinai to the Suez canal, defeating units of the Egyptian army.

As the land bridge between Asia and Africa, Sinai retains considerable importance in middle eastern affairs.

SINAIA, a town of Rumania, on the railway from the city of Ploeşti to Braşov in the region of Ploeşti. Pop. (1956) 9,006. It resembles a large model village, among the pine forests of the lower Carpathians and along the banks of the Prahova, a swift alpine stream. The monastery of Sinaia, founded by Prince Michael Cantacuzino in 1695, was the residence of the royal family until the present chateau was built. Its library contains valuable jewels belonging to the Cantacuzene family. Castle Peleş, the modern palace, named after the hill on which it stands, is of a mixed style of architecture on the whole Germanic. Until 1850 Sinaia consisted of little more than the monastery and a group of huts.

SINALOA, a Mexican state on the Gulf of California and Pacific ocean. established in 1830. Pop. (1950) 635,681; area 22,-582 sq.mi. Sinaloa is bounded north by Sonora, east by Chihuahua and Durango and south by Nayarit, with about 400 mi. of coast on the west. The state is coastal. barren and tropical, with mountains on its eastern border. Five main streams and river valleys run from these mountains to the coast. Each river valley system is relatively isolated and is the scene of extensive irrigation, hydroelectric and communications projects. The Miguel Hidalgo dam on the Fuerte river, completed in 1956, waters about 123,550 acres.

Sinaloa is primarily an agricultural area which raises wheat, chick-peas, cotton, tobacco?sugar cane. tomatoes, fruits and winter vegetables on irrigated lands. Its cities and towns support local manufacturing, notably production of beer, ice, cigarettes, cooking oils, soap, cotton textiles and an iron foundry and a plating and galvanizing establishment.

The most important coastal industry is fishing, chiefly for sharks, the livers of which are processed into vitamin products, and for shrimps, canned and frozen locally. Tourism and game fishing are also significant.

The'backbone of Sinaloa is the Mexican Southern Pacific railway, acquired from its U.S. owners by Mexico in 1951. It runs from Nogales to Guadalajara and, in its course through Sinaloa, parallels the coast and ties the river valleys together. A spur of the Southern Pacific line extends to the water's edge at Mazatlán, where there are improved port works and a large airport. The Pacific highway, which reaches Nogales, ties Culiacbn (*q.v.*), the state capital and commercial centre, to Mazatlán (*q.v.*), and both to Guadalajara.

A railway between Mazatlán and Durango opened agricultural and mining outlets. The latter are of considerable importance, as Sinaloa produces salt, graphite, manganese, gold, silver, copper, iron and lead. (J. A. Cw.)

SINANTHROPUS (PEKING MAN). Remains of this significant fossil mere found in a cave or fissure filling at Chou-k'ou-tien, about 31 mi. S.W. of Peking. The site was discovered in 1921 by G. Anderson, W. Granger and O. Zdansky and the latter conducted the first excavations in 1923. In a Middle Pleistocene faunal assemblage, containing rhinoceros, deer, horse, pig, bears, sabre-toothed tiger, hyena, giant beaver (*Trogontherium*), etc., several human teeth were found (*Homo* sp.): a large lower molar of unusual pattern, discovered by B. Bohlin on Oct. 16, 1927, is the type specimen of *Sinanthropus pekinensis*.

During the excavations up to 1940, remains of about 45 individuals of *Sinanthropus* were found, including many isolated teeth, parts of lower jaws and the remains of 14 skulls, but of the rest of the skeleton little is known. The skulls had been damaged for the purpose of extracting the brains — in all cases the surrounding of the foramen magnum was damaged and this was the only part of the skull which could not be reconstructed — and the long bones had been broken to extract and, presumably eat, the marrow. The industry associated with the bones consisted of crude tools, made largely in quartz. Layers of ashes showed that Sinanthropus also used fire.

Since D. Black (1932) pointed out the close relationship between Sinanthropus and Pithecanthropus *erectus* from Java, some authors write Pithecanthropus pekinensis or even Pithecanthropus *erectus* pekinensis rather than Sinanthropus, putting the latter into the same genus as Java Man.

The thick skull is long and low with a prominent continuous supraorbital ridge and a cranial capacity varying from about 915 to 1,225 c.c. The dentition is robust, the pattern of the molars being complicated by secondary wrinkles. The chinless lower jaws exhibit a strong sexual dimorphism. Body height is estimated as about 5 ft. for the males and 43 ft. for the females.

D. Black's and F. Weidenreich's material was lost during World War II, after which only a few teeth were found at Chou-k'ou-tien, but more complete finds were reported from southern China.

See also MAN, EVOLUTION OF: Pithecanthropus; PITHECANTHROPUS.

For original descriptions of Sinanthropus (including industry and fauna) see Bull. geol. *Soc.* China (1930), and Palaeont. *Sinica* (1931–45). (G. H. R. V. K.)

SINCLAIR, the name of an old Scottish family, members of which have held the titles of earl of Orkney and earl of Caithness. The word is a variant of Saint Clair.

SIR WILLIAM SINCLAIR, OR SAINT CLAIR (c. 1260–c. 1303), was the descendant of a line of Anglo-Norman barons, one of whom obtained the barony of Rosslyn from King David I. in the 12th century. Sir William took part in the dispute over the succession to the crown of Scotland in 1292, and was one of the leaders of the Scots in the revolt against Edward I. His grandson SIR WILLIAM SINCLAIR, was slain by the Saracens in August 1330, while journeying through Spain to Palestine with Sir James Douglas, the bearer of the heart of Bruce. This Sir William Sinclair married Isabel, daughter of Malise, earl of Strathearn, Caithness and Orkney (d. c. 1350), and their son Sir Henry Sinclair (d. c. 1400) obtained the earldom of Orkney by a judgment of the Norwegian king Haakon VI. in 1379. He then helped to conquer the Faeroe Islands, and took into his service the Venetian travellers, Niccolo and Antonio Zeno, sailing with Antonio to Greenland.

WILLIAM, the 3rd earl of his line, whose earldom of Orkney was a Norwegian dignity, was made chancellor of Scotland in 1454 and Lord Sinclair and earl of Caithness in 1455. When in 1470 the Orkney Islands were ceded by Norway to King James III. he resigned all his rights therein to his sovereign and was known merely as earl of Caithness. His eldest son, William, having offended his father by his wasteful habits, the earl settled his earldom on his eldest son by another marriage, also called William, who was killed at Flodden in 1513. The elder William, however, inherited the title of Lord Sinclair, and the family was thus split into two main branches.

GEORGE, 4th earl of Caithness (*c.* 1525–1582), a son of the 3rd earl, was a Roman Catholic and a supporter of Mary Queen of Scots, but he was mainly occupied with acts of violence in the north of Scotland. His grandson George, the 5th earl (c. 1566–1643), was outlawed and compelled to fly to the Shetlands. He left many debts, and his great-grandson and successor, George, the 6th earl (d. 1676), who was childless, arranged that his estates should pass to a creditor, Sir John Campbell, afterwards earl of Breadalbane.

Campbell was created earl of Caithness in 1677, but the title was also claimed by George Sinclair (d. 1698), a grandson of the 5th earl, and in 1681 the privy council decided in his favour. When Alexander, the 9th earl, died in 1765 the title was successfully claimed by William Sinclair (d. 1779), a descendant of the 4th earl, who became the 10th earl.

The title of Lord Sinclair passed from William, the 2nd lord, who died about 1488, to John (1610–1676), who became the 9th lord in 1615. At first a covenanter, afterwards he became a royalist, and was taken prisoner at the battle of Worcester. He died without male issue and the title became dormant. His estates, however, passed to his grandson, Henry St. Clair (1660–1723), the son of his daughter Catherine (d. 1666) and her husband, John St. Clair of Herdmanston, and in 1677 Henry was created Lord Sinclair with the precedence of the older title. He had two sons, John Sinclair (1683–1750) the Jacobite, and James Sinclair, who became a general in the British army, and was also ambassador at Vienna and Turin and a member of parliament for many years. After the attainder of John, in consequence of his share in the rising of 1715, the family estates were settled on James, but he resigned them to his elder brother when the latter was pardoned in 1726. The pardon, however, did not include the restoration of the title. Earlier in life John Sinclair had killed a man named Shaw in a duel and had afterwards shot this man's brother. He was tried by court-martial and sentenced to death, but was pardoned. An account of the proceedings in the court-martial was edited by Sir Walter Scott for the Roxburghe Club (Edinburgh, 1828). Sinclair himself wrote Memoirs *of the Rebellion*, published by the Roxburghe Club in 1858.

Neither of the brothers left male issue, and the title devolved upon a cousin, Charles St. Clair (d. 1775), who was not included in the attainder. Charles did not claim it, but in 1782 his grandson Charles (1768–1863) was declared to be Lord Sinclair. He was a Scottish representative peer from 1807 to 1859 and is the ancestor of the present holder of the title.

See Sir R. Douglas, *The Peerage of Scotland*, new ed. by Sir J. B. Paul; G. E. (Cokayne), *Complete Peerage;* Sinclair, *The Sinclairs of England* (1887); Sir R. Gordon and G. Gordon, *The Earldom of Sutherland* (Edinburgh, 1813), and Hay, *Genealogy of the Sinclairs of Roslin* (1835).

SINCLAIR, SIR JOHN, BART. (1754–1835), Scottish writer on finance and agriculture, was the eldest son of George Sinclair of Ulbster, a member of the family of the earls of Caithness, and was born at Thurso Castle on May 10, 1754. After studying at Edinburgh, Glasgow, and Trinity College, Oxford, he was admitted to the faculty of advocates in Scotland, and called to the English bar, but never practised. He established at Edinburgh a society for the improvement of British wool, and was the first president of the board of agriculture. His reputation as a financier and economist had been established by the publication. in 1784, of his *History* of *the Public Revenue of the British Empire;* in 1793 widespread ruin was prevented by the adoption of his plan for the issue of exchequer bills. He died Dec. 21, 1835.

SINCLAIR, UPTON BEALL (1878–), U.S. author of the "muckraking" school, was noted for his denunciations of U.S. business practices and of the alleged malign influence of big business in education, religion and the law courts. Born in Baltimore, Md., on Sept. 20, 1878, he was graduated from the City College of New York in 1897 and pursued graduate study at Columbia university.

An extremely prolific writer, Sinclair. produced many early novels, but first won wide recognition nith *The Jungle* (1906), a realistic study of social conditions among immigrant workers in the Chicago stockyards that was instrumental in the passage of pure food laws. With the proceeds he founded the Helicon Home colony, Englewood, N.J., a socialist community. He continued his career as a propaganda novelist with such works as *King Coal* (1917), based on his investigations of the Colorado coal strike in 1913; *100%* (1920), based on the Tom Mooney preparedness day bombing case of 1916 in California; *Oil!* (1927), an examination of the Teapot Dome scandal, the film industry and popular evangelism; and *Boston* (1928), a treatment of the controversial Sacco-Vanzetti case. Between 1917 and 1927 he also wrote a series of nonfiction studies of aspects of U.S. life. *Tlze Profits of Religion* (1918); *The Brass Check* (1919), a study of journalism; *The Goose-Step* (1923) and *The Goslings* (1924), dealing with education; *Mammonart* (1925); and *Money Writes!* (1927); and an autobiographical account of his early life, *American Outpost* (1932). Sinclair ended his long activity in the Socialist party in 1933 by organizing the EPIC ("End Poverty in California") movement in California; in 1934 he was defeated as Democratic candidate for governor.

In 1940 Sinclair began a widely read series of contemporary historical novels covering the period preceding and including World War I. The hero of the series, Lanny Budd, witnesses the rise of Naziism in Germany and later becomes a personal representative of Pres. Franklin D. Roosevelt. Included in the series were *World's End* (1940); *Between Two Worlds* (1941); *Dragon's Teeth* (1942; Pulitzer prize fiction, 1943); *Wide is the Gate* (1943); *Presidential Agent* (1944); *Dragon Harvest* (1945); A *World* to *Win* (1946); *Presidential Mission* (1947); *One Clear Call* (1948); and *O Shepherd, Speak!* (1949). *In* 1953 he published *The Return* of *Lanny Budd.*

Sinclair's intense political preoccupations inject an often heavy didacticism into his works. Always vigorous and far-ranging, his writings stimulated his generation to a critical re-examination of the American scene. His numerous books were widely published and translated in other countries. *See* also MUCKRAKERS.

See Floyd Dell, *Upton Sinclair* (1927); Carl Van Doren, *Contemporary American Novelists, 1900–1920,* rev. ed. (1940).

SIND, the region of West Pakistan east and southeast of Baluchistan and south of the Punjab. Strictly, the name should belong only to the alluvial plain created and watered by the Indus: excluding, that is, westward the Kohistan, or uplands north of Karachi, and the fringe of the Kirthar range, and eastward the Registan or Thar (Thal) desert extending from the Nara channel into Indian Rajasthan. Politically it refers to a former autonomous province of British India and of Pakistan, which excluded the principality of Khairpur and, from 1948 to 1955, the federal capital area (Karachi diltrict and division). which were administered separately. Areas (sq.mi.): Sind province 50,397; Khairpur 6,050; icderal capital 812. Pop. (1951) Sind 4,608,514; Khairpur 319,543; federal capital 1,126,417 (Karachi city 1,064,557). There were eight administrative districts in Sind: Upper Sind Frontier (later Jacohabad). Sukkur. Larkana and Nawabshah, later. with Khairpur state. forming the Khairpur commissioner's division of West Pakistan; Hyderabad, Tatta, Dadu and Tharparkar (lnter divided into Mirpurkhas and Sanghar). lnter forming the Hyderabnd division. Karachi (*q.v.*) was the seat of the Sind government from 1843 to 1948, when it was restored to Hyderabad city. The population (1951) of Sind was mainly composed of Sunni Moslems. Xlovements of population following the 1947 partition produced in Sind, as in other parts of Pakistan. large numbers of reiugees who were being gradually absorbed into the population in the 1950s. The prevailing language is Sindhi. but Rajasthani, Baluchi, Punjabi and Gujarati are also spoken *(see* SINDHI LANGUAGE).

Soils and Vegetation. — The generally fine fertile alluvium of Sind is coarser toward the north. where it retains moisture better and is easier to plow; the south rarely yields such rich harvests. All regions are liable to the deposition of kalar salts. which so reducc fertility that land seriously infested is useless. the worst effects being observed in the fine-textured soils of southern Sind.

Toward the desert parts of Mirpurkhas, the soil approximates increasingly to pure sand, fertile only if well fertilized and watered. The richest soil is that resulting from recent inundation (kacho).

Aridity limits forest to about 1,200 sq.mi. near the Indus from Ghotki to the mid-delta. Babul (*Acacia arabica*) is most characteristic in lower Sind and yields fuel and timber for boats; its bark is used for tanning and the leaves and pods are fodder for camel and goat. Kandi *(Prosopis spicigera)* gives fuel and fodder; bahan (*Populus euphratica*) building timber and lacquer wood, and tamarisk (lai or *Tamarix gallica,* and jhao or T. *dioicn)* fuel and wood for turning and for farm implements. The bahantamarisk zone is on land subject to flood, the kandi zone is farthest from the river, the babul zone is intermediate. The lower delta is without forest. apart from mangrove growths used for fuel and fodder. Tamarind and tali (*Dalbergia sissoo*) were introduced. the latter into the north. Arid and dune areas show growth of herbs and shrubs, often adapted to salt conditions. (See *Agriculture*, below.)

Fauna. — Wild animals include hyaena, gurkhar or wild ass (in the south of the Mirpurkhas district), wolf, jackal, fox, wild hog, antelope, pharho or hog deer. hares and porcupines. Of birds of prey, the vulture and several varieties of falcon may be mentioned. Flamingo, pelican, stork. crane and Egyptian ibis frequent the shores of the delta. Besides these there are the ubara or tilur (hustard). the rock grouse. quail. partridge and various kinds of parrots. Waterfowl are plentiful; in the cold season the lakes or *dhandhs* are covered with wild geese. kulang, ducks, teal, curlew and snipe. There are scorpions, lizards, centipedes and many snakes. (X.)

History. — Changes of the Indus channels make it difficult to picture even the Sind of Alexander the Great (32j B.C.), although a picture of a very much earlier civilization. about 3,000–2,000 B.c., akin to the Sumerian, began to be afforded in the 20th century by excavations at the "lost city" of Mohenjo Daro, 180 mi. N.E. of Karachi. At Alexander's death (323 B.C.) Sind passed to Seleucus Nicator, who yielded it in jog to Chandragupta Maurya (*q.v.*). After a phase of Buddhist influence under Asoka (about 274–232 B.c.), came inroads from west and north. A Sudra dynasty ruling from the Salt range to the sea. with capital at Aror (Alor), was followed by Brahman rule (7th century A.D.) and Islamic invasion (711) under Mohammed ibn Kasim. The invasion was by land through Makran; and for nearly three centuries Sind remained nominally subject to the Arab caliphs.

Though conquered by Mahmud of Ghazni, who raided into India, Sind long remained semi-independent, under local dynasties. the Sumras and the Sammas. both Rajput, but Mohammedans in religion. The latter had their capital at Tatta, in the Indus delta. a seaport until the 18th century. The Sammas rrere followed by the Xrghuns. of Persian origin, and the Xrghuns by the short-lived Turkhan dynasty. It was not till the time of Akbar, himself horn at Umarkot in Sind, that the province was regularly incorporated in the Delhi empire. When that empire broke up. on the death of Aurangzeb, local dynasties again arose. The first of these was the Kalhoras. succeeded by the Talpurs. of Baluch descent. who were ruling under the title of mirs, with their capital at Hyderabad, at the coming of the British.

The East India company had established a factory at Tatta in 1758; but the Talpur mirs were never friendly to trade. and the factory was withdrawn in 1775. In 1830 Alexander Burnes was permitted to pass up the Indus on his way to the court of Ranjit Singh at Lahore. and two years later Henry Pottinger concluded a commercial treaty with the mirs.

During the first Afghan War (1839–42), the British army under Sir John Keane marched through Sind, and the mirs were compelled to accept a treaty by which they paid a tribute to Shah Shuja. surrendered the fort of Bukkur to the British and allowed a steam flotilla to navigate the Indus. In 1842 Sir Charles Napier arrived in Sind and fresh terms were imposed on the mirs. The Baluch army resented this loss of independence and attacked the residency near Hyderabad, which was bravely defended by Outram. Then followed Sir Charles Napier's decisive victory of Rleeanee (*q.v.*) and the British annexation of Sind.

Napier's earlier successes in this campaign were reported in his memorable and humourous message — "Peccavi" (I have sinned).

Sind was formally administered. in the days of British rule, as a nonregulation province attached to Bombay, but under a commissioner residing in Karachi. On April 1. 1936, it became a governor's province by the transfer of the Sind division from the Bombay presidency. On April 1, 1937, it became autonomous! its legislative assembly being then composed of 60 members. On Aug. 1j. 1947, the transfer of power led to its becoming a governor's province under a Pakistani governor. When West Pakistan was consolidated into a single province on Oct. 14, 1955, the separate Sind government ceased to exist. (A. V. W.; X.)

Agriculture. — About 90% of the people derive their income from agriculture. the remaining 10% being engaged in manufacturing industries. mostly of the cottage type. There are two principal cultivating seasons. *kharif* and *rabi*. In general. the former extends normally from the beginning of June to the end of October and coincides for the first three months with 'the height of the Indus inundation. Ordinarily, the rabi season covers the period from early October to the close of March. The chief *kharif* crops are rice. millets (bajri and jowari) and cotton. Wheat, pulses, oilseeds. barley and vegetables constitute the main rabi sowings.

Rice. the main crop, occupies in an average crop year about 1,250,000 ac. It is particularly identified with two tracts: one in northern Sind centring on Larkana. where the finest is grown, and the other in southern Sind, centring on Hyderabad. The former accounts for about one-third, the latter for more than one-fifth, of the total rice acreage. Bajri and jowari are the main food of the working classes. The former is the more wholesome and occupies about 1,000,000 ac., while jowar is grown over about half this area. Nawabshah is the main seat of bajri; jowari is identified particularly with northern Sind. There also wheat is found, which rivals jowari in the area normally occupied. Other cereals are insignificant. Among pulses. matar (chickling vetch), grown in northern districts. is the chief. Rape and jambho (a variety of mustard) are noteworthy oilseeds; they are fairly widespread outside the desert. and the average area occupied by the two crops together exceeds 300,000 ac. Cotton stands fourth in area among *kharif* crops, being surpassed by rice, bajri and jowari only. It is limited entirely to the left bank of the Indus, where it reaches its maximum development under the eastern Nara canal system.

The net area sown nith food crops is about 5,000,000 ac.. of which paddy (rice) constitutes 57%, wheat 27%, millet 9% and barley and other food crops the remainder. In addition, there were about 20 000 ac. (1952–53) under sugar cane.

Grasses and fodder crops are less important for the Sind pastoralist than shrubs and trees. The best milch cows of Sind are famous; and its buffaloes, sustained on the swampy tracts in the delta. are the basis of a large export of *ghee* (clarified butter). The camel — the main beast of burden in the province — thrives on salt marsh feed, and the abundance of poor dry land together with the hilly tracts, supports large herds of sheep and goats. Small hardy horses are also in evidence, and Jacobabad district breeds mares. Mules, asses and bullocks are well represented. Poultry was undeveloped at the mid-19jos.

Irrigation in Sind is virtually synonymous with canal irrigation. About 80% of the cropped area is irrigated The major irrigation work in the province is the Sukkur (Lloyd) barrage at Rohri, one of the world's largest darns which commands about 7,500,000 ac. The lower Sind or Kotri (Ghulam Muhammad) barrage at Jamshoro opened in 1955 was expected eventually to command a cultivable area of 2,750,000 ac.; the upper Sind barrage at Gudu go mi. from Sukkur, 2,300 ooo ac (including areas to be irrigated in Baluchistan).

Manufacturing **Industries.**—Sind remains well known for its famous pottery and tiles. leather and lacquer work. carpets and silk embroidery, though all declined with the advent of the age of machine-made goods. Other crafts for which the province was once renowned, such as armoury work and the fashioning of precious metals, are little more than a memory. There are numerous cotton ginning mills. mainly in Hyderabad, and rice husking factories, primarily in Larkana. Karachi and its neighbourhood have cotton presses, metal foundries, bone mills, printing presses, a glass and tile factory, an arsenal and the railway and Port Trust workshops; taken together, these furnish employment to several thousands. This employment was being increased in the 1950s on the Sind Industrial Trading estate on the outskirts of the capital. which accommodated various medium and light industries. Karachi district also supplies salt by evaporation from the sea. Another industry with a considerable number dependent upon it is the making of mats (*phanka*) from the rank grasses in the delta. Karachi receives natural gas from Sui in Baluchistan.

Trade. — The overseas exports of Sind embrace, in order of value. raw cotton, wheat, wool, rapeseed, flour, unhusked rice. raw skins, bones and rawhides. Leading imports include cotton manufactures, sugar. railway materials and machinery, mineral oil, woollen goods. motorcars and associated items. The chief port is Karachi, the natural collecting and distributing centre for Pakistan and northern India and the focus of a number of trade routes which ramify through Afghanistan and central Asia. The overseas trade of Sind is limited to Karachi; its subordinates. Keti Bandar and Sirpanda, only engage in coastal trade. handling mainly rice. The coasting trade of Karachi includes, on the import side, benzine and gasoline from Burma; cotton twist yarn and piece goods from Bombay; gunny hags mainly from Indian West Bengal; coconut oil from Madras; coal from West Bengal; *ghee* from Baluchistan and Saurashtra; pepper from Travancore and Bombay, and teak from Burma. On the export side. the items are similar to the overseas items, with the addition of rice.

Sind normally receives raw cotton and wheat from the Punjaband from India (Uttar Pradesh and Rajasthan). which adds wool also.

From Asia come livestock, pastoral products and silk. In return Sind gives of its own staple products in addition to what it passes on from overseas.

Communications.—Sind is traversed by the North-Western railway. which. entering from the Punjab, follows the Indus southward and terminates at Karachi. The Indus is twice bridged: at Rohri, where the main line crosses the river (nearby at Ruk a branch goes off via Jacobabad to Sibi and Quetta) and at Kotri opposite Hyderabad. From the latter place a metre-gauge railway runs east via Mirpurkhas to link Sind with India (Rajasthan); there is one feeder to this route from Hyderabad south to Badin and two from Rlirpurkhas, one south to Jhudo and the other north to Khadro and to Nawabshah on the Hyderabad-Rohri chord. This chord line evades the erosion of the Indus and serves as an alternative from Karachi to the northwest. The desert part of the region is accessible only by camels. the roads being rough tracks of heavy sand. The few metalled main roads in Sind mostly follow the railways. In the eastern part of the Indus delta the traffic is almost entirely by water. The area is riddled with interlacing creeks, and small boats can make their way at high tide up to 20 mi. inland. Numerous ferries serve the river and, generally speaking, the canals are adequately bridged.

Karachi has a major international airport.

SINDBAD THE SAILOR, VOYAGES OF, a collection of Arabic travel-romances, partly based upon experiences of oriental navigators (especially in the 8th–10th centuries); partly upon ancient poetry, Homeric and other; partly upon Indian and Persian collections of *mirabilia.* In Sindbad's First Voyage, from Baghdad and Basra, the incident of the Whale-Back island may be compared with the Indian ocean whales of Pliny and Solinus, covering four *jugera,* and the *pristis* sea-monster of the same authorities, 200 cubits long. With the Island of tha Mares of Ring Mihraj, or Mihrjan, we may find (rather imperfect) parallels in Homer's *Iliad* (the mares impregnated by the wind), in Ibn Khurdadbih and Al Kazwini, and in Wolf's account of the three *Ilhas de Cavallos* near Ceylon, so called from the wild horses with which they abounded, to which the Dutch East India merchants of the 17th century sometimes sent their mares for breeding purposes. Sindbad's account of the kingdom of Mihraj (Mihrjan) is perhaps derived from the *Two Musulman Travellers* of the 9th century; it would seem to refer to one of the greater East Indian islands, perhaps Borneo. Sindbad's Valley of Diamonds has fairly complete parallels in Al Kazwini, in Benjamin of Tudela, in Marco Polo and in the far earlier Epiphanius, bishop of Salamis in Cyprus, who died AD. 403. As to the Mountain, or Island, of Apes in the Third Voyage, Ibn Al Wardi and Idrisi each recognizes an island of this kind, the former in the China sea, the latter near Sokotra. Sindbad's negro cannibal adventure reproduces almost every detaii of the Cyclops story in the *Odyssey;* among the Spice islands, and perhaps at Timor, may be located the island rich in sandal-wood, where the wanderer rejoins his friends. The cannibal land of the Fourth Voyage, producing pepper and coco-nuts, where Sindbad's companions were offered food which destroyed their reason, has suggested the Andamans to some enquirers and certain districts of Sumatra to others; with this tale we may compare the lotus-eating of the *Odyssey,* Plutarch's story of Mark Antony's soldiers maddened and killed by an "insane" and fatal root. in their Parthian wars, a passage in Davis's *Account* of *Sumatra* in 1599, and more complete parallels in Ibn Al Wardi and Al Kazwini. The burial of Sindbad in, and his escape from, the cavern of the dead is faintly foreshadowed in the story of Aristomenes, the Messenian hero, and in a reference of St. Jerome to a supposed Scythian custom of burying alive with the dead those who had been dear to them; the fully-developed Sindbad tale finds an echo in "Sir John Mandeville." For the "Old Man of the Sea," in the Fifth Voyage, we may also refer to Al Kazwini, Ibn Al Wardi and the romance of Seyf Zu-1 Yezen; Sindbad's tyrannical rider has usually been explained as one of the huge apes of Borneo or Sumatra, improved to make a better story.

See Richard Hole, *Remarks on the Arabian Nights' Entertainments, in which the Origin of Sindbad's Voyages . . . is particularly considered* (1797); Eusebius Renaudot's edition of the *Two Musulman Travellers* (1718, translated into English, 1733, as *Ancient Accounts of India and China by two Mahommedan Travellers . . . in the 9th Century*); *J. T.* Reinaud, *Relations des voyages faits par les Arabes et les Persans dans l'Inde et à la Chine dans le IX^e^ siècle* (1845); E. W. Lane's translation of the *Ambiun Nights* (1859), especially the notes in vol. iii. pp. 77–108; M. J. de Goeje, *La Légende de Saint Brandnn* (1890); C. R. Beazley, *Dawn of Modern Geography* (1897), i. 235–238, 438–450.

SINDHĪ LANGUAGE is spoken by over 4,000,000 people in the province of Sind (1951 census of Pakistan). With Lahndā and Kashmiri it belongs to the northwestern group of Indo-Aryan languages (*q.v.*) Sindhi-speaking people are also found in neighbouring districts, in the Rann of Cutch, and in Kathiawar. Many Sindhi-speaking Hindus from Pakistan have migrated to Bombay and other Indian cities. *e.g.* Delhi, Xjmer, Jaipur, and Gwalior.

Linguistically, Sindhi is bounded on the west by the Balōchī language (*q.v.*), an Iranian language, and by the Lahndii language (*q.v.*), to which it is closely akin, on the west. Of the four dialects of Sindhi, Vichōlī (Hyderabad), is standard, being employed for literary purposes. Another important dialect, Kacchī, is spoken in Cutch, and is strongly influenced by Gujariiti.

Moslem influence, over 1,000 years, gave a large number of Persian and Arabic borrowings, and the written character used for Sindhi is a variety of the Persian, with necessary modifications for sounds peculiar to the language; Hindus use a form of Devanāgarī.

Phonology.––The Sindhi system corresponds, in general, to that of Indo-Aryan. It shares one peculiarity with Kāshmīrī, viz., instead of a single final consonant, it has the consonant plus a voiceless vowel—for example, *chōkar*^{u} "boy" and *chōkar*^{e} "girl." Another feature is the series of "recursive" consonants, transcribed $\bar{g}$, $\bar{j}$, $\bar{d}$, $\bar{b}$ (or gg, *jj,* dd, *bb),* which are pronounced by drawing in (instead of expelling) the breath. with the larynx lowered and the glottis closed. These may occur initially. Still another feature is the occurrence of cerebrals where dentals are found in other Indo-Aryan languages. (*Cf.* Sindhi *ḍ̄iaṇ* and Hindi *dēnā* "give.")

Morphology.—Sindhī has two genders, masculine and feminine, and two numbers, singular and plural. Generally, case relationship is indicated by means of postpositions added to the oblique forms. An adjective agrees in gender, number and case with its noun. Sindhi, like Lahndā and Kāshmīrī, uses pronominal suffixes attached, as in Lahndā, to nouns as well as participial forms, while in Kashmiri they are used only with verbs.

The Sindhi verb has two conjugations, intransitive and transitive. Compound tenses consist of combinations of participles plus auxiliary. (For Sindhi *see* the *Linguistic Survey of India,* vol. viii. pt. i, 1919.)

Literature.— Until recently little Sindhi literature had been printed, activity quickened during the nineteen twenties with the formation of literary societies and availability of publishing outlets. The Sindhi Sahitya Mandal (Sindhi Literary circle) was Founded in 1949 in Bombay; others are active in other Sindhi cities.

SINDING, CHRISTIAN (1856–1941) Norwegian composer and pianist, best remembered for his piano music. Born at Kongsberg. Jan. 11, *1856,* he was trained at the Leipzig Conservatoire and studied in Munich and Berlin before settling in Oslo. An annual grant and later a life pension from the Norwegian government enabled him to devote himself to composition.

More than his compatriot Grieg, Sinding was influenced by the German surroundings of his formative years, and his style, although not without romantic Nordic features! remained noticeably Wagnerian. Outside his own country, one best seller, the piano piece *Rustle* of *Spring,* has maintained his name. But his orchestral works and his chamber music, especially his pianoforte quintet, were much in vogue during the earlier part of the 20th century. He died at Oslo, Dec. 3, *1941.* (H. GA.)

SIN EATER, a man who for trifling payment was believed to take upon himself, by means of food and drink, the sins of a deceased person. The custom was once common in many parts of England and in the Highlands of Scotland. Usually each village had its official sin eater to whom notice mas given as soon as a death occurred. He at once went to the house, and there, a stool being brought, he sat down in front of the door, A groat, a crust of bread and a bowl of ale were handed him, and after he had eaten and drunk he rose and pronounced the ease and rest of the dead person, for whom he thus pawned his own soul.

In the earlier form the sin eater was taken into the death chamber, and a piece of bread and possibly cheese, having been placed on the breast of the corpse by a relative, usually a woman, was afterward handed to the sin eater, who ate it in the presence of the dead. He was then handed his fee and at once hustled and thrust out of the house amid execrations and a shower of sticks, cinders or other missiles. The custom of sin eating is generally supposed to be derived from the scapegoat in Lev. xvi, 21, 22. A symbolic survival of it was witnessed in 1893 at Market Drayton, Shropshire. After a preliminary service had been held over the coffin in the house, a woman poured out a glass of mine for each bearer and handed it to him across the coffin with a "funeral biscuit." In Upper Bavaria sin eating long survived; a corpse cake was placed on the breast of the dead and then eaten by the nearest relative.

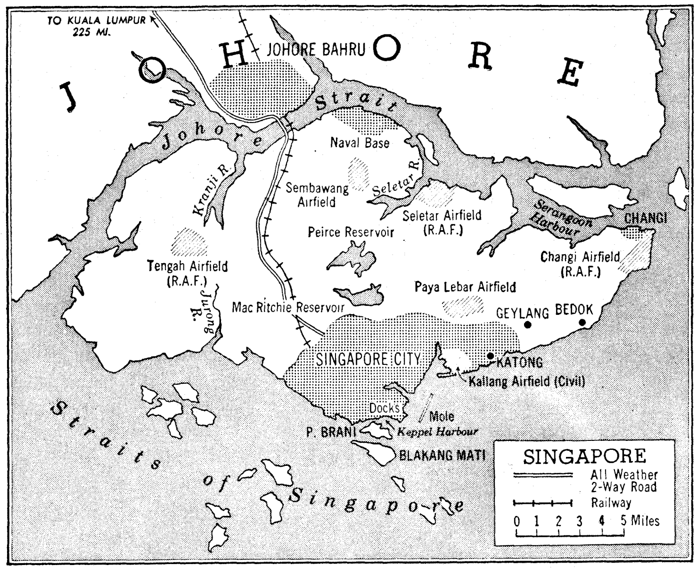
SINECURE, properly a term of ecclesiastical law for a benefice without the cure of souls. In the English Church such sinecures arose when the rector had no cure of souls nor resided in the parish, the work of the incumbent being performed by a vicar. Such sinecure rectories were expressly granted by the patron. They were abolished by parliament under the Ecclesiastical Commissioners act of 1840.

Other ecclesiastical sinecures were certain cathedral dignities to which no spiritual functions attached or incumbencies where by reason of depopulation and the like the parishioners disappeared or the parish church was allowed to decay. Such cases eventually ceased to exist.

The term is also used of any office or place to which salary emoluments or dignity but no duties are attached. The British civil service and the royal household, for example, were loaded with innumerable officeswhich by lapse of time had become sinecures and were only kept as the rervard of political services or to secure voting power in parliament. They were prevalent in the 18th century, but were gradually abolished by statutes during that and the following century.

SINEW, a tendon, a cordlike bundle of fibrous tissue at the end of a muscle forming the attachment to the bone or other hard part. The broad, flat tendons are usually called aponeuroses. See MUSCLE AND MUSCULAR SYSTEM; CONNECTIVE AND SUPPORTING TISSUES.

SINGAPORE, island and internally self-governing state within the British Commonwealth, situated at the southern end of the Malay peninsula with which it is connected by a rail and road causeway ($\frac{3}{4}$ mi.) across the Johore strait. The island, bounded south by the Singapore strait, is roughly diamond shaped *(26* mi. by *14* mi.) with an area of *209* sq.mi. and a mid-point of 1° 22′ N., 103° 50′ E. Within the state are about *40* small islands totaling 15 sq.mi. Until *1941,* with Malacca and Penang (*qq.v.*), Singapore formed the British colony called the Straits Settlements.



Singapore owes much of its wealth and continued prosperity to its focal position in southeast Asia on international sea and air routes. Its strategic position and deepwater harbour have enabled the city of Singapore to become the largest port in southeast Asia, the natural outlet for the products of the Malay peninsula and one of the world's greatest commercial centres. The island also serves as an important naval and air base.

Physical **Geography.**—An outlier of rocks and structures running through the Malay peninsula. Singapore has a central granite zone culminating in Bukit Timah, *581* ft., west of which Triassic quartzites and shales dip to the southwest and form low degraded scarps which are heavily eroded into hills aligned in a northwest-southeast direction with the steepest ridge behind Pasir Panjang. East of the granite zone lies a mass of weathered detritus averaging 100 ft. in height. Weathered red and yellow lateritic soils and thick ironpan cap all rocks. A quarter of the island is lower than *25* ft. and mangrove swamps fringe the coast, extending inland and almost dividing the surface into three islands. Only Pasir Panjang has a steep coast, and the deepwater channel of Keppel harbour is sheltered from the south by the hilly Blakang Mati and Brani Islands. Elsewhere the coast is silting and has dangerous coral reefs and sandbanks lying offshore. The Johore strait has a deep scoured channel at its eastern end, permitting large vessels to approach the naval dockyard at the northern corner of Singapore Island. The solid causeway across the strait prevents the through movement of vessels and hastens silting at the western end. On the central granite hills is the only remnant of the forest of dense. mixed evergreen trees which protects three reservoirs formed by damming small streams; they are now inadequate for the island and water is piped from south Johore. The climate is equatorial with temperatures throughout the year varying a fen- degrees either side of the 82° F. mean. There is no well-defined wet or dry season and the annual rainfall of 95 in. is evenly distributed throughout the year. Prevailing winds are from the northeast from November to

February and from the south during May to August, but strong daily land and sea breezes maintain agreeable physiological conditions. Heavy rains and high seas come during the northeasterlies, from which the harbour is well protected. Singapore river?a tidal estuary which afforded protection for early shipping, remains a shelter for lighters and is the city centre. Everywhere within a six-mile radius of the river is built over multistoried workers' flats and large residential suburbs. (E. H. G. D.)

History.—Malay tradition confirms that the first colonizer of Singapore was a prince from Palembang, the Sumatran capital of Srivijaya. It may have been Rajendracola Deva I (1012–44), ruler of Tanjore, who, to commemorate the lion courage of his men, gave the island the Indian name of Singapore ("Lion city"). He almost certainly attacked the island in A.D. 1025 during his descent on Srivijaya and its colonies. In Javanese inscriptions and Chinese records down to the end of the 14th century the commoner name for the island is the Javanese Tumasik from *tasek,* "sea." In 1275. when he raided Pahang, the Javanese king Kritanagara probably attacked Tumasik, and it may have been he who erected the stele in the Singapore river that was blown up by the British to widen the entrance. According to a Chinese traveler, Wang Tayuan, just before 1349 about 70 Siamese war boats besieged Tumasik for a month but had to withdraw. A Javanese work. the *Nagarakritagama,* written in 1365, includes Turnasik among the conquests of the Javanese empire of Majapahit. Jewelry of Majapahit workmanship, buried beneath a tree on Fort Canning, may have belonged to Singapore's last ruler, a Palembang prince, the *Parameswara,* before he and his Majapahit consort were driven upcountry by another Siamese attack. Clearly what Wang Tayuan describes as a den of pirates was at once a pest and a prize for Siam and Java: though both were too far away to control and develop it, and after the destruction of its suzerain Srivijaya at the end of the 14th century, it fell into decay and was supplanted by Parameswara's new port. Malacca. Yet in 153'2 it was still a port of call from which St. Francis Xavier dispatched letters to Goa, and João de Barros, writing in 1553, describes it as "a resort not only of Indian shipping but of traders from China, Siam, Champa, Cambodia and the Malay archipelago." John Crawfurd, resident of Singapore from 1823 till 1826, claimed to have traced the remains of a walled settlement that ran a mile inland and was half a mile broad.

On Jan. 28, 1819, Sir Thomas Stamford Raffles (*q.v.*) of the British East India company, forestalled in his search for a factory site by the Dutch at Riouw (Riau, Rhio) and having found the Carimon Islands unsuitable, landed at Singapore. He found only a fen Chinese planters, some aborigines and a few Malays, and was told by the hereditary chief. the *temenggong* (direct ancestor of the sultans of modern Johore); that there were no Dutch there and that the company could purchase land. The *temenggong,* however, was a subordinate of his cousin Xbdul Rahman, sultan of Riouw, Lingga, Pahang, Johore and Singapore, who was under Dutch surveillance. Abdul Rahman was a younger son and not a sultan *de jure*. Raffles. disobeying instructions not to offend the Dutch, took advantage of this fact by withdrawing his own recognition of Abdul Rahman as sultan of Singapore and installing Rahman's elder brother, Husain, to validate the purchase of land there on behalf of the company. The Dutch protested. In London the court of directors, though it decided Raffles had contravened instructions, took no action. In 1824 an Anglo-Dutch treaty left Malaya and Singapore in the British sphere. On Xug. 2, 1824, the whole of Singapore Island was ceded to the British for a money payment. By 1825, while Malacca's trade stood at £300,000 and that of Penang at £1,000,000, the trade of Singapore was estimated at £2.610.440. Already the free port was fulfilling its dual functions of helping the Canton (China) trade of the British East India company and breaking the Dutch monopoly of trade in the Malay archipelago. In 1526 Singapore; Penang and Malacca were combined as the Straits Settlements to form an outlying presidency of India. In 1830 they were reduced to a residency under Bengal. In 1832 Singapore became their capital. However the British East India company now lost its monopoly of the China trade and with it, its interest in Malaya. The settlements were transferred to the direct control of the governor general of India in 1851; in 1867 they were made a crown colony under the colonial office. Meanwhile! the trade of Singapore had suffered from British development after 1842 of a rival port. Hong Kong, as later it was to suffer from the French occupation of Indochina. the development of Saigon and Haighong, and from the establishment of Dutch ports and shipping lines in the Netherlands Indies. With the opening of the Suez canal in 1869 and the advent of steamships. an era of prosperity began that led eventually to the construction of three miles of wharves at Tanjong Pagar and finally in 1921 to a naval base. The economic growth of the Malay states after becoming British protectorates enlarged transit trade. Finally the demand of the motor industry for tin (European processes of tin smelting were introduced in 1887) and rubber made Singapore one of the greatest ports in the world. Steps were taken for its defense. But the naval base afforded no protection against a totally unexpected overland attack and an airfield mas useless in the absence of an adequate air force. On Dec. 8, 1941, the Japanese landed in Kelantan and by Jan. 30, 1942, the peninsula was conquered and Japanese troops were opposite the island of Singapore. On Feb. 8 they landed on the one coastal spot that was concealed by a mangrove belt. Gen. Xrchibald Wavell ordered a fight to the end. But 36.000 troops newly arrived were raw and Japanese bombs hindered the landing of equipment. Above all the island's water supply from the hills of Johore was cut. On Feb. 15 the British surrendered. The Japanese ruled the island under the alias of Syonam until it was recovered bloodlessly on Sept. 5, 1945, by forces under Lord Louis (later Earl) Mountbatten.

Following the expulsion of the Japanese the island's history was that of constitutional progress. .After 1946. when a union of all the Malay states plus Penang and Malacca was made, it was deemed politically unwise to include Singapore in the union. mainly because of its predominantly Chinese population. Singapore remained a crown colony. A new constitution was introduced in Feb. 1955. Under its provisions. 25 out of 32 members of its legislature were elective, and elected ministers became heads of all departments other than defense and external affairs, which still remained the concern of Great Britain. After 1955 the British governor was bound to consult and accept the advice of the chief minister. In 1959 the British colony became internally self-governing, with a locally born head of state, who was also the queen's representative, appointed by the crown in consultation with the Singapore government. *(See* also *Administration and Social Conditions,* below.) (R. O. WT.)

Population.—At the census of the colony of Singapore taken in June 1957 the population numbered 1,445,929, comprising 1,090,595 Chinese (75.4% of the total),197.060 Malaysians, 124,084 Indians and Pakistanis, 11.332 Eurasians, 10.826 Europeans, 5,426 Ceylonese and 6,556 others. When British rule was first established on the island in 1819 there were fewer than 200 inhabitants, but the rapid influx of Chinese and Indians brought the total population to 10.683 in 1824, the year in which the first census was taken. In 1860 it was 81.734. of whom more than 50% was Chinese, and by 1931 it was 559,945, of whom the Chinese formed nearly 75%. During the 1930s, immigration was reduced and a quota system established to regulate the entry of aliens into Singapore. After World War II there was a great increase in the number of immigrants and selective immigration was introduced. The religions are mainly Moslem, Buddhist and Hindu; the languages, Chinese. Malay, Tamil and English, which is the official language.

Administration and Social Conditions. — On June 3, 1959, a new constitution came into being. establishing the state of Singapore with full internal self-government. The queen's representative is a *yang di-pertuan negara,* or head of state, who must be Malayan-born. There is a cabinet of nine ministers presided over by a prime minister and a fully elected legislative assembly of 51 members, presided over by a speaker and a deputy speaker elected by the legislative assembly members themselves. The cabinet ministers are collectively responsible to the legislative assembly. but have full executive authority over their own departments. The right to vote in elections to the legislative assembly is confined to citizens as defined by the Citizenship act passed in 1957. The U.K. government is responsible only for defense and external affairs. The Singapore government is responsible for internal security, subject to the oversight of an internal security council, composed of representatives of the U.K. and Singapore governments and of the government of the Federation of Malaya.

Local government of Singapore city is by city council (see SINGAPORE, city), while the state's rural areas are administered by three district councils.

Income Tax.—In the early 1960s income tax was levied on income accruing in or derived from Singapore or received in Singapore from outside. Resident individuals paid tax on a sliding scale ranging from 5% on the first M$1,500 of chargeable income to 50% on incomes exceeding M$50,000. Personal allowances were M$3,000 for an unmarried person and M$5,000 for a married couple There was a sliding scale of allowances for children and deductions were also allowed in respect of life assurance premiums and contributions to approved pension or provident funds.

Housing.—The Singapore Improvement trust, partly financed by the government, was the recognized government agency and planning authority in the early 1960s. It was responsible for the building of nearly 15,000 dwellings after World War II. With an estimated population of 2,000,000 in Singapore by 1965, plans were made for building houses at the rate of 10,000 a year in the congested city area and in the rural areas. In the latter three new self-contained townships with a total population of about 200,000 were projected.

Labour and Welfare.—In the late 1950s there were more than 200 registered trade unions with a total membership of about 140,000. Conditions of employment are regulated by ordinances covering working hours, paid holidays and the employment of women and young persons, etc. Social security services available included a workmen's compensation scheme, a central provident fund scheme, free medical treatment and hospital services, homes for orphans and old people and a public assistance scheme.

Health.—In the early 1960s the ministry of health in Singapore controlled nine hospitals, containing more than 7,000 beds. There were 23 static dispensaries, 9 traveling dispensaries, 2 floating dispensaries and 63 main and subsidiary maternal and child welfare centres serving the population in the rural areas. The Institute of Health, opened in 1958, houses the city council outpatient clinic, the government school health services and the university's department of social medicine and public health, and also provides training facilities for public health personnel. The extensive tuberculosis-control program in operation had made vaccination available in all parts of the island and a tuberculosis-control unit has been established. The hospital system was being decentralized: a district hospital was opened in 1959, and an outpatient treatment centre for leprosy patients was started. There is a medical faculty in the University of Malaya where training is also given in dental surgery. A school of nursing provides general training in nursing. The Singapore birth rate of 41.9 per 1,000 is one of the highest in the world and more than half the population is under the age of 19. The gross expenditure of public funds on medical and health services in 1958 amounted to M$42,100,000, compared with M$6,300,000 in 1947.

Justice.—In Singapore there is a supreme court of justice, comprising a high court, a court of appeal and a court of criminal appeal. The supreme court is composed of a chief justice and five or more puisne judges. Appeal may be made from the supreme court to the privy council.

Education.—In the late 1950s Singapore provided education for about 325.000 pupils in 729 regular schools. The University of Malaya in Singapore had an enrollment of more than 1,000 men and about 400 women. A teachers' training college gave courses for approximately 1,150 men and more than 1,100 women students, about 2,000 of these being on part-time courses while working as trainee teachers in primary schools. There were also more than 600 students in technical schools and adult and evening classes were maintained and aided by the government. Of the pupils attending regular schools, more than 50% were being taught in English, about 40% in Chinese and 10% in the vernacular languages. About 15% of the pupils were taught in secondary schools. Nanyang university (founded in 1954), with more than 1,300 students, had faculties of arts, science and commerce. The Singapore polytechnic had 2,700 students attending classes in five departments: general education, science and technology, engineering, building and architecture, and commerce. More than 400 were full-time students, 500 were attending one day and two evenings a week and the remainder were evening students. The net cost of education in 1958 was M$81,400,000, compared with M$4,725,000 in 1948.

Defense.—Singapore is the headquarters of U.K. armed forces in the far east and a base for other Commonwealth forces. Local troops consist of the regular 1st battalion Singapore infantry regiment and various part-time forces.

Political Parties.—In 1955 elections were held under the constitution giving the legislative assembly an elected majority. The Labour front won ten seats and formed a government in coalition with an alliance of the United Malay National organization (U.M.N.O.), the Malayan Chinese association (M.C.A.) and the Singapore Malay union (S.M.U.), which altogether won three seats. The main opposition group, the People's Action party (P.A.P.), had three seats. In Nov. 1958 the Labour front was dissolved and in its place was formed the Singapore People's alliance, comprising the Labour front, the U.M.N.O.-M.C.A.-S.M.U. alliance and parts of the Liberal Socialist and Workers' parties. In the 1959 election the P.A.P. emerged as the dominant party, winning 43 seats out of a total of 51. (X.)

The Economy.—This city-state is based on its harbour and international trade; its agricultural and mineral resources are negligible. Old rubber and coconut plantations on the island have become housing estates; market gardens, piggeries and chicken farms totaled only about 9,000 ac. in the late 1950s. Large acreages are used for reservoirs, the dockyard and five airfields, the largest being the international airport at Paya Lebar (opened 1955) where more than 10,000 passengers and 9,000,000 lb. of air freight were handled in 1958. The offshore islands are unproductive except for fishing. Hundreds of fixed Chinese fishing traps and many Chinese trawlers land more than 14,000 tons annually.

The commerce of the harbour, the largest and best serviced within 1,500 mi., arises from handling goods and commodities from other places for re-export. These include: (1) Malayan produce, rubber, tin ore, copra and timber, which move outward by sea and are mostly raw, apart from a little copra milled into oil and some refined tin from Brani in the harbour. (2) Sumatran, Thai and Bornean produce which comprises rubber, tin ore, rice, timber and dried fish, and arrives in small steamers either for regrading and bulking into ocean-going vessels or for local consumption. Oil from North Borneo and Sumatra is stored on Pulau Bukum for redistribution inland and overseas and for fueling the passing ships, replacing Singapore's old function as a coaling station. (3) Textiles, machinery, equipment, European and Asian foodstuffs are brought from overseas for distribution to the Federation of Malaya, Thailand, Indonesia and Borneo. Forwarding, shipping, reshipping, rebulking, grading and distribution give rise to the modern warehouses, offices and banks which line the multistoried, European-style water front. In 1958 the harbour handled about 18,000,000 tons of cargo. Such entrepdt trade means that similar goods appear in both import and export statistics and it flourishes with free port facilities. These came to an end when the first independent government in 1959 introduced protective tariffs. The naval dockyard and the aerodromes serve functions similar to those of the harbour. Many people are employed in servicing and maintaining shipping, vehicles, planes and machinery. Fear that nationalism in surrounding territories will reduce entrepôt trade has led to the growth of small factories for remilling rubber, making rubber footwear, electric batteries, bottles, furniture, pipes, industrial gases, soap, metal windows and plywood, though local labour costs and unrest have been prejudicial. For power, the island depends on diesel-generated electricity from Pasir Panjang, which has a yearly output of 500,000,000 kw.hr. and enables more homes, offices and factories to be electrified than anywhere else in southeast Asia.

Roads radiate from the city of Singapore to satellite towns and suburbs at Pasir Panjang, Woodlands (opposite Johore Bahru), Changi, Seletar and Sembawang; the 280 mi. of metaled roads are used by more than 65,000 local motor vehicles (1958) and by truck traffic to and from the Federation of Malaya along the arterial road to Johore Bahru. The terminus of the Singapore-Kuala Lumpur-Bangkok railway adjoins the harbour. Radio and cable links to business centres of the world make Singapore an important centre for telecommunications.

Singapore currency is the Malayan dollar (M$), tied to sterling at 2s. 4d. (33 U.S. cents) for the last 50 years under currency commissioners common to Singapore, Malaya and North Borneo.

In 1957 the island's external trade including entrepôt movements was valued at about £1,000,000,000 exports and £1,190,000,000 imports, western European, British and far eastern markets dominating. In that year, Singapore received commodities worth £280,000,000 from the federation and sent to it goods worth £250,000,000. These movements included 250,000 tons of rubber and more than 1,000,000 tons of mineral oil. Singapore revenue in 1958 was M$282,000,000 (39% from customs and 40% from income taxes), and expenditure M$277,000,000 (23% administration, 27% social services and 12% police). (E. H. G. D.)

SINGAPORE (city), capital of the self-governing British colony of Singapore, is situated at the southern end of Singapore Island and occupies an area of 31.5 sq.mi. Pop. (1957 census) 912,343. The settlement of Singapore dates from 1819. The town then planned and founded by Sir Thomas Stamford Raffles (*q.v.*) centred on a landing place at a small river mouth with a roadstead sheltered in some degree by the neighbouring islands. The place had great commercial possibilities and considerable strategic value, and these assets were enhanced by the opening of the Suez canal in 1869. However, with the growth of trade and of the size of ships the old harbour proved inadequate. Keppel harbour took the place of the old river mouth and the original roadstead was left to coasting craft. The present commercial harbour centres on the Empire dock and Main wharf with the other docks and wharves adjacent to the railway station in Keppel road. The docks, warehouses and wharves were first developed by the Tanjong Pagar Dock company, but after 1905 they were controlled by the Singapore Docks and Harbour board. Of the islands which shelter Keppel harbour, some are fortified and some afford sites for a tin-smelting works and for petroleum storage tanks.

Round the older part of the city are grouped the public buildings and principal offices. Business is mostly done in or near Raffles place, the government offices being on the opposite side of the river. Next to these are the Victoria Memorial hall and theatre, the supreme court, the city hall and St. Andrew's cathedral (Anglican). The Raffles museum and library is at some little distance from this central group, in Stamford road. The museum contains collections covering the zoology, ethnography and archaeology of the Malaysian region. The library has about 120,000 volumes, including many books on Malaya. Farther out of the city in a northwesterly direction are the botanical gardens and the buildings of the University of Malaya.

An extensive building program was being carried out in Singapore during the 1950s and the construction of modern multistoried buildings has given the water front a distinctive sky line. Singapore is not only an important seaport for long-distance and coasting trade, but is also an airport of growing significance and the focal point of air communications in southeast Asia. The civil airport at Kallang, built on reclaimed land, proved inadequate for jet-propelled aircraft, which had initially to use the Royal Air Force base at Changi. The new airport at Paya Lebar, opened in 1955, is $7\frac{1}{2}$ mi. from the city centre and has an 8,000-ft. runway.

The royal charter granted Singapore in 1951 gave control to a primarily elected city council, under a president nominated by the governor. In Dec. 1957 the council became a completely elected body presided over by an elected mayor. The council was dissolved after Singapore colony became self-governing (see SINGAPORE [state]). (C. N. P.)

SINGER, ISAAC MERRIT (1811–1875), U.S. inventor who developed the first practical domestic sewing machine and brought it into general use, was born on Oct. 27, 1811, in Rensselaer county, N.Y. In 1851 he developed and patented a sewing machine which embodied a spring presser foot and feed synchronous with the needle action and thus permitted continuous and curved stitching. An overhanging arm projecting the needle bar over the work, which was spread over a horizontal table, made it possible to sew on any part of the work. Singer's machine was the first that could perform these necessary functions, and its basic design features have been followed in almost all subsequent machines. Nonetheless, Elias B. Howe (*q.v.*) must be credited with the first employment of the basic eye-pointed needle and lock stitch (in 1846), nhich, since Singer had embodied these in his machine, resulted in Howe's winning an infringement suit against Singer in 1854. The suit did not prevent Singer from manufacturing his machine, however, and in June 1851 he formed a partnership with Edward Clark, their company becoming, by 1860, the largest producer of sewing machines in the world. Singer left commercial development of his invention to Clark while he supervised manufacturing and the "experimental department," where he perfected other improvements. In 1863 he and Clark formed the Singer Manufacturing company and Singer retired to England. where he died on July 23, 1875. (A. B. J.)

SINGER, ISRAEL JOSHUA (1893–1944), Polish-born U.S. Jewish author and playwright, was born at Bilgoraj, Pol., on Nov. 30, 1893. He prepared for a career as a clergyman at the Rabbinical Yeshivah school in Warsaw, but abandoned theological studies at an early age and worked at various occupations, including artist's model, traveling tutor and compulsory labourer for the German army which occupied Warsaw in 1915.

In 1917 he went to Kiev in the Ukraine, where he became a proofreader for a Yiddish newspaper and began to write short stories. He returned to Warsaw in 1921 and first came to public notice with the publication of a number of short stories, collected in a volume entitled *Pearl* (1923) after the first story in the book. He was invited to contribute articles to the *Jewish Daily Forward* by the editor in New York and continued to serve thereafter as a correspondent for the publication and fiction writer.

In 1932 appeared the novel *Yoshe Kalb,* produced as a play in the same year at the Yiddish Art theatre in New York city. The book was translated into English as *The Sinner* in the following year. The plot concerns the tribulations of a rabbi who committed a grave act of sin.

In 1934 Singer, who had visited the United States earlier in connection with the production of *Yoshe Kalb,* settled in New York city. In 1939 he became a U.S. citizen. His *The Brothers Ashkenazi* (Yiddish title *Di Brider Ashkenazi)* was translated into English in 1936 and also into several other languages. It was produced on the stage by the Yiddish Art theatre. Other works by Singer which were translated into English include a collection of short stories, *The River Breaks Up* (1938), and the novel *East of Eden* (1939). produced as a play by the National theatre, New York city, in 1939. In 1943 his play *The Family Carnovsky* was a popular success. Singer died on Feb. 10, 1944.

SINGER, SIMEON (1846–1906), Jewish preacher, lecturer and public worker, was born in London. In 1867 he became minister of the Borough synagogue, London. In the following year he married. He moved to the new West End synagogue in 1878, and remained minister of that congregation until his death.

He introduced regular sermons to children. and as a preacher to the young, Singer showed rare gifts. His pulpit addresses in general won wide appreciation, his services often being called for at public functions. In 1890 the rabbinical diploma was conferred on him by Lector Weiss of Vienna; in the same year he showed evidence of his self-denial by declining the stand for the post of associate chief rabbi.

Singer was a power in the community in the direction of moderate progress; he was a lover of tradition, yet at the same time he recognized the necessity of well-considered changes. In 1892 at his instigation the first English Conference of Jewish Preachers was held. and some reforms were then and at other times introduced, such as the introduction of Bible readings in English, the admission of women as choristers and the inclusion of the express consent of the bride as well as the bridegroom at the marriage ceremony.

Singer did much to reunite Conservatives and Liberals in the community, and he himself preached at the Reform synagogue in Manchester. He had no love for minute critical analysis of the Bible, but he was attracted to the theory of progressive revelation, and thus was favourably disposed to the modern treatment of the Old Testament.

His cheerv optimism was at the basis of this attitude and strongly coloured his belief in the messianic ideals. He held aloof from all Zionist schemes.

His interest in the fortunes of foreign Jews led him to make several continental journeys on their behalf; he was one of the leading spirits of the Russo-Jenish committee. of the International Jewish Society for the Protection of Women and of other philanthropic organizations.

Despite his devotion to public work, Singer published some important works. In 1896 was published *Talmudical Fragments in the Bodleian Library*, of which Singer was joint author. His most famous work was his new edition and English translation of the *Authorized Daily Prayer Book*, first published in 1870, a work which went through many large editions and which proved to be popular with both Jews and Christians.

See *The Literary Remains of the* **Rev.** *Simeon Singer*, 3 vol., with memoir (1908). (I. A.)

SINGHBHUM, a district in the Chota Nagpur division of Bihar, India. The administrative headquarters are at Chaibasa, 162 mi. W. of Calcutta; pop. (1951) 16.474. Area of district is 5,123 sq.mi., after the absorption in 1948 of certain former hereditary territories. Pop. (1951) 1,685,195. Singhbhum is a hilly district on the fringe of the Chota Nagpur plateau with mountains in the northwest rising to a height of 2.joo ft.. and in the southwest. where they are called the Saranda hills, to nearly 3,000 ft. The central part consists mainly of well-cleared country. which is the most fertile tract in the district. The south is another undulating plateau. The eastern part of the district, called Dhalbhum. contains the valley of the Subarnarekha, the principal river. Over one-third of Singhbhum is covered with primaeval forest, in which tigers, leopards. bears, bison and deer are found. Valuable timber is obtained from the forest. a minor product of which is sabai grass for the manufacture of paper, ropes and string. Nearly two-thirds of the inhabitants belong to aboriginal tribes. among whom the Hos. meaning simply "men." are predominant. Their warlike character won for them the name of Larka. or fighting, Kols among outsiders. They were not finally subjugated until 1836, when the Kolhan. the area in the centre and southwest of the district, was brought under British rule. In Porahat they broke out in rebellion during the Mutiny, and after a long campaign submitted in 1859.

Singhbhum became one of the most important industrial tracts in Bihar. largely the result of the establishment of the works of the Tata Iron and Steel company and of subsidiary concerns at Jamshedpur (pop. 193,775), 20 mi. E. of Chaibasa, and in its neighbourhood. The deposits of iron ore in the Saranda hills, reputed to be among the finest in the world, supply material to large works near Asansol, in West Bengal. There is a belt of copper extending for about 80 mi.; mining has been in operation for many years. Other mineral resources include chromite, manganese ore, apatite and gold. Several companies also were formed for the production of silica bricks. firebricks and pottery. for which materials are obtained northeast of the mineral area. Jainshedpur contains one of the undergraduate colleges of Bihar university.

SINGING. Singing is vocal expression with words and music. It is indeed the art of using the voice freely and effectively according to a musical pattern. Beautiful singing requires a healthy body and vocal organs, an alert mind, expressive and pleasing tonal quality. a musical ear, sound musicianship and excellent vocal technique. In addition, it demands that the singer have a clear idea about the meaning of the lyrics and that he has the ability to project his understanding so that the song will have significance to his listeners. In short, he must interpret the composition intelligently.

Not all singers, however, are trained and not all attain a high

degree of skill. The singer of popular songs. for example, produces his voice quite differently from the operatic and concert singer and often his production violates the best principles of artistic singing. In church, community and school where spontaneous singing is done by many as well as in much solo performance the results cannot be described as tonally beautiful. Nevertheless it is "singing," and its sincerity and the emotional feeling it arouses generally are pleasing to both performers and listeners. It should be noted also that untrained and natural singing varies with peoples and civilizations, being conditioned by anatomic structure. language, culture and environment. For example. the folk-type singing of orientals is as different from that of western peoples as are their ideas and ways of living. The voices of the Indians are unlike those of the Negroes. The open vowels of the Italian language. the nasal sounds of the French and the guttural consonants of the Germans influence the singing of natives of these nations.

The voice in singing, as in speaking, is produced by the outgoing breath setting into vibration the vocal cords or lips located in the larynx. The sound'initiated there is reinforced or strengthened by the cavities of the throat. head and mouth—the resonators. Words are formed by the lips. teeth, tongue and palate—the articulators. Although produced by the same organs, singing differs from speaking in that the range of voice is often extensive and the vowels are prolonged. Moreover, a singer must conform to a definite musical design whereas the speaker can inflect his voice and determine his phrasing and rate of utterance at will.

The vocal instrument is the same in men and women except for size, the vocal cords being usually longer and thicker and the resonating cavities being usually larger in men than in women. In boys and girls it is the same until the age of puberty. Length of the vocal cords determines the pitch of voice, the longer cords producing lower pitches than the shorter ones. Therefore: the adult man's voice is about an octave lower than the woman's.

A division of singing is made on the basis of sex and age—namely, men and women, boys and girls. adults. youths and children. Further classification is made with reference to timbre or quality and, to some extent, range of voice. The number of pitches a person can sing, however, varies with individuals and with training. But, as a rule: the well-tutored adult singer has a compass of approximately two octaves. Men's voices from the lighter and higher to the heavier and lower are tenor, baritone and bass. Women's voices in the same order are soprano, mezzo-soprano and contralto. Another division denotes quality. such as lyric tenor. dramatic tenor. bass baritone, basso cantante. basso profundo, lyric soprano. dramatic soprano and coloratura soprano.

The lyric tenor voice is light and flexible. The dramatic tenor has a more robust quality. The baritone is heavier in texture than the tenor but lighter than the bass. The bass baritone is a lighter voice than the real bass but heavier than the baritone. The words *cantante* (singing) and *profundo* (profound or deep) characterize bass voices. Descriptions for lyric and dramatic tenor apply also to lyric and dramatic soprano. The mezzo-soprano, between the soprano and contralto. bears the same relationship to these voices that the baritone does to the tenor and bass. The coloratura soprano is a high and extremely flexible and clear voice. The true contralto has deep, rich. mellow tones.

Children's singing voices are called treble or soprano because the range is within the G or treble staff. Range as well as quality, however. differs with individual children. As a rule, the quality is light, lacking the resonance of mature voices. Even so, children are capable of singing superbly, singly or in groups, as is attested by boy sopranos and many choirs or choruses. At adolescence, voices of boys and girls change in quality and the boy's voice drops in pitch. first moving into alto and then into what is often designated as alto-tenor, a mixed voice of limited range. From this stage it develops into the adult tenor. baritone or bass. Before the change occurs, the upper tones of boys frequently become clear and brilliant; during mutation their voices often are rough and reedy in quality and are difficult to control. At puberty, some girls' voices also become lower in pitch but not to the extent of boys'; and their quality is often husky.

Singing is done by individuals alone or in groups, as in solos, duets, trios. quartets, quintets. sextets, glee clubs and choruses. Ensembles sing from one to eight (possibly more) parts, the common number for a male and a mixed group being four. for women's three and four, for children's one, two and three parts. When persons sing together their voices should blend if the effect is to be musical. Therefore. each member must be willing to submerge his musical interests and identity for the sake of the group. Although less demanding in regard to vocal range. control and beauty than solo performance, even a small chorus under an able conductor can produce tonal richness and variety. Some organizations may rival the qualities of musical precision and impressiveness of symphonic orchestras and instrumental chamber groups. In fact. in the opinion of some choral enthusiasts. nothing can surpass the performance of a carefully selected and directed *a cappella* chorus — that is, a group singing without instrumental accompaniment.

Singing, first in unison and later in parts, was introduced into religious worship in early centuries. and measures were soon taken to train singers to perform the chant. It is believed that it required nine years for singers to complete the course at the Roman Schola Cantorum, established about 590. During the 12th and 13th centuries, the crusades gave impetus to the growth of music outside the church. The development of secular singing also was furthered during these centuries by the troubadours and trouvères in France and the minnesingers in Germany, whose contests or tournaments gave opportunity to display vocal and musical talent. Songs with lute accompaniments. motets, madrigals and the mass indicate that by the 15th century singers must have had excellent technical skill to adequately perform both secular and sacred music. In the 16th century, the time of Giovanni Pierluigi da Palestrina (?1526–94), the art of singing was ready to meet the demands of the new musical forms of the next era.

Solo singing came into prominence about 1600 with the development of opera and oratorio. The music required of singers voices of wide range, great flexibility and tonal purity. In order that their compositions be sung properly, composers often became teachers and succeeded in producing many fine singers. Among them were the *castrati* (male sopranos and contraltos) whose artificial voices of ethereal quality could perform spectacular vocal feats. Their popularity in opera waned during the 18th century when composers ceased to give them prominent roles. They, however, sang in some church choirs through the 19th and even into the 20th century.

During the 17th and 18th centuries, known as the age of *bel canto* (beautiful singing), singers studied long and diligently to acquire technical perfection instrumental in character. Niccolo Antonio Porpora (1686–1766), recognized as the outstanding teacher of his time and credited with being the founder of the old Italian school of singing. had his pupil Caffarelli practise one page of exercises for several years. some say six. He then dismissed him saying. "You are now the greatest singer in the world." Among the famous teachers of this period were Pier Francesco Tosi (c. 1650–1732) and Giambattista Mancini (1716–1800). Outstanding in the 19th century mas Manuel Garcia (1805–1906) who probably marked the beginning of scientific interest in vocal training by his invention in 1855 of the laryngoscope, an instrument for examining the larynx. Other teachers of the 19th century who gained eminence were Mathilde Marchesi, a pupil of Garcia, Michelle Pauline Garcia Viardot, his sister, Giovanni Sbriglia, and Francesco and Giovanni Lamperti, father and son.

Many of the principles and methods of the early teachers have been perpetuated because beauty of tone and technical facility are still essential for artistic singing. In the 20th century. however, instructors have had recourse to audio-visual aids unknown in previous centuries. For example, hi-fi (high-fidelity) phonograph recordings, radio and television provide pupils many opportunities to learn through hearing and seeing. The recording machine whereby singers may record and play back their performances help both them and their teachers in critical analysis. Xevertheless, despite these inventions and scientific studies pertaining to singing, much of the teaching and learning continues to be empirical. This must of necessity be so because singers cannot easily observe the action of their own voices and it is difficult to give accurate descriptions. Therefore, teachers must provide exercises and imaginative concepts to establish good singing habits, to release nervous and muscular tensions, and to help pupils co-ordinate the singing organism. Differences in methods are the result of various ideas and ideals of teachers. But whatever means teachers advocate, doubtless all would agree that the voice must be musical and produced without strain.

Different types of compositions and changing points of view affect both styles of singing and teaching procedures. For example, in the age of *bel canto* purity of tone and virtuosity were the fashion In the 19th century, composers and audiences alike wanted much more from singers than beautiful voices nith flawless technique. In the songs by Franz Schubert qnd Robert Schumann vocal artists found opportunity for lovely singing but not vocal exploitation In the songs by Johannes Brahms, Richard Strauss and Hugo Wolf. they could give voice to profound feelings. In his operas. Richard Wagner exacted vocal and dramatic strength from singers. The arias of Giuseppe Verdi's operas had emotional and melodic appeal requiring variety in tonal colour. To render modern music with its difficult intervals, intricate rhythms and indefinite tonality a singer must have a keen musical ear and superior vocal control. Often he must seek realistic rather than beautiful effects.

Because of musical and histrionic demands, singers usually become specialists in grand or light opera, musical comedy, *lieder* or song and popular music. Within these fields there is also specialization. Some achieve renown in the operas by Wagner. others in those by Puccini; some excel in songs by French composers, others in those written by Germans. In popular music. some become known as crooners, others as blues, folk or ballad singers. Pet there are versatile singers who have been successful in two or more fields, as Helen Traubel, well-known Wagnerian opera soprano and night club entertainer, Ezio Pinza famous in both grand and light opera, and Lotte Lehmann, notable in grand opera and in *lieder* or song.

(Ann Arbor, Mich., 1955). (A. E. PE.)

SINGLESTICK, a slender, round stick of ash about 34 in. long and thicker at one end than the other, used as a weapon of attack and defense, the thicker end being thrust through a cup-shaped hilt of basketwork to protect the hand. The original form of the singlestick was the "waster," which appeared in the 16th century and was merely a wooden sword used in practice for the backsword, and of the same general shape. By the first quarter of the 17th century wasters had become simple cudgels provided with sword guards, and when: about 25 years later. the basket hilt came into general use, it was employed with the cudgel also, the heavy metal hilt of the backsword being discarded in favour of one of wickerwork. The guards, cuts and parries in singlestick play were at first identical with those of backsword play, no thrusts being allowed *(see* FENCING). The old idea, prevalent in England in the 16th century, that hits below the girdle were unfair, disappeared in the 18th century, and all parts of the person were attacked.

Under George I and George II, backsword play with sticks was immensely popular under the names "cudgel play" and "single-sticking." not only in the cities but in the country districts as well, wrestling being its only rival. Toward the end of the 18th century the play became very restricted. The players were placed near together, the feet remaining immovable and all strokes being delivered with a whiplike action of the wrist from a high hanging guard. the hand being held above the head. Blows on any part of the body above the waist were allowed, but all except those aimed at the head were employed only to gain openings, as each bout was decided only by a "broken head"; *i.e.,* a cut on the head that drew blood. At first the left hand and arm were used to ward off blows not parried with the stick, but near the close of the 18th century the left hand grasped a scarf tied loosely round the left thigh, the elbow being raised to protect the face.

The French cane fencing *(q.v.)* has a general similarity to singlestick play but is designed more for defense with a walking stick than as a school for the sabre.

SINGLE TAX, as the term originally developed in the United States, referred to a tax upon land values, or, in other words, on the annual economic rent of land, proposed as the sole source of government revenues, to replace all existing taxes. The term ultimately came to be used in reference to a tax of this type whether or not it was to be the only tax imposed.

The idea of a single tax on land is centuries old, appearing for example in the writings of the 18th-century physiocrats and of the famous English economist David Ricardo. But the term itself and the modern single-tax movement originated with the publication of *Progress and Poverty,* the first systematic presentation of the plan, written by a San Francisco newspaper editor, Henry George *(q.v.)* in 1879. The proposal gained substantial strength in ensuing decades, and then gradually declined in popular appeal. There were, however, in the second half of the 20th century still a number of very devoted disciples, the best known of whom was Harry Gunnison Brown, and publications in the field were sponsored by the Schalkenbach foundation, established for this purpose.

The basic arguments for the single tax were twofold. On the one hand it was argued that land rent, unlike other income, is a product of the growth of the economy. not of individual effort, and thus society is justified in recovering it to support the costs of government. Since land rent is a surplus return, a tax on it cannot be shifted forward to consumers, and cannot reduce the supply of land available to the economy. Land rent is essentially an "unearned increment" and thus governments are justified in taxing it at a 100% annual rate. On the other hand, use of the tax would allow elimination of other forms of tax, and particularly taxes on buildings, which interfere with construction and economic development generally. Thus the tax would stimulate gromth of the economv.

The critics of the proposal condemn the tax as contrary to usual standards of ability to pay, since there is no correlation between land ownership and total wealth and income. Portions of other incomes may be regarded as much "unearned" as land rent. If the tax were imposed today it would in large measure rest on the wrong persons, on those who had invested their capital in land rather than those who had benefited from the increase in land values. Furthermore, as a practical matter, separation of land values from those of buildings and other improvements would be extremely difficult.

While no attempt has ever been made to use the land tax as a single tax. and it is universally recognized that the levy could not meet all needs of governments, some of the states of Australia and municipalities in the western provinces of Canada have applied their property taxes to land only instead of to land and buildings, and several local governments in the United States and Canada have deliberately taxed land more heavily than buildings. The single-tax supporters claim that the use of the plan in Australia has greatly stimulated building in the states using it, but the evidence is not conclusive.

BIBLIOGRAPHY.—Henry George, *Progress and Poverty* (1879); H G. Brown, *The Economic Basis of Tax Reform* (1932), *Land-Value Taxation Around the World* (1955); A. N. Young, *The Single Tax Movement in the United States* (1916). (J F. D.)

SINGLETON, ESTHER (1865–1930), U.S. author, editor and antiquarian. published anthologies and books on various countries and cities, historic events: antique furniture, music and other topics. Her interests ranged widely and her books were based on painstaking research. Born at Baltimore, Md., on Nov. 4, 1865, she was educated there in private schools and by private teachers.

In 1887 she went to New York city to study music, and for the rest of her life made New York her permanent place of residence. Her first book, entitled *Turrets, Towers and Temples: The Great Buildings of the World as Seen and Described by Famous Writers,* was published in 1898. The following year her guide to the opera appeared and in 1909 a guide on modern opera was published. Other books on music included *The Orchestra and Its Instruments* (1917), *The Music Dramas of Richard Wagner* (1898) and *Musical Education* (1903), the two latter English translations of Albert Lavignac's works in French.

Editor of the *Antiqzrarian,* from 1923 to 1930, she turned to antiques and history for several books—The *Furniture of* Our *Forefathers,* 2 vol. (1900); *Social New York Under the Georges* (1902); *Historic Buildings* (1903j; *Great Events of the World's History,* j vol. (1903); *Historic Buildings of America* (1906); *Dutch New York* (1909); etc.

She died at Stonington, Conn., on July 2, 1930.

SINGLETON, the oldest town of the Hunter River valley *(see* HUNTER RIVER) in New South Wales, Austr., about 150 mi. N.W. of Sydney. Pop. (1954) 4,506. Though the town is situated in a river valley liable to floods, the possibility of petroleum in its neighbourhood, the production of good-quality coal from both opencut and tunnel mines. its grazing, timber cutting and sawmilling, mixed agriculture, fruit and vegetable growing and vineyards from which the renowned Hunter valley wines are made, co-operative dairying and cheese and butter making, cattle, sheep and pig marketing typify the growth of the area in which it occupies a central, linking position. The town has an efficient rail and road transport system, being served by the New England highway and two main roads.

Around Singleton there are large estates and timber cutting continues but farming, dairying and fruit and vegetable growing have increased during the 20th century. Sydney is to a large extent dependent upon this area for its milk supply. Singleton was formerly regarded as a rural area, but the production of coal from both opencut and tunnel mines has placed the town in the industrial category also, and it now competes with the Newcastle-Cassnock area as the chief source of coal production in New South Wales. (*See* also NEWCASTLE.)

SINGORA or SONGKHLA (the *Sangore* of early navigators), a port and *changwad* (province) of Thailand on the east coast of the Malay peninsula. Singora is situated in 7° 12′ N. and 100° 35' E.

Singora was settled at the beginning of the 19th century by Chinese from Amoy, the leader of whom was appointed by Siam to be governor of the town and district. Having been sacked more than once by Malay pirates, the town was encircled. about 1850, by a strong wall, which, as both Chinese governors and Malay pirates became things of the past, later supplied the public works department with good road metal. The population of Songkhla *changwad* (area, 2,576 sq.mi.) was 488,050 in 1960, having increased from 350,687 in 1947. The town became an important administrative centre; good roads and the railway connected it with Kedah and other places in the peninsula; mining was developed in the interior.

In the 20th century plans mere studied for improving the port so as to give all-year access to the inland sea. Singora by the time of World War II acquired a new importance through improved communication with the capital.

SINHA, SATYENDRA PRASSANO, 1ST BARON OF RAIPUR (1864–1928), Indian statesman, was born of an ancient family of the Kayashta or writer caste in the village of Raipur, Birbhum district, Bengal, in June 1864. From the Presidency college. Calcutta, he went to London in 1881 to join Lincoln's Inn, where he won many prizes and scholarships and was called to the bar in 1886.

On his return to India Sinha at once began to plead before the high court in Calcutta. In 1903 he became standing counsel to the government. He was the first Indian to be appointed advocate-general of Bengal (1908), and the first to become a member of the government of India. He held the law portfolio from April 1909 to Nov. 1910. He then resumed his lucrative practice at the bar. He presided at the Indian National congress session at Bomhay in 1915; in his presidential speech he begged the British government to declare their policy with regard to the development of constitutional government. He and the maharaja of Bikaner were the first Indians to participate in empire deliberations in London, for in 1917 they jointly assisted the secretary of state at the meetings of the imperial war cabinet. and were members of the Imperial War conference. Sinha joined the Bengal executive council in the same year, but returned to England in 1918 as a member of the imperial war cabinet and Imperial War conference. subsequently becoming a representative of India at the peace conference.

Knighted in 1914, in 1918 Sinha was made K.C., a distinction not previously conferred upon a barrister of Indian birth or practice. At the beginning of 1919 he joined the Lloyd George ministry as undersecretary for India, being raised to the peerage as Baron Sinha of Raipur and made a member of the privy council. He skilfully conducted the Government of India act. 1919, through the house of lords. At the close of 1920 he was appointed governor of Behar and Orissa. being the first Indian to preside over a British province. Ill-health prevented him from serving his full term in that office; in 1921 he resigned. In 1926 Sinha was appointed a member of the judicial committee of the privy council. He was opposed to the setting up of the statutory commission on the government of India at an earlier date than that indicated in the Government of India act, 1919, in view of the divided state of India; but, the decision once taken. he supported the Simon commission. He died March 5. 1928.

Sinha is remembered by Indians as the first to break down all the barriers against Indians. and by lawyers as a learned. patient and courteous judge. Circumstances drove him into politics but his real interests lay in the progress of education.

SINHAILIEN, (HSIN-HAI-LIEN). an important city and rail-terminal seaport on the Yellow sea in north Kiangsu province, China. It is an amalgamation of several settlements founded at different times. bearing many individual names between 1900 and 1949. Haichow (Hai-chou) mas the name once applied to an old junk port at the coastal end of a canal system. Sinpu (Hsin-p'u) was the early inland eastern terminal of the Lunghai railway. Lao-yao and Lien-yun-kang appeared on some maps to name a new deepwater port built in the 1930s south of the unusable silted estuary of the Yun-yen Ho and Shu Ho. Tung-hai and Ta-p'u both were used as names for the central portion of the urban complex. Sinhailien. applied to the whole city, and Lien-yun-kang, applied to the port, were both in use in the second half of the 20th century. Pop. (1953) 207.600. (J. E. SR.)

SINING (HSI-NING), capital of Tsinghai province. China, on the south bank of Sining river, a tributary of the Yellow river! and 110 mi. W.N.W. of Lanchow. Sining, which is situated on the northeast margin of the Tibetan highlands at an elevation of 7,500 ft., is the centre of an agricultural district east of Lake Koko-Nor. producing spring wheat and barley. Wool, hides and salt are also marketed. Long linked only by highways with the rest of China. the city was in 1959 reached by a railroad from Lanchom. Sining is the gateway to the Tsaidam basin. where the Chinese have developed new petroleum fields and mining industries. Pop. (1953) 93.700. (T. SD.)

SINKIANG (HSIN-CHIANG), name of a former province of westernmost China, converted Sept. 1955, into the Sinkiang Uigur Autonomous Region (Hsin-chiang Uigur Tzu-chih Ch'ü), a political division at the provincial level set aside for the Uigur ethnic minority. Area 635.829 sq.mi.; pop. (1957 est.) 5,640,000. The name Sinkiang means "new borderland" and is roughly coextensive with what was historically known as Chinese Turkistan.

Sinkiang is bordered on the northeast by the Mongolian Peoples Republic. on the southwest by Kashmir and a narrow strip of Afghanistan, and on the west and north by the Central Asian republics of the Soviet Union. Physiographically, Sinkiang consists of two mountain-ringed basins separated by the east-west-trending Tien Shan (*q.v.*). The Dzungarian basin, in the north, has an elevation of 600 to 1,500 ft., and receives summer rainfall that makes Dzungaria (*q.v.*) ideal as a grazing land. The Tarim (*q.v.*) basin, south of the Tien Shan, has an average elevation of 2.500 to 3,000 ft. It is much more arid than Dzungaria, and its centre is occupied by the sandy Takla Makan (*q.v.*) desert. At the eastern end of the Tarim basin lies the salt lake and marshland of Lop Nor (*q.v.*).

Sinkiang is multinational. The Uigurs, a Moslem Turkic-speaking people, the most important ethnic group, numbered 3,640,125 persons (1953) and comprised 75% of the regional population. They settled primarily in irrigated agricultural oases along the northern foot of the Tien Shan, and around the edge of the Tarim basin. The second largest ethnic group is the Kazakh. also a Moslem Turkic people. related to the Kazakhs of the Soviet Cnion. They numbered 475.000 in Sinkiang in the 1953 census. Unlike the Uigurs, the Kazakhs are primarily nomadic herders and graze their livestock in the Dzungarian pasture lands where a separate political division (Ili Kazakh Autonomous Chou, with its capital at Kuldja) was set aside for them. The Kazakhs also have two autonomous *hsien* (counties); at Mu-lei-ho and Barkol (Chen-hsi), in eastern Sinkiang (see also TURKS OR TL-RKIC PEOPLES.)

There were about 300,000 Chinese in Sinkiang, residing mainly in cities and towns. where they worked as government officials, merchants and professional people. Chinese Moslems (*Hui*), numbering 200.000 in 1953. were concentrated in the Urumchi area in the Ch'ang-chi Autonomous Chou and also in the Yen-ch'i Autonomous district. south of the Tien Shan. There were 120.000 Mongols in Sinkiang occupied mainly as livestock herders. Mongol autonornous areas include the Boro Tala. Autonomous Chou, on the south slopes of the Dzungarian Ala-Tau on the Soviet border; the Bayin Gol Autonomous Chou in the basin of the lake

Baghrash Kol south of the Tien Shan; and the Kobuk-Sai-li Autonomous district, on the slopes of the Saur range on the Soviet border. The Kirghiz people (70,000 in 1953) constitute the Kizil Darya Autonomous Chou, north and west of Kashgar, adjoining the Kirghiz S.S.R. of the Soviet Union. About 20,000 Sibo people, a Tungusic group near Kuldja, and 15,000 Tadzhiks are also set up in an autonomous district. (See also MONGOLS; KIRGHIZ, TUNGUSES; TAJIKS.)

Sinkiang's economy is primarily agricultural. Its cultivated land was expanded after 1949 through addition of new irrigated areas, such as the Manas river project on the northern foot of the Tien Shan. Grain crops, mainly wheat, corn, kaoliang and sorghum and ginned cotton are important products of the Tarim basin oases. Sinkiang's livestock herds, estimated about 21,000,000 head in the late 1950s, included about one-quarter of China's sheep, which yielded more than 60% of the nation's wool. In the early 1960s industry was in an early stage of development. with handicrafts (cotton goods. paper. rugs, leather goods and jade articles) accounting for two-thirds of the total value of manufacturing. The principal cities and their 1953 census populations are: the regional capital, Urumchi (140,700), Kashgar (91,000), Yarkand (80,000) (*qq.v.*), I-Ning (Kuldja) (108,200) and Aksu (90,000). The development of modern industry depends in part on the development of the region's mineral resources and the construction of modern transportation routes. Petroleum was produced on a small scale at Tu-shan-tzu, near Wu-su. A large petroleum centre at Karamai, 70 mi. N. of Wu-su. was under development in the early 1960s. Mineral prospects also include tungsten, molybdenum and other nonferrous metals, as well as coal and iron ore. A major railroad crossing Sinkiang from Kansu province to the junction of Aktogai on the Turksib railroad in the Soviet Union was completed in the early 1960s.

South Sinkiang was controlled by China (200 B.C.–A.D. 220) during the Han dynasty. The Uigurs ruled for many centuries until the area was conquered by Jenghiz Khan and his successors and later by the Kalmucks, Sinkiang eventually came under Chinese control in the 17th century during the Manchu dynasty. It became a Chinese province in 1884. During the Kationalist period, warlords ruled Sinkiang, sometimes with Soviet support. Chinese Communists seized control in Oct. 1949. (T. SD.)

SINKING FUNDS: see DEBT, PUBLIC.

SINO-JAPANESE WAR: see CHINESE-JAPANESE WAR (1894–95).

SINOP, the capital of an *il* on the north coast of Turkey, on a low isthmus joining the promontory of Boz Tepé to the mainland. Though it possesses the only safe roadstead between the Bosporus and Batum, the difficulties of communication with the interior and rivalry of Ineboli on the west and Samsun on the east prevented Sinop from becoming a great commercial centre. It is shut off from the plateau by forest-clad mountains. Pop. (1960) 9,899. On the isthmus stands a huge but for the most part ruined castle, originally Byzantine and afterward strengthened by the Seljuk sultans. The Mohammedan quarter is surrounded by massive walls. Of early Roman or Greek antiquities there are only the columns. architraves and inscribed stones built into the old walls; but the ancient local coinage furnishes a very beautiful and interesting series.

See M. Six, paper in *Numismatic Chronicle* (1885); Babelon and Reinach, *Recueil des monnaies grecques d'Asie* Mineuve (1903).

Sinop, whose origin was assigned by its ancient inhabitants to Autolycus, a companion of Hercules, was founded 630 B.C. by the Ionians of Miletus, and ultimately became the most flourishing Greek settlement on the Euxine, as it was the terminus of a great caravan route from the Euphrates through Pteria to the Black sea, over which were brought the products of central Asia and Cappadocia (whence came the famous "Sinopic" red earth). In the 5th century B.C. it received a colony of Athenians, and by the 4th it had extended its authority over a considerable tract of country. Its fleet was dominant in the Euxine. except toward the west, where it shared the field with Byzantium. When in 220 B.C. Sinop was attacked by the king of Pontus, the Rhodians enabled it to maintain its independence. But where Mithradates IV failed, Pharnaces succeeded; and the city, taken by surprise in 183 B.C., became the capital of the Pontic monarchy. Under Mithradates VI the Great, who was born in Sinop, it had just been raised to the highest degree of prosperity, with fine buildings, naval arsenals and well-built harbours, when it was captured by Lucullus and nearly destroyed by fire (70 B.c.). In 64 B.C. the body of the murdered Mithradates was brought home to the royal mausoleum. Under Julius Caesar the city received a Roman colony, but was already declining with the diversion of traffic to Ephesus, the port for Rome, and in part to Amisus (Samsun). In the middle ages it became subject to the Greek empire of Trebizond. and passed into the hands of the Seljuk Turks. and in 1461 was incorporated in the Ottoman empire. In Kov. 1853 the Russian vice-admiral Nakhimov destroyed there a division of the Turkish fleet and reduced a good part of the town to ashes.

SINS, SEVEN DEADLY, a classification that goes back to the early history of Christian monasticism. A sin was classified as deadly not merely because it was a serious offense morally but because "it gives rise to others. especially in the manner of a final cause" or motivation (Thomas Aquinas). The traditional catalogue of the seven deadly sins is: (1) vainglory or pride; (2) covetousness; (3) lust, understood as inordinate or illicit sexual desire; (4) envy; (5) gluttony. which usually included drunkenness; (6) anger; and (7) sloth. sometimes called acedia or accidia. The classical discussion is in Thomas Aquinas, *Summa* theologine, i–ii. Q. 84. art. 4. (J. J. PN.)

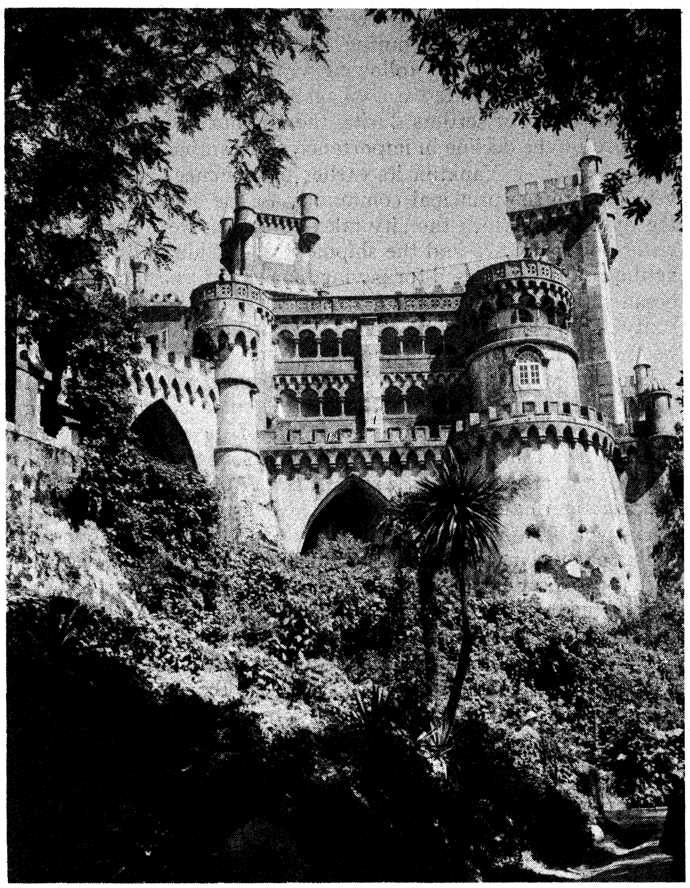
SINTER, in petrology, certain mineral deposits, more or less porous or vesicular (cinderlikei in texture. At least two kinds of sinter are recognized: one siliceous, the other calcareous. Siliceous sinter is a deposit of opaline or amorphous silica from hot springs and geysers. occurring as an incrustation around the springs, and sometimes forming conical mounds or terraces. The deposition of siliceous sinter is largely due to the action of algae and other forms of vegetation in the thermal waters. Siliceous sinter has also been called geyserite and fiorite.

Calcareous sinter is a deposit of calcium carbonate. exemplified by travertine. which formed the principal building stone of Rome. and was named from the Italian *travertino,* a corruption of *tiburtino,* the stone of Tibur. now Tivoli (see STONE). So-called petrifying springs, not uncommon in limestone districts, yield calcareous waters which deposit a sintery incrustation on objects exposed to their action.

The cavities in calcareous sinter are partly due to the decay of mosses and other vegetable structures which have assisted in its precipitation. Even in thermal waters, like the hot springs of Carlsbad, Bohemia, which deposit *Sprudelstein,* the origin of the deposits is mainly due to organic agencies, as shown as far back as 1862 by the German botanist Ferdinand Julius Cohn. While calcareous deposits in the open air form sinterlike travertine, those in caves constitute stalactites and stalagmites. See also CALCITE; STALACTITES AND STALAGMITES.

SINTRA (CINTRA), a town of Lisboa district, west central Portugal, lies 28 km. (17 mi.) W.N.W. of Lisbon by rail or road. Pop. (1960) 83,646 (municipal). It is picturesquely situated on the northern slope of the Serra de Sintra. a rugged mountain mass largely overgrown with pine, mimosa, cedar, eucalyptus, cork and other trees, above which rise bare and jagged gray rocks (Cruz Alta. 1,732 ft.). The beauty of Sintra is celebrated by Lord Byron in *Childe* Harold and by Luis Vaz de Camões in *Os* Lusiadus. On one of the peaks is the Palacio da Pena, a fantastic 19th-century building. partly an adaptation of a 16th-century monastery and partly an imitation of a medieval fortress. On another peak is the Castelo dos Mouros, an extensive Moorish fortification. In the town itself is a 12th–15th-century royal palace, partly Moorish. partly debased Gothic, and remarkable for the decoration of its rooms and its two immense conical chimneys. On the road to the village of Colares are the palace and park of Montserrate. The park, with its tropical luxuriance of vegetation and its variety of lake, forest and mountain scenery, is one of the finest examples of landscape gardening in the Iberian peninsula.

Sintra has given its name to two conventions, one in 1509 between Portugal and Castile settling differences concerning voyages



BURTON HOLMES FROM EWING GALLOWAY

PALACIO DA PENA, SINTRA, CASTLE OF FANTASTIC DESIGN BUILT IN THE EARLY 19TH CENTURY

of exploration, and one in 1808 by which the British and Portuguese allowed the beaten French army to return home during the Peninsular War.

SINUIJU, (Japanese, SHINGISHU) a city and capital of North Pyongan province, North Korea, was developed by the Japanese during their occupation (1910–1945) at a site 7 mi. W. of the old city of Uiju where a railroad bridge mas built across the Yalu river connecting with the Manchurian city of An-tung. Sinuiju (or New Giju) is an industrial and commercial city and wood rafted down the Yalu forms the base of a large forest products industry. Trade with Manchuria and China is funneled through the city to Korea. Pop. (1958 est.) 200.000. (S. McC.)

SINUS, in anatomy, is a space filled with blood (as in the sinuses of the brain) or air (as in the cranial bones). The word is also used by surgeons to signify a discharging tract that will not heal and has in many cases a foreign body or dead bone at the bottom. Popularly, however, the term sinus is used most often to designate one of the air-containing cavities connected with the nose. The largest of these cavities (the maxillary sinus. or antrum of Highmore) is contained in the cheek bone; the next in size in the forehead (frontal sinus); smaller cavities open into the back (sphenoidal sinusj and sides (ethmoidal cells) of the nose. The paranasal sinuses are bilateral extensions of the nasal air chambers and are lined with ciliated mucous membrane continuous with that of the nose. *See* SINUSITIS. (S. HA.; X.)

SINUSITIS, in common usage, refers to disease of the paranasal sinuses (see SINUS).

Acute Sinusitis. — This may occur as an aftermath of a cold, due to secondary bacterial infection, or it may be precipitated by faulty breathing habits in swimming or by sudden changes in barometric pressure in flying or diving. Allergy and conditions resulting in lowered general resistance may predispose to attacks. Infections of the upper molar and bicuspid teeth may cause acute maxillary sinusitis.

Symptoms are pain and headache, tenderness over the affected area, nasal obstruction and discharge and malaise. Conservative treatment, bed rest, fluids, heat externally, sedation for pain. and vasoconstrictor sprays to relieve obstruction generally are effective. Persistence of symptoms may indicate the use of suction to promote drainage, and antibiotic therapy, based upon culture and sensitivity studies. X-rays may suggest irrigation of the maxillary or external drainage of the frontal sinus.

Chronic Sinusitis. — Chronic sinusitis may follow repeated or neglected attacks of acute sinusitis, particularly if there is impaired nasal breathing and drainage due to intranasal obstruction. These may be aggravated by poor environmental conditions, dust or excessively dry air of heated dwellings. Dental infection in the upper molar and bicuspid area may cause chronic disease in the maxillary sinus

Symptoms are tendency to colds, purulent nasal discharge, obstructed breathing, loss of smell and sometimes headaches. Pain is rare except during acute phases. Foul-smelling discharge may indicate dental origin. While there may be increased postnasal discharge. its significance often is overstressed. as the normal drainage from the nose is posteriorly to the pharynx Frequently symptoms attributed to sinusitis may be manifestations of general conditions (particularly allergy or disturbance of the endocrine system) or result of faulty nutritional or living conditions or of habitual use of nasal sprays or drugs. Stress and tension may be contributing factors.

Successful treatment depends upon a thorough systematic evaluation of the patient, including X-rays and other diagnostic studies, to determine not only the status of the sinuses but also the significance of any underlying conditions. Surgery may be indicated to restore ventilation and drainage, to eliminate irreversibly diseased tissues and to avoid complications. (F. T. HI)

SION, the capital of the Swiss canton of Valais (1,680 ft. above sea level). There are (1960) 16,051 inhabitants (mainly Roman Catholics). The majority of the population of the town is French-speaking. Sion (Sedunum) dates from Roman times. and the bishop's see was removed thither from Martigny (Octodurum) about 580. In 999 the bishop received from Rudolf III, king of Burgundy. the dignity of count of the Valais, and henceforward was the temporal as well as the spiritual lord of the Valais, retaining this position, at least in part, till 1798. Sion is one of the most picturesque little cities in Switzerland. being built around two prominent hillocks. The north hillock is crowned by the castle of Tourbillon (built 1294, burned 1788), which was long the residence of the bishops. The south hillock bears the castle of Valeria (which contains an historical museum) with the interesting 13th-century church of St. Catherine.

SION COLLEGE, in London. an institution founded as a college. guild of parochial clergy and almshouse. under the will (1623) of Thomas White, vicar of St. Dunstan's in the West. The clergy who benefit by the foundation are the incumbents of the city parishes, of parishes which adjoined the city bounds when the college n·as founded and of parishes subsequently formed out of these. The original buildings in London Wall were on a site previously occupied by Elsing Spital, a hospital for the blind founded in 1320, and earlier still by a nunnery. They comprised the almshouses, a hall and chapel and the library added to the foundation by John Simson, rector of St. Olave's, Hart street; one of White's executors. There were also: at least originally, apartments for students. In 1884 the almshouses were abolished and the almsfolk became outpensioners. It was subsequently found possible to extend their numbers from the original number of 10 men and 10 women to 40 in all, and to increase the pension. In 1886 Sion college was moved to new buildings on the Victoria embankment and is now principally known for its theological library. A governing body appointed by the members to administer the foundation consists of a president, two deans and four assistants.

SIOUAN INDIANS. This great family of American natives takes its name from that of the largest tribe, the Sioux or Dakota (*q.v.*). Next to the Algonkin, they were perhaps the most populous stock north of Mexico. They held three territories, the largest mainly west of the Mississippi river, another, east of the Appalachian mountains in Virginia and the Carolinas; the smallest, in two fragments, in Mississippi. The last two divisions are nearly extinct. The culture was not uniform, but accorded with the region in which each tribe lived. Physical types probably varied similarly. In the Plains area, the Siouans were the preponderant linguistic stock. The principal Siouan tribes were (those asterisked being separately treated): (1) in the nest, *Dakota and *Assiniboin, the former really seven tribes: *Mandan, *Hidatsa and *Crow; *Winnebago; tribes speaking the Chiwere dialect, namely the Iowa, Oto Missouri; tribes speaking Dhegiha, viz., *Omaha, Ponca, Kansa, *Osage, Quapaw or Arkansas; (2) in the south, Ofo and *Biloxi; (3) in the east, Monacan, Manahoac, Tutelo, Saponi, Occaneechi, Woccon, *Catawba, Santee, Cheraw or Sara, and probably Wateree, Congaree, Pedee and others. About 40,000 remain; the original numbers were probably at least twice as great. See also Index references under "Siouan Indians" in the Index volume. (A. L. K.; X.)

SIOUX CITY, a city of northwestern Iowa, U.S., is located on the bluffs of the Missouri at the mouths of the Big Sioux and Floyd rivers, where the states of Iowa, South Dakota and Nebraska meet; a port of entry and the seat of Woodbury county.

In 1804 Captains Meriwether Lewis and William Clark visited the site of Sioux City and there buried Sgt. Charles Floyd, the only man lost on their famous journey (see LEWIS AND CLARK EXPEDITION). Theophile Bruguier, a French-Canadian fur trader, settled there in 1849 and married the daughter of War Eagle, a powerful chief of the Yankton Sioux. In 1854 John K. Cook platted Sioux City while surveying the region for the U.S. government. It prospered originally as a supply centre for the northern plains and as a land-office town. The first steamboat from St. Louis reached Sioux City in 1856 and in 1857 the city, with a population of 400, was incorporated. The first railroad arrived in 1868 and the first meat-packing plant was opened a few years later. During the boom of the 1880s, when settlers occupied northwestern Iowa and the Dakotas, the packing industry expanded and the population jumped from 7,366 to 37,806. Although retarded by depression in the 1890s, during which its population dropped, Sioux City grew rapidly between 1900 and 1920 when its population topped 70,000. Pop. (1960) 89,159; standard metropolitan statistical area (Woodbury county) 107.849.

Early settlers in Woodbury county came mainly from the Ohio valley, New York, Pennsylvania and older Iowa. French Canadians, Germans and Scandinavians also settled there and a Russian group was present by 1900. A community of Negro packing-house workers developed after 1910.

The Sioux City stockyards receive large consignments of local and out-of-state livestock for slaughter and packing. Commerce is also marked by heavy wholesale trade and grain exchange activity. Besides meat packing, industries include food processing and feed and clothing production, as well as other diversified manufactures.

Morningside college, a Methodist liberal arts institution which maintains a conservatory of music, was founded in Sioux City as the University of the Northwest in 1889. In 1930 the Sisters of St. Francis established Briar Cliff college (Roman Catholic) for women. Sioux City has a symphony orchestra and an extensive park system in which are preserved memorials of. Indian days including War Eagle's grave and the Council Oak of the Sioux. Sioux City adopted a commission form of government in 1910 and in 1953 switched to the council-manager plan. (A. G. Bo.)

SIOUX FALLS, the seat of Minnehaha county, in southeastern South Dakota, U.S., a few miles from the Minnesota border and about 75 mi. N. of Sioux City, Ia., on the rolling hills and in the wooded valley bordering the Big Sioux river. Pop. (1960) 65,466; standard metropolitan statistical area (Minnehaha county) 86,575. (For comparative population figures see table in SOUTH DAKOTA: Population.) The population of the city is much like that of the Dakota farm area, heavily Scandinavian and German. There are few Indians.

Except for an early fur-trading establishment that later became Fort Pierre, Sioux Falls is the oldest community in South Dakota. It was founded in 1857 by Iowa and Minnesota land speculators who were disappointed when in 1861 Yankton, rather than Sioux Falls, was named capital of the new Territory of Dakota. The settlement was deserted during the uprising of the Minnesota Sioux which started the following year. Settlement dates from 1870; it was incorporated as a village in 1877 and as a city in 1883. With the influx of settlers during the Dakota boom of the 1880s, followed by the decline in importance of steamboat transportation which had given Yankton its earlier prominence, Sioux Falls developed into the principal community in the state. The falls of the river, from which the city takes its name, were harnessed for water power in 1873 and the shipment of "Sioux Falls granite." a hard quartzite once used for paving blocks and as a building stone, began with the arrival of the first railroad in 1878. Because of the laxity of the South Dakota divorce laws prior to 1908 Sioux Falls was for a time nationally famous as a "divorce mill."

Located in an area of diversified farming where corn is the principal crop and livestock feeding the main source of income, Sioux Falls came into its own as a result of the wide use of trucks and the increasing dependence of farmers upon specialized farm machinery, fertilizers and mixed feeds. A distributing centre for the neighbouring farm area of Iowa, Minnesota and South Dakota, it has over 200 wholesale firms. Its main industries are food processing, particularly meat packing, and wood and metal fabrication. Farm prosperity of the World War II period, which lasted several years after the war, also helped to build Sioux Falls as a shopping, entertainment and commercial centre.

Educational facilities include Augustana, a Lutheran college founded in 1860, and Sioux Falls coflege, a Baptist institution established in 1883. The city has several parks and two golf courses. It has superior medical facilities, including a veterans hospital and a crippled children's hospital. The state penitentiary and a school for the deaf are also located there. (E. W. ST.)

SIOUX INDIANS: *see* DAKOTA.

SÍPHNOS (It. SIPHANTO; mod. Gr. SIPHÉNO), an island of the Greek archipelago, 30 mi. S.W. of Sýros (area 32 sq.mi.). Along the west slope of a limestone ridge, whose principal summits, Hagios Elias and Hagios Simeon, are crowned by old Byzantine churches, lies a series of villages, each whitewashed house with its own garden and orchard. Apollonia, the modern capital, has the name of an ancient town: Kastro has medieval fortifications, and the town hall bears the date 1365. Inscriptions show that Kastro represents the ancient city of Siphnos. Another ancient town, Minoa, is marked by two Hellenic white marble towers known as the Pharos (lighthouse) and St. John. Byzantine churches and convents are scattered about the island. The School of the Holy Tomb was founded by Greek refugees from the iconoclastic persecutions at Byzantium and became a centre of culture. Its endowments are held by the Gymnasium of Syra. In ancient times Siphnos was colonized by Ionians from Athens. It refused tribute to Xerxes, and sent one ship to fight on the Greek side at Salamis. It was famous for its gold and silver mines, easily recognized by excavations and refuse heaps. In antiquity, as now, it exported pottery. During the Venetian period it was ruled first by the Da Corogna family and after 1456 by the Gazzadini, who were expelled by the Turks in 1617.

SIPHON (SYPHON), an instrument, usually in the form of a bent tube, for conveying liquid over the edge of a vessel and delivering it at a lower level (Lat. sipho; Gr. siphon, "a tube"). The action depends upon the difference of the pressure on the liquid at the extremities of the tube, the flow being toward the lower level and ceasing when the levels coincide. The instrument affords a ready method of transferring liquids over a hump or elevation, and is made of glass, india rubber, copper or lead, according to the liquid which is to be transferred. The simple siphon is used by filling it with the liquid to be decanted, closing the longer limb with the finger and plunging the shorter into the liquid; and it must be filled for each time of using. Innumerable forms have been devised, adapted for all purposes and provided with arrangements for filling the tube or for keeping it full and starting it into action automatically when required. Pipes conveying the water of an aqueduct across a valley and following the contour of the sides are sometimes siphons, when they depend on the principle of the above instrument. Such a large siphon must be fitted with a valve for getting rid of entrapped air at the top of the hump or upper elevation of the siphon pipeline. In the siphon used as a container for aerated waters a tube passes through the neck of the vessel, one end terminating in a curved spout while the other reaches to the bottom of the interior. On this tube is a spring valve which is opened by pressing a lever. The vessel is filled through the spout, and the water is driven out by the pressure of the gas it contains, when the valve is opened. The "Regency portable fountain." patented in 1825 by Charles Plinth, was the prototype of the modern siphon, from which it differed in having a stopcock in place of a spring valve. The "siphon champenois" of Deleuze and Dutillet (1829) was a hollow corkscrew, with valve, which was passed through the cork into a bottle of effervescent liquid, and the "vase siphoïde" of Antoine Perpigna (Savaresse *père*), patented in 1837, was essentially the modern siphon, its head being fitted with a valve which was closed by a spring.

SIPHONAPTERA, an order of insects (*q.v.*) comprising the flea (*q.v.*), which are also known as the Aphaniptera.

SIPPAR, a city of ancient Mesopotamia, situated in 33° N., 44° E. The site today lies 5 mi. E. of the Euphrates, just south of the Royal canal (Nahr al Malik), but in ancient times the Euphrates flowed by the city. The temple of E-Babbar, "the House of the Sun," and its stage tower (ziggurat) occupied a terrace beside the river with a superficial area of about 1,300 sq.ft. East of the temple area and separated from it by a wide avenue lays the residential quarter, the whole city being surrounded by a wall. This wall forms a rectangle, 860 yd. wide and 1,400 yd. long, the long sides facing north and south. The excavations in the northern part of the eastern mound and on the ziggurat produced more than 60,000 tablets, chiefly contracts, and religious and grammatical texts of Neo-Babylonian date. The antiquity of the city, however, is shown by the fact that there are ancient records of the Euphrates being called the river of Sippar. Its Sumerian name appears to have been Zib-Bar Nun. The Sumerian sun-god was identified with the Semitic Shamash, and it was in this city that the sun-god had his principal cult. In ancient times the two rivers approached closely there and the site therefore commanded the entrance to the southern plain from the north.

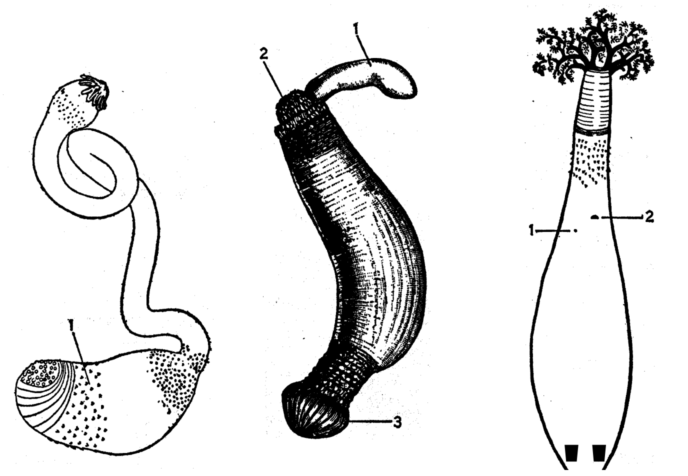
See Cambridge Ancient History, vol. i, with bibliography (1923).

SIPUNCULIDA, a phylum of marine worms which inhabit burrows, tubes or borrowed shells and which are adapted for this mode of life by a forward displacement of the anus, situated on the dorsal surface near the base of the proboscis. The body is thus elongated in a ventral direction almost at right angles to the anteroposterior axis, as it is in Bryozoa (see POLYZOA) and Phoronida (*q.v.*). This curious arrangement led E. R. Lankester to coin the name Podaxonia for them. The Sipunculida are distinguished from the Annelida (*q.v.*) not so much by the position of the anus —in some annelids the anus may be displaced dorsally—as by an apparent total lack of segmentation. The phylum Gephyrea, created by Jean L. A. de Quatrefages de Bréau to include Sipunculida, Echiurida (*q.v.*) and Priapulida (*q.v.*), cannot be sustained in view of the lack of relationships between its members, although it has persisted with remarkable tenacity in the literature.

External Characters.—The body of a sipunculid is divided into two regions, a trunk consisting chiefly of the elongated belly of the worm and a retractile proboscis which bears the mouth at its anterior end. The mouth is partly or completely surrounded by tentacles or tentacle-bearing folds. Many authors prefer to call the proboscis an introvert, to distinguish it from the proboscis-like prostomium of the Echiurida, which is a preoral lobe projecting forward above the mouth. Retractor muscles, of which the typical number is four but which may be reduced to two or only one, originate from the body wall of the trunk region and are inserted at the base of the tentacles. Contraction of these muscles serves to withdraw the proboscis which is invaginated into the body like the finger of a glove. Evagination depends upon hydraulic pressure, which is developed in the coelomic fluid by contraction of the circular muscles of the body wall. In *Sipunculus,* according to J. von Uexkull, this contraction may cause a pressure of nearly 600 mm. of mercury, approaching one atmosphere.

The number and arrangement of the tentacles varies widely (fig. 6). The mouth of *Sipunculus* is completely encircled by a lobed fold, frequently indented dorsally so that it assumes the shape of a horseshoe. In many genera the tentacles arise individually and they may or may not form a complete circle. Sometimes, as in most species of Phascolosoma, there are several concentric rings, while four to six branching plumose tentacles characterize the genus Dendrostoma (fig. 1[C]) of tropical and subtropical waters. In very small species, as of the genus *Onchnesoma*, the tentacles may be reduced or represented by tentacular discs.

The proboscis may be smooth but more frequently it is armed with chitinous spines and hooks whose form and arrangement as-



(A) AFTER GEROULD. "PROC. U.S. NAT. MUS."; (B) FROM SHIPLEY, "CAMBRIDGE NATURAL HISTORY" (MACMILLAN AND CO., LTD.); (C) FROM FISHER. "ANN. AND MAG. NAT. HIST." (TAYLOR AND FRANCIS, LTD.)

FIG I.— REPRESENTATIVE SPECIES OF SIPUNCULIDA

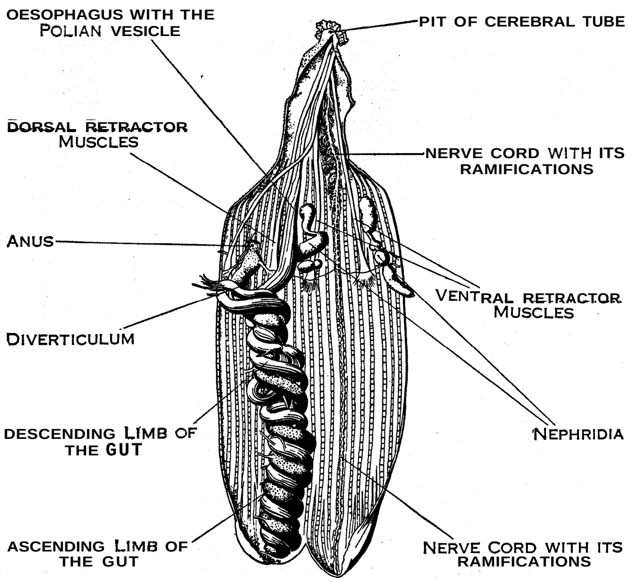
(A) Phascolion *strombi*: (1) holdfasts; (B) Aspidosiphon *truncatus*: (1) prostomium, (2) preanal plate, (3) apical plate; (C) Dendrostoma *petraeum*: (1) right nephridial pore, (2) anus

sumes importance in the identification of species. The anus, usually situated at the base of the introvert, is said to be shifted forward onto the proboscis itself in Onchnesoma. In *Cloeosiphon* the proboscis base is encircled by a calcareous collar formed by rows of close fitting calcified plates. The coral inhabiting symbiont Aspidosiphon (fig. 1[B]) uses a shield-shaped preanal plate to close the mouth of its burrow and on account of the presence of this plate the proboscis itself is displaced ventrally and appears to arise at an angle from the body. In the related genus *Lithacrosiphon* there is a remarkable calcified preanal cone.

The shape of the trunk varies greatly in the different genera. It may be short and saclike or long and vermiform. In Phascolion *strombi* (fig. 1[A]), a common North Atlantic species which inhabits self-cemented tubes of sand grains or empty shells of mollusks. the shape of the body depends upon that of the house in which it lives. Those individuals which inhabit gastropod shells acquire a spiral twist which is almost completely lacking in those that dwell in straight tubes. Nevertheless, in this genus, there is a fundamental asymmetry of the body, only the right nephridium being developed. In correlation with its habit of living in shells, Phascolion is provided with forwardly directed papillae, armed with U- or V-shaped chitinous holdfasts, which are especially abundant toward the apex of the body. Glands in the body wall secrete a substance which cements the lining of the tube and also a conical cap which partially closes the entrance hole. Those genera which have preanal shields often have chitinous or calcified thickenings at the apex of the body. Aspidosiphon has a caplike structure resembling an acorn.

Body Wall.—A simple epithelium secretes a chitinous cuticle, thicker on the trunk than on the proboscis. When horny or calcareous plates are present. they are special secretions of the epidermis. Glandular and sensory papillae, frequently accompanied by hooks and holdfast organs, are found on the trunk and on the proboscis, variously distributed in the different genera and species.

Some are almost completely smooth. Beneath the epidermis there is a connective tissue layer which seems to be more fully developed in some of the larger species. In *Sipunculus,* as in two closely related genera described by J. W. Spengel, coelomic diverticula penetrate into the body wall and may form longitudinal canals beneath the skin. The muscular coat consists of three layers, circular, oblique and longitudinal. The longitudinal coat may be continuous or divided into bundles and this provides a convenient, if not very fundamental, taxonomic character. The retractor muscles of the proboscis are special developments of the longitudinal coat. The muscle fibres are smooth, but histological preparations fixed in a state of isometric contraction simulate an appearance of cross striation (M. Olson, 1940).



FROM THEEL, "NORTHERN AND ARCTIC INVERTEBRATES" (VETENSKAPSAKADEMIEN)

FIG. 2.—GENERAL DISSECTION OF SIPUNCULUS PRIAPULOIDES FROM THE DORSAL SURFACE SHOWING THE INTERNAL ORGANS IN POSITION

Body Cavity.—The body cavity is a schizocoele. It is traversed by muscular strands and small mesenteries which support the internal organs but shows no evidence of true segmentation, although partitions resembling septa have been described in one species, *Siphonosoma cumanense.* It would be difficult to interpret a regular series of folds of this sort as true segmentation, in view of the extreme displacement of the anus and podaxonial elongation of the body. Evidence of true metamerism is found in the larval mesoderm, however *(see* below). Chlorogogue tissue similar to that of the Annelida is found on the coelomic surface of the intestine and its function presents similar problems in the two groups.

Coelomic Fluid.—The fluid itself is isotonic with sea water and contains only traces of protein. Among the various types of corpuscles may be mentioned phagocytic amoebocytes, free chlorogogue cells often aggregated in clumps and nucleated hemerythrocytes. The coelomic fluid also contains complex ciliated structures known as urns and in mature individuals, developing sex cells. Hemerythrin, the respiratory pigment of the hemerythrocytes, is madder pink when oxidized and colourless when reduced. Outside of the sipunculids, it is known only from a single species of polychaet *(Magelona).* It differs from hemoglobin both spectrographically and in its chemical properties. Although it is an iron-containing protein, the prosthetic group has never been identified, and G. F. Marrian believes that it is not hemin. The molecular weight is low, as in the intracorpuscular respiratory pigments of some annelids and vertebrates and differing strikingly from the macromolecular respiratory pigments found in solution in the plasma of other annelids and various invertebrates. According to M. Florkin, the dissociation curve is such that the pigment gives up oxygen to the tissues only when there is an extreme deficiency and as in the intracorpuscular hemoglobin of the echiurid *Urechis,* its main function is to serve as a reservoir which may be drawn upon during times when the worm is confined'to its burrow.

The ciliated urns (fig. 3) are budded off from the coelomic epithelium in certain regions, in *Sipunculus* from the surface of the so-called dorsal Polian vesicle *(see* below), in *Physcosoma* from the gut wall. Each urn is a closed vesicle, covered by flat peritoneal cells and containing fluid with connective tissue strands in its interior. A single ciliated cell sits like a cap on the vesicle, its circlet of cilia forming the brim, as it were, of the hat. The urns are believed to perform two functions: by their movement they aid in the circulation of the coelomic fluid, and the ciliary beat is such that foreign particles are collected in the central crown of the cap. In this way the coelomic fluid is very rapidly cleared of injected particles, as of india ink; such particles are not taken into the interior of the vesicle, but it is supposed that the accumulation is delivered in some way to the nephridia for elimination from the body. Although the presence of these remarkable bodies is very characteristic of the sipunculids, similar structures are found in other invertebrates, as in *Synapta.*

Tentacular System and Polian Vesicles.—Canals lined by an endothelium similar to that of the coelom form the so-called vascular system (fig. 4). A circular lophophoral vessel forms a ring surrounding the mouth and closely associated above with the brain; canals extend forward from it into the tentacles while one or two backwardly projecting blind tubes lie against the wall of the esophagus, above and below. These tubes, the so-called hearts or Polian vesicles, are named after a fancied resemblance to structures of that name in echinoderms. In small forms with reduced tentacles they may be lacking, while in some species of *Phascolosoma* the esophagus is studded with large numbers of little vesicles communicating with the main tube. The embryological origin of this system is not known but the canals contain corpuscles similar to those of the coelom and, in *Sipunculus,* the urns are budded off from both surfaces of the Polian vesicle, forward into the lacuna and backward into the coelom. Morphologically, the tentacular system is therefore probably a part of the body cavity; physiologically it appears to perform two different functions. P. R. Awati and L. P. Pradhan have shown that in *Dendrostoma signifer,* a tropical species with branching tentacles, the Polian vesicle is a pulsating organ which pumps the fluid alternately in and out of the lophophoral canals by frequent reversals of its beat. The fluid is thus kept in motion and hemerythrocytes are circulated in and out of the tentacles by lateral and median vessels. On the other hand, in forms like *Sipunculus* in which the tentacles are short, the respiratory function of the canals may be subservient to a hydrostatic function. When the proboscis is everted the pressure set up in the body cavity compresses the Polian vesicles and fluid is thus forced forward into the tentacles, causing them to become extended.

Digestive System.—The mouth lacks jaws. A ciliated esophagus lying in the proboscis is followed by the long, coiled mid-gut. The latter passes backward in a loop to the apex of the body and then forward again to the anus. The limbs of this loop are usually twisted together in a spiral. This spiral is frequently supported by a spindle muscle which originates near the anus, traverses the central axis of the spiral and inserts itself apically. The mid-gut opens into a short hind-gut which often receives a blind sac and with which are associated anal glands of unknown function.

Sipunculids feed on organic matter contained in mud and sand which is taken up by the tentacles and swept into the mouth by ciliary action. The mid-gut is generally laden with such material and it has been suggested that these worms play an important role in the comminution of mineral matter on the floor of the ocean, similar to that played by earthworms on the land.

Vascular System.—A true vascular system appears to be rudimentary but it is probably represented by a closed system of lacunae in the walls of the intestine. The functions of the blood are largely taken over by the coelomic fluid. The tentacular lacunae, discussed above, are frequently considered to be blood vessels.

Respiration.—Respiratory exchanges probably take place through the skin and in forms like *Sipunculus,* which have sub-epidermal coelomic skin canals, this function must be greatly facilitated. In others, as in *Dendrostoma,* the gill-like branching tentacles may be the chief respiratory organ.

Excretory Organs.—A pair of metanephridia of relatively simple structure opens on the ventral surface of the body in front of the level of the anus. In *Phascolion* and *Onchnesoma* the development of one member of the pair, usually the left, is suppressed. The tube may be straight or U shaped, and the limbs of the U may be more or less completely fused. Excretion takes place through the mediation of special cells lining the tube and also, apparently, by the migration. of excretophores from the coelomic fluid into the lumen. The ciliated nephrostome may also play a part in collecting waste products, but it is believed to serve primarily as a collecting organ for the genital products which develop in the coelom.

Nervous System.—Paired cerebral ganglia form a bilobed brain which is situated above the pharynx and closely associated with the special sense organs (fig. 5). The brain may lie quite superficially beneath the skin, as in *Phascolosoma verrillii,* or it may be more or less deeply sunken at the bottom of a cephalic tube that communicates with the exterior by a small opening behind the tentacles. According to J. H. Gerould, the development of the cephalic tube is probably an adaptation to burrowing; it reaches an extreme condition in species like *Sipunculus nudus* which may dig themselves down to nearly a metre in loose sand. In some species the cephalic tube is said to open into the mouth, a condition which led M. A. Hérubel to make an interesting if somewhat fantastic comparison with the vertebrate hypophysis.

In addition to the neurones of the special sense organs, the brain receives sensory nerves from the tentacles and sends motor nerves to the retractor muscles of the proboscis. Circumpharyngeal connectives unite the brain with the ventral nerve cord which is ganglionated along its whole course and gives off mixed nerves to the body wall. There is no evidence of metameric segmentation. The speed of conduction in the ventral cord approaches that of the somatic motor nerves of cold-blooded vertebrates, 10–20 cm. per second.

Sense Organs.—The surface of the body responds both to tactile and chemical stimuli; sense organs vaguely resembling taste buds are located in the skin papillae and may contain both bipolar sensory neurones and gland cells. Gerould clarified our understanding of the special sense organs, which are of three sorts:

1. The frontal organ, a lobe of the brain which projects forward and is united with an epithelial cushion at the base of the cerebral tube or depression. This cushion consists of a loose mass of epithelial cells several layers in thickness and covered by a very thin cuticle; in it are embedded the spindle-shaped terminations of sensory neurones whose nuclei are situated in the anterior part of the brain. The function is unknown.

2. The nuchal organ, a ciliated paired or quadripartite elevation, resembling the organ of this name in Polychaeta, is present in some genera, above the frontal organ. *Sipunculus,* which has the frontal organ at the bottom of a long cerebral tube, lacks a nuchal organ but the dorsal wall of the canal bears long cilia. Although well innervated its function is unknown.

3. Paired eyes are present in sipunculid larvae and persist in the adults of various species. In larvae they are simple pigment spots associated with the future brain; in adults they may disappear or, if present, they may become deeply sunken at the bottom of ocular tubes which lie embedded in the brain and are closed to the exterior by cuticular plugs. Within the ocular tubes a secretion forms a lenslike body. Neurons from sensory cells at the base of the eye communicate by a direct reflex pathway with the motor nerves of the retractor muscles. Retraction in response to a light stimulus is extremely rapid in species which have well-developed eyes.

Reproductive Organs.—The sexes are separate but externally similar. The gonads are attached at the origin of the retractor muscles from the body wall and are of various forms. In *Sipunculus* there are paired branching glands on little stalks; in *Dendrostoma* there is a single transverse ridge. The sex cells are shed into the coelom at an early stage and grow to maturity nourished by the coelomic fluid. The eggs are usually spherical but in *Physcosoma* they are flattened. The nephridia function as gonoducts.

Development.—Segmentation is of the annelidan-molluscan type with spiral cleavage, but developmental studies have only been made upon a very few species. The blastopore forms the mouth, the anus develops later and is situated somewhat dorsally from the very beginning. The retractor and circular muscles are derived from mesectoderm. In *Phascolosoma vulgare* no trace of metamerism was found by Gerould. His later studies show that the "mesoblastic somites" described in parasagittal sections of a larva of *P. gouldii* were probably caused by contraction of the trunk and buckling of the viscera. The free-swimming trochophore of *Phascolosoma* differs from that of annelids in the large yolk-filled cells bearing the preoral, or adoral, band of cilia (prototroch). These cells, disintegrating at metamorphosis, shed their yolk granules and nuclei into the freely circulating coelomic fluid.

The locomotor function of the prototroch is taken over by a metatroch, provided with much longer cilia, which encircles the body below the level of the mouth. In *Sipunculus,* the prototroch, cells form a thin, ciliated mantle, or serosa, cast off at metamorphosis (B. Hatschek).

Natural History.—The sipunculids are bottom dwellers but since the anus is shifted forward toward the mouth it is not necessary for them to inhabit U-shaped tubes with entrance and exit holes, as in the case of echiurids and many tubicolous annelids.

The proboscis is used in digging and some species burrow to considerable depths. Others construct tubes of their own by cementing sand grains together while yet others take up their abode in tubes of annelids or shells of mollusks. In some species of *Aspidosiphon* there is a kind of symbiosis between the worm and a coral which grows on the outside of the shell. As the coral grows, the worm enlarges its tube which becomes encased in the calcareous base of the coral. In this genus and in others there are horny or calcareous preanal plates which are used to close the mouth of the burrow.

Zoogeographical studies by various authors (M. A. Hérubel, W. Fischer, A. C. Stephen and others) indicate that sipunculids may provide useful marine faunistic indices. North sea species are divided into deep and shallow water groups; an Indo-Pacific element in the South African intertidal fauna is absent, as might be expected, from the west coast. Some species, like those found in the Baltic or *Thalassema dendrorhyncus* from the Chilka lake, are tolerant of low salinities while, according to W. Harms, the Sumatran species *Physcosoma lurco* is terrestrial, living in dry mangrove soil like an earthworm. The probable role of sipunculids in the comminution of the sea bottom has already been referred to. The supposedly planktonic genus *Pelagosphaera* is undoubtedly a larval stage; C. N. Dawydoff observed the metamorphosis of a larva of this type from the coast of Annam.

Classification. — There appear to be 10 or 12 accepted genera comprising more than 130 species, but the group is badly in need of revision. Since the Sipunculida are so frequently treated as a family of the Gephyrea, there has been no attempt to group the genera into families and in view of the close interrelationships it is probable that any such attempt would be doomed to failure. J. H. Gerould believes that species of the genus *Phascolosoma* provide an ancestral group whose divergent members became specialized in different directions. The only clear-cut distinction appears to lie between those genera which possess calcareous or horny plates and those which do not, but even this grouping is probably artificial.

The following grouping of the genera may prove useful: group **A,** with horny or calcareous preanal and apical plates: *Aspidosiphon* and *Lithacrosiphon;* group B, mith preanal plates only: *Cloeosiphon;* group C, without plates, the longitudinal muscles in bundles: *Sipunculus, Xenosiphon, Siphonosoma* and *Physcosoma;* group D, without plates, the longitudinal muscles in a continuous sheath: *Dendrostoma, Phascolosoma* (= *Golfingia*), *Phascolion, Onchnesoma* and *Siphonomecus.* The arrangement of the tentacles (fig. 6) and the number of retractor muscles provide valuable taxonomic characters.

Fossil Remains. — It is uncertain whether any of the remarkable Middle Cambrian forms, some of which were referred by C. D. Walcott to the Gephyrea, can be regarded as sipunculids since the intestine, when preserved, appears to be straight. *Epitrachys,* a supposed sipunculid, has been described from the lithographic shales of Germany (Mesozoic).

Relationships. — There can be no doubt that the sipunculids have pronounced annelidan affinities in spite of their apparent lack of segmentation. The latter condition is possibly a suppression, correlated with the forward displacement of the anus. Molluscan relationships have also been claimed, on embryological grounds; in both groups the blastopore forms the mouth and the sipunculidan prototroch has been compared with the velum of a molluscan larva. The term "Podaxonia" (Lankester), implying close relationships mith the Phoronida (*q.v.*), is misleading. It does not apply accurately to the Sipunculida. the development of which from an extremely simple unsegmented trochophore, by terminal growth backward, is entirely unlike the peculiar larval growth of *Phoronis.*

The total lack of setae may be a primary character but could equally well result from a suppression correlated with the mode of life of the animal; setae are absent in various aberrant annelids, including the entire class of the Hirudinea.

Relationships between Sipunculida, Priapulida and Echiurida are discussed under the title ECHIURIDA.

BIBLIOGRAPHY.—A good account of the Sipunculida is given by F. Baltzer in Kukenthal and Krumbach, *Handbuch der Zoologie,* vol. 2, part 2 *(1931);* the article by W. Harms in the *Handw. Naturwiss.,* 2nd. ed., vol. 9 *(1934)* can also be recommended. There is no modern account in the English language but the article by **A.** Shipley in the *Cambridge Natural History,* vol. 2 (1901), is still interesting and usable although in some respects out of date. *Taxonomy and classification:* keys to the sipunculid genera have been published by many authors but most are either out of date or refer to restricted geographical regions. That given by F. Baltzer appears to be most complete but it includes two genera which are not generally accepted as distinct (*Tylosoma* = ? *Phascolion* and *Petalostoma* = *Phascolosoma)* and excludes the remarkable genus *Lithacrosiphon.* The following provide for the identification of species from certain restricted regions: W. Fischer, *Die Tierwelt der Nord-und Ostsee,* sec. *6 (1925)*; A. C. Stephen, "The Echiuridae, Sipunculidae and Priapulidae of Scottish and Adjacent Waters," *Proc. R. Phys. Soc. Edinb.,* vol. *22,* pp. 159–185 *(1934)*; J. H. Gerould, "The Sipunculids of the Eastern Coast of North America," *Proc. U.S. Nat. Mus.,* vol. *44,* pp. 373–437 *(1913)*; H. Sato, "Studies on the Echiuroidea. Sipunculoidea and Priapuloidea of Japan," *Sci. Rep. Tôhoku Imp. Univ.* (4), vol. *14,* pp. *359–362 (1939)*; for more complete information consult the *Zoological Record. Morphology:* P. R. Awati and L. P. Pradhan, "The Anatomy of Dendrostoma Signifer Selencka and De Man," **J.** *Univ. Bombay,* vol. *4,* pp. 119–125 *(1936)*; *J. SIQUEIROS, DAVID ALFARO (1896–), youngest of the "big three" of 20th-century Mexican mural painters (the others being José Clemente Orozco and Diego Rivera; *qq.v.*), was born in Chihuahua on Dec. 29, 1896. Although he signed his painting "Siqueiros," his true patronymic was Alfaro. A sublieutenant in the Constitutionalist army at the age of 15, Siqueiros had already entered upon a lifelong dual career as artist and militant propagandist. In Paris from 1919 to 1921, he later visited the U.S.S.R., the U.S. and various Latin-American countries. In the 1920s he helped to found the Mexican magazine Machete. During the Spanish civil war of 1936–39 he served in the republican army.

Alone or with organized groups of colleagues, Siqueiros produced thousands of square metres of vivid wall paintings, indoors and outdoors, commonly using synthetic lacquer colours sprayed from paint guns to produce his powerful, brightly coloured effects. In his studio paintings as well as on public walls, he portrayed social, political and industrial change and ferment with a dazzling mixture of photographic realism, illusion and fantasy. His most persuasive and permanent murals are to be seen at the headquarters of the Electrical Workers' syndicate, the Palace of Fine Arts, the Polytechnic institute, the National university, the nurses' home at Social Security hospital no. 1, all in Mexico City, and at Chillán in Chile. Scores of his easel paintings—signed "El *Coronelazo*" after 1943—are in private collections and museums, notably the Museum of Modern Art in New York city.

SIRENIA, an order of aquatic placental mammals, comprising the manatees (*Trichechus*), the dugongs (Dugong), the extinct (since the 18th century) Steller's sea cow (Hydrodamalis), as well as their fossil relatives of the Tertiary period. The torpedo-shaped body ends behind in a horizontal tail fluke, as in the dolphins; but in contrast with the latter the broad muzzle is truncate and the transversely expanded lips are very mobile. The name Sirenia was given in allusion to the supposed resemblance of these animals to mermaids. A dugong as seen at a distance from the deck of a ship and especially if floating half upright, with its baby under its flipper, might well be mistaken for a mermaid; and many legends gathered around them in the early days of exploration of the Indian ocean. For the evolutionary history and relationships of the Sirenia, see UNGULATA. See also DUGONG; MANATEE; SEA COW.

SIRENS, in Greek mythology, the daughters of Phorcys the sea-god (Gr. Seirones) or, in later legend, of the river-god Acheloiis and one of the nymphs. In Homer they are two in number (in later writers generally three); their home is an island in the western sea between Aeaea, the island of Circe, and the rock of Scylla.

They are nymphs of the sea, who lured mariners to destruction by their sweet song. Odysseus, warned by Circe, escaped the danger by stopping the ears of his crew with wax and binding himself to the mast until he was out of hearing (Odyssey xii). When the Argonauts were passing by them, Orpheus sang so beautifully that no one had ears for the Sirens. After one or other of these failures they drowned themselves. When the adventures of Odysseus were localized on the Italian and Sicilian coasts, the Sirens were transferred to the neighbourhood of Neapolis (Naples) and Surrentum, the promontory of Pelorum at the entrance to the Straits of Messina, or elsewhere. The tomb of one of them, Parthenope, was shown in Strabo's (v, p. 246) time at Neapolis, where a gymnastic contest with a torch race was held in her honour.

Perhaps the most reasonable explanation of the Sirens is that they are soul birds; *i.e.,* winged ghostly figures who brought the living to join them. They are in this respect not unlike the Harpies (*q.v.*). In early art, they were represented as birds with the heads of women; later, as female figures with the legs of birds, with or without wings.

SIRGUJA (properly SURGUJA), a district in Madhya Pradesh, India. Area 8,623 sq.mi. Pop. (1951) 822.041. In the central part there is fairly well-cultivated country, surrounded on three sides by massive hill barriers and tablelands, of which the Jamirapat, a winding ridge 2 mi. in width, separates it from Chota Nagpur. The southern barrier of the state is the Mainpat, a fine tableland 18 mi. by 6 mi., rising to 3,700 ft. The Ramgarh hill is a rectangular mass of sandstone rising abruptly from the plain, containing a remarkable natural tunnel, many rock caves and remains of temples made of enormous blocks of stone. There are other ruins in the jungles, indicating a higher state of civilization at an earlier epoch than that now prevailing. The majority of the population is made up of a remarkable variety of aboriginal tribes. Surguja, formerly one of the Chhattisgarh states within the Eastern States agency and ruled over by a Rajput family, was merged in Madhya Pradesh on Jan. 1, 1948. The state had been ceded to the British in 1818. The chief town is Ambikapur (pop. 10,-362).

SIRHIND, a tract of land in the Punjab, India. It consists of the northeastern portion of the plain between the Jumna and Sutlej rivers, and is watered by the Sirhind canal, which draws its water supply from the Sutlej near Rupar. The canal, which was opened in 1882, irrigates over 2,000 sq.mi.

SIRICIUS, SAINT (c. 334–399), pope from 384 to 399, was a Roman by birth. In spite of the antipope Ursinus, Siricius was unanimously elected pope in Dec. 384. He often followed the lead of St. Ambrose (*q.v.*), but was conscious that he bore "the burdens of all who are burdened, or rather, the Blessed Apostle Peter carries them in our person," as he wrote to Himerius, bishop of Tarragona, in answer to disciplinary questions. These responses are the earliest surviving texts of papal decretals. St. Jerome's departure from Rome, while not forced by Siricius, was not unwelcome to him. Jerome's later activities in anti-Origenism displeased the pope. Ambrose and Siricius ended the Meletian controversy at Antioch by recognizing Flavian as patriarch. Although he opposed Priscillianism and other errors, Siricius disapproved of Catholic extremists. Siricius was pope when the emperor rebuilt the basilica of St. Paul; a still surviving column commemorates Siricius's dedication. He is venerated as a saint; his feast day is Nov. 26. (W. M. K.)

SIRIONO INDIANS, a group of seminomadic, Guarani-speaking aborigines who live in isolated pockets of tropical forest land in eastern Bolivia. Of a total population of about 2,000 less than a third still roam the forests near the Rio Blanco, the Rio Grande and the Rio Piray. The remainder live in missions or under conditions of forced labour on farms and cattle ranches in the political departments of the Beni and Santa Cruz.

Few tribes of the world are more technologically handicapped than the Siriono in their native state. Their only weapon is a cumbersome bow and arrow; their only tool, a digging stick of palm. They live almost exclusively by hunting and by gathering wild fruits and nuts, although occasionally maize, cassava and papaya are planted in natural clearings in the forest. They wear no clothing and live on the margin of subsistence the year around. They are not warlike, being preoccupied with food getting. The aged and infirm are sometimes abandoned, as is the house when a person dies.

The Siriono are organized into endogamous bands of from 60 to 100 persons. An entire band lives in a single hut, a crude, roughly rectangular palm shelter providing little resistance to wind and rain. Within the hut the matrilineal family groups cluster around a series of hammocks and hearths.

In part because of the difficult nature of supplying sufficient food for survival, ceremonial, aesthetic and religious life are also not highly elaborated among the Siriono. A form of ring dance is practised but no other forms of art are developed. Religion is highly animistic, centred on a fear of evil spirits and monsters.

See Allan R. Holmberg, Nomads of the Long Bow, Institute of Social

Anthropology, publ. no. 10 (1950) for a full account of Siriono life and a bibliography related to the Siriono Indians. (A. R. Ho.)

SIRIUS (the Dog star) is the brightest star of the constellation Canis Major (*q.v.*); it is also visually the brightest star in the heavens. Intrinsically, it is a normal blue star 21 times as luminous as the sun; it is somewhat larger than the sun and has a considerably higher surface temperature. Its apparent brilliance in the skies is mainly because of its relative nearness to Earth. The distance of Sirius from the solar system is 8.6 light-years, which is only twice the distance of the nearest known star beyond the sun. (See also STAR.)

Sirius was known as Sothis to the Egyptians, who early in their history were aware that this star made its first appearance of the season in the twilight before sunrise at about the time when the annual floods were beginning in the Nile delta. The Egyptians long believed that Sothis caused the Nile floods and accordingly was the "creator of all green growing things," as a Pyramid text declares. They discovered that the heliacal risings of the star occurred at intervals of $365\frac{1}{4}$ days rather than the 365 days of their calendar year, a correction incorporated by Julius Caesar (in 45 B.C.) by use of the plan of leap years in his reform of the Roman calendar. Among the Romans the hottest part of the year was associated with the heliacal rising of the Dog star, a connection that survives in the modern expression "dog days."

The fact that Sirius is a binary star was reported in 1844 by F. W. Bessel at Konigsberg. He had observed that the bright star was pursuing a wavy course among its neighbours in the sky instead of going ahead uniformly in a straight line, as a single star would do. Bessel concluded that Sirius had a traveling companion, with which it revolved in a period of about 50 years. This discovery constituted the first chapter in what came to be known as the "astronomy of the invisible"; *i.e.*, the detection of unseen celestial bodies by their effects on visible bodies. The discovery of the planet Neptune two years later by its gravitational effects on Uranus was another famous example. Whereas Neptune was sighted soon after its place in the sky was predicted, the companion of Sirius waited nearly 20 years for direct telescopic verification. The companion was first seen in 1862 by Alvan Clark, a U.S. telescope maker who was using the bright star for testing the lens of the 184-in. refractor now at the Dearborn observatory.

Sirius and its companion revolve together, once around in 49.9 years, in orbits of considerable eccentricity and with average separation of the stars equal to the distance of Uranus from the sun. Despite the glare of the bright star, the 8th-magnitude companion is readily seen with a large telescope except when the two appear closest together, as they did in 1944. The two stars are respectively 2.3 and 1.0 times as massive as the sun. Although the companion has one-third the mass of Sirius and about the same surface temperature, its light is only $\frac{1}{10,000}$ as bright as that of the brilliant star. The conclusion seemed inescapable that the companion has the mass of a star, the size of a planet and therefore a density many thousand times the density of water. Although so high a density of matter seemed surprising at that time when little was known about atomic structure, a test of the conclusion was available from the theory of general relativity. Albert Einstein showed that the lines in the spectrum of a star should be displaced to the red by an amount that is directly proportional to the cube root of the star's mean density. Small enough in the case of the sun to be masked by other factors, this displacement would be conspicuous in the spectrum of an extremely dense star.

W. S. Adams reported (1925) on his observations of the spectrum of the companion of Sirius. He had found the lines displaced in the predicted direction, but by an amount somewhat different than might be expected. It may be that the diffused light of the bright star was confused in the spectrum with that of the companion. Later, D. M. Popper studied the spectrum of another excessively dense star, the 9th-magnitude white dwarf companion of the star 40 Eridani; he reported a red shift of the lines in satisfactory agreement with the shift that would be predicted from the calculated density in this case. *See* also Index references under "Sirius" in vol. 24. (R. H. BR.)

SIRMOOR, a district in Himachal Pradesh, north India. Area 1,095 sq.mi. Pop. (1951) 166,077. In British days it was a princely state subject to the Lahore resident. It was also called Nahan after its chief town (pop. 9,431), which is 33 mi. E.N.E. of Ambala.

The district is in the lower ranges of the Himalayas, between Simla and Mussoorie. On the northern border Chor Peak is at about 12,000 ft. above sea level.

SIROCCO: see WIND.

SIROHI, a municipality and a district in the southwest of Rajasthan. India. The town in 28 mi. N. of Abu Road station, on the main Delhi-Bombay line via Ahmadabad. It manufactures sword blades and other weapons. Pop. (1951) 11,956.

SIROHI DISTRICT (1,973 sq.mi.) had a population in 1951 of 289.791. It is most of the former princely state (1.988 sq.mi.), which under British rule was controlled through the Rajputana agency. After India became independent it was merged with Bombay (Jan. 5, 1949). but ethnic considerations led to its being transferred to Rajasthan (Jan. 24, 1950), with the exception of Abu Road tehsil and part of Dilwara tehsil. The Aravalli range traverses the district from northeast to southwest; 12 mi. S.W. of Sirohi is Mt. Abu (*q.v.*). Much of the district is covered with jungle, in which tiger, bear, leopard and other wild animals abound. Many splendid ruins bear witness to the former prosperity of the country. On Abu the average annual rainfall is about 64 in.; at Erinpura, less than 50 mi. N. it is only 13 in.

In 1823 Sirohi state concluded a treaty with the British. The chief, whose title was maharao, was a Deora Rajput of the Chauhan clan.

SIS (KOZAN; anc. SISION or SISKIA, later FLAVIOPOLIS or FLAVIAS), a kaza in the Adana vilayet of Asiatic Turkey, situated on the left bank of the Kirkgen Su, a tributary of the Jihun (Pyramus), and at the south end of a group of passes leading from the Anti-Taurus valleys to the Cilician plain and Adana. It was besieged by the Arabs in 704 but relieved by the Byzantines. The caliph al-Mutawakkil took it and refortified it; but it soon returned to Byzantine hands. It was rebuilt in 1186 by Leo II, king of Lesser Armenia, who made it his capital. In 1374 it was taken and demolished by the sultan of Egypt, and it never recovered its prosperity. In the 20th century it was only a big village of about 3,000 inhabitants. It has had, however, a great place in Armenian ecclesiastical history from the times of St. Gregory the Illuminator. Gregory himself was there consecrated the first catholicus in A.D. 267, but transferred his see to Vagarshapat (Echmiadzin, Etchmiadzin), whence, after the fall of the Arsacids, it passed to Tovin. After the constitution of the kingdom of Lesser Armenia, the catholicate returned to Sis (1294), the capital, and remained there 150 years. In 1441, Sis having fallen from its high estate, the Armenian clergy proposed to remove the see, and on the refusal of the actual catholicus, Gregory IX, installed a rival at Echmiadzin, who, as soon as Selim I had conquered Greater Armenia, became the more widely accepted of the two by the Armenian Church in the Ottoman empire. The catholicus of Sis maintained himself nevertheless, and was supported in his pretensions by the Porte up to the middle of the 19th century, when the patriarch Nerses, declaring finally for Echmiadzin, carried the government with him. In 1885 Sis tried to declare Echmiadzin schismatic, and in 1895 its clergy took it on themselves to elect a catholicus without reference to the patriarch; but the Porte annulled the election, and only allowed it six years later, on Sis renouncing its pretensions to independence. The lofty castle and the monastery and church built by Leo II, and containing the coronation chair of the kings of Lesser Armenia, are interesting. (D. G. H.)

SISAK, a town of Croatia, Yugoslavia. Pop. (1953) 19,238. Sisak was a flourishing city under Roman rule. Augustus made it a military station; Tiberius chose it as his headquarters against the Pannonian rebels; and Septimius Severus made it the centre of a military government. In the 3rd century the city contained the chief imperial mint and treasury; and an engraved coffer, found in Croatia, dating from the 4th century, represents

Siscia among the five foremost cities of the empire. Its bishopric was removed to Salona in 441, when Attila appeared, and thenceforward the city declined. For a brief period in the 7th and 8th centuries it was held by the Serbian princes, but in the 10th century it was sacked by the Magyars, and in 1092 its territories were bestowed upon the cathedral chapter of Zagreb (Agram) by Ladislaus I. king of Hungary.

Under the walls of its castle, built by this chapter in 1544, the Turks were thrice defeated in 1593. At a fourth venture the city fell, only to be evacuated in 1594. It witnessed a final Turkish defeat in 1641. and from that date until 1918 it was included in the Austro-Hungarian empire.

See C. de St. Aymour, *Les Pays sud-slaves de l'Autriche-Hongrie* (1883).

SISAKET, a province in northeast Thailand, formerly known as Khukhan. Area 3,403 sq.mi. Pop. (1956 est.) 537,890. Chief products include rice, cattle, timber and forest products. In the Dongrek mountains in the south, through which runs the Cambodian boundary, is the lofty Khmer temple complex of Khao Phra Wihan (Preah Vihear), which is one of the most spectacular ruins in southeast Asia. The southern part of the province is peopled primarily by Cambodians and Kui; Thai-Lao predominate in the more densely populated Mun river valley in the north. Sisaket town (pop., 1957, 9,519), the provincial capital, is on the railroad, 31 mi. from its eastern terminus at Ubon. (G. W. Sk.)

SISAL FIBRE, a hard fibre obtained from the leaves of Agave sisalana (family Amaryllidaceae), also known as sisal hemp. It is entirely different from true hemp—the product of Cannabis sativa, which is soft fibre. A closely related plant, Agave fourcroydes, produces the henequen fibre of Yucatán and Cuba, known in the trade as Yucatán sisal and Cuban sisal. Both sisal and henequen are indigenous to Mexico, but the east African colonies, Indonesia and Haiti are the main sources of supply of true sisal fibre.

The common century plant, Agave americana, suggests the habit of sisal and henequen. Both of these plants consist of a large rosette of rigid, straight, fleshy leaves arising from a short trunk. The sisal leaves are dark green in colour and have a terminal spine but ordinarily no marginal prickles. The life period of this plant is from five to ten years. The henequen plant has grayish-green leaves which bear both a terminal spine and marginal prickles. The life period of this plant is from 15 to 25 years. Both sisal and henequen, when mature, produce a flower stalk or pole which develops from the centre of the leaf cluster and grows to a height of 15–25 ft. The light-yellow flowers are borne in dense clusters at the ends of the lateral branches. The flowers of the sisal plant are followed by small bulbils, and those of the henequen plant by both bulbils and seed pods. The plants die after flowering. Both sisal and henequen may be propagated either from the bulbils or from suckers that grow from the rootstocks. The suckers are ordinarily used for commercial plantings. In harvesting, the lower mature leaves are cut off at the base, the spines and prickles are removed and the leaves are carried in bundles to the cleaning machines. The cleaning of these fibres is a scraping process in which the leaves as they pass through the machine are carried over curved metal plates and are scraped by rapidly revolving scraping wheels that remove the pulp and waste material. The fibre is then dried either in the sun or by artificial drying methods, is sometimes brushed and is then graded and baled for market.

COURTESY OF U.S BUREAU OF PLANT INDUSTRY, SOILS AND AGRICULTURAL ENGINEERING

HENEQUEN OF YUCATAN

The leaves are cut, one at a time, with a butcher knife. The first crop of leaves is cut when the plants are 6 or 7 years old, and afterward, two tiers are cut every 6 or 8 months for 8 to 15 years. The best plants average about 250 leaves during their lifetime

These fibres are white to yellowish-white in colour, strong, flexible and in value for cordage purposes are second only to abaci. Henequen is used principally for the manufacture of binder twine, while sisal is used for binder twine and many other types of cordage. These fibres have a limited use in the manufacture of coarse fabrics. See also FIBRE PLANTS. (H. T. Es.)

SISINNIUS, a Syrian, was pope from about Jan. 15 to Feb. 4, 708.

SISKIN (ABERDEVINE; *Carduelis spinus*), a canarylike bird which has long been known in England as a cage bird, is one of the finches (*q.v.*). It often feeds upon the catkins of alder or birch, frequently hanging upside down like a titmouse. Above, the male is olive green marked with black and yellow, and beneath, yellowish-white marked with black. The hen is grayer and streaked with white on its underparts. The male's song is a rapid musical twitter pierced with high squeaky call notes. The siskin breeds locally throughout Europe, and its range stretches across Asia to Japan.

Coniferous woods and thickets are favoured as nest sites. The nest of the siskin is like that of the goldfinch, but not so neatly built; the eggs, except in their smaller size, resemble those of the greenfinch.

A larger and more brightly coloured species, C. spinoides, inhabits the Himalayas. In the United States of America the name siskin or pine siskin is sometimes used for the pine finch (*Spinus pinus*).

SISLEY, ALFRED (1839–1899), French Impressionist painter, essentially a colourist who, like Monet, delighted in recording the changing effects of light in the successive hours of the day, and paid little attention to form, was born in Paris on Oct. 30, 1839, of English parents. He studied painting under Charles Gleyre and was afterward influenced first by Corot and then by the Impressionists Monet and Renoir. He worked both in France and in England and made the Seine, the Loing and the Thames the subjects of many pictures that are remarkable for the subtle appreciation of the most delicate colour effects. His life was one of constant poverty and hard struggle. Sisley died at Moret-sur-Loing on Jan. 29, 1899.

SISMONDI, JEAN CHARLES LÉONARD DE (1773–1842), whose real name was Simonde, was born at Geneva, on May 9, 1773. During the revolutionary disturbances of 1793–94 the Simonde family took refuge in England. On their return the greater part of the family property was sold, and with the proceeds they emigrated to Italy, bought a small farm at Pescia near Lucca, and set to work to cultivate it themselves. Sismondi's experiences gave him the material of his first book, Tableau de *l'agriculture* toscane, which, after returning to Geneva, he published in 1801. In 1803 he published his *Traité* de la richesse commerciale. As an economist, Sismondi represented a humanitarian protest against the dominant orthodoxy of his time. In his first book he followed Adam Smith, but in his principal subsequent economic work, Nouveaux Principes *d'économie politique* (1819), he insisted on the fact that economic science studied the means of increasing wealth too much, and the use of wealth for producing happiness too little.

Meanwhile he began to compile his great *Histoire* des *Républiques Italiennes* du moyen *âge,* and became intimate with Madame de Stael. He was invited or commanded (for Madame de Stael's invitations had something of command) to accompany her on the journey into Italy, described in *Corinne*. During this journey he made the acquaintance of the countess of Albany (*q.v.*) Louisa of Stolberg, widow of Charles Edward. Sismondi's relations with her were close and lasted long, and they produced much valuable and interesting correspondence. In 1807 appeared the first volumes of his history. The completion of this book, which extended to 16 volumes, occupied him for the next 11 years. He lived at first at Geneva, where he held a minor official post. In 1813 he visited Paris for the first time. During the Hundred Days he defended Napoleon's constitutional schemes or promises, and had an interview with the emperor. After the Restoration he left Paris. On completing (1817) his great book on the Italian republics, he undertook (1818) a still greater, the *Histoire* des *Français,* of which during the remaining 23 years of his life he published 29 volumes.

Sismondi died at Geneva on June 25, 1842.

Among his other works are: *Littérature du midi de l'Europe* (1813), an historical novel entitled *Julia Severa ou l'an 492* (1822), *Histoire de la Renaissance de la libertk en Italie* (1832), *Histoire de la chute de l'empire romain* (1835), *Précis de l'histoire des Français*, an abridgment of his own book (1839), with several others, chiefly political pamphlets. Sismondi's journals and his correspondence with Channing, with the countess of Albany and others have been published chiefly by Mlle. Mongolfier (1843) and M. de Saint-René Taillandier (1863). The latter work serves as the chief text of two admirable *Lundis* of Sainte-Beuve (Sept. 1863), republished in the *Nouveaux Lundis*, vol. vi.

SISSALA. A people resembling the Nunuma who inhabit the borders of Upper Volta (Gourounsi) and the Northern Territories, Ghana, Africa, and speak a language related to Nunuma and Kassena. A subtribe known as the Puguli live about 70 mi. west of Leo and Tumu in the Diébougou district of Upper Volta.

See Tauxier, *Le Noir du Soudan* (1912).

SISTERHOODS (MODERN ANGLICAN). The dissolution of religious houses in England (1536–1540) under Henry VIII swept away more than 140 nunneries, and the Anglican Church was left without sisterhoods for three centuries. But as these had for 900 years formed part of its system, there were protests from time to time and attempts at restoration. Among such protests, which generally dwelt a good deal on the want of provision for unmarried women, may be mentioned three in successive centuries. The historian Fuller would have been glad "if such feminine foundations had still continued," only without vows (Bk. vi). Richardson the novelist, in *Sir Charles Grandison*, wishes there could be a Protestant nunnery in every county, "with a truly worthy divine, at the appointment of the bishop of the diocese, to direct and animate the devotion of such a society"; in 1829 the poet Southey, in his *Colloquies* (cxiii), trusts that "thirty years hence this reproach also may be effaced, and England may have its Beguines and its sisters of mercy. It is grievously in need of them." Also small practical efforts were made in the religious households of Nicholas Ferrar at Little Gidding, 1625, and of William Law at King's Cliffe, 1743; and under Charles II, says Fr. Bede "about 12 Protestant ladies of gentle birth and considerable means" founded a short-lived convent, with Sancroft, then dean of St. Paul's, for director.

Southey's appeal had weight, and before the 30 years had passed compassion for the needs of the destitute in great cities, and the impulse of a strong church revival, aroused a body of laymen, among whom were included Gladstone, Sir T. D. Acland, A. J. Beresford-Hope, Lord Lyttelton and Lord John Manners (chairman), to exertions which restored sisterhoods to the Church of England.

On March 26, 1845, the Park Village community was set on foot in Regent's Park, London, to minister to the poor population of St. Pancras. The "rule" was compiled by E. Pusey, who also gave spiritual supervision. In the Crimean War the superior and other sisters went out as nurses with Florence Nightingale. The community afterward united with the Devonport Sisters, founded by Miss Sellon in 1849, and together they form what is known as Ascot priory. The St. Thomas's sisterhood at Oxford commenced in 1847; and the mother superior of the Holy Trinity convent at Oxford, Marian Hughes, dedicated herself before witnesses to such a life as early as 1841 (Liddon's *Life of Dr. Pusey*, iii).

Practically all Anglican sisterhoods originated in works of mercy, and this fact largely accounts for the rapidity with which they have won their way to the good will and confidence of the church. This change in sympathy, again, has gained a hearing from modern historians, who tend more and more to discredit the wholesale defamation of the dissolution period. Another modern feature is the fuller recognition of family ties: rule 29 of the Clewer sisters directs that "the sisters shall have free intercourse with relations, who may visit them at any time." But in most essential respects modern sisterhoods follow the ancient traditions. They devote themselves to the celibate life, have property in common, and observe a common rule of prayer, fellowship and work. Government is by a sister superior, assisted by various officers. The warden and chaplain are clergy, and the visitor is commonly a bishop.

In one important regard there has been hesitation, and authorities like Dr. Littledale and Bishop Grafton contend strongly for the primitive ideal of the convent as family, with a constitutional government, as against the later and widespread Jesuit ideal of the convent as regiment, with a theory of absolute rule and obedience. On the other hand, the doctrine of obedience itself, as applied to Anglican Sisterhoods, is subject to the atmosphere of free institutions and a respect for individuals

For religious orders of women in the Roman Catholic Church *see* MONASTICISM: *Women's Part.*

SISTOVA (Bulg. *Svishtov*), a town of Bulgaria, capital of the department of the same name, on the Danube, 40 mi. W. of Rustchuk. Pop. (1956) 18,537. A branch line connects it with the main Sofia-Rustchuk railway. It is an important commercial centre. exporting wine and grain and importing petroleum. The Roman colony Novae, mentioned by Ptolemy, lay a little westward of the present town, which has been destroyed and rebuilt many times (1797, 1810, 1829, 1878). The treaty of Sistova, determining the Austro-Turkish boundary. was signed there (1790). Near by are the ruins of the palace of Theodoric the Goth. The Walachian town of Alexandria was founded by fugitives from Sistova in 1878.

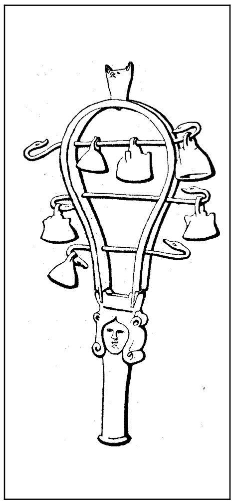
SISTRUM, an ancient Egyptian instrument of percussion of indefinite musical pitch, a kind of metal rattle. It consisted of an oval metal frame fastened to a handle and crossed by metal horizontal rods passing through holes large enough to allow them to rattle when the instrument was shaken.

The sistrum could also be played by beating it with a metal stick. This ancient instrument was extensively used by the priests in the temple of Isis to attract the attention of worshippers to different parts of the ritual.

The Egyptians attributed to it, as well as to the tambourine, the power of dispersing and terrifying evil spirits.

Queen Cleopatra made use of a large number of sistra at the battle of Actium (31 B.C.), and accordingly the instrument nas satirically called Queen Cleopatra's war trumpet.

SISYPHUS (etymology uncertain), son of Aeolus and Enarete, and king of Ephyra (Corinth). He was the father of the sea-god Glaucus and (in post-Homeric legend) of Odysseus. He was said to have founded the Isthmian games in honour of Melicertes, whose body he found lying on the shore of the Isthmus of Corinth From Homer onward Sisyphus was famed as the craftiest of men. When Death came to fetch him, Sisyphus put him into fetters so that no one died till Ares came and freed Death. and delivered Sisyphus into his custody. But Sisyphus was not yet at the end of his resources. For before he died he told his wife that when he was gone she was not to offer the usual sacrifice to the dead. So in the underworld he complained that his wife was neglecting her duty, and he persuaded Hades to allow him to go back to the upper world and punish her. But when he got back to Corinth he did no such thing and so lived until he died of old age (Pherecydes, frag. 119, Jacoby). In the underworld Sisyphus was compelled to roll a big stone up a steep hill; but before it reached the top of the hill the stone always rolled down. and Sisyphus had to begin all over again *(Odyssey,* xi, 593). The reason for that punishment is not mentioned in Homer. According to some. he had revealed the designs of the gods to mortals;



BY COURTESY OF METROPOLITAN MUSEUM OF ART

EGYPTIAN SISTRUM, USED BY PRIESTS IN THE TEMPLE OF ISIS according to others. he was in the habit of attacking and murdering travellers. The subject was a commonplace of ancient writers and was depicted by the painter Polygnotus on the walls of the Lesche at Delphi (*Pausanias*, x, 31).

According to the solar theory. Sisyphus is the disk of the sun that rises every day and then sinks below the horizon. Others see in him a personification of the waves rising to a height and then suddenly falling, or of the treacherous sea. It was suggested that the legend is symbolical of the vain struggle of man in the pursuit of knowledge.

The name Sisyphus was generally explained as a reduplicated form of σοφός ("the very wise"); Otto Gruppe, however, held that it may be connected with σίσυς ("a gdat's skin"), the reference being to a rain charm in nhich goats' skins were used.

S. Reinach (*Revue archéologique*, 1904) found the origin of the story in a picture, in which Sisyphus was represented rolling a huge stone up Acrocorinthus. symbolical of the labour and skill involved in the building of the Sisypheum. When a distinction was made between souls in the underworld, Sisyphus was supposed to be rolling up the stone perpetually as a punishment for some offense committed on earth; and various reasons were invented to account for it.

The way in which Sisyphus cheated Death is not unique in folk. tales. Thus in a Venetian story the ingenious Beppo ties up Death in a bag and keeps him there for 18 months; there is general rejoicing, nobody dies and the doctors are in high moods.

In a Sicilian story an innkeeper corks up Death in a bottle; nobody dies for years, and the long white beards are a sight to see.

In another Sicilian story a monk keeps Death in his pouch for 40 years. For several examples, see T. F. Crane, Italian Popular Tales (1885).

The German parallel is Gambling Johnny, who kept Death up a tree for seven years, during which time no one died (Grimm, Household Tales).

The Norse parallel is the tale of the Master Smith (E. W. Dasent, *Popular* Tales *from* the *Norse*). A Lithuanian parallel was covered in A. Schleicher's *Litauische Märchen, Sprichworte,* Ratsel und Lieder (1857) and Slavonic parallels appeared in F. S. Krauss's *Sagen und Märchen* der Sudslaven, ii. nos. 125 and 126.

SITAPUR, a municipality, with tehsil (administrative subdivision), and a district in the Lucknow division of Uttar Pradesh, India. The town is on the Sarayan river. 50 mi. N.N.W. of Lucknow. Pop. (1951): town 44,397; tehsil (511 sq.mi.) 389,408. It has a cantonment and is at an important junction of the Northern and North-Eastern railways. It has a considerable grain trade. There is a well-equipped eye hospital.

SITAPUR DISTRICT has an area of 2,206 sq.mi. Pop. (1951) 1,380,472. It is a vast plain, well wooded with numerous groves and well cultivated, except in those parts where the soil is barren and cut up by ravines. Except in the eastern part, which lies in the doabs between the Kewani and Chauka and the Gogra and Chauka rivers, the soil is as a rule dry. but even this moist tract is interspersed with patches of land covered with saline efflorescence called reh. The principal rivers are the Gogra, navigable throughout the year, and the Chauka.

SITKA (formerly NEW ARCHANGEL), historically the most notable settlement of Alaska, U.S.. on the west coast of Baranof Island, in Sitka sound. The city is on an island-studded and mountain-locked harbour, with a background of forest and snow-capped mountain cones; an extinct volcano, Mt. Edgecumbe (3,201 ft.), on Kruzof Island, is a conspicuous landmark in the bay. Monthly mean temperatures range from 33° F. (January) to 56° F. (August). Normal rainfall is 85.97 in. and annual snowfall averages 26.1 in.

Old Sitka or Ft. Archangel Gabriel. 6 mi. from the present town, was founded in May 1799 by Aleksandr Baranov, first Russian governor of Alaska. The fort was destroyed by the Tlingit Indians in 1802; the present town was founded in Sept. 1804 when Baranov moved his headquarters there from Kodiak. Commonly known by its Indian name, Sitka. probably the name of a local tribe or village, it was the headquarters of the Russian-American company until 1867. It was the leading trading post of Alaska and had shipyards, sawmills, flour mills, foundries and other industrial establishments. The formal transfer of Alaska to the U S. took place at Sitka on Oct. 18, 1867. From 1867 until 1906 Sitka was the capital of Alaska. The modern industries are logging and lumber manufacture, fishing and fish processing. There are salmon canneries, facilities for cold storage and processing of halibut, salmon and other fishery products and a large fishing fleet.

The public schools are attended by both whites and Indians of the Tlingit tribe. The Presbyterian-supported Sheldon Jackson high school and junior college are accredited schools. Other institutions include the Alaska Pioneers home for aged residents of the state; Sitka National monument, a 54-ac. natural park; Sitka National cemetery; Sheldon Jackson Ethnological museum; Magnetic and Seismological observatory of the coast and geodetic survey; St. Michael's cathedral, of the Orthodox (Russian) Church (1848); St. Peter's by the Sea (Episcopal, 1899); Lutheran church (founded in 1840, the first Protestant church in Alaska); Presbyterian and Roman Catholic churches.

On 475-ac. Japonski Island, in the harbour, the federal Alaska native service has established the Mt. Edgecumbe vocational boarding school for natives, a tuberculosis sanatorium and the Mt. Edgecumbe Orthopedic hospital, maintained jointly with the state of Alaska.

The population is about 3,000. (J. E. CL.)

SITTER, WILLEM DE (1872–1934), Dutch astronomer and cosmologist, whose papers on relativity published in London during World War I brought Einstein's General Theory to the notice of British scientists, with important consequences for cosmology. De Sitter was born at Sneek, Friesland. Neth., on May 6, 1872. He studied at the University of Groningen to become a mathematician, but, on the invitation of Sir David Gill, her majesty's astronomer at the Cape of Good Hope, he spent two years (1897–99) at the Cape observatory, as a result devoting himself to astronomy thereafter. In 1908 he was appointed professor of astronomy at Leiden, and in 1918 he became director of the Leiden observatory. There he trained student astronomers, many of whom obtained important posts abroad, especially in the U.S. As a practical astronomer he established a station at Johannesburg to observe the southern sky and sent expeditions to stations near the equator in Kenya to determine fundamental declinations by azimuth observations of stars at low altitudes.

From the time of his visit to the Cape, De Sitter had studied the motion of Jupiter's four great satellites. Theoretical discussions published in 1918, 1919 and 1925 used observations dating from 1668 and included results obtained by him from several observatories. He died at Leiden on Nov. zo, 1934. (J. JN.)

SITTIDAE: see NUTHATCH.

SITTINGBOURNE AND MILTON, an urban district in the Faversham parliamentary division of Kent, England, formed in 1930 by the union of Milton Regis with Sittingbourne. Pop. (1951) 21,904. Area 7.7 sq.mi. It is on a navigable creek of the Snale, 38 mi. E.S.E. of London by road. Sittingbourne consists principally of one long street, the Roman Watling street. Papermaking is its chief industry, brick and cement making and fruit preserving are also important, and as an agricultural market town it is the centre of the Kentish cherry-growing area. Sittingbourne is mentioned in Saxon documents in 989 and frequently in contemporary records of the 13th and 14th centuries. The first charter was obtained in 1573; a second in 1599.

From Roman until comparatively recent times Milton was a noted oyster fishery centre. It was a royal manor whose revenues formed part of the dowry of successive queens. An earthwork known as Castle Rough. in the marshes below Milton, was probably the work of Hasten the Dane in 892, and Bayford castle, 1 mi. distant, occupies the site of one said to have been built in opposition by King Alfred.

Tong castle, about 2 mi. E. of Sittingbourne, consists of a high mound surrounded by a moat and is said to have been erected by Hengest. The story of the founding of the castle resembles that connected with the city of Carthage. Vortigern is said to have granted Hengest as much land as an ox-hide could encompass, and the hide being cut into strips the site of Tong castle was accordingly marked out. The same tradition attaches to Tong castle in Shropshire. Tradition also asserts. according to the 12th-century chronicler, Geoffrey of Monmouth, that it was in Tong castle that Vortigern met Rowena, Hengest's daughter, and became so enamoured of her as to resign his kingdom to her father.

SITTING BULL (*c.* 1831–1890), a chief of the Teton Dakota or Prairie Sioux and son of Jumping Bull, was born on Grand river, in what is now South Dakota, about 1831. Fearless in battle with other tribes, he soon became leader of the Strong Heart Warrior society, and attacked U.S. troops invading his hunting grounds, 1864–68. He became principal chief of the northern hunting Sioux in 1866, and in 1868 made peace with the whites. But his failure to go upon a reservation led, in 1876, to the campaign in which Gen. George A. Custer (*q.v.*) and his immediate command were killed. Fearing retaliation, Sitting Bull and his band crossed into Canada in 1877.

Famine forced his return and surrender in 1881, and after 1883 he lived at the Standing Rock agency, where he vainly opposed the sale of tribal lands. Hunger, disease and rumours of a coming Indian Messiah who would sweep away the whites caused such unrest among the Sioux that, as a precaution, Indian police and soldiers were sent to arrest the chief. Seized by the police on Grand river, Dec. 15, 1890, Sitting Bull was killed while his warriors were trying to rescue him. (W. S. C.)

SIVA (*Shiva*), in post-Vedic mythology the destroyer-god who with Brahma the creator and Vishnu the preserver forms the Indian trinity. In the Vedas *shiva* ("auspicious") was the epithet applied to any god, even euphemistically to the baleful Rudra (*q.v.*).

In the Epic literature Siva has many attributes and various functions. He is lord of spirits (*bhuts*), protector of cattle (as Pasupati) and god of letters, music and dancing. As Nataraja ("dance-king"). however, his worship is confined to southern India; and there, too. is to be found one of his peculiar sects, the Lingayats (*q.v.*). His spouse is essentially Devi ("the goddess") under the various names, Uma, Parvati, Durga (*q.v.*), Kali (*q.v.*), or Karali.

See W. E. Hopkins, *Epic Mythology* (Strasbourg, 1915); O. C. Ganpoly, *South Indian Bronzes* (Calcutta, 1915).

SIVAJI (1627–1680), founder of the Maratha power in India, was born in April 1627. He was the son of Shahji Bhonsla, a Maratha soldier of fortune who held a jagir under the Bijapur government and regarded himself as appointed to free the Hindus from the Mohammedan yoke. Forming a national party among the Hindus of the Deccan, he opposed in turn the vassal power of Bijapur and the imperial armies of the Mogul of Delhi. By intrigue and hard fighting) Sivaji won for the Marathas practical supremacy in western India.

In 1659 Sivaji lured Afzul Khan, the Bijapur general, into a personal conference and killed him with his own hand. while his men attacked and routed the Bijapur army. In 1666 he visited the Mogul emperor Aurangzeb at Delhi, where, on his expressing dissatisfaction at not being treated with sufficient dignity. he was placed under arrest. Having effected his escape in a sweetmeat basket, he raised the standard of revolt and assumed the title of raja and the prerogative of coining money in his own name. He died in 1680. Sivaji had a genius both for war and for peaceful administration, but he always preferred to attain his ends by fraud rather than by force. He is the national hero of the Marathas.

SIVAS, a *vilayet* in Turkey. Pop. (1955) 590,890. SIVAS (anc. *Megalopolis-Sebasteia*), altitude 4,420 ft., is the chief town of the province. It is situated in the broad valley of the Kizil Irmak. on one of its right-bank tributaries, the Murdan Su. Pop. (1955) 66,350. The climate is healthful but severe in winter. Coarse cotton cloth and woolen socks are manufactured. The *medresses* (colleges), built in the 13th century by the Seljuk sultans of Rum, are among the finest remains of Moslem art in Asia Minor. In one of them is the tomb of its founder, Izz ud-din Kai Kaus I (1210–1219). Near the town is the Armenian monastery of the Holy Cross, in which are kept the throne of Senekherim and other relics. Under Diocletian Sebasteia became the capital of Armenia Minor, and in the 7th century that of the Sebasteia Theme. Justinian rebuilt the walls and. under the Byzantine emperors, it was second only to Caesarea in size and wealth. In 1021 Senekherim, king of the Armenian province of Vaspuragan (Van), ceded his dominions to Basil II, and became the Byzantine viceroy of Sebasteia and the surrounding country. This position was held by his successors until the town fell into the hands of the Turkomans after the defeat of Romanus II by the Seljuks (1071).

After having been ruled for nearly a century by the Danishmand amirs. Sivas was taken (1172) by the Seljuk sultan of Rum, and in 1224 was rebuilt by Sultan Xla-ed-din Kaikobad I. In 1400, when captured by Timur, the city is said to have had 100,000 inhabitants, and to have been famous for its woolen stuffs. On this occasion the bravest defenders were massacred, and 4.000 Armenians were buried alive. Mohammed the "Conqueror" restored the citadel, and the place was for many years an important Ottoman provincial capital. Early in the 19th century, like all other Ottoman towns, it was terrorized by janissaries. with whom Mahmud II commissioned the great Dere Bey of Yuzgat, Chapan Oglu. to deal in 1818. The news of his drastic success provoked a dangerous riot in Stambul, which postponed by some years the final tragedy of the janissaries. Mechithar, the founder of the Mechitharists (*q.v.*) and of the famous monastery at Venice. was born (1676) at Sivas. Sivas is connected with Angora by a railway which was extended to Erzeroum.

SIVATHERIUM, a gigantic extinct giraffe, larger and heavier than the living giraffe but with short legs. The female was hornless, but the male had a large pair of posterior horns, widespreading and simply branched, and a small conical pair over the eyes. *Sivatherium* is from the Pleistocene of India. Closely allied fossil giraffesoccur in the Pliocene of Europe and Asia and in the Pleistocene of Africa. (G. G. SI.)

SIVRI-HISSAR, "Pointed-Castle," a kazah in the Eski Shehir vilayet in Turkey, situated 8 mi. N. of the site of Pessinus, at the foot of a lofty double-peaked ridge of rock, which bears the ruins of a Byzantine castle. It is a road and commercial centre, with a trade in opium and mohair. Pop. (1955) 6,257. The town occupies the site of ancient *Paliæ*, refounded and renamed Justinianopolis by the emperor Justinian. It was one of the chain of fortresses on the Byzantine military road across Asia Minor, and became the chief city of Galatia Salutaris about. A.D. 700.

SIWA, an oasis in Western Desert province, Egy., near the Libyan frontier and about 350 mi. W.S.W. of Cairo. Also known as the oasis of Amon or Jupiter Ammon, its ancient Egyptian name was *Sekhet-am* (Palm land). Its chief town, also called Siwa, is situated in 29" 12' N., 25° 30' E. The oasis is about 6 mi. long by 4 to 5 wide, with a population (1956 est.) 1,100. Ten miles northeast is the small oasis of Zetun, and westward a chain of little oases and small salty pools extends for about 50 mi. Two rock outcrops provide the sites of the old walled ruins of Siwa and Aghurmi, veritable fortresses. The Siwans, who live in mudbrick houses at the foot of their old strongholds, are a mixture of Berber, Bedouin and Sudanese; they are distinct from the Egyptians, being connected more closely with north Africa than the Nile valley. They speak their own Berber dialect, although most of the men understand Arabic and about 10% of the people are literate. The only properly developed industry is basketmaking. The oasis is extremely fertile, with about 200 springs, of which 80 are important. Evidence suggests that in ancient times the area of cultivated land was greater than at mid-20th century, but modern attempts to enlarge the agricultural area have failed, mainly through lack of labour. Many kinds of fruit and cereals are grown, although some food is imported. The export of dates and olive oil provides the chief source of income; there are about 40.000 olive trees and 200,000 date palms. Desert caravans for trading are rare since the introduction of motor transport and the road connecting with the railway at Mersa Matruh.

The oasis owes its distinction to the oracle temple of Amon (*q.v.*), already famous in the time of Herodotus and consulted by Alexander the Great. The fragmentary remains of the temple, with inscriptions dating from the 4th century B.C., lie in the ruins of Aghurmi. The oracle fell into disrepute during the Roman occupation of Egypt. Half a mile from Aghyrmi is the ruined temple of Umm Beda, of the same period, with reliefs depicting the prince of the oasis making offerings to Amon. There are many remains of the Roman period. The area of the Libyan frontier is dominated by the Senussi sect who formerly prevented various explorers from penetrating westward beyond Siwa. The first European to reach Siwa since Roman times was William George Browne, who visited the oasis in 1792. In 1910 a telegraph line was built across the desert from Alexandria to the oasis. (A. B. M.)

SIWALIK HILLS, the Himalayan foothills extending from Dehra Dun district, Uttar Pradesh. India. across Himachal Pradesh (Sirmur district), and into Punjab state (Hoshiarpur. Nalagarh and Patiala districts). The range runs parallel with the Himalayan system from Hardwar on the Ganges to the Beas. with a length of 200 mi. and an average width of 10 mi. The elevation varies from 2,000 to 3,500 ft. Geologically speaking the Siwaliks belong to the tertiary deposits of the outer Himalayas, and are chiefly composed of low sandstone and conglomerate hills, the solidified and upheaved detritus of the great range in their rear. The intermediate valley lying between the outer hills and the Mussoorie mountains is known as the Dehra Dun (or Dehra valley) and was a popular residential area of Europeans and Anglo-Indians. The principal pass is that of Mohan by which the main road from Saharanpur to Dehra and Mussoorie traverses the range. The Siwalik formation (distinguished for its extraordinary wealth of paleontological remains) is found on the northwest frontier of Pakistan occupying much the same position relatively to the Suliman range as it does to the Himalayas. *i.e.,* it faces the plains and becomes the outermost wall of the hills.

SIWARD (d: 1055), a Danish warrior of whose origin nothing is certainly known. He appears as earl in the later charters of King Canute. His first sphere of government seems to have been Yorkshire, but from 1041 until his death in 1055 he was ruler of the whole Northumbrian earldom. His task was to hold the northern frontier of England against the Scots and to establish public order in the north after the general confusion of the previous generation. His life was spent in perpetual warfare, partly against the Scots, whose king. Macbeth, he defeated in a notable battle in 1054, but also against the more independent subjects of his own earldom. It was chiefly due to him that the far north of England became an integral part of the English kingdom. He died in 1055, at York. and was buried there in a minster which he had founded to the honour of God and Olaf. the sainted king of Norway, a contemporary of his own youth.

SIX NATIONS: see IROQUOIS.

SIXTUS, the name of five popes.

SIXTUS I (Xystus). saint. pope for nine or ten years in the second and third decades of the 2nd century. was the-successor of Alexander I and thus the sixth bishop of Rome after St. Peter.

SIXTUS II (Xystus), saint. pope from 257 to 258, succeeded Stephen I in Aug. 2j7. He restored the relations with the African and Asiatic churches that had been severed by his predecessor on the question of heretical baptism. He suffered martyrdom under the emperor Valerian and is commemorated on Xug. 6.

SIXTUS III (Xystus), saint, pope from 432 to 440. succeeded Celestine I on July 31, 432. He had previously been suspected of favouring the Pelagians. but on becoming pope he disappointed their expectations and repelled their attempts to enter again into communion with Rome. The dispute between Cyril of Alexandria and John of Antioch, who had been at variance since the Council of Ephesus. was settled in 433, but Sixtus himself had some difficulties with Proclus of Constantinople with regard to the vicariate of Thessalonica. He died on Aug. 18, 440, and is commemorated on ?\larch 28.

SIXTUS IV (Francesco della Rovere), pope from 1471 to 1484, was born of a poor family near Savona on July 12, 1414. He entered the Franciscan order at an early age and studied philosophy and theology at the universities of Padua and Bologna. He was chosen general of his order in 1464. Three years later. in 1467, he was, to his own surprise, made cardinal-priest of S. Pietro in Vincoli by Paul II. He was elected pope in succession to Paul on Aug. 9, 1471. The fleet that he sent. under Cardinal Caraffa, against the Turks in 1472 participated in the landing at Smyrna, but a new expedition in the following year was a failure. His relations with France were strained because of the Pragmatic Sanction of 1438 and more so after Louis XI's ordinance of 1475 requiring that no papal decree be published in France without the royal placet. Sixtus likewise continued in 1474 and in 1476 his predecessor's negotiations with the grand duke Ivan III of Muscovy for the reunion of the Russian Church with the Roman see and for support against the Turks, but without result. He was visited in 1474 by King Christian of Denmark and Norway, and in the following year he established the University of Copenhagen. Sixtus soon abandoned universal interests in order to concentrate attention on Italian politics and showed himself a confirmed nepotist. He was cognizant of the conspiracy of the Pazzi (1478), plotted by his nephew, Girolamo Riario, against Lorenzo de' Medici. He entered into a fruitless and inglorious war with Florence which kept Italy for two years (1478–80) in confusion. He next incited the Venetians to attack Ferrara (1481) and then, after having been delivered by their general Roberto Malatesta from a Neapolitan invasion (1482), turned upon them and eventually laid them under an interdict (1483) for refusing to desist from the hostilities which he had himself instigated. He relied on the co-operation of Ludovico Sforza, who speedily forsook him, and vexation at having peace forced upon him by the princes and cities of Italy is said to have hastened his death (Aug. 12, 1484).

In 1475 Sixtus instituted the office of the Immaculate Conception for Dec. 8; in 1478 he formally annulled the decrees of the Council of Constance; by a brief of Jan. 1482 he condemned abuses in the Spanish Inquisition; and in April 1482 he canonized St. Bonaventura. He granted many privileges to the Mendicant Orders, particularly to his own Franciscans. The most praiseworthy side of his pontificate was his munificence as a founder or restorer of useful institutions and as a patron of letters and art. He established and richly endowed the first foundling hospital, built and repaired numerous churches, constructed the Sistine chapel (1473–81) and the Sistine bridge, improved church music and instituted the Sistine choir, commissioned paintings on the largest scale. pensioned men of learning (notably Bartolomeo Platina) and. above all, immortalized himself, from 1471, as the second founder of the Vatican library. These great works, however, were not accomplished without grievous taxation. Annates were increased and simony flourished.

See J. Burckhardt, *The Civilization of the Renaissance in Italy,* Eng. trans., new ed. (London. 1951); L. Pastor, *History of the Popes,* vol. iv, Eng. trans. (London, St. Louis, Mo., 1894); E. Frantz, *Sixtus IV. und die Republik Florenz* (Regensburg, 1880). (X.)

SIXTUS V (Felice Peretti), pope from 1585 to 1590, was born at Grottainmare in the march of Xncona, near Montalto, on Dec. 13. 1521. Brought up in poverty. he entered a Franciscan monastery in 1533. He early showed rare ability as a preacher and as a dialectician. Sent to Rome in 1552, he attracted the attention of the future popes Paul IV (Caraffa) and Pius V (Ghislieri). He was appointed inquisitor general in the Venetian republic in 1557 but became involved in disputes and had to leave (1560). Sent to Spain with the legation under Cardinal Boncompagni (later Gregory XIII) in 1565, he conceived a strong dislike for Boncompagni and hurried back to Rome on the accession of Pius V, who made him vicar apostolic of the Franciscans and bishop of Sant' Agata de' Goti in 1566 and cardinal on May 17, 1570. Henceforth, as cardinal, Peretti was known by the name of Montalto. During the pontificate of Gregory XIII he lived in retirement, occupied with the care of his villa and with his studies (the first volume of his edition of the works of St. Amhrose appeared in 1580). Yet he did not neglect to follow the course of affairs, though carefully avoiding every occasion of offense. This discreetness contributed not a little to his election to the papacy on April 24, 1585.

The terrible condition in which Gregory XIII had left the states of the church called for prompt and stern measures. Against the prevailing lawlessness Sixtus proceeded with an almost ferocious severity, bringing thousands of brigands to justice by proceeding with vigour against their supporters among the powerful nobility. Within a short time the country was again quiet and safe, but Sixtus had made many enemies. He turned next to financial reform. By the sale of offices: by the creation of new *monti* (loans) and by levying new taxes, he accumulated a vast reserve: which he kept against certain specified emergencies, such as a crusade or the defense of the Holy See. He moreover pursued an active economic policy by regulating food prices and by encouraging agriculture and the production of wool and silk. Immense sums were spent on public works and buildings, yet Sixtus ended his reign as one of the richest princes in Europe, having begun it with an almost penniless treasury.

It is because of his achievements in reforming the central administration of the church that Sixtus must be reckoned as one of the greatest popes. By the bull *Postquam terris* (Dec. 3, 1586) the college of cardinals was given its definitive form, its number being limited to 70. The secretariat of state was reorganized, and in Jan. 1j88 the entire administrative system of the curia was overhauled. The number of congregations was increased to 15, of which 6 dealt with secular administration and the other 9 with spiritual matters. It was through the machinery thus established that the decrees of the Council of Trent were effectively enforced. In particular, Sixtus insisted that the decrees regulating residence and investiture be strictly observed. So he must be counted as one of the founders of the Counter Reformation. His intervention in doctrinal affairs was not so happy. He had good grounds for supposing that the commission appointed to prepare a revised edition of the Vulgate, which had benefited enormously by his injection of a spirit of urgency into its deliberations, had not sufficiently considered the practical problems created by their work of scholarship. His reaction was typical: he rejected the work of the commission and took the whole task into his own hands. After 18 months of intense application, he produced the *editio Sixtina* in May 1590. But his revision was far too hurried and far too conservative, and the opportunity afforded by its numerous printer's errors was taken to postpohe promulgation. Sixtus' death then intervened, and his edition was eventually abandoned. By the same event, Robert Bellarmine's book on doctrinal controversies was saved from official condemnation and the Society of Jesus from a drastic revision of its constitution.

In his political relations with foreign princes, Sixtus was faced by a dilemma. Distrusting Philip II of Spain, he viewed with misgiving the extension of Philip's power but was obliged to abet him as Henry III of France showed himself ever less able to hold his own between the pro-Spanish party of the Guises and the Huguenots under Henry of Navarre and as Elizabeth of England, whose personality Sixtus greatly admired, was an obstinate heretic. Thus he excommunicated Henry of Navarre (1585), promised subsidies for a Spanish invasion of England and denounced Henry III after the coup against the Guises. In the last months of his life. however, he saw the hope that Henry of Navarre would make good his claim to the crown of France (as Henry IV) and be converted to Catholicism. Sixtus could then begin to withstand the demands of Philip's immediate ambition, confined as this was to France since the defeat of the Armada. Negotiating still both with Philip's and with Henry's envoys, he died on Aug. 27, 1590.

Posterity ranks Sixtus one of the greatest popes. He was hasty, obstinate, severe, autocratic; but his mind was open to large ideas, and he threw himself into his undertakings with an energy and determination that often compelled success. Few popes can boast of greater enterprise or larger achievements.

See J. A. von Hübner, *Sixte-Quint*, 3 vol. (Paris, 1870; new ed., 1882; Eng. trans. by H. E. H. Jerningham, *Sixtus V*, 2 vol., London, 1872); H. Balzani, *Sisto Quinto* (Geneva, 1913). (I. F. B.)

SIXT VON ARMIN, FRIEDRICH (1851–1936), German general, was born at Wetzlar, Nov. 27, 1851. He took part in the war of 1870–71 and was severely wounded at St. Privat. After having occupied different positions on the general staff, he was appointed in 1903 director of the general department of war in the Prussian War ministry, and in 1911 general in command of the 4th army corps at Magdeburg. During World War I he led his corps as a part of the 1st and of the 6th army; he was appointed in 1917 commander in chief of the 4th army in Flanders, where he succeeded, in the spring offensive in 1918, in taking Armentières and the Kemmel hill. At the close of the war he retired from the army.

SKAGERRAK, the arm of the North Sea which gives access to the Cattegat and so to the Baltic. It is about 140 mi. long and 75 mi. broad. On the Danish shore, which is low and beset with sandbanks, the strait is shallow. Towards the steep Norwegian coast its deepest part is found. 2,6j8 ft.

For the currents, temperature and salinity of the water, etc., *see* NORTH SEA. For battle, *see* JUTLAND, BATTLE OF.

SKAGWAY, a town of Alaska, U.S., situated at the north end of Lynn canal, a deep and narrow arm of the sea thrust far up between picturesque mountain ranges, in 59° 28′ N. and 135° 20′ W., is at the head of navigation in the waters of southeastern Alaska. Skagway owes its importance to being the seaward terminus of the White Pass and Yukon railway. This road, built in the years 1898–1900, extends up the valley of the Skagway river to the summit of White pass, 20 mi., crossing there the international boundary and continuing thence down on the Canadian side 91 mi. to Whitehorse, head of navigation on the Yukon.

Historically, it is of interest as the landing place of large quantities of supplies and many thousands of people during the struggle of 1897–98 (known as the Klondike rush) to reach the newly discovered rich deposits of gold in the upper (Canadian) Yukon.

SKANDERBEG or **GEORGE CASTRIOTA** (1403–1468), the national hero of the Albanians, "ranked by Sir William Temple among the seven chiefs who have deserved, without wearing. a royal crown," was of Serbian origin. The founder of the family of Castriota was a certain Branilo, who mas governor of Kanina in 1368, and whose grandson, Giovanni, lord of Mat and Vumenestia, married Voisava Tripalda, daughter of a Serbian magnate. The offspring of this union was George Castriota. Thus. as the Albanians gave to Greece several leaders of her War of Independence, Serbia furnished the chief figure of their struggle for freedom. George's uncle had, however, married an heiress of the leading Albanian clan of Thopia and thus acquired. together with the fortress of Kruje. some of that family's influence. Born in 1403, George was 11 years old when the Turks began to occupy Albania. and, while the castle of Kruje became the seat of a Turkish governor, he was sent as a hostage to Constantinople. Educated there as a Moslem he received the Turkish name of Iskander ("Alexander"). applied to him by Byron in *Childe Harold*, with the title of bey—subsequently abbreviated by his countrymen into Skanderbeg. Like Albanians in later times, he rose to eminence in the Turkish service; he was promoted to the government of a *sanjak*, and for many years fought for his Turkish masters against Venetians and Serbs, till! in 1443, while serving in the Turkish army which had been defeated by Janos Hunyadi's troops near Nish, he heard that his native land had risen against the Turkish garrison.

Then, at the age of 40, he realized that his mission was to free Albania, and the rest of his life was devoted to that object. Seizing Kruje by stratagem, he made it his capital, proclaimed himself a Christian, and gathered the wild Albanian clansmen about him. His personal influence was increased by his marriage with Andronica. daughter of Arianites Comnenus, a prominent Albanian chief, who had vainly endeavoured to drive out the Turks. The other chiefs rallied round his standard; the Montenegrins, whose ruler, Stephen Crnojevich, was his brother-in-law. came to his assistance. and at a gathering of the clans at the Venetian colony of Alessio he was proclaimed Captain General of Albania. Venice, then mistress of the Albanian coast as far south as Durazzo, at first regarded him as a rival, but subsequently took him into her pay as an ally against the common foe. The pope and the king of Naples helped the Albanian cause, as fellow Christians and neighbours, and the latter, mindful of the claims of the Neapolitan Angevins beyond the Adriatic, received the homage of the Albanian champion. But Mohammed II, partly by working upon the proverbial jealousy of the other Albanian chiefs, partly by force of arms, temporarily eliminated him, and in 1461 concluded with him a ten years' armistice.

But long before it elapsed, Skanderbeg, at the instigation of Pius II, broke it, with fatal results. That pope's projected crusade was prevented by its author's death; Skanderbeg, abandoned by his western allies, was left to fight singlehanded against the great sultan, who himself in 1466 besieged Krujë. The fortress held out, but Skanderbeg went to seek help from Pope Paul 11 in Rome, where a lane near the Quirinal still commemorates his name and visit. Returning. he died in the Venetian colony of Alessio on Jan. 1;, 1468. whereupon the Turks easily conquered Albania, except Krujë, ceded by his son to Venice, and the other Venetian possessions. His son Giovanni and other Albanian chiefs emigrated to southern Italy, and his posterity formed part of the considerable Albanian colonies there; in modern times a self-styled Castriota claimed the Albanian throne on the ground of his alleged descent from the national hero.

Skanderbeg's grave in the church of St. Nicholas at Xlessio was opened by the Turks, who touched his bones with superstitious reverence and wore them as amulets; but the ruins of the castle which he built on Cape Rodoni remain. the Mirdites still wear mourning for him, and the independent Albania of to-day has placed his image on some of her postage stamps. He has been made the subject of a Latin poem by de Bussières, an Italian poem by Signora Sarrocchi, and an English tragedy. *Scanderbeg: or Love and Liberty,* by Whincop (1747). Gen. Wolfe wrote that "he exceeds all the officers, ancient and modern, in the conduct of a small defensive army." His resistance to the Turkish advance helped Christendom, but did not save Albania—a country too small and too much divided by the clan system to stand against a powerful Turkey. (W. M.)

SKARA BRAE, the most perfect Stone Age village in Europe, was embalmed under a sand dune on the shore of the Bay of Skaill on the Atlantic coast of Mainland Island. largest of the Orkneys. Scot. Exposed by a great storm in 1851, four buildings were excavated during the 1860s by William Watt, of Skaill house. After another storm in 1926 further excavations were conducted by the ancient monuments branch of the ministry of works, that had assumed guardianship of the monument. supervised from 1928 to 1931 by V. G. Childe, of the University of Edinburgh. Before 1939 the age of the site and the cultural status of its builders remained uncertain, but in that year excavation by Walter G.

PHOTOGRAPH, J. ALLAN CASH

EXCAVATED DWELLING AT SKARA BRAE

Grant at a contemporary village, Rinyo, on Rousay, established that the dwellings of Skara Brae were built before the first people to use bronze in Great Britain, the "Beaker folk," reached Orkney, and so belonged to the New Stone Age (of Orkney, of course).

Though the dwellings at Skara Brae are built of undressed slabs of stone from the beach, put together without any mortar, the drift sand that filled them immediately after their evacuation preserved the walls in places to a height of 8 ft. (but unfortunately not the roofs). Moreover, because of the absence of trees on the island, articles of furniture that would normally be carved in perishable wood had to be made of stone and have, therefore, survived. At the same time the dwelling explored in 1928 was found exactly as it had been left by its occupants who had been forced to abandon it in precipitate haste by a violent storm. The village consisted of several one-roomed dwellings, each constructed on the same plan. Each is a rectangle with rounded corners, the largest measuring 21 ft. by 20 ft. square. Entering through a narrow doorway only 4 ft. high that could be closed by a stone slab held in place by a sliding bar, the visitor finds in the centre of the room a rectangular fireplace still filled with peat ash. Behind it against the rear wall stands an erection of two tiers of stone shelves precisely like a modern dresser. On either side of the central hearth are enclosures of stone slabs exactly similar to the fixed beds of planks built in the 19th century in Norwegian peasant houses, that on the right being always the larger. Tall uprights of stone at the corners like bed posts served to support some sort of canopy. In the wall above the bed are recesses that must have served as keeping places for personal possessions. Sunk in the floor are several cubical boxes lined with stone slabs and luted with clay along the joints, evidently designed to hold some sort of liquid. One or more small cells in the thickness of the walls open off the main room. Beneath its floor a slab-lined drain runs to debouch into a main sewer.

At the moment of its abrupt desertion the village had consisted of seven or eight such huts linked together by paved alleys. By this time six huts had been put artificially underground by banking round them midden consisting of sand and peat ash stiffened with dung and other refuse, and the alleys had become tunnels through this midden roofed with slabs. On the west (the east end has been destroyed by the sea) the main tunnel gave through a doorway, identical in design with those of individual dwellings, onto an open space paved with slabs, but unroofed. A hut, entered from this space and standing free of the general midden-heap cover. differed to some extent in arrangement and furniture from the rest; it contained a kiln where the dresser should have stood and had been used for the manufacture of chert implements. The whole residential complex was drained by a built sewer into which the drains from individual huts discharged.

The inhabitants of the village lived mainly on the flesh and presumably the milk of their herds of tame cattle and sheep. on limpets and other shell fish, supplemented exceptionally by red deer, wild boar, seal and whale. There is no positive evidence that they cultivated any cereals or that they spun and wove wool or other material. Presumably they dressed in skins. Bone tools suitable for preparing and piercing such skins were very numerous, while large pins made of narwhal ivory. whalebone or the penis-bones of seals could be used for fastening them. Peat was regularly burned as fuel, while fire may have been made by striking nodular haematite against flint or chert. For their equipment the villagers relied exclusively on local materials. Axheads, or rather adz blades, were made of stone sharpened by grinding and were sometimes attached to their handles with the aid of perforated sleeves of stag's antler. Knives were made by splitting beach pebbles along their bedding planes. The bones of cattle and sheep served for the manufacture of awls, needles, fabricators and various tools of uncertain use probably employed in dressing hides. Vessels were made of pottery. Though the clay was exceedingly coarse and included large grits, and the firing was not sufficient to convert it into pottery right through, most vessels were quite richly decorated with elaborate patterns in relief formed by applying to the surface strips and pellets of clay. Vessels were also made out of the vertebrae of hales and blocks of sandstone.

No weapons at all were found at Skara Brae unless some unique objects carved out of hard volcanic stone were so used. These include balls covered with pyramidal spikes and other spikey forms, all carved with great accuracy. As ornaments the villagers wore pendants and beads made out of the marrow bones of sheep, the roots of cows' teeth (the nerve canal serving as a string hole), the teeth of killer whales and boars' tusks.

Nearly 1,000 finished beads were found together in one cell, and unfinished beads in all stages of manufacture lay about the hut floors. Red, yellow and white pigments contained in little paint pots of stone or cetacean bone were presumably used in painting the person. Games were played with dice of walrus ivory and uith knucklebones.

The skeletons of two old women, buried together doubled up, were found in a cist under the wall of the hut discovered in 1928 and have been interpreted as a foundation sacrifice. Watt had previously discovered a skeleton in a niche beside the main alley, but the village cemetery has not been identified. The two old women must have stood about 5 ft. 2 in. in height, not much, if anything, below the average of the female stature prevailing in the mid-20th century. Both had suffered from osteoarthritis. The leg bones show peculiarities due to habitual squatting. The skulls are just dolichocranial (index 74.5).

A number of stones in the walls of the huts and alleys have been roughly scratched with lozenges and similar rectilinear patterns.

Beneath the walls of the huts just described the foundations of older huts were discovered in 1930. In plan and furniture these agreed precisely with the former and the relics on their floors were of the same kind as those described above. The pottery from the lower levels was adorned with incised as well as relief designs. Among these was the true spiral represented on one sherd—the only example of this pattern in pottery known in prehistoric Britain.

SKAT, a game of cards, much played in Germany and by people of German origin throughout the world. It is an elaboration of *Schafkopf* (sheepshead), a Wendish game believed to date at least to the middle 1700s. In 1811 a resident of Altenburg who had newly learned *Schafkopf* carried it into the local tarok club, where it was modified by the addition of features from tarok and kalabrias. The very name of the game is a tarok term, derived from the Italian *scartare,* "to discard," or *scatola,* a "place of safekeeping." In the earliest writings, the game is spelled "scat." Much of the early development of skat is credited to F. F. Hempel, an advocate in Altenburg. The first book on it was published by his cousin, J. F. L. Hempel, in 1848. After a long period of experimentation, the game was codified by a congress of more than 1,000 skat players, convened at Altenburg on Aug. 7, 1886. Subsequent modifications chiefly concerned the use of the skat (widow) and elimination of the game *frage.*

Skat is very popular in some sections of the United States. There are hundreds of skat clubs and large tournaments are played for prizes. Laws of the game are promulgated by the North American Skat league and do not in all respects conform to the procedure of play in Germany.

Skat is played by three players with a pack of 32 cards. Each receives ten cards and t o are dealt face down for a skat (widow). The players bid by numbers, in multiples of two, and the high bidder then names his game. In the game tournee the trump suit is fixed by a card turned from the skat—it may be a grand (only knaves are trumps) if a knave is turned. Solo is played without help of the skat, and the player may name a suit or grand. Gucki is a grand using the skat. Null is a bid to take no tricks, at no trumps. Ramsch is played only if all three players pass, the object being to win fewest points in tricks, with knaves trumps.

The bidding and scoring values of the games are determined by their base values times the sum of all due multipliers. The multipliers arise from various sources—points won in play. prediction or announcement as to this outcome, and matadors, which are top trumps in unbroken sequence.

To make his bid, the player must take a majority of the 120 card points: each ace 11, ten 10, king 4, queen 3, knave 2. Except in ramsch, the other two players combine in temporary partnership to try to defeat him.

A modem variant, *Räuber Skat,* popular in club play but not in tournaments, eliminates the game tournee. Instead, the high bidder always has the option of taking the skat or of playing without it. In the latter case, handplay, he earns an extra multiplier.

SKEAT, WALTER WILLIAM (1835–1912), English philologist whose greatest work in pure philology was his etymological dictionary, was born in London on Nov. 21, 1835, and educated at King's college school, Highgate grammar school and Christ's college, Cambridge, of which he became a fellow in July 1860. In 1878 he was elected Ellington and Bosworth professor of Anglo-Saxon at Cambridge. His work on Middle English literature includes the three parallel texts of *Piers Plowman* (1886), the Oxford edition of Chaucer (6 vol., 1894), with a supplementary volume of *Chaucerian Pieces* (1897), and important editions for the Early English and Scottish Text societies. His *Etymological English Dictionary* was published in 4 parts, 1879–82 (revised and enlarged, 1910). In the publications of the English Dialect society he had a hand as the founder of the society and afterward its president.

Skeat died at Cambridge on Oct. 7, 1912.

SKEET SHOOTING: *see* TRAPSHOOTING AND SKEET SHOOTING.

SKEGNESS, a seaside resort in Lincolnshire, Eng.; 131 mi. N. by E. from London by Eastern region railway. Pop. (1951) 12,539. Since 1873, it has attracted excursionists. and possesses good hotels and a pier. There are broad, firm sands.

SKELETON, INVERTEBRATE. The function of the skeleton is to provide a more or less rigid framework upon which the muscles can react. In many invertebrate animals no such framework exists; the necessary rigidity is provided by the hydrostatic pressure of the body fluids acting upon a soft and pliable integument. This is seen in caterpillars and, to a lesser extent, in soft worms and in mollusks, where the necessary pressure is maintained by the steady contraction of an interlacing sheet of superficial muscles, the so-called turgor muscles. The muscles which move the body are attached to the integument, which is made rigid by this internal pressure. The firmness of some invertebrate animals is maintained by a mechanism similar to that in many plants; the individual cells which form the body wall are more or less distended by water to give some degree of rigidity. But in many invertebrates rigid skeletal materials are deposited either on the outer surface of the body or within the cells. In some animals these rigid structures do not give attachment to the muscles but merely provide a protective armour.

It is usual to classify skeletal structures as external (exoskeleton) or internal (endoskeleton). But the one type merges with the other, even within the same animal; and in many examples of what appears to be an exoskeleton. the hard material is laid down inside the cells which form the outer covering.

The invertebrate skeleton is exceedingly varied as to the material of which it is composed and as to sites in which the hard substance is deposited. These variations cut across the ordinary classification of animals. In the Protozoa, for example, there are all grades between soft forms such as *Amoeba,* forms with a semisolid pellicle such as *Paramecium,* and forms with a cuticle, which may be proteinaceous as in *Monocystis* or composed of cellulose as in the plantlike flagellates. Other protozoa have definite shells, which may be composed of protein with various foreign bodies incorporated in it, or of siliceous plates, or of lime as in most Foraminifera, or of cellulose as in the resting stages of Mycetomycetes (Mycetozoa). The Radiolaria have an internal lattice of silica laid down inside the cell, a kind of endoskeleton.

Other groups show a similar variation. Some sponges deposit needlelike spicules of calcium carbonate in the jelly (mesogloea) beneath the outer epithelium; others produce spicules of silica held together by a horny substance termed spongin; and yet others have a skeleton of spongin alone and no spicules. Similarly, among coelenterates, there are Hydrozoa which have a horny perisarc protecting the polyps, and others with an external calcareous skeleton. Actinozoa show the same diversity. In *Alcyonium* (deadman's-fingers) the skeleton is mainly internal, consisting of spicules of calcium carbonate in the mesogloea. In the red coral of commerce (*Corallium*) the spicule-bearing cells migrate inward and build up a central skeleton. In the common reef-building corals the calcareous skeleton is secreted by that part of the ectoderm which forms the basal disc. This secretory process is continuous so that the polyp raises itself progressively upon a growing stem of lime.

In the echinoderms the calcareous deposits are laid down in the mesoderm. They may be so scattered that they merely serve to impart a leathery consistency to the skin (as in holothurians); or they may form well-articulated ossicles united by muscles and thus serve as a typical internal skeleton (as in the arms of brittle stars or Ophiuroids); or they may be set closely together to form a rigid armour (as in the sea urchins). Many sea urchins have projecting spines on which the epidermis has been worn away so that the calcareous substance is exposed.

The shell of mollusks is an example of an external skeleton. It is secreted by the ectodermal epithelium of the mantle, and consists of an outer layer of the horny substance conchiolin, an intermediate prismatic layer composed of calcite, and a smooth inner layer (the nacreous layer). also composed mainly of calcium carbonate. The first two layers are secreted by a marginal band of cells, so that the shell grows at its outer margin. The nacreous layer is secreted by the general surface of the mantle and is the material of which pearls are formed around foreign bodies introduced into the mantle cavity.

The exoskeleton attains its most elaborate forms in the arthropods (crustaceans, insects, etc.). Many soft invertebrates, such as worms and mollusks. secrete a protective layer of slime or mucus over the surface of the integument. In the arthropods a solid substance termed chitin forms the basis of the exoskeleton. Chitin is related chemically to mucus. It consists of a nitrogen-containing carbohydrate (a polysaccharide, polyacetyl glucosamine) intimately associated with protein. If the protein component is removed from natural chitin there remains a material, often called pure chitin, the physical properties of which are very similar to those of the cellulose of plants.

Natural chitin forms a cuticle which is tough but distensible and not rigid. It exists in this state in the integument of caterpillars. which, as noted above, have a hydraulic type of skeleton dependent on internal turgor. It exists in this soft state also in the joints of the limbs or between one segment of the body and the next. But in most arthropods the segments of the body or of the limbs are in the form of rigid plates that form a true exoskeleton linked to adjacent segments by flexible membranes. The hard material responsible for this change in the chitin is termed sclerotin, and the hardening process is called sclerotization.

The chemical nature of sclerotization is not fully understood, but it is certainly closely related to the hardening of proteins by tanning. Substances capable of causing tanning (notably certain quinones) are almost certainly produced in the cuticle of arthropods during the hardening process. The resulting product (sclerotin) is a kind of natural plastic. In its horny consistency it closely resembles keratin, both are cross linked or polymerized proteins, but the chemical nature of the linkage is different in the two substances. It is probable that other skeletal proteins in invertebrates, such as the spongin of sponges and the conchiolin of mollusks, are also tanned proteins allied to sclerotin.

In many crustaceans (crabs, lobsters, etc.), much of the cuticle is rendered hard by the incorporation in its substance of lime in the form of aragonite or calcite. But sclerotin is actually harder than calcite, and those parts of crustaceans which need to be of maximum hardness, such as the mandibles and the tips of the claws, are in fact composed of sclerotin. The hardest parts of insects are often the darkest; the hardening and darkening processes are closely associated chemically.

Besides functioning as a skeleton, the cuticle of terrestrial arthropods must act as a waterproof covering in order to prevent these small animals from drying up. This waterproofing is effected by the secretion of a layer of crystalline wax on the surface layer of the cuticle. Such a wax layer, if freely exposed, would be excessively fragile. It is commonly protected by a thin layer of cement substance poured over its surface by small dermal glands. Other glands may discharge quantities of wax, lac and other products upon the surface of the insect.

The cuticle of arthropods is the product of a single layer of epidermal cells; indeed cytoplasmic processes from these cells (so-called pore canals) penetrate far into the cuticle, so that it is really a living structure. It can undergo endless modifications of form to produce sensory hairs, pigment-bearing scales, claws, wings and other kinds of tools. In some insects it shows brilliant metallic colours that result from the presence of some periodic structure in the cuticle (multiple thin plates or ridges) which gives rise to interference. In order that the arthropod may grow, the old cuticle is shed from time to time, after a new and larger cuticle has been laid down beneath it. This process is termed molting or ecdysis. Until the new cuticle hardens, the arthropod is in a very vulnerable condition. See also ARTHROPODA; SKELETON, VERTEBRATE.

SKELETON, VERTEBRATE. In many animals and in all vertebrates, the general form of the body is maintained by means of certain elements that are hardened to form a skeleton. This persists after death for a variable length of time after the rest of the body has disintegrated. In higher vertebrates, the skeleton is rendered more rigid and permanent by the formation of bone. In many animals the shape and relative positions of the various parts of the skeleton determine the general body form.

In most invertebrates, the skeleton is on the surface to form a protection as well as a supporting framework, and is called an exoskeleton. In vertebrates there is an internal or endoskeleton, and the exoskeleton is either greatly modified or completely suppressed. In the following account the human skeleton is treated as an example of the mammalian skeleton. There are brief supplementary reviews of skeletal development and of the comparative osteology of vertebrates. For the skull and exoskeleton, see SKULL and SKELETON, INVERTEBRATE.

This article is divided into the following sections:

I. Vertebral or Spinal Column
II. Thoracic Skeleton
III. Appendicular Skeleton
  A. Upper Limb
  B. Lower Limb
  C. Sesamoid Bones
IV. Development of the Skeleton
V. Comparative Anatomy
VI. Comparative Anatomy of the Appendicular Skeleton

I. VERTEBRAL OR SPINAL COLUMN

The vertebral column (also known as the backbone or spine) consists of a series of vertebrae connected together by thick elastic intervertebral discs and by other ligaments (see fig. 1). The column lies in the middle of the back of the neck and trunk and is surmounted by the cranium. Each vertebra, with certain exceptions. consists of a thick anterior part, the body, and a posterior part. the neural arch (see fig. 2).

The paired nerves connected with the spinal cord emerge on each side of the vertebral column between successive vertebral bodies and neural arches. The bodies, with the intervertebral discs, form the weight-bearing portion of the vertebral column. The neural arches form partial protection for the spinal cord and for the proximal parts of the lower spinal nerves. Each neural arch consists primarily of two cylindrical pedicles, projecting backward from the body, and two flattened laminae, which meet in the midline posteriorly. At the junction of each pedicle and lamina, there is a laterally directed transverse process, and vertically disposed superior and inferior articular processes (pre- and postzygapophyses). The superior articular processes of one neural arch articulate with the inferior articular processes of the arch above at a synovial joint. A spinous process projects backward from the fused laminae and can be felt under the skin.

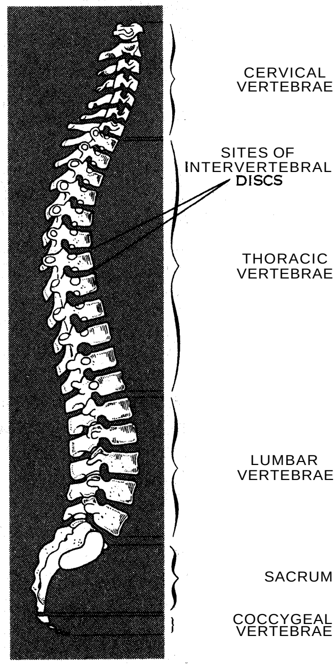

FIG. 1.—LATERAL VIEW OF THE VERTEBRAL COLUMN

In the young child, the vertebral column consists of 33 separate vertebrae. In the adult, some of these are fused together, so that there are only 26 separate bones. The vertebrae are grouped from above downward according to position into cervical, thoracic, lumbar, sacral and coccygeal. For the human infant, the number of vertebrae in each group is expressed in the formula C_7, Th_{12}, L_5, S_5, Coc_4, but in the adult the five sacral vertebrae have fused to form a single triangular bone, the sacrum, and the four coccygeal to form the coccyx.

Vertebrae. — The cervical vertebrae are distinguished by the presence of a foramen in the transverse process. These foramina, excepting that of the 7th vertebra, are in succession traversed by the vertebral artery carrying the blood to part of the brain. The 1st cervical vertebra, or atlas, is atypical in that it has no body but is in the form of a ring. On each side of it there is a thick mass of bone by which it articulates above with the occipital bone of the skull and below with the 2nd vertebra, the axis. The body of the latter is surmounted by a stout, toothlike odontoid process, which is regarded as the body of the atlas. This process forms a pivot round which the atlas moves, with the skull, when the head is turned from side to side.

The typical thoracic vertebrae (1st to 9th) are distinguished by the presence, on each side of their body, of two small, smooth articular surfaces or facets for articulation with the head of a rib. In addition, these vertebrae have an articular facet on each transverse process for the tubercle of a rib. The body of the 10th thoracic vertebra, however, articulates only with one rib. In the case of the 11th and 12th vertebrae, there are articular facets on the body but not on the transverse processes.

The lumbar vertebrae have neither foramina in the transverse processes nor articular facets on the bodies. The bodies are massive in order to transmit the weight of the trunk.

The sacrum is a large triangular bone formed by the fusion of five vertebrae; with the two hipbones, it forms the pelvis. The anterior (or pelvic) surface of the sacrum is concave and is marked by four transverse lines which indicate the sites of fusion of the original five sacral elements. On each side of the fused bodies there are foramina for the transmission of the anterior divisions of the upper four sacral nerves. The convex posterior surface shows four rudimentary spinous processes, and on each side of these are two rows of tubercles representing the articular processes and the transverse processes. Between the rows of tubercles four pairs of foramina transmit the posterior divisions of the sacral nerves. The part of the sacrum lateral to the foramina is known as the lateral mass. The upper lateral aspect of this mass presents an L-shaped articular surface for articulation with the corresponding hipbone. Posterior to the articular surface, the lateral mass is rough, for the ligaments that attach the sacrum to the hipbone. The human sacrum is broader in proportion to its length than that of other mammals, so that great solidity is given to the lower part of the spine; this breadth is probably correlated with the firmness of the sacrum's articulation with the hipbones, as an adaptation of the spine to man's erect posture. The sacrum is broader in women than in men and hence the whole pelvis is wider.

The coccyx consists of four rudimentary vertebral bodies fused together and, in the adult, commonly joined to the sacrum. The first body has a pair of small projections which are the vestiges of the neural arch.

Articulated Vertebral Column. — The vertebrae are held firmly together by a number of strong ligaments. The main ligaments are the intervertebral discs, the anterior and posterior longitudinal ligaments between the bodies, and the ligamentum flavum betueen the laminae. The intervertebral discs form flexible connections between the bodies of adjacent vertebrae from the axis above to the sacrum below. Each disc consists of fibrocartilage which encloses a central mass, the nucleus pulposus. The fibrocartilage is firmly attached to the adjacent vertebrae, whereas the nucleus pulposus is a semifluid structure acting as a shock absorber and can be deformed by pressure. Occasionally, the pressure developed in the nucleus pulposus is so great that the surrounding fibrocartilage ruptures and the nucleus protrudes.

The articulated vertebral column forms the central axis of the skeleton and supports the weight not only of the head and trunk but also of the upper limbs. It gives attachment to the muscles that move the column itself and to other muscles that move the head and limbs.

The vertebral column of an adult in the ordinary standing position exhibits curves in the sagittal (anteroposterior) plane of the body (see fig. 1), and minor curves in the coronal (transverse) plane. In the infant at birth, there are two primary sagittal curves concave forward which meet at the sacrovertebral junction. The lower curve involves the sacrum and coccyx, the upper affecting the remainder of the vertebral column. When the infant begins to lift up its head, a secondary sagittal curve, convex forward, develops in the neck region, and when the child begins to walk, a further secondary sagittal curve convex forward is developed in the lumbar region. In the adult spine, therefore, there is a series of alternating convex and concave curves formed in adaptation to the erect posture of man. As a result of these curves the weight of the body is transmitted to the sacrum with the least expenditure of muscular effort. The curves in the coronal plane are not constant; the frequent convexity to the right has been attributed to the greater use of the right arm.

Movements of the vertebral column are: (1) forward bending, known as flexion, and the opposite movement, extension; (2) lateral bending, known as lateral flexion; and (3) rotation, which occurs about an axis passing vertically through the bodies of the

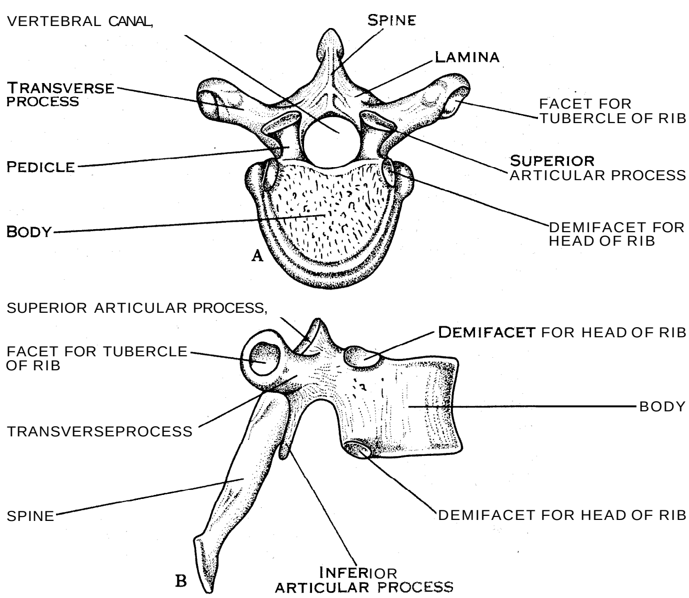

FIG. 2.— TYPICAL THORACIC VERTEBRA SEEN FROM ABOVE (A) AND FROM THE SIDE (B)

vertebrae concerned. The range and kind of movements show great variations in the different parts of the column. They are greatest in the cervical region, at the thoracolumbar junction and at the lumbosacral junction. The limits of movement are determined by the planes of the joints between the articular processes, by the flexibility of the intervertebral discs and by the extensibility of the muscles and ligaments. In the thoracic region movements of the vertebral column are more restricted because the ribs and costal cartilages resist distortion.

II. THORACIC SKELETON

The thoracic skeleton consists of the thoracic part of the vertebral column, the ribs with their costal cartilages and the sternum. The bodies of the vertebrae project into the thoracic cavity from behind so that there is a recess of the cavity on each side of them.

The sternum or breastbone consists of three parts—an upper, the manubrium; a middle, the body; and a lower. the xiphoid process (see fig. 3). The anterior and posterior surfaces of the body are marked by transverse lines, indicating its division into four originally distinct segments. Each lateral margin of the sternum presents seven notches for articulation with the seven upper costal cartilages; at each side of the upper margin of the manubrium is a depression where the clavicle articulates; the xiphoid process remains cartilaginous up to a late period in life.

Most skeletons have 12 pairs of ribs, which articulate behind with the thoracic region of the vertebral column. Occasionally cervical or lumbar ribs are present. From the vertebral column the ribs are directed first backward, then downward and forward, to end at a lower level by joining the costal cartilages. The upper seven ribs are attached to the sternum by their costal cartilages and are called true ribs. The lower five ribs are called false ribs. The cartilages of the 8th, 9th and 10th ribs do not reach the sternum directly but join the cartilages of the ribs immediately above. The cartilages of the 11th and 12th ribs have no anterior attachments, and these ribs are known as floating ribs.

A typical rib (from 3rd to 9th) consists of head, neck and shaft. The head articulates with two adjacent vertebral bodies. A short neck separates the head from a tubercle, articulating with a transverse process. Beyond that the shaft curves round the side of the thorax to the costal cartilage.

III. APPENDICULAR SKELETON

The upper and lower limbs in man resemble one another in their general plan, but differ greatly in their detailed structure and in their mode of attachment to the trunk. Their functions also have undergone pronounced modifications; the upper limbs have been freed from supporting the body weight and have become prehensile organs, whereas the lower limbs have to be used not only to propel the body but also to act as struts to prevent it from falling forward during locomotion. Each limb is attached to the axial skeleton by means of a bony girdle; that of the upper limb is called the shoulder (pectoral) girdle, and that of the lower limb the pelvic girdle. The shoulder girdle, consisting of the clavicle and scapula (see fig. 3, 4), has considerable mobility on the trunk; its sole skeletal connection with the trunk is through the articulation of the clavicle with the upper end of the sternum at the sternoclavicular joint. There is a wide range of free movement of the upper limb on the shoulder girdle, and this is supplemented by movements of the girdle on the trunk. The movements at the shoulder joint can take place about an infinite number of axes. Specific names are given for these movements, such as flexion, extension, abduction, adduction, rotation and circumduction.

The lower limb articulates with the hipbone. This is firmly connected with the sacrum to form the pelvic girdle (see fig. 3, 4), which acts as a single skeletal unit in all ordinary body movements. It is through the hipbone that the weight of the trunk is transferred from the sacrum to the head of the femur. Conversely, the pelvis transmits to the trunk the forces that arise from action of the lower limb. Movements at the hip joint, like those at the shoulder joint, take place about a number of axes; the movements, however, are more limited. Certain of them are distinguished by names. The forward movement of the thigh relative to the pelvis is called flexion, the backward movement extension. The movement of the limb toward the midline of the trunk is called adduction, the movement away from it abduction. Medial and lateral rotation of the limb can also occur, and the combination of all the movements is called circumduction.

Each of the limbs consists of three segments—proximal, intermediate and distal.

The proximal segment in both arm and leg contains one long bone, the humerus in the arm and the femur in the leg.

The intermediate segment consists of two bones, the radius and ulna in the forearm and the tibia and fibula in the leg (see fig. 5). The articulation of the intermediate with the proximal segment in each limb is hingelike; the joint is termed the elbow in the upper limb and the knee in the lower limb. Axial rotation (rotary movement) is fairly extensive at the knee except when the leg is completely straightened (extended) but is negligible at the elbow. The movements possible in the intermediate parts of the two limbs differ considerably; rotation, known as pronation and supination, can take place within the forearm by a movement between the radius and the ulna, but in the lower limb no comparable movement is possible.

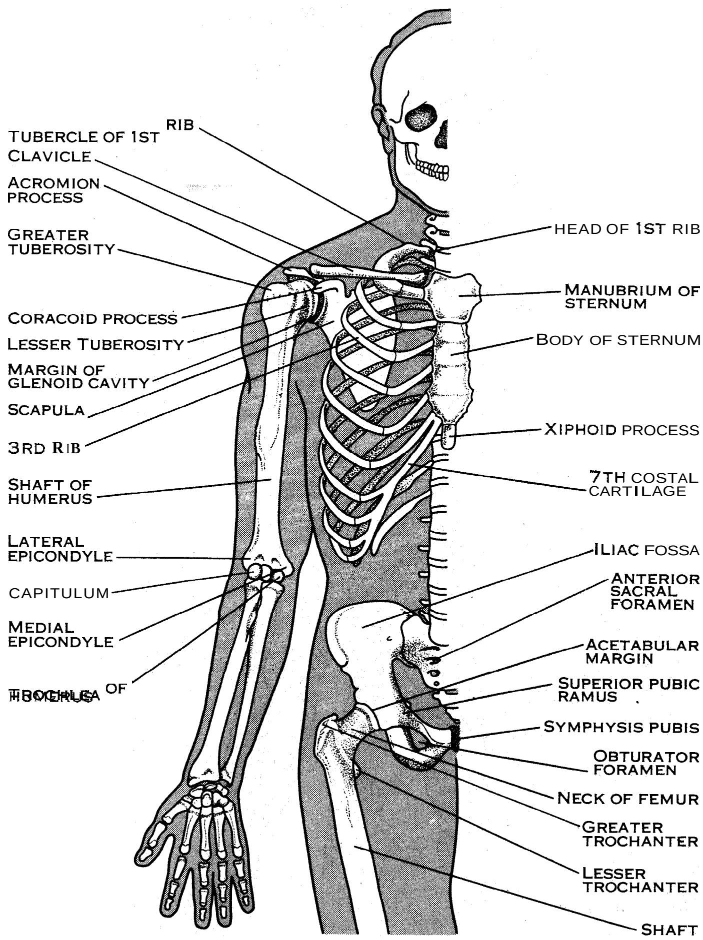

FIG. 3.—ANTERIOR VIEW SHOWING RIGHT HALF OF SKELETON OF THE TRUNK AND UPPER LIMB

The distal segments of the upper and lower limbs consist respectively of the hand and foot. These comprise: (1) a series of small bones, called the carpus or tarsus; (2) five elongated bones, metacarpals or metatarsals, each of which supports (3) a digit, finger or toe. Each digit has three phalanges; the thumb and great toe are exceptional in having only two. The articulation of the carpus with the radius and ulna, known as the wrist joint, allows movements round a transverse axis (*i.e.*, movements producing flexion and extension of the hand) and round an anteroposterior axis permitting abduction and adduction of the hand. The movements at the articulation of the tarsus with the tibia and fibula, known as the ankle joint, are almost restricted to a hingelike flexion and extension. In the foot there is a considerable range of movement between certain of the tarsal bones. The movement that turns the sole of the foot to face inward is known as inversion, while the movement by which it can be turned outward is known as eversion. These movements permit the sole of the foot to adapt itself to the surface contour on which it rests.

There is a general resemblance between toe and finger movements, but the joint at the base of the thumb between the first metacarpal and the adjacent carpal bone (trapezium) permits a variety of movements which is lacking in the big toe. At the metacarpophalangeal, metatarsophalangeal and interphalangeal joints, hingelike flexion and extension movements take place. The movements are freer in the hand than in the foot.

A. Upper Limb

The upper limb consists of the shoulder region, the arm, the forearm and the hand.

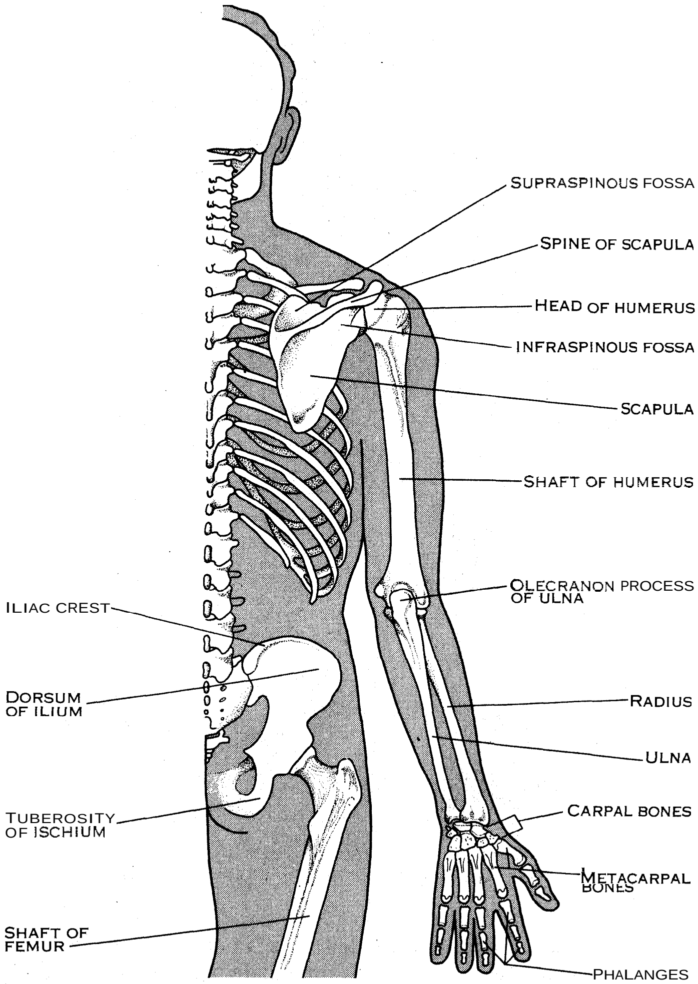

FIG. 4.— POSTERIOR VIEW SHOWING RIGHT HALF OF SKELETON OF THE TRUNK AND UPPER LIMB

Clavicle.—The clavicle, or collarbone, is an elongated bone which extends horizontally from the upper end of the sternum outward, to articulate with the acromion of the scapula (see fig. 3). It presents a strong sigmoidal curve, and is slender in the female but robust in muscular males. Its sternal end is thick; its acromial end, flattened from above downward, has an articular surface that meets a corresponding surface on the acromion. Strong ligaments connect the ends of the clavicle with the sternum and 1st rib and with the acromion and coracoid process of the scapula. The shaft gives attachment to muscles of the shoulder girdle.

Scapula. — The scapula, or shoulder blade, lies upon the upper part of the back of the chest, between the levels of the 2nd and 8th ribs. It is triangular in outline. Its anterior surface, which is concave, faces the ribs. Its posterior surface is crossed obliquely by a prominent ridge, the spine, which subdivides this aspect of the bone into a supraspinous and an infraspinous fossa. The spine and these two fossae give attachment to muscles which act in rotating the arm. The spine arches forward to end in the broad flat acromion by which the scapula articulates with the clavicle. To the margins of the scapula are attached muscles which participate in moving or fixing the shoulder as demanded by the prehensile movements of the upper limb. Of the three angles of the scapula, the outer is thickened and presents the shallow glenoid fossa, which articulates with the head of the humerus to form the shoulder joint. Overhanging the glenoid fossa is a beaklike projection, the coracoid process.

Humerus. — The humerus is a typical long bone, and as such presents a shaft and two expanded ends. The upper end possesses a hemispherical head with a smooth surface which articulates with the glenoid fossa of the scapula; where head and shaft merge, two tubercles are found, to which are attached rotator muscles which arise from the scapular fossae. Between the tubercles is a groove which carries the long tendon of the biceps muscle. The shaft of the humerus is three-sided in section above, but flattened and expanded below. A broad, shallow groove winds round the back of the bone, lodging the radial nerve. The lower end of the bone consists of articular and nonarticular regions. The lateral articular region, the capitulum, articulates with the head of the radius, and the medial, the trochlea, articulates with the ulna. The nonarticular regions have projections, the medial and lateral epicondyles; each is surmounted by a supracondylar ridge. The medial epicondyle and ridge give attachment to the muscles that pronate the forearm and flex it and the fingers; the lateral epicondyle gives origin to muscles which participate in supination and in extension of the wrist and fingers.

Radius. — The radius, the lateral bone of the forearm, conforms to the type of a long bone. The upper extremity, or head, which is disc-shaped, articulates above with the humerus; the margin of the disc articulates with the ulna and with the annular ligament. The head of the bone is joined to the shaft by a neck, below which is a tuberosity into which the biceps muscle is inserted. The shaft of the radius affords attachment for muscles which act upon the fingers and the wrist. Its sharp inner margin gives attachment to the interosseous membrane, which forms a partition between the structures of the front and back of the forearm, affording surfaces for muscle attachments. The lower, or distal, end of the radius is much broader than the proximal end, and is marked posteriorly by grooves that lodge the muscle tendons passing to the back of the hand. From its outer margin a pointed styloid process projects downward. The inner margin of the distal extremity has a smooth concave surface for articulation with the lower end or head of the ulna, and its broad concave lower surface articulates with the scaphoid and lunate bones of the wrist.

Ulna. — The ulna is the long bone on the medial side of the forearm. Its proximal end is subdivided into two strong processes by the trochlear notch, the smooth surface of which articulates with the humerus. The lower, or coronoid, process is rough, receiving the insertion of the chief flexor of the forearm, the brachialis muscle, whereas the upper and posterior process, the olecranon, gives insertion to the powerful extensor of the forearm, the triceps muscle from the back of the arm. Immediately behind the trochlear notch on the lateral side of the ulna is the radial notch for articulation with the margin of the head of the radius. The shaft of the bone has three surfaces giving attachment to muscles which act upon the wrist and fingers and in the movements of both pronation and supination. The sharp lateral margin of the shaft gives attachment to the interosseous membrane. The lower end, or head, of the ulna, much smaller than the upper, has a styloid process and an articular surface, the lateral surface of which meets the lower end of the radius. The lower part is in contact with a fibrocartilage which binds the ulna to the radius and separates the distal end of the former from the wrist joint.

The ulna. much more than the radius, establishes the hinge joint at the elbow. The radius, although entering into this joint, is involved, functionally, less with the arm than with the hand with which it alone articulates. By muscular action the radius revolves about the stationary ulna, carrying the hand in the movement called twisting the wrist. When the palm faces for ard in supination, the radius and ulna are parallel. When it faces backward in pronation, the radius crosses obliquely over the ulna.

Hand. — The hand consists of the carpus or wrist, the metacarpus or palm and the five digits individually named. Anatomists describe it with the palm turned to the front, and with its long axis in line with the long axis of the forearm.

The carpal or wrist bones, eight in number, are arranged in two rows. Named in order from the radial to the ulnar side, the proximal row comprises the scaphoid, lunate, triquetral and pisiform hones, and the distal row the trapezium, trapezoid, capitate and hamate bones.

The metacarpal bones are five in number. They are miniature long bones. The metacarpal of the thumb is the shortest. and diverges outward from the rest; its carpal extremity is saddle-shaped for articulation with the trapezium. Its shaft is somewhat flattened, and its distal end is smooth and rounded, articulating with the first phalanx of the thumb. The bases of the other metacarpal bones articulate with the trapezoid, capitate and hamate bones; the distal end or head of each articulates with the proximal phalanx of a finger.

The five digits of the hand are distinguished by the names of pollex or thumb, index, medius, annularis and minimus. The skeleton of the thumb consists of two phalanges while that of each finger has three. Each phalanx is a miniature long bone.

The carpal bones are firmly connected together, yet permit siight movements that are essential in the mechanism of the hand as a prehensile organ. The palmar contour of the wrist skeleton is like a gutter, bridged over by a dense ligament that makes it into a tunnel through which pass blood vessels, nerves and tendons for the fingers. The thumb enjoys great range and variety of movement, a human characteristic made possible in part by the conformation of the base of its metacarpal with the trapezium. The other carpometacarpal joints permit only slight motion, in contrast with the free movement of the fingers.

B. Lower Limb

The lower limb consists of the hip region, the thigh, leg and foot. The bone of the hip (the innominate bone, or os coxae) forms the pelvic girdle by articulating behind with the side of the sacrum, and by arching forward to articulate with the opposite bone in the midline at the symphysis pubis.

The hipbone is a large irregular plate which forms the lateral and anterior wall of the pelvis. In early life it is made up of three separate elements — ilium, ischium and pubis — which unite about the 18th to the 20th year into a single bone. At the site of junction of the three elements there is a cup-shaped depression, the acetabulum, for the head of the femur (see fig. 3, 4). From the acetabulum the ilium extends upward and laterally, the ischium downward, the pubis forward and medially. Below the acetabulum is a large opening, the obturator foramen, bounded by the pubis, the ischium and the ilium.

Ilium. — The ilium is a broad, bony plate, the lower, narrower part of which enters into the formation of the acetabulum, whereas the upper, expanded part presents an elongated free margin, the sinuous crest of the ilium. This crest affords attachment to the broad muscles that form the wall of the abdominal cavity. The external or lateral surface of the ilium gives origin to the muscles of the buttock. The internal surface is hollowed out anteriorly and gives origin to the iliacus muscle, which flexes the thigh. Posteriorly the ilium has an L-shaped surface articulating with the side of the sacrum in the sacroiliac joint.

Pubis. — The pubis consists of a body and two rami and is therefore somewhat U-shaped. The body is the flattened portion adjacent to the symphysis, and has an outer and an inner surface. The upper ramus passes backward to become continuous with the ilium; the lower ramus is continuous aith the ramus of the ischium.

Ischiurn. — The ischium also is somewhat U-shaped. One extremity (the upper) completes the acetabulum, whereas the lower is united with the inferior ramus of the pubis, and together these form the lower boundary of the obturator foramen. The conjoined rami afford origin to the adductor muscles that act in drawing the thigh toward the middle line. The upper, posterior branch is a stout bone which gives origin to the powerful hamstring muscles of the back of the thigh. The spine of the ischium separates the greater from the lesser sciatic notch. In the sitting position the body rests on the tuberosity of the ischium.

Pelvis. — Through articulation of the two hipbones with each other at the pubic symphysis, and with the sides of the sacrum behind, the osseous walls of the cavity of the pelvis are formed. This cavity is subdivided into a major (false) and a minor (true) pelvis. The true pelvis encloses a short, wide canal and possesses a superior opening. or inlet, a cavity and an inferior opening, or outlet. The false pelvis consists of the iliac fossa of each side above the level of the inlet of the true pelvis. Because of the inclination of the pelvis, the upper part of the sacrum is nearly ten centimetres higher than the upper margin of the pubic symphysis. The female pelvis is distinguished from the male by certain sexual characteristics. The bones are more delicate and the ridges and processes for muscular attachment are less prominent. The depth is less. the inlet more nearly circular, the pubic arch wider, the distance between the ischial tuberosities greater and the acetabulum smaller in the female than in the male. In addition, the pelvis is broader and its capacity greater, and this contributes to the greater breadth of the hips in women. The greater capacity of the female pelvis affords room for expansion of the uterus during pregnancy and for the passage of the child at the time of birth.

Femur. — The femur is the longest bone in the body. At its upper extremity is the smooth hemispherical head, articulating with the acetabulum. Supporting the head is a strong, elongated neck which extends downward and outward to join the shaft. At the junction of neck and shaft two processes or trochanters are situated. To the lateral, or greater, trochanter are attached muscles that rotate the thigh; into the lesser trochanter is inserted the iliopsoas muscle, a flexor of the thigh. The neck of the femur in the adult forms an angle of about 125° with the shaft. The shaft is almost cylindrical at its centre, but it is expanded above and below. Its front and sides give origin to the extensor muscles of the leg; behind, there is a long ridge, the linea aspera, into which are inserted the adductor muscles of the thigh. The lower end of the femur is adapted to the upper surface of the tibia and presents a large, smooth, articular surface, the anterior portion forming a trochlea or pulley for the patella (see fig. S). The lower and posterior part, subdivided into two convex condyles, moves upon the condyles of the head of the tibia. In the deep fossa between the femoral condyles are attached the cruciate ligaments that control and limit movements at the knee joint.

Patella. — The patella, or kneecap, is a triangular, flattened, sesamoid bone developed in the tendon of the great extensor muscles of the leg. Its anterior surface and sides are rough, giving attachment to tendinous fibres; its posterior surface is smooth, and enters into the formation of the knee joint by articulating with the anterior part of the lower end of the femur.

Tibia. — The tibia is the medial and larger of the two bones of the leg (see fig. 5). The femur moves and rests upon its upper end, and through it the weight of the body in the erect position is transmitted to the foot. Its upper extremity (head) is broad and expanded into two condyles, the lateral one bearing inferiorly a small articular facet for the head of the fibula. Superiorly, the two condyles have nearly flat surfaces. articulating with the condyles of the femur. The two condyles are separated by an intermediate rough surface, from which an intercondyloid eminence projects; standing opposite the intercondylar fossa of the femur, this eminence affords attachments to the interarticular cruciate ligaments and the meniscoid cartilages of the knee. These cartilages are movable rings which help to compensate for the flatness of the condylar articular surfaces by making shallow sockets for the femoral condyles The shaft of the tibia is three-sided. Its medial surface is subcutaneous and forms the shin (see fig. 5). Its lateral and posterior surfaces give origin to muscles which move the foot. The anterior margin is the sharp ridge of the shin, and terminates superiorly in a tubercle into which the great tendon of the extensor muscles of the leg is inserted. The lateral margin of the bone gives attachment to the interosseous membrane of the leg. The lower end of the tibia, smaller than the upper, is prolonged into a broad process, the medial malleolus, which forms the inner prominence of the ankle. The lower end of the tibia articulates with the talus.

Fibula. — The fibula is the long, slender bone buried in the muscles of the lateral side of the leg (see fig. 5). The upper end, or head, articulates with the lateral condyle of the tibia. The

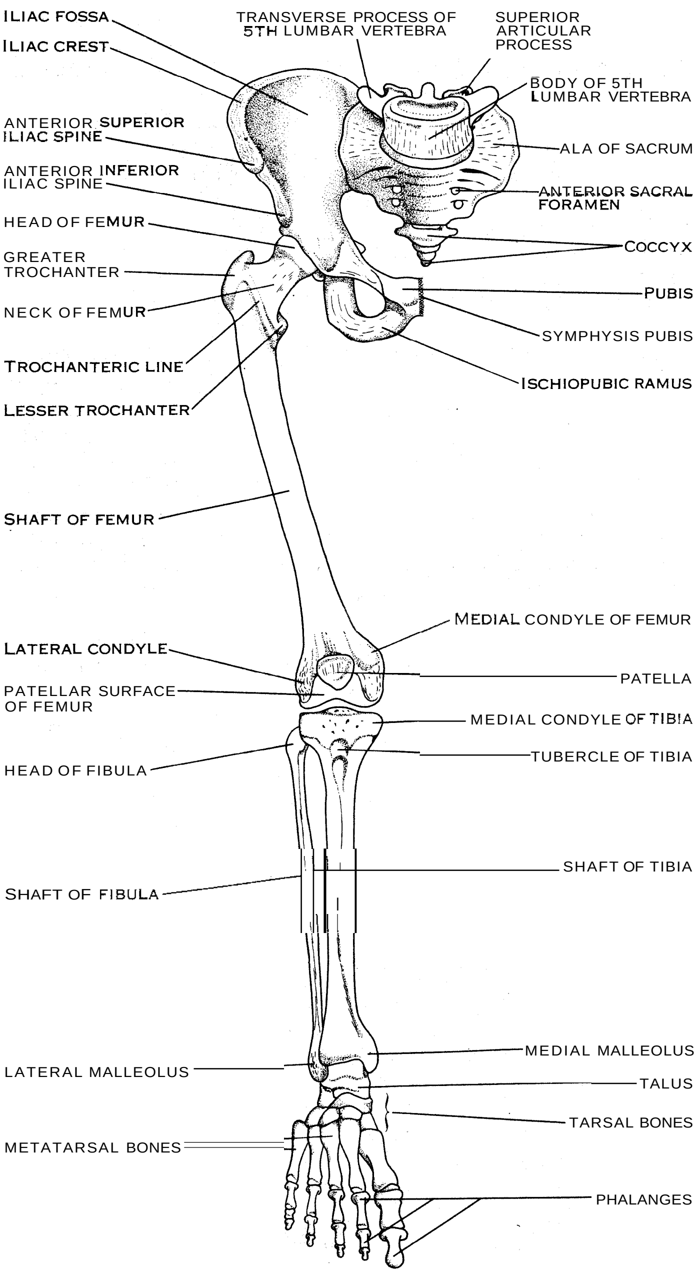

FIG. 5. — ANTERIOR VIEW OF SKELETON SHOWING RIGHT HALF OF THE PELVIS AND RIGHT LOWER LIMB

shaft is four-sided and gives attachment for many muscles. Separating the anterior from the medial surface is a slender ridge giving attachment to the interosseous membrane. The lower end expands into a strong process, the lateral malleolus, forming the lateral prominence of the ankle and presenting a smooth medial surface articulating with the talus. Behind this is a rough surface where the strong ligaments that bind the tibia and fibula together are attached.

Foot.—The foot consists of the tarsus, the metatarsus and the five fret digits, or toes (see fig. 5). The human foot is placed in the prone position, with the dorsum or back of the foot directed upward. The axis of the foot is at about a right angle to the axis of the leg, and the great toe, or hallux, corresponds to the thumb.

The bones of the tarsus, or ankle, seven in number, are arranged in three transverse rows—a proximal, consisting of the talus and calcaneus; a middle, consisting of the navicular; and a distal, composed of the first, second and third cuneiform bones and the cuboid bone. The tarsal like the carpal bones are short and, with the exception of the cuneiforms, which are wedge shaped, are irregularly cuboidal. The dorsal and plantar surfaces are rough for the attachment of ligaments except those of the talus which, since it is mortised between the bones of the leg and the calcaneus, presents articular surfaces on its dorsal and plantar surfaces as well as on its sides.

The posterior portion of the calcaneus projects backward to form the prominence of the heel. With this exception the tarsal bones have articular surfaces upon their anterior and posterior surfaces. Their lateral and medial surfaces are also articular, excepting the lateral surfaces of the calcaneus and cuboid, which form the lateral or outer margin, and the medial surfaces of the calcaneus, navicular and first cuneiform, which form the medial or inner margin of the tarsus.

The metatarsal bones and phalanges agree in number and in general form with the metacarpal bones and the phalanges in the hand. The bones of the great toe are more massive than those of the other digits, and this digit, unlike the thumb, does not diverge from the other digits but lies almost parallel with them.

C. Sesamoid Bones

In addition to the bones described above, certain supernumerary bones are present in certain tendons of the muscles of the hand and foot; these are known as sesamoid bones.

IV. DEVELOPMENT OF THE SKELETON

The skeleton is developed from the embryonic mesoderm. so it is necessary to refer briefly to the origin of this tissue. At about the 15th day after fertilization of the ovum, when the embryo consists of a bilaminar disc with layers called ectoderm and endoderm, a longitudinal thickening appears in the posterior part of the embryonic disc as the result of multiplication of the ectodermal cells. This thickening, called the primitive streak, gives rise to the notochord and to the mesoderm. The primitive streak is comparable to the blastopore of lower vertebrate embryos. The axis of the embryo is first laid down by the formation of a cylindrical mass of cells, the notochord, proliferated from the primitive (Hensen's) node at the anterior end of the primitive streak. The notochord lies ventral to the developing central nervous system and forms the first supporting structure for the developing embryo.

In fishes such as the shark, cartilaginous vertebrae are formed round the notochord and to some extent compress it. Nevertheless, it persists as a continuous structure through the length of the vertebral column. In the higher vertebrates, including man, the notochord is a temporary structure which persists only as a minute canal in the bodies of the vertebrae and in the central part of the nucleus pulposus of the intervertebral discs.

While the notochord is being laid down, cells proliferate from the sides of the primitive streak. These form the mesoderm, which spreads out as a sheet on each side and, as a result of migration and multiplication of cells, soon comes to occupy most of the space between the ectoderm and the endoderm on each side of the notochord. The mesodermal sheets soon become differentiated into: (1) a mass lying on each side of the notochord (paraxial mass) which undergoes segmentation into hollow blocks, the mesodermal somites; (2) a lateral plate which becomes separated into an outer layer, the somatopleuric mesoderm, against the future body wall, and an inner layer, the splanchnopleuric mesoderm, against the endoderm of the future gut; (3) an intermediate mass, the nephrogenic cord, which gives rise mainly to the urinary apparatus.

The segmentation of the paraxial mesoderm is a fundamental feature of the development of the vertebrates. The axial skeleton and associated structures develop from part of the somite, while the appendicular skeleton arises from the somatopleuric mesoderm of the lateral plate. Each somite differentiates into: (1) a lateral and superficial plaque, the dermatome, giving rise to the integumentary tissue; (2) a deeper lateral mass, the myotome, which gives origin to the muscles; and (3) a medial ventral mass, the sclerotome. The sclerotomic cells from each pair of somites migrate medially until they meet in the middle line round the notochord to separate it from the neural tube dorsally and from the aorta ventrally. The sclerotomic tissue retains its original segmentation and becomes condensed to form the forerunner or blastema of the body of the future vertebra. From each posterolateral half of the condensation extensions pass backward and eventually meet posteriorly round the neural tube to form the blastema of the neural arch of the vertebra. In the interspaces between adjacent myotomes of each side, an extension from each sclerotomic mass passes laterally and forward to form the costal or rib element. It is only in the thoracic region that the costal elements develop into the definitive ribs. In the other regions the costal elements remain rudimentary. As early as the seventh week of fetal life (the embryo being approximately 18 mm. in length), the mesenchymal blastema of the future vertebra becomes chondrified; *i.e.*, the mesenchymal cells are converted into cartilage cells. In this cartilaginous vertebra, ossification centres appear about two weeks later, and the cartilage is gradually replaced by bone. The mesenchyme of the primordia of the ribs also undergoes chondrification and later ossification. In the thoracic region, where costal elements are best developed, a cartilaginous sternal bar is formed in relationship with their anterior or growing ends.

The appendicular skeleton begins to develop in the primitive limb bud at the fifth week of fetal life in the core of mesenchyme derived directly from the unsegmented somatopleuric mesoderm. This mesenchyme becomes condensed to form the blastemal masses of the future limb bones. By the seventh week of fetal life, the mesenchyme has become transformed into the cartilaginous precursors of the individual bones (except in the case of the clavicle). The cartilaginous models determine the general shape and relative size of the bones, and there is convincing evidence from experimental investigations that the shape of the bones of higher vertebrates is determined by intrinsic factors inherent in the tissues and that extrinsic influences are concerned with providing the proper conditions for maintaining the normal structure once development has begun.

The first mesenchymal condensations of the appendicular skeleton are in the region of the future girdles, and those for the shoulder girdle appear a little earlier than those for the pelvic girdle. The mesenchymal condensations for the other bones of the limbs appear in a proximodistal sequence.

Ossification of Bone.—The ossification of bone is usually described as occurring by two different methods—endochondral (in cartilage) and intramembranous (in membrane), but in each case the fundamental process is the same since the cells that are responsible are identical.

All the bones of the skeleton (excluding certain of the skull bones and the clavicle) are developed in cartilage; *i.e.*, by endochrondral ossification. It must be emphasized that there is no direct transformation of the cartilage into bone. The cartilage of the model becomes calcified and is then removed by a process of erosion and replaced by bone (see Bone; Connective and Supporting Tissues: Anatomical Types of Connective Tissues: Bone).

V. COMPARATIVE ANATOMY

Just as in the embryonic development of man the notochord forms the earliest structure that stiffens the embryo, so in the animal kingdom it appears before the true vertebral column is evolved. In the ascidians or sea squirts (Urochordata) the notochord is present in the larval stage, in the tail region only, disappearing after the animal's metamorphosis to the adult form. In amphioxus (Cephalochordata) the notochord is permanent and extends the whole length of the animal.

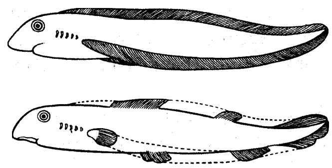
In the lampreys (Cyclostomata) the notochord and its sheath persist throughout life, and in the adult lamprey (Petromyzon) rudimentary cartilaginous neural arches are found. Among the bony fishes, the sturgeon (Acipenser) has a persistent notochord with fibrous sheath upon which appear the paired cartilaginous dorsal neural arches and ventral hemal arches. The modern shark (*Scyllium*) possesses a vertebral column composed of cartilaginous, partly calcified, centra which have their origin within the sheath of the notochord, causing its partial absorption.

The vertebrae of the salmon and cod (Teleostei) are completely ossified; each centrum develops in the sclerotomic mesoderm outside the notochordal sheath (perichordal development).

A vertebra of a modern tailed amphibian (*e.g., Ambystoma*) is in one piece, and the neural and hemal arches are in continuity with the centrum. In general, a vertebra is formed from the sclerotomic tissue of two somites, the tissue from the posterior part of one somite joining that from the anterior part of an adjacent one. Articulation between neural arches of adjacent vertebrae is by special articular processes (zygapophyses). The first vertebra of the amphibian vertebral column, the atlas. presents a pair of sockets on the anterior surface of the centrum. These sockets articulate with the two condyles of the skull. The second vertebra does not differ from those following.

In living reptiles the vertebrae are completely ossified. The neural arch has a spinous process and pre- and postzygapophyses; at the junction of arch and centrum there is a facet for articulation of the head of a rib. Groups of vertebrae can be distinguished; for example, the cervical vertebrae can be recognized, as the neck is differentiated from the body. The atlas, in the form of a ring, lacks a centrum, and articulates with the single condyle of the skull by a facet on the anterior surface of the ventral bar of the ring. The second vertebra, the axis, possesses a centrum which articulates anteriorly with the odontoid process; this process is the dissociated centrum of the atlas and lies within the ring of the latter in contact with its ventral bar. The costal elements of two sacral vertebrae unite the pelvic girdle with the axial skeleton. In the tail region hemal arches are found enclosing the caudal artery and vein. In some species the hemal arches are separate and are called chevron bones. A special feature of the caudal vertebrae in the lizard is the transverse division of the centra, adapted to the shedding of the tail. The fibrocartilaginous intervertebral discs uniting the centra of crocodiles have been identified as representing intercentra (interpreted as ossifications in the hypochordal bars). Ribs are present in the cervical, thoracic and lumbar regions, and in the tortoises they fuse with the cervical vertebrae. The more cranial thoracic ribs are attached to the stemum through cartilaginous sternal ribs; the other ribs do not reach the sternum. In the crocodiles and the lizardlike *Sphenodon*, a spur from each thoracic rib overlaps the next rib behind and is known as an uncinate process. These processes are developed in connection with the origin of the external oblique muscle of the abdomen. The ventral elements of some of the hinder ribs of crocodiles lie unattached in the intersections (inscriptiones tendineae) of the rectus and internal oblique muscles and are known as abdominal ribs. The sternum may be calcified but is seldom ossified in the reptiles. In the lizards it is a cartilaginous plate articulated with the coracoid processes of the pectoral girdle and with the anterior thoracic ribs. The sternum is absent in the turtles and in the snakes; in the crocodiles it is a wide plate joined by the coracoids and by two pairs of ribs.

The skeletons of modern birds show reptilian features with some specialized adaptations to their bipedal locomotion and power of flight. Between the bodies of the vertebrae are intervertebral discs. The neck is very movable, and with its variation in length the number of cervical vertebrae ranges from 25 in the swan to only 9 in some of the small birds. The tendency for the vertebrae to fuse in certain regions is a characteristic of birds. The two true sacral vertebrae become secondarily fused with adjacent lumbar vertebrae, and indirectly even with thoracic, to constitute a synsacrum. This fuses with the ilium of the pelvic girdle, making a rigid support for the posterior part of the bird's body. The caudal vertebrae are fused into a single bone, the pygostyle, that supports the tail. The stemum is a very large bone standing like a shield in the front of the chest. In flying birds (Carinatae) a median keel, the carina, projects ventrally, providing additional surface for the attachment of the pectoral muscles that move the wings. The nonflying ostrich-like birds have a keelless. raft-like sternum.



FROM WILDER'S HISTORY OF THE HUMAN BODY

FIG. 6.— DRAWING ILLUSTRATING THE THEORY OF ORIGIN OF THE MEDIAN AND PAIRED FINS OF THE FISH AS THE RESULT OF THE PER- [illegible] MEDIAN AND LATERAL FIN FOLDS

In mammals, the vertebral centra articulate by means of intervertebral discs of fibrocartilage. Epiphyseal bony plates formed on the generally flat ends of the centra are characteristic of mammals; they are rudimentary in the duck-billed platypus and in the sea cows. Regional differentiation in the mammalian backbone is marked. The number of vertebrae in each group, excepting the caudal, is moderately consistent with few exceptions. Some exceptions to the group averages may be cited. Whereas 7 cervical vertebrae are the rule, there are 9 or 10 in the three-toed sloth and only 6 in the two-toed sloth and the manatee. The thoracic vertebrae commonly number 13 or 14, although they vary from 9 in some whales to 24 in the two-toed sloth. The average number of lumbar vertebrae may be taken as 6; there are but 2 in the duck-billed platypus and 21 in the dolphin. Rib elements are fused to the transverse processes of the cervical vertebrae, and in the lumbar vertebrae they form the so-called transverse processes. There is an increase in the number of vertebrae that compose the sacrum. The sacrum consists of the true sacral vertebrae fused to form a single bone. In the early developmental stages of human embryos the beginnings of the hipbones lie opposite those segments of the spinal column that go to form the lower lumbar and upper sacral vertebrae. As development proceeds, the sacroiliac joints become established between the hipbones and the upper sacral vertebrae; the sacrum, derived from the 25th to the 29th vertebrae inclusive, becomes a single bone by their fusion. The whales and sea cows lack a sacrum, although vestiges of a pelvis occur. In some anteaters the posterior sacral vertebrae are fused with the ischium through ossification of the sacrotuberous ligament. The sacrum of some armadillos consists of 13 vertebrae, caudal vertebrae having become fused with it. The cervical vertebrae of some whales are fused together. The centrum of the atlas of most mammals fuses with that of the axis and projects from it as the dens, but in the duck-billed platypus it is a separate bone as it is in reptiles. The spinous processes of the thoracic vertebrae, excepting the last. point caudally and those of the lumbars generally point cranially; at the transitional zone between these groups the spines of one or two thoracic vertebrae are upright and the name anticlinal is given to them. Lying ventral to the intervertebral discs in some mammals (whales, pangolin) are paired ossicles, the intercentra, homologous with the anterior arch of the atlas. The tail vertebrae vary in number from none in the bat to 49 in the pangolin.

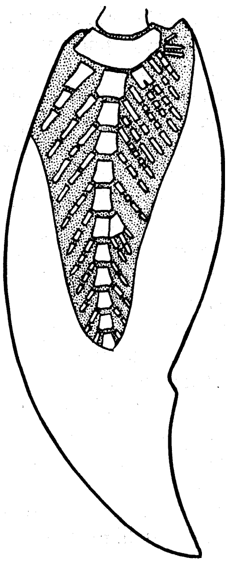
The ribs in mammals correspond in number of pairs to the number of thoracic vertebrae. The tubercle articulates with the transverse process; the head of the rib with the capitular facets of two vertebrae, that with which the tubercle articulates and the one anterior to it. The ribs of some whales articulate only with the transverse processes of the vertebrae. The ventral ends of the ribs join the costal cartilages, the relations of which follow, with minor variations, the pattern described for the human skeleton. Sternal ribs, connecting the more anterior vertebral ribs with the sternum. may be cartilaginous, calcified or ossified. The mammalian sternum is composed of several pieces—the presternum anteriorly, followed by the mesosternum, made up of a number of segments, and a terminal single xiphisternum. The sternum of the rorqual whale and of the manatee is a single bone.

VI. COMPARATIVE ANATOMY OF THE APPENDICULAR SKELETON

The paired appendages or limbs are not found in ancestral vertebrates and are not yet present in the living cyclostomes or jawless vertebrates. Appendages make their first appearance during the early evolution of the fishes. Usually two pairs of appendages are present and consist of fins (ichthyopterygium) in the fishes and limbs (cheiropterygium) in land vertebrates. Each appendage includes not only the skeletal elements within the free portion of the limb but also the basal supporting structure, the limb girdle. This portion of the appendage lies partly or wholly within the trunk and forms a stable base for the fin or limb. Each girdle consists of ventral and dorsal masses and in lower fishes these are composed of cartilage; in bony fishes and in land vertebrates the masses become more or less completely ossified.

The anterior appendages, the pectoral fins or forelimbs, articulate with the pectoral girdle, which is situated just caudal to (behind) the gill region in fishes and in a comparable position at the junction of the neck and thorax in land vertebrates.

The posterior appendages, called pelvic fins or hindlimbs, articulate with the pelvic girdle: which is situated in the trunk region usually just cranial to (in front of) the anus or cloaca. It is by way of the girdles that the weight of the body in land vertebrates is transmitted to the limbs. As the hind limb is usually of greater importance in weight bearing, especially in bipedal vertebrates, it articulates with the vertebral column by means of the costal elements of the sacral vertebrae. The vertebrae to which the pelvic girdle is attached usually fuse to form the sacrum. In fishes, however, since the posterior appendages usually do not support the body weight but are used only in l'ocomotion, a sacrum as such does not develop.

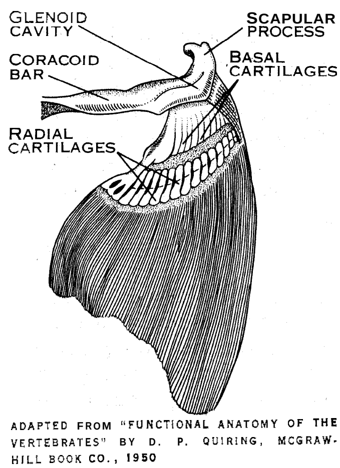


FROM NILS HOLMGREN IN "ACTA ZOOLOGICA," ALBERT BONNIERS FÖRLAG, STOCKHOLM

FIG. 7.— PECTORAL GIRDLE OF THE LUNGFISH (CERATODUS) SHOWING A CENTRAL ARCHIPTERYGIUM WITH LATERAL RAYS

The origin of paired fins has been much debated and many theories have been put forward in explanation. In the most probable theory, the fin-fold theory, the paired limbs are derived from the local persistence of parts of a continuous fold which, in ancestral vertebrates, passed along each side of the trunk and fused behind the anus into a single fin (see fig. 6[A] and 6[B]). The primitive paired fins were attached to the body by a broad base and carried no weight. Their main function, it would appear, was to act as horizontal stabilizing keels which tended to prevent rolling movements and possibly also fore and aft pitching. It is generally agreed that the limbs of tetrapods (land vertebrates) have been evolved from the paired fins of fishes and have become organs for propulsion. They are thought to have their ancestral counterpart in the fins (see fig. 7) of certain extinct lobe-finned fishes (Crossopterygii). The coelacanth is a living example of this group.

Limb Girdles.—The skeleton of the primitive fin consists of a series of endoskeletal rods each of which undergoes subdivision into a series of three or four pieces. The proximal (*i.e.*, nearer to the trunk) or basal pieces tend to fuse into larger pieces. The most cranial (anterior) of the basal pieces fuses across the middle line with its fellow of the opposite side to form a primitive girdle in the form of a cartilaginous bar. The more distal or radial pieces persist to form the dermal fin rays.



ADAPTED FROM "FUNCTIONAL ANATOMY OF THE VERTEBRATES" BY D. P. QUIRING, MCGRAW-HILL BOOK CO., 1950

FIG. 8.—LEFT PECTORAL GIRDLE AND LIMB OF AN ELASMOBRANCH

Pectoral Girdle.—Fishes.—In the dogfish the pectoral girdle consists of a U-shaped endoskeletal cartilaginous inverted arch with its ends extending dorsally. The crosspiece of the "U" forms the coracoid bar, the ends passing dorsally on each side to form the scapular processes. At the junction of the coracoid with the scapular process is an articular region or glenoid fossa for articulation with the basal cartilages of the fin (see fig. 8).

In all other major groups of vertebrates the pectoral girdle is a composite structure consisting of the endoskeletal structures to which secondary dermal components are added as the result of ossification of dermal elements. These become ossified to form dermal bones.

In bony fishes such as the lungfishes, sturgeon and coelacanths, the main element added is a vertically placed structure, the cleithrum, which supports the scapula (see fig. 9). The cleithrum may be joined by a supracleithrum, which in turn is surmounted by a posttemporal element, so that the shoulder girdle is connected with the otic region of the skull.

The most ventral of the added dermal bones are the clavicles, which unite below the gill chamber with each other or with the sternum. In the holostean fishes (*e.g.,* gar pike) and in the teleosts (*e.g.,* salmon and codfish) the clavicle is lost, leaving only the cleithrum.

Amphibians.—In tailed amphibians such as newts and salamanders the dermal elements of the pectoral girdle have been completely lost and only the endoskeletal parts remain; they have reverted mainly to being cartilaginous bars. This retrogression is probably the result of their adaptation chiefly to an aquatic

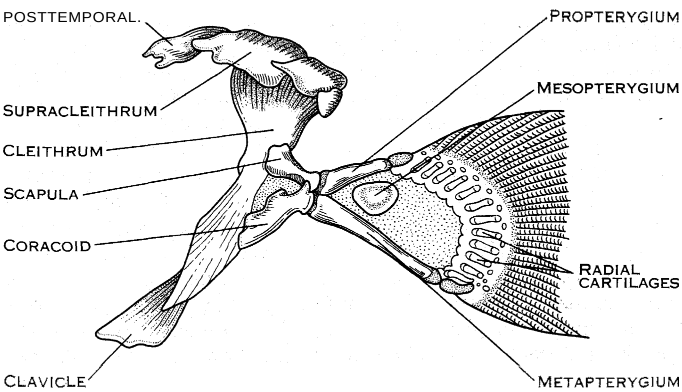


FIG. 9.— RIGHT SHOULDER GIRDLE OF TELEOST FISH

mode of life where less support by the girdles is required. The ventral part of the girdle forms the coracoid and the dorsal part the scapula; the latter is the only part which becomes ossified, and only a rudimentary sternum is developed.

In the frog, the pectoral girdle consists of a dorsally placed, ossified scapula, to the end of which is joined an incompletely ossified plate, the suprascapula. The precoracoid and coracoid are quite distinct, the former being cartilaginous and overlaid by an investing dermal bone, the clavicle.

Reptiles.—In most reptiles there is a primary girdle for the forelimb, consisting of a scapula and a single coracoid. The pectoral girdle of the lizard consists of bones formed in cartilage; the scapula and the large coracoid, participating in the glenoid cavity, and the dermal, membrane bones, the clavicle and interclavicle, the latter being a single T-shaped bone, with the stem in the midline and in contact with the sternum. The curved clavicles articulate with each other at their medial ends. The cartilaginous suprascapula is present.

In the alligator the pectoral girdle consists of a stout dorsal scapula and a well-developed precoracoid. Clavicles are absent, but there is a well-developed midventral dagger-shaped interclavicle.

Birds.—In birds the pectoral girdle is essentially similar to that found in the reptiles. The precoracoid forms a stout bar which reaches to the sternum. The wishbone, or furcula, is formed from the dermal part of the girdle and consists of two clavicles united together in the middle line by the interclavicle. The Carinatae (birds with a keeled sternum) have a sabre-shaped scapula and a stout coracoid joined together by ligaments, where the glenoid cavity for articulation with the humerus is located. The coracoid is jointed to the sternum; at its dorsal end is the acrocoracoid process. The furcula stands in front of the coracoids, its ends connected by ligaments with the acrocoracoid and with the rudimentary acromion process of the scapula. The girdle of the nonflying ostrichlike birds is little developed, being represented by an ankylosed scapula and coracoid.

Mammals.—Among mammals, the monotremes have two coracoids, articulating medially with the presternum and laterally with the scapula, which enter into the formation of the glenoid cavity. An interclavicle (episternum) and an investing clavicle resembling these bones in reptiles are also present. The clavicle articulates with the acromion of the scapula. In the opossum the scapula has a spine ending in the acromion, with which the clavicle articulates. A much-reduced coracoid fuses with the scapula and does not meet the sternum. The scapula of the placental mammals has a spine ending, generally, in an acromion, and the body of the bone is triangular. In mammals which use the forelimb for support in standing, the vertebral margin is the shortest and the long axis of the scapula runs from it to the glenoid cavity; but in those whose forelimb is used for prehension, such as the primates, or for flight, such as the bats, the vertebral margin is elongated and the distance from it to the glenoid cavity is decreased, so that the long axis is parallel with that of the body instead of being transverse. In the placental mammals, the coracoid, although developing independently, has dwindled to a beaklike process, and fuses with and becomes part of the scapula and does not articulate with the sternum. There has occurred a change in the structure of the pectoral girdle, from its form in animals in which the fore part of the body is propped up on the forelimbs when the coracoid is functional, as in reptiles, to a form in pronograde mammals by which the fore parts are suspended between the two scapulae by the serratus anterior muscles. These spring from the ribs and are inserted into the vertebral margin of the scapula.

The clavicle is present generally in those placental mammals that have prehensile forelimbs (primates, many rodents and marsupials and others), or whose forelimb is adapted for flying (bats). In many mammals it is suppressed, as in cats, or absent, as in whales, sea cows and hoofed animals.

Pelvic Girdle.—Fishes.—The pelvic girdle of the elasmobranch fishes consists of a curved cartilaginous puboischial bar or pair of bars lying transversely in the ventral part of the body anterior to the cloaca; projecting dorsally on each side is an iliac process. Connected with it is a basal cartilage carrying a series of radialia, the skeleton of the paired pelvic fins. The pelvic girdles of many bony fishes are situated far forward near the gills.

Amphibians.—There are marked variations in the form of the pelvic girdle in the amphibians. In the frog the three parts of the hip bone (ilium, ischium and pubis) are present. The pubic elements, however, remain wholly cartilaginous. The hip bone is characterized by the great length and forward extension of the ilium. The girdle is connected with the costal element of one vertebra, thus establishing a sacral region of the vertebral column. The acetabulum is situated at the junction of the three elements.

Reptiles.—The pelvic girdle of some reptiles has a loose connection with the spine. In most reptiles, the ilium is joined to two sacral vertebrae. Both the pubic and the ischial parts usually meet in the ventral symphysis, from which a cartilage or bone, the hypoischium, projects backward to support the margin of the cloacal orifice, and another, the epipubis, projects forward. In a few snakes vestiges of a pelvis and of a limb skeleton appear.

Birds.—In most birds the ilium extends forward and backward and is fused with the many vertebrae which form a synsacrum. The slender ischia and pubes do not form symphyses except in the ostrich.

Mammals.—In most mammals the ilium articulates with the sacrum and the pubes meet in a symphysis anteriorly. A cotyloid bone, formed in the cartilage in the bottom of the acetabulum, is usually found. The symphysis pubis is not present in certain mammals (*e.g.,* moles). In monotremes and marsupials, the mar-

Key: R = radiale, I = intermedium, U = ulnare, C = centralia, 1–5 = carpalia

supial bones that support the pouch have been regarded as part of the epipubis.

Limbs.—Fishes.—The pectoral fin of the elasmobranchs has basal cartilages articulating with the shoulder girdle and carrying a number of radial cartilages consisting of varying numbers of short segments beyond which are delicate fin rays (see fig. 8).

The proximal segment of the pelvic fin of sharks is supported by a single basal cartilage and by one or two radialia. In the pectoral fin of the living crossopterygian fish Polypterus, three elements constitute the proximal segment of the fin, bony rods named pro- and metapterygium on the margins and an intermediate cartilage partly ossified, the mesopterygium (see fig. 9).

Other Vertebrates.—In the land vertebrates, many modifications have occurred in the appendages as a result of the transformation of the fins from balancing organs to weight-bearing propulsive levers. Limbs with digits replace the paired fins. The position of the limbs undergoes progressive changes in adaptation to new conditions. The skeleton of the free limb of the land vertebrate is divisible into three segments.

The proximal segment consists of a single bone, known as the humerus in the forelimb and as the femur in the hindlimb. The humerus articulates by its rounded head with the glenoid cavity of the scapula and by condyles with the bones of the forearm. Its shaft is usually twisted and presents ridges and tuberosities for the attachment of muscles. In many species the distal expanded end is perforated by epicondylar foramina. Foramina are characteristic of the humerus of most reptiles; an entepicondylar foramen is characteristic in some. These foramina are absent in crocodiles. The humerus of flying (carinate) birds, like many of their bones, is hollowed out and contains air. It is short and has, next to the head, a large tuberosity for the insertion of wing muscles. Epicondylar foramina are absent. In nonflying (ratite) birds, the skeleton of the wing is greatly reduced. The entepicondylar foramen is widely distributed among mammalian orders and seems to be linked, in part, with the prehensile limb, as is suggested by its presence in cats and absence in dogs and in the hoofed animals. The entepicondylar foramen transmits the median nerve and brachial artery. The supracondylar process sometimes found in man is a vestige of the boundary of the foramen.

The femur is essentially a cylindrical structure with expanded ends. At the proximal end, for articulation with the acetabulum, is the rounded head, and near it there are usually two elevations, trochanters, for the attachment of muscles. The occurrence of three trochanters is characteristic of certain mammals; *e.g.,* horse and rhinoceros. Distally, the femur expands into two condyles for articulation with the tibia. In many types there is an articular facet on the lateral surface for the head of the fibula.

The typical skeleton of the next segment contains two bones, radius and ulna in the forelimb and tibia and fibula in the hindlimb. In the forelimb, the radius is anterior or preaxial, and the ulna postaxial in the adjustment of the limb for support and locomotion on land. The radius and ulna are fused in some amphibians, for example, in the tailless amphibians (as frogs and toads), and are separate in others, for example, in the urodeles, as they are in all of the reptiles. The ulna is the stouter bone in the bird's wing and supports the secondary feathers. In pronograde mammals the radius is fixed in pronation; that is, the forelimb is rotated so that the shaft of the radius crosses in front of that of the ulna. The radius transmits the aeight of the fore part of the body to the forefeet; whereas it is the ulna that makes the elbow joint with the humerus, and into its proximal end are inserted the flexor and extensor muscles of the forelimb.

Tibia and fibula are separate in urodeles, united in tailless Amphibia. In land reptiles the tibia, the larger bone of the leg, articulates with both condyles of the femur and with the tritibiale of the ankle; the fibula articulates with the postaxial femoral condyle and with the tritibiale and fibulare. The tibia of birds is long but the fibula reduced. In mammals the fibula is generally reduced. It may be fused with the tibia and excluded from the knee joint.

The distal segment of the limb comprises the carpus, metacarpus and phalanges in the upper limb, and the tarsus, metatarsus and phalanges in the lower limb. In a typical limb there are five digits (fingers or toes) which contain the phalanges.

The carpus and tarsus of the higher vertebrates are probably derived from a primitive type by the fusion or suppression of certain of its elements. The bones of a generalized carpus (or tarsus), as that of a tortoise and certain other reptiles, are in three transverse rows: a proximal row of three, named radiale (or tibiale), intermedium and ulnare (or fibulare); a distal row of five carpalia (or tarsalia), numbered one to five from the radial (or tibial) margin; and an intermediate row of one or two centralia.

In many of the urodele amphibians (*e.g.,* salamanders) the carpus is generalized. In the frogs and toads, however, it is more specialized, only six carpals being present, the third, fourth and fifth carpalia having probably fused with either or both centralia. In birds the radiale and ulnare are distinct, but the distal bones are fused with the metacarpus to form a carpometacarpus. In mammals various examples of fusion and suppression occur. In man the radiale forms the scaphoid; the intermedium, the lunate; the ulnare, the triquetral; the pisiform, an ulnar marginale, represents the remains of an extra digit, which may, however, be simply a sesamoid bone. The trapezium and trapezoid are carpalia 1 and 2, the capitate is derived from carpal 3; whereas carpalia 4 and 5 have fused to form the hamate. An os centrale is present in the carpus of many monkeys. In mammals the number of digits varies but the number of phalanges in each digit present usually corresponds with that of man. In some species, however, the phalanges are more numerous, as when the limb is modified to form a paddle —*e.g.,* in the whales.

The tarsus of urodele amphibians has the typical composition; in the frogs and toads the intermedium is absent; two long bones are identified as tibiale and fibulare. Among the reptiles there is much variation in the composition of the tarsus. Generally the hinge of the ankle is intratarsal, the row of tarsalia being distal to the hinge. In most living reptiles the tibiale and intermedium fuse to form the talus. In birds the ankle hinge is of the reptilian pattern in being intratarsal. The three tarsal cartilages of the embryo fuse to form the talus, which fuses with the tibia forming

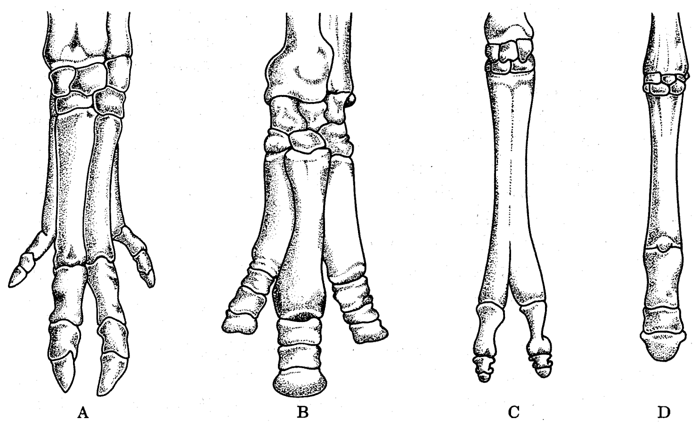

FIG. 11.—LEFT FOREFEET OF UNGULATES: (A) PIG, (B) RHINOCEROS, (C) CAMEL, (D) HORSE

the tibiotarsus. The tarsalia fuse with the ends of the united metatarsals to make a tarsometatarsus. In the mammalian tarsus the talus is generally composed of the fused tibiale and intermedium, but in some a centrale is included to form a tritibiale. The ankle hinge is not intratarsal, but located between the bones of the leg and the first row of tarsal bones—tibia and talus usually.

With the suppression of digits, which occurs among certain mammals, a rather frequent order of sequence occurs (*see* fig. 11). The pollex (or first) is the first to go, then the minimus (or fifth), index (or second) and annularis (or fourth). Thus, among the even-toed ungulates (artiodactyls), for example, in the pig and hippopotamus, the pollex has disappeared and the other four digits are present, although the second and fifth are much reduced. In the camel only the third and fourth digits persist and are of equal importance. Among the odd-toed ungulates (perissodactyls) the right digit is dominant and the others reduced to mere rudiments or splints as in the horse.

SKELTON, JOHN (*c.* 1460–1529), English poet, is variously asserted to have belonged to a Cumberland family and to have been a native of Diss in Norfolk. He is said to have been educated at Oxford. He certainly studied at Cambridge, and he is probably the "one Scheklton" mentioned by William Cole (manuscript *Athen. Cantabr.)* as taking his M.A. degree in 1484. In 1490 Caxton writes of him, in the preface to *The Boke of Eneydos Compyled by Vyrgyle,* in terms which prove that he had already won a reputation as a scholar. "But I pray mayster John Skelton." he says, "late created poete laureate in the unyversite of Oxenforde, to oversee and correct this sayd book . . . for him I know for suffycyent to expomne and englysshe every dyffyculte that is therein. For he hath late translated the epystlys of Tulle, and the boke of dyodorus siculus, and diverse other works . . . in polysshed and ornate termes craftely . . . I suppose he hath drunken of Elycons well." The laureateship referred to was a degree in rhetoric. Skelton received in 1493 the same honour at Cambridge.

Skelton found a patron in the pious and learned countess of Richmond, Henry VII's mother, for whom he wrote *Of Mannes Lyfe the Peregrynacioun,* a translation. now lost, of Guillaume de Deguilleville's *Pèlerinage de la vie humaine.* An elegy "Of the death of the noble prince Kynge Eduarde the forth," included in some of the editions of the *Mirror for Magistrates,* and another (1489) on the death of Henry Percy, 4th earl of Northumberland, are among his earliest poems. In the last decade of the century he was appointed tutor to Prince Henry (afteruard Henry VIII). He wrote for his pupil a lost *Speculum principis,* and Erasmus, in dedicating an ode to the prince in 1500, speaks of Skelton as "unum Britannicarum literarum lumen ac decus." In 1498 he was successively ordained subdeacon, deacon and priest. He seems to have been imprisoned in 1502, but no reason is known for his disgrace. Two years later he retired from regular attendance at court to become rector of Diss, a benefice which he retained nominally till his death.

Skelton frequently signed himself "regius orator" and poet laureate, but there is no record of any emoluments paid in connection with these dignities. His parishioners thought him, says Anthony a Wood, more fit for the stage than for the pulpit. He was secretly married to a woman who lived in his house, and he had earned the hatred of the Dominican monks by his fierce satire. He was censured by Richard Nix, bishop of the diocese, and appears to have been temporarily suspended.

After his death a collection of farcical tales, no doubt chiefly. if not entirely, apocryphal, gathered round his name—The *Merie Tales of Skelton.* During the rest of the century he figured in the popular imagination as an incorrigible practical joker. His sarcastic wit made him some enemies, among them Sir Christopher Garnesche or Garneys, Alexander Barclay, William Lilly and the French scholar. Robert Gaguin (*c.* 1425–1502). Earlier in his career he had found a friend and patron in Cardinal Wolsey, and the dedication to the cardinal of his *Replycacion* is couched in the most flattering terms. But in 1522, when Wolsey in his capacity of legate dissolved convocation at St. Paul's, Skelton put in circulation the couplet:

> Gentle Paul, laie doune thy sweard
> For Peter of Westminster hath shaven thy beard.

In *Colyn Cloute* he incidentally attacked Wolsey in a general satire on the clergy, but *Speke, Parrot* and *Why Come Ye nat to Courte?* are direct and fierce invectives against the cardinal who is said to have more than once imprisoned the author. To avoid another arrest Skelton took sanctuary in Westminster abbey. He was kindly received by the abbot, John Islip, who continued to protect him until his death on June 21. 1529.

In his *Garlunde of Laurell* Skelton gives a long list of his works, only a few of which are extant The garland in question was uorked for him in silks. gold and pearls by the ladies of the countess of Surrey at Sheriff Hutton castle, where he was the guest of the duke of Norfolk. The composition includes complimentary verses to the various ladies concerned, and a good deal of information about himself.

But it is as a satirist that Skelton merits attention. *The Bowge of Court* is directed against the vices and dangers of court life. He had already in his *Boke of the Thre Foles* drawn on Alexander Barclay's version of the *Narrenschiff* of Sebastian Brant, and this more elaborate and imaginative poem belongs to the same class. Skelton, falling into a dream at Harwich, sees a stately ship in the harbour called the *Bowge of Court,* the owner of uhich is the Dame Saunce Pere. Her merchandise is Favour; the helmsman Fortune; and the poet, who figures as Drede (modesty), finds on board Favell (the flatterer). Suspect. Harvy Hafter (the clever thief), Dysdayne, Ryotte. Dyssymuler and Subtylte, who all explain themselves in turn, until at last Drede, who finds they are secretly his enemies. is about to save his life by jumping overboard, when he wakes. Both of these poems are written in the seven-lined Chaucerian stanza. but it is in an irregular metre of his own that his most characteristic work was accomplished.

The Boke of Phyllyp Sparowe, the lament of Jane Scroop, a schoolgirl in the Benedictine convent of Carowe near Norwich, for her dead bird, was no doubt inspired by Catullus. It is a poem of about 1,400 lines with many digressions. We learn what a wide reading Jane had in the romances of Charlemagne, of the Round Table, the Four Sons of Aymon and the Trojan cycle. Skelton finds space to give his opinion of Chaucer, Gower and Lydgate. He seems fully to have realized Chaucer's value as a master of the English language. Gower's matter was, he said, "worth gold." but his English antiquated. The verse in which the poem is written, called from its inventor "Skeltonical," is here turned entirely to whimsical use. The lines are usually six-syllabled, but vary in length, and rhyme in groups of two, three, four and even more. It is not far removed from the old alliterative English verse, and well fitted to be chanted by the minstrels who had sung the old ballads.

For its comic admixture of Latin Skelton had abundant example in French and Low Latin macaronic verse. He makes frequent use of Latin and French words to carry out his exacting system of frequently recurring rhymes. This breathless, voluble measure was in Skelton's energetic hands an admirable vehicle for invective, but it easily degenerated into doggerel. By the end of the 16th century he was a "rude rayling rimer" (Puttenham, *Arte of English Poesze),* and at the hands of Pope[1] and Warton he fared even worse. His own criticism is a just one:

> For though my ryme be ragged,
> Tattered and jagged,
> Rudely rayne beaten,
> Rusty and moughte eaten,
> . . . .
> It hath in it some pyth.

[1]Pope said: "Skelton's poems *are* all low *and bad, there* is nothing in *them* that is worth *reading" (Spence,* **Anecdotes, p.** *87).*

Colyn Cloute represents the average country man who gives his opinions on the state of the church. There is no more scathing indictment of the sins of the clergy before the Reformation. He exposes their greed, their ignorance, the ostentation of the bishops and the common practice of simony, but takes care to explain that he writes in defense of, not against, the church.

The charge of coarseness regularly brought against Skelton is based chiefly on *The Tunnynge of Elynoure Rummynge,* a realistic descriptibn in the same metre of the drunken women who gathered at a well-known alehouse kept by Elynour Rummynge at Leatherhead, not far from the royal palace of Nonsuch. "Skelton Laureate Against the Scottes" is a fierce song of triumph celebrating the victory of Flodden. "Jemmy is ded And closed in led, That was theyr owne Kynge," says the poem; but there was an earlier version written before the news of James IV's death had reached London.

This, which is the earliest singly printed ballad in the language, was entitled *A Ballade of the Scottysshe Kynge,* and was rescued in 1878 from the wooden covers of a copy of *Huon de Bordeaux.* "Howe the douty Duke of Albany, lyke a cowarde knight" deals with the campaign of 1523, and contains a panegyric of Henry VIII. To this is attached an *envoi* to Wolsey, but it must surely have been misplaced, for both the satires on the cardinal are of earlier date.

Skelton also wrote three plays, only one of which survives. *Magnificence* is one of the best examples of the morality play. It deals with the same topic as his satires, the evils of ambition; its moral, "how suddenly worldly wealth doth decay," being a favourite one with him. Thomas Warton in his *History of English Poetry* described another piece, *Nigramansir,* printed by Rynkyn de Worde in 1504, and dealing with simony and the love of money in the church; but no copy is known to exist, and some suspicion has been cast on Warton's statement.

Illustration of the hold Skelton had on the public imagination is supplied from the stage. A play (1600) called *Scogan and Skelton,* by Richard Hathway and William Rankins, is mentioned by Henslowe. In Anthony Munday's *Downfall of Robert, earl of Huntingdon,* Skelton acts the part of Friar Tuck, and Ben Jonson in his masque, *The Fortunate Isles,* introduced "Skogan and Skelton in like habits as they lived."

Very iew of Skelton's productions are dated, and their titles are here necessarily abbreviated. Wynkyn de Worde printed the *Bowge of Court* twice. *Divers Balettys and dyties solacious devysed by Master Skelton Laureat,* and *Skelton Laureate agaynste a comely Coystroune . . .* have no date or printer's name, but are evidently from the press of Richard Pynson, who also printed *Replycacion against certain yong scolers,* dedicated to Wolsey. *The Garlande or Chapelet of Laurell* was printed by Richard Faukes (1523); *Magnificence, A goodly interlude, . . .* probably by John Rastell about 1533, reprinted (1821) ior the Roxburghe Club. *Hereajter foloweth the Boke of Phyllyp Sparowe* was printed by Richard Kele (1550?), Robert Toy, Antony Kitson (1560?), Abraham Veale (1570?), John Walley, John Wyght (1560?). *Hereafter foloweth certaine bokes compyled by mayster Skelton . . .* including "Speke, Parrot," "Ware the Hawke," "Elynoure Rummynge" and others, was printed by Richard Lant (1550?), John King and Thomas March (1565?), and John Day (1560). *Hereafter foloweth a litle boke called Colyn Cloute* and *Hereafter . . . why came ye nat to Courte?* were printed by Richard Kele (1550?) and in numerous subsequent editions. *Pithy, plesaunt and profitable workes of maister Skelton, Poete Laureate. Nowe collected and newly published* was printed in 1568, and reprinted in 1736 A scarce reprint of *Elinour Rummin* by Samuel Rand appeared in 1624.

SKENE, ALEXANDER JOHNSTON CHALMERS (1837–1900), U.S. surgeon, who contributed to theory, practice and teaching in gynaecology during the latter part of the 19th century. was born at Fyvie, Scot., on June 17, 1837. He first studied medicine at King's college, London. When he was 19 Skene went to America, studied medicine in Toronto, Ont.. in 1860 and at the University of Michigan, Ann Arbor, 1861–62, and received his M.D. degree from the Long Island (N.Y.) College Hospital medical school in 1863. He was an assistant surgeon in the volunteer corps of the Union army in 1863, and in 1864 began to practice in Brooklyn, N.Y.

His teaching career began in the same year when he was appointed adjunct professor at the Long Island College Hospital medical school, becoming professor of gynaecology in 1872 and dean in 1886. He also taught gynaecology at the New York Post-Graduate hospital (1883–86). In 1884 he opened his own sanitarium in Brooklyn with W. M. Thalon, and in 1899 Skene's Hospital for Self-Supporting Women.

He was a founder of the American Gynecological society, of which he was president in 1886–87, and of the International Congress of Gynecology and Obstetrics, of which he was honorary president in 1896.

In 1880 his discovery of the urethral glands named for him established his reputation internationally. The inflammation of these glands, skeneitis, and an instrument for examining them, the skeneoscope, were also named for him. He devised 31 medical and surgical instruments, notably Skene's catheter. As a surgeon and teacher he established important operative procedures.

He wrote more than 100 medical articles, served as editor for various general and specialized medical journals, and wrote numerous medical textbooks, including *Diseases of the Bladder and Urethra in Women* (1878), *Treatise on Diseases of Women, for the Use of Students and Practitioners* (1888), and *Medical Gynecology* (1895). He also wrote a novel, *True to Themselves* (1897), and was a sculptor, several of his works being on exhibit at the Kings County Medical society.

Skene died on July 4, 1900, at his country home in the Catskills at Highmount, N.Y. A bust of Skene was ,preserved in Prospect park. Brooklyn.

SKENE, WILLIAM FORBES (1809–1892), Scottish historian and antiquary, was the second son of Sir Walter Scott's friend, James Skene (1775–1864), of Rubislaw, near Aberdeen. In 1832 he became a writer to the signet, and shortly afterward obtained an official appointment in the bill department of the court of session, which he held until 1865. His early interest in the history and antiquities of the Scottish Highlands bore its first fruit in 1837, when he published *The Highlanders of Scotland, Their Origin, History and Antiquities.* His chief work, however, is *Celtic Scotland, a History of Ancient Alban* (3 vol., Edinburgh, 1876–80), perhaps the most important contribution to Scottish history written during the 19th century. In 1881 he became historiographer royal for Scotland. He died in Edinburgh on Aug. 29, 1892.

The most important of Skene's other works are: editions of John of Fordun's *Chronica gentis Scotorum* (Edinburgh, 1871–72); of the *Four Ancient Books of Wales* (Edinburgh, 1868); of the *Chronicles of the Picts and Scots* (Edinburgh, 1867); and of Adamuan's *Vita S. Columbae* (Edinburgh, 1874); an *Essay on the Coronation Stone of Scone* (Edinburgh, 1869); and *Memorials of the Family of Skene of Skene* (Aberdeen, 1887).

SKEPTICISM. Extreme skeptics deny that the human mind can attain knowledge. Total skeptics extend this denial to all kinds of claims to knowledge. But even the original Greek school of skeptics included few, if any. who were not partial or moderate: the former allowed that certain kinds of claims to knowledge were valid; the latter refrained from dogmatic denials of the possibility of knowledge and merely advised suspense of judgment. This restraint was more in harmony with the etymology of the word "skeptic," which is derived from the Greek word *skeptesthai,* "to examine." Dogmatic denials of the possibility of knowledge are always difficult to substantiate, and sometimes they seem to imply knowledge of the existence of the very things which are said to be unknowable.

Differences within the Greek school of professed skeptics have caused uncertainty about the classification of philosophers outside the school. Evidently a skeptic need not be dogmatic. But if a philosopher shows moderate skepticism it may not be a systematic doctrine. but perhaps only an attitude of mind. It may even be unconscious, and possibly the philosopher himself would repudiate the suggestion that he was a skeptic. For if partial skepticism is allowed it is by no means clear what kind of claims to knowledge must be admitted by everyone who is not a skeptic. Consequently the title "skeptic" has no agreed application, and its use reveals as much about the person who applies it as about the person to whom it is applied. For instance, skepticism about ordinary claims to knowledge is quite a different thing from skepticism about the claims of speculative philosophers, so that ordinary people and speculative philosophers are likely to disagree in their diagnoses of skepticism. Also, the same people who apply the word pejoratively to the rejection of their own claims to knowledge at other times may use it as a term of praise to point the contrast with credulity or superstition. However, most systematic skeptics, who stand at the centre of these extensions of their title, do have one tendency in common: they are reluctant to allow claims to knowledge about anything beyond the claimant's own immediate reactions; and consequently systematic skepticism has often been closely associated with some radical forrn of empiricism.

Greek skepticism passed through three stages. The school was founded by Pyrrho toward the end of the 4th century B.C. Next, in the 3rd and 2nd centuries, its ideas were absorbed, extended and modified by the philosophers of the Middle Academy and of the New Academy. Finally, it was revived as an independent school by Aenesidemus in the 1st century B.C. and carried on by Menodotus, Sextus Empiricus and others in the next two centuries.

Pyrrho's chief interest was ethics. He taught that, since knowledge is unattainable. the only way to achieve happiness is to practise suspense of judgment. He appears to have formulated this moral precept without any reservations. So he was neither a total nor an extreme skeptic. Perhaps it was the definiteness and simplicity of his moral teaching which enabled his follower Timon to claim that his philosophy did not conflict with common sense. Pyrrho's skepticism was directed chiefly against the dogmatic speculative theories on which the Epicureans and Stoics based their moral doctrines. However, skeptics who begin by attacking the recondite theories of philosophers often end by colliding with common sense, and Pyrrho's skepticism was not confined to philosophers' claims to knowledge.

The skeptical teaching of Pyrrho's school was taken over by Arcesilaus, the founder of the Middle Academy, and worked out in a more systematic way. This development was continued by Carneades, who founded the New Academy. Both were interested in epistemology for its own sake, unlike Pyrrho, who took it up because of its bearing on ethics. They produced a sustained and thorough criticism of the theory of knowledge which had been elaborated by the Stoics. But their work was not entirely negative. For though Carneades denied the possibility of knowledge. he offered a substitute: he admitted that judgments may have different degrees of probability.

The new skeptical school founded by Aenesidemus owed much to the nork of the Middle and New Academies. It was systematic and self-conscious and classified the arguments which it inherited under ten headings (tropoi). Aenesidemus also took over the criticism of the powers of reason, which had been begun by his predecessors, and carried it much further. This inevitably raised a methodological problem: if reason is unreliable, the philosophical arguments which support this conclusion are themselves unreliable. This difficulty was usually evaded by a simile: the skeptic's arguments would be compared, perhaps, to fire, which consumes both its fuel and itself. Such comparisons are hardly adequate to remove the difficulty; what was needed was some way of distinguishing, as Kant did. between legitimate and illegitimate uses of reason. But the lack of any such distinction did not halt the attack on reason. Deductive reasoning was declared invalid, and inductive reasoning was submitted to a criticism which on many points anticipated Hume's views on causation. The conclusions of inductive arguments were rejected if they could not in principle be checked by observation. Even those which merely moved from phenomena to phenomena were said to yield something less than certainty. But at this point skepticism was tempered by the school's interest in medicine. This they regarded not as a science but as an art (techne), based on repeated and careful observation of the phenomena, never claiming absolute certainty and never postulating unobservable causes. In an instructive passage Sextus commends the grammar which children learn but condemns abstruse theories about the nature of the letters and their origin. Evidently his views on empirical matters were practical. cautious and positivistic. but not obviously skeptical. However, some philosophers would detect skepticism even here, on the ground that inductive arguments involve more than Sextus allows.

Outside the school of professed skeptics the attribution of the title is highly debatable, except in the case of the Middle and New Academies, which stood consciously within the skeptical tradition. But when the historian of ideas considers philosophers outside this continuous Greek tradition, it is as if he had moved out of harbour into the open sea. However, it is just this move which is most likely to lead to some understanding of the nature of skepticism.

Michel de Montaigne is often classified as a skeptic because, in his Essais, he discussed every question in a detached and critical way. He certainly was not an extreme skeptic. But almost all philosophers have something of Montaigne's spirit. So. if Montaigne counts as a moderate skeptic, as no doubt he should, few philosophers have entirely lacked moderate skepticism, even in the Middle Ages. which constituted in some ways the least skeptical of all periods in the history of thought.

However, the rather more extreme forms of skepticism are perhaps worth diagnosing. But here too a great range of variation is encountered. Skepticism about a particular human faculty can be used by two different philosophers to support two entirely different conclusions. This is not altogether surprising, since the same doubt can be associated and contrasted with different certitudes. Plato impugned the reliability of the senses and claimed that the intellect could apprehend a transcendent world of "forms." Sextus rejected all speculation about transcendent reality, took over the Greek corpus of arguments against the senses and accepted medicine as something less than science. Sextus' combination of skepticism about the senses with empiricism is not as inconsistent as it might appear to be. For it is possible to try to allow for sources of error in perception and so to claim that it provides an adequate basis for probable conclusions.

Even Berkeley (*Principles* of *Human* Knowledge, 1710), who maintained that perception yields information only about the sensations of the perceiver, sincerely believed that this did not make him a skeptic. In this he was not entirely unjustified. For, if sensations are the only direct objects of perception (which not everyone would admit), it is not clear how the existence of anything beyond them could be validly inferred. Moreover, Berkeley claimed that material objects were merely collections of sensations in the minds of human beings and God, and this theory might well seem to be less skeptical than any theory which treats sensations as clues to the existence and nature of objects which are never directly perceived.

Berkeley's investigation of perception raises two connected questions about the nature of skepticism. When a philosopher says, not that a certain kind of thing exists but is unknowable. but that it does not exist. is he a skeptic? If. for instance. God's existence is denied. there is no doubt that this is true skepticism. But if a philosopher can plausibly claim that ordinary empirical judgments, nhen they are correctly construed, do not commit the speaker to belief in the existence of a certain type of thing, then the denial that these things exist is not obviously skeptical. This raises the second question. which is a question about the relation between ordinary judgments and philosophical doctrines: how is it possible to decide whether a philosopher's account of what ordinary judgments imply is correct? Many would say that Berkeley does not give a correct account of what ordinary perceptual judgments imply. But it is not easy to adjudicate in cases like this, if only because ordinary people do not often consider such matters deeply. Yet, until this question is decided. it is impossible to say whether a philosophical doctrine like Berkeley's is skeptical or not; unless. of course, the analysis of ordinary judgments is abandoned and the question is decided by appeal to some speculative theory.

Skepticism about the powers of reason can also lead in diverse directions. It led Sextus to pare donn all ambitious claims to knowledge. leaving only the probable results of strictly empirical inquiries, shorn of all theoretical superstructure. It took Pascal, in his *Pensées,* to an entirely different conclusion: the impotence of reason seemed to him to leave all science open to doubt and to show up by contrast the reliability of religious faith. The difference between the sciences which these two had in mind probably explains their divergent estimates of the bearing of skepticism about reason on the claims of scientists. Clinical medicine is largely concerned with symptoms, probabilities and happy diagnoses, whereas applied mathematics is rigorous and theoretical.

Hume, who was also a skeptic about the powers of reason, gave a much more subtle account of science *(Treatise of Human Nature,* 1739; and *Dialogues Concerning Natural Religion,* 1779). Like Sextus, he condemned all theories which postulate unobservable causes behind the phenomena. Like Sextus too, he believed that reason, working on the results of observation, could not possibly establish any contingent general statements. For reason can establish only a priori statements (on this point he was more liberal than Sextus). Contingent general statements are believed not on rational grounds but only because continued observation of a conjunction of events has produced a habit of expectation. Such expectations are based on feeling and not on reason, and no justification of feeling is possible. It is merely an ultimate fact that human beings have this feeling. So there are two central propositions in Hume's philosophy: matters of fact cannot be established purely by a priori reasoning; they can only be established in a precarious way by nonrational inference; or else, perhaps, by direct observation. But even direct observation was not left unscathed by Hume. By an elaborate argument he sought to prove that no rational account of perceptual judgments is possible, and here too he fell back on feeling. Human beings, he said, are so constituted that they must believe in the existence of material objects beyond their sensations even though they can give no rational account of this belief.

Hume's account of inference inevitably seems skeptical to speculative philosophers. For it confines a posteriori inference to phenomena, and it declares a priori inference incapable of yielding new factual conclusions. However, when it is judged at the bar of common sense, it is not so easy to see how it should fare. Hume himself often said that, judged by these standards, it was skeptical, but it is not clear that he was right. Admittedly his refusal to allow that a posteriori inference is rational conflicts with ordinary ideas and linguistic usage. But on the other hand ordinary people might well rest fairly content with his account of the evidence which supports such inferences. For contingent general statements are based ultimately on the observed conjunctions of events, and it is not obvious that they assert anything more than that these conjunctions have always held and will always hold. No doubt the theory needs qualifying and modifying in various ways if it is to fit the facts exactly. But it is doubtful if ordinary people would agree with the much larger complaint of Hume's philosophical critics, that his theory altogether fails to account for the necessity of contingent general statements. However, Hume's theory of inference, like Berkeley's theory of perception, goes far beyond the point to which ordinary people carry the analysis of their judgments. Consequently it is not easy to estimate their reactions to the theory, or, in particular, whether they would call it skeptical.

However, it is possible to detect a pattern in the development of such difficult cases and so to understand why they are difficult. The ordinary person makes judgments which he does not analyze. Some philosophers hold that these judgments commit him to hypotheses which transcend the available evidence. Then other philosophers, allegedly skeptics, react by saying that they commit him to nothing beyond the bare phenomena. The controversy proceeds by a kind of diastole and systole. Perhaps neither the expanding nor the reducing theories are correct, but rather something intermediate. In any case this pattern of philosophical controversy explains why it is so difficult to decide whether reducing theories like Hume's are, from the point of view of the ordinary person, skeptical.

Kant thought that Hume's theory was skeptical, and he tried, in his *Critique of Pure Reason,* to work out a theory of knowledge which would be acceptable to an empiricist and yet free from what he thought was skepticism. At the same time he wished to curtail the speculative flights of reason. What he had in mind was not so much the speculative hypotheses which philosophers sometimes reach in the course of analyzing ordinary judgments, but rather the elaborate deductive systems of the metaphysicians of the 17th century. He called his own philosophy critical, to distinguish it both from what he regarded as skepticism and from what he regarded as dogmatism. This word "critical" is close to the etymology of the word "skeptic," in fact closer than the popular connotation of skeptic. The whole field would be easier to survey if Kant's distinction between criticism and skepticism had always been observed. As it is, the word "skeptic" usually covers both. However, even Kant's use of the word is not free from ambiguities. It can mean one who denies that something exists, or one who allows that it exists but maintains that its nature cannot be known, or one who claims that a whole area of so-called knowledge is vitiated by inconsistencies. Hume's theory of perception belongs to this third type.

Kant believed that human reason imposes certain categories on the raw material of experience which somehow comes from things in themselves. Phenomena are the result of this operation. Causality is one of the categories. So, if a philosopher doubted the validity of causal inferences, as Kant thought that Hume did, he could be answered by the contention that causality is already an ingredient in phenomena as we know them. This illustrates the positive part of Kant's philosophy: reason is rehabilitated in the sphere of phenomena. Kant's negative teaching was that reason cannot extend its operation beyond phenomena. For instance, any attempt to use the category of causality to reach some speculative conclusion would inevitably lead to contradictions; the apparatus of reason, having no material to work on, would cease to function properly.

In spite of Kant's intention there is an element of skepticism in his system. Ostensibly it is critical and only seeks the limits of the powers of reason. But it gives these limits in terms which imply awareness of the existence of things in themselves. It is hard to see how Kant can consistently allow this awareness of the existence of things in themselves. However, since he does allow it and since at the same time he denies the possibility of any kno ledge of the nature of things in themselves. he is on this point a skeptic. On the other hand, he was not in the least skeptical about the possibility of knowledge of what he called phenomena.

Kant used the term "phenomenon" in a neutral way that did not imply an unfavourable contrast with things in themselves. Most of his idealist followers thought that this was an inconsistency and rejected the hypothesis of things in themselves. Some rejected even the claim that phenomena are knowable, supporting this rejection with arguments very like those which Kant had used to show that things in themselves are unknowable. They tried to establish that there are latent contradictions even in quite ordinary claims to knowledge. This kind of dialectical argument, which they inherited from Kant and adapted to a more subversive use, had existed in antiquity and had often been used to undermine the beliefs of ordinary people in just this way. Hume's treatment of perception is an example of this kind of reasoning, but it is as old as Zeno. It produces a special kind of skepticism, which is conspicuous in the writings of 19th-century idealists and was taken to the extreme limit by F. H. Bradley *(Appearance and Reality,* 1893), who found that all claims to knowledge are self-contradictory.

This kind of skeptic does not deny that things of a certain kind can be known to exist; nor does he admit that they exist but deny that their nature can be known: instead he maintains that parts, or perhaps even the whole, of what is alleged to be knowledge cannot be knowledge since it contains hidden contradictions. The first two of these three kinds of philosophical skepticism rely on analogies with ordinary situations in which people refrain from claims to knowledge, perhaps misleading analogies, but at least intelligible ones. This third kind of skepticism is more difficult to understand. A pragmatist would ask how anything which works so well as science could possibly be self-contradictory. An idealist such as Bradley would reply by introducing the doctrine of degrees of reality. What the scientist discovers cannot be perfectly real, since it contains contradictions, but nevertheless it is not sheer illusion, since successes can be achieved even on lower levels of reality. But the scientist must appreciate that he is on a lower level and must not make any claims about ultimate reality, which is the domain of the metaphysician. This kind of system is, from the point of view of the ordinary person, skeptical, and skeptical in a very peculiar way. But the philosophers who build such systems would say that they give every claim to knowledge its due and would confine the title "skeptic" to those who reject transcendent reality.

These speculative adventures inevitably produced reactions in the 19th century. Both pragmatists and positivists defended science and common sense against these dialectical attacks and professed themselves at least agnostic about transcendent reality. However, their defense of science was often associated with very reductive theories, similar to Berkeley's and Hume's, and this controversy provides yet another example of the perennial pattern of extreme contraction alternating with extreme expansion. Also agnosticism about transcendent reality is a difficult position to maintain because, if it is really true that ordinary judgments commit people to belief in transcendent reality, agnosticism about transcendent reality is strictly inconsistent with the claim to understand and accept ordinary judgments.

These two weaknesses in the empiricist reaction were not irremediable. The pragmatists investigated the meaning of scientific statements in a sympathetic way and claimed that they contained no contradictions and did not point to any transcendent reality. They also investigated the meaning of other kinds of empirical statements and tried to give a comprehensive criterion of meaningfulness. Their work was carried on by the logico-analytic school in the 20th century; and, though it sometimes produced reductive theories, this did not always happen. When it did happen, it was not because there is any good reason why theories about the meaning of empirical statements should be reductive, but rather because the logico-analytic school inherited the tradition of Berkeley and Hume and because in any case extreme reaction is natural.

G. E. Moore, Bertrand Russell and Ludwig Wittgenstein were the three most important philosophers of this school. Its attitude to speculative philosophy was critical rather than skeptical because when its members rejected speculative theses, it was on the ground not that they were false but that they were meaningless, or at least involved misuse of language. However, if the idealist attack on empirical statements is to be classified as a kind of skepticism, then it might be correct to call the logico-analytic philosophers skeptics because of their attack on speculative philosophy. For, though the objects of the two attacks were different, their methods, the detection of contradictions and the diagnosis of meaninglessness, were very similar. But, if the word "skeptic" is used pejoratively, it is important to remember that there is a certain presumption in favour of common sense. The logico-analytic school did not merely rest on this presumption: it tried to show that both the apparent contradictions in ordinary empirical statements and the apparent meaningfulness of speculative theses are the results of illusions; *cf.* particularly Moore's "Defence of Common Sense," in *Contemporary British Philosophy,* 2nd series (1925); and Russell's *Mysticism and Logic* (1918).

Two different tendencies can be detected in the writers of this school. Some of its adherents tried to give a single criterion of meaningfulness which would cover all ordinary statements and exclude those of speculative philosophers. In this way they hoped to evade the difficulty which Kant had failed to evade, the difficulty of limiting knowledge without implying some awareness of what lies beyond the limit. For if statements about what lies beyond the limit could be shown to be meaningless, the inconsistency would be avoided. This systematic attempt to delimit the sphere of meaning was made in Wittgenstein's *Tractatus Logico-Philosophicus* (1921), which was closely related to Russell's work in logic. Its weakness was that it set up scientific statements as the type to which all meaningful statements must conform. This places it in the tradition of the 19th-century pragmatists and positivists. In fact some of the philosophers who tried to work out these ideas of Wittgenstein in more detail called themselves logical positivists. The other tendency within the school was a reaction against any attempt to give a systematic account of meaning. Every type of ordinary statement should be examined separately and judged by its own standards. This tendency begins in the writings of G. E. Moore. It also appears in the later writings of Wittgenstein, who added the corollary that, if speculative philosophers are wrong in thinking thnt their statements mean something, this too should be established by a detailed examination of each individual case. This tendency, judged by ordinary standards, was obviously not skeptical. In fact it was a vindication of common sense in which many speculative philosophers would detect credulity.

There are many reasons why the diagnosis of philosophical skepticism will always be debatable. Greek skepticism had many facets, and outside the Greek school different philosophers show different combinations of these facets. However, when the word "skeptic" is used about the rejection of particular claims to knowledge on ordinary grounds the difficulties are less formidable. In such cases both the claimant and the rejector will usually be appealing to similar standards: they will differ in their application of these standards; and they may also differ about the force of the word "skeptic," whether it is pejorative, commendatory or neutral. These complications need to be unraveled, but the task of unraveling them is comparatively easy. But when philosophers question whole departments of knowledge, they are really questioning the standards which are ordinarily taken to be reliable within these departments. At the same time they frequently offer different, stricter standards and sometimes make strange new claims to knowledge of their own. This enormously widens the scope of the debate and makes it very hard to decide which philosophers are skeptics, which dogmatists and which merely critical. It might appear that this question could be safely settled only by a philosopher who adopted the standpoint of common sense. But even here the difficulties do not end. In fact the greatest difficulty of all is to understand the intricate relations between ordinary beliefs and philosophical doctrines. For few philosophers entirely abandon ordinary beliefs. Even those who do not analyze them sympathetically usually recast them and let them stand in an altered form. And there is no simple way of deciding when justice has been done.

For theological skepticism *see* AGNOSTICISM.

SKIBBEREEN, a market town of County Cork, Ire., on the Ilen about 3 mi. from its estuary, 53 mi. S.W. of Cork by road. Pop. (1956) 2,202. The river is navigable for small vessels to Skibbereen, and for larger ones to Old Court on the estuary. Trade is in corn and other agricultural produce and there is sea and river fishing. The district suffered much in the famine of 1847 and many were buried in the graveyard adjoining the ruined Cistercian cell of Abbeystrowry (1 mi. W.).

Skibbereen is the seat of the Roman Catholic bishopric of Ross, which comprises part of west County Cork. The procathedral was built in 1826.

SKIING, a way of moving over snow wearing a pair of long flat runners called skis attached to the shoes or boots. It is practiced for recreational, competitive or utilitarian purposes. On the level or on slight grades, the skier uses a gliding gait; downhill he slides effortlessly over the snow, turning to avoid obstacles, to slacken speed or to change direction; special steps are used in climbing steeper slopes. Ski jumping is usually performed on hills of varying size especially designed for the sport.

Skis were first used in northern countries for utilitarian purposes, in order to get from one place to another, for hunting and in warfare, and they are still so used. Recreational skiing was a natural outgrowth of such uses. In the Americas and in western Europe the sport developed chiefly as downhill skiing.

At first, only the mountain railways and aerial cable cars of the Alps were available for the uphill transportation of skiers. In the early 1930s, many new devices were designed and built for this purpose, including chair lifts, T-bar tramways, gondola lifts and in the United States and Canada rope tows, as well as many additional aerial tramways. These greatly promoted the popularity of skiing, for they made possible four or five times as much downhill skiing in a day as when the skier had to climb uphill. In the Scandinavian countries and eastern Europe touring and cross-country skiing developed as the more popular sports. Competitive skiing comprises the Nordic (or classic) events, cross-country racing and jumping; and the Alpine events, downhill (or straight) racing, slalom (zigzag downhill racing) and giant slalom (see *Competitive Skiing,* below).

EQUIPMENT

The Ski.—The three chief types of skis, downhill, jumping and cross-country, have certain characteristics in common. They are pointed, turned up and usually slightly wider at the front (the tips or shovel) and are squared at the rear (or heel). They are thickest in the mid-section, under the foot, thinnest just before the ends, and are built with a slight arch, or camber, so as to distribute the skier's weight along the length. Over the years skis have been refined in their shape and camber and in precision of stiffness. The design is graceful and functional.

The downhill ski normally varies in length according to the height and weight of the user. It is about three inches in width, and for the average adult man about seven feet long, although much shorter skis have enjoyed some vogue in Europe. They were formerly fashioned from one piece of wood, usually hickory, but later laminated constructions also were used. After 1950, plastic running surfaces were introduced to increase speed and durability and skis of metal, usually with a wood or plastic core, became increasingly popular. The downhill ski typically has a shallow groove running longitudinally along the centre of the bottom (or sole); this imparts directional stability. The skis also have sharp edges of steel along the undersurface, in order to bite into hard snow or ice.

Jumping skis are longer, wider, thicker and heavier and ordinarily have three grooves in the bottom. They have no steel edges.

Cross-country skis are narrower and lighter in weight than downhill skis and often are made of woods other than hickory. They have one groove but no metal edges.

Other Equipment.— For downhill skiing, the skier wears close-fitting, heavy leather boots with extremely stiff soles in order to exercise precise control over his skis. His boots are firmly attached to the skis by bindings which are made almost exclusively of metal, with steel cables supplanting the crude straps used in the 1930s. So-called safety or release bindings were developed to free the skier's foot in case of severe falls. For jumping, and especially for cross-country, a lighter and more flexible boot is used, with a special binding which allows the heel to be raised.

For downhill and cross-country skiing a light pole, or stick, of metal or wood, about four feet long, is carried in each hand. These aid the skier in pushing himself along on the level, and in climbing. They also are used in maintaining balance when running downhill and to assist in turning. Each stick has a wrist strap at the top and a ring, or wheel, near the bottom, which prevents the point from sinking too deeply into the snow. Various waxes are used on the bottoms of skis to prevent snow from sticking to them, to reduce friction or to aid in climbing. For the latter purpose, strips of sealskin or plush are sometimes strapped to the bottoms in order to grip the snow.

The refinements in ski equipment after World War II were accompanied by a great increase in the proficiency of the average recreational or competitive skier, so that he skis as well or better than the most skillful performers of a generation ago. As the parallel (slideslipping) technique supplanted the earlier stemmed (Christiana) turns, speed and maneuverability were greatly increased.

Appeal of Skiing.— The sensation of downhill skiing is similar to the sensation of flight. Its popular appeal is attested to by the rapid growth of the sport in all parts of the world where there is snow and hilly or mountainous country. This is true both of competitive and of recreational skiing. Two of the chief attractions of the sport are the fact that the snow conditions to be coped with are of infinite variety and constantly changing, and the fact that there is virtually no limit to the degree of skill that can be developed. In downhill skiing, skill consists largely in being able to run steadily at high speed and to turn with agility and precision on all kinds of snow and terrain, whether bumpy, steep or wooded.

HISTORY

The oldest ski that has been found, at Hoting in Sweden, is believed to be at least 4,500 years old. The oldest pictorial representation of skiing is a carving on a rock found at Roedoey, Tjoetta, in northern Norway, dating from about 2000 B.C., which is preserved in the Norwegian ski museum. However, some sort of skis or skilike snowshoes were probably used long before these times in regions where men found them useful in order to travel, hunt or carry on warfare in snow-covered country. Procopius, the Byzantine historian, mentions a race of "Skridfinns," that is, gliding Finns, in apparent contrast to the Finns who did not glide.

Military Skiing.— Skis were probably used for military purposes as early as they were used for ordinary travel. In 1199, Saxo, the Danish historian, described how the Finns waged war on skis, and in the following year, King Sverre sent out a company on skis to reconnoitre before the battle of Oslo. In World War I, when the Austrian-Italian front ran through the Alps, and during the Russian invasion of Finland in 1939–40, much use was made of ski-equipped mountain troops.

Development of Skiing as a Sport.— Although there is a record of a military ski competition in Oslo in 1767, the real beginnings of skiing as a competitive sport were in Norway 100 years later and in California about 1870. The famous Holmenkollen, Nor., jumping meeting began in 1892. In 1888 Fridtjof Nansen led a party across Greenland on skis, dragging sledges. His book, *Paa Ski Over Grönland,* exerted a great influence on the development of skiing throughout Europe. It was at this time the first skis were imported into the Alps and the Black Forest of Germany.

As the sport spread, both proficiency and equipment developed rapidly. Because the terrain in the Alps was steeper and more difficult, a new skiing technique was needed. The erect, Norwegian Telemark and Christiana style was gradually supplanted by an Alpine way of skiing downhill and turning. This found its first complete and practical expression in the Arlberg system developed by Hannes Schneider, of St. Anton, Aus. The Swiss ski schools carried on these methods. Since 1936, the leading ski racers of the Alpine countries have had a great influence on technique, culminating in the new official Austrian system of teaching the *wedeln* turns.

The principal architects of Alpine skiing were Mathias Zdarsky and Col. Bilgeri of Austria; Hans Klopfenstein and Col. Iselin of Switzerland; W. Paulcke and Henry Hoek of Germany; and Sir Arnold Lunn and Vivien Caulfeild of Great Britain.

COMPETITIVE SKIING

Downhill races are run on defined courses of a length, steepness and difficulty appropriate to the skill and endurance of the entrants. For men's Olympic and world's championship events, a vertical descent of at least 2,625 ft. is prescribed, with sufficient steep and difficult terrain. Such courses may be between one and one-half and three miles long, although some races are considerably longer. Average speed of the winners is usually between 40 and 50 m.p.h. In 1955 a speed of 109 m.p.h. was unofficially recorded on a short prepared course in Chile by Ralph Miller of the United States:

For a slalom race the course is defined by gates consisting of pairs of poles with flags, between which the runner must pass. The course is carefully set so as to test the skill and judgment of the competitor. For Olympic and world championship events the men's course must have a vertical drop between 650 and 975 ft. and for other international races between 390 and 650 ft. Sixty to seventy-five gates are usual, although up to 100 gates are sometimes included. For less skilled groups, courses are shorter and less difficult. The Arlberg-Kandahar race rotates between Mürren, Switz., St. Anton, Aus., Chamonix, France, Sestrière, Italy, and Garmisch-Partenkirchen, Ger., and is the oldest open international event decided on the results of a downhill and a slalom, having been first run in 1928.

The giant slalom has characteristics of both the downhill and the slalom. The gates are set wider and farther apart, the length of the course approaches that of the downhill and the average speeds achieved are between those of the two other Alpine events. Because of the persistent efforts of Sir Arnold Lunn, who devised the modern slalom race, the International Ski federation recognized downhill racing in 1930, and the first downhill and slalom world's championships were held in Miirren in 1931.

The best Alpine competitors have come from Austria and the other western European countries. American women have won several world championships.

Cross-country races (also called Langlauf and *Dauerlauf*) are held over rolling terrain. The standard distances are 15, 30 and 50 km. for men, and 10 km. for women, although the Vasa race in Sweden is 56 mi. long. A variation of the cross-country race is the relay, in which four men each run a 10 km. course, or three women a 5 km. course.

Jumping competitions are held on carefully graded and prepared hills, classed according to size as 100-m., 80-m., 70-m., etc. The approach, or inrun, often starts on a scaffold, or tower; down it the jumper in a crouched position accumulates speed until he reaches the take-off, where he leaps outward, upward and forward. The best competitors lean far over toward the points of their skis in order to minimize wind resistance and to get an aerodynamic lifting effect to increase the length of their jump. The landing is made on the steep landing hill in a more upright position with the shock of contact taken up by the knees. After the slope levels off, the jumper stops by turning on the outrun. The performance is decided half by the distance covered and half on form, as marked by the judges, on the basis of a complicated set of style marks.

The best jumpers and cross-country runners have come from the Scandinavian countries, Finland and eastern Europe.

A combination of the results of the downhill and slalom is called the Alpine combined event, and the jump and cross-country together are called the Nordic combined. Skijoring, in which the skier is pulled by a horse, is little practiced.

ORGANIZATION OF THE SPORT

The International Ski federation (FIS) was founded, and the first winter Olympic games were held in Chamonix, in 1924, but with Nordic ski events only. The Alpine events were included for the first time in 1936, in Germany.

The first ski club in the United States was the Ishpeming (Mich.) Ski club, founded in 1900. The Ski club of Great Britain began three years later. The first intercollegiate ski meet, between McGill, Dartmouth and Montreal, was held in Quebec, at Shawbridge, in 1914.

The basic skiing organization is the local club, which is composed of individuals. In the United States, most clubs are members of one of the seven regional associations (or divisions) which compose the National Ski Association of America. The latter, along with the national associations of the 35 other skiing nations throughout the world, compose the FIS, which sets the rules for and sanctions international competitions in all forms of the sport, and engages in other co-ordinating activities.

SKI-MOUNTAINEERING

Skis have been used in winter mountaineering since the 1890s. The first important expedition was the incomplete traverse of the main massif of the Bernese Oberland by a German party, including W. Paulcke. Two of this party were killed two years later in an avalanche, the first fatal accident on skis. Most of the great ski-mountaineering successes of the following ten years, Monte Rosa, Mont Blanc, Matterhorn and Finsteraarhorn were scored by Germans, but the Swiss soon took an active part, as did the British, Italians and French. See WINTER SPORTS; OLYMPIC GAMES.

SKIMMER, an aquatic bird of the family Rynchopidae, unique in having a bill with the lower mandible much longer than the upper and compressed to knifelike thinness. The birds fly low over the water, the mandible just immersed, as though skimming the surface, whence the name. However, it is debatable whether most of their food is secured in this manner.

There are three species: the black skimmer. Rynchops nigra, of the Americas; R. *flavirostris* of Africa; and R. *albicollis* of India. They frequent coastal waters and large rivers, and their other habits resemble those of their close relatives, the terns (*q.v.*). (A. L. RD.)

SKIN, the covering (or integument) of an animal, as distinguished from the internal parts. In animals with backbones (vertebrates) skin is complex in structure and is a vital organ in that some of its functions are essential for the maintenance of life. In all vertebrates the skin consists of two major layers. The richly cellular. relatively thin outer layer. deriving from the embryonic ectoderm, is called the epidermis; the thicker and tougher inner part, of mesodermal origin, which is largely composed of fibrous connective tissue, is called the dermis, cutis or corium.

Skin in Lower Vertebrates. — Before considering in detail the skin of man. the integuments of various classes of vertebrates will be briefly surveyed in the order of their position on the evolutionary scale.

Cyclostomes.—In the lamprey the surface of the skin is smooth, with no scales. Gland cells producing slime are mixed with the epithelial cells, as in most aquatic vertebrates.

Elasmobranchs.—Among the elasmobranchs, sharks have a very tough skin. Over it are scattered denticles or placoid scales, each with a pulp cavity, around the edge of which is a layer of odontoblasts. These cells secrete the dentine or calcareous material of the scale Outside the dentine is the enamel secreted by the overlying ectoderm. Usually the denticles pierce through the ectoderm, after which no more enamel can be added.

Fishes. — The dominant fishes of the modern era are teleosts, characterized by scales, which are internal structures in that they are covered by skin. The epithelium of a trout's epidermis provides the animal with an inert covering of keratin. The scales lie in the dermis as thin, overlapping. bony plates with the exposed part bearing the pigment cells. The bone of the scale is deposited in a series of rings, since its growth is not constant but occurs rapidly in spring and summer and hardly at all in winter; the age of the fish can be determined from these rings.

Amphibia.—All existing amphibia of the terrestrial vertebrates have skin that is moist and used for respiration. Its outer layers are cornified, a character typical of land vertebrates. In the adult frog the epidermis is renewed at intervals by a process of molting, which is under control of the pituitary and thyroid glands. The wartiness of the skin of toads is due to local thickenings that are of interest in considering the origin of feathers and hair. Both mucous and poison glands derived from the epidermis are present in the skin of amphibia. The secretion of the poison glands generally does not harm human skin; when swallowed it produces nausea and an action on the heart similar to that of digitalis.

Reptiles. — The skin of reptiles is dry and contains few or no glands. The outer division is horny or scaly and is shed in flakes; bony plates may be present in the dermis, especially over the head. Many reptiles have elaborate colour patterns, which may change from time to time, as in the chameleon, and thus serve for concealment.

Birds. — Birds are characterized by having feathers appended to a thin, loose, dry skin. The only gland is the oil-excreting uropygial or preen gland located at the base of the tail. It is especially well developed in aquatic birds. Feathers are the major keratinous structures. but scales like those of reptiles are present on the legs and feet and sometimes elsewhere. The bill and claws are also specialized scalelike structures and may be molted. Nerve endings are present throughout the skin. The feathers perform two main functions, heat insulation and flight; in addition, they provide sensation. protective coloration and sexual display. The same follicle produces many generations of feathers, which may differ in type as the bird matures. The feathers are provided with muscles at the base that control their position. important in flight and in heat loss, and with nerve fibres in the papilla that make them organs for the sensation of touch. They are not spread uniformly over the body but are localized in tracts separated by bare areas.

Mammals. — The presence of hair appended to the skin (even though the area may be extremely small) is a requisite for classification within the group. In addition to hairs, which include both the long tactile bristles or vibrissae and the smaller hairs more generally distributed over the body, horns, claws, hoofs, nails and glands may be found as skin appendages. The armadillo is the only living mammal that has a true bony exoskeleton.

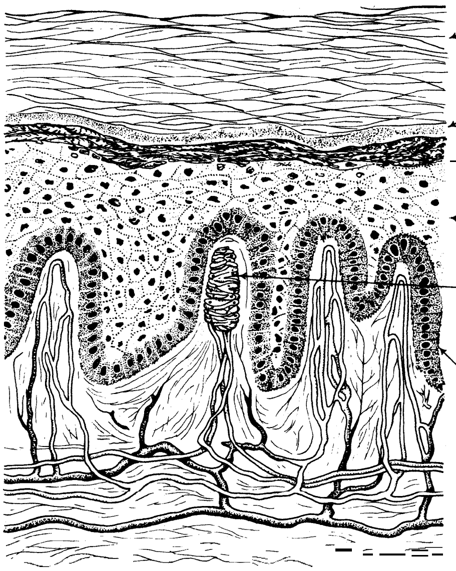

FIG 1 — VERTICALSECTION OF EPIDERMIS AND PAPILLAE OF CORIUM

Horns are of three kinds. The antlers found in members of the deer family are true bone with a covering of very vascular skin (velvet), which disappears soon after growth is completed The antlers are shed annually and are replaced rapidly. The small horns of giraffes are also bony structures though permanent The horns of ruminants are hollow cases of hardened epidermis that fit over a bony core and are permanent except in the pronghorn, which sheds its horns periodically The horns of the rhinoceros are a mass of hairlike horny fibres, which grow from dermal papillae and are cemented together by cells. Claws and nails are found in the dorsal aspect of the distal phalanges of the digits, whereas hoofs extend across the end and reach the plantar surface as well; all three represent specially thickened parts of the epidermis.

Skin in Man. — The skin of man, from the surface to the point where the dermis merges with the usually adipose subcutaneous tissue layers varies in thickness from less than one millimetre on the eyelids to three millimetres or more on the interscapular area palms and soles It is elastic and presents a smooth, soft, pliable surface broken by intersecting lines, folds, ridges and tiny pores The more or less parallel, closely set, fine ridge patterns of palmar and plantar skin are characteristic for each individual and form the basis for the widely used fingerprint system of personal identification

Epidermis — The average thickness of the epidermis is only about 0 1 mm, although on the palms and soles, or where subjected to rubbing or pressure, it may be 10 to 15 times thicker, largely because of the greater thickness of its outermost, cornified layers The epidermis can be differentiated into several distinct layers (see fig 1) The deepest layer, which rests on the dermis, is called the stratum gerrninativum (or basal-cell layer) and consists of a single layer of columnar epithelial cells arranged in regular palisade fashion Interspersed betueen and slightly below the cells of this layer, along the junction betueen it and the dermis, is a network of melanin pigment-forming cells (melanocytes) having many slender, branchlike, cytoplasmic extensions; these extensions communicate with one another as well as extend between the cells of the deeper portions of the epidermis, to which they can transfer melanin pigment. There are about 1,000 to 3,000 melanocytes in each square millimetre of skin.

The layer above the basal cell layer is called the stratum mucosum, spinosum or prickle-cell layer. This layer is several cells thick; its cells have irregular polyhedral shapes, and they appear to be connected with one another by numerous microscopic intercellular bridges, spines or prickles. In the next layer, the stratum granulosum, which is from two to four cells thick, the cells become flattened and diamond shaped, and a granular material, keratohyalin. appears in their cytoplasm. The next layer, the stratum lucidum, is not always apparent. Where well developed it appears as a clear, homogeneous line in microscopic cross-sectional preparations. It contains a lipid-resembling substance called eleidin. The major barrier against the passage of water and salts through the skin lies at the level of the stratum lucidum. The most superficial layer. the stratum corneum. consists usually of 10 to 20 layers of very flat, dead, dry, keratinized cells, which adhere to one another tightly except nearest the surface, where they are continually shed as microscopic flakes

Cell division in the epidermis takes place in the basal cell layer and in the lover layers of the prickle-cell layer. As a result of such proliferation, cells are continuously pushed toward the surface, and as they move outward in this fashion they undergo a sequence of changes in which they die and their proteins become transformed into the tough, chemically inert, fibrous protein called keratin There are no blood vessels in the epidermis, which therefore has to receive its nutrition from tissue fluids that diffuse through the spaces between the intercellular spines of the stratum mucosum.

Dermis — The dermis, or coriurn, has an outer thin, relatively loose, papillary layer adjoining the epidermis and an inner thick, dense, reticular layer that blends into the subcutaneous connective tissue Papillae of the outer layer (from about 40 to 140 per square millimetre. depending on the region) are tiny. fingerlike processes that fit into sheathlike sockets in the overlying epidermis. The papillae carry capillary vascular loops and also may contain specialized sensory nerve endings A thin layer of mucoprotein cement substance lies at the junction between the corium and the epidermis.

Most of the structural material of the corium consists of the fibrous proteins collagen and elastin. When suitably treated by a process called tanning, these tough, elastic, fibrous materials as found in the coriurn of animal skins make commercial leather. Boiling of collagen fibres partially hydrolyzes them to give rise to gelatin Electron microscopic examination of collagen fibres reveals them to be composed of bundles of very fine fibrils showing a characteristic regular pattern of cross striations The fibrous components of the coriurn are imbedded in a complex matrix of ground substance consisting of mucopolysaccharides as well as proteins, water and miscellaneous dissolved substances. This ground substance has important functions in regulating the diffusion of material through the coriurn

The fibres of the corium run in all directions, but predominantly in the plane of the body surface and parallel to the lines of tension and compression of the skin in ordinary movements. A round puncture wound becomes elliptical after withdrawal of the instrument, and a linear incision gapes more widely if it is transverse to the prevailing fibres The corium is well supplied mith blood vessels and nerves. Striated muscle extends into the dermis about the face and neck to permit facial movements such as those that give expression to emotions Smooth muscle is widely distributed in the coriurn in the form of thin bundles attached to hair follicles. Their contraction elevates hairs to a more erect position and produces "goose flesh."

Cutaneous Appendages. — The cutaneous appendages in man consist of pilosebaceous units, sweat glands and nails.

The nails are platelike, translucent, keratinous structures that grow over the ends of all digits from specialized, proximal epidermal matrices or nail roots; these extend to the distal edge of the lunula, a moon-shaped whiter area often visible at the base of the nail plate. Nails consist of densely compacted, highly cornified, dead epithelial cells containing only remnants of degenerated nuclei. The distal edges of the nails are free, and on the fingers serve to assist in the manipulation of small objects as well as for scratching. Six to seven months are required for a newly generated portion of nail to be pushed over the nail bed to reach the distal free edge.

Eccrine sweat glands occur throughout the skin of man in large numbers, although in many other mammals they occur only on the foot pads. Each eccrine sweat gland is an independent, slender, blind tubule about 20 μ in diameter and consists of two cell layers, an inner epithelial lining (either secretory or ductal in type) and an outer myoepithelial layer of more or less contractile cells. The secretory portion of the gland lies coiled in a ball-like structure in the lower dermis or upper subcutaneous tissue. From there the duct follows a slightly spiral course through the dermis and then a much more tightly spiral course through the epidermis and especially the stratum corneum to open in a tiny sweat pore. The total number of sweat glands in man is over 2,000,000, with an estimated total tubular length of about eight miles. These glands actively secrete sweat, a thin. watery fluid containing salts and other solutes found in blood plasma but in individual concentrations often much lower or higher than in plasma. For example, urea is about twice as concentrated in sweat as in plasma, while glucose occurs in sweat only in trace amounts.

Sweat secretion is subject to various controlling mechanisms, chief among which is the secretory innervation of these glands by nerve fibres of the sympathetic nervous system. Under extreme conditions of heat as much as eight litres of sweat may be produced per day by an adult man. The fluid and salts lost in this manner must steadily be replaced if the man is to survive. The chief function of sweat secretion in man is the regulation of body temperature by means of evaporative cooling. Sweat also helps maintain normal hydration of the outer layers of the skin, and on the palms its moisture enhances the grip. Sweating of the palms and soles is particularly influenced by nervous activity in higher brain centres and becomes profuse under conditions of mental or emotional tension.

Pilosebaceous units are found densely distributed in almost all parts of the skin (fig. 2). Each unit consists of a hair follicle with its hair and its appended sebaceous gland and erector muscle. In the axillae, perineal and pubic regions, and about the nipples, apocrine sweat glands are also appended to the pilosebaceous units. These glands, which open into the pilosebaceous canal, have a complex, branched, tubular structure with lumina about ten times larger than those of eccrine sweat glands. Their mode of secretion also differs from that of eccrine glands in that part of the cytoplasm of the secretory cells is pushed off in the process (decapitation secretion). Apocrine secretion is an opalescent fluid that under bacterial action gives rise to odorous substances partly responsible for unpleasant body odours.

Sebaceous glands are multilobulated structures 0.2 to 2 mm. in diameter with short ducts that open into the necks of the hair follicles. These glands excrete a highly complex mixture of lipids? called sebum, which diffuses upward in the follicle, impregnates the hair and surrounding horny layers of the skin to participate in forming the greasy skin surface film. This film helps maintain normal pliability of the skin by retarding loss of water from the horny layer, delays absorption of many foreign substances and contains substances that are protective against exogenous infections. In the process of sebum formation, germinative cells in the periphery of the gland proliferate, and as the maturing cells move toward the centre of the gland, discrete droplets of lipid progressively accumulate in their cytolasm. Finally, these cells burst and liberate the enclosed lipid material.

Hair, in man. has little functional value when compared with its role in fur-bearing animals. Nevertheless, human hair and hair growth have considerable cosmetic and general biological interest. Hair filaments are dead, thin, flexible, shafts of highly keratinized epithelial cells developing within slanting tubular invaginations of the epidermis—the hair follicles. The deepest portion of each follicle is enlarged to enclose a vascular papilla, projecting from the dermis into the bulb. The epithelium immediately above and around this papilla is the germinative matrix for the hair. There are great individual and regional variations in types and distribution of hair. On the scalp, where hair is usually densest and longest, the average total number of hairs is between 100,000 and 150,000. Hair is continually shed and renewed by the operation of alternating cycles of growth, rest, dedifferentiation and renewal of growth of the hair follicle and its associated structures. This cyclic activity is intrinsic in the individual pilosebaceous units. The average life of different varieties of hair varies from $4\frac{1}{2}$ months for downy hairs to three to five years for long scalp hairs. Caucasoid scalp hair grows approximately 1 cm. per month and reaches an average length of 60 to 75 cm.

***Skin* Functions.**—Human skin has primarily protective, sensory and body-temperature-regulating functions. Furthermore, vitamin D (the antirachitic vitamin) is produced in the epidermis when the skin is exposed to sunshine. There are also absorptive, secretory and excretory, and respiratory functions of the skin. The integument serves as a remarkably effective protective barrier against a wide range of potentially injurious chemical, physical and biological factors. Since it is nearly waterproof it enables the relatively fluid body to exist in dry air, to be immersed in fresh water without becoming swollen and in salt water without becoming shrunken. The keratinized layers of the skin, which are practically inert chemically and are poor conductors of heat and electricity, also serve, together with melanin pigment, as an effective screen against potentially harmful amounts of ultraviolet radiation. Body temperature regulation is achieved by virtue of the extensive vascular plexuses distributed in the skin and by the cooling effect of sweat evaporation from its surface. Sensory functions are carried out through a rich variety of nerve endings, which bring the primary sensory modalities of touch, heat, cold and pain into consciousness from discrete receptor points in the skin. Total body respiration, as well as excretion of metabolic wastes, is aided by the skin only slightly. Most substances are very poorly absorbed through intact skin except in the gaseous state. Materials readily soluble in both lipid and water are generally better absorbed than those soluble in only one or the other.

(A. L. Lz.)

SKIN, SENSORY FUNCTIONS OF. Sensory nerve impulses from the skin are employed either in keeping the "mind" informed of the relationship between the body and its immediate surroundings, or in the control of mechanisms for counteracting the effect of changes in the physical conditions within or at the surface of the skin. The sensory functions of the skin are not concerned solely with conscious experience related to common sensation; *i.e.,* touch, warmth, cold and pain sensibility.

This complex role can be demonstrated in many ways; for instance, if a beam of invisible (infrared) heat energy is transferred to the skin at a suitable rate, a report of warmth is evoked; the temperature of the skin surface starts to rise, at first rapidly, then more slowly until a steady state is reached, despite the fact that heat is still being transferred to it at virtually the same rate. The new state of equilibrium is brought about by reflex action. The sensory impulses evoke a discharge of motor impulses which result in a local increase in the blood flow, thus enabling the heat to be removed as fast as it is received. As soon as the surface temperature of the skin stops rising, the sensation of warmth is no longer perceived despite the fact that the skin is still being irradiated.

By contrast, if the experiment is repeated, using a much greater rate of heat transfer, the subject will almost instantaneously withdraw from the path of the beam and a report of pain will be made even though the actual rise in temperature of the skin surface has not been particularly large.

These observations make it clear, among other things, that the conscious experience evoked by stimulation of the skin is conditional both upon the physical characteristics of the stimulus and upon the conditions prevailing within the skin itself at the time of stimulation. In other words, in respect of heat transfer, the skin does not behave like a thermometer, for the number of impulses reaching the central nervous system from the skin does not merely reflect alterations in the physical state of the environment but also depends upon the changes brought about in the skin itself.

Further, even if the nerve impulses reaching the central nervous system from the skin do not vary, the conscious experience evoked depends upon the precise conditions prevailing in the central nervous system at the time of stimulation. Stimuli which consistently evoke reports of pain in a subject at rest may fail to reach consciousness when the same person is absorbed in a game of chess.

Although the sensory functions of the skin are not limited to arousing conscious experiences, these are of the more immediate interest, primarily because of their well-known relationship to disease and also because more is known about them than about most of the other sensory functions of the skin.

Physical Background of Common Sensibility.—It was formerly believed that the skin contained a mosaic of discrete nerve tertninations divided into four species, each of which was specialized structurally and functionally to serve one of the primary modalities of common sensation (*i.e.,* touch, warmth, cold and pain).

This concept probably arose directly from the necessary codification of common experience into convenient abstract terms. Moreover, it proved to be a useful working hypothesis, for it led to the recognition that impulses which evoke pain travel up to the brain in a different part of the spinal cord from those transmitting detailed tactile information. More critical and refined work, however, has yielded observations which cannot be reconciled with the data upon which this hypothesis was erected.

Anatomy of the Cutaneous Nerve Terminals.—The greater part of the human body in both sexes is covered with hairy skin, although the hairs in certain zones are so fine that they cannot be seen without the aid of a lens. Indeed. the only zones where hairs are entirely absent are the palms of the hands, the soles of the feet and certain exposed mucous membranes, such as those of the lips, the anus and parts of the external genital organs. In hairy skin there are only two kinds of nerve termination: (1) compact basketlike networks surrounding the necks of the follicles through which the hair shafts pass and (2) diffuse arborizations of fine filaments which intermingle extensively with one another and end freely and at random among the various tissue elements in the skin. In hairless zones, compact nerve entanglements of diverse shapes and sizes, often enclosed within cellular capsules, take the place of the basketlike networks around the hairs, but it is not possible to classify them taxonomically into sharply demarcated groups.

These observations strike at the roots of the hypothesis upon which the mechanism of cutaneous sensibility was originally erected. For it is clear that over the greater part of the body there are only two types of nerve terminal to subserve four sensory modes. Further, since it is unlikely that the stimulation of hairs arouses in conscious experience sensations unrelated to touch, the diffuse arborizations (which incidentally are impossible to distinguish from one another on anatomical grounds) must be related, among other things, to the conscious experiences reported as warmth. cold and pain.

Pattern of Innervation of the Skin.—It has been demonstrated that individual nerve terminals do not have private lines of communication passing directly to the central nervous system. On the contrary, each parent nerve subserves many terminals which are evenly scattered over a relatively large area by means of a mazelike network of nerve fibre bundles in the skin itself. Indeed, the arrangements are such that random destruction of up to one-quarter of the parent nerve fibres in a sensory nerve trunk (a bundle into which parent nerves are gathered as they pass between the skin and the spinal cord) results in degeneration of a small proportion of nerve terminals evenly scattered throughout the area of skin subserved by the whole trunk. Moreover. the subject is usually quite unaware of any alteration in the sensory capacity of the skin involved; certainly none can be detected by the use of such test objects as needles and wisps of cotton wool.

Although little quantitative information concerning the pattern of innervation of human skin had been obtained by the late 1950s, the innervation of the hairs in the skin of the rabbit ear had been analyzed in some detail, and comparative studies leave no doubt that hairs are innervated on the same principle in man. Briefly, there are around 100.000 hairs in the rabbit ear but no more than 5,000 nerves to innervate them. Yet even the smallest hair is supplied by at least 2 parent nerves, "guard hairs" by as many as 20, an average hair by 6. Each parent nerve supplies on the average 120 hairs sparsely scattered over relatively large areas, in some cases extending over as much as one-half of the ear. It has also been found that an individual hair is subserved by parent nerve fibres of slightly different thickness which conduct impulses at different speeds so that they reach the spinal cord at different times. In addition to this, the hairs themselves are so grouped that it is virtually impossible to stimulate a single hair in isolation, unless it be a large guard hair (which is subserved by many parent axons, by any form of naturally occurring stimulus. Thus, any significant stimulus must result in a highly complex spatiotemporal pattern of impulses reaching the cord. The sensory experience evoked must therefore be the result of the integration of this pattern of impulses with other incoming patterns, the transfer of the new pattern which emerges to higher centres where further integration probably takes place, and the final transfer of resulting activity to circuits responsible for perception.

In the case of the rabbit, it has been calculated that these peripheral arrangements require fewer parent nerve fibres to carry an equivalent amount of information as compared with the system envisaged in the original hypothesis, which assumed that each terminal in the skin had a private line of communication with the central nervous system. A corollary of this is the negligible effect on sensory acuity caused by destruction of up to one-quarter of the parent fibres in any part of a sensory nerve trunk passing between the skin and the spinal cord. Focal disturbances of sensation within the area supplied are not encountered.

Density of Innervation.—This varies considerably from place to place over the body surface. The skin of the back of the trunk for example, is not subserved by so many parent nerve fibres as the skin covering the face and the extremities, particularly that covering the palms of the hands and soles of the feet. On the other hand, the nerve terminals which end freely within such sparsely innervated areas of skin are almost as numerous as (though they are finer than) those in more densely innervated zones.

Skin which is supplied by a large number of parent nerve fibres is generally capable of resolving fine details in the configuration of the environment. For instance, the skin covering the finger pads, as is well known, can be used by blind people for reading by the Braille system. Pain evoked from lavishly innervated areas, such as the face, is always reported as being more intense, and it certainly is more prone to cause fainting than that evoked by the same stimulus from less densely innervated areas of skin.

The effect of stimulation on conscious experience is not, however, always directly proportional to the density of innervation of the area concerned. The foreskin and mucous membranes of the glans penis and clitoris are among the most lavishly innervated surfaces of the body, in terms of both parent nerves and the density and size of their terminal ramifications. Yet these regions are virtually "silent" as compared with those covering the trunk when the same stimulus is used. Moreover, the sensation evoked is peculiarly uninformative, both as regards the position and clarity of image which is perceived. Despite this apparent insensitivity, it is known that a large outburst of activity follows stimulation of the monkey's glans penis with a wisp of cotton wool even when the animal is fully anesthetized. Division of cutaneous nerve fibres in this region (*i.e.*, circumcision) evokes pain of greater intensity than that which follows an incision of comparable length through skin covering the body elsewhere.

From this it can only be concluded that the nature of the conscious perception evoked by naturally occurring stimuli (short of severe injury) in these zones is not dependent upon the sensory impulses evoked but solely upon the state of the nerve cells upon which they project; these may be either in the spinal cord or elsewhere. Experience suggests that it is such as to prevent the majority of impulses reaching the level of consciousness except upon specific occasions. This arrangement is in contrast to that obtaining elsewhere, for preoccupation of the mind usually results in preventing sensory impulses from reaching consciousness, not in raising them to a higher level of consciousness.

Specificity of **Nerve** Terminations in the Skin.—It is accepted that the nerve terminals related to hairs and compact nerve terminals help to keep the "mind" informed of the relationship between the body and its immediate surroundings. It is, then, of more than passing interest to find that such endings, as well as the spinal tracts associated with them, are absent in aquatic animals whose watery environment is relatively homogenous and where such information is presumably less necessary to survival. It is not known whether hairs can be stimulated in such a way that nerve impulses specifically related to the terminals evoke reports of pain. Pulling on a hair is usually considered to involve diffuse nerve endings, for vibratory impulses are invariably ineffective in this respect. However, in certain pathological conditions in which the pattern of the discharge from hairs in a given area is disturbed, the sensations evoked by their stimulation are referred to as "unpleasant" and at times "painful," but the subject always adds that sensations are not of the kind he experiences in everyday life and he is unable to describe them adequately. In this connection, it is perhaps significant that tactile stimulation in man under local anesthesia of the spinal pathways conducting the impulses from hairs (and other proprioceptive organs; *i.e.*, impulses from deeper structures) gives rise to a report of intolerable pain.

More is known concerning the specificity of diffuse nerve endings, although the evidence concerning their precise function in human skin is indirect. Clearly, it is possible that, despite their lack of anatomical differentiation, close interrelationship and complex patterned arrangement, they may be highly specific from a functional point of view.

Unfortunately, there is no known area of skin subserved solely by nerves which end diffusely. They are invariably accompanied by nerves which form compact terminals of one kind or another, which may affect the sensory experience they evoke. On the other hand, the transparent covering of the eye, the cornea, does contain only diffuse nerve endings. It is true that it is structurally unlike skin, but it is highly significant that when it is suitably stimulated, reports in each of the four primary modalities are invariably evoked. Fortunately, the microscopic anatomy of the cornea varies little from animal to animal, including man. Moreover, it is a relatively uncomplicated tissue in that it contains neither blood vessels nor nerves having other than sensory functions. Experimental observations in the cat, then. are likely to reflect conditions in man; and in the cat it has been shown that one and the same nerve ending discharges impulses along its parent nerve when the cornea is stimulated by objects which in man evoke reports related to each of the four sensory modes. The amount of activity evoked by a particular stimulus varies from ending to ending. Moreover, different stimuli evoke different patterns of activity from the same ending. For instance, light touch evokes a short, high-frequency outburst in the case of all active terminals. Injury (pain) evokes a prolonged outburst, the frequency of which depends upon the degree of damage which has been inflicted. Thermal stimuli usually evoke a discharge with a sharp rise and fall in frequency. In the case of some terminals, the activity evoked by warmth is far greater than that evoked by an equivalent amount of cold and vice versa; in the case of others, the responses evoked by either warmth or cold stimuli are indistinguishable. More rarely, while tactile and injurious stimuli evoke activity from the terminal, thermal stimuli are ineffective. These observations strongly suggest that stimuli having different physical characteristics evoke different patterns of activity from nerve endings, the specificity being due to their varied environmental conditions. Certain activity patterns which are intimately concerned with the preservation of the organism from environmental hazards are recognized and made linguistically explicit for the purposes of collective security.

Conclusions.—The anatomical configuration and environmental arrangement of the cutaneous nerves and their terminals are such that it is probable that the great majority of stimuli encountered in everyday life evoke a unique space-time pattern of activity which is projected onto the central nervous system. Here the impulse pattern is first integrated with other incoming impulse patterns. The resulting pattern either increases, decreases or has no effect on the excitatory state of the neurons to which these impulses project. The result is usually to set up yet another impulse pattern, which is projected to yet another set of sensory cells where further reanalysis ensues until at last the impulses are perceived as a sensation localized in the skin. The pattern on its way to the brain may become dissipated or transformed at each relay station, the degree of transformation depending upon the excitatory state of the station and the number of sensory impulses which converge upon it at a given time. There are no groups of specially modified terminals in the skin reporting by private lines the local state in respect of four clear-cut modalities. On the contrary, the amount of information available from the periphery is far more complex and varied. The particular information which dictates activity can be divided into four sensory modalities, but this selection is made in the central nervous system as the result of learning. As everyone knows, pain is not a single entity, but acts as a warning signal. It has innumerable forms, many of which can be used in the diagnosis of specific disease processes. Pain ordinarily follows when an unusually large and prolonged series of impulses from the skin or sensory relay station converge onto the circuits responsible for conscious experience. Warmth and cold can be regarded as preliminary warnings, informing the organism of impending danger. Touch evoked from diffuse endings, such as that produced by an insect crawling over the skin, can also be regarded as a warning signal which puts the organism in an alert state against a possible bite.

The skin innervation in lower vertebrates (teleost fish) and in Amphioxus exhibits a pattern resembling that in the cornea of most vertebrates and in human skin. Moreover, the sensory functions of the skin in these animals appear analogous; the integument of Amphioxus can transmit centrally a variety of stimuli resulting from changes in its environment, which alert the animal and enable it to evade injury. *See* also NERVE; NERVE CONDUCTION; NERVOUS SYSTEM; SENSATION. (A. G. M. W.)

SKIN DISEASES. The human skin is subject to a large number of diseases, some of them inconsequential, others chronic and productive of prolonged partial or total disability, and others associated with internal medical diseases of varying seriousness. At mid-20th century, much less basic research had been done on the skin than on other organs of the body such as the liver, kidney, gastrointestinal tract, etc. Although the cause of some skin conditions was definitely known and the treatment reasonably precise and effective, there remained a large number for which no cause had definitely been established and for which the treatment was empiric and relatively unsatisfactory.

The skin is a highly complex organ, with accessory glands of various types. It is the largest organ of the body. The functions which the normal skin carries out admirably may be summarized as follows:

(1) It regulates body temperature through convection of heat and the evaporation of sweat. In persons with decreased or absent functioning of a large proportion of sweat glands, marked intolerance to a warm environment may be noted, and this is the commonest cause of acute heat prostration or a more chronic disabling condition known as tropical asthaenia.

(2) It protects the body from many harmful external agents in various ways. The complex nerve structure in the skin warns promptly of excessive heat or cold, and of mechanical injury. In persons in whom this nerve mechanism is disturbed, marked injury to the skin may be produced before the individual is aware of it. This occurs in some forms of leprosy, and in certain other conditions in which structural damage to nerve endings or nerve trunks has occurred. The normal skin has a remarkably effective method of protecting itself against prolonged exposure to sunlight in the form of a precise mechanism to lay down melanin pigment, which produces tanning. In some persons with deficient capacity to produce pigment in the skin, such as those with very blond or redhead complexions, this deficiency may lead to repeated severe sunburn, and eventually to more permanent changes such as warty keratoses and skin cancer. The skin, through its corneous upper layer, normally has a remarkable ability to withstand the effects of chemical agents, both acids and alkalis. In the normal human skin there is a tendency to build up an increased thickness of horny tissue rapidly in response to repeated mild to moderate injury. The most common example of this is an ordinary callus.

The intact healthy skin also possesses a remarkable resistance to bacteria. The number of bacteria normally on the skin surface is large; by scrubbing the hands and forearms for 15 minutes with soap and water, anywhere from 1,000,000 to 20,000,000 or more bacteria may be removed. These bacteria are ordinarily not capable of producing disease, and are known as the normal resident flora. If the skin is subjected to prolonged harmful influences, such as excessive moisture, or chronic dermatitis or eczema, or an injury, marked decrease in the self-disinfecting property of the skin may occur.

(3) Another essential function of the skin is the maintenance of an adequate amount of lipoid or fatty substances on its surface, and within the structure of the skin itself. An oily film is maintained by the sebaceous glands. The complex nature of the fatty substances and waxes within the skin itself is poorly understood, but deficiencies rapidly become apparent in dryness and cracking of the skin, particularly during cold weather, and a decreased resistance to chemical substances such as soap. This disturbance of lipoids within the skin is frequently congenital, and becomes more severe in old age. In the skins of some individuals, there is an excessive secretion of oil from the sebaceous gland, and this leads to acne and to an increased tendency to superficial infection.

Diseases of the skin, and also marked general disturbances, may be produced by excessive sweating. Sweating is produced mainly by two types of stimuli, a warm environment or nervous tension. In excessive sweating caused by heat, provided there is opportunity for the sweat to evaporate, no damage ordinarily results. However, if evaporation is prevented, and the surface of the skin is kept wet for long periods of time, resistance to infection by bacteria and by fungi is greatly reduced. If sweating is prolonged, a large amount of salt may be lost, and it is necessary for the individual to take increased amounts of salt by mouth. Sweating caused by nervous tension occurs principally on the hands and feet rather than on the body, and is a common source of itching and of various chronic eruptions in these areas. In prickly heat, there is an obstruction to the free flow of sweat onto the surface of the skin, and the sweat excreted piles up within the tissues. This may produce marked itching and inflammation. Although prickly heat had been recognized as a common disease of the skin for centuries, it was only during World War II that it was discovered that prickly heat was due to a blockage of the sweat ducts, either because of some preceding disease of the skin or a mild injury such as that produced by the application of adhesive tape.

The skin possesses a marked resistance to absorption of chemicals. Such absorption as does occur is principally through the hair follicles and the sebaceous glands. This is the reason that common eruptions such as poison ivy dermatitis rarely appear on the palms of the hands, where there are no hairs.

Definite figures on the comparative incidence of various skin diseases were difficult to obtain prior to World War II. However, the carefully compiled medical records of enormous numbers of patients in the armed forces showed that skin diseases were a very significant source of disability. In statistics from various U.S. and British military hospitals throughout the world, patients admitted because of a disease affecting the skin accounted for from 4% to 20% of the total number of patients. The varying percentages were dependent on several factors. A tropical climate increases the incidence of skin diseases greatly; these are not usually exotic tropical infections, as commonly supposed, but severe forms of common skin conditions such as dermatitis, eczema, prickly heat and fungus or bacterial infections. Diphtheria infections of the skin, rarely seen in temperate climates, become a significant problem in tropical areas. Parasitic infestations such as scabies, which was widely prevalent in England and on the continent during World War II, produced much disability. From the southwest Pacific area, the number of U.S. soldiers returned to the United States because of skin diseases frequently exceeded all other classifications with the exception of neuropsychiatric disorders, and throughout the war were in excess of soldiers returned home because of battle injuries.

Diseases of the skin may be classified in several ways. There are those which arise solely within the skin and remain confined to it, such as superficial fungus infections. In other diseases, particularly bacterial infections, actual spread of the infection or absorption of toxic agents may produce disease of internal organs. It has been shown, for instance, that superficial bacterial infections of infants and children may sometimes be the source of chronic kidney disturbances. Another large group of skin diseases is composed of those in which the skin changes are an expression of an internal medical disease of varying significance. This includes such contagious diseases as scarlet fever, measles and chicken pox, and more or less common serious infections such as tuberculosis of the skin, lupus erythematosus, early and late phases of syphilis, leprosy, various diseases of the blood-forming organs such as leukaemia, Rickettsial infections such as Rocky Mountain spotted fever and typhus, cutaneous manifestations of various types of internal cancer, deep fungus infections such as coccidioidomycosis (San Joaquin Valley fever), etc.

The most common diseases of the skin are the following:

Acne vulgaris.—This disease is so common during adolescence as to be almost a normal physiologic process (70%–80%). Coincident with the development of secondary sex characteristics during puberty, there occurs an increased activity of the sebaceous or oil glands of the skin. Some of these glands become plugged, with the formation of blackheads. The ends of these plugs of cheese-like sebaceous material become black through chemical changes, not because of dirt. The lesions, as might be expected, occur where sebaceous glands are present in the greatest numbers, on the face and upper portions of the trunk. In severe cases of acne, inflammatory lesions may resemble boils, and sometimes produce rather severe scarring. The primary disturbance, however, is not that of a bacterial infection, and treatment with antibacterial agents such as penicillin is usually not effective. While a tendency to acne ordinarily subsides within a year or two as the patient passes through adolescence, some patients have persistent recurrent lesions for many years. In addition to the progressive scarring which such lesions may produce, rather marked psychoneurotic changes may occur because of the young patient's continued concern about his or her pimply appearance, and the production of new scarred areas. While very mild acne does not require treatment, patients with repeated inflammatory lesions deserve understanding competent medical attention. Lotions and drying creams containing sulphur, resorcin and other agents are often quite effective Attention to the diet in regard to foods which seem to produce more acne lesions is essential. though it is important not to restrict the diet of growing children and young adults to the point where it may produce loss of weight and possible injury to general health. Although the basic changes in acne are known to be produced by normal changes in the endocrine glands, treatment with various endocrine substances is usually not effective. X-ray therapy is sometimes used, but should be employed only after other less drastic methods of treatment have failed, and under conservative expert direction of a physician trained and experienced in the treatment of skin diseases with X-rays.

Superficial Fungus Infections. — The two most common types of superficial fungus infections are ringworm of the scalp, occurring predominantly in children, and ringworm of the feet (athlete's foot) and groin (jock-strap itch) occurring principally in adults. Prior to World War II, ringworm of the scalp was seen almost entirely in larger metropolitan centres among children living under poor economic and hygienic conditions. In 1942–44 a marked increase in the number of cases was noted, and this seemed to reach a peak about 1949–50. The disease is apparently transmitted most frequently by barber's clippers, contaminated hats, combs and brushes. direct contact and the backs of theatre seats. Some children are apparently immune. Two types of infections are noted, those due to animal fungi, which may also be found in cats, dogs and other animals, and those due to human fungi. which apparently affect man only. The infection tends to get well spontaneously, but may persist for several months to two or three years or longer in the case of some fungi. The only certain method of treatment is to produce temporary loss of the infected hair by means of X-rays, but this method of treatment is tedious and difficult to carry out, and even under the most expert administration carries a slight risk of some permanent loss of hair. At mid-century, no entirely satisfactory method of local treatment had yet been developed.

Superficial fungus infections of the feet are very common, occurring in 60% to 80% of persons of college age. The disease is a penalty of civilization, and does not occur in races accustomed to going barefoot. The primary site of involvement is almost always between the toes, but spread to other areas may be noted, particularly in warm climates. The symptoms consist of itching and burning, and the appearance of small to large vesicles or blisters, with fissuring, denuded areas of skin and secondary bacterial infection. The diagnosis of a fungus infection of the feet should always be confirmed by laboratory studies. The organisms may be cultured, or may be demonstrated by a simple stain, the Hotchkiss-McManus method, which was first adapted for this purpose in 1950. Fungus infections of the feet are frequently confused with other conditions, such as reactions to various components of shoes, bacterial infection or excessive sweating. It is probably true that more harm than good results from many methods of treatment of fungus infections, because they are too strong, and produce increased irritation. There is no completely satisfactory method of treatment in the sense of killing off the responsible fungi without damaging the skin. Good foot hygiene is of the greatest importance, and this includes thorough removal of soap and drying of the skin after bathing, wearing of aerated shoes during warm weather, avoidance of the wearing of rubber-soled shoes in susceptible individuals and the regular use of a drying dusting powder. Foot baths for prevention are probably useless.

Bacterial Infections constitute another major type of skin diseases. These may occur suddenly and acutely on normal skin, as in impetigo, which is caused by staphylococci and streptococci. This infection is extremely contagious among infants, but not particularly contagious among adults. The availability from about 1935 of an increasing number of antibacterial substances such as sulfonamides, penicillin, etc., greatly increased the efficiency of treatment. Secondary bacterial infection of irritated skin, such as that resulting from fungus infections or from eczema, occurs quite frequently.

When the infection is principally around the hairs, folliculitis or boils may be noted, and such infections may be extremely chronic and recurrent, even with the most modern methods of treatment.

Dermatitis and Eczema. — A dermatitis is any type of inflammation of the skin not caused by an infectious agent, and may result from an extremely wide variety of substances. Eczema is, essentially, a chronic dermatitis, and in some types there may be a marked familial history of various allergic diseases such as eczema, asthma, hay fever, hives, etc. Dermatitis may commonly result from an external source, such as poison ivy. There are literally thousands of natural and synthetic chemicals which are capable of sensitizing the human skin. Dermatitis from numerous external contactants is a significant source of disability in industry. It is entirely possible for a person who has worked with a particular chemical for months to many years to become sensitive to it rather abruptly. In the treatment of dermatitis from external contacts, determination of the responsible substance or group of substances is essential. However, this may be extremely difficult at times. Other types of dermatitis or eczema result from substances which are circulating through the blood stream, and which produce inflammation of the lower layers and blood vessels of the skin. These may be substances which are inhaled, such as pollens or dust, or foods or drugs which are taken by mouth, or reactions to fungus or bacterial infections elsewhere on the body. In this group of more or less chronic eruptions, psychosomatic and emotional factors play an important role, and may perpetuate the itching and inflammation of the skin long after the original cause has been determined.

Parasitic Infestations. — A wide variety of insects regard the human animal as an attractive food or habitat. Biting insects such as mosquitoes, flies, chiggers and ticks produce local reactions in the skin varying from a small hive to a large blister. Some insects are capable of transmitting serious infections such as malaria, Rocky Mountain spotted fever and typhus. Various species of lice infect the scalp (pediculosis capitis), the groin (pediculosis pubis — crab lice) and the body (pediculosis corporis). Adequate hygiene and the availability of antiparasitic agents such as DDT have 'made lice infestations almost completely preventable. Infestation of the clothing, which occurred with great frequency among troops in R'0rld War I, was almost unknown in troops in World War II who were supplied with DDT powder.

Another common infestation is by the *Acarus scabiei*, which produces scabies. Under conditions which produce poor hygiene and crowding of the population. such as those encountered in the British Isles during the air raids of World War II, scabies may become epidemic. Transmission occurs principally by skin to skin contact, and not to any great extent through wearing apparel and bedding. The damage is chiefly produced by the female *Acarus*, which burrows along the upper layers of the skin in warm, protected areas of the body. She lays her eggs within the skin, and is capable of producing considerable inflammation and marked itching, the latter being noted particularly while the patient is in bed. If the infestation is undetected, marked secondary infection may occur from scratching. Treatment is highly effective if properly carried out, the principal useful compounds being sulphur and benzyl benzoate. A great rise in the incidence of scabies may be expected under conditions of war, and returning troops spread the infestation among the civilian population.

Virus Infections. — In addition to generalized infections caused by various viruses, certain virus infections may remain localized principally on the skin. These include warts, cold sores (herpes simplex), shingles (herpes zoster) and molluscum contagiosum. Warts are extremely common. They may vary in number from 1 to 100 or more on an individual. and can be spread from one part of the body to another. In moist areas, the lesions may be very large and exuberant in growth (venereal warts). When warts occur on the sole of the foot (plantar wart), considerable pain and disability may result. Warts may appear or disappear for no apparent reason. In children particularly, they may be successfully treated by psychotherapy (Pennsylvania-Dutch hexing). There is no chemical which specifically kills the virus of warts, and methods of removal such as application of cauterant compounds or the use of electrosurgical methods are employed. X-ray or radium therapy is sometimes used. but the effect is unpredictable and there is grave danger of late untoward changes if the method is used inexpertly or to excess.

Herpes simplex usually occurs about the mouth, but may be encountered on any other area of the body, sometimes recurrently in exactly the same place. Once the infection is acquired, the virus apparently remains in the skin indefinitely and may be reactivated by various factors such as a cold, excessive exposure to sunlight, some drugs and foods, menstrual periods and nervous or emotional tension. In infants, the initial infection with herpes simplex may be a serious disease, and adults with active cold sores should be careful not to transmit the infection to babies. There is no satisfactory treatment other than the application of soothing drying preparations.

Herpes zoster or shingles is caused by the same virus as that of chicken pox. The virus affects the skin and nerve structures. and may at times be accompanied or followed by severe neuralgic pain, especially in older patients, When the process involves nerves reaching the eye, severe visual damage may result. Molluscum contagiosum is a much less common virus infection resembling warts to some extent, and occurring principally in children.

Psoriasis. — This is a rather common and extremely persistent disease of the skin, with raised red areas having a characteristic silvery scale. The cause is completely unknown. Various types of treatment have temporary palliative effects. The best method of treatment is ordinary natural sunlight. The disease ordinarily is not accompanied by any change in general health, though arthritis may be noted in some patients.

Dandruff. — The term "dandruff," a mild form of seborrhoeic dermatitis, simply indicates a moderate to excessive increase in the scaling of the scalp. One type is seen in persons whose skins are generally dry, though the most common type is in persons whose skins tend to be oily, and who may have had some acne during adolescence. In children, ringworm infections of the scalp may be mistaken for ordinary dandruff in mild cases. A brief examination with a special lamp equipped with the Wood's glass is ordinarily adequate to determine whether or not ringworm is present. It is not generally believed that seborrhoeic dermatitis is directly responsible for loss of hair, though in some individuals it may seem to be contributory. The basic cause of dandruff is not well understood, and treatment is therefore largely empiric. At mid-20th century no infectious agent had been proved to be responsible.

Hives. — Urticaria or hives is a local and usually transitory oedema of the skin produced by the release of a substance resembling histamine. The simplest example of a hive is the reaction resulting from an ordinary mosquito bite. Extensive hives may result from the eating of some food to which the patient is allergically sensitive. Various drugs, including penicillin particularly, may give rise to extensive and persistent urticaria. In some patients with chronic urticaria, the cause may be exceedingly difficult to determine. Psychosomatic influences frequently play a role. The various antihistaminic drugs are useful for producing temporary disappearance of hives.

Pigmentation Disturbances. — The enzymatic mechanisms concerned in pigmentation of the skin are well understood, but the factors which produce disturbances of these mechanisms, with resultant increase or loss of pigmentation, are not well understood. Vitiligo is a fairly frequent disturbance, in which the skin loses its power to produce melanin pigment. The loss of pigment may affect only a small area, but patients are sometimes seen in whom almost all the skin is affected. In persons with dark skins, the cosmetic changes may be very marked. As a rule, there is no underlying disturbance of general health. Vitiligo produces some disability, however, because the affected skin does not tan in response to exposure to sunlight, and the vitiliginous areas sunburn very easily.

Skin Cancer. — Cancer of the skin is one type of cancer in which possible cure approaches 100% if the precancerous or cancerous condition of the skin is recognized early, and if adequate treatment is applied. This statement does not apply, however, to malignant moles or melanoma. Cancer of the skin may be divided into two main types, basal cell epitheliomas (rodent ulcer) and prickle or squamous cell epitheliomas. Basal cell epitheliomas are ordinarily slow growing, and do not spread by metastasis, that is, through the lymphatics or blood stream to other parts of the body. Basal cell epitheliomas commonly arise from some accessory structure of the skin, principally the hair follicles or sebaceous gland. They spread slowly by extension, and if the lesion is recognized when it is small, surgical removal by complete excision, or electrosurgical methods, or treatment with X-rays is ordinarily curative. Squamous or prickle cell carcinoma is a more malignant type of skin cancer which may spread to neighbouring lymph nodes and other structures quite rapidly. This type is usually preceded by a long-standing precancerous lesion, usually a senile keratosis. It is therefore important to recognize and remove such lesions before they have become truly malignant. Cancer of the lip is ordinarily of the squamous cell type, and occurs much more frequently in smokers than in nonsmokers. At the time of removal of any lesion of the skin which may be malignant, it is of extreme importance to determine the exact nature of the changes microscopically, by means of a biopsy. In some instances, a lesion which looks quite benign externally may be found to be of highly malignant character, and more radical removal or X-ray treatment may be necessary.

Certain chronic stimuli are known to promote degenerative changes in the skin which may result in cancer. By far the most important of these is excessive exposure to sunlight. This is well shown by the fact that cancer of the skin is much more common in areas where there is a high proportion of sunlight, and in individuals whose work keeps them in sunlight a great deal (farmers and sailors). Persons whose skins do not tan are far more susceptible to untoward late changes from excessive sunlight. While some exposure to natural sunlight is beneficial and healthful, persons who are addicted to baking and bronzing their skin excessively and repeatedly are inviting senile changes which may result in cancer. Another stimulus which may in later years result in cancer is overexposure to X-ray or to radium. If used expertly and conservatively, these agents are reasonably safe, but overexposure may lead to atrophic changes which frequently result in a highly malignant type of skin cancer. Some chemicals, such as pitch and tar, encountered in certain occupations, may result in an increased incidence in skin cancer.

SKIN DIVING is the most ancient diving technique and undoubtedly has been practised since the time man learned to swim. By strict definition, the term skin diving applies only to "natural" diving, that is, without the use of any underwater breathing apparatus. This method is employed by pearl and sponge divers in many parts of the world. After the end of World War II, the term skin diving came to include, in addition to natural diving, diving with self-contained underwater breathing apparatus (SCUBA). The basic difference between this type of equipment and conventional diving gear is that with the former there are no connections between the diver and the surface, the breathing gas being carried in tanks strapped to the diver's body. Thus, the self-contained (or "free") diver propelling himself by swimming gains a tremendous advantage in mobility over his counterpart dressed in the conventional suit and helmet who must walk upright much encumbered by his heavy equipment and connected with the surface by a lifeline and air hose. The traditionally outfitted diver, however, derives a degree of security from his unlimited supply of air and more protective suit that for certain missions may more than outweigh the great advantage in mobility he must concede the free diver.

Both types of equipment have a distinct place in diving. The major factors governing the choice of apparatus are depth and duration of the dive and the degree of mobility required. Deep dives of long duration nearly always dictate the use of the suit and helmet. If mobility is an important consideration, however, and especially if the terrain is rough or obstructed. the use of self-contained equipment may be indicated. While SCUBA generally is inadvisable for dives deeper than 130 ft., useful work has been accomplished at much greater depths, and several descents to more than 300 ft. have been made by free divers.

Self-contained equipment falls into two categories: open-circuit and closed-circuit. While both systems were developed before 1880, they were refined for military applications during World War II. Thereafter they gained widespread acceptance by both professionals and amateurs. The first popular open-circuit SCCBA was developed in 1943 by J. Y. Cousteau and E. Gagnan. It was called the "Aqua-Lung," a trade name that often has been applied erroneously to all SCUBA. Open-circuit units consist essentially of two parts: an air reservoir made up of from one to three cylinders charged with the breathing mixture (usually compressed air) to a pressure of from 150 to 200 atm., and a demand regulator which feeds air through a hose and mouthpiece to the diver at ambient pressure when he inhales. Some regulators incorporate a second hose which returns the exhaled gas to the regulator where it is discharged directly into the water through a one-way valve. others exhaust through a similar valve at the side of the mouthpiece. All these systems release gas into the water upon exhalation. causing an intermittent discharge of bubbles.

The closed-circuit SCUBA (also called oxygen rebreathers or regenerative systems) releases no bubbles into the water except during ascent, and, therefore, in spite of certain severe limitations, has found extensive military use where the consideration of stealth is paramount. These units consist essentially of three parts: (1) a relatively small steel cylinder charged with the breathing gas (usually pure oxygen) to a pressure of from 150 to zoo atm.; (2) a cannister of soda lime or other carbon dioxide absorbent into which exhaled gas passes for removal of carbon dioxide; and (3) a breathing bag which acts as a reservoir for oxygen at ambient pressure between the cylinder and inhaling hose. Closed-circuit systems using pure oxygen are limited in depth to 30 ft. Prolonged respiration of a pure oxygen atmosphere at greater pressure ultimately results in convulsion and unconsciousness. Closed-circuit units are suitable for use only by specially trained and experienced free divers.

Other than the breathing apparatus, equipment used in self-contained diving is identical to that required for skin diving: rubber swim fins shaped like duck feet are used for propulsion and the ordinary flutter kick is standard technique; a face mask covering eyes and nose and fitted with a flat glass pane permits underwater vision; in cold waters, a tight-fitting and flexible protective rubber suit is worn, usually necessitating the use of a weight belt to restore neutral buoyancy. Further accessories include depth gauge and wrist watch (both niandatory in deep SCUBA diving), knife, compass, "snorkel" (a short breathing tube with a mouthpiece) and self-inflating rescue device.

SKINNER, OTIS (1858–1942), U.S. actor, who played hundreds of roles in all parts of the world in a career extending over more than 60 years, was born in Cambridge. Mass., June 28, 1858, the son of a minister. His first stage appearance was at the Philadelphia museum in 1877 in *Woodleigh.* After tuo years in the stock company at the Walnut Street theatre in Philadelphia, Skinner made his New York debut at Niblo's Gardens, Sept. 4, 1879 in The *Enchantment.* During the next five years he developed a classical repertory and a successful acting style, first with Ednin Booth, at Booth's theatre, and then, for three years, with Lawrence Barrett. In 1884 he joined Augustin Daly's company at Daly's theatre, remaining with it for four years. He made his London debut in 1886 with Daly's company, playing at the Strand theatre. After two years with the Booth-Modjeska company, he became, in 1892, leading man opposite Helena Modjeska. In 1903 he starred with Ada Rehan. In addition to his Shakespearean roles, Skinner's chief successes were in *Kismet,* which he played between 1911 and 1914, and *Blood and Sand* (1921), in which he played the matador, Juan Gallardo. Skinner was active in the theatre until his death on Jan. 4, 1942. He was the author of *Footlights and Spotlights* (1924) and *Mad Folk of the Theatre* (1928).

Skinner's daughter, CORNELIA OTIS SKINNER (1901–), actress and monologist, was also the author of many sketches, a play, *Captain* Fury, verse and light essays. (S. W. H.)

SKINNER'S CASE, the name usually given to the celebrated dispute between the house of lords and the house of commons over the question of the original jurisdiction of the former house in civil suits.

In 1668 a London merchant named Thomas Skinner presented a petition to Charles II asserting that he could not obtain any redress against the East India company. which, he asserted, had injured his property. The case was referred to the house of lords, and Skinner obtained a verdict for £5,000. The company complained to the house of commons which declared that the proceedings in the other house were illegal. The lords defended their action, and after two conferences between the houses had produced no result the commons ordered Skinner to be put in prison on a charge of breach of privilege; to this the lords replied by fining and imprisoning Sir Samuel Barnardiston, the chairman of the company. Then for about a year the dispute slumbered, but it was renewed in 1669, when Charles II advised the two houses to stop all proceedings and to erase all mention of the case from their records. This was done and since this time the house of lords has tacitly abandoned all claim to original jurisdiction in civil suits.

SKINS: *see* HIDE.

SKIPPON, PHILIP (d. 1660), English soldier, was born at West Lexham, Norfolk. At an early age he adopted the military profession and in 1622 was serving with Sir Horace Vere in the Palatinate. He took part in most of the battles and sieges of the time in the Low Countries. At the sieges of Breda in 162j and 1637 he mas wounded, and under his old commander, Lord Vere, he was present when Bois-le-Duc ('s Hertogenbosch) and Maestricht were attacked in 1629.

A veteran of considerable experience, Skippon returned to England in 1639, and was appointed to a command in the (Honourable) Artillery company. In Jan. 1642 Skippon was made commander of the City troops. He was not present at Edgehill, but he cheered his raw militiamen at Turnham green, in the face of the king's victorious army. The earl of Essex. the lord general of the parliament forces, made Skippon his major general, a post which carried with it the command of the foot and the duty of arranging the line of battle. In Sept. 1644 Essex' desertion at Lostwithiel left Skippon in command; compelled to surrender without firing a shot, he bore himself with calmness and fortitude in this adversity *(see* CIVIL WAR, ENGLISH). Soon after the second battle of Newbury (Oct. 27) he became major general of the New Model army. In this capacity he supported Sir Thomas Fairfax. its commander in chief, as loyally as he had supported Essex, and at Naseby refused to quit the field although dangerously wounded.

He took part in the negotiations bet een parliament and the army in 1647 and was named one of Charles I's judges, though he took no part in the king's trial. Under the Commonwealth he held office, military and civil, but ceased to influence events. He was a member of Oliver Cromwell's house of lords, and was universally respected and beloved. He died in March 1660. Skippon was a deeply religious man, and wrote several books of devotion for the use of soldiers. (R. B. WM.)

SKIPTON, a market town and urban district in the Skipton parliamentary division of the West Riding of Yorkshire, Eng., on the Leeds and Liverpool canal, 43 mi. E. of York by road. Pop. (1961) 12,988.

Lying in the hilly district of the upper valley of the Aire where it is joined by the Eller Beck from the north, it is the nodal town of the Craven gaps, the lowest ways through the Pennines between Trent and Tyne, and so has become an important route centre and the principal market town of Craven. Weekly sales of cattle and sheep take place.

During the middle ages the Craven gaps were the chief routes through the Pennines along rvhich the Angles, and later the Danes, moved westward. and Skipton was the capital of Craven. At the Norman conquest, it became part of the possessions of Earl Edwin and mas granted to Robert de Romille, who built the castle in the 11th century. It was taken by the parliamentary forces in 1645 after a three-year siege, partly demolished in 1648. restored by Lady Anne Clifford in 1657–58 and now consists chiefly of the gateway with its two round towers and an original Norman arch to the inner court. In the grounds are the remains of the castle chapel. The parish church of the Holy Trinity, mainly Perpendicular, was also partly destroyed during the Great Rebellion but has been restored. The grammar school was founded in 1548.

There are rayon and silk factories in the town and a large limestone quarry nearby.

SKOBELEV, MIKHAIL DIMITRIEVICH (1843–1882), Russian general, was born near Moscow on Sept. 29, 1843. After graduating as a staff officer at St. Petersburg he was sent to Turkestan in 1868 and, with the exception of an interval of two years, during which he was on the staff of the grand duke Michael in the Caucasus, remained in central Asia until 1877. He commanded the advanced guard of General Lomakine's column from Kinderly Bay, in the Caspian, to join General Verefkin, from Orenburg, in the expedition to Khiva in 1874. and, after great suffering on the desert march, took a prominent part in the capture of the Khivan capital. Dressed as a Turkoman, he intrepidly explored in a hostile country the route from Khiva to Igdy, and also the old bed of the Oxus. In 1875 he was given a command in the expedition against Khokand under General Kaufmann. For his great services he was promoted to be major general and appointed the first governor of Fergana. In the Turkish War of 1877 he seized the bridge over the Sereth at Barborchi in April, and in June crossed the Danube with the 8th corps. He commanded the Caucasian Cossack brigade in the attack of the Green Hills at the second battle of Plevna. He captured Lovtcha on Sept. 3, and distinguished himself again in the desperate fighting on the Green Hills in the third battle of Plevna. In command of the 16th division, he took part in the investment of Plevna and also in the fight of Dec. 9. when Osman Pasha surrendered, with his army. In January 1878 he crossed the Balkans in a severe snowstorm. defeating the Turks at Senova, near Schipka, and capturing 36,000 men and 90 guns. Dressed in white uniform and mounted on a white horse, and always in the thickest of the fray, he was known and adored by his soldiers as the "White Genera!." He returned to Turkestan after the war. and in 1880 and 1881 further distinguished himself in retrieving the disasters inflicted by the Tekke Turkomans, captured Geok-Tepe, and, after much slaughter, reduced the Akhal-Tekke countn to submission. He was advancing on Askabad and Kalat i-Nadiri when he was disavowed and recalled. He was given the command at Minsk. in the last years of his short life he engaged actively in politics, and made speeches in Paris and in Moscow in the beginning of 1882 in favour of a militant Panslavism. predicting a desperate strife between Teuton and Slav. He was at once recalled to St. Petersburg. He was staying at a Moscow hotel, on his way from Minsk to his estate close by, when he died suddenly of heart disease on July 7, 1882.

SKOKIE, a residential and light industrial village of Cook county, in northeastern Illinois, U.S., is on the northern edge of Chicago and west of Evanston. Called Niles Center until 1940, Skokie was first settled in 1834 and attracted a colony of settlers from Luxembourg. By the time of its incorporation in 1888 the trading centre was known primarily for its greenhouse industry, started during the previous decade.

In the late 1920s a development boom occurred in the community following the extension of service by the Chicago and North Western and the Chicago, North Shore and Milwaukee railroads. The depression of the 1930s halted the growth of the village but World War II began a great influx of industry. The community nevertheless retained much of its earlier residential character, and residential and commercial building (including extensive shopping facilities) increased sharply in the postwar years. in the decade 1950–60 the population increased from 14,832 to 59,364. (For comparative population figures see table in ILLINOIS: *Population.*)

The village adopted a council-manager form of government in 1957. (AR. C. H.)

SKOPAS: see SCOPAS.

SKOPLJE (SKOPJE), the capital of Macedonia, Yugos. (Turkish *Üsküb*). It lies on a fertile plain, with the Vardar running through it, and is completely encircled by a Turkish cemetery. Pop. (1961) 161,993, comprising Serbs, Albanians, Turks, Bulgars and a few gypsies. The agricultural production of the district includes maize, oats and barley, and silkworm culture is extensively carried on. There is an important opium market and Skoplje is the distributing centre for a very large area. At the outbreak of World War I it possessed a steam flour mill, a brewery, distilleries, tanneries, braid, soap, horseshoe and sugar factories, and was the centre of the silver filigree industry. Antimony, saltpetre and veins of pure magnesite are found in the district.

The principal buildings are the citadel, the palace of the former Turkish governor, a Roman aqueduct. many churches and mosques. The second urban Serbian school in Macedonia was opened there in 1830. and the first Macedonian newspaper published there in 1908. Skoplje is strategically the most important point in Macedonia, and perhaps in the Balkans. several main arteries of communication, and four railways, converging upon it. Its fall in 1941 decided the German victory in the Balkans. The town came under Bulgarian occupation.

The name is derived from *Scupi*, an ancient town whose ruins lie near by, and which was destroyed by an earthquake in 518, and rebuilt by Justinian. In the 13th century Skoplje was taken by King Milutin of Serbia and made his capital, and his successor, Stephen Dushan was crowned there in 1346, and composed his famous code.

SKOULOUDIS, STEPHEN (1836–1928), Greek statesman, a Chiot, was born an Ottoman subject, in Constantinople in 1836. He founded the Banque de Constantinople. and after retiring from business lived in Athens and became a Hellenic subject. He was several times elected member of the Greek chamber (1879 and 1892–1906). He was appointed minister in Spain in 1883, and minister of marine in the Trikoupis cabinet of 1892. As minister for foreign affairs in the Ralli cabinet of 1897, his knowledge of the Turks enabled him to exert his influence on the terms of peace after the war of 1897. He then resigned office. and retired into private life until 1912, when Venizelos obtained his appointment on the delegation to meet the Turks in London. In Nov. 1915 he became prime minister, in succession to Zaïmis. Soon after his appointment he announced his policy of benevolent neutrality. The confidence of the Allies was, however. shaken by his reported intention, at the instigation of German ministers. to disarm Serbian troops who were being forced into Greek territory by the German and Bulgarian advance, and the commercial blockade of Greece by the Allies (Nov. 18) mas followed by an ultimatum which Skouloudis accepted. After six months' continued effort to satisfy both sides in the world conflict. Skouloudis resigned on June 19, 1916, shortly after the evacuation of Fort Rupel by the Greek garrison. A charge of treasonable correspondence was afterward brought against him, but was not proved. He died on Aug. 20. 1925.

SKRAM, PEDER (c. 1500–1581), Danish senator and naval hero, born between 1491 and 1503, at his father's estate at Urup near Horsens in Jutland. He first saw service in the Swedish war of Christian II at the battle of Brannkyrka, 1518, and at the battle of Uppsala two years later he saved the life of the Danish standard-bearer. For his services he was rewarded with an estate in Norway. During "Grevens Fejde," or "the Count's War," Skram was sent by the Danish government to assist Gustavus Vasa, then in alliance with Christian III against the partisans of Christian II, to organize the untried Swedish fleet; and Skram seems, for the point is still obscure, to have shared the chief command with the Swedish Admiral Måns Some. Skram greatly hampered the movements of the Hanseatic fleets who fnught on the side of Christian II, captured a whole Lubeck squadron off Svendborg, and prevented the revictualling of Copenhagen by Lubeck. But the incurable suspicion of Gustavus I minimized the successes of the allied fleets throughout 1535. Skram's services were richly rewarded by Christian III. As a senator he contributed to the victory of the Danish party over the German in the councils of Christian III. In 1555, feeling too infirm to go to sea, he resigned his post of admiral; but when the Scandinavian Seven Tears' War broke out seven years later, the new king, Frederick II, offered Skram the chief command. He put to sea in August 1562, and compelled the Swedish admiral, after a successful engagement off the coast of Gotland, to take refuge behind the Skerries. He was superseded at the end of the year by Herluf Trolle. Skram was twice (1565–1568) unsuccessfully besieged by the Swedes in his castle of Laholm, which he and his wife defended with great intrepidity. Skram died at Urup on July 11, 1581.

Skram's audacity won for him the nickname of "Denmark's dare-devil," and he contributed perhaps more than any other Dane of his day to destroy the Hanseatic dominion of the Baltic. His humanity was equally remarkable; he often imperilled his life by preventing his crews from plundering.

See Axel Larsen, *Dansk-Norske Heltehistorier* (Copenhagen, 1893).

SKRZYNECKI, JAN ZYGMUNT (1787–1860), Polish general, organised the Polish army at the revolution of 1830. After his defeat by Diebitsch at Ostrolenka he had to resign his command. He took refuge at Cracow, where he died.

SKRZYNSKI, ALEXANDER, COUNT (1882–1931), Polish statesman, was born at Zagorzany, Galicia. Educated at Cracow and Munich, he entered the diplomatic service in 1906 and was appointed secretary to the ambassador to the Holy See in 1910. When the World War broke out he was secretary to the Austro-Hungarian Ambassador in Paris. After a short military service at the beginning of the War, he completed his studies for the Bar, receiving the degree of Doctor of the Law at the University of Vienna. When the new Polish State was established, he was appointed Polish Minister Plenipotentiary at Bucharest, and later succeeded in concluding a Polish-Rumanian political treaty in 1921. In Dec. 1922, after the murder of Narutowicz, the first international President of the Republic, Skrzynski became Minister of Foreign Affairs. He threw himself energetically into the task of settling all open questions, inaugurated a pacific policy based on the final stabilisation of frontiers and gained the necessary confidence of the Powers. When a Cabinet of the Right was formed in May 1923, Skrzynski thereby lost office, and he was appointed in the following month Polish delegate to the League of Nations. In Aug. 1924 he again became Minister of Foreign Affairs in the Grabski Cabinet.

By a number of conventions, the regulation of the British and American debts, the concordat with the Vatican, the rapprochement with Czechoslovakia, Skrzynski strengthened Poland's international position, taking an active part in the League of Nations in elaborating the scheme for the Geneva Protocol and in securing settlement of the Danzig disputes in a manner favourable to Poland. He tried to disarm the suspicions of Moscow as to the new configuration of Europe by receiving Chicherin at Warsaw (Sept. 1924). In the negotiations in connection with the German proposals with regard to the Locarno Pact (1925), Skrzynski sought to reconcile Polish interests with the general scheme of the conference, and signed an arbitration agreement with Germany and also a convention with France in accordance therewith. After the fall of Grabski's Government Nov. 13, 1925, Skrzynski was entrusted with the formation of a government by Wojciechowski, the President of the Republic, and with the participation of the Socialists formed a coalition cabinet in which he himself was Prime Minister and Minister of Foreign Affairs, In May 1926, however, the Socialists seceded from the Cabinet on account of the refusal of their financial proposals, which involved inflation. After the Pilsudski *coup d'état* of that month Skrzynski remained in retirement. See also POLAND.

SKUA, sea-birds forming the genus *Stercorarius* of the *Laridae* (see GULL). Except during the breeding season, when they obtain their own food, the skuas live almost exclusively by preying upon gulls, which they compel to disgorge what they have caught. For this purpose they are swift of flight, powerfully armed and endowed with great courage. The largest species, equalling a herring gull (Larus argentatus) in size, is *S.* skua, the great skua or bonxie. The plumage is dark brown above, lighter beneath, with a patch of white at the base of the primaries. It breeds in the Faeroes. Shetlands, and Iceland, laying its two dark olive eggs in a nest in the heather. Out of the breeding season it occurs all over the north Atlantic. *S.* antarcticus, the Port Egmont hen, from the Pacific, closely resembles it. Maccormick's skua (S. maccormicki) breeds on the Antarctic continent, where it plunders the penguin colonies.

The Arctic or Richardson's skua (S. crepidatus) is interesting as showing great variety in the colour of the underside from dark to white, with a thin dark collar. In the Arctic, skuas nest only in years when food is plentiful. The skuas have a remarkable injury-feigning performance to lure intruders from the nest. If this does not succeed, they swoop at the intruder's head. Some species may strike severe blows. American ornithologists assign three of the skuas, which they call jaegers, to the genus *Stercorarius:* the pomarine jaeger (S. *pomarinus*), the parasitic jaeger (*S. parasiticus*), and the long-tailed jaeger (*S. longicaudus*).

SKULL. The skull is the skeleton of the head. It comprises the brain case and the facial skeleton, which includes the upper and lower jaws. The function of the skull, apart from providing for the suspension of the jaws, is to protect the delicate brain (*q.v.*) and the organs of special sense, the nose, the eye and the ear. The skull is poised on the first or atlas vertebra through a joint which permits nodding movements of the head. Rotation of the head is carried out by movement of the atlas around the axis of the so-called odontoid peg of the second or axis vertebra. The following account of the human skull considers its structure, the infant skull, evolution of the skull and the skull in anthropology.

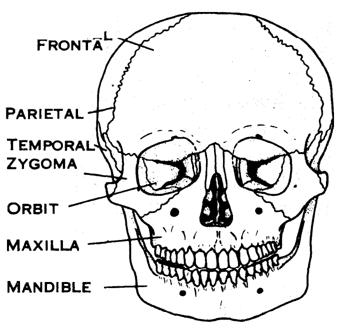

FIG. 1.—ADULT HUMAN SKULL FROM THE FRONT

Structure. — The adult human skull (seen from the front in fig. 1) has a dome-shaped brain case, the walls of which are composed of a number of flat bones —the frontal over the forehead and the parietals and temporals at the sides. The bones of the cranial vault are joined to each other at the sutures, which are actually fibrous joints and are shown in the figure as irregular lines between the bones. They serve in the young skull to join the bones together rigidly yet allow a slight degree of movement between them. This arrangement also confers some elasticity on the skull, enabling it to withstand blows of considerable force. The sutures become progressively and slowly obliterated by the formation of a bony union between the individual bones, this process beginning in the young adult skull and being advanced by the time of middle age.

The human forehead is smooth and almost vertical and there is not a well-developed brow ridge such as occurs in many great apes. The orbits or eye sockets, roughly quadrilateral in shape, face forward and slightly outward; this position of the eyes in man is of great importance since it permits an overlap of the visual fields that makes true stereoscopic or binocular vision possible. This overlap of the visual fields is also favoured by the great reduction of the snout and nose area in the human skull. In the horse the eyes are placed far over on the sides of the head. The orbits of the human skull are bounded at the outer edge by the zygomatic bone. The orbital cavities are conical in shape and taper as they are traced deep into the skull. At the apex of the orbit are several holes through which the nerves to the eye and to the eye muscles gain entrance to the orbit. The bones forming the interior walls of the orbit are thin and delicate; those of the roof and floor are more solid.

In the centre of the face may be seen the external orifice of the nasal cavities. The bridge of the nose is made by the flat nasal bones and the rest of the nasal orifice is bounded by the maxillary bones, one on either side. The external projection of the nose on the face of a living person is due almost entirely to cartilaginous structures that are not properly a part of the skull. The greater part of the nasal cavities lies deeply buried within the skull; some of the bony structures within it may be seen in fig. 1. On the outer wall of each nasal cavity are two scrolls of bone, the turbinate bones, not shown in the figure. In life the scrolls are covered by a thick mucous membrane which is believed to assist in warming the incoming air before it passes into the lungs.

In the mid line between the nasal cavities is the bony nasal septum or partition. The maxillary bones, one on either side, make up the main mass of the upper jaws and carry 16 teeth in the adult. Internally the maxillary bones are hollowed out to form the maxillary sinuses, which are lined with mucous membrane continuous with that of the nose. The mandible is the skeleton of the lower jaw; like the maxilla it bears 16 teeth. There are 2 incisors, 1 cuspid, 2 premolars (or bicuspids) and 3 molars on each side in each jaw, making a total of 32. The holes in the frontal, maxillary and mandible bones provide for the exit of branches of the trigeminal nerve passing to the skin of the face.

When the skull is seen from the side *(see* fig. 2), bones making up the vault of the skull include the frontal, the parietal, the sphenoid, the temporal and the occipital. At the outer margin of the orbit the zygomatic bone (Gr. *zygon,* "yoke") sends backward a prolongation which meets a similar process of the temporal bone to form the zygomatic arch. The space between the zygomatic arch and the side of the brain case allows the powerful temporalis muscle to gain attachment to the mandible; its function is to close the mouth. Note the position of the external auditory canal or ear hole. Its walls are made up chiefly by a tubular bone, the tympanic. A spicule (splinter) of bone projecting down from the base of the skull from a point just behind the tympanic bone is the styloid process (Gr. *stylos,* "pillar"). A fibrous band or ligament is found in the living person attached above to the tip of the styloid process and below to the hyoid bone. The ligament is indicated by dotted lines in fig. 2. The hyoid bone is further discussed below, in the section *Evolution of the Skull.* Behind the external auditory canal is a bulging area of bone called the mastoid process. It is a typical feature of the human skull and

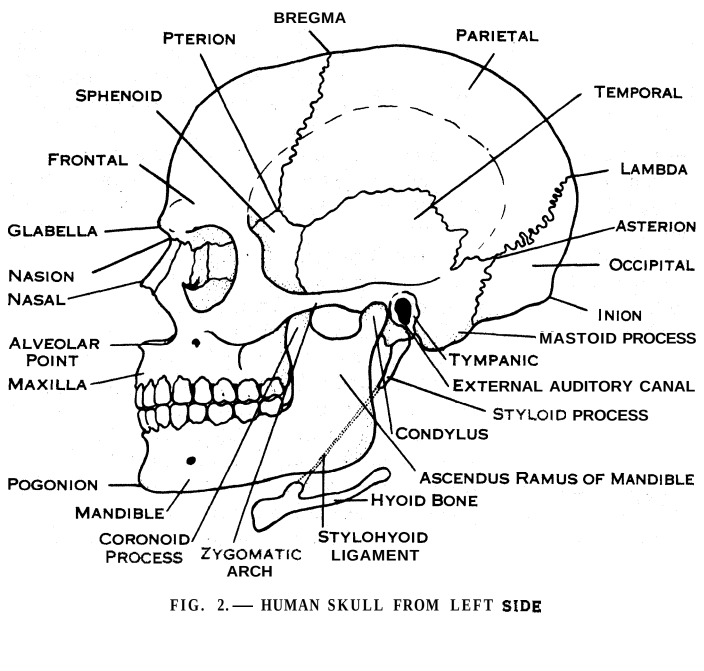

FIG. 2.— HUMAN SKULL FROM LEFT SIDE

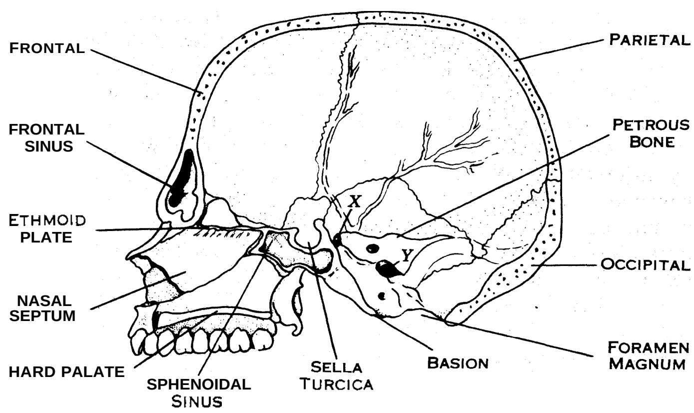

FIG. 3.— HUMAN SKULL IN SECTION FROM INNER SIDE

contains many small cavities or air cells continuous with the cavity of the middle ear. These cells are readily infected and may give rise to serious trouble.

The shape of the mandible can be recognized more clearly from the side. It consists of a horizontal body which carries the teeth on its upper surface and an ascending ramus (Lat. *ramus,* "oar"). At the upper margin of the ramus are two prominences, one in front called the coronoid process (Lat. *corona,* "crown") and one farther back called the condylus (Lat. *condylus,* "knuckle" or "joint"). The condylus is rounded and coated with cartilage in life. It fits into a depression in the undersurface of the temporal bone to form with it a movable joint, the temporomandibular joint, which permits opening and closing of the mouth and also side to side movement as in chewing.

Certain terms of anthropological interest are included in fig. 2. Of special note are the pterion (Gr. *pteron,* "wing") at the junction of the frontal, the parietal and the sphenoid bones. The conformation of the sutures at this point is very distinctive in the human skull and is of interest when comparing the human skull with that of a closely related species such as the anthropoid apes. From the surgeon's standpoint the pterion is of importance as a landmark since it more or less overlies the large middle meningeal artery on the inside of the skull. This artery is frequently torn as a result of a severe blow on the side of the head, giving rise to a characteristic train of symptoms possibly ending in death if the resulting hemorrhage is not arrested.

A section through the middle of the skull shown in fig. 3 serves to illustrate some important features of the interior of the skull. The relative thinness of the bones of the vault of the skull overlying the brain is evident. In a young person the bones in this area consist of three layers, an inner and outer table of compact bone with a middle layer of bone marrow. The latter layer is called the "diploe" (Gr. *diploos,* "double") and disappears with advancing age. When a blow is administered to the skull the inner table is apt to be more severely damaged than the outer table and sharp spicules (slivers) of bone may be driven into the brain. Moreover, since the dome of the skull is somewhat elastic, at least in the young person, by virtue of its sutural pattern, the force of the blo may be transmitted around to the base of the skull producing a fracture there.

The brain has an additional protection in the dura mater (Lat., "hard mother") which is a tough fibrous envelope within the skull itself. Associated with the dura mater are numerous large veins of exceptionally wide calibre. These dural veins are known as the cranial venous sinuses and are not to be confused with the air sinuses within such bones as the maxilla. The inner surface of the skull also bears a sutural pattern and sinuous grooves mark the course and branching of the middle meningeal artery.

The base of the skull is made up from front to back by the frontal, ethmoid, sphenoid and basioccipital bones. The base supports the superincumbent weight of the brain which is further protected by the development of fluid-filled spaces or "cisterns" between it and the base of the skull; it is thus supported, as it uere, on a fluid cushion. There are large air sinuses within the frontal bone above the nasal cavity and a similar excavation, the sphenoidal air sinus, exists within the body of the sphenoid. All these are continuous with the cavity of the nose. Behind the frontal bone is the ethmoid bone (Gr. ethmos, "a sieve"). In the floor of the skull the ethmoid forms a perforated plate through which pass the nerves to the nose. It also has an upward projection, the crista galli (Lat. "coxcomb"), and a downward projection which forms the upper part of the bony septum of the nose. The upper surface of the sphenoid bone is hollowed out to form the sella turcica or "Turkish saddle" in which the pituitary gland lies. This important gland, on which the proper functioning of all the other endocrine glands depends (see ENDOCRINOLOGY), is thus situated in a most inaccessible and invulnerable place in the skull. For this reason, its surgical approach presents many difficulties.

A massive wedge of bone in the floor of the skull, called the petrous bone (Gr. *petra*, "rock"), is the hardest bone in the body. It houses the organ of hearing. On the inner side of the petrous bone is a hole for the passage of the auditory nerve to the ear. There is a large circular hole in the floor of the skull called the foramen magnum (Lat., "big hole") through which the medulla oblongata of the brain and the spinal cord are continuous with each other. The great internal carotid artery gains access to the skull at the point indicated by X (fig. 3) and the great internal jugular vein leaves the skull at the point indicated by Y.

It has been noted that the ethmoid bone takes part in the formation of the nasal septum. The rest of the septum consists of the vomer (Lat., "a plowshare") and the maxillary bones. The hard palate in the roof of the mouth is made up of the maxillary bones and the palatine bones.

The Infant Skull. — The skull of a newborn baby is illustrated from the left side in fig. 4. The skull at this stage shows clearly the multiple bones in the brain case. These bones are uidely separated by sutures which thus confer great flexibility on the skull and permit overriding of the bones upon each other during the process of birth. The size of the facial skeleton is very small relative to the brain case. The maxillary bones are very small, a fact due to the absence of teeth except in rudimentary form and to the absence of the maxillary air sinuses. The mandible is distinctly different in shape from that found in the adult in that there is almost no angle between the body and the ramus. There is no mastoid process and the external auditory canal is absent. The canal develops after birth by bony extensions from the tympanic ring.

In certain areas the sutures between the bones of the brain case are very wide. At such points the baby's skull presents localized areas of relative softness and weakness. These are called the fontanels, the most important of which is at the bregma (where the frontal and parietal bones adjoin at the top of the skull). Others are found at the lambda (where the parietal and occipital bones adjoin at the rear of the skull) and at the pterion and asterion (where the temporal, parietal and occipital bones adjoin on the side of the skull).

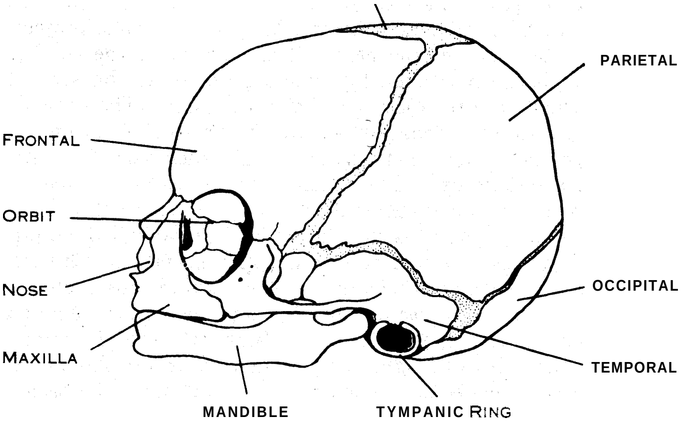

FIG. 4. — SKULL OF NEWBORN INFANT FROM LEFT SIDE

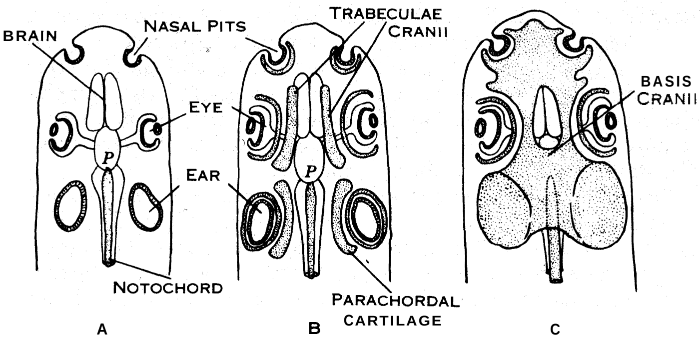


AFTER "HISTORY OF THE HUMAN BODY" BY H. H. WILDER; HENRY HOLT & CO., N.Y., 1909

FIG. 5. — DIAGRAMS SHOWING THREE STAGES IN THE EVOLUTION OF A SKULL: (A) HEAD OF A HYPOTHETICAL PREVERTEBRATE ANIMAL: (B) LATER STAGE OF ANIMAL WITH VERTEBRAL COLUMN; AND (C) VERTEBRATE WITH PRIMITIVE SKULL

Evolution of the Skull. — In order to facilitate an understanding of the way in which the mammalian skull is built up, a brief survey of the evolution of the skull will be presented. The head of a hypothetical animal which may have preceded the vertebrates is illustrated in fig. 5(A). The head already possesses a well-developed brain and also special sense organs, namely, two nasal pits, two eyes and two ears, the latter being concerned only with balance. Instead of a bony vertebral column there is a semirigid rod called the notochord which traverses the full length of the animal below the spinal cord and ends in front just behind the pituitary gland (P in fig. 5[A]). At a later stage in the evolution of the skull (fig. 5[B]) certain additions are made to the head. Cartilaginous envelopes are formed around the special sense organs, investing these partially in the case of the nasal pits and the eyes and completely in the case of the ears; these coverings are known as the special sense capsules.

In addition, the need for added rigidity is met by the development of two rods of cartilage on either side, the trabeculae carnii in front and the parachordal cartilages at the back of the head. At a still later stage (fig. 5[C]) a general consolidation of the cartilaginous elements of the primitive skull takes place by the fusion of the trabeculae cranii and the parachordal cartilages into a single cartilaginous skull base (basis cranii) and the fusion of this in turn nith each of the special sense capsules. Further extensions of the cartilaginous skull also take place above the brain. This sequence of events in the evolution of the skull can be deduced with a fair degree of confidence since it is essentially what takes place in the development of the human embryo and indeed in the embryos of all vertebrates.

Speculation about the skull becomes fact with the conditions present in the skulls of a large group of modern fish having cartilaginous skeletons, the Elasmobranchii. These primitive fish, which include the sharks and rays. have skulls essentially similar to that depicted in fig. 5(C). The next stage in the evolution of the skull is the appearance of added protection for the head in the form of bony plates or scutes (Lat. *scutum*, "shield"). The living primitive fish the Ganoidei have this armour plating over the head and some of the body. These fish include the sturgeon, the garpike and the bowfin. The bony plates of the skull are actually developed from the connective tissues of the skin and are called dermal bones. There are many of these bony plates in the skull region, and their names, which include the frontals. parietals, temporals and many others, have become familiar through study of the human skull.

The dermal skull bones become extremely numerous in the bony fish known as Teleostei, which include most of the ordinary fish. A striking feature of the dermal bones in all vertebrates above the fish is their development not on the surface of the head but deep in the connective tissues under the skin. This is the uay they develop in the human embryo.

Meanwhile important changes have occurred in the cartilaginous skull lying inside the outer skull of dermal bones. Centres of bone formation appear within the basis cranii and the special sense capsules and convert them into solid bone. This change is foreshadowed in the Elasmobranchii and is well advanced in the Teleostei. At the same time there are varying degrees of fusion between the dermal bones and between these and the underlying basis cranii and special sense capsules. In essence this completes the story of the evolution of the skull. There is, however, an infinite variety in the detailed arrangements of the elements of the skull in different groups of animals.

There remains to be considered the so-called visceral skeleton. This includes the jaws and the hyoid apparatus (see fig. 2). In the fish the gills are supported by cartilaginous bars, the branchial or visceral arches. The upper jaw consists of a plate of cartilage, the palatoquadrate bar; the lower jaw consists of Meckel's cartilage. The jaw joint is formed between the quadrate and the articular cartilages, which are merely the hind ends respectively of the palatoquadrate and of Meckel's cartilages.

In the Ganoidei and Teleostei new dermal bones are laid down around the cartilages of the jaws; the articular and quadrate cartilages continue to form the jaw joint. In higher vertebrates there are profound modifications in the visceral skeleton of the skull. A new joint is developed between the dermal lower jaw and the temporal bone. The quadrate and articular cartilages are thus no longer necessary. They do not disappear, however, but are apparently transformed into the small bones of the ear, the quadrate becoming the incus or anvil bone and the articular becoming the malleus or hammer bone.

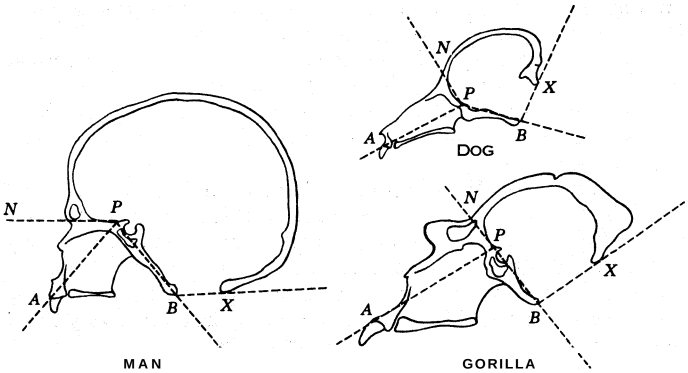
The remaining gill arches of the fish also become greatly modified with the disappearance of the gills and the development of lungs. The second and third gill arches become transformed into the hyoid bone together with the styloid process and the stylohyoid ligament (see fig. 2). The stapes or stirrup-bone of the ear appears to be developed from the second arch. The remaining arches become modified in man as the cartilaginous framework of the larynx or voice box.

The human skull, then, may be regarded as consisting essentially of an inner skull, very ancient from the evolutionary point of view, which includes the base of the skull and the special sense capsules; and an outer, more recent skull, made up of the so-called dermal bones. The dermal bones are typically found in the dome of the skull, the face and the mandible. In the first situation they have proved extremely plastic in adapting themselves to the enormous development of the brain that characterizes man.

The **Skull** in Anthropology. — The skull occupies a key position in the study of fossil remains for a number of reasons. Whereas the bones of the limbs give important information about the mode of progression and the posture of the individual when alive, the skull gives unique information about the intellectual development of the individual. Moreover, the conformation of the teeth and jaws gives some insight into dietary habits. Certain parts of the skull, due to their compact and durable nature, notably the mandible and the teeth, are apt to be preserved over the centuries. The student of fossilized remains who wishes to establish their possible affinities with man must keep clearly in mind exactly what criteria make a skull typically human. Doing so necessitates a thorough knowledge of the many natural variations of the skull in different groups and races of mankind. Some of the distinctly human features are reviewed below.

The capacity of the brain case is relatively and absolutely large in the human skull in all known races. When the capacity is less than 1,350 c.c. the skull is called microcephalic; a skull with a capacity of 1,350–1,450 c.c. is designated as mesocephalic; a capacity of over 1,450 c.c. is characteristic of a macrocephalic skull. Another characteristic feature of the human skull is the smooth, almost vertical forehead, lacking the pronounced brow ridges found in many apes and certain extinct forms of man. There is a marked concavity above the cuspid (or canine) tooth in, the upper jaw, the canine fossa, which is absent or is replaced by a convexity in apes and in extinct man. The mandible is characterized by a definite angle between the ramus and the body. The condylus of the jaw joint is also typical. The bony prominence of the chin is also a distinctive human trait, as is the absence of a shelf of bone at the back of the chin known as the simian shelf, found in all apes but generally absent in the mandible of early man. The mastoid and tympanic region and certain sutural areas, such as the pterion, also serve to distinguish the human from the anthropoid skull.

Of particular significance in this respect is the poise of the skull on the end of the vertebral column. To illustrate this a series of sections of the skull of a man, of a gorilla and of a dog are shown in fig. 6. Certain planes of reference are indicated in dotted lines. Thus the plane of the foramen magnum (BX) is horizontal in the human skull, slightly inclined to the horizontal in the gorilla and almost vertical in the dog. This indicates that in man, who is truly an erect animal, the skull is perfectly balanced on the top of the spine. In the gorilla this is not so and powerful muscles are developed at the back of the neck to counterpoise the huge weight of the face with its massive jaws. In the dog, which walks on all fours, the skull is held at right angles to the axis of the spine (BX). Other angles, indicated in fig. 6, may be of value in establishing that a skull is not anthropoidal. The sphenethmoidal angle (NPB) is drawn by projecting a line (PN) forward in the plane of the ethmoid plate from a point just behind this plate known as the prosphenion (P) and another line (PB) from the latter point passing through the axis of the base of the skull to



DRAWN FROM "MORPHOLOGY AND ANTHROPOLOGY" BY W. L. H. DUCKWORTH: CAMBRIDGE UNIVERSITY PRESS, 1915

FIG. 6.— FACIAL ANGLES IN THE SKULLS OF A MAN, DOG AND GORILLA

the front of the foramen magnum (B). The difference in this angle in the skulk of man, gorilla and dog is striking. In man the plane of the ethmoid plate has been rotated downward and forward. a change associated with the enormous development of the frontal lobes of the brain believed to be correlated with his unique intellectual powers. The sphenomaxillary angle (APB), determined by adding a line (PA) from the prosphenion to the alveolar point *(A)* just above the upper incisor teeth, indicates that there has been a striking reduction in the projection of the face or snout area in man together with some rotation of the maxillary area downward.

Certain cranial indices can be calculated from measurement of the diameters of the skull that can be carried out with some precision. The length of the skull is the distance from the glabella (the mid-point between the two brow ridges) and the most projecting point at the back of the head. The breadth of the skull is the distance between the most projecting points at the side of the head, usually a little above and behind the ear. The cephalic index is the breadth × 100 divided by the length. An index of less than 75, indicating a long. narrow skull when seen from the top, is characteristic of a dolichocephalic (Gr. dolicho, "long") skull and is found among native Australians and the Kaffirs. An index of between 75 and 80 is characteristic of the so-called mesaticephalic or oval skull found among Europeans and the Chinese. An index of over 80, indicating a broad, short skull, is observed in a brachycephalic (Gr. brachys, "short") skull which is common among Mongolians and the Andaman Islanders. Other cranial indices are the index of height and the gnathic or alveolar index. The former is calculated as the height of the skull from the basion (front of the foramen magnum) to the bregma (see fig. 2) × 100 divided by the breadth. The latter is reckoned as the basialveolar length (from basion to alveolar point, see fig. 6) × 100 divided by the basinasal length (from basion to nasion [root of the nose]) and gives a measure of the degree of prognathism or snout projection of the skull.

SKULL, SURGERY OF. Fractures of the vault of the skull may occur without the bone being driven in to compress the brain, and in such cases their existence may be revealed only after death. But if there is also a severe scalp wound the line of fracture may be traced in the bare bone as a thin red crack. The patient with a suspected fracture of the skull is put to bed in a dark, quiet room, and is watched. It may be that the crack has extended across a bony groove in which an artery is running, and, the artery being torn, hemorrhage may take place within the skull and symptoms of compression of the brain may supervene.

Compression of the brain may be the direct and immediate result of a head injury. a piece of the vault of the skull being driven in, and a local or a general paralysis of muscles being at once observed. In addition to the muscular paralysis, there may be insensibility, laborious breathing, dilated pupils that do not react to light. In such cases the treatment is trephining.

Fractures of the base of the skull are always serious, in that they may run across important nerves and large blood vessels; passing through the roof of the nose, or the ear, they may communicate with air cavities. Thus. the dangers of sepsis are added to those of concussion or compression of the brain. Fractures of the base of the skull are often associated with bleeding from the nose, mouth or ear, or with extravasation of blood over the eyeball. Facial paralysis is the result of the line of fracture passing across the bony channel in which the seventh or facial nerve is running. When the fracture passes across the temporal bone and the middle ear and ruptures the membrane of the tympanum. not only blood may escape from the ear. but an apparently unlimited amount of cerebrospinal fluid. When the fracture extends through the anterior part of the base of the skull this same clear fluid may escape from the nose. In both cases its appearance implies that the dura mater has been lacerated and the subdural space opened.

Concussion of the brain (stunning) may result from a blow upon the head or from a fall from a height. The symptoms may be those of mere giddiness and a feeling of stupidity, which may quickly pass off, or they may be those of severe shock (*see* SHOCK). The person may die from the concussion, or he may slowly or quickly recover. As a rule, the pupils react to light. One of the first signs of returning consciousness is that the person vomits, and after this he gradually comes round. As a result of the injury, however, he may remain irritable, liable to headache or to lapses of memory. See also NERVOUS SYSTEM, SURGERY OF.

SKULLCAP (*Scutellaria*), the common name for a numerous genus of herbs and subshrubs of the mint family (Labiatae, *q.v.*), comprising about 200 species of nearly world-wide distribution. They have numerous blue, violet, yellow, scarlet or white flowers, borne in opposite pairs or in axillary or terminal, slender. one-sided spikelike racemes. The corolla has a long tube, dilated at the throat and surmounted with two unequal lips, the upper usually entire and the lower notched. The persistent calyx bears a conspicuous protuberance on the upper lip, giving it a helmetlike appearance, whence the common name.

Besides the common skullcap. which is found across the continent, about 2; other species occur in North America. Two species occur in the British Isles, the common or marsh skullcap (S. *galericulata*), with handsome violet-blue flowers, and the lesser skullcap (S. *minor*).

SKUNK, a North American carnivorous mammal, belonging to the family Mustelidae and noted for its evil smell arising from a secretion of the anal glands. This is under the control of the animal, which can propel the yellow liquid to a distance of 8 or 12 ft. The common skunk (Mephitis mephitis) inhabits North America from Hudson bay to Texas. About the size of a cat, though more heavily built. it has black fur, usually with two streaks of white on the back. The muzzle is long and pointed, the tail long and bushy. Insects form its staple diet, but it will also eat mice. eggs, frogs and carrion, and occasionally rob hen roosts. The skunk evinces little dread of man or other animals, and its normal gait is a walk. No animal attacks it knowingly, and its leisurely gait and conspicuous coloration well advertise its disagreeable properties. During very severe weather the animal hibernates. Four to seven young are brought forth each spring. Several other forms inhabit Central and South America.

THE COMMON SKUNK

The skunk lives in dens or burrows, and is chiefly nocturnal in its habits. Since colonial times it has been trapped and sometimes reared for its valuable fur.

SKUNK CABBAGE (*Symplocarpus* joetidus), a fleshy herbaceous plant of the arum family, Araceae, so called because of its fetid odour and large leaves, native to eastern North America and northeastern Asia. It grows in swampy places and in very early spring (March or sometimes February) it sends up from thick rootstocks grotesque, swollen, shell-like, purple-brown spathes, each enclosing many small flowers borne in a short thick cluster. These are soon followed by numerous ovate leaves: one to three feet long, and later by large globular masses of fleshy berries. The similar western skunk cabbage (*Lysichiton*) occurs in western North America.

SKY, the apparent covering of the atmosphere. the overarching heaven (M.E. skie, "cloud"; O.E. *skua,* "shade"; connected with an Indo-European root *sku,* "cover," whence "scum," Lat. *obscurus*, "dark." etc.).

The Colour **of the** Sky.—It is a matter of common observation that the blue of the sky is highly variable, even on days that are free from clouds. The colour usually deepens toward the zenith and also with the elevation of the observer. It is evident that the normal blue is more or less diluted with extraneous white light, having its origin in reflections from the grosser particles of foreign matter with which the air is usually charged. Closely associated with the colour is the polarization of the light from the sky. This takes place in a plane passing through the sun, and attains a maximum about 90° therefrom. Cnder favourable conditions more than half the light is polarized.

As to the origin of the normal blue, very discrepant views have been held. Some writers, even of good reputation. have held that the blue is the true body colour of the air, or of some ingredient in it such as ozone. It is a sufficient answer to remark that on this theory the blue would reach its maximum development in the colour of the setting sun. It should be evident that what we have first to explain is the fact that we receive any light from the sky at all. Were the atmosphere nonexistent or absolutely transparent, the sky would necessarily be black. There must be something capable of *reflecting* light in the wider sense of that term.

A theory that received much support in the past attributed the reflections to thin bubbles of water, similar to soap bubbles, in which form vapour was supposed to condense. According to it, sky blue would be the blue of the first order in Newton's scale of colours. The theory was developed by R. Clausius (*Pogg. Ann.* vols. 72, 76, 88), who regarded it as meeting the requirements of the case. It must be noticed, however, that the angle of maximum polarization would be about 76° instead of 90°.

Apart from the difficulty of seeing how the bubbles could arise, there is a formidable objection, mentioned by E. W. Briicke (Pogg. *Ann.* 88. 363), that the blue of the sky is a much richer colour than the blue of the first order. Briicke also brought forward an experiment of great importance, in which he showed that gum mastic, precipitated from an alcoholic solution poured into a large quantity of water, scatters light of a blue tint. He remarks that it is impossible to suppose that the particles of mastic are in the form of bubbles. Another point of great importance is well brought out in the experiments of John Tyndall (Phil. *Mag.* [4], 137, 388) upon clouds precipitated by the chemical action of light. Whenever the particles are sufficiently fine, the light emitted laterally is blue in colour and, in a direction perpendicular to the incident beam, is completely plane-polarized.

The dependence of the amount of scattering upon the wave-length of the light can be settled in the case of very small particles by an application of the method of dimensions. The particle acts as a centre for a radiating beam. The amplitude of the light sent out by it at a distance R varies inversely as R; it is also proportional to the volume of the particle when this is small compared with the wave-length of the light. Thus the ratio of the scattered to the incident *intensity* varies as $\frac{V^2}{R^2}$; that is a quantity whose dimensions are those of the fourth power of a length. The ratio of intensities must, however, be a pure number; and since the wave length X is the only other linear quantity that can be concerned, the ratio must also depend on the inverse fourth power of X.

Lord **Rayleigh's** Theory.—A more detailed investigation was conducted by the third Lord Rayleigh (Phil. Mag. XLI., 107, 275) based on an elastic-solid theory of light. This enquiry showed that both the intensity and the polarization could be satisfactoriiy accounted for on such a theory, if (and only if) the vibrations are perpendicular to the plane of polarization and the difference between the substance of the particles and that of the surrounding medium is one of density only.

Later (Phil. Mag. XII. 81–101, 1881) Rayleigh examined the question from the point of view of the electromagnetic theory in which the particles are treated as dielectric spheres. Maxwell's equations can be applied exactly in the case of vanishingly small spheres. The azimuth of the electric displacement travelling in any direction in the scattered wave is at right angles to that direction and is in the plane containing the scattered ray and the azimuth of the incident displacement; further the intensity is proportional to the square of the sine of the angle between these two lines. It follows that when this angle is zero the scattered light in the given direction is zero. This occurs in the direction at right angles to the incident ray. Thus, in this case, if unpolarized light is incident the light scattered at right angles is completely polarized.

According to either theory, sunlight in penetrating through the earth's atmosphere should fall off according to an exponential law for each colour.

In order to test the theory Rayleigh compared the blue light of the sky taken from near the zenith with sunlight diffused through white paper. For different wave-lengths the ratios calculated from the formula are given together with observed values for comparison:—

Fraunhofer line	C	D	b_3	F
Calculated	25	40	63	80
Observed	25	41	70	90

It appears that the sky light when compared with that diffused through white paper was bluer than that required by theory; but this may possibly arise from yellowness of the paper or from the yellowness of the sunlight when it reaches us compared with its colour at higher levels.

A much more important calculation has reference to the size and number of the particles concerned in the production of the blue of the sky. Since the light scattered by each particle is proportional to the square of its volume the total amount scattered per unit volume depends not only upon the quantity of matter therein but upon its fineness of division 'also. Assuming that the molecules of the air are the effective scatterers Rayleigh in 1899 calculated (taking Maxwell's value 19×10^{18} for the number of moletules per unit volume of a gas at standard pressure and temperature) that sunlight should diminish to $\frac{1}{e}$ of its value in passing through a distance of 83 kilometres in normal air. This value might agree roughly with the visibility of Mount Everest from Darjeeling but Rayleigh considered that it implied too high a visibility since there is certainly suspended matter to be reckoned with as well. Small particles of saline or other matter (including organic germs) must play a part and to them may be attributed much of the bluish haze by which the moderately distant landscape is often suffused.

American Investigations.—In recent years considerable attention has been paid to this question in America where advantage could be taken of the remarkable clearness and dryness of the air above Mount Wilson in California. F. E. Fowle in these investigations has obtained values of the transparency coefficients for zenith observations for 30 different wave-lengths between $0{\cdot}34\ \mu$ and $2{\cdot}24\ \mu$ (μ = one millionth of a metre). The logarithms of the observed coefficients were plotted as ordinates against the corresponding quantities of precipitable atmospheric moisture as abscissae. The curves which were very nearly straight were extrapolated to zero moisture so as to obtain the transparencies for perfectly dry air. From these values for dry air the number of molecules per c.c. was calculated by means of Rayleigh's formula. The value obtained was $2{\cdot}7\times10^{19}$, while the best value obtained by Millikan by other methods is $2{\cdot}705\times10^{19}$. The conclusion drawn from this result is that for the clear air above Mt. Wilson the scattering is almost entirely due to the molecules of air themselves. (Fowle, *Astroph.* J. 1914.)

Tyndall's Residual Blue.—The experiments of Tyndall upon precipitated clouds have been mentioned. When the precipitated particles are very fine, the light dispersed in a perpendicular direction is sky-blue and fully polarized. At a further stage of their growth the particles disperse in the perpendicular direction a light which is no longer fully polarized. When quenched as far as possible by rotation of a nicol prism, it exhibits a residue of a more intense blue colour; and further it is found that the direction of the most nearly complete polarization becomes inclined to the direction of the primary rays.

Electromagnetic Theory.—A discussion of these and other questions upon the basis of the electromagnetic theory of light is given in the Phil. Mag., 1881, 12, p. 81. Here we must be content with a statement of some of the results. So long as the particles are supposed to be very small and to differ little from their environment in optical properties, there is little differencebetween the electric and the elastic solid theories. Whatever may be the shape or size of the particles, there is no scattered light in a direction parallel to the primary electric displacements. In order to render an account of Tyndail's "residual blue" it is necessary to pursue the approximation further, taking for simplicity the case of spherical shape. We learn that the light dispersed in the direction of primary vibration is not only of higher order in the difference of optical quality, but is also of order k^2c^2 in comparison with that dispersed in other directions, where c is the radius of the sphere, and $k=2\pi/\lambda$. The incident light being white, the intensity of the component colours scattered in this direction varies as the inverse eighth power of the wave-length, so that the resultant light is a rich blue.

As regards the polarization of the dispersed light as dependent on the angle at which it is emitted, we find that although, when terms of the second order are included, the scattered light no longer vanishes in the same direction as before, the peculiarity is not lost but merely transferred to another direction. The angle θ through which the displacement occurs is measured backwards, *i.e.*, towards the incident ray, and its value is given by

$$\theta=\frac{\Delta K}{K}\,\frac{k^2c^2}{25}, \qquad (23)$$

AK being the difference of dielectric constants.

Experiments upon this subject are not difficult. In a darkened room a beam of sunlight (or electric light) is concentrated by a large lens of 2 or 3 ft. focus; and in the path of the light is placed a glass beaker containing a dilute solution of sodium thiosulphate (hyposulphite of soda). On the addition, well stirred, of a small quantity of dilute sulphuric acid, a precipitate of sulphur slowly forms, and during its growth manifests exceedingly well the phenomena under consideration. The more dilute the solutions, the slower is the progress of the precipitation. A strength such that there is a delay of 4 or 5 minutes before any effect is apparent will be found suitable, but no great nicety of adjustment is necessary.

Polarization. — In the optical examination we may, if we prefer it, polarize the primary light; but it is usually more convenient to analyze the scattered light. In the early stages of the precipitation the polarization is complete in a perpendicular direction, and incomplete in oblique directions. After an interval the polarization begins to be incomplete in the perpendicular direction, the light which reaches the eye when the nicol is set to minimum transmission being of a beautiful blue, much richer than anything that can be seen in the earlier stages. This is the moment to examine whether there is a more complete polarization in a direction somewhat oblique; and it is found that with θ positive there is, in fact, a direction of more complete polarization, while with θ negative the polarization is more imperfect than in the perpendicular direction itself.

The polarization in a distinctly oblique direction, however, is not perfect, a feature for which more than one reason may be put forward. In the first place, with a given size of particles, the direction of complete polarization indicated by (23) is a function of the colour of the light, the value of θ being 3 or 4 times as large for the violet as for the red end of the spectrum. The experiment is, in fact, much improved by passing the primary light through a coloured glass. Not only is the oblique direction of maximum polarization more definite and the polarization itself more complete, but the observation is easier than with white light in consequence of the uniformity in the colour of the light scattered in various directions. If we begin with a blue glass, we may observe the gradually increasing obliquity of the direction of maximum polarization; and then by exchanging the blue glass for a red one, we may revert to the original condition of things, and observe the transition from perpendicularity to obliquity over again. The change in the wave-length of the light has the same effect in this respect as a change in the size of the particles, and the comparison gives curious information as to the rate of growth.

But even with homogeneous light it would be unreasonable to expect an oblique direction of perfect polarization. So long as the particles are all very small in comparison with the wave-length, there is complete polarization in the perpendicular direction; but when the size is such that obliquity sets in, the degree of obliquity will vary with the size of the particles, and the polarization will be complete only on the very unlikely condition that the size is the same for them all. It must not be forgotten, too, that a very moderate increase of dimensions may carry the particles beyond the reach of our approximations.

The fact that at this stage the polarization is a maximum, when the angle through which the light is turned *exceeds* a right angle, is the more worthy of note, as the opposite result would probably have been expected. By Brewster's law this angle in the case of regular reflection from a plate is *less* than a right angle; so that not only is the law of polarization for a very small particle different from that applicable to a plate, but the first effect of an increase of size is to augment the difference.

Sunset **Colours.**—The simple theory of the scattering of light by small particles suffices to explain not only the blue of the zenith, but the comparative absence of small wave lengths from the direct solar rays and the brilliant orange and red coloration of the setting sun and of the clouds illuminated by its rays. The hyposulphite experiment here again affords an excellent illustration. But we must not expect a simple theory to cover all the facts. It is obvious that the aerial particles are illuminated not only by the direct solar rays but also by light dispersed from other parts of the atmosphere and from the earth's surface. On this and other accounts the coloration of the sky is highly variable. The transition from blue to orange or red at sunset is usually through green, but exceptional conditions may easily disturb the normal state of things. The brilliant sunset effects observed in Europe after the Krakatoa eruption may naturally be attributed to dust of unusual quality or quantity in the upper regions of the atmosphere.

To illustrate further the complications that arise when the particles are not infinitely small it may be mentioned that if the solution of hypo prepared as above be observed for a longer time it becomes more opaque as a result of the growth of the sulphur particles and afterward becomes more transparent again even though kept well stirred; and further that in this last stage it transmits blue more than red and consequently scatters red more than blue. This is a complete reversal of the blue-sky effect. (Keen and Porter, *Roy. Soc. Proc. A. 89*, 370, 1914.) A similar phenomenon had previously been observed by Capt. W. de W. Abney and by W. Ritz. Abney says in connection with certain suspensions of silver bromide in collodion: "In some cases I obtained it in such a state which, when viewed by transmitted light, appeared of a sky-blue colour inclining to green." (Abney, *Phil. Trans. Roy. Soc.*, pt. ii, p. 653, 1880; W. Ritz, *Comptes Rendus 143*, 167, 1906.) This phenomenon is well known to preparers of emulsions for photographic plates.

Related to abnormalities of colour we may expect to find corresponding abnormalities in polarization. Of this nature are the neutral points, where the polarization changes character, observed by F. J. D. Arago, J. Babinet and Sir D. Brewster for an account of which reference may be made to Mascart, *Traitk d'optique.* (R.; *A.W.* Po.)

SKYE, the largest island of the Inner Hebrides, Inverness-shire, Scot. From the mainland it is separated by the Sound of Sleat, Kyle Rhea, Loch Alsh and the Inner sound, and from the Outer Hebrides by the Minch and Little Minch. At Kyleakin, on the western end of Loch Alsh, the channel is only about $\frac{1}{4}$ mi. wide, and there is a ferry. The length of the island from southeast to northwest is $48\frac{1}{2}$ mi., but its coast is deeply indented, so that no part of the interior is more than 5 mi, from the sea. It has a total area of 670.3 sq.mi. The population was 23,082 in 1841, 9,908 in 1931 (or 10.3 to the sq.mi.) and 8,632 in 1951.

The chief arms of the sea are Lochs Snizort and Dunvegan in the north, Loch Bracadale in the west, Lochs Scavaig and Eishort in the south and Loch Sligachan in the east. The jagged mass of the Cuillin hills (Coolins) dominates the view whether by land or sea. Their highest point is Sgurr Alasdair (3,309 ft.) and at least six other peaks exceed 3,000 ft.

To the north of Loch Slapin stands the grbup of Red hills of which the highest points are Ben Caillich and Beinn Dearg Mor and near Loch Ainort rises Ben Glamaig. About 8 mi. N. of Portree is the curious basaltic group of the Storr, consisting of pinnacles and towers, the most remarkable of which, the Old Man, forms a landmark for sailors.

Most of the land is moor and hill pasture but during the first half of the 20th century there was a considerable development in agriculture. The crofting system was still general at mid-20th century and while more crops were grown, the climate appeared to be better adapted for sheep and cattle. In 1953 there were approximately 104,284 sheep and 11,000 cattle on the island. The farms and small holdings were stocked principally with Black-faced sheep although there were also Cheviot stocks. The condition of the crofters, which was pitiable in the extreme, was greatly improved by the Small Landholders (Scotland) acts 1886–1911, and in later years by the introduction of the government subsidies for cattle, potatoes and, until mid-20th century, sheep. The introduction of grants for various purposes enabled the black houses to be replaced principally by houses built of brick or concrete. With the opening in 1952 of the Storr Lochs hydroelectric power scheme, approximately 95% of the houses were supplied with electricity. The many ejections between 1840 and 1880 and the emigration that followed were mainly responsible for the serious decline of the population.

While the railheads at Kyle of Loch Alsh and Mallaig make the mainland markets accessible, road transport is extensively used. The fishing industry, which was at one time the mainstay of the population, declined during the first half of the 20th century. Whisky is distilled at Carbost. At Loch Cuithir, 4 mi. N. of Storr, work on the extensive diatomite deposits was restarted and in 1953 a factory, in which the raw material is processed, was opened at Uig. An afforestation scheme led to the reopening in 1953 of one of the 18 forestry schools closed as a result of the depopulation of the island.

The inhabited isles off the coast of Skye are mainly situated near the eastern shore. Of these the principal is Raasay, 13 mi. long by about $3\frac{1}{2}$ mi. at its widest. Off its northwestern shore lies the isle of Fladda. To the north of Raasay is Rona (seal island, from the Gaelic *ron,* a seal), $4\frac{1}{2}$ mi. long with a maximum breadth of $1\frac{1}{4}$ mi. The island is now unoccupied except for the lighthouse keepers whose families were removed to Portree in 1952. Scalpay, immediately south of Raasay, has a hill of 1,298 ft. The other isles are Pabay, Ornsay and Soay. The islanders of Soay mere evacuated in 1953 to Mull where they were established on new holdings by the department of agriculture for Scotland.

Portree (pop. of parish 1,766), the capital, lies at the head of a fine harbour about the middle of the eastern seaboard. Steamers run daily to and from Mallaig and Kyle of Loch Alsh. There is a factory for tweeds, tartans and other woolens. During the cattle sales, held twice a year, large numbers of sheep and cattle are transported to the railhead at Kyle of Loch Alsh. The name Portree was derived from the fact that James V landed there during his tour of the western Highlands. The place thus became, in Gaelic, Port-an-Righ (the king's harbour).

It was to Portree that Flora Macdonald (1722–90) conducted Prince Charles Edward when he escaped from Benbecula. The sheriff's courthouse is situated in Portree.

Among other places in Skye associated with the Young Pretender are Prince Charles's point near Monkstadt, where he landed with Flora Macdonald, and Kingsburgh, on the eastern shore of Loch Snizort. The castle of the Macleods of Macleod, on a rocky promontory at Dunvegan. was erected in the 9th century and is reputed to be the oldest continually inhabited house in Scotland. The MacCrimmons, the famous race of hereditary pipers, hailed from this quarter of Skye and mere attached to the Macleods of Dunvegan. At Duntulm is the ruined castle of the Macdonalds. another of the great clans of Skye chieftains. There is also much of archaeological interest in Skye. (J. Pp.)

SKYSCRAPER: see ARCHITECTURE.

SLAG. A waste substance of many kinds formed during smelting operations. Thus, in the blast furnace, limestone is charged with the coke and iron ore to form with the ash of the fuel and the gangue of the ore a lime silicate or slag which is run out of the furnace liquid, taking with it the sulfur. Blast furnace slags are of variable composition, the quantity of limestone used varying with the nature of the ore. In the basic process of steel manufacture, which employs phosphoric ores, the resulting slag, rich in phosphorus (as soluble calcium phosphates) is known as "basic slag" and forms a very valuable manure. See IRON AND STEEL; METALLURGY: Basic Steel.

SLANDER: see LIBEL AND SLANDER.

SLANG, an informal and colloquial variation of or addition to standard speech. It may be a variation in any element of a language — in its sounds ("atta dirl"). in its stress ("positively"), in its intonation ("Is that so?"), in its syntax ("We was robbed"); but it is in vocabulary ("spiv") and meaning ("She's a peach") that slang is commonest.

Slang is formed by normal linguistic processes found in all living languages, processes such as compounding ("low-down," "sob-stuff"), word clipping ("pro," "mike," "pix"), abbreviation ("O.K.," "v.i.p.," "snafu," "q.t."), onomatopoeia ("boom," "whiz," "bang"), generalization of proper names ("bobby," "guy," "real McCoy"), borrowing from dialects and foreign languages ("vamoose," "savvy," "pronto," "loco") and extension of meaning by analogy ("Park your hat," "He got pickled").

Slang and Society. — People belonging to the same social group — of the same trade, profession, hobby, age or social position — tend to behave in the same way. This behaviour influences not only the clothes they wear but also the language they use. The language of a social group, particularly its slang, is one of several forms of behaviour that keep the group distinct from other groups. As a verse writer has aptly put it, "The chief use of slang/Is to show that you're one of the gang" (R.D.C. in the New Statesman and Nation, London. Nov. 16. 1946).

One of the commonest social groupings is that of people who work together. Students have their "lab" and their "gym." Secondhand car dealers have their "creampuffs" (excellent cars) and their "dogs" (dilapidated ones). For an order of poached eggs on toast a waitress may tell the cook to "drop two on." To a television producer a poor show may be a "wart." A circus "geek" (conditioned freak) can use a "stick" (decoy) to attract a "tip" (prospective customer); but this is not the same sort of tip that a hotel porter might expect from a "front" (inexperienced traveler). A professional flyer may wear a "brain bucket" (crash helmet) in case he has to "buy a farm" (crash); but his "soup" (horsepower) has nothing to do with the "soup" (nitroglycerin) of the professional safe-cracker. "Cat" does not refer to the same thing in the underworld as it does in the jazz world. Yet both underworld and jazz slang formed the basis of much of the "teen talk" of the 1950s.

Some social conditions are more favourable than others to the creation of slang. Excitement, crowding and the sudden regrouping of people for a particular purpose, as in wartime, may result in the formation of a large number of slang words. This goes on from person to person, from ally to ally and from one side to the other. All the participants learn things about the others, and all come out with larger vocabulariee. Forceful expressions by the thousand are created and used by members of the armed forces. "Big Bertha" is remembered as the nickname of the long-range German cannon in World War I, immortalizing Bertha Krupp of the munitions family. The innocent-sounding "pineapple" of the same war was a hand grenade with markings suggestive of the fruit. World War II added another type of grenade, the "Molotov cocktail," and a vast new vocabulary of slang including such words as "blitz," "doodlebug" and "walkie-talkie." The Korean war also had its slang; Korean soldiers were known as "gooks" and as "ROKs."

A few slang expressions have spread far beyond their original linguistic boundaries. This is the case of "O.K.," the international sign of approval. Originally an American term, it has become a household word in languages throughout the modern world. There are a number of theories on the origin of this popular expression. One is that it stands for the nickname "Old Kinderhook." meaning Martin Van Buren. eighth president of the United States, who was born and died at Kinderhook, N.Y. It was used by his supporters as early as 1840, and within a few years acquired its present meaning.

How Slang Develops. — The witticism of a single person may be enough to launch a new slang form. The novelty may produce a response so effective that it is taken up by others and soon becomes widespread. The more it is used, the more popular it becomes, especially if it is used by associates or admired persons. But after much use the novelty wears off, and the expression, having no special effect and therefore no further function, dies out. If, however, the older form or its central meaning has in the meantime gone out of fashion, the slang expression may remain in use as the normal form. This was the case when the Latin word testa (earthen pot), used jocularly to describe the head of a baldheaded man, supplanted the normal word *caput* and later became the usual form for head in Italian (testa) and in French (*tête*). Similarly. gamba ("hoof"). the Latin slang word for leg, became the standard word for leg in both French (*jambe*) and Italian (gamba), the latter being the word from which "gam" in modern American slang was most probably derived.

When literary men in the 17th century wrote about the "common people" they often used a Latin expression, mobile *vulgus,* meaning the fickle or movable crowd. Sometimes in writing this was abbreviated to mob. vulg. Later the vulg. was dropped, and careless writers began to use mob. alone, still pronouncing it in full, *mobile.* The next step was to say simply *mob,* which was considered shockingly low and regarded as the crudest type of slang. The usage persisted, and in the 18th century "mob" became tolerated in conversation, although not in writing. Early in the 19th century came another promotion, and the word, at long last, entered the ranks of standard English. A similar process was responsible for about 2% of English "dictionary" words; such words as "trip," "bet," ".donkey," "shabby," "chap," "bore," "cab" and "kidnap" were once condemned as slang.

Some words may remain as slang for centuries, neither disappearing nor becoming part of the standard vocabulary Such is the case of the medieval "booze," the Elizabethan "rook" (verb) and the 18th-century "swop." The same applies to certain expressions such as "dead as a doornail," which was used in the 14th century and may have been old even then. In the 16th century Shakespeare, in *Twelfth Night,* wrote "laugh yourselves into stitches." In the 17th century George Fox, founder of the Quakers, wrote about a professional man who had "done his stuff," proving early currency for another expression still in use.

Yet for every slang expression that has lived, hundreds of others have died. "Gamp" was once the usual slang name for an umbrella. It was named after a large, bulging umbrella carried by Sairey Gamp, a character in Charles Dickens' *Martin Chuzzlewit,* published in 1844. In the latter part of the 19th century it became a well-established colloquialism, but it was hardly important enough to last.

It is in the area of fundamental emotions that slang is most changeable and most productive The slang of approval ("swell," "nifty," "bong," "zorch," "the end." "real dizzy") and disapproval ("phooey," "nuts," "boloney," "hogwash," "balderdash." "poppycock") may change within a generation. So may the words for woman and girl ("skirt." "biscuit," "swan"). and these are usually numerous in any generation. When a young man refers to his sweetheart as his "soul mate," his "steady." his "main dish," his "heavy" or his "onliest" he has hardly made a beginning; he could use a different expression every day for three years and still have words left over for variety. It is the same with money, which has unconventional synonyms by the bookful, including such picturesque terms as "berries," "cabbage," "chink," "ducats," "honey," "jack," "mazuma," "potatoes," "simoleons," "spondulics" and "wampum." The expression "to die" seems much too commonplace; a person is said to "drop off," "fade out," "go to grass," "go under," "go up," "go west," "kick the bucket," "ring down the curtain," "shuffleoff" or "push the clouds." with probably a thousand variations. A person suffering from the effects of drinking to excess is said to be "afloat," "blowed," "boozy," "cockeyed," "corned," "disguised," "fractured." "groggy," "high as a kite," "ratty," "stewed," "vulcanized" or "zigzag." The idea of stealing is expressed in slang in many forms, some of them with a disarming suggestion of innocence, such as "promote," "salvage," "rustle" and even "liberate." Other synonyms. ranging all the way from "annex" and "appropriate" to "souvenir" and "freeze onto," would easily exceed the thousand mark. The same may be said of all fundamental words, the ones first used by children and by "primitive" people. They seem to seek synonyms—humorous. satirical, poetical, euphemistic or merely roughly descriptive—in slang.

Catch Phrases.—Catch phrases, more or less related to slang, are of many kinds, ranging from the whimsical and witty to the meaningless and inane. Popular catch phrases in the 19th century included "Who stole the donkey's bed?" addressed to men wearing straw hats; "What a tail our cat has," a bantering reference to a woman's new dress; "Does your mother know you're out?" a supposedly funny remark of wide application. Many 19th-century examples were based on music-hall songs, as "Where did you get that hat?"; "Shoo, fly, don't bother me"; and "A hot time in the old town tonight." A similar specimen in the 20th century, "Yes, we have no bananas," might very well have invited the retort "and no sense." Catch phrases still come and go, and still will bear study, for they tend to reveal the processes, mental or emotional, of the people who utter them.

Artificial Types.—Since one of the functions of slang is to prevent members of other groups from understanding what is said, it is not surprising that attempts have been made to create systems of slang to function as secret languages. These include such artificial types as rhyming slang, back slang and centre slang. Rhyming slang was used by certain Cockney groups as early as 1840; it spread to the Australian underworld and in the 1950s became popular among the young "teddy boy" gangs in London and other English cities. In rhyming slang a wife becomes "trouble and strife," a road a "frog and toad" and a suit a "whistle and flute." This becomes even more secret when the rhyming word is omitted, whereby a road becomes a "frog," a suit a "whistle," a hat a "tit for" (tat) and mouth a "north" (and south). Back slang consists in saying a word backward with any alteration necessary to make it more pronounceable. In this way a game becomes an "emag," a market a "tekram," drunk "kennurd" and police "slop." In centre slang, the first syllable of the slang word is formed from the first vowel of the standard word and the consonant that follows it; the other syllables may be made in a number of ways, either with fixed or free suffixes. To call a man a fool in centre slang, such terms as "oolfoo," "oolerfer" and even "hoolerfer" could be used.

National Slang.—Since about half the world's English-speaking people are citizens of the United States, it is not surprising that world English shows traces of American influence. This influence, which tends to create variety but not disunity, extends into the field of slang. The Americanizing process has been aided by radio and films; but it should be pointed out that communication is a two-way street and that Americans have not been slow to import "Briticisms."

A study of the lists of American and British slang appended to this article will show that the line between the two is becoming increasingly tenuous. Australian and New Zealand slang, of which lists are also given, are relatively independent of outside influence, European or American.

On the continent of Europe, slang was being recognized as early as the 12th century and studied at least as early as the 15th, when François Villon used it and probably added to it in some of his immortal ballades. A generation later. in Germany, Martin Luther wrote a preface to the 1529 edition of *Liber Vagatorum (Book of Vagabonds)* and gave his views on the vocabulary of vagabonds' slang featured in that work. Villon and Luther had one thing in common—they were both writers, and writers recognized, then as now. the strong human appeal of certain types of slang.

Attitudes Toward Slang.—Some writers have condemned all slang, especially that of hostile classes. They have called it vulgar, corrupted, uncultured, secret and false, the dialect of the rabble, of beggars, of gypsies and of thieves. Others have praised slang as creative activity. In England the critic G. K. Chesterton said that "all slang is metaphor." In the U.S. the semanticist S. I. Hayakama called slang "the poetry of everyday life." According to the scientific view, slang in itself is neither good nor bad. It is part of the natural growth of language. A living language must continually change. and some of the changes first appear as slang. Some slang makes the language capable of new and delicate shades of meaning or adds vividness, clarity and directness to everyday expressions. Other slang expressions are vague in meaning, cover too much ground or duplicate better conventional vocabulary. The use of slang is sometimes quite appropriate in informal writing, but it is usually out of place in formal, scientific or academic writing.

Reasons for Studying Slang.—When Elisha Coles issued his *English Dictionary* in 1676, he explained the inclusion of a number of slang words and expressions by saying, " 'Tis no Disparagement to understand the Canting Terms: It may chance to save your Throat from being cut, or, (at least) your Pocket from being pick'd." Reasons less ominous impel the modern student, who knows that from slang much can be learned about the history, customs, fashions, the very thoughts of people far away or long ago. The study of unconventional speech is of immense value to authors and playwrights.

Bibliography.—For practical purposes, books regarding slang can be divided into two classes, early (virtually unobtainable) and modern (1900 to date). The latter include a few popular works, such as the

Dictionary of Slang and Unconventional English, 4th ed. (New York, 1952) by Eric Partridge, or his *Dictionary of the Underworld, British and American* (New York, London, 1950). In *American Thesaurus of Slang* by Lester V. Berrey and Melvin Van den Bark, 2nd ed. (New York, London, 1953), the words and expressions, though not individually defined, are minutely classified and indexed. H. L. Mencken's *The American Language,* 4th ed. (New York, 1945), and its two supplements (1945, 1948) contain much lively material on slang. *A Dictionary of Americanisms on Historical Principles* (Chicago, London, 1951), ed. by Mitford M. Mathews, includes many slang expressions, with dated quotations. Current studies, many of them of interest in British circles, appear in the periodical *American Speech* (1925–). Australasian slang is discussed in Sidney J. Baker's *Australia Speaks* (London, 1953) and *New Zealand Slang* (Christchurch, 1941). War slang is represented in *A Dictionary of Forces' Slang, 1939–1945* (Philadelphia, London, 1948) by Eric Partridge, Wilfred Granville and Frank Roberts; also in *Dictionary of Service Slang* (New York, 1944) by P. Kendall. *The Literature of Slang* by W. J. Burke (New York, 1939) is a useful bibliography. Underworld slang is represented in Hyman E. Goldin (ed.), *Dictionary of American Underworld Lingo* (New York, 1950). French slang, from ancient times to the 20th century, is described, classified and indexed in Albert Dauzat's authoritative book *Les Argots* (1929). German slang is likewise discussed and listed in *Wörterbuch der Kunden-und Gaunersprache* (1939) by A. Bertsch. (A. McQ.; W. F. My.)

AMERICAN SLANG

Following is a list of American slang of various periods but still in use after 1957. See also the list of British slang, some of which is used by Americans.

Attaboy (that's the boy), fine!
Back number, superannuated
Balled up, confused; mixed up
Bang up, excellent
Bat, a spree
Bawl out, to rebuke sharply
Beanery, cheap eating place
Beasted, stuck on a date
Beat it, to get out; make a rapid exit
Berry, dollar
Biff, to strike

Tanner, a sixpence
Topping, excellent
Tuck in, to eat heartily
Wangle, obtain by cunning
Whack, a share; **to share out**
(A. McQ.; W. F. MY.)

CANADIAN SLANG

Much American and British slang is understood in different parts of Canada (population, almost 16,000,000 in 1957). More than three-quarters of the slang used in Canada is American; the remainder is made up of British slang (old and new) and Canadian localisms of which the following are samples:

Bangbelly, bread and molasses pudding
Banker, fishing vessel
Bennett buggy, automobile drawn by horses
Beveraged, licensed to sell liquor
Blue ruin, gin
Clinkerbells, icicles
Colony house, pigsty
Dog's nose, beer mixed with **gin**
Dolly varden, cup
Devil-dodger, parson
Forty-rod. strong whisky
Gob-stick, spoon or fork
Gridiron, U.S. flag
Hard-rock, rough, uncouth person
Herring choker, Maritimer, esp. from Nova Scotia
Hydro, electric power commission
Jig, day's work
Liveyer, Newfoundlander
Mountie, member of the Royal Canadian Mounted Police
Nitchie, native Indian
Pea soup, French Canadian
Prairie oyster, raw egg yolk in whisky or hot sauce
Pump-sucker, nondrinker
Salt chuck, ocean
Scouch, stew
Solomon gouse, pork and cabbage
Spotted dog, raisin pudding
Storms, storm windows
(W. F. MY.)

AUSTRALIAN SLANG

In proportion to Australia's population (less than 10.000.000 in 1957) and history (since 1788), its slang is probably the most vigorous linguistic growth of its kind in the world. More than 10.000 Australianisms have been listed; representative examples:

Abo, aboriginal; aborigine
Art union, a lottery, the prizes of which are in kind, not money
Aussie, Australia; an Australian
Backblocks, sparsely inhabited inland areas
Bail up, to hold up and rob; to corner
Banker, a flooded river running banks high
Barrack, to shout or jeer at opponents; also, barrack for, to support; barracker, a partisan
Berley, small pieces of food scattered on water to attract fish
Billabong, a quasi-oasal river bend
Billy, a tin can used for boiling tea and cooking; also, billycan
Binghi, an aboriginal; also, boong, blackfellow
Block (do one's), to become angry or excited
Blow-in, a newcomer
Bludge, to impose on; whence, bludger
Blue, a summons; an error; a fight
Bluey, a swagman's bundle; also called a swag, drum or matilda
Board, the floor of a shearing shed
Bombo, cheap wine; also called plonk
Bone, to direct a ceremonial "death curse" against a person; also point (sing) a bone
Bonzer, good, excellent
Borak at (poke), to jeer at; make fun of
Bowyang, a strap or string fixed below the knees of a worker's pants to keep the cuffs off the ground
Boxer, a bowler hat
Brumby, a wild horse
Bucker, buckjumper, a refractory horse
Buckley's chance, no chance at all
Bullocky, a bullock driver
Bumper, a cigarette butt; "not worth a bumper," worthless
Bung (to go), to peter out, to die
Burl (give it a), to make an attempt at
Bush. forestlands; the inland country in general; also, "go bush." to decamp or hide; "bushed," confused; "bushranger," an outback bandit
Cat (whip the), to cry over spilt milk
Chloe (drunk as), extremely

drunk
Chromo, a prostitute
Chyack, impudence; cheek
Cobber, a friend
Cockatoo, a small farmer; also, cocky

Cooee, a penetrating cry; also verb
Cossie, a swimming costume
Cow, an objectionable person or thing
Crack hardy, to put on a brave face against misfortune
Crook, ill; worthless; "go crook," to become angry
Cut out, to complete a task
Damper, bush bread baked in ashes or a camp oven
Dead ring of, exactly similar to
Deaner, a shilling
Digger, an Australian soldier
Dillybag, a native bag made of grasses or fur twisted into cord
Dingo on (someone), to betray
Dinkum, true; honest; also, "dinky die," "fair (square) dinkum"
Do a perish, almost to die for want of a drink
Doover, a thingumbob
Dreaming, any source of native legend-
Drop one's bundle, to become panicky
Duffer, a cattle thief; whence, duffing
Fizgig, a police informer
Fossick, to search for surface gold; to look for something; whence, fossicker
Full as a goog, completely full; extremely drunk
Furphy, a baseless rumour or canard
Game as Ned Kelly, highly reckless or courageous
Gin, a native woman
Graft, hard work
Gumtree (up a), in a quandary
Guyver, tall talk; affectation
Hard case, a reckless or amusing person
Hatter, a man who lives and works alone
Haven't a skerrick, to be penniless
Haven't the bolter's, to have no chance at all of success
Hop, a policeman; also John Hop
Humpy, a hut; a small shack
In smoke, in hiding
Jackeroo, a young station hand, learning sheep or cattle farming
Jacko, a kookaburra; also, jack, jackass
Jimmy Woodser, a solitary drinker
Joey, a young kangaroo; a baby; a lie
Jumbuck, a sheep
Keep nit. to mount guard while some illegal activity is afoot; also, to cockatoo
Kidstakes, pretence; foolery, nonsense
Lair, a flashily dressed youth; "lairy," flashily or showilv dressed
Larrikin, a street tough or hoodlum
Larry (happy as), completely happy
Lolly, a sweetmeat
Lubra, a young native woman
Lurk, a scheme; racket; also, dart, rort
Maoriland, New Zealand; also, Enzed, Pig Islands, Shakey Isles
Merino (pure), first class in quality
No good to gundy, worthless
Nohoper, a person who has no prospects of success
Nuggety, short; thickset; sturdy
Offsider, a helper or companion
Old identity, an old, noted inhabitant of a locality
Oscar, money; ready cash
Outback, the inland country or bush
Paddock, any fenced area of land
Pastoralist, any farmer engaged in the primary industries
Perform, to curse luridly; to give way to temper
Plonk, cheap wine
Poddy, a hand-fed calf
Point, to take unfair advantage of another; to loai; to malinger
Pommy, an English-born person
Possie, a place or position
Push, a gang or clique
Put the hard word on, to lodge an urgent demand
Putty (up to), worthless
Rafferty rules, no rules at all
Ratbag, an eccentric person
Ready up, to conspire; to fake; as a noun, a conspiracy, a "stew"
Reff, reffo. a refugee from Europe
Removalist, a person or firm engaged in shifting household effects
Ridge, excellent, genuine
Ringer, the fastest shearer in a woolshed; any expert
Ropeable, angry; savagely ill-tkmpered
Rough as bags, unpolished; crude
Rouseabout, a handy man on a sheep or cattle station
Rouse on, to upbraid; reprove
Run, a large farm for sheep or cattle
Sandy blight, a form of ophthalmia
Scale, to ride on a tram, train or bus without paying
Shanghai. a catapult
Sheila, a girl
Shicer, shyster; a swindler or crook
Shicker, intoxicating liquor; whence, "shickered," drunk
Shivoo, a spree; party
Shout, to stand treat
Silvertail, a social figure; a social climber
Slygrog, liquor sold illegally; also, a place where such liquor is sold
Smoodge, to make love to; to curry favour
Snags, sausages; also, snorks, snorkers
Sool on. to incite
Southerly buster, a wild wind or gale from the south
Squatter, the owner of a large sheep or cattle station
Squib, a coward
Station, as for "run"
Stickybeak, an inquisitive person
Stoush, to hit; thrash; as noun, violence
Sundowner, a tramp of indolent habits
Swag, see Bluey; swagman, swagger, swaggie, a tramp
Swy, as for "two-up"
Tassie, Tasmania; a Tasmanian
Tinny, extremely lucky
Tipslinger, a race tipster
Top end, far north Australia; whence, "topender," a resident of the far north
Tote, a totalizator or pari-mutuel
Trot (a good), a sequence of successes; "bad trot," a sequence of failures
Tucker, food
Two-up, a gambling game played with two pennies
Urger, a race tipster; a trickster's confederate
Waddy, a stick or club
Wake-up (a), an alert person
Waler, whaler, an idolent tramp; especially, Murrumbidgee waler
Walkabout (go), to travel; wander
Wallaby (go on the), to wander in the outback
Waltz matilda, to go on the tramp
Weekender, a week-end holiday residence
Whacko! an ejaculation of pleasure
Whinge, to complain; grouse; whence, whinger, whinging
White ant (to), to undermine or sabotage
Willy willy, a wild storm of tornadic type
Wog, a germ; parasite; small insect
Woolshed, the building on a run or station wherein sheep shearing takes place
Woop Woop, the (hypothetically) most rustic of all rustic townships
Wowser, a puritanical fanatic; bluestocking
Yabber, to talk; chatter
Yacker, work
Zack, sixpence
Ziff, a beard

NEW ZEALAND SLANG

Most of the terms listed under Australian slang are known in New Zealand (population less than 3,000,000 in 1957). Some of the following, all of which originated in New Zealand, are also common to both countries.

All Blacks, New Zealand representative footballers
Batch, a small shack or cottage; "batcher," one who lives alone
Bot, a cadger or parasite
Box of birds, happy; in full health
Enzed, New Zealand; "Enzedder," a New Zealander
Fire in the fern, trouble; smouldering discontent
Half-pie, worthless
Have the wood on, to have an advantage over
Hoot, money
Kai, food
Kit, a shopping basket
Over the fence, unreasonable
Pakeha, a white man
Pie at, expert at; efficient
Wahine, a woman
Whare, a small shack or cottage

(S. J. Br.)

SLATE, in geology, fine-grained argillaceous or clayey metamorphic rock which cleaves or splits readily into thin slabs having great tensile strength and durability. Some other rocks that occur in thin beds are improperly called slate because they can be used for roofing and similar purposes. True slates do not, as a rule, split along the bedding, but along planes of cleavage, which may intersect the bedding at any angle, usually, in the case of good roofing slates, at high angles. The original material was a fine clay, sometimes with sand or volcanic dust, and the bedding of the sediment as originally laid down may be indicated by alternating bands, differing in colour or in lithological character, sometimes to be seen on the cleavage faces of the slates. Cleavage is a superinduced structure, the result of pressure acting on the rock at some time when it was deeply buried beneath the earth's surface. On this account slates are found chiefly among the rocks of the older geological systems, although some occur in regions where comparatively recent rocks have been folded and compressed as a result of mountain-building movements in the earth's crust.

In thin sections for microscopic examination, slates show much colourless mica in small, irregular scales, which in the best average about 2,000 to the inch in breadth and 6,000 to the inch in thickness. Green chlorite in flakes is also usually abundant, the principal other ingredient being quartz, in minute lens-shaped grains. In colour, slates may be black, blue, purple, red, green or gray; dark slates usually owe their colour to carbonaceous material or to finely divided sulfide of iron, reddish and purple varieties to the presence of oxide of iron in the form of hematite and green varieties to the presence of much chlorite.

Slates are made or split from quarried blocks about three inches thick. A chisel, placed in position against the edge of the block, is lightly tapped with a mallet; a crack appears in the direction of cleavage, and slight leverage with the chisel serves to split the block into two pieces with smooth and even surfaces. This is repeated until the original block is converted into 16 or 18 separate "slates," the thickness of which depends upon many circumstances, such as quality of rock, size required and purpose for which it is to be used, the average thickness of a roofing tile of the best kinds of slate being about $\frac{1}{6}$ in. The slates are afterward trimmed to size, either by hand, in which case they are cut between a fixed sharp edge and a movable knife acting on the principle of a paper cutter, or by means of machine-driven rotating knives.

Slate is sold both as dimension slate and crushed slate (granules and flour). Dimension slate is used mainly for electrical panels, laboratory table tops, roofing and flooring and blackboards. Crushed slate is used on composition roofing, in aggregates and as a filler. Principal production in the United States is from Pennsylvania and Vermont; lesser quantities are quarried in Maine, New York, Virginia, Georgia, Arkansas and California. North Wales provides most of the slate used in the British Isles. See also STONE. (F. J. N.; F. J. P.)

SLATIN, SIR RUDOLF CARL VON (1857–1932), Anglo-Austrian soldier and administrator in the Sudan, was born on June 27, 1857, at Ober St. Veit near Vienna. At the age of 17 he made his first journey to the Sudan, reaching Khartum by the Nile route in Oct. 1875 in company with Theodor von Heuglin (*q.v.*). Thence he went through Kordofan to Dar Nuba, exploring the mountains of that region. He returned to Khartum in consequence of a revolt of the Arabs against the Egyptian government. There Slatin met Emin (Emin Pasha) and with him purposed visiting Gordon at Lado, Gordon at that time being governor of the equatorial provinces. Slatin, however, was obliged to return to Austria without accomplishing his desire, but Emin went to Lado, and at Slatin's request recommended the young traveller to Gordon for employment in the Sudan. In 1878, while Slatin was serving as a lieutenant in the crown prince Rudolf's regiment in the Bosnian campaign, he received a letter from Gordon inviting him to the Sudan, of which country Gordon had become governor general. Slatin arrived at Khartum in Jan. 1879. After a brief period during which he was financial inspector, Slatin was appointed mudir (governor) of Dara, the southwestern part of Darfur, a post he held until early in 1881, when he was promoted governor general of Darfur and given the rank of bey. While administering Dara, Slatin conducted a successful campaign against one of the Darfur princes in revolt, and as governor of Darfur he endeavoured to remedy many abuses. He had soon to meet the rising power of the mahdi Mohammed Ahmed (*q.v.*). Early in 1882 the Arabs in southern Darfur were in revolt. With insufficient resources and no succour from Khartum, Slatin gallantly defended his province. Though victorious in several engagements he lost ground. His followers attributing his nonsuccess to the fact that he was a Christian, Slatin nominally adopted Islam. But all hope of maintaining Egyptian authority vanished with the news of the destruction of Hicks Pasha's army, and in Dec. 1883 Slatin surrendered, refusing to make any further sacrifice of life in a hopeless cause. In the camp of the mahdi an attempt was made to use him to induce Gordon to surrender. This failing, Slatin was placed in chains, and on the morning of Jan. 26, 1885, an hour or two after the fall of Khartum, the head of Gordon was brought to the camp and shown to the captive. Slatin was kept at Omdurman by the khalifa, being treated alternately with savage cruelty and comparative indulgence. At length, after more than 11 years' captivity, he was enabled, through the instrumentality of Sir Reginald (then Major) Wingate of the Egyptian intelligence department, to escape, reaching Egypt in March 1895.

In a remarkable book, Fire and Sword *in the* Sudan, written in the same year and issued in English and German in 1896, Slatin gave not only, as stated in the subtitle, "a personal narrative of fighting and serving the dervishes," but a connected account of the Sudan under the rule of the khalifa. Raised to the rank of pasha by the khedive, Slatin received from Queen Victoria the C.B. He served as staff officer in the campaigns of 1897–98 which ended in the capture of Omdurman and was made a K.C.M.G. and in 1906 was ennobled by the emperor of Austria. He was inspector general of the Sudan from 1900 to the outbreak of World War I. His mastery of Arabic and his profound knowledge of the land and peoples proved invaluable in the work of reconstruction. In 1907 he was made an honorary major general in the British army, and in 1912 was made G.C.V.O. During World War I he presided over the Austrian Red Cross for the Aid of Prisoners of War. He died Oct. 4, 1932.

SLATING: see ROOF.

SLAUGHTERHOUSE or ABATTOIR. The slaughtering of meat animals is conducted in many ways. The farmer slaughters a single animal or a few animals depending on the needs of his family. Some retail butchers slaughter a few animals, but usually only that number which is sufficient to supply their retail trade. These slaughtering operations are frequently conducted under quite primitive conditions. Slaughtering on a wholesale basis with a volume slightly larger than the retail butcher and ranging to the capacities of large packing plants such as those located in Chicago brings into the picture the conventional slaughterhouse or abattoir. The types of slaughterhouses vary according to the volume of slaughtering operations conducted and the degree of governmental control exercised over them in a particular community.

Slaughterhouses have been a factor in the public meat supply from antiquity. Whenever, with the increase of populations, man congregated in large communities, slaughter of food animals on a wholesale basis was a natural development. Even governmental control of slaughterhouses goes back to Roman days. In Europe the slaughterhouse has continued to be largely a local institution. Its size and capacity have been determined primarily by the local needs. Moreover, its method of functioning depends to a large extent on the kind of local governmental control exercised over it. Denmark is a good example of a European country in which slaughterhouses function at the local level. That is, they are usually just large enough to satisfy the local demand for meat. Furthermore, it is required in that country that all meat offered for sale must have been produced in an abattoir which comes under governmental supervision. Under these conditions well-equipped and properly supervised slaughterhouses function at their best in providing a public meat supply.

By contrast with the European slaughterhouse whose production supplies primarily the local need, in the United States large slaughtering centres have developed in which are located slaughterhouses that ship their products to all the states in the union. This developed quite naturally because the large livestock-producing areas are several hundreds of miles from the large meat-consuming sections of the country. The history of the development of these large slaughterhouses in the United States has an interesting aspect in relation to governmental control of their slaughtering and meat-processing operations. Whereas the governmental control of slaughterhouse operations in Europe has been principally a local concern, in the United States by virtue of large meat packing concerns doing a nation-wide business, the meat inspection control is exercised by a federal agency.

Other factors of importance which are entitled to consideration in understanding the slaughterhouse development in the U.S. are connected with the development of rail transportation. The advent of the refrigerated railroad car made it possible to slaughter meat animals many hundreds of miles from the localities in which the meat is to be consumed. Large slaughterhouses in Chicago, for example, receive carloads of livestock which come from the western plains many hundreds of miles away. They ship in refrigerated cars carcasses produced from these animals as far as the eastern seaboard to the large centres of population there. An efficient utilization of many by-products of the slaughtering operations has been one of the results of slaughtering large numbers of animals in a single plant. There has been production in large volume of such materials as fertilizer, soap, soap fats, hair, animal casings, hides, skins, bone products, pharmaceutical products and many technical products. Many interesting adjustments in the slaughtering operation have been made from time to time to accomplish an efficient production of large quantities of meat. So-called moving chain conveyor production which has become an important factor in many other industries is reputed to have originated on the slaughtering floors of these large establishments. This development also has its personal interest. Butchers in slaughterhouses at one time were highly trained craftsmen who efficiently and with some artistry conducted all the dressing operations on a carcass. Today, with the moving chain conveyor operation, the dressing of a carcass has been separated into a number of simple, easily learned functions which are divided among a number of men, each doing his small specialized part.

Structure. — A properly planned slaughterhouse requires a considerable area of ground and should have ready access to railroad facilities and to the public highway. This calls for a location outside of the metropolitan area but still close enough to it to ensure an adequate labour supply.

Livestock pens should be large enough to hold a considerable supply of animals. This is necessary so that as the livestock are unloaded from railroad cars or trucks they may be driven into comfortable holding pens where they can be fed and watered and rested. The pens are paved and drained so that they can be cleaned and washed down regularly. An ample supply of water is piped throughout the pen area for watering purposes and so that during the hot summer months the livestock can be sprinkled regularly to avoid their becoming overheated. Cleanliness in the livestock pens avoids their becoming a nuisance and also aids materially in maintaining clean conditions in the slaughtering department. Livestock may bring a considerable quantity of debris onto a slaughtering floor from unclean pens.

The slaughtering department is the hub of all operations; therefore, it is planned carefully to make certain that its facilities and equipment are adequate to handle the intended production. Different species of animals are handled with equipment specialized for the particular purpose. Furthermore, the flow of dressing operations must be smooth and orderly to assure efficiency of production and the maintenance of sanitary conditions. Wherever possible, handling is done mechanically rather than manually. The slaughtering department is usually located on the second- or third-floor level. The livestock are driven up a long, inclined ramp to the slaughtering floor. With the slaughtering department at the top level it is possible to provide abundant light and ventilation. The additional and probably more determining consideration is the fact that with the slaughtering operations being conducted at the top level, the products, both edible and inedible, may gravitate to the lower levels where they are given their final preparation.

The animal as it reaches the slaughtering department consists of a combination of edible and inedible products. The properly done slaughtering operation succeeds in separating efficiently the edible parts from the inedible parts, at the same time avoiding any contamination of the products which are prepared for human consumption. From the removal of the hide to the separation from the carcass of such parts as intestines, bladder and the like, a strict regard is given to maintaining the cleanliness of the edible portions. For example, the hide is removed without permitting its outside surface to contact the carcass and as soon as it is removed it is dropped through an opening in the floor into a chute which conveys it directly to the hide cellar. Furthermore, this chute is so vented as to direct any odours to the outside air. Those inedible portions of the carcass which are rendered into soap fats and fertilizer are separated from the edible portions of the carcass by skilled operators using specialized equipment, and these inedible materials are conveyed by chute or other mechanical means to the inedible-rendering department.

The inedible-rendering department is entirely separate from the other departments of the slaughterhouse. This is necessary so that the edible products may in no way be subjected to any possible contamination. Even the loading dock of the inedible-rendering department is entirely separate from the dock which is used to load out meats and other edible products. The inedible-rendering department is constructed with floors and walls of impervious material which can be washed down thoroughly and the floors are sloped to drains so as to facilitate this cleanup. The equipment is adequate to handle the volume expeditiously; *i.e.,* there are sufficient rendering tanks which are provided with odour-control devices.

While turning out a properly dressed carcass in the slaughtering department, the organs removed from the body cavities must be taken care of. These are handled in what is called the viscera-separating department, which is immediately connected with the slaughtering department. This viscera-separating department is so equipped that the various organs can be separated from each other without contamination. Sausage casings are a product of this department.

The edible products which include the dressed carcasses, livers and other edible organs, are conveyed to the refrigerators. The body heat is removed promptly from these edible meat products. The carcasses are hung spaced from overhead rails, and the edible organs are either spread out on trays or hung individually from hooks on racks. Since proper chilling determines to a great extent the quality of the edible products as they are subsequently shipped from the plant, the refrigeration facilities must be adequate for the volume of production. This applies both to the amount of refrigeration space and the temperature maintained in those areas.

Water Supply. — An abundant supply of water is piped to all operating departments. That used in the slaughtering and other departments where edible products are handled must be clean and potable. The outlets must be numerous and so located that both hot and cold water under good pressure are available wherever needed. Hot water is particularly important for cleanup in the slaughtering department, because cold water will not cut the fat which is always present to some extent in the debris that accumulates in connection with the dressing operation. This cleanup is progressive during the operation, so that the department may be kept clean at all times.

It is sometimes difficult and usually quite expensive to obtain potable water in the large amounts necessary for properly operating the inedible-rendering department and the condenser lines in the refrigeration system. Also, frequently nonpotable water is the only supply available in amounts adequate for fire control. When nonpotable water is used for these purposes, no lines carrying this water pass through edible-product departments and there are no cross connections between the potable and nonpotable water systems.

The slaughterhouse employees are furnished dressing-room and laundry facilities. The lockers provided for them are adequate to accommodate their working clothes and equipment. Their outside garments are of washable material, and they are laundered regularly. The dressing rooms in which the lockers are located are separated from adjoining toilet rooms by tight, full-height walls or partitions. The toilet rooms are not entered directly from workrooms. The intervening dressing room serves as a ventilated vestibule between the toilet rooms and the edible products departments. In addition to the toilet facilities, which are sufficient for the number of employees at a particular plant, showers are also provided.

Sewage Disposal. — The sewage lines from floor drains and other affluents from edible-product departments are separate and apart from sanitary sewage lines. These lines enter the main sewer separately. This avoids the contamination which would result in edible-products departments should there be any stoppage in the sanitary sewage lines. Also, it is the usual practice for sewage from operating departments to be passed through catch basins where the fat is salvaged. The fat rises to the surface in these catch basins, is skimmed off regularly, and taken to the inedible-rendering department. The catch basins are drained and washed out daily.

Meat Inspection. — The slaughterhouse, however well-laid out and equipped, requires the supervision of government inspection to assure its being maintained in a sanitary condition and to ensure the clean handling of meat and meat products for human consumption. The animals before slaughter must be examined by a government inspector to eliminate from food channels all those that are unfit. Also, each carcass at the time of slaughter must be examined by the inspector to search out all diseased and otherwise unfit carcasses and parts. To facilitate examination of the live animals, the pens are so arranged and lighted as to permit the inspector to pass among the animals and examine them at rest and while moving about. The animals which are suspected of being unfit for meat production are segregated and placed in a pen provided for the purpose. These animals are again examined and those considered unfit are taken directly to the inedible-rendering department where they are destroyed under the supervision of the inspector. Since only a few instances of disease occurrence in animals can be detected in the inspection of the live animal, each carcass is examined during the dressing operation immediately after slaughter. Equipment provided in the slaughtering department permits the inspector to examine the carcass and its organs. Diseased and otherwise unfit carcasses and parts condemned by the inspector are destroyed under his supervision. Equipment which has been contaminated by condemned material is required to he sterilized, using water at high temperatures.

The manufacturing processes used in preparing meat products also require inspectional supervision. The inspector prohibits the use of harmful preservatives as well as unfit or unclean ingredients generally. The preparation of chopped meat products such as sausages, meat loaves and the like, receives the inspector's close attention to guard against adulteration. Only clean, wholesome meats and other ingredients are permitted to be used, and the proportion of meat to other ingredients is maintained at a level which is consistent with consumer expectancy.

SLAVE COAST, a term denoting the low-lying deltas and sandbars that stretch for 700 mi. between the Volta river and Mt. Cameroon; used (but now rarely) to distinguish this shore line from the Gold. Ivory and Grain coasts. The name derives from its position as a principal source of African slaves for 350 years. especially the section of it that fronts on the Bight of Benin (Dahomey. Lagos). (D. WH.)

SLAVEIKOV, PENCHO (1866–1912), Bulgarian poet. best known for his epic poem. *Karvava Pessen* ("Song of Blood" [1911–12]) describing the sacrifices of the Bulgarian people in their struggle for independence. He was born in Trevna. Bulg.. on April 27, 1866, the son of P. R. Slaveikov (*q.v.*). He studied literature and philosophy in Leipzig and subsequently held the posts of director of the national library and director of the national theatre in Sofia.

Slaveikov died at Brunate, on Lake Como, Italy, where he retired in poor health in 1911. His remains were transferred to his native country in 1921.

A highly individualistic lyrical poet whose thought was moulded under the influence of the German poets and philosophers of the 19th century. Slaveikov was also inspired by the simple eloquence and realism of Bulgarian folk songs. A collection of folk songs was published posthumously in 1917.

See E. Damiani, "La figura e l'opera di Pencho Slaveikov nella letteratura bulgara," *Riv. di let. slave,* iii (1928). (L. BY.)

SLAVEIKOV, PETKO RACHEV (1827–1895), first modern Bulgarian poet, outstanding writer and politician who played a considerable part in the renaissance of his country by re-establishing the vernacular language in literature. He was born at Trnovo, Bulg.. April 2, 1827. and received there an elementary education. the only one that was possible under Turkish rule. He wished to become a monk but, inspired by Paissi's *History;* decided to fight for the national revival.

A self-educated man, Slaveikov worked from 1843 as a teacher. He also wrote lyrical and patriotic poems (first published in 1852) and spoke against the Turkish oppressors and the spiritual domination of the Greek ecumenical patriarchate.

In 1863 Slaveikov moved to Istanbul where. from 1866, he edited the *Mukedonia,* a Bulgarian political journal. In 1872 the Turks suspended its publication. He was arrested. On his release he returned to Bulgaria, again earning his living as a teacher. After his country's partial liberation he was one of the prominent Liberal members of the national assembly that met at Trnovo in 1878 and the following year was elected its president.

In 1880–81 Slaveikov was minister of education and later minister of the interior in the L. Karavelov government. After the 1881 *coup d'état* he moved to Plovdiv, then in so-called Eastern Rumelia, where he edited the newspaper *Nezavisimost* ("Independence").

Returning to Sofia in 1883, he was a co-publisher of the Liberal newspaper *Trnooska Konstitutsia* (1884–88).

Slaveikov died in Sofia on June 9, 1895.

See P. *R.* Slaveikov, *Izbrani proizvedenya* ("Selected Poems") (Sofia, 1945); E. Damiani, "Il primo poeta bulgaro," *Riv. di let. slave,* II (Rome, 1927).

SLAVERY. It appears to be true that, in the words of Dunoyer. the economic régime of every society which has recently become sedentary is founded on the slavery of the industrial professions. In the hunter period the savage warrior does not enslave his vanquished enemy. but slays him; the women of a conquered tribe he may, however, carry off and appropriate as wives or as servants, for in this period domestic labour falls almost altogether on their sex. In the pastoral stage slaves will be captured only to be sold, with the exception of a few who may be required for the care of flocks or the small amount of cultivation which is then undertaken. It is in proportion as a sedentary life prevails, and agricultural exploitation is practised on a larger scale, whilst warlike habits continue to exist, that the labour of slaves is increasingly introduced to provide food for the master, and at the same time save him from irksome toil. Of this stage in the social movement slavery seems to have been, as we have said, a universal and inevitable accompaniment.

But wherever theocratic organizations established themselves slavery in the ordinary sense did not become a vital element in the social system. The members of the lowest class were not in a state of individual subjection: the entire caste to which they belonged was collectively subject. It is in the communities in which the military order obtained an ascendancy over the sacerdotal, and which were directly organized for war, that slavery (as the word is commonly understood) had its natural and appropriate place. It is not merely that in its first establishment slavery was an immense advance by substituting for the immolation of captives, often accompanied by cannibalism, their occupation in labour for the benefit of the victor. This advantage, recalled by an old though erroneous[1] etymology, is generally acknowledged. But it is not so well understood that slavery discharged important offices in the later social evolution—first, by enabling military action to prevail with the degree of intensity and continuity requisite for the system of incorporation by conquest which was its final destination; and, secondly, by forcing the captives, who with their descendants came to form the majority of the population in the conquering community, to an industrial life, in spite of the antipathy to regular and sustained labour which is deeply rooted in human nature. As regards the latter consideration, it is enough to say that nowhere has productive industry developed itself in the form of voluntary effort; in every country of which we have any knowledge it was imposed by the strong upon the weak, and was wrought into the habits of the people only by the stern discipline of constraint. From the former point of view the freeman, then essentially a warrior, and the slave were mutual auxiliaries, simultaneously exercising different and complementary functions-each necessary to the community. In modern slavery, on the other hand, where the occupations of both parties were industrial, the existence of a servile class only guaranteed for some of them the possibility of self-indulgent ease, whilst it imposed on others the necessity of indigent idleness.

It was in the Roman State that military action—in Greece often purposeless and, except in the resistance to Persia, on the whole fruitless—worked out the social mission which formed its true justification. Hence at Rome slavery also most properly found its place, so long as that mission was in progress of accomplishment. As soon as the march of conquest had reached its natural limit, slavery began to be modified; and when the empire was divided into the several States which had grown up under it, and the system of defence characteristic of the middle ages was substituted for the aggressive system of antiquity, slavery gradually disappeared, and was replaced by serfdom.

We have so far dealt with the political results of ancient slavery, and have found it to have been in certain respects not only useful but indispensable. When we consider its moral effects, whilst endeavouring to avoid exaggeration, we must yet pronounce its influence to have been profoundly detrimental. In its action on the slave it marred in a great measure the happy effects of habitual industry by preventing the development of the

[1]*Servus* is not cognate with *servare,* as has often been supposed, it is really related to the Homeric εἴρερο and the verb ἐίρω, with which the Latin *sero* is to be connected. It may be here mentioned that *slave* was originally a national name; it meant a man of Slavonic race captured and made a bondman to the Germans. "From the Euxine to the Adriatic, in the state of captives or subjects, . . . they [the Slavonians] overspread the land, and the national appellation of the *Slaves* has been degraded by chance or malice from the signification of glory to that of servitude" (Gibbon, *Decline and Fall,* ch. Iv.). The historian alludes to the derivation of the national name from *slava,* glory. *See* Skeat's ***Etym. Dict.,*** *s.v.; see* also SLAVS.

sense of human dignity which lies at the foundation of morals. On the morality of the masters—whether personal, domestic or social—the effects of the institution were disastrous.

GREECE

We find slavery fully established in the Homeric period. The prisoners taken in war are retained as slaves, or sold (*Il.* xxiv. 752) or held at ransom (*Il.* vi. 427) by the captor. Sometimes the men of a conquered town or district are slain and the women carried off (Od. ix. 40). Not unfrequently free persons were kidnapped by pirates and sold in other regions, like Eumaeus in the Odyssey. The slave might thus be by birth of equal rank with his master, who knew that the same fate might befall himself or some of the members of his family. The institution does not present itself in a very harsh form in Homer, especially if we consider (as Grote suggests) that "all classes were much on a level in taste, sentiment and instruction." The male slaves were employed in the tillage of the land and the tending of cattle, and the females in domestic work and household manufactures. The principal slaves often enjoyed the confidence of their masters and had important duties entrusted to them; and, after lengthened and meritorious service, were put in possession of a house and property of their own (Od. xiv. 64). Grote's idea that the women slaves were in a more pitiable condition than the males does not seem justified, except perhaps in the case of the aletrides, who turned the household mills which ground the flour consumed in the family, and who were sometimes overworked by unfeeling masters (Od. xx. 110–119). Homer marks in a celebrated couplet his sense of the moral deterioration commonly wrought by the condition of slavery (Od. xvii. 322).

Historic Period—Sources of Slavery.—It is, however, in historic Greece, where we have ample documentary information, that it is most important to study the system. The sources of slavery in Greece were: (1) Birth, the condition being hereditary. This was not an abundant source, women slaves being less numerous than men, and wise masters making the union of the sexes rather a reward of good service than a matter of speculation (Xen. Oecon. 9. 5). It was in general cheaper to buy a slave than to rear one to the age of labour. (2) Sale of children by their free parents, which was tolerated, except in Attica, or their exposure, which was permitted, except at Thebes. The consequence of the latter was sometimes to subject them to a servitude worse than death, as is seen in the plays of Plautus and Terence, which, as is well known, depict Greek, not Roman, manners. Freemen, through indigence, sometimes sold themselves, and at Athens, up to the time of Solon, an insolvent debtor became the slave of his creditor. (3) Capture in war. Not only Asiatics and Thracians thus became slaves, but in the many wars between Grecian States, continental or colonial, Greeks were reduced to slavery by men of their own race. Callicratidas pronounced against the enslavement of Greeks by Greeks, but violated his own principle, to which, however, Epaminondas and Pelopidas appear to have been faithful. (4) Piracy and kidnapping. The descents of pirates on the coasts were a perpetual source of danger; the pirate was a gainer either by the sale or by the redemption of his captives. If ransomed, the victim became by Athenian law the slave of his redeemer till he paid in money or labour the price which had been given for him. Kidnappers (andrapodistae) carried off children even in cities, and reared them as slaves. Whether from hostile forays or from piracy, any Greek was exposed to the risk of enslavement. (5) Commerce. Besides the sale of slaves which took place as a result of the capture of cities or other military operations, there was a systematic slave trade. Syria, Pontus, Lydia, Galatia, and above all Thrace were sources of supply. Egypt and Ethiopia also furnished a certain number, and Italy a few. Of foreigners, the Asiatics bore the greatest value, as most amenable to command, and most versed in the arts of luxurious refinement. But Greeks were highest of all in esteem, and they were much sought for foreign sale. Greece proper and Ionia supplied the petty Eastern princes with courtesans and female musicians and dancers. Athens was an important slave market, and the State profited by a tax on the sales; but the principal marts were those of Cyprus, Samos, Ephesus and especially Chios.

Employment of Slaves.—The slaves were employed either in domestic service—as household managers, attendants or personal escorts—or in work of other kinds, agricultural or urban. In early Attica, and even down to the time of Pericles, the landowners lived in the country. The Peloponnesian War introduced a change; and after that time the proprietors resided at Athens, and the cultivation was in the hands of slaves. In manufactures and commerce, also, servile gradually displaced free labour. Speculators either directly employed slaves as artisans or commercial and banking agents, or hired them out, sometimes for work in mines or factories, sometimes for service in private houses, as cooks, flute-players, etc., or for viler uses. There were also public slaves; of these some belonged to temples, to which they were presented as offerings, amongst them being the courtesans who acted as hieroduli at Corinth and at Eryx in Sicily; others were appropriated to the service of the magistrates or to public works; there were at Athens 1,200 Scythian archers for the police of the city; slaves served, too, in the fleets, and were employed in the armies—commonly as workmen, and exceptionally as soldiers.

The condition of slaves at Athens was not in general a wretched one. Demosthenes (In Mid. p. 530) says that, if the barbarians from whom the slaves were bought were informed of the mild treatment they received, they would entertain a great esteem for the Athenians. Plautus in more than one place thinks it necessary to explain to the spectators of his plays that slaves at Athens enjoyed such privileges, and even licence, as must be surprising to a Roman audience. The slave was introduced with certain customary rites into his position in the family; he was in practice, though not by law, permitted to accumulate a private fund of his own; his marriage was also recognized by custom; though in general excluded from sacred ceremonies and public sacrifices, slaves were admissible to religious associations of a private kind; there were some popular festivals in which they were allowed to participate; they had even special ones for themselves both at Athens and in other Greek centres. Their remains were deposited in the family tomb of their master, who sometimes erected monuments in testimony of his affection and regret. They often lived on terms of intimacy either with the head of the house or its younger members; but it is to be feared that too often this intimacy was founded, not on mutual respect, as in the heroic example of Ulysses and Eumaeus, but on insolent self-assertion on the one side and a spirit of unworthy compliance on the other, the latter having its *raison d'être* in degrading services rendered by the slave. Aristophanes and Plautus show us how often resort was had to the discipline of the lash even in the case of domestic slaves. Those employed in workshops, whose overseers were themselves most commonly of servile status, had probably a harder lot than domestics; and the agricultural labourers were not unfrequently chained, and treated much in the same way as beasts of burden. The displeasure of the master sometimes dismissed his domestics to the more oppressive labours of the mill or the mine. A refuge from cruel treatment was afforded by the temples and altars of the gods and by the sacred groves. Nor did Athenian law leave the slave without protection. He had, as Demosthenes boasts, an action for outrage like a freeman, and his death at the hand of a stranger was avenged like that of a citizen (Eurip. Hec. 288), whilst, if caused by his master's violence, it had to be atoned for by exile and a religious expiation. Even when the slave had killed his master, the relatives of the house could not themselves inflict punishment; they were obliged to hand him over to the magistrate to be dealt with by legal process. The slave who had just grounds of complaint against his master could demand to be sold; when he alleged his right to liberty, the law granted him a defender and the sanctuaries offered him an asylum till judgment should be given. Securities were taken against the revolt of slaves by not associating those of the same nationality and language; they were sometimes fettered to prevent flight, and, after a first attempt at escape, branded to facilitate their recovery. There were treaties between States for the extradition of fugitives, and contracts of mutual assurance between individuals against their loss by flight.

Emancipation.—The slave could purchase his liberty with his *peculium* by agreement with his master. He could be liberated by will, or, during his master's life, by proclamation in the theatre, the law courts or other public places, or by having his name inscribed in the public registers, or, in the later age of Greece, by sale or donation to certain temples—an act which did not make the slave a hierodulus but a freeman. Conditions were sometimes attached to emancipation, as of remaining for life or a definite time with the former master, or another person named by him, or of performing some special service; payments or rights of succession to property might also be reserved. By manumission the Athenian slave became in relation to the State a metic, in relation to his master a client. He was thus in an intermediate condition between slavery and complete freedom. If the freedman violated his duties to his patron he was subject to an action at law, and if the decision were against him, he was again reduced to slavery. He became a full member of the State only, as in the case of foreigners, by a vote in an assembly of 6,000 citizens; and even this vote might be set aside by a *graphē paranomōn*. Slaves who had rendered eminent services to the public, as those who fought at Arginusae and at Chaeronea, were at once admitted to the status of citizens in the class of (so-called) Plataeans. But it would appear that even in their case some civic rights were reserved and accorded only to their children by a female citizen. The number of freedmen at Athens seems never to have been great. (*See* further GREECE: *History*.)

Theoretic Views on Slavery.—It is well known that Aristotle held slavery to be necessary and natural, and, under just conditions, beneficial to both parties in the relation—views which were correct enough from the political side, regard being had to the contemporary social state. His practical motto, if he is the author of the *Economics* attributed to him, is—"no outrage, and no familiarity." There ought, he says, to be held out to the slave the hope of liberty as the reward of his service. Plato condemned the practice, which the theory of Aristotle also by implication sets aside as inadmissible, of Greeks having Greeks for slaves. In the *Laws* he accepts the institution as a necessary though embarrassing one, and recommends for the safety of the masters that natives of different countries should be mixed and that they should all be well treated. But, whilst condemning harshness towards them, he encourages the feeling of contempt for them as a class. The later moral schools of Greece scarcely at all concern themselves with the institution. The Epicurean had no scruple about the servitude of those whose labours contributed to his own indulgence and tranquillity. The Stoic regarded the condition of freedom or slavery as an external accident, indifferent in the eye of wisdom; to him it was irrational to see in liberty a ground of pride or in slavery a subject of complaint; from intolerable indignity suicide was an ever-open means of escape. The poets—especially the authors of the New Comedy—strongly inculcate humanity, and insist on the fundamental equality of the slave. The celebrated "homo sum" is a translation from Alexis, and the spirit of it breathes in many passages of the Greek drama. A fragment of Philemon declares, as if in reply to Aristotle, that not nature, but fortune, makes the slave. Euripides, as might be expected from his humanitarian cast of sentiment, and the "premature modernism" which has been remarked in him, rises above the ordinary feelings of his time in regard to the slaves. As Paley says, he loves "to record their fidelity to their masters, their sympathy in the trials of life, their gratitude for kindness and considerate treatment, and their pride in bearing the character of honourable men. · · · He allows them to reason, to advise, to suggest; and he even makes them philosophize on the follies and the indiscretions of their superiors" (compare *Med.* 54; *Orest.* 869; *Hel.* 728; *Ion.* 854; *Frag. Melan.* 506; *Phrix.* 823). (For the Helots in Laconia, see HELOTS.)

ROME

We have already observed that the Roman system of life was that in which slavery had its most natural and relatively legitimate place; and accordingly it was at Rome that, as Blair has remarked, the institution was more than anywhere else "extended in its operations and methodized in its details."

Sources of Slavery.—We must distinguish from the later slavery at Rome what Mommsen calls "the old, in some measure innocent" slavery, under which the farmer tilled the land along with his slave, or, if he possessed more land than he could manage, placed the slave—either as a steward, or as a sort of lessee obliged to render up a portion of the produce—over a detached farm. Though slaves were obtained by the early victories of Rome over her Italian neighbours, no large number was employed on the small holdings of those periods. But the extension of properties in the hands of the patricians, and the continued absences of citizens required by the expanding system of conquest, necessarily brought with them a demand for slave labour, which was increasingly supplied by captives taken in war. Of the number furnished from this source a few particulars from the time of the mature republic and the first century of the empire will give some idea. In Epirus, after the victories of Aemilius Paullus, 150,000 captives were sold. The prisoners at Aquae, Sextiae and Vercellae were 90,000 Teutons and 60,000 Cimbri. Caesar sold on a single occasion in Gaul 63,000 captives. But slavery, as Hume has shown, is unfavourable to population. Hence a regular commerce in slaves was established, which was based on the "systematically-prosecuted hunting of man," and indicated an entire perversion of the primitive institution, which was essentially connected with conquest. The pirates sold great numbers of slaves at Delos, where was the chief market for this kind of wares; and these sales went on as really, though more obscurely, after the successful expedition of Pompey. There was a regular importation to Rome of slaves, brought to some extent from Africa, Spain and Gaul, but chiefly from Asiatic countries—Bithynia, Galatia, Cappadocia and Syria.

There were other sources from which slavery was alimented, though of course in a much less degree. Certain offences reduced the guilty persons to slavery (*servi poenae*), and they were employed in public work in the quarries or the mines. Originally, a father could sell his children. A creditor could hold his insolvent debtor as a slave, or sell him out of the city (*trans Tiberim*). The enslavement of debtors, overwhelmed with usury in consequence of losses by hostile raids or their own absence on military service, led to the secession to the Mons Sacer (493 B.C.). The Poetelian law (326 B.C.) restricted the creditor's lien (by virtue of a *nexum*) to the goods of his debtor, and enacted that for the future no debtor should be put in chains; but we hear of debtors *addicti* to their creditors by the tribunals long after—even in the time of the Punic Wars.

Employment of Slaves.—There were *servi publici* as well as *privati*. The service of the magistrates was at first in the hands of freemen; but the lower offices, as of couriers, servants of the law courts, of prisons and of temples, were afterwards filled by slaves. The execution of public works also came to be largely committed to them—as the construction of roads, the cleansing of the sewers and the maintenance of the aqueducts. Both kinds of functions were discharged by slaves, not only at Rome, but in the rural and provincial municipalities. The slaves of a private Roman were divided betneen the *familia rustica* and the *familia urbana*. At the head of the *familia rustica* was the *villicus*, himself a slave, with the wife who was given him at once to aid him and to bind him to his duties. Under him were the several groups employed in the different branches of the exploitation and the care of the cattle and flocks, as well as those who kept or prepared the food, clothing and tools of the whole staff and those who attended on the master in the various species of rural sports. A slave prison (*ergastulum*) was part of such an establishment, and there were slaves whose office it was to punish the offences of their fellows. To the *familia urbana* belonged those who discharged the duties of domestic attendance, the service of the toilet, bath, table and kitchen, besides the entertainment of the master and his guests by dancing, singing and other arts. There were, besides, the slaves who accompanied the master and mistress out of doors and were chosen for their beauty and grace as guards of honour, for their strength as chairmen or porters, or for their readiness and address in remembering names, delivering messages of courtesy and the like. There were also attached to a great household physicians, artists. secretaries, librarians, copyists, preparers of parchment, as well as pedagogues and preceptors of different kinds — readers, grammarians. men of letters and even philosophers — all of servile condition, besides accountants, managers and agents for the transaction of business. Actors. comic and tragic, pantomimi, and the performers of the circus were commonly slaves, as were also the gladiators. These last were chosen from the most warlike races — as the Samnites, Gauls and Thracians. *Fumiliae* of gladiators were kept by private speculators. who hired them out; they were sometimes owned by men of high rank.

Several special examples and other indirect indications show that the wealthier Romans possessed large *familiae.* This may be inferred from the *columbaria* of the house of Livia and of other great houses. The slaves of Pedanius Secundus, who, in spite of a threatened outbreak of the indignant populace, mere all put to death because they had been under their master's roof when he was murdered, were 400 in number.

Pliny tells us that Caecilius, a freedman of the time of Augustus, left by his will as many as 4.116. The question as to the total number of slaves at Rome or in Italy is a very difficult one, and it is not, perhaps, possible to arrive with any degree of certainty at an approximate estimate. Gibbon supposes that there were in the Roman world in the reign of Claudius at least as many slaves as free inhabitants. But Blair seems right in believing that this number, though probably correct for an earlier period, is much under the truth for the age to which it is assigned. He fixes the proportion of slaves to free men as that of three to one for the time between the conquest of Greece (146 B.C.) and the reign of Alexander Severus (A.D. 222–235). The entire number of slaves in Italy would thus have been, in the reign of Claudius. 20.832.000.

Laws. — By the original Roman law the master was clothed with absolute dominion over the slave, extending to the power of life and death, which is not surprising when we consider the nature of the *patria potestas.* The slave could not possess property of any kind: whatever he acquired was legally his master's. He was. however, in practice permitted to enjoy and accumulate chance earnings or savings, or a share of what he produced. under the name of *peculium.* A master could not enter into a contract with his slave, nor could he accuse him of theft before the law; for, if the slave took anything, this was not a subtraction, but only a displacement. of property. The union of a male and female slave had not the legal character of a marriage; it was a cohabitation *(contubernium)* merely, which was tolerated, and might be terminated at will, by the master; a slave was, therefore, not capable of the crime of adultery. Yet general sentiment seems to have given a stronger sanction to this sort of connection; the names of husband and wife are freely used in relation to slaves on the stage, and even in the laws, and in the language of the tombs. For entering the military service or taking on him any State office a slave was punished with death. He could not in general be examined as a witness, except by torture. A master, when accused, could offer his slaves for the "question," or demand for the same purpose the slaves of another; and, if in the latter case they were injured or killed in the process, their owner was indemnified. A slave could not accuse his master, except of adultery or incest (under the latter name being included the violation of sacred things or places); the case of high treason was afterwards added to these. An accused slave could not invoke the aid of the tribunes. The penalties of the law for crime were specially severe on slaves.

Treatment of Slaves. — Columella, like Xenophon, favours a certain friendliness and familiarity in one's intercourse with his farm slaves. Cato ate and drank the same coarse victuals as his slaves, and even had the children suckled by his wife, that they might imbibe a fondness for the family. But he had a strict eye to profit in all his dealings with them. He allowed the *contubernium* of male and female slaves at the price of a money payment from their *peculium.* Columella regarded the gains from the births as a sufficient motive for encouraging these unions, and thought that mothers should be rewarded for their fecundity; Varro, too, seems to have taken this view. The immense extension of the rural estates *(latijundia)* made it impossible for masters to know their slaves, even if they were disposed to take trouble for the purpose. Effective superintendence even by overseers became less easy; the use of chains was introduced, and these were worn not only in the field during working hours but at night in the *ergastulum* where the slaves slept. Urban slaves had probably often a life as little enviable, especially those who worked at trades for speculators. Even in private houses at Rome, so late as the time of Ovid, the porter was chained. In the *familia urbana* the favourites of the master had good treatment, and might exercise some influence over him which would lead to their receiving flattery and gifts from those who sought his vote or solicited his support. Doubtless there was often genuine mutual affection; slaves sometimes, as in noted instances during the civil wars, showed the noblest spirit of devotion to their masters. Those who were not inmates of the household, but were employed outside of it as keepers of a shop or boat, chiefs of workshops, or clerks in a mercantile business, had the advantage of greater freedom of action. The slaves of the *leno* and the *lanista* were probably in most cases not only degraded but unhappy. The lighter punishments inflicted by masters were commonly personal chastisement or banishment from the town house to rural labour; the severer were employment in the mill *(pistrinum)* or relegation to the mines or quarries. To the mines also speculators sent slaves; they worked half-naked, men and women, in chains, under the lash and guarded by soldiers. Vedius Pollio, in the time of Augustus, was said to have thrown his slaves, condemned sometimes for trivial mistakes or even accidents, to the lampreys in his fishpond. Cato advised the agriculturist to sell his old oxen and his old slaves, as well as his sick ones; and sick slaves were exposed in the island of Aesculapius in the Tiber; by a decree of Claudius slaves so exposed could not be reclaimed by their masters, in case of their recovery.

Though the Roman slaves were not, like the Spartan Helots, kept obedient by systematic terrorism, their large numbers were a constant source of danger. The law under which the slaves of Pedanius were put to death, probably introduced under Augustus and more fully enacted under Nero, is sufficient proof of this anxiety, which indeed is strongly stated by Tacitus in his narrative of the facts. There had been many conspiracies amongst the slaves in the course of Roman history, and some formidable insurrections. The growth of the *latifundia* made the slaves more and more numerous and formidable. Free labour was discountenanced. Cato, Varro and Columella all agree that slave labour was to be preferred to free except in unhealthy regions and for large occasional operations, which probably transcended the capacity of the permanent *familia rustica.* Cicero and Livy bear testimony to the disappearance of a free plebs from the country districts and its replacement by gangs of slaves working on great estates. The worst form of such predial slavery existed in Sicily, whither Mommsen supposes that its peculiarly harsh features had been brought by the Carthaginians. In Sicily, accordingly, the first really serious servile insurrections took place. The rising under Eunus in 133 B.C. was with some difficulty suppressed by Rupilius. Partial revolts in Italy succeeded; and then came the second Sicilian insurrection under Trypho and Athenio, followed by the Servile War in Italy under Spartacus (*q.v.*). Clodius and Milo used bands of gladiators in their city riots, and this action on the part of the latter was approved by Cicero. In the First Civil War they were to be found in both camps, and the murderers of Caesar were escorted to the Capitol by gladiators. Antony, Octavius, and Sextus Pompeius employed them in the Second Civil War; and it is recorded by Augustus on the Monumentum Ancyranum that he gave back to their masters for punishment about 30,000 slaves who had borne arms against the State.

Blair, in comparing the Greek and Roman systems of slavery, points with justice to the greater facility and frequency of emancipation as the great superiority of the latter. No Roman slave, he says, "needed to despair of becoming both a freeman and a citizen." Manumission was of two kinds—*justa* or regular, and *minus* justa. Of *manumissio* justa there were four modes: (1) by adoption, rarely resorted to; (2) by testament, already recognized in the Twelve Tables; (3) by census, which was of exceptional use, and did not exist later than the time of Vespasian; and (4) by vindicta, which was the usual form. In the last method the master turned the slave round, with the words "liber esto," in the presence of the praetor, that officer or his lictor at the same time striking the slave with his rod. The manumissio minus justa was effected by a sufficient manifestation of the will of the master, as by letter, by words, by putting the *pileus* (or cap of liberty) on the slave, or by any other formality which had by usage become significant of the intention to liberate, or by such an act as making the slave the guardian of his children. This extra-legal sort of manumission was incomplete and precarious; even after the lex *Junia Norbana* (A.D. 19), which assimilated the position of those so liberated to that of the Latin colonists, under the name of Latini juniores, the person remained in the eye of the law a slave till his death and could not dispose of his *peculium* by gift or testamentary disposition.

A freedman, unless he became such by operation of law, remained client of his master, and both were bound by mutual obligations arising out of that relation. These obligations existed also in the case of freedmen of the State, of cities, temples and corporations. The freedman took his former master's name; he owed him deference (*obsequium*) and aid (*officium*); and neglect of these obligations was punished, in extreme cases even with loss of liberty. Conditions might be annexed by the master to the gift of freedom, as of continued residence with him, or of general service or some particular duty to be performed, or of a money payment to be made. But the praetor Rutilius, about the beginning of the 1st century B.C., limited the excessive imposition of such conditions, and his restrictions were carried further by the later jurists and the imperial constitutions. Failing natural heirs of an intestate freedman, the master, now patron, succeeded to his property at his death; and he could dispose by will of only half his possessions, the patron receiving the other half. Freedmen and their sons were subject to civil disabilities; the third generation became *ingenui* (full citizens). Thus the slave element tended to merge itself in the general popular body.

It was often a pecuniary advantage to the master to liberate the slave; he obtained payment which enabled him to buy a substitute and at the same time gained a client. This, of course, presupposes the recognition of the right of the slave to his *peculium;* and the same is implied in Cicero's statement that a diligent slave could in six years purchase his freedom. Augustus set himself against the undue multiplication of manumissions. probably considering the rapid succession of new citizens a source of social instability. and recommended a similar policy to his successor. The lex Aelia Sentia (about A.D. 3) forbade manumission, except in strictly limited cases, by masters under 20 years of age or of slaves under 30; and the lex Furia Caninia (about A D 7) fixed the proportion of a man's slaves which he could liberate by testament, and forbade more than 100 being so enfranchised, whatever might be the number of the familia. Under the empire the freedmen rose steadily in influence; they became admissible to the rank of equites and to the senate; they obtained provincial Governments, and were appointed to offices in the imperial household which virtually placed them at the head of administrative departments. (See article on NARCISSUS) Freedmen of humbler rank, on the other hand, filled the minor offices in the administrative service, in the city cohorts, and in the army; and we shall find that they entered largely into the trades and professions when free labour began to revive. They appeared also in literature, *e.g.,* Tiro, the amanuensis of Cicero; Hyginus, the librarian of Augustus; Livius Andronicus, Caecilius, Statius, Terence, Publilius Syrus, Phaedrus and Epictetus.

In the 2nd century of the Christian era we find a marked change with respect to the institution of slavery, both in the region of thought and in that of law. Already the principles of reason and humanity had been applied to the subject by Seneca. But it was in the 2nd century, as we have said, that "the victory of moral ideas" in this, as in other departments of life, became "decisive. . . . Dio Chrysostom, the adviser of Trajan, is the first Greek writer who has pronounced the principle of slavery to be contrary to the law of nature" (Mark Pattison). And a parallel change is found in the practical policy of the State. The military vocation of Rome was now felt to have reached its normal limits; and the emperors, understanding that, in the future, industrial activity must prevail, prepared the abolition of slavery as far as was then possible, by honouring the freedmen, by protecting the slave against his master, and by facilitating manumissions. The general tendency both of the imperial constitutions and of the maxims of the legists is in favour of liberty. The practices of exposure and sale of children, and of giving them in pledge for debt, are forbidden. Diocletian forbade a free man to sell himself. Kidnappers (*plagiarii*) were punished with death. The insolvent debtor was withdrawn from the yoke of his creditor. While the slave trade was permitted, the mutilation of boys and young men, too often practised, was punished with exile and even with death. In redhibitory actions (for the annulment of sales), if a slave were returned to the seller, so must also be his parents, brothers and personae contubernio *conjunctae.* In the interpretation of testaments it was to be assumed that members of the same family were not to be separated by the division of the succession. The law also favoured in special cases the security. of the peculium, though in general principle it still remained the property of the master. The State granted to public slaves the right of bequeathing half their possessions; and private persons sometimes permitted similar dispositions even to a greater extent, though only within the *familia.* Hadrian took from masters the power of life and death and abolished the subterranean prisons. Antoninus Pius punished him who killed his own slave as if he had killed another's. Already in the time of Nero the magistrates had been ordered to receive the slave's complaint of ill-treatment; and the *lex* Petronia, belonging to the same or an earlier period, forbade masters to hand over their slaves to combats with wild beasts. M. Aurelius gave to masters an action against their slaves for any cause of complaint, thus bringing their relation more directly under the surveillance of law and public opinion. A slave's oath could still not be taken in a court of law; he was interrogated by the "question"; but the emperors and jurists limited in various ways the application of torture, adding, however, as we have mentioned, to the cases in which it could previously be appealed to that of the crime of *majestas.* For certain alleged offences of the master the slave could bring an action, being represented for the purpose by an *adsertor.* Emancipation mas facilitated. The power of imposing conditions on testamentary manumissions was restricted, and these conditions interpreted in the sense most favourable to freedom. The emperor could confer liberty by presenting a gold ring to a slave with the consent of the master, and the legal process called restitutio *natalium* made him a full citizen

Influence of Christianity.— The rise of Christianity in the Roman world still further improved the condition of the slave The sentiments it created were not only favourable to the humane treatment of the class in the present, but were the germs out of which its entire liberation was destined, at a later period, in part to arise. It is sometimes objected that the Christian Church did not denounce slavery as a social crime and insist on its abolition. We have seen that slavery was a fundamental element of the old Roman constitution. When the work of conquest had been achieved, it could not be expected that a radical alteration should be suddenly wrought either in the social system which was in harmony with it, or even in the general ideas which had grown up under its influence. The latter would, indeed, be gradually affected; and accordingly, we have observed a change in the policy of the law, indicating a change in sentiment with respect to the slave class, which does not appear to have been at all due to Christian teaching. But the institution itself could not be at once seriously disturbed. The results must have been disastrous, most of all to the slave population itself. Before that end could be accomplished, an essentially new social situation must come into existence. But in the meantime much might be done towards further mitigating the evils of slavery, especially by impressing on master and slave their relative duties and controlling their behaviour towards one another by the exercise of an independent moral authority. This was the work open to the Christian priesthood, and it cannot be denied that it was well discharged. Whilst the fathers agree with the Stoics of the 2nd century in representing slavery as an indifferent circumstance in the eye of religion and morality, the contempt for the class which the Stoics too often exhibited is in them replaced by a genuine sympathy They protested against the multiplication of slaves from motives of vanity in the houses of the great, against the gladiatorial combats (ultimately abolished by the noble self-devotion of a monk) and against the consignment of slaves to the theatrical profession, which was often a school of corruption. The Church also encouraged the emancipation of individual slaves and the redemption of captives. And its influence is to be seen in the legislation of the Christian emperors, which softened some of the harshest features that still marked the institution. But a stronger influence of Christianity appears in Theodosius, and this influence is at the highest in the legislation of Justinian. Its systematic effort is, in his own words, "pro libertate, quam et fovere et tueri Romanis legibus et praecipue nostro numini peculiare est." Law still refused in general to recognize the marriages of slaves; but Justinian gave them a legal value after emancipation in establishing rights of succession. Unions between slaves and free women, or between a freeman and the female slave of another, continued to be forbidden, and were long punished in certain circumstances with atrocious severity. As witness, the slave was still subject to the question; as criminal, he was punished with greater rigour than the freeman. If he accused his master of a crime, unless the charge was of treason, he was burnt. But he could maintain a legal claim to his own liberty, not now merely through an adsertor, but in person. A female slave was still held incapable of the offence of adultery; but Justinian visited with death alike the rape of a slave or freedwoman and that of a free maiden. Already the master who killed his slave had been punished as for homicide, except in the case of his unintended death under correction; Constantine treated as homicide a number of specially enumerated acts of cruelty. Even under Theodosius the combats of the amphitheatre were permitted. if not encouraged. by the State authorities; these sports were still expected from the candidates for public honours. Combats of men with beasts were longest continued; they had not ceased even in the early years of the reign of Justinian. A new process of manumission was now established. to be performer1 in the churches through the intervention of the ministers of religion; and it was provided that clerics could at any time by mere expression of will liberate their slaves. Slaves who were admitted to holy orders, or who entered a monastery, became freemen, under certain restrictions framed to prevent fraud or injustice Justinian abolished the personal conditions which the legislation of Augustus had required to be satisfied by the master who emancipated and the slave who was manumitted, and removed the limitation of number. The liberated slave, whatever the process by which he had obtained his freedom, became at once a full citizen, his former master, however, retaining the right of patronage, the abolition of which would probably have discouraged emancipation.

Transition to Serfdom.—The slavery of the working classes was not directly changed into the system of personal freedom. There was an intermediate stage which has not always been sufficiently discriminated from slavery. We mean the régime of serfdom. In studying the origin of this transitional state of things, four principal considerations have to be kept in view. (1) As Gibbon observes, the completion of the Roman system of conquest reduced the supply of slaves. It is true that, when the barbarian invasions began in the 3rd century, many captives were made, who, when not enrolled in the army, were employed in agriculture or domestic service: but the regular importation was increasingly diminished. This improved the condition of the slave by rendering his existence an object of greater value to his master. It was clearly to the interest of each family to preserve indefinitely its own hereditary slaves. Hence the abolition of the external slave trade tended, in fact, to put an end to internal sales, and the slaves became attached to the households or lands of their masters. (2) The diminished supply of slaves further acted in the direction of the rehabilitation of free labour. A general movement of this kind is noticeable from the 2nd century onwards. Freemen had always been to some extent employed in the public service In private service superior posts were often filled by freedmen; the higher arts—as medicine, grammar, painting—were partly in the hands of freedmen and even of *ingenui;* the more successful actors and gladiators were often freedmen In the factories or workshops kept by wealthy persons slave labour was mainly employed; but free artisans sometimes offered their services to these establishments or formed associations to compete with them. We have seen that free persons had all along been to some extent employed in the cultivation of land as hired labourers, and, as we shall presently find, also as tenants on the great estates. How all this operated we sha!! understand when we examine the remarkable organization of the State introduced by Diocletian and his successors. (3) This organization established in the Roman world a personal and hereditary fixity of professions and situations which was not very far removed from the caste system of the East. The purpose of this was doubtless to resist by a strong internai consolidation the shock of the invasions, to secure public order, to enforce industrious habits, and to guarantee the financial resources of the State. Personal independence was largely sacrificed, but those still more important ends were in a great measure attained. This system, by diminishing the freeman's mastery over himself and his power to determine his occupation, reduced the interval between him and the slave; and the latter on the one hand, the free domestic servant and workshop labourer on the other, both passed insensibly into the common condition of serfdom. (4) The corresponding change, in the case of the rural slaves, took place through their being merged in the order of *coloni* The Roman *colonus* was originally a free person who took land on lease contracting to pay to the proprietor either a fixed sum annually or (when a *colonus partiarius*) a certain proportion of the produce of the farm. Under the emperors of the 4th century the name designated a cultivator who. though personally free, was attached to the soil, and transmitted his condition to his descendants; and this became the regular status of the mass of Roman cultivators. The class of coloni appears to have been composed partly of tenants by contract who had incurred large arrears of rent and were detained on the estates as debtors (obaerati). partly of foreign captives or immigrants who were settled in this condition on the land, and partly of small proprietors and other poor men who voluntarily adopted the status as an improvement in their position. They paid a fixed proportion of the produce (pars agraria) to the owner of the estate, and gave a determinate amount of labour (operae) on the portion of the domain which he kept in his own hands (*mansus dominicus*). The law for a long time took no notice of these customary tenures, and did not systematically constitute them until the 4th century. It was, indeed, the requirements of the fiscus and the conscription which impelled the imperial Government to regulate the system. The coloni were inscribed (*adscripti*) on the registers of the census as paying taxes to the State, for which the proprietor was responsible, reimbursing himself for the amount. In a constitution of Constantine (A D 332) we find the colonus recognized as permanently attached to the land. If he abandoned his holding he was brought back and punished; and anyone who received him had not only to restore him but to pay a penalty. He could not marr, out of the domain; if he took for wife a colona of another proprietor. she was restored to her original locality, and the offspring of the union were divided between the estates. The children of a colonus were fixed in the same status. They and their descendants were retained in the words of a law of Theodosius, "quodam aeternitatis jure," and by no process could be relieved from their obligations By a law of Anastasius, at the end of the 5th century, a colonus who had voluntarily come into an estate was by a tenure of 30 years for ever attached to it. The master (dominus) could inflict on his coloni "moderate chastisement," and could chain them if they attempted to escape, but they had a legal remedy against him for unjust demands or injury to them or theirs. In no case could the rent or the labour dues be increased The colonus could possess property of his own, but could not alienate it without the consent of the master. Thus, whilst the members of the class were personally free, their condition had some incidents of a semi-servile character. They are actually designated by Theodosius, "servi terrae cui nati sunt." And Salvian treats the proposition "coloni divitum fiunt" as equivalent to "vertuntur in servos." This is, indeed, an exaggeration; the *colonatus* was not an oppressive system; it afforded real security against unreasonable demands and wanton disturbance, and it was a great advance on the system of the *familia rustica.* But the point which is important is that there was a certain approximation between the condition of the colonus and the slave which tended towards the fusion of both in a single class.

Besides the coloni there were on a great estate—and those of the 4th century were on a specially large scale—a number of predial slaves, who worked collectively under overseers on the part of the property which the owner himself cultivated. But it was a common practice to settle certain of the slaves (and possibly also of the freedmen) on other portions of the estate, giving them small farms on conditions similar to those to which the coloni were subject. These slaves are, in fact, described by Ulpian as *quasi coloni.* They had their own households and were hence distinguished as *casati.* In law these slaves were at first absolutely at the disposal of their masters; they had no property in the strict sense of the word, and could be sold to another proprietor and separated from their families. But the landlord's interest and the general tone of feeling alike modified practice even before the intervention of legislation; they were habitually continued in their holdings, and came to possess in fact a perpetual and hereditary enjoyment of them. By a law of Valentinian I. (377) the sale of these slaves was interdicted unless the land they occupied was at the same time sold. The legal distinction between the coloni and the slave tenants continued to exist after the invasions; but the practical difference was greatly attenuated. The colonus often occupied a servile mansus, and the slave a mansus originally appropriated to a colonus. Intermarriages of the two classes became frequent. Already at the end of the 7th century it does not appear that the distinction between them had any substantial existence.

The influence of the Northern invasions on the change from slavery to serfdom was, in all probability, of little account. The change would have taken place, though perhaps not so speedily, if they had never occurred. For the developments of the middle ages *see* SERFDOM and *VILLEINAGE.*

MODERN SLAVE TRADE

Not very long after the disappearance of serfdom in the most advanced communities comes into sight the new system of colonial slavery, which, instead of being the spontaneous outgrowth of social necessities and subserving a temporary need of human development, was politically as well as morally a monstrous aberration.

Spanish Colonies.—In 1442, when the Portuguese under Prince Henry the Navigator were exploring the Atlantic coast of Africa, one of his officers, Antam Goncalves, who had captured some Moors, was directed by the prince to carry them back to Africa. He received from the Moors in exchange for them ten blacks and a quantity of gold dust. This excited the cupidity of his fellow-countrymen; and they fitted out a large number of ships for the trade, and built several forts on the African coast. Many negroes were brought into Spain from these Portuguese settlements, and the colonial slave trade first appears in the form of the introduction into the newly discovered western world of descendants of these negroes. When Nicolas de Ovando was sent out in 1502 as governor of Haiti, whilst regulations, destined to prove illusory, were made for the protection of the natives of the island, permission was given to carry to the colony negro slaves, born in Seville and other parts of Spain, who had been instructed in the Christian faith. It appears from a letter of Ovando in 1503 that there were at that time numbers of negroes in Haiti; he requested that no more might be permitted to be brought out. In 1510 and the following years King Ferdinand ordered a number of Africans to be sent to that colony for the working of the mines.

Before this time Columbus had proposed an exchange of his Carib prisoners as slaves against live stock to be furnished to Haiti by Spanish merchants. He actually sent home, in 1494, above 500 Indian prisoners taken in wars with the caciques, who, he suggested, might be sold as slaves at Seville. But, after a royal order had been issued for their sale, Queen Isabella, interested by what she had heard of the gentle and hospitable character of the natives and of their docility, procured a letter to be written to Bishop Fonseca, the superintendent of Indian affairs, suspending the order until enquiry should be made into the causes for which they had been made prisoners, and into the lawfulness of their sale. Theologians differed on the latter question, and Isabella directed that these Indians should be sent back to their native country.

Bartolomé de las Casas, the celebrated bishop of Chiapa, accompanied Ovando to Haiti, and was a witness of the cruelties from which the Indians suffered under his administration. He came to Spain in 1517 to obtain measures in their favour, and he then made the suggestion to Charles that each Spanish resident in Haiti should have licence to import a dozen negro slaves. Las Casas, in his *Historia de las Indias* (lib. iii. cap. 101), confesses the error into which he thus fell. Other good men appear to have given similar advice about the same time, and, as has been shown, the practice was not absolutely new; indeed, the young king had in 1516, whilst still in Flanders, granted licences to his courtiers for the importation of negroes into the colonies, though Jimenes, as regent of Castile, by a decree of the same year forbade the practice. The suggestion of Las Casas was no doubt made on the ground that the negroes could, better than the Indians, bear the labour in the mines, which was rapidly exhausting the numbers of the latter. He has sometimes on this plea been exonerated from all censure; but, though entitled to honour for the zeal which he showed on behalf of the natives, he must bear the blame for his violation or neglect of moral principle. His advice was unfortunately adopted. "Charles," says Robertson, "granted a patent to one of his Flemish favourites, containing an exclusive right" of supplying 4,000 negroes annually to Haiti, Cuba, Jamaica and Porto Rico. "The favourite sold his patent to some Genoese merchants for 25,000 ducats"; these merchants obtained the slaves from the Portuguese; and thus was first systematized the slave trade between Africa and America.

England.—The first Englishman who engaged in the traffic was Sir John Hawkins (*q.v.*). The English slave traders were at first altogether occupied in supplying the Spanish settlements. Indeed, the reign of Elizabeth passed without any English colony having been permanently established in America. But in 1619 a Dutch ship from the coast of Guinea visited Jarnestown in Virginia, and sold a part of her cargo of negroes to the tobacco-planters. This was the beginning of slavery in British America; the number of negroes was afterwards continually increased—though apparently at first slowly—by importation, and the field-labour was more and more performed by servile hands, so that in 1790 the State of Virginia contained 200,000 negroes.

The African trade of England was long in the hands of exclusive companies; but by an act of the first year of William and Mary it became free and open to all subjects of the Crown. The African company, however, continued to exist, and obtained from time to time large parliamentary grants. By the Treaty of Utrecht, the asiento, or contract for supplying the Spanish colonies with 4,800 negroes annually, which had previously passed from the Dutch to the French, was transferred to Great Britain; an English company was to enjoy the monopoly for a period of 30 years from May 1, 1713. But the contract came to an end in 1739, when the complaints of the English merchants on one side and of the Spanish officials on the other rose to such a height that Philip V. declared his determination to revoke the asiento, and Sir Robert Walpole was forced by popular feeling into war with Spain. Between 1680 and 1700 about 140,000 negroes were exported by the African company, and 160,000 more by private adventurers, making a total of 300,000. Between 1700 and the end of 1786 as many as 610,000 were transported to Jamaica alone, which had been an English possession since 1655. Bryan Edwards estimated the total import into all the British colonies of America and the West Indies from 1680 to 1786 at 2,130,000, being an annual average of 20,095. The British slave trade reached its utmost extension shortly before the War of American Independence. It was then carried on principally from Liverpool, but also from London, Bristol and Lancaster: the entire number of slave ships sailing from those ports was 192 and in them space was provided for the transport of 47,146 negroes. During fhe war the number decreased, but on its termination the trade immediately revived. When Edwards wrote (1791), the number of European factories on the coasts of Africa was 40; of these 14 were English, 3 French, 15 Dutch, 4 Portuguese and 4 Danish. As correct a notion as can be obtained of the numbers annually exported from the continent about the year 1790 by traders of the several European countries engaged in the traffic is supplied by the following statement: "By the British, 38,000; by the French, 20,000; by the Dutch, 4,000; by the Danes, 2,000; by the Portuguese, 10,000; total 74,000." Thus more than half the trade was in British hands.

The hunting of human beings to make them slaves was greatly aggravated by the demand of the European colonies. The native chiefs engaged in forays, sometimes even on their own subjects, for the purpose of procuring slaves to be exchanged for Western commodities. They often set fire to a village by night and captured the inhabitants when trying to escape. Thus all that was shocking in the barbarism of Africa was multiplied and intensified by this foreign stimulation. Exclusive of the slaves who died before they sailed from Africa, 12½% were lost during their passage to the West Indies; at Jamaica 4½% died whilst in the harbours or before the sale and one-third more in the "seasoning." Thus, out of every lot of 100 shipped from Africa 17 died in about 9 weeks, and not more than 50 lived to be effective labourers in the islands. The circumstances of their subsequent life on the plantations were not favourable to the increase of their numbers. In Jamaica there were in 1690, 40,000; from that year till 1820 there were imported 800,000; yet at the latter date there were only 340,000 in the island. One cause which prevented the natural increase of population was the inequality in the numbers of the sexes; in Jamaica alone there was in 1789 an excess of 30,000 males.

Movement Against the **Slave** Trade.—When the nature of the slave trade began to be understood by the public, all that was best in England was adverse to it. Among those who denounced it—besides some whose names are now little known, but are recorded in the pages of Clarkson—were Baxter, Sir Richard Steele (in *Inkle and Yarico*), the poets Southern (in *Oroonoko),* Pope, Thomson, Shenstone, Dyer, Savage and above all Cowper *(see* his *Cizarity,* and *Task,* bk. 2), Thomas Day (author of *Sandford and Merton*), Sterne, Warburton, Hutcheson, Beattie, John Wesley, Whitfield, Adam Smith, Millar, Robertson, Dr. Johnson, Paley, Gregory, Gilbert Wakefield, Bishop Porteus, Dean Tucker. The question of the legal existence of slavery in Great Britain and Ireland was raised in consequence of an opinion given in 1729 by Yorke and Talbot, attorney-general and solicitor-general at the time, to the effect that a slave by coming into those countries from the West Indies did not become free, and might be compelled by his master to return to the plantations. Chief-justice Holt had expressed a contrary opinion; and the matter was brought to a final issue by Granville Sharp in the case of the negro Somerset. It was decided by Lord Mansfield, in the name of the whole bench, on June 22, 1772, that as soon as a slave set his foot on the soil of the British islands he became free. In 1776 it was moved in the House of Commons by David Hartley, son of the author of *Observations on Man,* that "the slave trade was contrary to the laws of God and the rights of men"; but this motion—the first which was made on the subject—failed.

The first persons in England who took united practical action against the slave trade were the Quakers, following the expression of sentiment which had emanated as early as 1671 from their founder George Fox. In 1727 they declared it to be "not a commenclable or allowed" practice; in 1761 they excluded from their society all who should be found concerned in it, and issued appeals to their members and the public against the system. In 1783 there was formed among them an association "for the relief and liberation of the negro slaves in the West Indies, and for the discouragement of the slave trade on the coast of Africa." This was the first society established in England for the purpose. The Quakers in America had taken action on the subject still earlier than those in England. The Pennsylvanian Quakers advised their members against the trade in 1696; in 1754 they issued to their brethren a strong dissuasive against encouraging it in any manner; in 1774 all persons concerned in the traffic, and in 1776 all slave holders who would not emancipate their slaves, were excluded from membership. The Quakers in the other American provinces followed the lead of their brethren in Pennsylvania. The individuals among the American Quakers who laboured most earnestly and indefatigably on behalf of the Africans were John Woolman (1720–72) and Anthony Benezet (1713–84), the latter a son of a French Huguenot driven from France by the revocation of the Edict of Nantes. The former confined his efforts chiefly to America and, indeed, to his co-religionists there; the latter sought, not without success, to found a universal propaganda in favour of abolition. A Pennsylvanian society was formed in 1774 by James Pemberton and Dr. Benjamin Rush, and in 1787 (after the war) was reconstructed on an enlarged basis under the presidency of Franklin Other similar associations were founded about the same time in different parts of the United States. The next important movement took place in England. Dr. Peckard, vice-chancellor of the University of Cambridge, who entertained strong convictions against the slave trade, proposed in 1785 as subject for a Latin prize dissertation the question, "An liceat invitos in servitutem dare." Thomas Clarkson obtained the first prize, translated his essay into English in an expanded form, and published it in 1786 with the title *Essay on the Slavery and Commerce of the Human Species.* In the process of its publication he was brought into contact with several persons already deeply interested in the question; amongst others with Granville Sharp, William Dillwyn (an American by birth, who had known Benezet), and the Rev. James Ramsay, who had lived 19 years in St. Christopher, and had published an *Essay on the Treatment and Conversion of the African Slaves in tlze British Sugar Colonies.* The distribution of Clarkson's book led to his forming connections with many persons of influence, and especially with William Wilberforce (*q.v.*). A committee was forrned on May 22, 1787, for the abolition of the slave trade, under the presidency of Granville Sharp. It is unquestionable that the principal motive power which originated and sustained their efforts was Christian principle and feeling. The most earnest and unremitting exertions were made by the persons so associated in investigating facts and collecting evidence, in forming branch committees and procuring petitions, information and support of those who pleaded the cause in parliament. To the original members were afterwards added several remarkable persons, amongst whom were Josiah Wedgwood, Bennet Langton (Dr. Johnson's friend), and, later, Zachary Macaulay, Henry Brougham and James Stephen.

In consequence of the numerous petitions presented to parliament, a committee of Privy Council was appointed by the Crown in 1788 to enquire concerning the slave trade; and Pitt moved that the House of Commons should early in the next session take the subject into consideration. Wilberforce's first motion for a committee of the whole House upon the question was made on March 19, 1789, and this committee proceeded to business on May 12 of the same year. After an admirable speech, Wilberforce laid on the table 12 resolutions which were intended as the basis of a future motion for the abolition of the trade. The discussion of these was postponed to the next session, and in 1790–91 evidence was taken upon them. At length, on April 18 of the latter year, a motion was made for the introduction of a bill to prevent the further importation of slaves into the British colonies in the West Indies. Opinion had been prejudiced by the insurrections in St. Domingo and Martinique, and in the British island of Dominica; and the motion was defeated by 163 votes against 88. Legislative sanction was, however, given to the establishment of the Sierra Leone company, for the colonization of a district on the west coast of Africa and the discouragement of the slave trade there. It was hoped at the time that that place would become the centre from which the civilization of Africa would proceed; but this expectation was not fulfilled. On April 2, 1792 Wilberforce again moved that the trade ought to be abolished; an amendment in favour of gradual abolition was carried, and it was finally resolved that the trade should cease on Jan. 1, 1796. When a similar motion was brought forward in the Lords the consideration of it was postponed to the following year, in order to give time for the examination of witnesses by a committee of the House. A bill in the Commons in the following year to abolish that part of the trade by which British merchants supplied foreign settlements with slaves was lost on the third reading; it was renewed in the Commons in 1794 and carried there, but defeated in the Lords. Then followed several years during which efforts were made by the abolitionists in parliament with little success. But in 1806, Lord Grenville and Fox having come into power, a bill was passed in both Houses to put an end to the British slave trade for foreign supply, and to forbid the importation of slaves into the colonies won by the British arms in the course of the war. On June 10 of the same year Fox brought forward a resolution "that effectual measures should be taken for the abolition of the African slave trade in such a manner and at such a period as should be deemed advisable," which was carried by a large majority. A similar resolution was successful in the House of Lords. A bill was then passed through both Houses forbidding the employment of any new vessel in the trade. Finally, in 1807, a bill was presented by Lord Grenville in the House of Lords providing for the abolition of the trade, was passed by a large majority, was then sent to the Commons (where it was moved by Lord Howick), was there amended and passed, and received the royal assent on March 25. The bill enacted that no vessel should clear out for slaves from any port within the British dominions after May 1, 1807, and that no slave should be landed in the colonies after March 1, 1808.

In 1807 the African Institution was formed, with the primary objects of keeping a vigilant watch on the slave traders and procuring, if possible, the abolition of the slave trade by the other European nations. It was also to be made an instrument for promoting the instruction of the negro races and diffusing information respecting the African continent.

The act of 1807 was habitually violated, as the traders knew that, if one voyage in three was successful, they were abundantly remunerated for their losses. This state of things. it was plain, must continue as long as the trade was only a contraband commerce, involving merely pecuniary penalties. Accordingly. in 1811. Brougham carried through parliament a bill declaring the traffic to be a felony punishable with transportation. Some years later another act was passed, making it a capital offence; but this was afterwards repealed. The law of 1811 proved effectual and brought the slave trade to an end so far as the British dominions were concerned.

French Abolition.—The abolition of the French slave trade was preceded by struggles and excesses. The western part of St. Domingo, nominally belonging to Spain, had been occupied by buccaneers, who were recognized and supported by the French Government, and had been ceded to France at the Peace of Ryswick in 1697. So vast was the annual importation of enslaved negroes into this colony before 1791 that the ratio of the blacks to the whites was as 16 to 1. In that year there were in French St. Domingo 480,000 blacks, 24,000 mulattoes and only 30,000 whites. The French law for the regulation of slavery in the plantations, known as the Code *Noir* (framed under Louis XIV. in 1685), was humane in its spirit; but we are informed that its provisions were habitually disregarded by the planters, whilst the free mulattoes laboured under serious grievances and were exposed to irritating indignities. A "Société des Amis des Noirs" was formed in Paris in 1788 for the abolition, not only of the slave trade, but of slavery itself. The president was Condorcet, and amongst the members were the duc de la Rochefoucault, the abbé Gregoire, Brissot, Clavière, Pétion and La Fayette; Mirabeau was an active sympathizer. The great motor of the parallel effort in England was the Christian spirit; in France it was the enthusiasm of humanity which was associated with the revolutionary movement. There were in 1789 a number of mulattoes in Paris, who had come from San Domingo to assert the rights of the people of colour in that colony before the national assembly. The Declaration of the Rights of Man in Aug. 1789 seemed to meet their claims, but in March 1790 the assembly, alarmed by rumours of the discontent and disaffection of the planters in San Domingo, passed a resolution that it had not been intended to comprehend the internal government of the colonies in the constitution framed for the mother country. Vincent Ogé, one of the muiatto delegates in Paris, disgusted at the overthrow of the hopes of his race, returned to San Domingo, and on landing in Oct. 1790 addressed a letter to the governor announcing his intention of taking up arms on behalf of the mulattoes if their wrongs were not redressed. He rose accordingly with a few followers, but was soon defeated and forced to take refuge in the Spanish part of the island. He afterwards surrendered, was tried and sentenced to be broken on the wheel. When the news of this reached Paris, it created a strong feeling against the planters; and on the motion of the abbé Gregoire it was resolved by the assembly on May 15, 1791 "that the people of colour resident in the French colonies, born of free parents, were entitled to, as of right, and should be allowed, the enjoyment of all the privileges of French citizens, and among others those of being eligible to seats both in the parochial and colonial assemblies." On Aug. 23 a rebellion of the negroes broke out in the northern province of San Domingo, and soon extended to the western province, where the mulattoes and blacks combined. Many enormities were committed by the insurgents, and were avenged with scarcely inferior barbarity. The French assembly, fearing the loss of the colony, repealed on Sept. 24 the decree of the preceding May. This vacillation put an end to all hope of a reconciliation of parties in the island. Civil commissioners sent out from France quarrelled with the governor and called the revolted negroes to their assistance. The white inhabitants of Cape François were massacred and the city in great part destroyed by fire. The planters now offered their allegiance to Great Britain; and an English force landed in the colony. But it was insufficient to encounter the hostility of the republican troops and the revolted negroes and mulattoes; it suffered from disease. and was obliged to evacuate the island in 1798. On the departure of the British the Government remained in the hands of Toussaint l'Ouverture (*q.v.*). Slavery had disappeared: the blacks were employed as hired servants, receiving for their remuneration the third part of the crops they raised; and the population was rapidly rising in civilization and comfort. The whole island was now French, the Spanish portion having been ceded by the Treaty of Basle. The wish of Toussaint was that San Domingo should enjoy a practical independence whilst recognizing the sovereignty and exclusive commercial rights of France. The issue of the violent and treacherous conduct of Bonaparte towards the island was that the blacks drove from their soil the forces sent to subdue them, and founded a constitution of their own, which was more than once modified. There can be no doubt that the Government of the Restoration, in seeking to obtain possession of the island, had the intention of re-establishing slavery, and even of reopening the slave trade for the purpose of recruiting the diminished population. But Bonaparte abolished that trade during the Hundred Days, though he also failed to win back the people of San Domingo, or, as it was now called by its original name, Haiti, to obedience. The Bourbons, when again restored, could not reintroduce the slave trade; the notion of conquering the island had to be given up; and its independence was formally recognized in 1825. (See HAITI.)

Progress of the Movement.—England had not been the first European Power to abolish the slave trade; that honour belongs to Denmark; a royal order was issued on May 16, 1792 that the traffic should cease in the Danish possessions from the end of 1802. The United States had in 1794 forbidden any participation by American subjects in the slave trade to foreign countries; they now prohibited the importation of slaves from Africa into their own dominions. This act was passed on March 2, 1807; it did not, however, come into force till Jan. 1, 1808. At the Congress of Vienna (Nov. 1814) the principle was acknowledged that the slave trade should be abolished as soon as possible; but the deterniination of the limit of time was reserved for separate negotiation between the Powers. It had been provided in a treaty between France and Great Britain (May 30, 1814) that no foreigner should in future introduce slaves into the French colonies, and that the trade should be absolutely interdicted to the French themselves after June 1, 1819. This postponement of abolition was dictated by the wish to introduce a fresh stock of slaves into Haiti, if that island should be recovered. Bonaparte, as we have seen, abolished the French slave trade during his brief restoration, and this abolition was confirmed at the second Peace of Paris on Nov. 20, 1815, but it was not eifectually carried out by French legislation until March 1818. In Jan. 1815 Portuguese subjects were prohibited from prosecuting the trade north of the equator, and the term after which the traffic should be everywhere unlawful was fixed to end on Jan. 21, 1823, but was afterwards extended to Feb. 1830; England paid £300,000 as a compensation to the Portuguese. A royal decree was issued on Dec. 10, 1836, forbidding the export of slaves from any Portuguese possession. But this decree was often violated It was agreed that the Spanish slave trade should come to an end in 1820, England paying to Spain an indemnification of £400,000. The Dutch trade was closed in 1814; the Swedish had been abolished in 1813. By the Peace of Ghent, Dec. 1814, the United States and England mutually bound themselves to do all in their power to extinguish the traffic It was at once prohibited in several of the South American States when they acquired independence, as in La Plata, Venezuela and Chile. In 1831 and 1833 Great Britain entered into an arrangement with France for a mutual right of search within certain seas, to which most of the other Powers acceded; and by the Ashburton Treaty (1842) with the United States provision was made for the joint maintenance of squadrons on the west coast of Africa. By all these measures the slave trade, so far as it was carried on under the flags of European nations or for the supply of their colonies, ceased to exist.

Anti-slavery Movement.—Meantime another and more radical reform had been in preparation and was already in progress, namely, the abolition of slavery itself in the foreign possessions of the several States of Europe. When the English slave trade had been closed, it was found that the evils of the traffic, as still continued by several other nations, were greatly aggravated. In consequence of the activity of the British cruisers the traders made great efforts to carry as many slaves as possible in every voyage, and practised atrocities to get rid of the slaves when capture was imminent. It was, besides, the interest of the cruisers, who shared the price of the captured slave-ship, rather to allow the slaves to be taken on board than to prevent their being shipped at all. Thrice as great a number of negroes as before, it was said, was exported from Africa, and two-thirds of these were murdered on the high seas. It was found also that the abolition of the British slave trade did not lead to an improved treatment of the negroes in the West Indies. The slaves were overworked now that fresh supplies were stopped, and their numbers rapidly decreased In 1807 there were in the West Indies 800,000; in 1830 they were reduced to 700,000. It became more and more evident that the evil could be stopped only by abolishing slavery altogether.

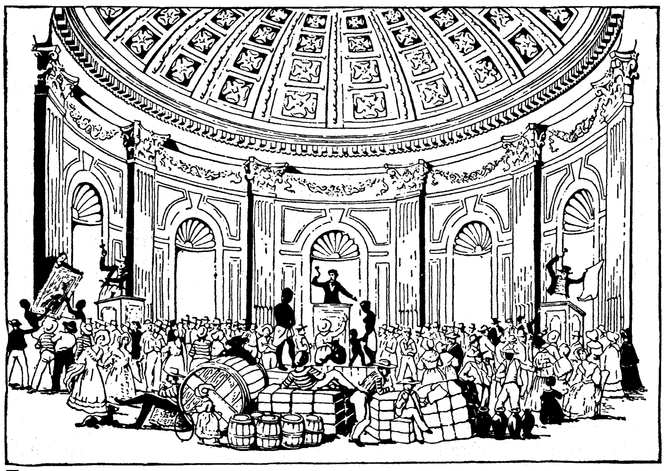
An appeal was made by Wilherforce in 1821 to Thomas Fowell Buxton to undertake the conduct of this new question in parliament. An anti-slavery society was established in 1823, the principal members of which, besides Wilberforce and Buxton, were Zachary Macaulay, Dr. Lushington and Lord Suffield. Buxton moved on May 5, 1823, that the House should take into consideration the state of slavery in the British colonies. The object he and his associates had then in view was gradual abolition by establishing something like a system of serfdom for existing slaves, and passing at the same time a measure emancipating all their children born after a certain day. Canning carried against Buxton and his friends a motion to the effect that the desired ameliorations in the condition and treatment of the slaves should be recommended by the home Government to the colonial legislatures, and enforced only in case of their resistance, direct action being taken in the single instance of Trinidad. which, being a Crown colony, had no legislature of its own. A well-conceived series of measures of reform was accordingly proposed to the colonial authorities. Thereupon a general outcry was raised by the planters at the acquiescence of the Government in the principles of the anti-slavery party. A vain attempt being made in Demerara to conceal from the knowledge of the slaves the arrival of the order in council, they became impressed with the idea that they had been set free, and accordingly refused to work. and, compulsion being resorted to, offered resistance Martial law was proclaimed; the disturbances were repressed with great severity; and the treatment of the missionary Smith, which was taken up and handled with great ability by Brougham, awakened strong feeling in England against the planters. The question, however, made little progress in parliament for some years, though Buxton, William Smith, Lushington, Brougham, Mackintosh, Butterworth and Denman, with the aid of Z. Macaulay, James Stephen, and others, continued the struggle, only suspending it during a period allowed to the local legislatures for carrying into effect the measures expected from them. In 1828 the free people of colour in the colonies were placed on a footing of legal equality with their fellow-citizens. In 1830 the public began to be aroused to a serious prosecution of the main issue. It was becoming plain that the planters would take no steps tending to the future liberation of the slaves, and the leaders of the movement determined to urge the entire abolition of slavery at the earliest practicable period. The Government continued to hesitate and to press for mitigations of the existing system. At length in 1833 the Ministry of Earl Grey took the question in hand and carried the abolition with little difficulty, the measure passing the House of Commons on Aug. 7, 1833, and receiving the royal assent on the 28th. A sum of 20 millions sterling was voted as compensation to the planters. A system of apprenticeship for seven years was established as a transitional preparation for liberty. The slaves were bound to work for their masters during this period for three-fourths of the day, and were to be liable to corporal punishment if they did not give the due amount of labour. The master was, in return, to supply them with food and clothing. All children under six years of age were to be at once free, and provision was to be made for their religious and moral instruction. Many thought the postponement of emancipation unwise. Immediate liberation was carried out in Antigua, and public tranquillity was so far from being disturbed there that the Christmas of 1833 was the first for 20 years during which martial law was not proclaimed in order to preserve the peace. Notwithstanding protracted and strenuous opposition on the part of the Government, the House of Commons passed a resolution against the continuance of the transitional system. When this was done the local legislatures saw that the slaves would no longer work for the masters; they accordingly cut off two years of the indentured apprenticeship, and gave freedom to the slaves in Aug. 1838 instead of 1840.

The example of Great Britain was gradually followed by the other European States, and some American ones had already taken action of the same kind. The immediate emancipation of the slaves in the French colonies was decreed by the Provisional Government of 1848. In 1858 it was enacted that every slave belonging to a Portuguese subject should be free in 20 years from that date, a system of tutelage being established in the meantime. This law came into operation on April 29, 1878, and the status of slavery was thenceforth illegal throughout the Portuguese possessions. The Dutch began the emancipation of their slaves in 1863. Several of the Spanish American states, on declaring their independence, had adopted measures for the discontinuance of slavery within their limits. It was abolished by a decree of the

Mexican republic on Sept. 15, 1829. The government of Buenos Aires enacted that all children born to slaves after Jan. 31, 1813, should be free; and in Colombia it was provided that those born after July 16, 1821, should be liberated on attaining their eighteenth year.

Three of the most important slave systems still remained in which no steps towards emancipation had been taken — those of the Southern United States, of Cuba and of Brazil.

Slavery in the United States. — Slavery was far from being approved in principle by the most eminent of the fathers of the American Union. Washington in his will provided for the emancipation of his own slaves; he said to Jefferson that it was "among his first wishes to see some plan adopted by which slavery in his country might be abolished by law," and again he wrote that to this subject his own suffrage should never be wanting. John Adams declared his abhorrence of the practice of slave-holding, and said that "every measure of prudence ought to be assumed for the eventual total extirpation of slavery from the United States." Franklin's opinions we have already indicated; and Madison, Hamilton and Patrick Henry all reprobated the principle of the system. Jefferson declared in regard to slavery, "I tremble for my country when I reflect that God is just" The last-named statesman, at the first Continental Congress after the evacuation by the British forces, proposed a draft ordinance (March 1, 1784) for the government of the North-west Territory, in which it was provided that "after the year 1800 there shall be neither slavery nor involuntary servitude in any of the said states, otherwise than in punishment of crime." This proviso, however, was lost; but in the ordinance of 1787 (July 13) for the government of the territory of the United States north-west of the Ohio river, which was introduced by Nathan Dane and probably drafted by Manasseh Cutler, slavery was forbidden in the territory. At the Convention of Philadelphia in 1787, where the constitution was drafted, the sentiments of the framers were against slavery; but South Carolina and Georgia insisted on its recognition as a condition of their joining the Union, and even an engagement for the mutual rendition of fugitive slaves was embodied in the Federal pact. The words "slave" and "slavery" were, however, excluded from the constitution, "because," as Madison says, "they did not choose to admit the right of property in man" in direct terms; and it was at the same time provided that Congress might interdict the foreign slave trade after the expiration of 20 years. It must not be forgotten that either before or soon after the formation of the Union the Northern States — beginning with Vermont in 1777, and ending with New Jersey in 1804 – either abolished slavery or adopted measures to effect its gradual abolition within their boundaries. But the principal operation of (at least) the latter change was simply to transfer Northern slaves to Southern markets.



THE SALE OF ESTATES. PICTURES AND SLAVES IN THE ROTUNDA, NEW ORLEANS; FROM A STEEL ENGRAVING BY J. M. STARLING EXECUTED AFTER THE PAINTING BY W. H. BROOKE

We cannot follow in detail the several steps by which the slave power for a long time persistently increased its influence in the Union. The acquisition of Louisiana in 1803, which gave a new field for the growth of the slave power, though not made in its interest, the Missouri Compromise (1820), the annexation of Texas (1845), the Fugitive Slave Law (1850), the Kansas-Nebraska bill (1854), the Dred Scott decision (1857), the attempts to acquire Cuba (especially in 1854) and to reopen the foreign slave trade (1859–60), were the principal steps — only some of them successful — in its career of aggression. They roused a determined spirit of opposition, founded on deep-seated convictions. The pioneer of the more recent abolitionist movement was Benjamin Lundy (1789–1839). He was followed by William Lloyd Garrison (1805–79), Elijah P. Lovejoy (1802–37) — a martyr, if ever there was one — Wendell Phillips, Charles Sumner, John Brown (b. 1800, hanged 1859), all of whom were in their several ways leading apostles or promoters of the cause. The best intellect of America outside the region of practical politics has been on the anti-slavery side. William E. Channing, R. W. Emerson, the poets Bryant, Longfellow, pre-eminently Whittier and Whitman, have spoken on this theme with no uncertain sound. The South, and its partisans in the North, made desperate efforts to prevent the free expression of opinion respecting the institution, and even the Christian Churches in the slave States used their influence in favour of the maintenance of slavery. But in spite of every such effort opinion steadily grew. Public sentiment in the North was deeply stirred by the *Uncle Tom's Cabin* (1852) of Mrs. Harriet Beecher Stowe, which, as Senior said, under the disguise of a novel was really a pamphlet against the Fugitive Slave Law. It gradually became apparent that the question could not be settled without an armed conflict. The election of Abraham Lincoln as president in Nov. 1860 was the signal for the rising of the South. The North at first took arms simply to maintain the Union; but the farsighted politicians from the first, and soon the whole nation, saw that the real issue was the continued existence or the total abolition of slavery. (See UNITED STATES.)

The war was practically closed by the surrender at Appomattox (April 9, 1865), but already in 1862 slavery in the territories had been abolished by Congress; on Sept. 22 of the same year Lincoln (*q.v.*) had issued the preliminary emancipation proclamation, followed on Jan. 1, 1863, by the emancipation of all slaves in the States in arms against the Union; and in Dec. 1865 a constitutional amendment was ratified abolishing and for ever prohibiting slavery throughout the United States.

Cuba. — The Spanish slave code, promulgated in 1789, is admitted on all hands to have been very humane in its character; and, in consequence of this, after Trinidad had become an English possession, the anti-slavery party resisted — and successfully — the attempt of the planters (1811) to have the Spanish law in that island replaced by the British. But notwithstanding this mildness of the code, its provisions were habitually and glaringly violated in the colonies of Spain, and in Cuba particularly the conditions of slavery were very bad. The slave population of the island was estimated in 1792 at 84,000; in 1817 at 179,000; in 1827 at 286,000; and in 1843 at 436,000. An act was passed by the Spanish legislature in 1870, providing that every slave who had then passed, or should thereafter pass, the age of 60 should be at once free, and that all yet unborn children of slaves should also be free. The latter, however, were to be maintained at the expense of the proprietors up to their eighteenth year, and during that time to be kept, as apprentices, to such work as was suitable for their age. This was known as the Moret Law, having been carried through the house of representatives by Señor Moret y Prendergast, then minister for the colonies. By the census of 1867 there was in Cuba a total population of 1,370,211 persons, of whom 764,750 were whites and 605,461 black or coloured; and of the latter number 225,938 were free and 379,523 were slaves. In 1873 the Cubans roughly estimated the population at 1,500,000 — of whom 500,000, or one-third, were slaves. In 1885, it was stated that "the institution was rapidly dying — that in a year, or at most two, slavery, even in its then mild form, would be extinct."

Brazil. — There was a convention between Great Britain and

Brazil in 1826 for the abolition of the slave trade, but it was habitually violated in spite of the English cruisers. In 1830 the traffic was declared piracy by the emperor of Brazil. England asserted by the Aberdeen Act (1845) the right of seizing suspected craft in Brazilian waters. Yet by the connivance of the local administrative authorities 54,000 Africans continued to be annually imported. In 1850 the trade is said to have been decisively put down. The planters and mine proprietors cried out against this as a national calamity. The closing of the traffic made the labour of the slaves more severe, and led to the employment on the plantations of many who before had been engaged in domestic work; but the slavery of Brazil had always been lighter than that of the United States. On Sept. 28, 1871, the Brazilian chambers decreed that slavery should be abolished throughout the empire. Though existing slaves were to remain slaves still, with the exception of those possessed by the Government, who were liberated by the act, facilities for emancipation were given; and it was provided that all children born of female slaves after the day on which the law passed should be free. They were, however, bound to serve the owners of their mothers for a term of 21 years. A clause was inserted to the effect that a certain sum should be annually set aside from fines to aid each province in emancipating slaves by purchase. Seven years before the passing of this act the emperor, whose influence had always been exerted in favour of freedom, had liberated his private slaves, and many Brazilians after 1871 followed his example. Finally, in 1888 the chambers decreed the total abolition of slavery, some 700,000 persons being accordingly freed.

Disguised Slave Trade.—In the colonies of more than one European country, after the prohibition of the slave trade, attempts were made to replace it by a system of importing labourers of the inferior races under contracts for a somewhat lengthened term; and this was in several instances found to degenerate into a sort of legalized slave traffic. About 1867 we began to hear of a system of this kind which was in operation between the South Sea islands and New Caledonia and the white settlements in Fiji. It seems to have begun in really voluntary agreements; but for these the unscrupulous greed of the traders soon substituted methods of fraud and violence. The natives were decoyed into the labour ships under false pretences. and then detained by force; or they were seized on shore or in their canoes and carried on hoard The nature of the engagements to go and work on the plantations was not fully explained to them, and they mere hired for periods exceeding the legal term. The area of this trade was ere long further extended In 1884 attention was drawn in a special degree to the Queensland traffic in Pacific Islanders by the "Hopeful" trials, and a Government commission was appointed to enquire into the methods followed by labour ships in recruiting the natives of New Guinea, the Louisiade archipelago and the D'Entrecasteaux group of islands. The result of the investigations, during which nearly 500 witnesses were examined, was the disclosure of a system which in treachery and atrocity was little inferior to the old African slave trade. These shameful deeds made the islanders regard it as a duty to avenge their wrongs on any white men they could entice upon their shores. The bishop of Melanesia, John Coleridge Patteson, fell a victim to this retaliation in the island of Nukapu on Sept. 20, 1871.

It now remains to consider the slavery of primitive origin which has existed within recent times, or continues to exist, outside of the Western world

Russian Serfdom.—In Russia, a country which had not the same historical antecedents with the Western nations, properly so called, and which is, in fact, more correctly classed as Eastern, whilst slavery had disappeared, serfdom was in force down to recent days The rural population of that country, at the earliest period accessible to our enquiries, consisted of (1) slaves, (2) free agricultural labourers and (3) peasants proper, who were small farmers or cottiers and members of a commune. The sources of slavery were there, as elsewhere, capture in war, voluntary sale by poor freemen of themselves, sale of insolvent debtors and the action of the law in certain criminal cases. In the 18th century we find the distinction between the three classes named above effaced and all of them merged in the class of serfs, who were the property either of the landed proprietors or of the State. They were not even *adscripti* glebae, though forbidden to migrate; an imperial ukase of 1721 says, "the proprietors sell their peasants and domestic servants, not even in families, but one by one, like cattle." This practice, at first tacitly sanctioned by the Government, which received dues on the sales, was at length formally recognized by several imperial ukases. Peter the Great imposed a poll-tax on all the members of the rural population, making the proprietors responsible for the tax charged on their serfs; and the "free wandering people" who were not willing to enter the army were required to settle on the land either as members of a commune or as serfs of some proprietor.

The system of serfdom attained its fullest development in the reign of Catherine II. The serfs were bought, sold and given in presents, sometimes with the land, sometimes without it, sometimes in families and sometimes individually, sale by public auction being alone forbidden, as "unbecoming in a European state." The proprietors could transport without trial their unruly serfs to Siberia or send them to the mines for life, and those who presented complaints against their masters were punished with the knout and condemned to the mines. The first symptoms of a reaction appear in the reign of Paul (1796–1801). He issued an ukase that the serfs should not be forced to work for their masters more than three days in each week. There were several feeble attempts at further reform, and even abortive projects of emancipation, from the commencement of the 19th century. But no decisive measures were taken before the accession of Alexander II. (1855). That emperor, after the Crimean War, created a secret committee composed of the great officers of State, called the chief committee for peasant affairs, to study the subject of serf-emancipation. Of this body the grand-duke Constantine was an energetic member. To accelerate the proceedings of the committee advantage was taken of the following incident. In the Lithuanian provinces the relations of the masters and serfs were regulated in the time of Nicholas by what were called inventories. The nobles, dissatisfied with these, now sought to have them revised. The Government interpreted the application as implying a wish for the abolition of serfdom, and issued a rescript authorizing the formation of committees to prepare definite proposals for a gradual emancipation. A circular was soon after sent to the governors and marshals of the nobility all over Russia proper, informing them of thisdesire of the Lithuanian nobles, and setting out the fundamental principles uhich should be observed "if the nobles of the provinces should express a similar desire." Public opinion strongly favoured the projected reform: and even the masters who were opposed to it saw that. if the operation became necessary, it would be more safely for their interests entrusted to the nobles than to the bureaucracy. Accordingly during 1858 a committee was created in nearly every province in which serfdom existed. From the schemes prepared by these committees, a general plan had to be elaborated, and the Government appointed a special imperial commission for this purpose.

The plan was formed, and, in spite of some opposition from the nobles, which was suppressed, it became law, and serfdom was abolished (Feb. 19–March 3, 1861). (See RUSSIA.) The total number of serfs belonging to proprietors at the time of the emancipation was 21,625,609, of whom 20,158,231 were peasant serfs and 1,467,378 domestic serfs. This number does not include the State serfs, who formed about one-half of the rural population. Their position had been better, as a rule, than that of the serfs on private estates; it might, indeed, R. D. M. Wallace says, be regarded as "an intermediate position between serfage and freedom." Amongst them were the serfs on the lands formerly belonging to the Church, which had been secularized and transformed into State demesnes by Catherine II. There were also serfs on the apanages affected to the use of the imperial family; these amounted to nearly three and a half millions. Thus by the law of 1861 more than 40 millions of serfs were emancipated.

(J. K. I.)

AFRICA AND THE EAST

Internal and External Slave-Trade—The conscience of the civilized world had revolted from the cruelties of the slave-depots on the West African coast and the horrors of the transit of the close-packed human cargoes across the Atlantic, but little was known of the methods by which the slaves were obtained, or of the raids and the burning of villages and the wholesale depopulation of large regions to supply the slave-markets in Mohammedan countries in the East, and the demand in Africa itself. These first became known to Europe from the descriptions of the early explorers in the middle of the 19th century—notably by Dr. Livingstone in the east, Dr. Barth in the west and Sir Samuel Baker in the north. It was estimated by Livingstone that at least ten lives were sacrificed for each slave who reached the coast, and probably 50% of those who were shipped never reached their destination. To these appalling figures must be added the numbers exported from the northern ports and those required for the internal market.

Land Routes and Internal Demand.—The principal routes from the regions south of the Sahara lay across the desert from Timbuktu, Kano and Kuka (Bornu) to Morocco and Bengasi on the Mediterranean littoral for export to Turkey, and from Tadjurah (Red Sea), Zanzibar, Kilwa and other ports on the East African coast for export to Arabia and Iran. The principal internal demand, which, unlike the Atlantic trade, included women and eunuchs for Moslem harems, was by the Mohammedan kingdoms in West and North Africa, by Morocco, Egypt and Zanzibar, and by the Christian kingdom of Abyssinia. There was also a demand by Negro kingdoms such as Uganda, Benin and Dahomey, while throughout Africa dominant tribes held their captives in war as slaves, and raided their neighbours to capture women. In these Negro kingdoms and tribes large numbers of slaves were sacrificed in pagan ceremonials, on the death of the chief or of their owners.

Abolition of Slavery.—The revelations regarding the nature of slavery which accompanied the long struggle for the abolition of the Atlantic trade conducted by Europe and America, and the practical demonstration of the futility of treaties and edicts even when backed by force to cope with smugglers (see below). had naturally given rise to a crusade against the institution of slavery itself, and for the emancipation of the slaves held by civilized nations. This was gradually achieved in varying conditions as regards compensation to onners and provision for the freed slaves. So far as Britain mas concerned total abolition in all British overseas possessions nas enacted as early as 1833. and the same result was effected more gradually in India by the abolition of the legal status of slavery in 1843. In the United States emancipation took place in 1863.

East African Slave-Trade.—The export of slaves from East Africa to Arabia. Iran and India had been a lucrative trade for centuries. In 1812 the British Government brought pressure to bear on Seyid-bin-Sultan. who had asserted his rule over Muscat in the Persian gulf and over the island of Zanzibar, which was the emporium of the trade from East Africa. It mas not however until 1822 that he agreed under the Moresby Treaty to restrict the overseas traffic within a limit which excluded Iran and India. In 1840 he transferred his capital to Zanzibar, and in 1845 he yielded to further pressure and agreed to prohibit entirely the export of slaves, from which he had derived a revenue of over £20,000 per annum.

The organized Arab bands in the interior continued to send slaves to the coast who were surreptitiously shipped in dhows under conditions even worse than the "Middle Passage" across the Atlantic had been, in spite of the patrol maintained by British war-vessels and the sultan's edicts The British Government therefore dispatched a mission under Sir Bartle Frere in 1872 to demand the complete abolition of the traffic and the closure of the slave-markets. The sultan was compelled to accept, and under the influence of Sir John Kirk did his best to enforce his decrees with the aid of a well organized force on the mainland. In 1876 on his own initiative he even concluded a treaty by which the access of slaves to the coast port was forbidden.

International Pledges.—International reprobation of the slave-trade was first expressed at the Congress of Vienna in 1815, and in 1885 the Berlin Act pledged the 13 nations of .Europe and the United States "to watch over the preservation of the native tribes . . . and to help in suppressing slavery and especially the slave-trade." Four years later (1889) when the "Partition of Africa" between the European Powers had taken definite shape, the signatories of the Berlin Act—to whom were added Iran, Zanzibar and the Congo Free State—assembled in Brussels at the instance of Queen Victoria, with the declared object of "putting an end to the crimes and devastations engendered by the traffic in African slaves, protecting effectively the aboriginal populations of Africa, and insuring for that vast continent the benefits of peace and civilization." As regards the sea-borne slave-trade reciprocal rights of search, capture and trial of vessels under 500 tons were prescribed by the "General Act" within the "Maritime Zone" (formed by the coasts of the Indian ocean from Baluchistan to Quillimane, S Lat. 18°, including the Persian gulf and the Red sea, and thence back, including Madagascar), and strict regulations were enacted as to the use of the flag of a signatory Power and the carrying of Negro passengers in native vessels.

As regards the internal traffic the Act prohibited the introduction into Africa between 20° North, and 22° South Lat. of all fire-arms and ammunition other than flint-lock guns and trade powder, except under effective guarantees It proposed the establishment of "strongly occupied stations" as refuges for the native population, of cruisers, fortified posts and expeditions for repressive action. Its framers could not foresee the astonishing rapidity with which the Powers in control, eager to substantiate their frontiers by "effective occupation," would hasten in the words of the Act "the progressive organization of the administrative, judicial, religious and military services, as the most effective means of counteracting the slave-trade."

Effect of European Control.—The internal slave-trade did not however disappear without a struggle In the eastern Sudan the suppression of the Turco-Egyptian slave-raiders by Baker and Gordon had been effaced by the sanguinary rule of the Mahdi, until conquered by Kitchener in 1898. The consolidation of French rule in the north. and the final defeat of Samory and other powerful Mohammedan potentates in the west, put an end to the organized traffic in slaves. In Nigeria the power of the Mohammedan rulers who annually employed large armies in raiding for slaves, and had depopulated great regions, was broken in 1902–03, and slave-raiding was stopped In the Congo region Tippoo Tib, Rumaliza and other notable east-coast Arabs mho were practically independent of Zanzibar were crushed by King Leopold of Belgium after a severe struggle In Nyasaland—a favourite hunting-ground of the Zanzibar slavers—a stand had been made by a Scottish trading company, and when control was assumed by Great Britain. the raids of the slavers were suppressed. The advent of Europe was probably only just in time to anticipate and prevent a Mohammedan domination in central Africa. Before the close of the first decade of the 20th century the whole of Africa except Abyssinia and Liberia had come under European control and a more or less effective administration had been established.

Abolition of Slavery.—The abolition of the Atlantic slave-trade had proved ineffective to cope with the illicit traffic until followed by the abolition of slavery itself. So also in Africa, though the conditions were not the same. In the United States and the West Indies slaves were required for work on plantations owned by white men, but in Moslem countries and in Abyssinia the institution was so intimately interwoven in the social fabric that sudden and enforced emancipation would bring ruin and misery to the slaves not less than to their owners.

Moslem and Mosaic Slavery—The Koran enjoins the good treatment of the slave, and manumission is encouraged as an act of piety. The child of a slave-concubine by her master is free-born, and the mother is usually freed also. The slave "born in the house" is generally regarded as a member of the family, and to sell such a slave. except for incorrigible misconduct, would be condemned by public opinion. The favourite slaves of a ruler often hold high office as confidential advisers, as administrators of provinces or as leaders in the army. The master is bound to care for his slave in sickness and old age, and to maintain his wife and family. Facilities are afforded for self-redemption and for ransom The so-called "praedial slaves" on the other hand would generally be members of a conquered tribe, who remained on the land which had passed into the hands of the conqueror. Their status differed entirely from that of a slave (see below). Somewhat similar conditions mere prescribed by the Mosaic code in Abyssinia, but in both cases constant raids for new slaves depopulated the adjacent tribes.

The Act of 1833 which emancipated the slaves in British colonies did not seriously affect Africa except the Cape Colony. for the newly acquired territories mere protectorates to which it did not apply. It mas possible therefore to proceed more gradually by abolishing the legal status of slavery instead of by immediate and compulsory emancipation. No court of law can then recognize any rights based on the claim of any person to property in the person of another. Every slave can assert his freedom without any ransom or formality, and an owner is liable to process of law for attempting to detain a slave against his will, or to capture a runaway. On the other hand, it is not a crime for a master to retain a slave if both desire to remain in that relationship. It is permissive as contrasted with compulsory emancipation. Local ordinances have at the same time enacted that the acquisition of new slaves and all dealings in slaves are a penal offence, and that all children born after the date of the ordinance are free-born. These methods were effective in Nigeria, and were adopted by the emperor of Abyssinia, with much success prior to the conquest of the country by Italy in 1936. (Lu.)

SLAVERY AFTER WORLD WAR I

The Convention of St. Germain-en-Laye, 1919.—At the close of World War I the Convention of St. Germain-en-Laye, 1919, was signed by the principal Allied powers in that war. It purported to have abrogated the provisions of the Berlin act of 188j and of the Brussels act, 1890, relating to slavery, as between those powers and it substituted for them a declaration that the contracting parties would "endeavour to secure the complete suppression of slavery in all its forms and of the slave-trade by land and sea." The Brussels act. 1890, is still in force as between parties to it which did not adhere to the Convention of St. Germain-en-Laye, 1919, and doubts are entertained by international lawyers of authority as to whether it was in fact abrogated even between psrties to the convention.

The Slavery Convention, 1926.—The need of a precise definition of "slavery in all its forms:" combined with the recrudescence of the slave-trade between Africa and Arabia and the conditions of servitude prevailing in Ethiopia (Abyssinia) and Liberia, prompted the League of Nations to investigate slavery. Resulting therefrom, the Slavery convention. 1926, was prepared by the League, art. I of which defined slavery as "the status or condition of a person over whom any or all the powers attaching to the right of ownership are exercised." This convention was ratified by 44 states and is still in force. The United Nations assumed the powers and functions of the League of Nations under this convention by a protocol which became effective in July 1955.

The Forced Labour Convention, 1930.—Article 5 of the Slavery convention: 1926, prohibited forms of forced labour which approximated to slavery, but the problem of forced labour was referred by the League of Nations to the International Labour office which prepared a Forced Labour convention. This draft convention was adopted in 1930 and it has been ratified by 40 states. Forced labour is defined in this convention as "work or service (other than penal labour), exacted under menace of a penalty." Any form of compulsory labour for private enterprise is prohibited and governments may exact forced labour only if the labourers are adequately paid and are employed under strict safeguards. In 1952 a Committee on Forced Labour, appointed jointly by the United Nations and the International Labour office, investigated forced labour again and as a result of its inquiries a new Forced Labour convention was prepared by the International Labour office.

The League of Nations Second Slavery Committee, 1932.—The six years following the making of the Slavery convention, 1926, were so barren of results for the suppression of slavery that in Jan. 1932 the assembly of the League of Nations decided to reconvene the Slavery commission of 1924, the recommendations of which had resulted in the preparation of the Slavery convention, 1,926. and among other things the commission was requested to advise what modifications (if any) were necessary in the existing machinery of the League for the suppression of slavery.

Its principal recommendation was that a Permanent Advisory Committee of Seven Experts on Slavery, all of different nationalities, should be established to report on the information furnished to the League by the parties to the Slavery convention, 1926.

The Permanent Advisory Committee of Seven Experts on Slavery.—This recommendation was opposed by certain powers who feared interference with their national sovereignty, but it was adopted by the League. An advisory committee of experts was set up and met annually from 1935 until 1938 inclusive. After 1938 it ceased to meet because of the outbreak of World War II. It was authorized to study the information submitted to the League by governments and to advise what action should be taken for the suppression of slavery. Its duties were strictly advisory to the council of the League. Forced labour was excluded from its functions. The report of each session was printed as a League document and copies of the documents examined by the committee were annexed to each report. The four reports deal in successive chapters with: (1) general progress in the suppression of slavery; (2) slave-raiding and the slave-trade; (3) born slaves; and (4) conditions analogous to slavery, viz., debt-bondage and pawning of persons, sham adoption of children to exploit their labour: sale of women into marriage without their consent and serfdom. In the four years that the committee functioned it did much valuable work. The work of the committee, as well as of the slavery bureau under the Brussels act, 1890, demonstrated the need for permanent machinery to supervise the application of the Slavery conventions.

The Work of the United Nations for the Suppression of Slavery.—In 1949 the assembly of the United Nations requested the Economic and Social council of the United Nations to study slavery. The council appointed an ad *hoc* committee of four experts on slavery to examine the problem and to make recommendations for the suppression of slavery. The committee recommended that the definition of slavery in the Slavery convention. 1926, was accurate and adequate and that the United Nations should assume the powers and functions of the League of Nations under the Slavery convention, 1926. This was done. It further recommended that a Supplementary Convention on Slavery should be prepared to remedy deficiencies found by experience to exist in the Slavery convention. 1926. This convention was drafted and was approved by a conference of plenipotentiaries of states held in Geneva. Switz., in Sept. 1956. The recommendation of the *ad hoc* committee on slavery that a standing committee of experts on slavery should be set up to supervise the application of the Slavery conventions did not immediately receive UN implementation.

The Existence of Slavery and Slave-Trading in Arabia.—The old form of chattel slavery involves in the Arabian peninsula a far greater number of persons than in any other part of the world. Except in the British colony of Aden, in the sultanate of Lahej in the Aden protectorate, and in Bahrein, Kuwait and Qatar on the Persian gulf the status of slavery was recognized by law throughout Arabia and there was still a slave trade from Africa into Xrabia and from other Asiatic countries into Xrabia in the late 1950s. The existence of slavery in Saudi Arabia received official confirmation from the fact that in 1936 King Ibn Saud made a decree regulating the condition of slaves and giving them the right to have their freedom under certain conditions. The same decree prohibited the importation of slaves by sea and it also authorized the minister of the interior to license slave traders. In 1953 the French ambassador in Saudi Arabia informed his government that slave traders in Saudi Arabia sent African emissaries back to Africa to recruit slaves. They went to West Africa, posed as Moslem missionaries and enticed Africans to accompany them on pilgrimages to Mecca. On arrival in Saudi Xrabia the pilgrims were arrested for landing in the country without a visa and were then handed over to slave traders who sold them into slavery. It was estimated in the late 1950s that there were between 500,000 and

700,000 slaves in Arabia.

Slavery in Ethiopia. — The existence of slavery in Ethiopia was urged against the admission of Ethiopia to the League of Nations in 1923, but the Ethiopian government gave a pledge that it would abolish slavery step by step and Ethiopia was admitted. In 1942 the legal status of slavery was abolished.

Debt-Bondage **and Serfdom.**—In countries in which the money economy is not yet firmly established'it is common for a man to pledge his services as security for a debt. The value of the services are not credited toward liquidation of the debt and the person pledged may remain enslaved for life.

SLAVONIA, historically the eastern part of Croatia, lying between the Drava, Danube and Sava rivers and including the towns of Osijek, Vukovar. Vinkovci and Slavonski Brod. In the 13th century. King Bela IV of Hungary and of Croatia detached Slavonia from Croatia and made it a separate kingdom under his crown. In 1538 the Habsburgs made it again a part of Croatia. Slavonia was made an Austrian crownland after the Hungarian rising of 1848, but was restored to Hungary on the establishment of the Austro-Hungarian dual monarchy in 1867. On Dec. 1, 1918, it became again part of Croatia. See YUGOSLAVIA: History.

SLAVONIC (SLAVIC) LANGUAGES. The Slavonic languages represent a western branch of the eastern. or satem, division of Indo-European (*q.v.*) and are very closely connected with the Baltic languages, which embrace Lithuanian, Latvian, and the now extinct Old Prussian.

Classification. — At mid-20th crntury Slavonic languages were spoken in parts of East Germany. in Poland, Czechoslovakia, Yugoslavia, Bulgaria and in most of the European part and large areas in the Asiatic part of the U.S.S R. There are 13 living Slavonic languages, classified in three groups. Russian (more specifically, Great Russian), Ukrainian (formerly called Little Russian or Ruthenian) and Byelorussian (or White Russian) comprise the East Slavonic group Polish, Slovak, Czech. and the High and Low Sorbian (also called Lusatian or Wendish) of East Germany form the Western group, while Slovene, Serbo-Croatian Macedonian, Bulgarian and Church Slavonic make up the Southern group. Church Slavonic is the liturgical language for all Orthodox and some Catholic Slavs, and its use is by no means confined to the South Slavonic area. The two Sorbian languages were guaranteed a place in schools and public life by East German laws promulgated in 1948 and 1950. The other ten are official state languages in their respective areas. Two additional languages may be noted, Polabian and Pomeranian. The former. once widely spread in the Elbe basin, became extinct in the 18th century. The latter is the conventional name for dialects once spoken along the Baltic, known from two remnants. Slovincian and Kashubian, which survived into the 20th century.

In spoken Slavonic dialects, there are scarcely any true linguistic frontiers, for transitional dialects connect all types, excepting, of course, in the area where the South Slavs are separated from the others by non-Slavonic Austrians, Hungarians and Rumanians. Almost any two intelligent Slavs can manage fairly quickly to establish elementary communication on a simple conversational level, for the languages have preserved a remarkable degree of uniformity in over-all grammatical pattern and in the vocabulary of everyday life. However. the myriad differences in the details oi phonetics, grammar, and above all of vocabulary cause misunderstandings even in the simplest of conversations, and the difficulties increase in the language of journalism, of belles-lettres, and especially in technological treatises, which tend to use newly created terminology. For a Slav to master effectively a second Slavonic language demands time and work.

History.—For at least a millennium before the 3rd century A.D. the Slavs lived to the north of the Carpathians. Scholars have not been able to reconcile archaeological and linguistic evidence to arrive at a wholly satisfactory delimitation of the area, but generally agree that its core extended from the Vistula to the Dnieper (Dnepr). Linguistic affinities indicate that the western neighbours of the Slavs were very likely first Illyrians, later perhaps Celts and then Teutons. In the southeast there was apparently contact with Iranian and various Altaic peoples. In the northeast were Finno-Ugric tribes, and in the north the Balts. In the first centuries A.D. the Slavs began to expand rapidly, first to the west and east! then southward through and around the Carpathians, appearing in the 6th century as a serious threat to the Roman Empire all along the Danube. By the 9th century they occupied Europe east of a line running roughly Kiel-Braunschweig-Magdeburg-Bamberg-Passau-Trieste, including all of the Balkan mainland except for parts of the littoral in Dalmatia and Greece. During the last millennium they have either retreated before or been absorbed by Germans in the west, Greeks and Albanians in the south, and Hungarians and Rumanians in the Danube basin. Only in the east was Slavonic expansion a continuous process, which carried the Russians to the Pacific in the 18th century.

A long period, fully three millennia, separates recorded Slavonic from any conceivable type of Indo-European from which Indic, Greek and Slavonic could all have sprung. The phonetic and morphological affinities now observable between Baltic and Slavonic demonstrate at least a long period of contiguity between Slavs and Balts, and perhaps, as some hold, an ancient Balto-Slavonic group. In any case, the Slavonic of the 9th century appears still to have been a single language. It was of course divided. like all languages, into regional dialects, but the points of divergence were relatively few in number and quite insignificant in quality.

The 8th–11th centuries brought enormous changes to the Slavs. Slavonic states arose and clashed with one another and with their non-Slavonic neighbours. Social and economic conditions were radically transformed. In language, too, change was relatively rapid; and by the 10th century the western and southern dialects had split into something like the present linguistic divisions, although in the east a greater uniformity prevailed.

No credible evidence attests to Slavonic writing before the 860s, when a mission was sent from Byzantium in answer to the request of Prince Rostislav of Moravia for teachers "in our own language." The mission was led by a brilliant scholar and diplomat, Constantine (later known as St. Cyril, d. 869), and his brother Methodius (d. 885) of Salonika, a Greek city entirely surrounded by Slavs. They created a new alphabet. the Glagolitic, and began to translate church books. Within two decades the Bible and many homiletic and liturgical texts had been translated, and some original works, including poetry, had been nritten in the new literary language. This language is called Old Church Slavonic (O Ch S.) because its local Macedono-Bulgarian origin is of less importance than its use as a literary language in the nest (Moravia, Bahemia. Pannonia), the south (Bulgaria, Macedonia), and the east (Russia) during the next two centuries. In time it was modified locally, and the Church Slavonic in use today shows clearly the hand of Russian editors.

In the West Slavonic area O.Ch S was suppressed during the 11th century, but its influence is to be seen in the vernacular literature which sprang up in Bohemia in the 13th century and flourished in the 14th–15th centuries. Czech culture was exported to Poland at this time, and the Poles quickly developed their own standard language and produced superior literature in the 16th and 17th centuries. The Slovaks, if writing Slavonic at all, used Czech until the national revival at the beginning of the 19th century. Sorbian texts began with Protestant translations in the 16th century.

In the south, Church Slavonic, in its progressively modified local forms, remained the exclusive written language for the Orthodox Serbs, Macedonians and Bulgars, and for those Croatian Catholics who clung to the Slavonic rite. It was the Renaissance which gave the impulse to vernacular literature in Croatia in the late 15th century, and the Reformation which produced the first works in Slovene in the 17th century (except for fragmentary texts from the 11th). The Serbs discarded Church Slavonic in favour of the vernacular early in the 19th century, and by 1850 a common Serbo-Croatian literary language had been elaborated. The development of modern standard Bulgarian had its roots in the 18th. but progressed little before the mid-19th century. Macedonian is the youngest Slavonic literary language, and can hardly claim to any history before 1934, nhen it was proclaimed the official language of the new Republic of Macedonia.

In the east, Church Slavonic continued in use well into the 18th century, although strongly vernacularizedmodifications were used for business documents and occasionally other writing. In Russia, the modern literary language grew out of a compromise style which utilized Church Slavonic elements to enrich the native Great Russian vernacular. The Ukrainians, on the contrary, rejected Church Slavonic in principle and based their writings chiefly on the spoken dialects. The first modern works appeared at the very end of the 18th century, but the real development of the contemporary Ukrainian literary language dates from the 1840s. The Byelorussians had used their own distinctively modified type of Church Slavonic in the 16th century, but literature in the vernacular came only three centuries later. It is difficult to speak of a Byelorussian literary language before the 20th century. Its most significant gronth came about after it achieved official status in 1918.

Alphabet.—Slavonic languages in the east and southeast are written in slightly variant forms of the so-called Cyrillic alphabet, which seems to have been devised in Bulgaria at the end of the 9th century, and nhich soon displaced Constantine's Glagolitic. In the west, Catholic Slavs use the Roman alphabet. mostly with the diacritics introduced by Jan Hus. Serbo-Croatian is written in Cyrillic by Serbs and Montenegrins, and in Roman by Croats

Vocabulary.—Much of the Slavonic lexicon is Indo-European in origin ("mother. house, be"). a significant portion may be called Balto-Slavonic ("head, hand"), and many words seem to be purely Slavonic ("human. dog"). Ancient borrowing from Iranian include important words of spiritual culture ("god, sacrifice"). and a somewhat later stratum from Germanic pertains to material culture ("coin, buy"). The vocabulary of the individual languages reflects more recent local influences, the most important being German in the west and Turkish in the Balkans. Loan-translations from Greek in the east and Latin in the west have served as patterns for creating new terminology with Slavonic elements in many languages. Inter-Slavonic borronings are manifold and often difficult to trace.

Morphology. — Common Slavonic (C.S.) retained the Indo-European case system almost intact, the only innovation being that the ablative merged with the genitive. Still discernible in late C S. was the older system of paradigms based on purely formal distinctions of stem and suffix-type: o- and jo-stems, a- and ja-stems, u-stems, i-stems, and. in restricted numbers, ū-stems and several kinds of consonant-stems. As early as O.Ch S.. however, a strong tendency prevailed to reorganize the system on the basis of gender. Thus o-, jo- and u-stems were united in a masculine-neuter paradigm which has slightly variant suffixes according to whether the stem ends in a palatal ("soft") or non-palatal ("hard") consonant, the usual feminine declension includes a- and ja-stems ("hard" and "soft"), and the i-stems are predominantly feminine. This principle of classification triumphed almost completely in the modern languages, except for Bulgarian and Macedonian, where the only remnant of declension

Phonological Divergences Between the Slavonic Languages

is in vestiges of a general objective case. The West Slavonic languages kept hard and soft variants of the masculine-neuter and the feminine a-declension, but in the Eastern and Southern groups there are only three paradigms for all but irregular nouns. The vocative disappeared completely in Russian, and is preserved only with a limited number of nouns in Slovak. Slovene, and Low Sorbian. Broadly speaking. the force of the cases is weaker in the west. while in Russian some scholars see a strengthening and extension of the case system in the relatively new forms which have specifically partitive or locative functions: over against the forms which are generally genitive or prepositional.

The C.S. verb lost the voices and moods of Indo-European, retaining special forms for two past tenses (the imperfect and aorist). the present, imperatives (derived from the old optative), and five participles, two passive and three active. The active resultative l-participle was used with auxiliaries to form a series of periphrastic perfects. Constructions with the reflexive pronoun. and to a lesser degree with passive participles, render the passive and middle voices of classical languages. The most significant innovation was the development of aspect, which remains the pivotal feature of all Slavonic verb systems. Every verb is either of perfective aspect, denoting an action viewed in its entirety, or of imperfective aspect, denoting an action not necessarily so viewed. In principle, every verbal idea is represented by a pair of verbs, one for each aspect. Most modern languages have lost aorist and imperfect, using the old perfect instead. The two are, however, completely living forms in eastern Serbocroatian. Macedonian and Bulgarian, where the perfect has come to signify a past action not witnessed by the speaker.

Phonology. — As a satem language. Slavonic has *s* and *z* for the Indo-European palatal stops $\hat{k}$ and $\hat{g}$. In a development paralleled by, but not identical with, Baltic and Iranian, Slavonic changed *s* to *x* (kh) after *i*, *u*, r, and k. As in Baltic and Germanic. o and a coincided in Slavonic. the short vowel eventually resulting in o and the long in a. With Baltic. Slavonic completely lost aspiration and maintained a sharp distinction between voiced and voiceless consonants. Specifically Slavonic features are: an insistence on the distinction between front and back vowels which led to mutual adaptations between vowels and adjacent consonants and resulted eventually in a distinction between soft and hard syllables; the change of short *i* and *u* to reduced, ultrashort vowels called jers; the gradual elimination of closed syllables by dropping final consonants or simplifying clusters, by reducing diphthongs ending in *i, u,* or nasal, and by various dialectal changes in diphthongs ending in l or *r;* the replacement of quantitative vocalic distinctions by qualitative ones. and the subsequent development of a new quantitative system with rising or falling intonation possible on short as well as long vowels.

The table gives examples of some common words to show typical phonological divergences between the Siavonic languages, while the relatively modern equivalents for "industrial worker" and "button" give a hint as to differences in roots and in word-formation. Some details are obscured by the different types of orthography current. Particularly significant for the classification of the languages are the development of *tj, dj, ě, ǫ, ę,* i and *ŭ*.

BIBLIOGRAPHY.—R. Jakobson, *Slavic Languages* (1955), includes a concise account of historical phonology and grammar and carefully selected bibliography. R. G. de Bray, *Guide to the Slavonic Languages* (1951), furnishes practical information. K. Horalek, *Úvod do studia slovanských jazyků* (1955), in Czech, is the only detailed introduction. A. Meillet, Le *slave commun* (1934), is the best description of Common Slavonic. (H. G. L.)

SLAVS. The Slavs are the most numerous linguistic group in Europe. Outside Europe there are the Russians in Siberia, a mere extension of the main body, and emigrants in America.

Divisions and Distribution. — The Slavs are divided geographically and linguistically into three main groups, Eastern, North-Western and Southern.

The Russians form the Eastern group. They hold all the East European plain from the 27th meridian to the Urals, the Finnish and Tatar tribes making up but a small proportion of the population: to the east they stretch into central Siberia and thence in narrow bands along the rivers all the way to the Pacific; on the west the Ruthenians of Galicia form a wedge between the Poles and the Magyars and almost touch the 20th meridian.

The North-Western group includes the Poles, in the basin of the Vistula; the Kashubes on the coast north-west of Gdansk; the High and Low Sorbs or Wends in Lusatia, Slavs completely surrounded by Germans, the Czechs and their eastern neighbours, the Moravians, now included in Czechoslovakia. Connecting up Ruthenians, Poles and Moravians, but most closely akin to the latter, are the Slovaks (*q.v.*). The now teutonized Slavs of central Germany, once stretched as far to the north-west as Rügen and Holstein and to the south-west to the Saale. They are generally called Polabs (*q.v.*), or Slavs on the Elbe.

The Southern Slavs, Slovenes (*q.v.*), Serbo-Croats and Bulgarians are cut off from the main body by the Germans of Austria proper and the Magyars, both of whom occupy soil once Slavonic, and have absorbed much Slavonic blood, and by the Rumanians of Transylvania and the Lower Danube. These Slavs occupy the main mass of the Balkan Peninsula downwards from the Julian Alps and the line of the Muhr, Drave and Danube. North of this all three races have considerable settlements in southern Hungary. Their southern boundary is very ill-defined, various nationalities being closely intermingled. To the south-west the Slavs march with the Albanians, to the south-east with the Turks, and to the south and along the Aegean coasts they have the Greeks as neighbours.

Linguistic Divisions. — Linguistically the separation is not sharp, though it coincides with the new political frontiers. Roughly speaking, the eastern half of the peninsula is held by the Bulgarians, the western half by the Se bo-Croats. This is the most divided of the Slavonic races; its members profess three forms of religion and use three alphabets — the Serbs and Bosnians being mostly Orthodox and using the Cyrillic alphabet, but including many Muslims; the Croats being Roman Catholics, writing with Latin letters; and the Dalmatians also Roman Catholics, but using, some of them, the ancient Glagolitic script for their Slavonic liturgy. The language also falls into three dialects independent of the religions, and across these lines run the frontiers of the political divisions. In the extreme north-west, in Carniola, in the southern parts of Styria and Carinthia, and over the Italian border in the province of Gdine and the Vale of Resia live the Slovenes, much divided dialectically. Between the Slovenes and the Croats there are transition dialects, and about 1840 there was an attempt (Illyrism) to establish a common literary language. In Macedonia and along the border are special varieties of Bulgarian, some of which approach Serbian. Akin to the Macedonians were the Slavs, who once occupied the whole of Greece and left traces in the place-names, though they long ago disappeared among the older population. Akin to the Slovenes were the old inhabitants of Austria and south-west Hungary before the intrusion of the Germans and Magyars.

History. — This distribution of the Slavs can be accounted for historically. Though traditions (*e.g.,* the first Russian chronicle of Pseudo-Nestor) bring them from the basin of the Danube, most evidence goes to show that when they formed one people they were settled to the north-east of the Carpathians in the basins of the Vistula, Pripet and Upper Dněstr (Dniester). To the N. they had their nearest relatives, the ancestors of the Baltic tribes, Prussians, Lithuanians and Letts; to the E. Finns; to the S E. the Iranian population of the Steppes of Scythia (*q.v.*); to the S.W., on the other side of the Carpathians, various Thracian tribes; to the N.W. the Germans; between the Germans and Thracians they seem to have had some contact with the Celts, but at first the Illyrians, Greeks and Italians probably came between. This location, arrived at by a comparison of the fragmentary accounts of Slavonic migrations and their distribution in historic time, agrees with the place taken by the Slavonic language among the other Indo-European languages *(see* below) and by what we know of the place-names of eastern Europe, seeing that within this area the place-names seem to be exclusively Slavonic, while outside it the oldest names belong to other languages.

In spite of the vast area which the Slavs have occupied in historic times there is no reason to claim for them before the migrations a wider homeland than that above defined beyond the Carpathians; given favourable circumstances a nation multiplies so fast that a comparatively small race could cover a wide area in the course of four centuries. Therefore we need not seek for the Slavs among any of the populous nations of the ancient world. Various investigators have seen Slavs in Scythians, Sarmatians, Thracians, Illyrians, and in fact in almost all the barbarous tribes which have been mentioned in the east of Europe, but we can be sure that none of these were Slavs.

The Slavs made no considerable migration from their first home until the 1st century AD. Their first Transcarpathian seat lay remote from the knowledge of the Mediterranean peoples. Herodotus (iv. 17, 51, 105) seems to mention the Slavs under the name of Neuri, on the upper waters of the Dněstr. They are in the right place for Slavs, and their lycanthropy suggests modern Slavonic superstitions; so we may equate Neuri and Slavs, though we have no direct statement of their identity. Other classical writers down to and including Strabo tell us nothing of eastern Europe beyond the immediate neighbourhood of the Euxine.

EARLY WRITERS

Pliny (N.H. iv. 97) is the first to give the Slavs a name which can leave us in no doubt. He speaks of the Venedi (*cf.* Tacitus, *Germania,* 46, *Veneti*); Ptolemy (Geog. iii. 5. 7, 8) calls them Venedae and puts them along the Vistula and by the Venedic gulf, by which he seems to mean the Gulf of Danzig: he also speaks of the Venedic mountains to the south of the sources of the Vistula, that is, probably the northern Carpathians. The name Venedae is clearly Wend, the name that the Germans have always applied to the Slavs. Its meaning is unknown. It has been the cause of much confusion because of the Armorican Veneti, the Paphlagonian Enetae, and above all the Enetae-Venetae at the head of the Adriatic. Though nowadays we have Slovenes just north of Venice, inscriptions in the Venetian language prove that it was not Slavonic. Other names in Ptolemy which almost certainly denote Slavonic tribes are the Veltae on the Baltic, ancestors of the Wiltzi, a division of the Polabs (*q.v.*), the Sulani and the Saboci, whose name is a Slavonic translation of the Transmontani of another source.

The sudden appearance in the 6th-century writers of definite names for the Slavs and their divisions means that by then the race had made itself familiar to the Graeco-Roman world, that it had spread well beyond its original narrow limits, and had some time before come into contact with civilization. This may have been going on since the 1st century A.D., and evidence of it has been seen in the southward movement of the Costoboci irito northern Dacia (Ptolemy) and of the Carpi to the Danube (A.D. 200), but their Slavonic character is not established. A few ancient names on the Danube, notably that of the river Tsierna (*Černa*, black), have a Slavonic look, but a coincidence is quite possible. The gradual spread of the Slavs was masked by the wholesale migrations of the Goths, who for two centuries lorded it over the Slavs, at first on the Vistula and then in south Russia. We hear more of their movements because they were more immediately threatening for the Empire. In dealing with Ptolemy's location of the Goths and Slavs we must regard the former as superimposed upon the latter and occupying the same territories. This domination of the Goths was of enormous importance in the development of the Slavs. It explains the presence of a large number of Germanic loan words common to all the Slavonic languages, many of them words of cultural significance. "King, penny, house, loaf, earring" all appear in Slavonic, from the Goths, although the things must have been familiar before. On the other hand "plough" is said to be Slavonic, but that is not certain. When the Huns succeeded the Goths as masters of central Europe, they probably made the Slavs supply them with contingents. Indeed their easy victory may have been due to the dissatisfaction of the Slavs. Priscus (Miiller, F.H.G. iv. p 69, cf. Jord. *Get.* xlix. 258) in his account of Attila's camp rnrntions words which are probably Slavonic, though they have also been explained from German. After the fall of the Hunnish power the Eastern Goths and Gepidae pressed southwards and westwards to the conquest of the Empire, and the Lombards and Heruli followed in their tracks. When next we get a view of northern Germany we find it full of Slavs, *e.g.*, from Procopius (B.G. ii. 15), they held the Mark of Brandenburg by 512; a settlement effected without attracting the attention of any contemporary writer. The expansion of the Eastern Germans in the last centuries B.C. was made at the expense of the Slavs, who, while no more peaceful than the Germans, were less capable than they of combining for successful war, so that Goths and others were dwelling among them and lording it over them. The mutual competitions of the Germans drove some of these against the Empire, and when this had become weakened, so that it invited attack, some tribes and parts of tribes moved forward without any pressure from behind; this took away the strength of the German element, and the Slavs, not improbably under German organization, regained the upper hand in their own lands and even spread westwards at the expense of the German remnant.

Almost as uncertain is the exact time when the Southern Slavs began to move towards the Balkans. If already at the time of Trajan's conquests there were Slavs in Dacia, it would account for the story in Ps. Nestor that certain Volchi or Vlachi, *i.e.,* Romance speakers, had conquered the Slavs upon the Danube and driven them to the Vistula, for the place that the name of Trajan has in Slavonic tradition, and for the presence of an agricultural population, the Sarmatae Limigantes subject to the nomad Sarmatae on the Theiss. In any case, we cannot say that the Slavs occupied any large parts of the Balkan Peninsula before the beginning of the 6th century, when they appear in Byzantine history as a new terror; there seems to have been an invasion in the time of Justin, and another followed in 527 (Procopius, B.G. iii. 40 and *Hist.* Arc. 18). At the same time as the Slavs, the Huns, the Bulgars, and after 558 the Avars, were also making invasions from the same direction. The first and last disappeared like all nomads, but the Bulgars, making themselves lords of one section of the Slavs, gave it their own name. By 584 the Slavs had overrun all Greece, and were the worst western neighbours of the Eastern Empire. Hence the directions how to deal with Slavs in the Strategicurn of the emperor Maurice (c. 600) and the Tactics of Leo.

By the end of the following century they were permanently settled throughout the whole of the Balkan Peninsula. These Southern Slavs, though divided into nationalities, are closely akin to one another. There is no reason to think the Serbo-Croats an intrusive wedge, although Constantine Porphyrogenitus (*De adm.* Imp. 30–33) speaks of their coming from the north in the time of Heraclius—the middle of the 7th century. Their dialects shade into one another, and there is no trace of any influence of the Korth-Western group. Constantine was probably led astray by the occurrence of the same tribal names in different parts of the Slavonic world. Meanwhile the Southern Slavs were cut off from the rest of the race by the foundation in the 6th century of the Avar kingdom in Pannonia, and after its destruction in the 7th, by the spread of the Germans south-eastwards, and finally by the incursion of another Asiatic horde, that of the Magyars, who have maintained themselves in the midst of Slavs for a thousand years. Their conquests were made chiefly at the expense of the Slovenes and the Slovaks, and from their languages they have borrowed many words in forms which have now disappeared.

Of the history of the Eastern Slavs, who were to become the Russian people, we know little before the coming of the Swedish Rus, who gave them their name and organization; we have but the mention of Antae acting in concert with the other Slavs and the Avars in attacking the Empire on the lower Danube, and scattered accounts of Muslim travellers, which show that they had reached the Don and Volga and stretched up northward to Lake Ilmen. The more southerly tribes were tributary to the Khazars.

CULTURE AND RELIGION

The general impression is one of a people which lived in small communal groups, so impatient of authority that they scarcely combined for their own defence, and in spite of individual bravery only formidable to others when cemented together by some alien element: hence they all at one time or another fell under an alien yoke; the last survivals of Slavonic licence being the veče of Novgorod, and the Polish diet with its unpractical regard for any minority. The Slavs were acquainted with the beginnings of the domestic arts, and were probably more given to agriculture than the early Germans, though they practised it after a fashion which did not long tie them to any particular district—for all writers agree in telling of their errant nature. They were specially given to the production of honey, from which they brewed mead. They also appear to have been notable swimmers and to have been skilled in the navigation of rivers, and even to have indulged in maritime piracy on the Aegean, the Dalmatian coast and most of all the Baltic, where the island of Rügen was a menace to the Scandinavian and German sea-power. The Oriental sources also speak of some aptitude for commerce. Their talent for music and singing was already noticeable.

Of their religion it is strangely difficult to gain any real information. The word Bogŭ, "god," is reckoned a loan word from the Iranian Baga. The chief deity was the Thunderer Perún (*cf.* Lith. Perkúnas), with whom is identified Svarog, the god of heaven; other chief gods were called sons of Svarog, Dažbog the sun, Chors and Veles, the god of cattle. The place of this latter was taken by St. Blasius. A hostile deity was Stribog, god of storms. There seem to have been no priests, temples or images among the early Slavs. In Russia Vladimir set up idols and pulled them down upon his conversion to Christianity; only the Polabs had a highly developed cult with a temple and statues and a definite priesthood, perhaps in imitation of Norse or even Christian institutions. Their chief deity was called Triglav, or the three-headed; he was the same as Svętovit, apparently a sky god in whose name the monks naturally recognized Saint Vitus. The goddesses are colourless personifications, such as Vesna, spring, and Morana, the goddess of death and winter. The Slavs also believed, and many still believe, in Vily and Rusalki, nymphs of streams and woodlands; also in the Bába-Jagá, a kind of man-eating witch, and in Běsy, evil spirits, as well as in vampires and werewolves. They had a full belief in the immortality of the soul, but no very clear ideas as to its fate. It was mostly supposed to go a long journey to a paradise (raj) at the end of the world and had to be equipped for this. Also the soul of the ancestor seems to have developed into the house or hearth god (Domovój, Křet) who guarded the family. The usual survivals of pagan festivals at the solstices and equinoxes have continued under the form of church festivals.

Christianity Among the Slavs.—The means by which the various Slavonic nations were converted to Christianity has probably had more influence upon their subsequent history than racial distinctions or geographical conditions.

Wherever heathen Slavonic tribes met Christendom missionary effort naturally came into being. This was so along the Dalmatian coast, where the cities retained their Romance population and their Christian faith. From the 7th century the Croats were nominally Christian, and subject to the archbishops of Salona at Spalato and their suffragans. From the beginning of the 9th century from Merseburg, Salzburg and Passau the Gospel spread among the Slavonic tribes on the south-eastern marches of the Frankish empire, in Bohemia, Moravia, Pannonia and Carinthia. Despite the zeal of these missionaries, as Germans they belonged to a nation which was once more encroaching upon the Slavs, and as Latins (though the Great Schism had not yet taken place) they were not favourable to the use of their converts' native language. Still they were probably the first to reduce the Slavonic tongues to writing, naturally using Latin letters and lacking the skill to adapt them satisfactorily. Traces of such attempts are rare; the best are the Freisingen fragments of Old Slovene now at Munich.

In the eastern half of the Balkan Peninsula the Slavs had already begun to turn to Christianity before their conquest by the Bulgars. These latter were hostile until Boris, under the influence of his sister and of one Methodius (certainly not the famous one), adopted the new faith and put to the sword those that resisted conversion (A.D. 865). Though his Christianity came from Byzantium, Boris seems to have feared the influence of the Greek clergy and applied to the Pope for teachers, submitting to him a whole series of questions. The Pope sent clergy, but would not grant the Bulgarians as much independence as they asked, and Boris seems to have repented of his application to him. He raised the question at the Council of Constantinople (A.D. 870), which decided that Bulgaria was subject to the Eastern Church.

Cyril and Methodius.—In the same way Rostislav, prince of Greater Moravia, fearing the influence of Latin missionaries, applied to Byzantium for teachers who should preach in the vulgar tongue (A.D. 861). The emperor chose two brothers, sons of a Thessalonian citizen, Methodius and Constantine (generally known as Cyril by the name he adopted upon becoming a monk). The former was an organizer, the latter a scholar, a philosopher and a linguist. His gifts had been already exercised in a mission to the Crimea; he had brought thence the relics of S. Clement, which he finally laid in their resting-place in Rome. But the main reason for the choice was that the Thessalonians, surrounded as they were by Slavonic tribes, were well known to speak Slavonic perfectly. On their arrival in Moravia the brothers began to teach letters and the Gospel, and also to translate the necessary liturgical books and instruct the young in them. But soon (in 864) Rostislav was attacked by Louis the German and reduced to complete obedience, so that there could be no question of setting up a hierarchy in opposition to the dominant Franks, and the attempts to establish the Slavonic liturgy were strongly opposed. Hearing of the brothers' work Pope Nicholas I. sent for them to come to Rome. On their way they visited with Kocel, a Slavonic prince of Pannonia, about Lake Balaton, and he much favoured the Slavonic books. In Venice the brothers had disputes as to the use of Slavonic service-books; perhaps at this time these found their way to Croatia and Dalmatia.

On their arrival in Rome Nicholas was dead, but Adrian II. was favourable to them and their translations, and had the pupils they brought with them ordained. In Rome Constantine fell ill, took monastic vows and the name of Cyril, and died on the 14th of February 869. Methodius was consecrated archbishop of Pannonia and Moravia, about 870, but Kocel could not help him much, and the German bishops had him tried and thrown into prison; also in that very year Rostislav was dethroned by Svętopluk, who, though he threw off the Frankish yoke, was not steadfast in supporting the Slavonic liturgy. In 873 Pope John VIII. commanded the liberation of Methodius and allowed Slavonic services, and for the next few years the work of Methodius went well. In 879 he was again called to Rome, and in 880 the pope distinctly pronounced in his favour and restored him to his archbishopric, but made a German, Wiching, his suffragan. Methodius was succeeded by Wiching, who had a new pope, Stephen V. (VI.) on his side. So the Slavonic service-books and those that used them were driven out by Svętopluk and took refuge in Bulgaria, where the ground had been made ready for them. Boris, having decided to abide by the Greek Church, welcomed Clement, Gorazd and other disciples of Methodius. Clement, who was the most active in literary work, laboured in Ochrida and others in various parts of the kingdom.

In spite of the triumph of the Latino-German party, the Slavonic liturgy was not quite stamped out in the west; it seems to have survived in out-of-the-way corners of Great Moravia until that principality was destroyed by the Magyars. Also during the life of Methodius it appears to have penetrated into Bohemia, Poland and Croatia, but all these countries finally accepted the Latin Church, and so were permanently cut off from the Orthodox Serbians. Bulgarians and Russians. (X.; N. B. J.)

SLED DOG RACING: *see* Dog Sled Racing.

SLEEP is a recurring state of inactivity, decrease of consciousness and decrease in responsiveness to events in the environment. The ease with which sleep can be terminated differentiates it from coma, general anesthesia, alcoholic stupor and seasonal lethargy of certain animals (*see* Hibernation). On the other hand, there are conditions of semiawakeness ("brown study," postepileptic automatism, hypnotic trance, fugue, etc.) that are intermediate in character, possessing some features of both sleep and wakefulness. Moreover, in the routine of living there are regular diurnal gradations in the depth of slumber and the degree of alertness, which alternate with each other like the crest and trough of a 24-hour wave.

Knowledge concerning the nature of sleep has been derived from observation and experiment; from the findings gathered by these two methods, theories of sleep have been elaborated and a hygiene of sleep developed.

Observational Data.—A conspicuous characteristic of sleep, for man and nearly all animals, is the horizontal posture of repose which permits a relaxation of the body musculature. Aside from producing overt movements, muscular contractions are also used to maintain station, or posture, through tonic activity—a state of partial contraction which manifests itself in resistance to passive or externally imposed movement. In raising gently an arm of a sleeping person, little opposition is met, and when the grip on it is released, the arm drops back limply.

A rather annoying (to others) aspect of this general relaxation of sleep is that it also involves the closers of the jaw, causing the mouth to open, and then the soft palate, with its appendage (the uvula), flutters with passage of the air in and out of the lungs, producing the well-known sounds of snoring.

Muscles are supplied with two types of nerve fibres: (1) efferent, motor, centrifugally conducting fibres, which carry impulses from the nervous system, resulting in overt as well as tonic contractions; and (2) afferent, sensory, proprioceptive ("self-feeling"), centripetally conducting fibres, which furnish conscious and unconscious information concerning the state of the different parts of the body and their relation to each other. This muscle sense, literally a sixth sense, contributes greatly to the continuous stream of afferent impulses from the sense organs to the cerebral cortex (see BRAIN; NERVOUS SYSTEM).

A person shuts off the streams of visual and auditory impulses by retiring to a dark, quiet room, and decreases cutaneous impulses by lying down on a soft, smooth surface, but the proprioceptive impulses, coming as they do from the body itself, are still there, gradually decreasing only when and as the body musculature is relaxed.

Muscular relaxation and immobility, however, are not absolute. From time to time, unless mechanically restrained, the sleeper moves one part of the body or another, or turns over completely, changing his position. A person's positional repertory may be small or large, and the total amount of motility varies with the degree of fatigue, environmental temperature, amount of bed coverings, width of the bed and the quantity and composition of food and beverage taken before going to bed. As a rule, the longer the duration of sleep, the greater the frequency of movement. Occurring altogether about 20 to 40 times in the course of one night, this motility entails at least a semiawakening and a partial awareness of external relations. The sleeper does not usually recall these multiple interruptions of rest, and the total time spent in motility is small, amounting to about 30 seconds per hour, or a few minutes for a whole night's sleep. The periodic change in the position of the body is probably brought on by, and relieves, the pressure on the skin in contact with the bed surface. Alcoholic intoxication, deadening sensitivity to discomfort, leads to decreased motility during sleep, often resulting in soreness and stiffness in a muscle or even a partial paralysis from pressure exerted on a nerve for several hours.

It is possible to sleep in a semireclining position (as on a reclining chair), sitting upright (at a lecture, theatre or in an easy chair at home) or, when very tired, while standing up or riding horseback. Some animals regularly sleep in a standing position.

Of greatest interest are the changes in the activity of the nervous system during sleep. In older children and adults this manifests itself in the abolition, or at least depression, of critical reactivity to external events. In the waking state the impulses coming from the different sense organs to certain areas of the cerebral cortex are analyzed in the light of the person's previous experience, and appropriate responses (which include movement as well as refraining from overt muscular activity) are elaborated or integrated in other cortical areas. Identical afferent impulses from sense organs will not elicit the same response in different persons. This individuality of reaction is lost during sleep and is replaced by stereotyped predictable reflexes from the lower centres of the nervous system. Furthermore, compared with wakefulness, the reflex excitability of the lower centres themselves is decreased during sleep. A more powerful stimulus (change) is required to obtain a response of a certain magnitude.

During sleep the amplitude and frequency of the electrical brain waves undergo characteristic changes, and it has been possible to associate particular electroencephalogram (EEG) patterns with certain stages of sleep. Epileptic persons show typically peculiar brain waves while awake, but even more revealing are their EEG's during sleep. Furthermore, whereas an epileptic fit in the waking state is almost always ushered in by a definite EEG complex, the same complex in sleep does not lead to overt convulsions unless the sleeping epileptic is awakened at that time. This suggests that in sleep there may be a functional de-efferentation of the lower centres of the nervous system.

In contrast to the general inactivity, muscular relaxation, lack of critical reactivity, and depression of reflex excitability—all involved in the external or animalistic relations of the organism—the internal, household, visceral or vegetative functions are either unaffected or somewhat enhanced during sleep. Circulation of the blood goes on, although the heart rate is decreased and the arterial blood pressure lowered. These changes are in part related to the assumption of the horizontal position, and often occur upon simply lying down and remaining awake. In sleep there are also modifications in the rate and depth of respiration, indicative of a decreased excitability of its regulating centre, along with that of other reflex centres, in the nervous system. As a result there are certain changes in the composition of the blood, which is less thoroughly purified than in the waking state. Digestion—the movements of the different parts of the gastrointestinal tract and the secretory activity of its glands—goes on unabated. The same seems to be true of the liver and kidneys, although some decrease has been detected in the functioning of these vital organs, as well as in the metabolic rate (oxygen consumption) of the organism. There is a marked drop in body temperature, often amounting to 1° F., which is undoubtedly related to muscular relaxation and a lowering of metabolic processes. Sweating, in general, as a means of cooling off the body by evaporation, may actually be accentuated during sleep, especially in warm weather, but is diminished in skin areas of the palms of the hands and soles of the feet.

Variation in each of the above-enumerated concomitants of sleep in the course of the night has been employed as an index of its depth. Unfortunately, there is no agreement among the several depth-of-sleep curves constructed in this manner. The most commonly used method is to determine the loudness of a sound required to awaken the sleeper. The figures obtained suggest that during the night sleep gets to be very deep in the first two or three hours and then becomes progressively lighter. Similar curves could be derived from data on quiescence (the reverse of motility), the increase in the carbon dioxide of the air in the lungs and the predominance of slow (3 to 0.5 per second) "delta" brain waves. Using arterial blood pressure or body temperature as a criterion, sleep is deepest in the middle of its course. Lastly, the lowest heart rate is not reached until the sixth or seventh hour of sleep. Thus, by proper selection of an index, it can be shown that sleep is deepest in the first, second or third quarter of the night. More important, study of the figures on which the different curves are based reveals that in any one night there may be repeated fluctuations in the depth of sleep. Instead of one curve there are many, with a shallowness, to the point of awakening, occurring again and again mith increasing frequency, and the depth of sleep between decreasing in magnitude.

A concomitant of sleep, information on which is based mainly on the sleeper's ability to recall and relate his observation, is the phenomenon of dreaming. Intriguing though the dream has proved to be through the ages, beginning mith the prophetic or premonitional dreams of the ancients and progressing to the dream interpretation in modern psychoanalytic practice and research, only the pattern of the dream is of help in elucidating the nature of sleep. This pattern is indicative of a low level of cortical analysis and integration, comparable to the operation of a very young child's mind.

An objective index of dreaming is an EEG pattern, closely resembling the "alpha" rhythm which is usually associated with resting wakefulness but makes its appearance repeatedly during a night's sleep. If the sleeper is awakened during the modified alpha EEG stage of sleep, he nearly always reports dreaming, but in other EEG stages. characteristic of deeper sleep, no dreaming is recalled. The modified alpha EEG is usually accompanied by rapid, jerky eyeball movements, distinctly visible even under closed eyelids but also recordable electronically as changes in the corneoretinal potential, and often by a quickening of respiration and pulse rate. The rapid eye movements probably represent a scanning of the scene of dream action, as their direction is related to the movement of objects and persons seen in the dream. The length of the dream narrative is proportional to the lapse of time between the appearance of the modified alpha EEG and the arousing and questioning of the sleeper. Contrary to anecdotal reports, the course of time during dreaming is about the same as in real life. Sound or light stimuli too weak to awaken the sleeper, if applied while dreaming is in progress, are occasionally incorporated into the dream story. After the cessation of the objective signs of dreaming, the ability to recall details of the dream content rapidly diminishes, and in a few minutes the sleeper may forget that he dreamed at all. That explains why many persons maintain that they seldom, or never, dream. However, even the latter invariably recall dreaming if aroused while showing a modified alpha EEG sleep pattern. The objective criteria of dreaming can be used to plot the incidence and duration of dreaming episodes during a night of undisturbed sleep. There are usually five or six periods of dreaming, the first, and shortest, occurring about one hour after the onset of sleep, and the succeeding ones, corresponding to 80- to 90-minute cycles of EEG pattern variation, progressively longer. The average duration of dreaming periods is from 5 to 50 minutes, with a total of about two hours for a whole night's sleep. (See also DREAMS.)

Experimental Data.—Sleep deprivation (keeping a person awake by constant watching and prodding) has been a favourite method used in study of the sleep problem. After about 60–90 hours of enforced wakefulness (four to six times the usual span of 16–17 hours). the most prominent effect is extreme muscular weariness. The subjects of such experiments want most to be allowed to close their eyes and lie down, but it is precisely this enforced muscular activity that enables them to remain awake. Lying down means failure of the experiment. Nothing is more illustrative of the importance of proprioceptive impulses in the maintenance of wakefulness and of muscular relaxation in the precipitation of sleep. Among other features of behaviour in sleep deprivation are irritability to the point of irascibility in normally even-tempered subjects, and a mental disorganization, leading to dreaming while awake, hallucinations and automatic behaviour, occasionally bordering on temporary insanity. It is easy to understand why the third-degree method of continuous interrogation for many hours will make a person sign a "confession," even if innocent of the crime he is accused of having committed. He wants to be permitted to sleep, and he fails to realize the seriousness of his self-incrimination.

Experiments on animals include inducing lesions in, and stimulation of, different parts of the central nervous system. Dogs surgically deprived of the cerebral cortex still show alternation of sleep and wakefulness. Such decorticated animals lose the greater part of their learning ability and no longer profit from their previous experience. They would starve to death, in the presence of an abundance of food and water, unless artificially fed. They do not recognize their keeper, and their behaviour in many mays resembles that of very young puppies. Like the latter they go to sleep after they are fed, become restless only when hungry, and their sleep-wakefulness cycle loses its usual relation to night and day.

Nature performs similar experiments on human beings, in the form of anencephalous infants (born without a cerebral cortex) who often remain alive for months or even years. Unlike normal infants, who learn in a few weeks to consolidate several short naps into one long night's sleep, anencephalous ones, as long as they live, sleep at irregular intervals. Their sleep-wakefulness cycle, like that of decorticated dogs, seems to be geared largely to the satisfaction of hunger. Evidently, primitive sleep-wakefulness alternation does not require cerebral cortical activity in either animals or man.

By modern electrocoagulation procedures, it is possible to burn out discrete regions of the brain stem without removing or injuring the cerebral cortex. Extensive damage to the hypothalamus, in the region of the mammillary bodies, in cats and monkeys induces profound somnolence or frank sleep. It would appear that the waking state is maintained by impulses sent from the hypothalamus to the lower centres of the nervous system. Conversely, afferent impulses from the periphery are capable of stirring the wakefulness centre of the hypothalamus into activity. Again, nature's experimentation, in the form of one kind of sleeping sickness (see ENCEPHALITIS), seems to confirm laboratory findings. In the latter disease the cerebral cortex is undamaged, but there are extensive lesions in the brain stem in the region of the wakefulness centre. Significantly, sleeping sickness patients can at times be aroused briefly. but they are unable to maintain wakefulness. No naturally occurring destruction in the brain stem or elsewhere in the nervous system has ever produced permanent insomnia, militating against the existence of a sleep centre.

A sleep abnormality that points to the importance of afferent impulses from the sense organs in wakefulness is narcolepsy, a disease in which bouts of almost uncontrollable drowsiness may occur several times daily for years. The incidence of these attacks increases when the narcoleptic is alone and is engaged in uninteresting activity, conditions conducive to drowsiness in nearly everyone. Of added interest is that narcolepsy is usually associated with cataplexis, a sudden complete loss of muscle tonus, causing the person to sink to the ground, with consciousness usually preserved. This sudden muscular relaxation, seldom lasting more than a few minutes, is brought on by some emotional stress, particularly laughter. The causes of narcolepsy and cataplexis are unknown, but their occurrence in combination suggests that a defect in the maintenance of tonus in the skeletal musculature and failure, at times, of wakefulness may have a common cause.

Theories of Sleep.—Partial theories pertain to the mechanism of going to sleep and attempt to explain how sleep is brought about; awakening is usually ascribed to a reversal of the changes that produce sleep. General theories deal with the reason for sleep, often without attention to the mode of its onset or termination. Complete theories try to explain both the mechanisms of and reasons for the phenomenon, sometimes by proposing the same scheme for both.

Circulatory theories, of the partial kind, ascribe sleep to a shifting of the blood out of or into an important organ, usually the brain. These theories are obsolete, as the absence of such a shift of blood has been definitely established. Also discarded are the neural theories, postulating a physical break in the chains of nerve cells that serve as conducting pathways in the nervous system. Inhibitory theories implicate widespread inhibition which decreases or abolishes the activity of the cerebral cortex, but they are clearly inadequate when it is considered that decorticated animals and newborn infants (whose cerebral cortex is not yet functioning) can sleep. Deafferentation theories are based on the fact that shutting off incoming sensory impulses to the cerebral cortex is incompatible with wakefulness, but they likewise fail to explain sleep after decortication. Biological theories are general in that they consider sleep an instinct and, as such, a positive act rather than a mere cessation of wakefulness. The vagueness of these theories is at once a strength and weakness; it is impossible either to refute them or to prove their correctness. Humoral or chemical theories stem from established changes in the composition of the blood and urine, modification of metabolic processes in the tissues and a possible variation in the secretory activity of the glands of internal secretion, occurring during sleep as compared with wakefulness. Either some substance required to maintain the waking state is exhausted, and sleep serves to replenish it; or, on the contrary, some toxic substances accumulated in wakefulness are excreted or destroyed in sleep. However, alertness and efficiency of performance are not at their best at the time of getting up in the morning, nor at their worst at bedtime at night.

An evolutionary theory distinguishes between the roles of the hypothalamic centres and the more recently evolved cortical centres in the maintenance of the waking state. According to this theory. sleep as a state of inactivity requires no explanation. Wakefulness of the primitive type, seen in the newborn infant or in decorticated animals, designed to meet the minimum needs for keeping alive and for protoplasmic growth, is a subcortical, probably hypothalamic, function. The higher type of wakefulness. with its attendant alertness, critical reactivity and wider interests. as well as the adaptation of the sleep-wakefulness cycle to the 24-hour alternation of night and day, is a function of the cerebral cortex. Wakefulness maintained by the cortex depends upon its receiving impulses from both the hypothalamic centres and the sense organs, particularly the skeletal muscles.

Hygiene of Sleep.—Although no proposed theory of sleep has met with universal acceptance, enough factual information is available for a rational hygiene of sleep. Acculturation to the family and community pattern of living begins at a very early age. Even in the first few days of life the human infant sleeps more at night than in the daytime. A continuous long period of sleep at night is achieved, with some training, in two or three months. Supplementary daytime naps are reduced to two at six months (by which time a distinct diurnal body temperature curve is in evidence) and to one by the end of the first year; they are given up entirely at the age of three to six years. The belief that very young babies sleep nearly all the time—about 20 or 22 hours out of 24—has been shown to be incorrect. The average total duration of sleep of a newborn infant is only about 14–15 hours and this is reduced to 13–14 hours at the age of six months. Thereafter there is a continuous decline to 7–9 hours of sleep per 24 hours in the adult.

The nightly sleep "ration" is made up of two components: an obligatory need for sleep, which varies with the physical, mental and temperamental characteristics of the individual, and an accessory indulgence in sleep, influenced by age, sex and day-to-day fluctuating environmental factors. A person's irreducible sleep fraction is best expressed by its complement, the maximum sustainable duration of wakefulness. At one extreme of the population distribution are persons capable of remaining alert for more than 18 hours daily, at the other those who succumb to uncontrollable drowsiness in less than 14 hours. Everyone, however, tends to overindulge in sleep in the absence of stimulating events in his immediate environment, simply as an escape from boredom. Thus, in routine uninteresting existence most people sleep longer than is necessary for their well-being. By the purely empirical test of freedom from sleepiness during the customary waking hours, each person can determine his minimum sleep requirement.

Aithough sleep is in no sense a habit, the adjustment to hours of retiring and getting up, to certain types of bed and bedding and to a host of environmental conditions depends on individual experience and training. The diurnal sleep-wakefulness rhythm, it will be recalled, is cortically conditioned, and by following a regular schedule of hours for various tasks and recreation, meals and sleep, this rhythm is fortified. The reward is tuofold: (1) a more prompt occurrence of sleep at night and spontaneous awakening in the morning, and (2) greater alertness during wakefulness. espetially at customary hours of activity.

Insomnia usually involves a difficulty in falling asleep. When it is caused by pain or physical discomfort, a hypnotic drug. prescribed by a physician, may have to be resorted to. Occasionally, grief over past events or worry over possible future misfortunes produces a muscular tension that prevents the onset of sleep. Under these conditions, anything that takes a person's mind off the disturbing thoughts promotes muscular relaxation and is thus conducive to sleep. A series of routine chores. such as grooming and bathing, for an hour or two before going to bed helps induce drowsiness. Reading in bed (if the subject matter is not emotionally charged) or listening to soothing music is soporific for some persons. However, what puts one person to sleep may keep another awake.

A particular difficulty faces those who are engaged in around-the-clock operations of some industries, public utilities, transportation and communication companies, police and fire departments, hospitals and military services. These persons have to work (and therefore also sleep) at unconventional hours and are subject to many inconveniences. The common practice of rotating work shifts at frequent, often weekly, intervals all but prevents the workers from developing a suitable individual sleep-wakefulness rhythm.

The temperamental make-up of the individual also affects his ability to conform to the community pattern of living. Early to bed and early to rise is easy for the "morning" type, whose body temperature and efficiency reach their maxima around noon. A marked "evening" type dislikes getting up at the conventional hour in the morning. depends upon an artificial mode of awakening, does not reach his height of efficiency until late in the afternoon (when the work day is practically over) and hates to go to bed at night. A satisfactory adjustment can be made by nearly everyone, though not nith equal ease.

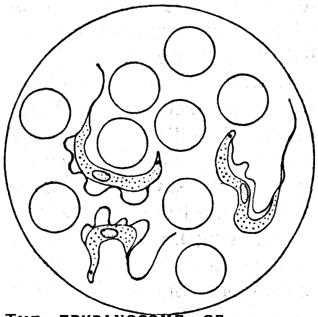
SLEEPING SICKNESS (AFRICAN TRYPANOSOMIASIS), a disease of the blood stream. lymph nodes and central nervous system, is confined to tropical Africa and has been known since the beginning of the 19th century. It is characterized by fever, inflammation of the lymph glands and, following the involvement of the brain and spinal cord, profound lethargy (hence the name "sleeping sickness"), frequently ending in death. The causative agents are *Trypanosoma gambiense,* with a distribution extending from the west coast of Africa eastward to the lakes district and southward to Angola and the southern border of the Belgian Congo, and T. *rhodesiense,* limited to the highlands of central east Africa. These trypanosomes are morphologically indistinguishable from one another and from the trypanosome of the antelope, T. *brucei,* which produces the fatal nagana disease in cattle.

Although sleeping sickness is occasionally transmitted mechanically, within two or three hours after an interrupted blood meal, by coitus or by mother's milk, an overwhelming majority of infections result from inoculation of the microorganisms by tsetse flies (primarily *Glossina palpalis* for *T. gambiense* and *G. morsitans* for *T. rhodesiense).* The fly becomes infected while feeding on the blood and tissue juices of patients and incubates the parasites; 15 or more days later it introduces the infective stage into another human being at the time of the next feeding.

The amount of experimental work which has been carried out in order that these relatively prosaic facts might be stated is very extensive and has occupied the lifetime of some of the most capable workers in tropical medicine. Thus, it was no simple task to prove that after a tsetse fly has bitten an infected human being, 12 to 15 days (*e.g.,* the incubation period within the fly) must elapse before the fly becomes infective for man. During this time the trypanosomes multiply by binary division in the mid-gut of the fly, then migrate to the salivary glands, become transformed into the infective stage and pass out of the fly's proboscis in droplets of saliva. Although experiments with human volunteers have with rare exceptions been consistently unsuccessful in attempts to infect man with T. *brucei* from wild game hosts, most workers believe that *T. rhodesiense,* and possibly *T. gambiense,* are strains of T. *brucei* that have become adapted to man. In favour of this view is the fact that strains of *T. rhodesiense* and *T. gambiense* are infective for many domestic mammals and for the wild game animals (*e.g.,* antelopes) that harbour *T. brucei.* Infection of cattle produces great economic loss and significantly reduces animal proteins available for the human population.

Pathogenesis and Symptoms.—T. *gambiense* and T. *rhodesiense* produce the same type of clinical picture during the incubation period, the septicemic and the glandular stages, but T. *rhodesiense* is much more rapid in its course and ends fatally before invasion of the central nervous system. After an incubation period in man averaging six to seven days, the trypanosomes are found in appreciable numbers in the circulating blood. Next, the lymph nodes and spleen are invaded, becoming swollen, soft and tender. The marked enlargement of these nodes in the posterior cervical triangle, known as Winterbottom's sign (after an early 19th-century traveler who noted this peculiarity), is relatively diagnostic of the disease. Irregular fever and delayed sensation to pain are also characteristic of this stage of the disease. In the Rhodesian type the toxemia becomes so profound that the victim soon succumbs; in the Gambian type the organisms proceed to invade the brain and spinal cord.



THE TRYPANOSOME OF AFRICAN SLEEPING SICKNESS

The neurological symptoms include severe headache, mental dullness and apathy. a weary shuffling gait, tremors, spastic or flaccid paralysis. chorea, profound sleepiness which develops during a meal or when the patient is standing or walking, increasing emaciation, coma and death. Occasionally there are mental disturbances which include dementia, melancholia, delusions and a syndrome mimicking central nervous system syphilis. Nevertheless, in many natives a tolerance to the infection develops. and the patient may live for many years as a carrier of the parasites.

Diagnosis is made by demonstration of the organisms in circulating blood during the septicemic stage; by their recovery from gland juice or from sternal bone marrow biopsy during the glandular stage. and from spinal fluid following invasion of the central nervous system. Prognosis is poor to grave in untreated cases of T. *gambiense* infection, and *T. rhodesiense* infection is always fatal unless treated early.

Treatment.—The earlier the disease is diagnosed and specific treatment is instituted, the greater are the chances of recovery. For the Gambian infection, a synthetic arsenical, tryparsamide, is highly effective, although it may produce acute optic neuritis, with possible loss of vision. In infections which have not reached the central nervous system stage, tryparsamide is nearly 100% curative. Older chronic cases with neurological manifestations require persistent treatment. Suramin sodium. also referred to as germanin, a nonarsenical, is also effective for the Gambian infection, as well as for the Rhodesian type during the early stage, but all treatment of T *rhodesiense* infection is useless once the fulminating toxemic stage has developed.

Prevention.—In few diseases have as heroic control measures been attempted as in African trypanosomiasis. For T. *gambiense* the following procedures have been carried out with profit: (1) isolation and proper treatment of all infected persons, including large numbers of asymptomatic chronic carriers; (2) protection of man from bites of tsetse flies by maintaining extensive clearings around villages and residence compounds; (3) prophylactic doses of suramin or of diamidine compounds once every 60 to 90 days for persons who must enter the jungle, so that they will not become infected from tsetse fly bites; and (4) occasional removal of entire native villages from endemic to free zones. Although these same measures apply in a more limited degree to Rhodesian trypanosomiasis, the need is at times suggested of exterminating wild game reservoirs of the disease near villages if man cannot otheraise be protected. Concerted campaigns were carried out to control African trypanosomiasis following the conference on sleeping sickness that met in London in 1925. In the Cameroons, by persistent tryparsamide treatment of all diagnosed cases, Gambian infection was reduced from a high percentage of extensive population groups to less than 1%, and entire tribes were saved from extincfion by this single measure. On the other hand, prophylactic chemotherapy failed in the Rhodesian endemic areas. The advent of potent insecticides. such as DDT, held promise of satisfactory destruction of the tsetse fly in areas of maximum human exposure.

SLEET, in the United States and Canada the popular name for precipitation of transparent, roundish, hard ice particles one to four millimetres in diameter, which in other countries are properly called grains of ice, ice pellets or frozen raindrops. These are often confused with graupel, small hail, soft hail (*q.v.*), granular snow and snow pellets, which resemble ice pellets somewhat in size and general appearance but are whitish, softer and less dense. Ice pellets mixed with rain and falling on surfaces having temperatures below freezing result in a pebbly surfaced crust of glaze (clear ice) forming over the surfaces.

Ice pellets are produced by raindrops formed in clouds in an upper warm-air layer becoming frozen while falling through a lower (or surface) air layer having a temperature well below freezing.

In British countries (except Canada) sleet refers to a mixture of rain and snow. (R. G. SE.)

SLEIDANUS, JOHANNES (1506–1556), German historian, the annalist of the Reformation, was born at Schleiden, near Aachen. He studied ancient languages and literatures at Liège and Cologne, and law and jurisprudence at Paris and Orléans. While among the humanists of Liège, he had adopted Protestant opinions and entering the service of Cardinal du Bellay, was employed in the futile negotiations of the French court to make an alliance with the German Protestants against the emperor Charles V. In 1542 he settled at Strasbourg. Sleidanus had been accustomed to copy all papers bearing upon the Reformation to which he had access, and Martin Bucer proposed to Philip of Hesse to appoint him historian of the Reformation, giving him a salary and access to all necessary documents. Sleidanus began his great work, finishing the first volume in 1545. In that year he went to England in a French embassy to Henry VIII. While there he collected materials for his history.

On his return he represented Strasbourg at the diets of Frankfort and Worms and went on to Marburg to explore the archives of Philip of Hesse. The War of the League of Schmalkalden interfered with this work and also prevented the payment of Sleidanus. who received a yearly pension from Edward VI. In 1551 Sleidanus represented Strasbourg at the Council of Trent, being charged to act also for the imperial cities of Esslingen, Ravensburg, Reutlingen, Biberach and Lindau.

He was afterward appointed professor of law in Strasbourg and finished his great task in 1554, though lack of money and other misfortunes compelled him to delay printing. Sleidanus died in poverty at Strasbourg in Oct. 1jj6. The book appeared in the preceding year—*Commentariorum de statu religionis et reipublicae, Carolo V. Caesare, libri XXVI;* it was translated into English by John Daws in 1560 and by G. Bohum in 1689. It was so impartial that it pleased no one, not even Melanchthon. It remains the most valuable contemporary history of the times of the Reformation and contains the largest collection of important documents.

SLEIGH (SLED or SLEDGE), a vehicle on runners instead of wheels, for traveling over snow or ice. The sleds used in bobsledding are referred to in the article BOBSLEDDING. Horse-drawn sleighs mere formerly much employed as ordinary means of conveyance in the U.S.S.R., North America and the Scandinavian countries. In the arctic regions dogs are harnessed to them. *See* TRANSPORT.

SLEMP, CAMPBELL BASCOM (1870–1943), U.S. politician, was born on Sept. 4, 1870, in Turkey Cove, Va. He graduated from the Virginia Military institute in 1891 and studied law at the University of Virginia. He became a successful businessman and made his debut in politics in 1905 when he was named chairman of the Republican state committee of Virginia and rapidly became a G O P. power in the south. In 1907 he was elected to congress to fill the unexpired house term of his father, who had died. He was re-elected eight times from 1909 to 1923.

During the 1920 presidential campaign, Slemp was leader of the Harding drive to crack the Democrats of the solid south. From 1923 to 1925 he was secretary to Pres. Calvin Coolidge, acting as the president's conciliator before congress. Slemp also helped Coolidge win the Republican nomination in 1924.

In 1928 Slemp supported Herbert Hoover. He later resigned as chairman of the party's committee in Virginia. He died on Aug. 7, 1943.

SLESSOR, SIR JOHN COTESWORTH (1897–), British air marshal, was born at Rhanikhet, India, on June 3, 1897, and educated at Haileybury college, Hertfordshire. In 1915 he was commissioned in the royal flying corps and served as a pilot in France, Egypt and the Sudan. Appointed to a permanent commission in the Royal Air Force in 1920, he served two years in India and afterward in various home appointments. In 1935–37 he commanded the wing supporting the Indian army in the Waziristan operations and for this was awarded the distinguished service order. On his return to England he served as director of the plans branch of the air ministry. In 1940, during World War II, Slessor visited the U.S. on a special mission. In 1942 he took the new and important post of assistant chief of the air staff (policy), so attending the chief Allied conierences. The following year he was appointed air officer commanding in chief, coastal command, and was able, in close co-operation with the Royal Navy and the U.S. forces, to contribute to the defeat of the German submarines in the battle of the Atlantic. In 1944 he became deputy air commander in chief of the Allied forces in the Mediterranean and a year later was made air member for personnel on the air council. In 1948 he became commandant of the Imperial Defence college before holding the highest of all posts in the R.A.F.—that of chief of the air staff. He retired in 1952. Air Marshal Slessor became well known also for books and articles on air strategy. He was created knight grand cross of the Order of the Bath in 1948. His book *The Central Blue* is largely autobiographical. (E. B. BN.)

SLEZAK, LEO (1873–1946), Czech tenor known for his performance of Wagnerian operatic roles. Born at Sumperk, Moravia, on Aug 18, 1873, he studied under Adolf Robinson and made his debut at Brno in *Lohengrin* in 1896. In 1908 he studied under Jean de Reske in Paris and in the following year established his reputation as a heroic tenor in the part of Otello in London and New York, his impersonation being helped by his imposing height, He was later esteemed for his interpretations of Wagnerian roles throughout Europe and the Cnited States. Slezak abandoned singing toward the end of his life and became known as a film comedian in Austria He died at Egern, Bavaria, on June 1, 1946.

See L. Slezak, *Song of Motley (1938).*

SLICK, SAM: *see* HALIBURTON, THOMAS CHANDLER.

SLIDELE, JOHN (1793–1871), U.S. diplomat whose seizure with James M. Mason precipitated the "Trent" case *(see* below), was born in New York city in 1793. A graduate of Columbia college in 1810, he moved to New Orleans, La., in 1819, where he practised maritime law, married into a distinguished Creole family and participated actively in politics. He sat in congress from 1843 to 1845.

In 1843 he was sent to Mexico by Pres. James K. Polk to secure territorial concessions and at the same time to avert the approaching war. Though he was not received officially by the Mexican government, he remained as an observer until the eve of war. Returning to the United States, he represented Louisiana in the senate from 1853 to 1861. He was a staunch supporter of Pres. James Buchanan and a vigorous opponent of Stephen A. Douglas.

When Louisiana seceded, Slidell cast his lot with the Confederacy. Entering the Confederate foreign service, he mas sent to France in late 1861, but on his way there he and Mason were removed by a Federal man-of-war from the British steamer "Trent" and imprisoned at Ft. Warren in Boston harbour. The British government strongly protested this action and the two men were released in Jan. 1862 at President Lincoln's insistence and over Secretary of State W. H. Seward's objections. In France. Slidell's relations with Napoleon III, though cordial, were unofficial. Thus this second mission, like that to Mexico, had little result, save that financial negotiations with the Erlangers of Paris and Frankfurt led to the Confederate cotton loan of 1863.

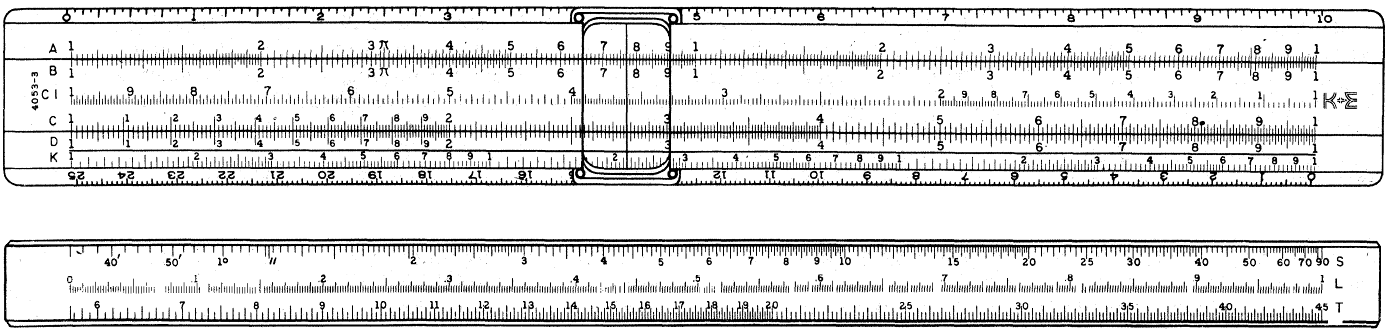
Following Lee's surrender at Appomattox, Slidell and his family lived in Paris until the Franco-German War, when he moved to London. Slidell died there on July 29, 1871.

See Louis Martin Sears, *John Slidell* (1925) ; Beckles Willson, *John Slidell and the Confederates in Paris (1862–65)* (1932). (L. M. S.)

SLIDE RULE, a rule consisting of graduated scales capable of relative movement. by means of which simple calculations may be carried out mechanically. In ordinary slide rules these operations include multiplication, division and extraction of square roots, as well as, in some cases, calculation of trigonometrical functions and logarithms. The slide rule has become an essential tool in the mathematics of science and engineering and is widely used in business and industry as well.

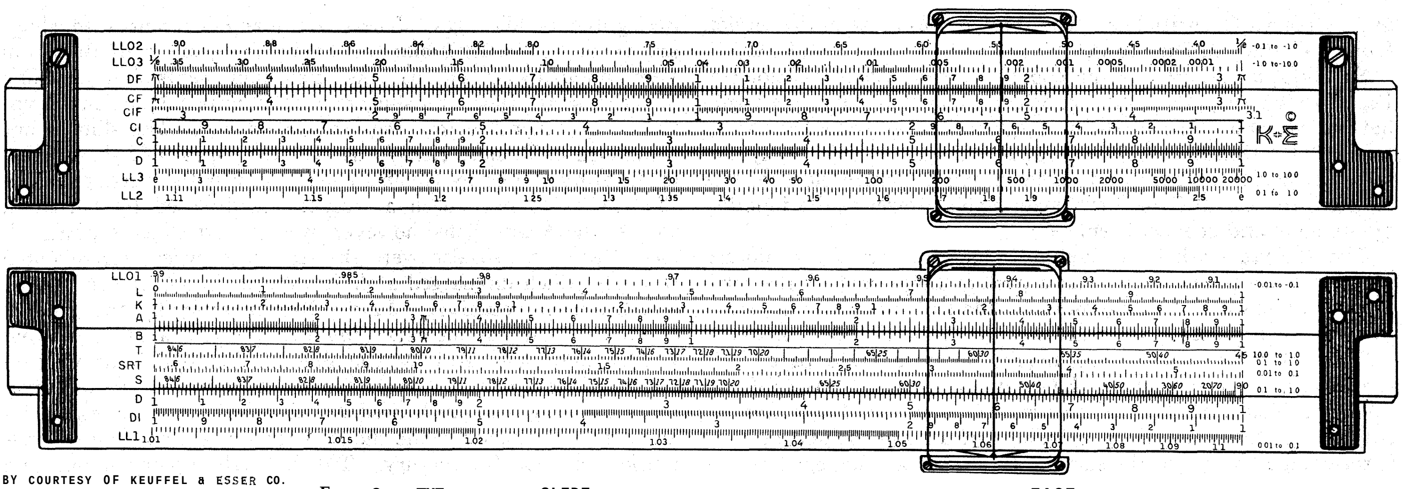
The logarithmic slide rule is a compact device for rapidly performing calculations with limited accuracy. The invention of logarithms in 1614 by John Napier of Merchiston, Scot., and the computation and publication of tables of logarithms made it possible to effect multiplication and division by the simpler operations of addition and subtraction. *(See* LOGARITHMS.) Napier's early conception of the importance of simplifying mathematical calculations resulted in his invention of logarithms. and this invention made possible the slide rule as we know it. In 1620 Edmund Gunter plotted logarithms on a two-foot straight line. With such scales, multiplication and division were performed by addition and subtraction of lengths by a pair of dividers.

William Oughtred, according to his own statement (1633), constructed and used as early as 1621 two of these Gunter's lines sliding by each other so as to do away with the need for dividers. The lines were used in both the straight and circular forms. In the former the scales were held against one another by the hands; in the latter, dividers were replaced by an "opening index"—really a pair of dividers fixed centrally on the circular scale.



BY COURTESY OF KEUFFEL & ESSER CO.

FIG. 1.— MANNHEIM SLIDE RULE



BY COURTESY OF KEUFFEL & ESSER CO.

FIG. 2. — THE LOG-LOG SLIDE RULE: TOP, FRONT FACE; BOTTOM. REVERSE FACE

Oughtred's two scales were the forerunners of the C and D scales, the basic scales on practically all slide rules from that time on.

The first known slide rule in which the slide worked between parts of a fixed stock was made by Robert Bissaker in 1654. Others were due to the enterprise of Seth Partridge (1657), Henry Coggeshall (1677) — a slide in a two-foot folding rule adapted to timber measure — and Thomas Everard (1683) for gauging purposes. The usefulness of the slide rule for rapid calculation became increasingly recognized, especially in England. during the 18th century. and the instrument was made in considerable numbers, with slight modifications.

Improvements in the direction of increased accuracy in graduation. etc , were initiated by Matthew Boulton and James Watt from about 1779 in connection with calculations in the design of steam engines at their works at Soho, Birmingham.

Amédée Mannheim. an officer of the French artillery, invented in 1859 what may be considered the first of the modern slide rules. This rule had scales on one face only and although it nas quite simple is basically of a type still made and designated by his name. The disposition of the scales in the Mannheim rule is the arrangement still adopted in the great majority of rules made in the 20th century (see fig. 1). This rule, which also brought into general use a cursor, or indicator, was much used in France, and after about 1880 was imported in large numbers into other countries. Up to this period the rule had been constructed usually of boxwood and occasionally of brass or ivory, but a great improvement was introduced in 1886 by Dennert & Pape in Germany by dividing the scales on white Celluloid, which gave a much greater distinctness in reading. This material was later almost universally adopted. and the slide rule attained a high degree of perfection.

In 1815 Peter M. Roget invented his "log-log" slide rule for performing the involution (q v.) and evolution (*q.v.*) of numbers (see fig. 2). The fixed scale, instead of being divided logarithmically, is divided into lengths which are proportional to the logarithm of the logarithm of the numbers indicated on the scale; the sliding scale is divided logarithmically.

Before 1890 slide rules were made only in England. France and Germany, but at that time an invention by William Cox led to the manufacture of rules in the United States. This invention introduced a revolutionary construction providing for scales on both front and back of the slide rule. An indicator with glass on both sides made it possible to refer to all the scales on both sides of the rule simultaneously.

Many refinements in both scale arrangements and mechanical constructions have been made since that time. The decade from 1940 to 1950 saw further developments of slide rules with scales on both faces. Most important of these improvements was the arrangement of the scales, trigonometric and log-log, so that they operate together and at the same time maintain consistent relationship to the basic C and D scales. This arrangement gave added speed and flexibility to the solving of many problems, simple and complex alike, since it produced solutions by continuous operation, without the need of intermediate readings.

See J. N. Arnold, *The Slide Rule; Principles and Applications (1954).* (A. W. K.)

SLIGO, a county of Ireland in the province of Connaught. Pop. (1956) 56.850. The area is 693.4 sq.mi. The coast line runs from Killala bay in the west to the southern side of Donegal bay, and is broken by the great triple indentation of Sligo bay. The relief is varied. Along the coast stretches a lowland area floored with Lower Carboniferous rocks which also form the foundation of much of the interior louland. The Ox mountains in the west are formed of very ancient pre-Cambrian metamorphic rocks, with intrusions of granite. They follow the Caledonian trend, striking northeastward to the hills south of Lough Gill. Along the borders of Roscommon, to the south, lies the Old Red Sandstone line of the Curlew hills.

In the east and northeast the Lower Carboniferous Limestone, sometimes capped with Millstone Grit, rises in great moorland plateaus. The west-facing escarpments of these form striking features, as in Benbulben (Ben Bulbin) (1,570 ft.). The principal streams drain through the Collooney gap to Ballysadare bay Numerous lakes occur, the largest being the lovely Lough Gill, immortalized by the poet W. B. Yeats.

The county was created by Sir Henry Sydney in 1579. At Drumcliffe (5 mi. N. of Sligo) are the only round tower remaining in the county and a Celtic cross 13 ft. in height. The principal monastic ruins are the abbey of St. Fechan at Ballysadare, with a church of the 11th or 12th century; the abbey of Sligo, and a group of buildings on the island of Inishmurray, which include a cashel, or walled enclosure. three oratories. two holy wells and also altars, pillar stones, inscribed slabs (one of which has an inscription partly in Latin) and several examples of beehive cells. This settlement is associated with Molaise, a saint of the early 6th century (not identical with the Molaise of Devenish in Loch Erne). and the remains still attract pilgrims.

The county, particularly in the low-lying areas, is well covered with boulder clay which often shows a strongly marked drumlin topography. The chief agricultural occupation is cattle raising, partly for milk but largely as dry stock. Oats and potatoes form the principal crops. Sea fishing is not now important but salmon fishing is carried on in many of the rivers. A number of scattered creameries exist and grain mills operate in Collooney and Ballysadare as well as in the port of Sligo. There, too, is a large bacon factory.

Lead was mined at Ballysadare. and the clay-ironstone from the east of the county was at one time smelted. A considerable general trade is carried on at the ports of Ballina (on the Moy) and Sligo, the county town.

The Great Southern lines from Limerick and from Dublin meet at Collooney junction which is also used by the Sligo, Leitrim and Northern Counties line. The three routes unite in the section from Collooney to Sligo town. (D G.)

SLIGO, a seaport and the county town of County Sligo. Ire. Pop. (1956) 12,947. It lies on Sligo bay and the river Garrogue between Lough Gill and the sea, 136 mi. N.W. from Dublin by road. The Dominican abbey, founded in 1252, was partly destroyed by fire in 1414 and again in 1642. Three sides of the cloisters remain, and the lofty quadrangular tower at the junction of the nave and chancel is entire.

The Roman Catholic cathedral (1869–74) serves the diocese of Elphin which includes a large part of Sligo, and of Roscommon and Galway. A castle, built by Maurice Fitzgerald in 1242, was in 1270 taken and destroyed by Goffraidh O'Domhnaill (O'Donnell); in 1310 it was rebuilt but was again partly destroyed in 1369 and 1394. Early in the reign of James I the town received a market and two annual fairs; in 1613 it was incorporated and received the privileges of a borough: and in 1621 it received a charter of the staple. In 1641 it was besieged by the parliamentary forces. but was afterward evacuated and occupied by the royalists until the termination of the war. In 1688 it declared in favour of James II, and, after being captured by the Enniskilleners, was retaken by Gen. Patrick Sarsfield, but ultimately surrendered to the earl of Granard. The borough was disfranchised in 1870.

Sligo takes rank with Galway and Limerick as one of the three principal ports of the west coast of Ireland. There is a considerable export trade in grain, flour, pork and cattle; while coals, iron, timber and provisions are imported. The harbour has commodious quays and basins. Brewing, flour milling and sawmilling are the chief industries, and there is a large butter market. Sligo is a centre of salmon and sea-fishing industries.

Three miles southwest of the town is a collection of megalithic remains. which has been taken to mark the site of the traditional battle of North Moytura. On Knocknarea (1,078 ft.). southwest of Sligo, is a cairn which tradition sets down as the burial place of Queen Mab (Meave of Connaught).

SLIM, SIR WILLIAM JOSEPH (1891–), British field marshal, best known for his work in the Burma campaign in World War II, was born in Bristol on Aug. 6, 1891, and educated at King Edward's school. Birmingham. In World War I he volunteered as a private, but within a few days he was commissioned. He saw active service in Belgium, France, Iraq and the Dardanelles. In 1920 he was granted a regular commission and transferred to the Indian army.

In 1940 Slim commanded the 10th infantry brigade of the famous 5th Indian division which landed in northeast Africa and advanced into Eritrea. He was wounded, but recovered in time to lead the 10th Indian division in Iraq and in Iran, where he decisively defeated the enemy and made the first contact with the Russian army at Teheran. For this he was awarded the Distinguished Service Order. In 1942 he commanded the 1st Burma corps and assisted in conducting an orderly retreat in Burma. Later, as commander in chief of the 14th army, he inflicted a crushing defeat on the Japanese; for, after repulsing the enemy at Imphal and Kohima and capturing Mandalay, he drove the Japanese down the Irrawaddy river to Rangoon. In 1945 he became commander in chief of Allied land forces in southeast Asia. In 1946 he was appointed commandant of the Imperial Defence college. He became chief of the imperial general staff in 1948 and was promoted to field marshal. In 1953 Slim was appointed governor general of Australia. In 1956 he published *Defeat Into Victory,* which gave a remarkable picture of the Burma campaign. (E. B. Bn.)

SLING, an implement for casting missiles. The sling was probably the earliest device by which force and range were given to the arm of a thrower of missiles. It consisted of a small strap or socket of leather or hide to which two cords were attached; the slinger held the two ends in one hand. whirled the socket and missile rapidly round his head and, loosing one cord sharply, dispatched the missile. The other type was the staff sling. in ahich the sling itself was attached to a short staff held in both hands. This was used for heavier missiles, especially in siege operations during the middle ages. There are many references to slings and to slingers in the Bible; the left-handed slingers of Benjamin were famous (Judg. xx, 16). Assyrian monuments show rhe sling of the ordinary type. and slingers were used in the ancient Egyptian army but not before the 8th century B.C. The sling is not mentioned in Homer; Herodotus (vii, 158) speaki of the slingers in the army offered by Gelon to serve against the Persians. The sling seems to have been a weapon chiefly used by barbarian troops: the Acarnanians, however, were expert slingers (Thucydides ii, 81), and so also were the Achaeans, who later invented the sling which discharged a shaft with an iron bolt head (Livy xlii. 65, from Polybius). In the Roman army by the time of the Punic wars the slingers (funditores) uere auxiliaries from Greece, Syria and Africa. The Balearic islanders, nho were in Hannibal's army, were always famous as slingers. In medieval times the sling was much used in the Frankish army, especially in defending trenches, while the staff sling was used against fortifications in the 14th century. Till the 17th century slings were used to throw grenades.

In modern times the word has taken on other meanings. It denotes a hanging loop to support a wounded arm, a chain with hooks for raising or lowering heavy goods, or a shoulder strap for carrying a rifle or carbine. A variation of the ancient sling as a hand neapon is the slingshot. a forked stick with an elastic band attached for hurling small pellets.

SLIPHER, VESTO MELVIN (1875–), U.S. astronomer whose discovery of the rotation and extraordinary space velocities of the spiral nebulae formed the first observational evidence for the expanding universe theory. He was born on a farm in Clinton county, Ind., Nov. 11, 1875, graduated from Indiana university, Bloomington, in 1901, and received his Ph.D. degree there in 1909. For about 40 years he directed the Lowell observatory at Flagstaff, Ariz., where he organized and guided the search which resulted in the discovery of the outermost planet, Pluto, predicted by Lowell.

Slipher made extensive investigations by methods of spectroscopy which resulted in the determination of the rotation periods of the planets; his discovery of molecular bands in the planetary spectrum ultimately led to the identification of their atmospheric composition. He demonstrated that many diffuse nebulae shine by the reflected light of the nearby stars. He also discovered the permanent sky and auroralike radiations of the night sky, their nocturnal intensity changes and the existence of interstellar sodium and calcium scattered throughout the depths of space. (H. L. G.)

SLIPWAY, the water-front space in a shipyard allotted to the building of a ship. It is fitted with foundations for keelblocks, shoring and inclined launching ways, and with cranes, which may be of many types, for handling materials. When a gate or side walls are provided to exclude the water from the lower or outboard end of the slipway, it is sometimes called a semisubmerged slipway. The term slipway is also used for an inclined railway extending into the water and fitted with a cradle, on wheels or rollers, on which a vessel is hauled out for cleaning, painting and repairs. Such a railway is usually called a marine railway in the United States and sometimes a patent slip in Great Britain.

A slipway should be distinguished from a slip. which is a space of water alongside a pier or wharf at which a ship may lie, as for loading or unloading.

A wet slip or wet basin in a shipyard is a berth alongside a pier, usually fitted with crane facilities, in which a vessel may lie afloat during completion after launching. (J. P. Ck.)

SLIVEN, a town of southern Bulgaria, 105 mi. E.N.E. of Philippopolis, near the southern entrance of the trans-Balkan defile known as the Iron Gate. Pop. (1956) 46,383. Sliven is the chief manufacturing centre in Bulgaria for the rough and fine homespuns known as *aba* and *skayak*, and its wine is locally celebrated. Mulberry orchards have been planted in connection with the silk industry. Sliven was frequently disputed in the middle ages between Byzantium and Bulgaria. After its capture by the Turks (1388) it was one of the privileged *voinik* towns *(see* BULGARTA) ; but these privileges were lost in the 16th century. In 1829

Sliven was occupied by the Russian army.

SLOAN, JOHN FRENCH (1871–1951), U.S. painter of the ash-can school, was born in Lock Haven, Pa., Aug. 2, 1871. He worked in a Philadelphia print shop, attending night art classes and in 1891 became a commercial artist. He moved to New York city in 1904; in 1908 he exhibited with "the Eight," a group of painters whose works were heatedly attacked by conservatives. Sloan's subjects were specially censured; he had to support himself by illustration, etching and intermittent teaching. His early painting (1900–20) is historically important — gay, caustic and warm. His liberalism was manifested in the illustrations for the socialist periodical The Masses that he executed until the U.S. entered World War I. As president of the Society of Independent Artists (1918–51) and as the author of The Gist of Art (1939), further aspects of his nonconforming spirit were indicated.

Another phase of Sloan's painting consisted of landscapes done in Massachusetts and New Mexico. From 1930 his portraits and nudes were emphasized by fine red contour lines, an innovation which was not generally accepted. A notable honour was the gold medal of the American Academy of Arts and Letters (1950). Sloan died at Hanover, N.H., on Sept. 7, 1951.

See Lloyd Goodrich, *John Sloan* (1952); Van Wyck Brooks, *John Sloan* (1954). (VL. B.)

SLOANE, SIR HANS (1660–1753), British physician. whose collection of books. manuscripts and curiosities formed the basis of the British museum. was born on April 16, 1660, at Killyleagh in County Down, Ire. He spent four years in the study of medicine in London and then traveled through France, taking his M.D. degree at the University of Orange in 1683. He returned to London with a considerable collection of plants. which were sent to John Ray and utilized by him for his History of *Plants*. Sloane was elected to the Royal society and attracted the notice of Thomas Sydenham. In 1687 he went to Jamaica as physician in the suite of the duke of Albemarle. Sloane's visit lasted only 15 months, but during that time he collected about 800 new species of plants. Of these he published an elaborate catalogue in Latin in 1606: at a later date (1707–25) he added two folio volumes. He became secretary to the Royal society in 1693 and edited the *Philosophical Transactions* for 20 years.

In 1716 Sloane was created a baronet. being the first medical practitioner to receive a hereditary title, and in 1719 he became president of the College of Physicians. In 1722 he was appointed physician general to the army, and in 1727 first physician to George II. In 1727 also he succeeded Sir Isaac Newton in the presidential chair of the Royal society. His purchase of the manor of Chelsea in 1712 has perpetuated his memory in the name of a "place," a street and a square. His great stroke as a collector was to acquire in 1701 the cabinet of William Courten, who had made collecting the business of his life. When Sloane retired from active work in 1741 his library and cabinet of curiosities had grown to be of unique value. On his death on Jan. 11. 1753. he bequeathed his collection to the nation, on condition that parliament pay to his executors £20.000. The bequest was accepted, and went to form the collection that was opened to the public as the British museum in 1759. Among Sloane's other acts of munificence was his gift to the Apothecaries' company of the botanical or physic garden, which they had rented from the Chelsea estate after 1673.

SLOCUM, HENRY WARNER (1827–1894), U.S. general, was born at Delphi, N.Y., on Sept. 24, 1827, and graduated at the U.S. Military academy, West Point, N.Y., in 1852. When the Civil War broke out he became colonel of the 27th New York volunteers and was promoted major general of volunteers (July 1862). He fought in all the Virginia campaigns from the first battle of Bull Run to Gettysburg. Transferred to the Tennessee valley, he took part in the Chattanooga and Atlanta campaigns. He resigned from the army in Sept. 1865, and was a Democratic representative in congress in 1869–73 and again in 1883–85. He died at Brooklyn on April 14, 1894.

SLOOP, a type of small sailing vessel which has one mast rigged fore and aft carrying a mainsail and a jib. Sloops may be fitted with either a gaff-topsail or a Bermuda rig consisting of a one-piece triangular mainsail. (J. B. HN.)

SLOTH, the name for a group of arboreal tropical American mammals belonging to the order Edentata (*q.v.*). Sloths are completely arboreal. living among the branches of trees, hanging beneath them, back downward and clinging with the hooklike organs to which the terminations of their limbs are reduced. When obliged to descend to the ground, which they rarely, if ever, do voluntarily, sloths (because of the unequal length of their limbs and the peculiar conformation of their feet) crawl along a level surface with considerable difficulty. Though generally slow and inactive, they can on occasions travel with considerable rapidity along the branches, availing themselves of the swaying of the boughs by the wind to cross the larger gaps. They feed on leaves and young shoots and fruits. Sloths are nocturnal, silent and solitary animals. and produce but one young at birth. They show an almost reptilian tenacity of life. Sloths fall into two subfamilies, the Choloepinae, including only the unaus (Choloepus), with two functional toes on the forefoot and three on the hind, and six or seven neck vertebrae; and the Bradypodinae, ais. comprising the genera *Bradypus* and Scaeopus, with three functional toes on each foot and nine neck vertebrae. Several other animals, *e.g.*, African potto lemurs and Asiatic lorises, are popularly called sloths.

SLOUGH, a municipal borough (from 1938) in the Eton and Slough parliamentary division of Buckinghamshire, Eng. 20 mi. W of London by road. At the beginning of the 20th century the population was 7,400; in 1961 it was 80,503 — an increase in great part caused by the transformation of a World War I mechanical depot into a trading estate. Slough is by far the biggest town in Buckinghamshire. with more than 250 industrial concerns and an area of 9 7 sq.mi.

SLOVAKIA (SLOVENSKO), a geographic region and at one time a country of central Europe bounded north by Poland, east by sub-Carpathian Ruthenia. south by Hungary and west by Austria and by Moravia. Slovakia now refers to a group of administrative regions of Czechoslovakia.

History.—Slovakia was inhabited in the first centuries of the Christian era by Illyrian, Celtic and then by Germanic tribes. The Slovaks, a people closely akin to. but distinct from, the Czechs, probably entered it (although in small numbers) from Silesia in the 6th or 7th century A.D. For a time they were subject to the Avars, but in the 9th century the area between the Morava and the central highlands formed part of the state of Great Moravia. when the population accepted the eastern form of Christianity from the brothers Cyril and Methodius (see CYRIL AND METHODIUS, SAINTS). In AD. 894 the German king Arnulf called in the Magyars to help him against Sviatopluk of Moravia. The Magyars defeated Sviatopluk and in 907 destroyed the Moravian state From the 11th century Slovakia was part of Hungary, and so remained until 1918.

The ethnic distribution, which thereafter remained practically unchanged until the most modern times. took shape early. The main ethnic frontier between Magyars and Slovaks ran along the line where the foothills merge into the plain, although there were also Magyar settlements in the larger valleys, and the landlord class and much of the urban population in the whole area was Magyar. On the other hand, as the country suffered from chronic overpopulation. a constant stream of Slovak peasants moved down into the plains. where they usually were Magyarized in two or three generations. In the east, part of the mountain population was Ruthene, and the mining areas of Spis were colonized in the 12th century with German settlers, wha founded flourishing cities. In the 1jth century Czech Hussites overran the country and for a time ruled parts of it. leaving behind them chiefly a cultural legacy. During the Reformation the German and Slovak converts adopted the Lutheran tenets, while the Magyars followed those of Calvin. The liturgical language used by the Slovak Protestants was Czech. The Counter-Reformation was, however, strongly, pressed home in Slovakia, which formed the greater part of that area of the kingdom of Hungary which was ruled de facto by the Habsburgs from 1526 to 1700.

Up to the latter date, and beyond it, the problems of the country had been exclusively social. No religious difference placed a barrier between its Catholic inhabitants. The economic interconnection between northern and central Hungary was very close.

A Slovak national renaissance began in the late 18th century. It did not affect all of the Slovaks. The peasants, who still comprised the vast majority, remained uninterested, while the small but rising middle class was divided. A group at one extreme identified the Slovaks with the Czechs as belonging equally to a Czechoslovak nation, with which they desired political unification. Others admitted kinship but not identity. Others again held the Slovaks to be a distinct nationality, to which both Czech and Hungarian nationalisms were dangerous. By this time the local Germans had largely lost their nationality, partly to the Magyars, partly to the Slovaks. The large Jewish population in the area was either unassimilated or Magyar speaking.

During the period of Austrian absolutism after 1849 northern Hungary was for several years de facto separated from the rest of the country under a regime which strongly favoured the non-Magyars. After 1867 the Hungarian government reversed this trend and pressed on Magyarization, meeting with much success, but stiffening the national feeling of the resisting minority. A Slovak National party held a few seats in the Budapest parliament.

During World War I the Czech *émigrés* in the west urged the Allies to unite the Czechs and Slovaks in an independent state. In an agreement signed at Pittsburgh, Pa., on May 30, 1918. between T. G. Masaryk and the local Slovaks. the latter agreed that the Slovaks should join the Czechs on a federal basis.

At Turciansky Svaty Martin, on Oct. 30, 1918, the Slovak national parties in Hungary voted for union with Czechoslovakia. The Paris peace conference sanctioned the union, drawing the frontiers of Slovakia so generously as to include a large Magyar minority in the south. Their release from Magyar pressure now gave the Slovaks leisure to develop irritation against the Czechs, whose regime was more centralist than they had expected.

On Oct. 6, 1938, following the Munich conference, the Slovaks proclaimed themselves autonomous within a federal Czecho-Slovak state. On Nov. 2 an arbitral award rendered by Germany and Italy restored to Hungary the southern rim of Slovakia, with most of its Magyar population. On March 18, 1939, Slovakia became a nominally independent state under German protection. It followed Germany faithfully until April 5, 1945, when it declared its return to a Czecho-Slovak state on a basis of complete equality between Czechs and Slovaks. In 1946 the 1919 Slovak-Hungarian frontier was restored (with a small extension south of Bratislava). Some of the Magyars were now expelled. Slovakia covered in 1947 an area of 18,902 sq.mi. with a population of 3,402,390; in 1956 the population was 3,816,037. The population of Bratislava, the capital. rose between 1947 and 1957 from 172.663 to 246.523.

On July 31, 1956, a new constitutional law made the Slovak national council (counterpart of the Czechoslovak national assembly) the organ of state power in Slovakia while its former legislative powers were increased. The council has the right to nominate and recall the board of commissioners (counterpart of the Czechoslovak council of ministers). The board of commissioners has full executive and administrative powers in Slovakia, with the exception of national defense, foreign affairs, foreign trade and some branches of heavy industry and of railway transport. In 1956 the industrial output of Slovakia nas 5.3 times larger than in 1937. (C. A. M.; X.)

BIBLIOGRAPHY.—E. Denis, Les *Slovaques* (1917); R. W. Seton-Watson, The New Slovakia (1924), (ed) Slovakia: Then and Now (1931); C. A. Macartney, Hungary and Her Successors (1937).

SLOVAK LANGUAGE. Slovak became in 1918 the official language of the eastern part of Czechoslovakia. In 1955 the estimated number of speakers of Slovak in Europe was about 3,500,000, and at the same time nearly 500,000 Slovaks in the U.S. continued to use their native tongue to some extent.

The Slovaks were under Hungarian rule from the 10th century until 1918, and for centuries there was no serious attempt to write Slovak. The flourishing Czech culture of the 14th and 15th centuries produced a written language which differed from most Slovak dialects little more than these dialects differed among themselves. By the 16th century a number of Slovak towns were keeping their records in Czech.

An attempt in the 1780s to raise the western Slovak dialects to the position of a literary language aroused little interest. In the 1840s a group led by L'udevit Štúr (1815–56) began to write in the central Slovak dialects. Štúr's language, as modified and codified by M. Hattala in 1852, rapidly gained approval and was accepted as standard.

Classification. — The contemporary literary Slovak and Czech languages differ in so many points of detail that even the shortest utterance can be identified as either Czech or Slovak. During the 1920s the official designation of both languages was Czechoslovak, but because of the striking and pervasive differences the term was abandoned. On the other hand, the over-all agreement in vocabulary, in word formation and in syntax reveal such a close relationship that the linguist is justified in speaking of a Czechoslovak subgroup of the West Slavonic languages.

The spoken Slovak dialects, as opposed to the standardized language of culture and state, fall into three major groups. The central one is the most distinctive type, and possesses certain features in common with South Slavonic. Eastern and Western Slovak are closer to each other than to the central dialects. Nowhere, however, is there a sharp linguistic frontier, for every local type of speech may be viewed as a transition dialect between the neighbours on every side. Eastern Slovak has certain affinities mith Polish (loss of long vowels, some consonantal features), but it passes into the typical Slovak of central Slovakia, which in turn is transitional to the Western Slovak dialects that shade into the Czech Moravian dialects and on to the typical Czech of Bohemia. The dialects are all mutually comprehensible, except perhaps the extreme Eastern Slovak and Bohemian Czech.

Characteristics. — Like Czech, Slovak has a system of long and short vowels and an automatic, nondistinctive stress which always falls on the first syllable of a word. The two vowel systems were doubtless almost identical in the early middle ages, but since the 14th century Czech has undergone far-reaching changes, while Slovak has been much more conservative. Slovak has retained long syllabic *l* and *r*, and a series of diphthongs (ie, *iu*, ia, *uo*). It possesses the open front vowel a (put', "five"; *mäso*, "meat"; Cz. *pět*, *maso*). In the consonantal system, Slovak did not develop the distinctive sibilant vibrant *ř* of Czech, but did retain the soft *l'* (*strieľať*, "to shoot"; Cz. *střileti*). It developed *dz* and *dž* as independent phonemes. In morphology, Slovak has suppressed certain consonantal alternations: *e.g.*, *veľký*, "big," pl. vel'ki (Cz. velci); ruka, "hand," dative ruke (Cz. ruce); *platím*, "I pay," *platený*, "paid" (Cz. *placený*). The first person singular of all verbs ends in *m*. The vocative has been lost except in a few words.

(H. G. L.)

SLOVAKS, a Slav people mostly living in Slovakia (*q.v.*). The Slovaks seem to have occupied this territory in the 5th or 6th century A.D. and to have stretched far to the south.

SLOVENE LANGUAGE, a member of the South Slavonic group of the Slavonic languages (*q.v.*), is one of the state languages of Yugoslavia. It was spoken in 1955 by about 1,500.000 people in the northwestern corner of Yugoslavia and neighbouring areas in Austria and Italy, and by some of the 180,000 Slovenes in the U.S.

History. — The earliest record of Slovene is generally agreed to be found in the Freising manuscript, from about A.D. 1000, which contains a confessional form, a short homily and a confessional prayer. After that the Slovenes. subject to the Austrians, did not write their own language until the Reformation, when a group of Protestants, led by Primož Trubar, translated some of the Scriptures and wrote tracts. Their religious works were destroyed early in the 17th century, during the Counter-Reformation, but their grammatical and orthographical usage served as a model for the few Catholics who wrote Slovene during the next 200 years. The Enlightenment brought a new interest in Slovene. and at the end of the 18th century a Slovene translation of the Bible appeared, followed quickly by grammars (by Jernej Kopitar in 1808 and by Valentin Vodnik in 1811), dictionaries and literature of all sorts. By the middle of the 19th century a standard written language was in use.

The agreement on matters of orthography and on the words and grammatical forms suitable for literature was not accompanied by an agreement on standard pronunciation. More than a century of discussion culminated in the publication of an authoritative handbook of orthography and pronunciation in 1950. Yet great diversity of pronunciation persisted, apparently little affected by the unifying influences of the schools, radio and modern transportation.

The reason for the lack of agreement lies in the extraordinary diversity of Slovene dialects, which developed during a millennium when the Slovenes had no major administrative or economic centres: no unifying political organization and lived in scattered communities with little communication between one another. The Alpine villages in the north and west were particularly isolated, and the multiplicity of dialects is correspondingly greater there. The leading Slovene authority, Fran Ramovš, distinguished seven dialect groups, with no fewer than 46 individual dialects. While there are significant differences in consonantism, morphology and vocabulary, it is the vowels and the accent which vary most widely. Slovenes tend to pronounce the literary language with the vowels of their own local dialect when speaking formally, and in informal conversation they often add dialect grammatical forms as well.

Slovene is closely related to its eastern neighbour, the Serbo-Croatian language (*q.v.*), and the transition from eastern Slovenian dialects to the kaj Serbo-Croatian of Croatia is gradual. Practically speaking: however, the two standard languages are more remote. Slovenes have some Serbo-Croatian in school and understand it at least passively, but the average Serb or Croat, without special preparation. can read Slovene only with great difficulty and understands little or nothing of the spoken language.

Phonology. — The recommended pronunciation is a compromise between that of the Lower Carniola dialect group (*dolenjski*), which covers the largest area, and the Upper Carniola group (gorenjski), which includes the dialect of Ljubljana, the capital of Slovenia. It distinguishes seven long vowels (i, e, e, a, o, o, u) plus syllabic *r*, occurring only under stress, with either rising or falling intonation, and six short vowels (i, e, u, o, *u*, a) plus syllabic *r* which may be stressed or unstressed. If there is a long vowel in a word, it must be stressed; otherwise the stress falls on the last syllable. It is a very strong stress; unstressed vowels tend to be reduced. and some of them disappear altogether in the pronunciation of many speakers. Normal spelling, utilizing only the five letters i, e, a, o, *u*, unfortunately gives little help in pronunciation of vowels.

Slovene is characterized by the development of Common Slavonic p > o, of both *ŭ* and *ĭ* to a in long and a in short syllables, tj > *č*, dj > *j*, syllabic *l* > *ou̯* (spelled *ol*), soft *r* > *rj*, and a general tendency for long vowels to be closed! short vowels open. None of these features is unique among the Slavonic languages, but they occur together only in Slovene.

Other Features. — In grammar, Slovene has preserved the dual in nouns and verbs, and the supine is usually distinct from the infinitive. The vocative has been lost. The future for both aspects is periphrastic: *bom* (<**bǫdǫ*) + I-participle; *e.g., bom **kupil/kupoval,*** "I shall buy/be buying." The vocabulary includes many borrowings from German. while Czech and Serbo-Croatian models have been important in creating modern technical terminology.

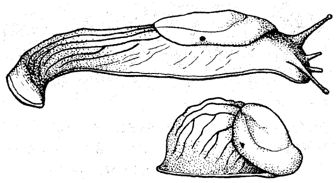
Bibliography.—*General:* R. G. de Bray, Guide to the *Slavonic* Languages (1951). *Dictionaries:* M. Pleteršnik, *Slovensko-nemški slovar* (1894–95), is the most complete source, although it lacks modern terminology; J. Kotnik, *Slovenian-English Dictionary* (1956). *Grammar:* A. Rreznik, *Slovenska slovnica* (1933). *Spelling* and pronunciation: Slovenski *pravopis* (1950). *History:* F. Ramovš, *Historična gramatika* slovenskega jezika, of which only two volumes appeared (ii, *Consonantism*; vii, Dialects), but supplementary material is found in Ramovš's Kratka zgodovina slovenskega jezika (1936) and *Morfologija* (1952). Dialertology: F. Ramovš, *Dialektološka* karta *slovenskega* jezika (1931). (H. *G.* L.)

SLOVENES, a Slavonic people, most of whom live in Yugoslavia, occupying Slovenia and the adjoining sections. The boundary on the east is difficult to fix. as the linguistic transition is gradual and a certain dialect of Croatian (marked by the use of kaj = "what") may have been originally Slovene.

SLOWWORM (Blindworm) (*Anguis* fragilis), a legless lizard, which is neither slow nor blind nor a worm. The slowworm is fairly common in Great Britain and ranges across Europe to western Asia. Because of the absence of legs it is oiten mistaken ior a snake It is quite harmless. feeding on worms. slugs, etc. Its American relative, *Ophisaurus ventralis*, the so-called glass snake, has rudimentary limbs. These, with a few other genera, comprise the family Anguidae.

SLUG, any snail with the shell reduced to an internal plate, a series of granules or completely absent. Generally the term reiers to a land mollusk, but members of the marine order Nudibranchia are called sea slugs.

Ranging in size from $\frac{1}{4}$ in. to more than 6 in.. slugs are restricted to very moist habitats. All are usually active only at night or on overcast days. Eggs are buried in the soil. and the animals live one to four years. All species are both male and female. some with one, others with two genital pores. Most slugs have the respiratory and excretory ducts combined into a single external opening. Usually slugs are mottled nith brown, gray. green or buff, but some species have brilliant markings of orange. red, purple or yellow.



COMMON SLUG (ABOVE) IN CRAWLING POSITION, (BELOW) INACTIVE

The approximately 300 species of land slugs are not closely related, since loss of an external shell happened several times during snail evolution. The common slugs (families Arionidae, Limacidae and Phiiomycidae) of temperate-zone fields, forests, gardens and greenhouses. feed on fungi, decaying plants and occasionally the leaves of living plants. Often a nuisance in gardens and greenhouses. they can be controlled by spreading ashes or a bait composed of bran and metaldehyde (30 to 1). The tropics have a few European species introduced by man and the very primitive plant-eating Veronicellidae. Other vegetarian slugs include the relict Athoracophoridae of Melanesia, Australia and New Zealand and the intertidal pulmonates of the family Oncidiidae. Slugs which feed on other snails or earthworms include the European Testacellidae, South African Aperidae and Malayan-Indonesian Rathouisiidae.

The sea slugs (nudibranchs) live in shallow reef waters. sand flats or rocky pools where they browse on minute algae. Delicately coloured and oiten translucent. they are among the most beautiful sea creatures. Retiring in habit, they are seldom seen by seaside visitors. (G. A. S.)

SLUMP: see Trade Cycle.

SLUTER, CLAUS (c. 1350–1406). the greatest sculptor of his time, was probably born at Haarlem in Holland. He entered the Brussels stonemasons' guild about 1380. and in 1385 was employed in the workshop of Jean de Marville. chief sculptor to Philip the Bold, duke of Burgundy. On Marville's death in 1389, Sluter succeeded to his posirion and to two major works then in progress, the portal of the ducal chapel at the Chartreuse de Champmol, Dijon (q v.), and the duke's tomb. which was to be installed in the same building. In 1392 he visited Paris, and in 1393 Mehun-sur-Yèvre, where he inspected the works executed ior the duke of Berry by André Beauneveu. In 1395 the duke of Burgundy commissioned a monumental Crucifixion group to crown a nell (the *Puits* de *Moise* or "Well of Moses") in the cloister of the Chartreuse. On Sluter's death. the direction of the workshop passed to his nephew and pupil, Claus de Werve.

The three works mentioned above still exist, albeit in damaged condition. The tomb (Dijon museum) has suffered severely and the effigy of the duke is a 19th-century replacement. The substructure, an open arcaded gallery along which passes a numerous procession of diminutive mourners, is an ingenious and original conception which is probably due to Marville. Two of these mourners were in existence in 1404 and others may have been completed by Sluter before his death; the best of them, despite their small scale, exhibit a masterly breadth and realism. The tomb was not finished, however, until 1410 and many of the figures were doubtless made under Werve's direction.

GIRAUDON
DETAIL OF AN ANGEL FROM THE "WELL OF MOSES" BY CLAUS SLUTER. IN THE DIJON MUSEUM, FRANCE

The life-size statues of the Chartreuse portal (complete by 1397) comprise the Virgin and Child (sometimes attributed to Marville) on the central pillar of the doorway and, on either side, figures of the duke and duchess (the latter finished by 1393) protected respectively by St. John the Baptist and St. Catherine (both finished by 1391). The imposing physical presence and intense psychological interaction of these figures seem almost to annihilate their architectural frame. The celestial personages hover in a swirl of near-baroque drapery; the ducal pair are living portraiture, reverend and grave. The Calvary group has been reduced to a battered torso of Christ and a base surrounded by six life-size prophets (executed 1400–05), which rank among the greatest masterpieces of European sculpture. Transcendental beings swathed in endless convolutions of Gothic drapery, they are at the same time living persons whose presence asserts itself like a physical shock. The sculptor's chisel, minutely exploring the wrinkles of ancient flesh, has drawn a map of the soul unparalleled in art, except in the late portraits of Rembrandt.

Sluter's work represents the culmination of a tradition—that of the France-Flemish realist sculpture whose older masters were Jean Pepin of Huy and Jean de Liège—but his genius was intensely personal. Both the painting and sculpture of northern Europe would have worn a different aspect in the 15th century, but for the prophets of the *Puits de Moise.*

See Henri David, *Claus Sluter* (1951). (D. Kg.)

SLUYS (Slois), **BATTLE OF,** fought on June 24, 1340, one of the two sea fights in which Edward III of England commanded in person, the other being Espagnols sur Mer (*q.v.*). The place of the encounter was in front of the town of Sluys (Sluis; Fr. Écluse) on the inlet between West Flanders and Zeeland. In the mid-14th century this was an open roadstead capable of holding large fleets. It was later silted up by the Eede. A French fleet, which the king, in a letter to his son Edward the Black Prince, put at 190 sail, had been collected in preparation for an invasion of England. It was commanded by Hue Quiéret, admiral for the king of France, and Nicholas Béhuchet, who had been one of the king's treasurers and was probably a lawyer. Part of the fleet consisted of Genoese galleys, which served as mercenaries under Barbavera.

Although English historians speak of Edward's fleet as inferior in number to the French, it is certain that he sailed from Orwell on June 22 with 200 sail, and that he was joined on the coast of Flanders by his admiral for the North sea, Sir Robert Morley, with 50 others. Some of these vessels were no doubt mere transports, for the king brought with him the household of his queen, Philippa of Hainault, who was then at Bruges. Edward anchored at Blankenberghe on the afternoon of the 23rd and sent three squires to reconnoitre the French position. The Genoese Barbavera advised his colleagues to go to sea, but Béhuchet, who as constable exercised the general command, refused to leave the anchorage. He probably wished to occupy it in order to bar the king's road to Bruges. The disposition of the French was made in accordance with the usual medieval tactics of a fleet fighting on the defensive. Quiéret and Béhuchet formed their force into three or four lines, with the ships tied to one another, and with a few of the largest stationed in front as outposts.

Edward entered the roadstead on the morning of the 24th, and after maneuvering to place his ships to windward and bring the sun behind him, attacked. The battle was a succession of hand-to-hand conflicts to board or to repel boarders. Edward makes no mention of any actual help given him by his Flemish allies, though he says they were willing, but the French say that they joined after dark. They also assert that the king was wounded by Béhuchet, but this is not certain. There is only legendary testimony for a personal encounter between him and the French commander, though it would not be improbable.

The battle ended with the almost total destruction of the French. Quiéret was slain. Béhuchet is said to have been hanged by Edward's orders. Barbavera escaped to sea with his squadron on the morning of the 25th, carrying off two English prizes. After the battle Edward remained at anchor several days, and it is probable that his fleet had suffered heavily. (D. H.)

SMALL ARMS, MILITARY. In military language, the term small arms includes a great variety of weapons designed to be carried on the person and held in the hands when used, or fired from light supports as in airplanes and tanks. Small arms are light, portable weapons distinguished from heavy artillery-type weapons that must be fired from mobile carriages or fixed mounts, but not all of them are small. During the first half of the 20th century the U.S. army fixed the dividing line between small arms and artillery at calibre .60, but this line is no longer universally observed because of the development of portable rocket launchers and recoilless rifles. Small arms are often placed in three broad categories: handguns (pistols and revolvers), shoulder weapons (muskets, rifles, carbines and others) and edged weapons (swords, daggers, pikes, lances, bayonets, etc.). After the invention of machine guns late in the 19th century, these weapons were assigned to the small-arms category although they were far heavier than rifles and normally had to be fired from a bipod, tripod or other support. A narrow interpretation of the term has been adopted for this discussion because there is a separate article on Machine Gun, another on Pistol and Revolver and still others on edged weapons (*see* Bayonet; Dagger; Dirk; Lance; and Sword). This article deals primarily with shoulder firearms, chiefly muskets and rifles. It treats the subject in broad historical terms to show the development of the basic principles of these weapons and their ammunition from their first appearance in the 14th century to the present day. The following outline indicates the main topics covered:

I. Historical Development to 1900
- A. Early History
  1. Hand Cannon
  2. Matchlock
  3. Wheel Lock
  4. Flint Arms
  5. Standardization of Arms
  6. Percussion System

  - 3. Types of Cartridges
  - 4. Types of Ammunition

I. HISTORICAL DEVELOPMENT TO 1900

A. Early History

1. Hand Cannon.— The first portable military firearms probably developed in the second quarter of the 14th century. The eariiest written records date from the 1360s, but it would seem that they refer to a weapon already in use. Variously called hand bombards, hand culverins. *gonnes*, *Handbüchsen* (handguns) or, in modern parlance. hand cannon, these primitive small arms usually consisted of a tube 8–12 in. long, closed at the breech end. with a touchhole bored through the top about two inches from the breech. Usually they were made of brass or bronze, but there are a few references to iron barrels.

To protect the shooter's hand from the heat of the discharge, and also to provide a lever for controlling the recoil, these barrels were attached to a straight wooden haft from five to eight or more feet in length, There were several means of attachment. Sometimes the tube was simply lashed to the haft with iron bands; sometimes it was set into the haft as well as being lashed by the bands: sometimes a socket was fastened to the breech end into which the haft could be inserted; and sometimes the breech was extended in a spike or tang which could be driven into the haft. All these variations are encountered in specimens made before 1400.

A German manuscript of about 1390 survives to indicate some of the details of loading and firing. The barrel was filled three-fifths full of powder well rammed down. Then a wooden sabot or wad was added, and finally the ball. The charge was ignited by inserting a red-hot wire through the touchhole in the top of the barrel or by using a glowing coal held in tongs. An improvement that was probably in use by 1400 was the use of a "match," a length of loose hemp rope soaked in a solution of saltpetre or spirits of wine so that it would burn slowly and steadily, much in the manner of the modern punk used to light firecrackers.

There were several methods of handling these guns, depending somewhat on their size. Small ones could be managed by one man, who clamped the haft between his left arm and his body and supported the piece just behind the breech with his left hand while he applied the wire or match with his right hand. In other instances the butt was rested on the ground and the fore end supported by a forked rest; the shooter had only to steady the weapon while he applied the fire. Still other guns needed the services of two men to hold and shoot them.

As time passed. iinprovements came rapidly. The touchhole was moved from the top of the barrel to the side, where it was better protected from the weather. A pan to hold a small amount of powder was affixed outside the touchhole to provide for surer ignition; the pan was soon fitted with a movable cover. The barrel was lengthened. The haft was shortened and broadened so that it could be held against the shoulder, and gradually a curve was introduced so that the recoil was directed upward instead of directly back against the user. The curved stock is thought to have developed first in France just before 1500.

Some years earlier, certainly before 1425, a most significant advance occurred with the addition of a pivoted S-shaped bar of metal with a pair of jaws on the top end for holding the match. Now all that the soldier needed to do was to raise the lower end of the lever. or serpentine. and the lighted end of the match would be automatically depressed and brought into contact with the powder in the pan. Only the pressure of a finger was necessary. One hand could be used for supporting the gun while the other controlled the serpentine. The shooter could look where he was aiming rather than fix his attention on the pan to make sure he touched the coal to it.

2. Matchlock.— The final major advance in the development of small arms fired by a lighted match came about 1450 with the development of the matchlock. This improvement consisted of adding a trigger and connecting the serpentine lo it by a simple link arrangement so that it acted against a spring. Pressure on the trigger depressed the serpentine and fired the gun. When the trigger was released the spring raised the serpentine and held it away from the pan. All working parts were now placed inside the lock plate and protected. It was at last a true lock. Further developments consisted only in lightening and improving the design of the weapon for easier handling and in replacing the early lever trigger with one that acted against a sear much in the manner of modern firearms. This last advance took place shortly before 1600.

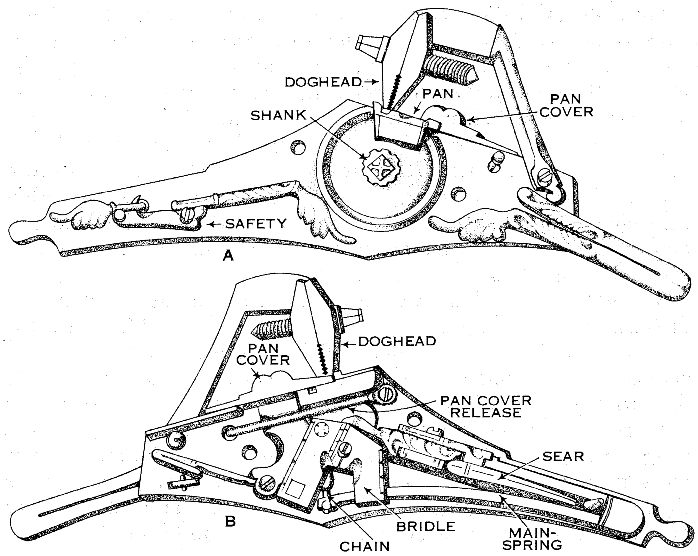
Many names were applied to these early matchlocks, including arquebus (*q.v.*), *Hak-büchse,* hacyuebut, hagbutt, hachbuss and other similar terms, as well as caliver and musket (*q.v.*). Because of the similarity of the terms and the indefinite and careless way in which they were used by contemporaries, much has been written in an attempt to obtain accurate definitions. Actually, they seem to have meant different things in difierent countries and in difierent periods. This is particularly true of the word arquebus and its cognates. Some authors applied it indiscriminately to any firearm. Other and more careful writers used it to designate a gun that was lighter than a musket and could be fired without a rest, thus making it for a short period synonymous with caliver. Still later, at the beginning of the 17th century, it was used to designate a wheel lock (see below) as opposed to a matchlock.

The term musket has always referred to a heavy military firearm. It is generally believed that the term was first used by the Spanish (ntosquete) to denote a military firearm developed shortly before 1.550 and introduced into the Spanish service by Fernando Álvarez de Toledo, duque de Alba. These first muskets weighed about 20 lb. and had a bore of 8 or 10 gauge. (In this sense, gauge indicated the number of spherical lead balls of the same diameter as the bore that were required to reach a weight of one pound.) As years passed, the size was reduced until by the middle of the 17th century the standard English musket weighed about 16 lb. and fired a 12-gauge ball from a 10-gauge bore.

Although the matchlock was a tremendous improvement over the primitive hand cannon. it still had many very serious drawbacks. It was slow and clumsy to use. The lighted match was a decided liability! It was a constant hazard in the presence of powder, and could not be used in the wind or rain; its glow and smell prevented its use in an ambush; it could not be lighted and used at a moment's notice but had to be kept burning whenever it seemed there was even a remote possibility of action.

Despite these many disadvantages, the matchlock remained the principal military firearm of Europe for many years after better and more efficient arms were developed. It was not completely supplanted in many armies on the continent until about 1700, although in America the change had taken place as much as 75 years earlier.

3. Wheel Lock.—Chronologically. the first of the improved ignition systems that eventually supplanted the matchlock was the wheel lock. Possibly invented by Johann Kiefuss of Nürnberg, Ger., about 1515, this lock worked on the same principle as the modern cigarette lighter: the spark was produced by holding a piece of iron pyrite against a revolving rough-edged wheel. The mechanism devised to produce this action was considerably



FROM H. L PETERSON. "ARMS AND ARMOR IN COLONIAL AMERICA"; REPRODUCED BY PERMISSION OF THE STACKPOLE COMPANY, HARRISBURG, PENNSYLVANIA

FIG. 1.— GERMAN WHEEL LOCK MECHANISM (C. 1565), PHANTOM VIEW: (A) RIGHT SIDE. (B) LEFT SIDE

more complex than the matchlock, yet it was sturdy and not likely to get out of order easily. The power for revolving the wheel was supplied by a heavy V-shaped mainspring. This spring was attached to the spindle of the wheel by a short chain of two or three links. When the wheel was wound by hooking a key or spanner over the outside shank of the wheel, this chain was wrapped around the spindle. and the mainspring mas compressed and locked in position by a laterally acting sear that engaged a hole in the inner surface of the wheel.

The flashpan of a wheel lock was attached to the lock plate just as it was in the later matchlock.. It differed from the pan of a matchlock in that it was pierced in the bottom to allow a portion of the wheel to intrude; and instead of a pivoted cover it possessed a sliding cover that was connected with the internal lock mechanism. The pyrite was held in the doghead, a miniature vise mounted on an arm that pivoted just in front of the pan. A spring fastened on the outside of the lock plate just below the arm of the doghead acted upon the arm in such a way that when the head was placed against the pan cover in firing position a constant downward pressure was maintained.

The loading and firing of a wheel lock was a comparatively simple and sure process. First, the wheel was wound. Then the charge was placed in the barrel in the normal manner. Next. the pan was filled with priming powder. the cover was slid shut and the doghead pushed down against it. The trigger was then pulled. The pressure on the trigger released the sear from its lodging in the hole in the wheel. The wheel thus freed began to turn, and as it did so a cam attached to it struck against a bar connected to the pan cover and automatically opened the pan. The doghead with its piece of pyrite. which had been held against the pan cover by its spring. was thus forced against the part of the revolving wheel that intruded through the slot in the pan. .\strong series of sparks was produced, and the priming powder ignited.

The wheel lock was a tremendous improvement over the matchlock. The lighted match was no longer needed. The weapon could be carried ready to fire at a moment's notice. It could be fired with one hand, thus making the pistol practical; and it could be fired from horseback. As cavalry could now be armed with firearms, radical changes in tactics resulted, especially in Germany and northern Europe.

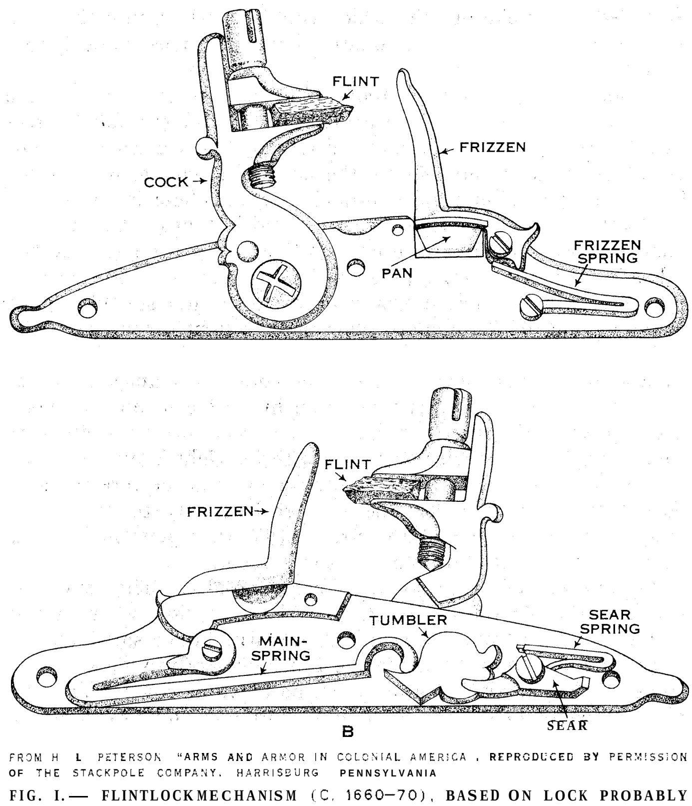
But the wheel lock was an expensive weapon; it never succeeded in supplanting the matchlock as the standard European military firearm. In America it was widely used because conditions there demanded a faster and more reliable gun than Europeans found necessary. In Europe generally it remained the weapon of horsemen and special troops.

4. Flint Arms.—The ignition system that finally supplanted the matchlock was a simple mechanism that produced its spark by striking flint against steel in a procedure similar to that for lighting household fires. In firearms the flint was held in a vise on one end of an arm, known as the cock. The other end of the arm was pivoted on the lock plate so that the flint-bearing end could be swung in an arc in the direction of the steel. The steel, which was also called the battery (now sometimes called the frizzen), was mounted on another pivoted arm and placed in a position opposing the cock. The flashpan was placed directly below the battery. When the trigger was pulled, the cock, impelled by a strong spring, moved forward in a short arc. The flint, held in the jaws of the cock, struck the steel a glancing blow producing a shower of sparks that dropped into the priming powder in the pan. If all went well, the flash of the priming powder penetrated to the powder in the bore and fired the weapon. But sometimes this failed to happen and there was only a "flash in the pan."

Modern students recognize at least six distinct types of flintlocks: the snaphance, English lock, dog lock, Scandinavian snap lock. miquelet lock and the "true" flintlock. These terms denote both different evolutionary stages in the development of the flintlock and regional variations. The first of these forms to appear was the snaphance, believed to have been developed in Scandinavia and the Low Countries about the middle of the 16th century. It was characterized by a separate battery and pan cover. Its name was derived from the Dutch words describing the action of the cock, snaphaan, or "snapping cock." This term was also adopted by English writers and used by them for over 150 years to indicate any form of firearm with a snapping cock, thus causing much confusion among arms historians in later years.

The miquelet lock developed almost as early as the snaphance, but it was confined to southern Europe. principally Spain and Italy. An exceptionally strong and simple lock, it remained virtually unchanged from the time of its invention until the opening years of the 19th century. Its main characteristics were an external mainspring and a battery and pan cover made in one piece.

The Scandinavian snap lock was also a product of the 16th century. It. too, had an external mainspring, and sometimes the battery and pan cover were combined as in the miquelet. There were, in fact, many points of similarity between the Scandinavian



FROM H L PETERSON "ARMS AND ARMOR IN COLONIAL AMERICA , REPRODUCED BY PERMISSION OF THE STACKPOLE COMPANY. HARRISBURG PENNSYLVANIA

FIG. I.— FLINTLOCKMECHANISM (C. 1660–70), BASED ON LOCK PROBABLY OF DUTCH ORIGIN: PHANTOM VIEW: (A) RIGHT SIDE. (B) LEFT SIDE and southern European types, unusual for such widely separated areas. The principal differences were in the shapes of the parts and in minor mechanical details.

The English lock and dog lock were variations of the Dutch snaphance in which the battery and pan cover were made in one piece. The internal mechanism was the same as that of the snaphance. There was no half-cock or safety position. and thus on the dog lock a dog catch mas pivoted on the outside of the lock to engage the tail of the cock and provide such a safety position. Both these forms were in concurrent use in England from the first quarter of the 17th century until about 1650. when the French flintlock began to supersede them. The dog catch, however, persisted on many guns until after 1700, though it no longer served a necessary function.

The true flintlock mas invented in France probably by Marin Le Bourgeoys about 1610–15. It combined features of both the snaphance and the miquelet and produced a simple, safe and reliable weapon. The battery and pan cover were combined in one piece so that the striking of the flint on the steel automatically opened the pan, and the internal mechanism was altered so that there was a haif-cock or safety position. From France this new lock quickly spread throughout most of western Europe, although it never succeeded in displacing the miquelet or, to a lesser degree, the Scandinavian locks. It soon became the standard system for all the better guns and after 1700 for almost all guns.

The chief advantages of the flintlock over the wheel lock lay in its simplicity and cheapness of construction and in the fact that the user no longer had to carry a separate spanner or wrench to operate it. Special troops were armed with the flintlock in Europe by 1650, and after 1700 it had completely replaced the matchlock as a military weapon. In America the change was somewhat more rapid; every colony had banned the matchlock by 1677.

5. Standardization **of** Arms.—The beginning of the 18th century also brought the standardization of military small arms. Some attempts at standardization had been made earlier, it is true. but real success was not achieved until well into the first quarter of the century. By that time royal manufactories and systems of inspection had been set up in several countries and official models adopted. Muskets were the first arms to be standardized in most countries. Pistols and carbines or musketoons followed.

The average musket of the period was a flintlock smoothbore weighing about 12 lb. Calibres ranged from .69 in France and Spain to .75 in England and even slightly larger in some of the German states. With such a musket a well-trained recruit was expected to be able to load and fire in 15 seconds.

These muskets mere not noted for accuracy. The best that could be expected was to hit the figure of a man at 80 to 100 yd. The military men of the period were more interested in rapidity of fire than in accuracy; they operated on the principle of laying donn fields of fire much in the manner of modern machine gunners. Carbines and musketoons were shorter and lighter versions of the musket and were carried by cavalry, artillery and other special troops. Pistols were still shorter arms, also smoothbore. with calibres almost as large and even less accurate. Most cavalrymen scorned them and looked on the sword as their only true and effective weapon. (See also PISTOL AND REVOLVER.)

6. Percussion System.—A Scottish clergyman, Alexander John Forsyth, revolutionized all firearms theory with the invention of a percussion compound that would explode when struck a sharp blow. Working at his manse. Forsyth made his first percussion lock in 1805 and patented it in 1807 after some months of experimenting at the Tower of London. His compound was basically potassium chlorate. When placed in a tube communicating with the bore of a gun and struck by the hammer it produced a flash strong enough to ignite the charge. Separate priming powder and free sparks were no longer necessary. Forsyth thus laid the basis for later self-contained metallic cartridges and for contact fuses in shells and opened a whole new field of possibilities.

The next task was to perfect methods of utilizing this new material efficiently. Pellets and tubes filled with the compound were tried in the so-called pill and tube locks. Then came the percussion cap claimed by several as an invention. Joshua Shaw, an Anglo-American living in Philadelphia, developed the device in the United States but was refused a patent because he was not a U.S. citizen at the time. The first caps, shaped somewhat like the top hat of the period, were made first of iron (1514). then of pewter (1815) and finally (1816) of copper. The bottom of the cavity contained a minute amount of the percussion mixture covered by a disk of tin foil; the whole mas sealed and made waterproof by a drop of shellac. In operation, this cap was placed over a tube, knoan variously as a cone or nipple, that projected from the barrel. The hammer, acting exactly in the manner of the cock on flint arms, struck the cap a sharp blow and produced a flash that was directed by the tube into the bore where it set off the propellent charge.

Despite the obvious advantages of the percussion system, a number of years passed before it was adopted as standard for military small arms. Military men could appreciate the fact that percussion guns were simpler to make, were surer to go off, and were not affectedby wind or even light rain. They saw, too, that it was no longer necessary to carry extra flints and to chip and adjust them as they wore down. Nevertheless. they were concerned about the supply of percussion caps, the methods of carrying them and the delicate process of applying them to the gun. Thus it was not until 1842 that either the United States or Great Britain began the manufacture of standard military muskets of the percussion type, though the United States had adopted the system for special weapons as early as 1833 and Great Britain in 1836.

B. Development of Rifling

Rifling, or the cutting of spiral grooves in the barrel of a firearm to impart a spin to the projectile and thus improve its accuracy. was invented between 1450 and 1500. Some authorities claim the invention for Leipzig. Ger., in 1498, while others assert that the honour belongs to Vienna. Be that as it may, a specimen exists bearing the arms of the emperor Maximilian I which can be dated definitely between 1493 and 1508. The grooves in many of these very early rifles were straight instead of spiral, and some students maintain that the purpose of the grooves was to receive the fouling from the gunpowder and not to impart stability to the projectile. Fowder fouling was a serious problem, especially with the earliest types of black powder, and such grooves would collect the powder somewhat so that more shots could be fired between cleanings. At the same time, however, it should be noted that the theory of stabilizing a projectile by causing it to revolve on its axis was well understood at that period and was utilized on crossbow bolts and some arrows. This. plus the fact that many of the early grooves are spiral, would seem to indicate that perhaps both purposes were intended.

If a ball were to take the spin imparted by the rifling. it had to fit the bore tightly. This meant that the ball had to be forced down the bore with repeated blows of the ramrod, or it had to be wrapped in a greased patch of cloth or leather that would ease its passage while still permitting a tight enough fit for it to take the rifling. Both methods were used from an early date, and descriptions of them can be found in manuals of the late 16th and early 17th centuries.

Rifling a gun barrel was a comparatively expensive process, and there were other drawbacks about these guns that prevented their rapid adoption as military neapons. The tight fit required of the ball made loading a slow process, even when the greased patch was used. This was a distinct handicap from the military standpoint. Ramrods mere apt to break because of the need to exert considerable pressure on the ball. and a gun without its ramrod was worthless in battle. The thicker barrels of the rifles tended to make them muzzle-heavy; they nere even harder to balance with a bayonet. Use of the early plug bayonet that fitted into the bore was, of course, out of the question with rifles. Finally, it took more skill to use a rifle to best advantage. a decided drawback in the eyes of the men who had to drill raw recruits and levies.

Despite these handicaps, some rifles saw military service at an early date. Christian IV of Denmark is said to have been the first to arm troops with this weapon early in the 17th century; soon thereafter the French royal horse guard could boast that they were armed with eight rifled carbines per troop. By the middle of the 18th century the use of the rifle as a military arm had spread widely on the continent, and most Scandinavian and Germanic countries had organized special troops provided with rifles. The Swedish model of 1761 mas even equipped with a bayonet.

Great Britain lagged far behind the other nations of Europe in the adoption of rifles for military service. Some of the continental troops employed by the British in the various European wars of the 18th century had had rifles, it is true. but it remained for the American rifle, encountered by British troops during the French and Indian War and the American Revolution, to wield the deciding influence in introducing the weapon to the regular British service. Copies of the American rifles were made in small quantities and issued to special troops; the Highlanders serving in America had them at least as early as 1760, and thereafter the practice spread. The breech-loading Ferguson rifle, described below, was tried briefly in 1776–77 and again late in the century, followed by the famous Baker rifles for the first official rifle brigade in 1800. .Interestingly, these Baker rifles followed German patterns more closely than they did American and were equipped with bayonets.

1. American Rifle.—The American rifles that so influenced the British had been developed by German and Swiss immigrants on the eastern seaboard, especially in Pennsylvania. For this reason they are frequently called Pennsylvania rifles and sometimes Kentucky rifles because of their popularity with the settlers of the territory that later became the states of Kentucky and Tennessee. The earliest of the rifles made by these immigrants in the 18th century were indistinguishable from the short, large-calibre rifles of their homelands. As the years passed, however, the colonists lengthened the barrels, decreased the size of the bore and added a brass patch box to hold the greased pieces of cloth with which they wrapped their bullets. In so doing, they achieved a distinctly American gun. Stocked in handsomely grained curly maple, it reached its fullest development between 1770 and 1810.

The American rifle was a supremely accurate weapon. In the hands of practised marksmen it could find its mark at unheard-of distances, striking a target at 300 yd., almost three times the effective range of the musket. For this reason it was an exceptionally valuable weapon for special troops such as light infantry and snipers who were supported by regular infantry with muskets. But because the rifle took considerable time to load and had no bayonet it could not replace the musket as the regular infantry arm. The tactics of the day called for rapidity rather than accuracy in laying down a field of fire before the enemy closed in with the bayonet and decided the issue in hand-to-hand fighting. This point has been overlooked frequently in the past by popular writers who were not trained soldiers and did not understand the tactical situation. A whole body of literature has developed criticizing the military authorities for not recognizing the superiority of the rifle and adopting it immediately as the standard infantry arm. George Washington, Anthony Wayne, Peter Muhlenberg, Daniel Morgan and other American generals, some of them trained riflemen themselves, recognized fully the values of the rifle but realized also that it needed improvement before it could replace the musket.

2. Ammunition for Rifles.—Attempts to make improvements in rifles occupied the time of leading gun designers throughout the western world for half a century following the American Revolution. The principal problem was to increase the speed of loading. Two notable attempts nere made with the round balls that had always been standard for rifles. In Great Britain, the Brunswick rifle was designed to fire a ball with a raised band around its equator to fit the gun's two-groove rifling. The British government adopted the Brunswick rifle in 1836, but it fouled badly and was often called by its contemporaries the worst military rifle in Europe. In France Henri Gustave Delvigne designed a rifle barrel with a narrow chamber at the breech just large enough to contain the powder charge. When the ball was dropped loosely down the barrel so that it rested against the opening of this chamber. several sharp blows with the iron ramrod would expand its diameter and make it fit the bore tightly. This distortion of the ball affected its accuracy, however, and the loading process, though more rapid than that with the patched ball, was still slower than the loading of a musket.

The answer lay not in the round ball but in the elongated projectile. As early as 1823 a Captain Norton of the British 34th regiment found the right approach in a bullet with a base hollowed in such a manner that the gases produced by the explosion of the charge would expand it and cause it to press tightly against the sides of the bore. In 1836 the British gun designer William Greener developed an elongated projectile with a conical plug fitted into the base cavity. On firing. the plug was driven far enough forward into this cavity to expand the walls of the missile into the rifle grooves. Both these bullets were tested by the British government and rejected.

In France, Delvigne, who had given up his experiments on round balls and switched to cylindroconoidal projectiles, teamed up with Colonel Thouvenin of the French artillery to produce a new system, usually known today as the Thouvenin system or the *carabine à tige*. In this rifle a stout pin or *tige* just long enough to pass through the powder charge mas fixed to the centre of the breech plug When the cylindroconoidal projectile was dropped down the barrel, its base struck against this pin, which acted as an anvil for flattening the bullet under blows from the ramrod. Since the ramrod had a shaped cavity in its tip, the bullet retained its form and its accuracy. The pin had a tendency to bend after repeated use, honever, and fouling presented a particularly difficult problem. The hammered bullet did not provide the answer.

It was another Frenchman who finally produced the solution. In 1849 Capt. Claude Étienne Mini6 perfected the projectile that made his name a household word throughout the world. In developing his bullet, Minié followed the pattern set by Norton and Greener—a cylindroconoidal slug with a hollow cavity in the base. At first Minié inserted in this cavity an iron cup that was driven forward by the force of the explosion to expand the base of the bullet until it fitted the bore tightly. Later cups of other materials were tried. and finally it was discovered that if the cavity itself were properly designed, no cup of any kind was necessary.

Here at last was the device that made the rifle a practical military weapon for all branches of the service. The Mini6 ball, as it came to be called, could be dropped down the barrel and rammed home as easily as a musket ball. The rifle could thus be fired as rapidly as the musket. As the rifle had the advantage of greater accuracy, only a few years passed before the smoothbore disappeared from the military scene. Rifled arms of the Mini6 system were adopted as standard by Great Britain in 1851 and by the United States in 1855.

In addition to the main course of rifle projectile evolution, there were also one or two side developments using specially shaped projectiles and bores that achieved some success. These mere the oval-bored and hexagonal-bored rifles. In these systems, instead of the usual grooves, the whole bore twisted to impart the proper spin to the bullet. Among these types, the oval bore has the longer history. Of the many guns that attempted to utilize it, one of the best known was the Greene bolt-action rifle used occasionally during the American Civil War. The hexagonal bore and projectile are associated primarily with the English gun designer Sir Joseph Whitworth, who produced both cannon and small arms utilizing this system. His guns were supremely accurate, and many saw service in the American Civil War in the hands of Confederate troops.

C. Breechloaders and Repeaters

Attempts to produce breech-loading and repeating firearms date back almost to the first appearance of small arms. Breech-loading cannon, in fact, predate the first handguns. Multishot firearms were known at least as early as the first part of the 16th century. Most of the primitive breechloaders used separate chambers that were wedged or screwed into place A few used metal tubes surprisingly similar to modern metallic cartridges All suffered from an excessive leakage of gas and flame and from the fact that fouling soon made them difficult or impossible to use. Xlultishot arms most often employed multiple barrels and locks. revolving cylinders or a Roman candle effect in nhich the priming charge set off the foremost explosive charge in a series of charges loaded one on top of the other in the barrel and a powder train carried the flame onward, setting off one shot after another until the barrel was empty.

1. Lorenzoni System.—During the first half of the 17th century an especially good breech-loading and repeating flintlock firearm was developed, possibly by the Florentine gunrnaker Michele Lorenzoni, and its use soon spread throughout Europe and, by the early 18th century. to America. In Europe the mechanism is known today as the *système Lorenzoni;* in the United States it is called the Cookson type, since the first such gun described in an American publication bore the name of the British gunsmith John Cookson. In this firearm, the balls and ponder were placed in separate tubular magazines in the stock. A single backward-and-forward motion of a lever on the reverse side of the gun caused a special revolving breechblock to select a ball and a charge of powder from their respective magazines. place them in their proper position in the barrel, prime the flashpan and set the gun at half cock.

Some guns based on this system were designed to fire five, six or seven shots. It was an excellent and efficient system, but its construction required the skill of a master gunsmith. It also suffered from the hazard of the possible ignition of the whole powder magazine if the breech were not closed properly at the time of discharge. Despite these dranbacks, guns of this type were still being manufactured as late as 1800.

2. Ferguson Rifle.—Among the breechloaders, the 18th century witnessed the development of several systems nhich, as far as is knonn, were the first such arms used by soldiers. France tried one in 1723. and Austria armed its dragoons and light cavalry with them in 1770. Both experiments were of brief duration. In England an excellent breech-loading rifle was developed slowly during the first half of the century, reaching its peak in time for the American Revolution. The man uho brought this rifle to its fullest development was Patrick Ferguson of the British army, and 100 or 200 men under his command were armed with this rifle for a short time during the American Revolution.

The Ferguson system was simple and efficient. A plug operating on a screw passed vertically through the breech of the barrel. The lower end of this plug was attached to the trigger guard. which acted as a handle. One revolution of the trigger guard in a clockwise direction lowered the plug until its top was flush nith the bottom of the chamber in the breech. The plug being thus depressed left a hole in the top of the barrel nhich communicated directly uith the bore. In order to load the gun rhe barrel was pointed slightly downward, the trigger guard revolved and the plug accordingly depressed. A ball was dropped into the hole in the top of the barrel whence it rolled forward until stopped by the lands of the rifling at the end of the chamber. The ball was followed by a charge of ponder, measured simply by filling the cavity of the chamber behind the ball. The trigger guard was then revolved in a counterclockwise direction, closing the opening in the top of the barrel and forcing out any excess powder that might have been poured in The pan nas then primed separately, and the piece was ready for firing. The Ferguson rifle was probably the finest military firearm used during the American Revolution. It could be fired six times in a minute It was accurate and was equipped with a bayonet. Nevertheless, it did not meet with official favour, and its active career was brief.

3. Hall Rifle.—It remained for the United States in 1817 to adopt the first breech-loading rifle as a standard military arm that saw long service. This was the Hall rifle, a flintlock weapon invented by John H. Hall of Yarmouth, Me., in 1811. In Hall's system a pivoted breechblock containing the lock mechanism and the chamber could be tipped up, loaded and then closed and locked in position by a spring catch. Since the junction of the chamber and the barrel mas a simple butt joint, there was considerable gas leakage. Nevertheless. the Hall system. in both flint and percussion. was used for rifles and carbines for almost 25 years, the last-known carbine contract being awarded in 1850. The Hall rifle also enjoyed the distinction of being the first military firearm made in America with completely interchangeable parts.

4. Dreyse Rifle.—In Europe the breechloader was also making its appearance on the military scene. Johann Nikolaus von Dreyse invented his famous needle gun in 1829, and it was adopted by the Prussian army in 1848. Dreyse's gun used a long. sharp firing pin to pierce the charge of propelling powder and strike the fulminate primer located in the base of the bullet. This needlelike firing pin gave the gun its name and also proved to be the arm's major weakness. for it tended to break or warp during heavy use. Dreyse's breech-closing mechanism included the bolt action; it was the first appearance of that very important device and was probably Dreyse's greatest contribution to firearms design. Despite the weakness of the firing pin, the needle gun remained standard in Prussia until it was replaced by the Mauser in 1871. In France, Antoine Alphonse Chassepot developed a rifle similar to Dreyse's but with a shorter pin and an improved cartridge. Elseahere, Norway adopted a breechloader with a tip-up breech designed by F. W. Scheel in 1842, and in other countries experimentation continued.

5. Sharps Rifle.—In the United States. Christian Sharps of Philadelphia. who had worked under Hall making the latter's breech-loading flintlock rifles. invented the first really satisfactory breech-loading system in 1848 In Sharps's guns the breechblock was raised and lowered in a vertical mortise by the action of a lever that usually served also as a trigger guard. When the breechblock was lowered, the chamber was exposed and a paper or linen cartridge could be inserted. As the breechblock was raised it sheared off the rear of the cartridge, exposing the powder to sparks from the priming pellet, nhich was not contained in the cartridge but was fed automatically over the nipple by the action of the hammer. The Sharps action was very strong and tight. It allowed no gas leakage, and it would not bend or crack, even with excessively large charges. The basic Sharps principle, in fact. is still in use today on some heavy arms and small cannon in which strength is needed.

6. Other Types.—During the 1850s and 1860s a large number of breech-loading arms were developed in the United States, and most of them saw service in the Civil War. It was only the war, in fact, that permitted most of them to get into production, since they were not good enough to have survived in a civilian market. In 1863 the United States government decided to look toward the adoption of a breechloader for its principal infantry and cavalry arms. In 1866 it began the conversion of muzzle-loaders then in use. and in 1873 the first new breechloaders firing .45–70 (calibre .45 with 50 gr. of ponder) metallic cartridges were manufactured. On these rifles and carbines, the top of the breech tipped up in a trap-door action alloning the insertion of the cartridge. The new metallic cartridge eliminated all norries about gas leakage. and the action mas strong. The 45–70 Springfield remained the principal U.S. military rifle until it was replaced by the Krag-Jorgensen in 1892.

Meanwhile experimentation with repeating weapons had not ceased with the *système Lorenzoni* discussed above The United States tried the Roman-candle principle briefly during the Revolution and again during the War of 1812. Sliding locks that could fire superimposed loads one after another also were tried. The British experimented with multibarreled carbines, and there were other attempts to obtain greater firepower.

7. Pistols and Revolvers.—The pistol makers were the first to achieve real success. first with the revolving barrels of the pepperbox and then with the revolving cylinders of the Colt revolver. The pepperbox pistols consisted of a series of barrels grouped around a central axis; they could be fired one after another by a single hammer. The system had developed slowly over a century and a half, reaching its height during the 1830s and 1840s. By this time, all were percussion arms and all were muzzle-loading. On some the barrels revolved automatically; on others it was necessary to turn them by hand. Normally these pistols had from 3 to 6 barrels. but occasionally there were more—8, 10, 12 or even 18. When first developed, they were the fastest-firing guns of their time.

Like the pepperbox, the revolver also developed slowly over a period of centuries. It was made a really practical arm by Samuel Colt in 1830 when as a boy of 16 he whittled out a model of a pistol in which the cocking of the hammer automatically revolved the cylinder. Colt's revolvers were all percussion until after the close of the American Civil War. Each chamber in the cylinder was loaded separately with a combustible cartridge, and the individual nipple for each chamber was capped by hand. The Colt revolver was an excellent weapon and one of America's greatest contributions to small-arms technology. As such it was soon copied by a host of other designers, in both the Cnited States and Europe, n-ho sought in various ways to avoid the patents that Colt held in the United States. Great Britain and France and that protected his system until they expired in 1856. By that time the revolver was firmly established. (See also PISTOL AND REVOLVER.j

8. Later Development of Repeaters.— Further advances in the field of repeating arms waited upon developments in ammunition. The evolution of the cartridge is discussed below, but its tie-in with the invention of practical repeating arms is particularly important here. through the work of two U.S. gunsmiths, Horace Smith and Daniel B. Wesson. These two young artisans became friends in 1852 and together developed a new repeating pistol and rifle using a new cartridge. The repeating mechanism was an improvement on one devised some time before by Walter Hunt and Lewis Jennings. As strengthened and simplified by Smith and Wesson, it formed the basis for the Volcanic pistols and rifles of 1855 and, later. with further improvements by B. Tyler Henry. for the famous Henry and Winchester rifles.

Before the Henry rifle reached its full development, it acquired a serious competitor in the form of the Spencer rifle and carbine. Christopher M. Spencer patented his gun March 6, 1860. It was an excellent firearm with a tubular magazine for seven metallic cartridges in the butt. It was sturdy. did not get out of order easily and was a great favourite with troops durir: . the Civil War, when more than 100.000 Spencer arms saw active service. After the war the Spencer company was purchased by Winchester, and manufacture of Spencer arms was discontinued.

During the second half of the 19th century almost all nations experimented with various repeating rifles and carbines. By 1900 almost all had adopted one form or another as their principal small arm. The Norwegians and Danes adopted the Krag-Jorgensen. as did the United States. after much experimentation with other systems, in 1892. The British adopted first the Lee-Metford in 1888, followed by the Lee-Enfield in 1895. The Germans chose the Mauser, and so on throughout Europe. All were bolt-action rifles with magazines for five or six shots. A few nations preferred the Winchester system, however, either manufacturing their own variations or buying arms directly from Winchester. Only the most backward clung to the old single-shot guns.

D. AMMUNITION

Many of the steps in the evolution of firearms design have been directly related to corresponding improvements in the types of ammunition available. It is impossible to understand one without the other.

1. Gunpowder.— First, there mere improvements in gunpowder (q v.) itself. From the time of its discovery in Europe. sometime in the 13th century, until the appearance of smokeless ponder late in the 19th century, all gunpowder was composed of three essential ingredients— saltpetre. charcoal and sulfur The earliest method of making ponder was to grind these three ingredients and mix them together. This resulted in a black substance of about the texture and consistency of fine coal dust. This form of powder was known as meal or serpentine powder. It was explosive, but it had many distinct disadvantages. It was first of all unstable. It was also hygroscopic. and when stored in a damp place it formed lumps that would burn slowly but would not explode. If the powder were rammed into the barrel with too great pressure it would form a lump and lose much, if not all, of its explosive force. Even when the complete charge remained in its mealy form, not all of it burned, and a gummy residue quickly fouled the gun barrel.

There were other disadvantages that related primarily to shipping and storing serpentine powder. Because of the dusty nature of its contents, a quantity of highly explosive dust was given off every time a container of the powder was shifted or jarred, which created a distinct safety hazard. Also, since the mixture of the three ingredients was purely a mechanical alignment, there was a tendency for these materials to settle out according to their specific densities if the powder were allowed to stand undisturbed for any period of time. Consequently. the periodic inverting of powder kegs was an important part of the routine of every well-run magazine.

Despite these obvious drawbacks, serpentine powder continued in use as the main propelling charge in firearms until about the middle of the 16th century, when "corned" powder began to supersede it. Corned or granulated powder was made by moistening the mixture and squeezing the resultant mass through sieves under considerable pressure. Corned powder overcame most of the disadvantages of the serpentine powder, and, in addition, it burned much more rapidly and thus added considerable force to the explosion. For these reasons, corned powder quickly supplanted the earlier variety as the main propellant for firearms. Serpentine powder, however, remained as the principal material for priming for at least another century.

At first, gunpowder was carried in flasks or horns. During the first half of the 16th century a device known as the bandolier appeared and became popular in many parts of Europe and in America. It consisted of a number of cylindrical containers, each holding enough powder for one charge, suspended from a belt that could be worn over the shoulder. Usually there was also a little flask for priming powder, and a bag for the bullets, which were carried separately.

2. Cartridges.— None of these methods was entirely satisfactory There was still the need for greater speed and safety. The answer lay in the individual cartridge. The first cartridges appeared in the second half of the 16th century. At first they mere simply charges of ponder wrapped in paper. The ball was still loaded separately. Before 1600, however, several methods had been devised for attaching the ball, and during the next century these were refined until by 1700 the ball was wrapped inside the paper with the powder in one self-contained unit. These paper cartridges were in nidespread use in America by 1650. and they were adopted as standard by most European armies during the opening years of the 18th century. They remained standard as long as muzzle-loading arms were used. To use one of these

MODERN SMALL ARMS

BY COURTESY OF (TOP, FIFTH ROW, SIXTH ROW, BOTTOM LEFT, BOTTOM RIGHT) U S ARMY, (SECOND ROW, THIRD ROW) OLIN MATHIESON CHEMICAL CORPORATION, WINCHESTER-WESTERN DIVISION, (FOURTH ROW) FABRIQUE NATIONALE D'ARMES DE GUERRE cartridges, the soldier simply bit off the end of the paper tube, poured a little powder into the pan (if the gun was a flintlock), dumped the rest down the barrel and then rammed the ball and the paper down on top.

The early breech-loading and multishot weapons brought forth a great variety of cartridges. Some were wrapped or covered with paper, some with linen, animal tissue, collodion. metal, rubber and even other materials. All, however, lacked an internal primer that would supply the spark to ignite the charge.

In 1846 a Paris gunsmith named B. Houiller patented two cartridges that represented the first completely self-contained metallic-cased ammunition for small arms. One, known today as the pin-fire cartridge, held a small percussion cap mounted sideways in its base with a pin poised above it and protruding through the case itself. A blow from the hammer drove the pin into the cap, exploding it and setting off the charge. The other was the first of the rim-fire cartridges with a compound of fulminate of mercury in a cavity that encircled the rim of the cartridge base. A blow from a sharp-nosed hammer set this cartridge off in the same manner as the percussion cap that utilized the same explosive compound. In these first rim-fire cartridges the fulminate of mercury also supplied the propelling force. and, as a consequence. the charges were weak In 1856 Smith and Wesson produced a rim-fire cartridge with a suitable charge of black powder as well as the detonating compound, and thus developed a truly useful cartridge.

The rim-fire cartridge gained widespread acceptance for every sort of firearm, but it had certain defects which still had to be overcome. It was difficult to spread the detonating compound evenly all around the rim cavity, and if the rim cavity was not filled all the way around there was a chance that the hammer would strike a blank space and produce a misfire. Also it was difficult to produce a brass case strong enough to withstand the pressures developed by the heavy charges in large-calibre guns and still weak enough in the rim to indent easily under the blow of the hammer.

The final answer to these problems was found in the centre-fire cartridge that was developed at about the same time as the rim-fire. Many men in England, France and the United States contributed to its evolution. In 1852 Charles Lancaster of Great Britain invented a cartridge with an internal perforated disk forming a small cavity at the base. This cavity was filled with fulminate and exploded nhen a blow from the hammer crushed the compound between the base of the case and the inner disk. This system was improved by A. M. Pottet of France in 1857 with a design that allowed a percussion cap to be inserted in a domed cavity in the base. Colonel Boxer of the British Royal laboratory improved Pottet's design in 1867 and produced the basic form of one of the tno standard types of centre-fire cartridges that are the universal standard — the type in which the anvil or inner surface against which the priming compound is crushed is made separately from the cartridge case. The other standard type was developed by Col. (later Gen.) Hiram Berdan of the United States in 1866. In it the anvil nas formed as an integral part of the case. After 1867 there were minor improvements in design and manufacturing techniques, and smokeless nitrocellulose ponder replaced black powder as the propelling charge. but there were no basic changes in these two systems.

BIBLIOGRAPHY.—As the literature dealing with firearms is huge, readers with special interests would do well to consult Ray Riling, *Guns and Shooting: a Selected Chronological Bibliography* (1951), which lists almost 3,000 titles. Some of the most generally useiul books are the following: Josef Alm, *Eldhandvapen* (1933); Torsten Lenk, *Flintlåset* (1939); J. N. George, *English Pistols atzd Revolvers* (1938) and *English Guns and Rifles* (1947); James E. Hicks, *Notes on French Ordnance, 1717 to 1936* (1938); J. Margerand, *Armement et équipement de l'infanterie française* (1945); W. Keith Neal, *Spanish Guns and Pistols* (1955); Harold L. Peterson, *Arms and Armor in Colonial America, 1526–1783* (1956); John G. W. Dillin, *The Kentucky Rifle* (1924 and subsequent editions); Ned H. Roberts, *The Muzzle-Loading Cap Lock Rifle, 3rd* ed. (1948); Arcadi Gluckman, *Cnited States Martial Pistols atzd Revolvers* (1939) and *United States Muskets, Rifles and Carbines* (1948); Berkeley R. Lewis, *Small Arms and Ammunition in the United States Service* (1936); William A. Albaugh and E. N. Simmons, *Confederate Arms* (1957); James E. Serven, *Colt Firearms, 1836–1954* (1954); Alden Hatch, *Rentington Arms in American History* (1956); Lewis Winant, *Pepperbox Firearnzs* (1952), *Firearms Curiosa* (1955), *Early Percussion Firearnzs* (1959); Charles E. Chapel, *The Gun Collector's Handbook of Values* (constantly being revised); and Herschel Logan, *Cartridges* (1948). (HD. L. P.)

II. 20th-CENTURY SMALL ARMS

By the year 1900. foot soldiers in the armies of all leading military powers had at their disposal a nide variety of high-powered repeating rifles, lightweight carbines, semiautomatic pistols and revolvers and fully automatic machine guns. All these weapons fired ammunition that was far superior to that in use a generation earlier. much of it being filled with the propellant known as smokeless powder. Lead bullets covered with a thin jacket of cupronickel or other metal could be fired with great accuracy and lethal effect at man-size targets more than 500 yd. distant; extreme ranges ran up to 3.000 yd. and more. Military small arms had not only become lighter, more dependable, more accurate and longer ranging than those of earlier years. but they had become faster firing. Rates of small-arms fire rose tremendously in the period 1890–1910 as magazine-fed repeating rifles and automatic machine guns became standard military weapons.

These developments in small arms changed the whole face of war during the first two decades of the 20th century. They helped bring to an end the long reign of the cavalry arm. They turned frontal attacks by infantry on \veil-defended positions into mass slaughter. The new small arms, along with improved artillery, forced armies to build elaborate fortifications or seek safety in underground trenches. For a time they so strengthened the defense that no army could hope to take the offensive against a determined enemy and gain more than a few miles without suffering heavy casualties. The ne weapons led to a long period of tactical stalemate on the western front during World War I, a condition that stimulated development of a new weapon, the armoured tank. that was destined to play a major role in World War II. (See TANK; TRENCH WARFARE.)

During the period after 1880 ingenious inventors brought forth such a great variety of small arms that a mere listing of them all, with but brief description of each, would fill a large book. As machine guns, pistols and revolvers are treated in separate articles, they are mentioned here only incidentally; this article is focused mainly on rifles, carbines and submachine guns, but does not attempt to describe or name all the countless varieties that have seen military service. It is limited to a discussion of broad trends of development. with specific mention of some of the most notable types. As the development of ammunition for small arms has been so closely related to development of the weapons themselves, some discussion of small-arms ammunition has been included.

A. REPEATING RIFLES

Among the many different types and models of military rifles that appeared during the 1890s and early 1900s, certain common characteristics stand out. They all weighed between 8 and 10 lb., had barrels ranging from 24 to 30 in. in length. and were between 43 and 52 in in over-all length. The new rifles were shorter and lighter than their predecessors of the mid-19th century, and they fired ammunition of about calibre .30 (7.62 mm.) rather than the heavier bullets of earlier years. They were magazine-fed and were usually loaded by five-round clips or chargers. They were designed to be rugged enough to withstand hard usage and to keep firing even under the worst weather conditions, though further improvements along these lines were constantly being sought.

The military rifle most widely used and copied during the first quarter of the 20th century was the German Mauser. It had first appeared in Germany in the 1880s and over the years had been adopted by a score of countries other than Germany. No other military rifle ever enjoyed such wide use. A bolt-action piece loaded with a five-shot charger, the Mauser was produced in many models, including both a standard rifle (*Gewehr*) and a shorter carbine (*Karabiner*). Improved models of 1898 served as the basic weapons of the German infantry throughout World Wars I and II.

1. Bolt Action. — The term bolt action calls for some explana-

tion because it is fundamental to an understanding of all modern rifles. The bolt or breech mechanism of a rifle operates on the same principle as the sliding bolt used to lock a door, though it is far more complicated and its manufacture calls for much more precise workmanship. The typical rifle bolt is a steel cylinder containing a firing pin; it slides back and forth in the frame or receiver. The bolt has a solid head and, like the door lock, is fitted with a projecting handle with a round knob at the end. One or more lugs near the front or rear of the bolt fit into slots in the receiver and hold the bolt firmly in place against the base of the cartridge in the chamber when the weapon is to be fired. When the trigger is pressed, a long slender firing pin within the bolt is pushed forward by a spring to strike the primer cap in the base of the cartridge. After firing, the shooter grasps the round knob, raises it slightly to turn the bolt and disengage the lugs, and then slides the bolt back to extract the fired case. Forward movement of the bolt strips a fresh cartridge from the magazine and forces it into the chamber; a downward pull on the knob locks the bolt in place. Straight-pull rifles such as the Austrian Mannlicher and Canadian Ross require no turning to permit the bolt to slide back.

2. U.S. and British Rifles.—In 1892 the U.S. army adopted the Norwegian Krag-Jorgensen rifle in preference to the Mauser and many other weapons tested. Produced as both a rifle and a carbine, it underwent several modifications during its short period of service. In 1903 it was replaced by the Springfield rifle, a modified copy of the Mauser manufactured at the U.S. army's Springfield (Mass.) armoury and at Rock Island (Ill.) arsenal. An excellent rifle, the Springfield served as the basic infantry weapon of the U.S. army for the next 35 years and helped win for the U.S. soldier a world-wide reputation for rifle marksmanship. As late as World War II, modified Springfields with telescopic sights continued to serve as sniper rifles. The 1903 Springfield was a calibre-.30 weapon with a 24-in. barrel, about 6 in. shorter than the Krag-Jörgensen. For this reason, no carbine type of Springfield was considered necessary for mounted troops.

In the British army, too, during the South African War; there was a demand for a shorter rifle with a magazine feed that could serve for both infantry and cavalry, thus eliminating the carbine. A committee was appointed in 1900 to study the matter, and in Dec. 1902 a new rifle described as the "short, magazine, Lee-Enfield, Mark I" (S.M.L.E.) was adopted. It replaced the Lee-Metford (1888) and the long Lee-Enfield (1895). Its over-all length of 44½ in. was approximately 5 in. shorter than the "long rifle." The S.M.L.E. combined the bolt action developed by an American, James P. Lee, with the Enfield type of rifling. It fired rimmed calibre-,303 ammunition, and its bolt locked on the rear as did that of the Krag-Jorgensen. An improved model known as Mark III was adopted in 1907, followed by Mark 111* in 1918, a model with no cutoff (a device to permit reloading with single cartridges) and no long-range sights. The S.M.L.E. was fed from a ten-shot box magazine loaded by five-shot clips or single rounds. Though not quite so accurate as the Mauser or Springfield at long range, the S.M.L.E. held twice the number of cartridges and was faster firing.

At the outbreak of World War I in 1914 the British army was about to adopt a new Enfield rifle chambered for calibre-.276 rimless ammunition. But, in the face of war, the British government abandoned its plans for mass production of a new rifle and new type of ammunition. Instead, the ,276 rifle was modified to fire the standard calibre-.303 rim-type cartridges, and orders for its production were placed with factories in the United States. Production was slow, and by 1917, when the United States entered the war, British need for these rifles had declined while the U.S. forces a-ere desperately short of Springfields. To meet this emergency the British rifles in production were converted to fire U.S. calibre-.30 ammunition and were standardized as the M1917, or American Enfield. Over 2,000,000 of these rifles were produced during the war at three U.S. plants. The Enfield thus became, in terms of quantity production, the leading U.S. rifle of World War I. The rifling of the Enfield, unlike that of most rifles of its era, consisted of five grooves with a left-hand twist.

Other notable military rifle types of the early 20th century were the Austrian Mannlicher, Russian Mosin-Nagant, Japanese Arisaka. French Lebel and Canadian Ross. As noted above, the Ross and the Mannlicher were of the straight-pull type. They sufferedfrom frequent jamming in mud or sand, and the Ross was dropped during World War I because of frequent maliunctioning.

B. Semiautomatic Rifles and Carbines

All the rifles described above were repeaters, not automatics or semiautomatics. They fired one shot each time the trigger was pulled (or squeezed. to use the preferred military term). but after each shot the user had to pull back the bolt by hand to eject the spent case and then slide it forward to bring another cartridge into the chamber. By 1900, and even much earlier, firearms designers had begun to think seriously of developing semiautomatic or seli-loading rifles that would automatically bring a fresh cartridge into firing position after each shot, using the force of recoil or gas pressure for the purpose. France and Germany experimented with semiautomatics on a small scale during World War I. France issuing a few of the St. Étienne model and Germany some Mondragons designed by a Mexican officer of that name. But neither type functioned well in combat. The United States was the first nation to achieve real success in this field.

1. Garand Rifle.—After a generation of experiment and test (mostly with calibre-,276 rifles during the 1920s) the U.S. army in Jan. 1936 adopted a calibre-.30 semiautomatic rifle developed by John C. Garand. a civilian engineer at the Springfield armoury. Replacing the 1903 Springfield, the Garand rifle, or M1 as it was officially designated, became the basic weapon of the U.S. infantry in World War II and the Korean war. It was a calibre-.30 gas-operated weapon fed by an eight-round clip and weighing about 94 Ib. Its 24-in barrel was rifled with four grooves.

As the gas-operating mechanism of the M1 differed from the manually operated bolt described above, it merits brief explanation at this point. A small hole or gas port on the underside of the barrel near the muzzle permitted part of the propellent gases to escape into a small cylinder holding a piston that was connected to the bolt. As the gas pressure forced back the piston and the bolt, the empty cartridge case was ejected and the hammer was cocked. A spring then forced the bolt forward. As it moved forward the bolt stripped the top cartridge from the magazine and seated it in the chamber ready to fire. Gas pressure thus performed automatically the reloading task formerly done by hand. For this reason, weapons of this type are often called self-loading or autoloading.

With the Garand rifle the U.S. army adopted a new cartridge of the same dimensions as its predecessor but with a lighter bullet —152 gr. as compared with 172 gr. Some critics considered this a backward step but military authorities defended it on two main counts: first. the lighter bullet caused less recoil and thus helped the training of recruits in marksmanship; second. the extreme range of the heavier bullet—over 3,000 yd.—was of little military value and proved dangerous in target practice on 1,000-yd. ranges. Rifles were seldom used in combat beyond about 600 yd.

2. Johnson Rifle.—Soon after the Garand rifle was adopted in 1936, and while Springfield armoury was tooling up for its manufacture, a serious competitor appeared on the scene and precipitated a major rifle controversy in the United States. This was the semiautomatic rifle designed as a private venture by Melvin M. Johnson. It had a 22-in, barrel, weighed about 9½ lb., operated on the short-recoil principle rather than the gas system of the Garand and was fed with a ten-shot rotary magazine. Largely because of defects that appeared in the first production models of the Garand, there arose a demand that the Johnson be adopted in its stead. But, after much public discussion and extensive tests in 1939–40, the U.S. army decided to retain the Garand after improving its gas take-off. The Johnson rifle meanwhile was adopted by the Netherlands Indies forces and saw some service with U.S. marine corps units in World War II.

3. German and Soviet Rifles.—The German and Soviet armies also employed semiautomatic rifles to some extent in World War II, but their performance fell short of expectations. The German semiautomatics that saw most service were the models *Gewehr* 41, 41-W and 41-M. *Gewehr* 43 and *Karabiner* 43. All were gas-operated and fired 7.92 mm. cartridges. The 41 and 41-W did not have a gas port in the barrel but employed a cone attached to the muzzle to trap some of the expanding gas. As early as 1936 the Soviet army adopted the 7.62-mm. Simonov gas-operated rifle, which was capable of both semiautomatic and fully automatic fire. Its gas port and piston were on top of the barrel, thus resembling the German *Gewehr* 43. Another Soviet gas-operated semiautoinatic rifle, the 7.62-mm. Tokarev, appeared in 1938 and 1910 models. But throughout World War II most German and Soviet troops carried manually operated repeating rifles or carbines.

Principal Dimensions and Weighfs of Representative Military Rifles

Country	Rifle	Calibre	Approximate weight (pounds)	Length over-all (inches)	Type
Switzerland	Schmidt-Rubin (1889)	7.5 mm.	9.8	51.5	straight-pull repeater
U.S.	Krag-Jörgensen (1892)	.30 in.	9.2	49	turning-bolt repeater
Austria	Mannlicher (1895)	8 mm.	8.4	50	straight-pull repeater
Germany	Mauser 1898)	7.92 mm.	9	49.4	turning-bolt repeater
Russia	Mosin-Nagant (*c*. 1900)	7.62 mm.	9	51.8	turning-bolt repeater
U.S.	Springfield (1903)	.30 in.	8.7	43.2	turning-bolt repeater
Japan	Arisaka (1905)	6.5 mm.	9	51	turning-bolt repeater
Great Britain	S.M.L.E. Mark III (1907; originally adopted 1902)	.303 in.	8.7	44.5	turning-bolt repeater
France	Lebel (1907; originally adopted 1886)	8 mm.	9.2	51.5	turning-bolt repeater
U.S.	Enfield (1917)	.30 in.	9.2	46.3	turning-bolt repeater
U.S.	Garand M1 (1936)	.30 in.	9.6	43.6	gas-operated semiautomatic
Japan	Model 99 (1939)	7.7 mm.	7.7	45	turning-bolt repeater
U.S.S.R.	Tokarev (1938–40)	7.62 mm.	8.8	47.8	gas-operated semiautomatic
Germany	*Gewehr* 41-W (1941)	7.92 mm.	10.8	45	gas-operated semiautomatic
U.S.	Carbine M1 (1941)	.30 in.	5.5	35.6	gas-operated semiautomatic
Germany	*Gewehr* 43 (1943)	7.92 mm.	9	43	gas-operated semiautomatic
Great Britain (also Canada, Australia and Belgium)	Fabrique Nationale (FN), light-barrel version (1954)	7.62 mm.	8.7	44.4	gas-operated semiautomatic and automatic
U.S	M14, light barrel (1957)	7 62 mm	8 7	44 1	gas-operated semiautomatic and automatic
US.	M15, heavy barrel (1957)	7.62 mm	137	45.5	gas operated semiautomatic and automatic

4. Carbines. — Early in World War II the U.S. army again adopted a carbine. This time the carbine did not serve as a cavalry weapon, as had carbines of the 19th century, but as a defensive weapon for service troops and operators of crew-served weapons whose positions might be overrun in mobile warfare. For such troops the pistol had too short a range and too little accuracy, while the standard rifle was unnecessarily heavy and ponerful. A gas-operated weapon developed by the Winchester Repeating Arms company, the U S. carbine M1 was similar in design to the Garand rifle but was 8 in. shorter. It weighed only about $5\frac{1}{2}$ lb and fired a different type of ammunition from a 15-round magazine. The M2 carbine that appeared late in the nar had a selector snitch that gave the user a choice of fully automatic or semiautomatic fire; it was fed from a 30-round magazine. Some airborne troops carried a carbine (M1A1) with a folding skeleton metal stock.

The British army also employed light rifles or carbines for certain types of troops in World War II. Rifle No. 4. Mark I* weighed only $6\frac{3}{4}$ lb. and was sometimes described as a carbine. Rifle No. 5, Mark I* was a British carbine especially designed for jungle fighting.

Most rifles and some carbines were equipped with detachable bayonets or bayonet knives for hand-to-hand combat, though bayonet fighting was not common in World War II or the Korean war and many observers considered the bayonet obsolete. Another attachment, the grenade launcher, enabled troops armed with rifles and carbines to hurl antitank and antipersonnel grenades for short distances. (*See* BAYONET; GRENADES.)

C. RIFLE DEVELOPMENTS AFTER WORLD WAR II

At the end of World War II small arms were overshadowed by the atomic bomb and long-range guided missiles, but they were by no means forgotten. All leading military powers sought to improve their small arms in the light of World War II experience. The main objectives were to make rifles lighter and faster firing. The United States and Great Britain, joined in 1949 by other members of the North Atlantic Treaty organization (NATO), made determined efforts to improve their military rifles and also to standardize their equipment, particularly ammunition. Agreement in this field was not reached overnight. The Korean war (1950–53) was fought in the main with small arms and ammunition of the World War II type.

1. NATO Cartridge. — Acceptance of a common small-arms cartridge came first, though not without some difficulty. The British government proposed that a rifle cartridge of calibre .280 (7 mm.) with lead-core bullet be adopted. The U S. government favoured a more powerful cartridge of calibre 30 with steel core. After extensive tests the U S. cartridge, known as T65 during its development at Frankford arsenal, gained NATO acceptance in Dec. 1953. Formal action to standardize the new ammunition for all NATO countries came in 1954. In line nith the policy of using the metric system, the new round was officially designated Cartridge, NATO, Calibre 7 62-mm. Its length. 2 84 in., nas $\frac{1}{2}$ in. shorter than the existing U S. M2 cartridge, and its weight was about 10% less. The saving in length and weight resulted from the use of improved propellants, such as ball powder, that required less space The 165-gr bullet of the new cartridge was capable of inflicting a fatal wound on personnel protected by standard steel helmets and body armour at a distance of approximately 1.000 yd. It was standardized for both rifles and machine guns. Many older weapons nere converted to take the new round.

2. FN Rifle. — The British government meanwhile brought forth a rifle, designated EM2, of unusual design and appearance, with pistol grip placed ahead of the magazine. It had a straight stock, weighed about eight pounds and nas chambered to fire the .280 cartridge. The Belgian firm Fabrique Nationale d'Armes de Guerre entered the competition with another rifle, popularly known as the FN and officially designated the T48 in U S tests. It also was designed to fire the .280 cartridge. The ordnance department of the U S. army carried on extensive development and test work at Springfield armoury nith designs based generally on modifications of the Garand rifle to provide both automatic and semiautomatic fire. After field tests and prolonged discussion, reaching up to the level of the British prime minister and U.S. president in 1952, the British government in 1954 adopted the FN rifle, which meanwhile had been altered to fire the 7.62-mm. cartridge and been designed in light barrel and heavy barrel models. Belgium, Canada and Australia also adopted the FN rifle in 1954.

The FN was a gas-operated weapon with selector switch for either semiautomatic or fully automatic fire. It weighed about $8\frac{3}{4}$ lb., had a 20-round magazine and extended to 44.4 in over-all length. including flash suppressor. In appearance the FN was markedly different from weapons of the Garand type, for it had a separate pistol grip behind the trigger guard and a carrying handle that could be swung up above the barrel. Because its butt could be swung downward on a hinge, thus permitting access to the receiver mechanism the FN mas easy to field strip and clean.

3. M14 and **M15** Rifles. — In 1957 the U S army announced that it had adopted a new semiautomatic rifle designated the M14, known during its test period as the T44. A gas-operated weapon, the M14 was similar in design to the Garand, or M1, which it was eventually to replace. Its weight was 8.7 lb., approximately 1 lb. less than the Garand. Like the Garand, it was developed at Springfield armoury. It fired the standard 7.62-mm. NATO cartridge. had a magazine capacity of 20 rounds and could be fitted with a selector switch to permit semiautomatic or fully automatic fire. A notable feature of both the U.S. rifle and the FN was a slotted flash suppressor at the muzzle. The new U.S. rifle, like the FN, was manufactured also in a heavy-barrel version (M15) that weighed approximately 13¾ lb. and was better adapted for fully automatic fire. This heavy-barrel version mas equipped with a bipod support for the muzzle.

Combined with the M60 ground machine gun, the new rifle formed a complete family of small arms for the U.S. army, all firing the same ammunition. The M14 rifle was designed to replace the Garand rifle. the carbine and the M3 submachine gun, except as the latter mas used on vehicles. The heavy-barrel M15 was to replace the Browning automatic rifle (BAR) as the automatic weapon of the infantry squad. The 23-lb. air-cooled light machine gun was to replace three existing models of calibre-.30 ground machine guns. The new rifle and machine gun would thus reduce the number of weapons in the U.S. army's small-arms system from seven to three, greatly simplifying logistical support and shortening the time needed for troop training.

4. Soviet Rifles.—The Soviet Union also adopted a new family of infantry weapons during the 1950s, including a rifle, submachine gun (see below) and light machine gun. All fired a standard short 7.62-mm. cartridge. The Soviet rifle, described as a semiautomatic carbine, was a gas-operated weapon with ten-round magazine and a permanently attached folding bayonet. It weighed about 8½ lb. and had a stock made of laminated wood. The Soviet light machine gun was designed to provide fully automatic fire for the rifle squad. It weighed about 14½ lb. and was fed by a drum-type magazine.

D. Automatic Rifles

Automatic rifles, sometimes classed as light machine guns, represent attempts to combine the burst fire of the machine gun with the mobile flexibility of the rifle. Their combat employment reached its peak in World War II, though several models saw service in World War I. The typical automatic rifle was a shoulder-fired weapon weighing between 20 and 30 lb. and equipped with a bipod to support the muzzle when firing from a prone position. One of the earliest weapons of this type was the 28-lb. gun developed by the U.S. army officer Isaac N. Lewis. The British army adopted the Lewis gun as a platoon weapon just before the outbreak of World War I, and it proved to be a major factor in British infantry firepower during 1914–18. It was later adopted by the U.S. navy but not by the U.S. army.

The most famous U.S. army weapon of this type, the calibre-.30 Browning automatic rifle (BAR), appeared too late to see service in World War I, but it served well for the next 40 years as the basic automatic weapon of the rifle squad. It was a shoulder-fired, gas-operated rifle weighing about 20 lb. complete with bipod support. A comparable British weapon that saw extensive service in World War II was the 22–26-1b. Bren machine gun, a weapon that by U.S. standards would be classed as an automatic rifle. The Bren took its name from Brno, Czech., where it was originally manufactured, and Enfield, Eng., where it was further developed. It was basically a calibre-.303 weapon but was produced also in 7.92-mm. size. A selector switch permitted either semiautomatic or fully automatic fire.

The German army used the MG34, developed secretly in 1934 in violation of the Versailles treaty, and the MG42, which had the extremely high cyclic rate of 1,500 shots per minute. For paratroops the Germans in 1944 adopted a special gas-operated 7.92-mm. rifle named *Fallschirmjägergewehr* 42 (FG42). It had a selector switch that permitted either semiautomatic or fully automatic fire. With sling, bayonet and bipod it weighed about 10½ lb. A 13-lb. light machine gun developed in 1940–41 by Melvin M. Johnson saw some service with U.S troops, the Dutch and other Allied nations in World War II.

E. Submachine Guns (Machine Carbines)

Since their introduction by the Germans and Italians in World War I, these weapons have been known variously as machine carbines in Britain, machine pistols in Germany and submachine guns in the United States. They are small, light weapons standing between the pistol and the rifle. They are far simpler in design than machine guns but they offer rapid-firing action. either semiautomatic or fully automatic. In spite of their limited range and poor accuracy they have proved to be useful for paratroops, commandos, tank crews and others who require a light gun able to deliver a high volume of fire at close quarters. Submachine guns normally fire pistol-type ammunition—calibre .45 in the United States and 9 mm. in western Europe—at rates ranging from 450 to 900 rounds per minute. Nearly all submachine guns have short barrels and heavy bolts and operate on the plain blowback principle. (See Machine Gun.)

Among the earliest weapons of this type to see military service were the Bergmann Muskete, the Villar-Perosa gun and the Beretta machine carbine. In the United States the most famous submachine gun was that patented in 1920 by a retired army officer, John T. Thompson. Popularly known as the Tommy gun, it gained notoriety as the weapon of U.S. gangsters during the prohibition era. The U.S. army adopted it in 1928, and the British army also used it. The Thompson submachine gun weighed about ten pounds and fired calibre-.45 ammunition from a circular drum holding 50 rounds or a box magazine holding 20 rounds.

During World War II and the Korean war, all major armies employed submachine guns in considerable numbers. They all developed weapons of simple design intended for cheap mass production and weighing between seven and ten pounds. Best known among them were the British Sten, Australian Austen and Owen, Finnish Suomi and German Schmeisser (MP38 and MP40). The latter, with folding stock, weighed about nine pounds, fired 9-mm. ammunition and was carried by paratroops and motorcycle units of the German army in its 1940 blitzkrieg. Later types firing 7.92-mm. ammunition were known as MP43, MP44 and *Sturmgewehr* 44. Following the German example, the U.S. army first simplified the Thompson gun and then turned in 1942 to a new all-metal submachine gun weighing about nine pounds and firing calibre-.45 pistol ammunition from a vertical magazine under the bolt. Officially designated the M3, it soon took the nickname "grease gun" because of its resemblance to the tool used to grease automobiles. The Soviet army also replaced its 1940 model (calibre 7.62 mm.) early in the war to speed production. First came the M41 PPSh, fed by a 71-round drum, and then the PPS-43 with folding metal stock and curved 35-round box magazine. The M41 gun was extensively used by the North Koreans during the Korean war. A new calibre-7.62 mm. Soviet submachine gun appeared in the 1950s. It weighed about 9½ lb. and was fed by a 30-round curved magazine. It was produced in two models, one with a conventional wooden stock and the other with a folding metal stock.

F. Antitank Weapons

To meet the need for a powerful infantry weapon to attack armoured vehicles, the British army adopted the Boys antitank rifle. It mas much like an ordinary bolt-action magazine rifle but fired a heavy, calibre-.55 armour-piercing bullet at high velocity. A little over five feet in length, the rifle weighed 36 lb. and could penetrate 24-mm. armour at 100 yd.

The most revolutionary light antitank weapon that appeared in World War II was the shoulder-fired U.S rocket launcher familiarly known as the bazooka. It was one of the simplest weapons employed during the war, and one of the most effective. The bazooka was an outgrowth of efforts to fire a powerful antitank grenade from a rifle and thus give the infantryman a means of defense against tanks. As the open-end rocket launcher had no recoil. it could fire a heavier round than could a conventional rifle. The bazooka gained its remarkable armour-piercing capability from the use of ammunition designed on, the shaped-charge principle. Its chief limitations were its short range, lack of accuracy and backblast. Though its bore diameter of 2.36 in. far exceeded the normal upper limit of calibre .60, the bazooka was usually classed as a small arm, or, more properly, an infantry weapon. The same was true of the 3.5-in. bazooka that saw service in the Korean war (see BAZOOKA).

G. Recoilless Rifles

Another new type of infantry weapon, the recoilless rifle. made its appearance in combat toward the end of World War II and saw much service in the Korean war. It had some of the characteristics of an artillery piece but, because of its light weight, was often classed as a small arm. Ordnance designers had long dreamed of creating a powerful meapon that would have no recoil and would therefore need no heavy recoil-absorbing mechanism. The dream was realized by designing a gun that permitted some of the propellent gases to escape through exhaust ports in the breech, thus giving the weapon a forward thrust equal to the normal recoil. The 57-mm. recoilless rifle developed for the US. army weighed less than 50 lb. and could be fired by one man from the shoulder (though not in the usual rifle firing position) or from a bipod or tripod mount. A larger 75-mm. recoilless rifle also saw some service with the U.S. army in World War II; after the war, 105-mm. and 106-mm. models nere developed to be mounted on a jeep or fired from a ground support. In 1559 the US. army announced a new 90-mm. recoilless rifle said to be capable of knocking out the heaviest tanks. It was a 35-lb., four-foot-long meapon that fired a shaped-charge projectile to an effective range of 500 yd.

Recoilless weapons are characterized by their simplicity, lightness and vented breechblocks. They fire high-explosive and antitank ammunition of unique design. Their cartridge cases are perforated to permit a portion of the propellent gases to escape to the rear; their shells are pre-engraved (*i.e.,* with rotating bands notched to fit the rifling). Recoilless rifles have lower muzzle velocity and much shorter range than do guns or howitzers of the same calibre. One of the greatest drawbacks to their tactical use is the rearward blast that betrays their location and makes them unsuitable for use in confined spaces.

H. Ammunition Developments

Remarkable progress was made in the improvement of small-arms ammunition during the period 1880–1910 with still further development during the next half century. Smokeless ponder, improved brass cartridge cases, better bullet design jacketed bullets, and clips and chargers for loading magazines—these were among the most noteworthy developments of the pre-World War I era The earlier shift from bullets of spherical to cylindro-conoidal shape had stimulated a trend toward smallbore rifles. since an elongated bullet had less diameter than did a spherical bullet of the same weight.

1. Bullets.—After P. M. E. Vieille's discovery of so-called smokeless poader in the 1830s. this propellant came into general use, ending the long reign of black powder. It gave off less smoke than black powder but mas not completely smokeless. The high muzzle velocities (over 2,000 ft. per second) attained nith smokeless powder were too much for conventional soft lead bullets to withstand. Bullets tore loose from the rifling, failed to spin properly and emerged from the muzzle unbalanced and hopelessly inaccurate. The answer to this problem lay in the jacketed or metal-patched bullet—a lead core covered nith a thin shell of steel or cupronickel. Credit for making great improvements during the 1880s in the work of earlier pioneers in this field is usually given to Eduard Rubin, a Swiss army officer. For a time the French army adopted a different solution, using a solid bronze bullet in its 8-mm. round for the Lebel rifle. but virtually all other nations adopted jacketed bullets, or compound bullets as they were sometimes called.

Soon after the turn of the century another change in bullet design occurred when the pointed bullet, known as the spitzer type, gradually supplanted the round-nosed bullet that had been standard in all armies for many years. Another apparently trivial but actually important development came in the early 1900s nith the discovery that further streamlining of bullets, accomplished by giving them a slight taper or boat tail at the base, increased their range. An early example of this type appeared in World War I, the French 8-mm. boat-tailed round known as *Balle* D. Some nations followed the French example. but others kept flat-based bullets in service for many years. Meanwhile the substitution of gilding metal (copper and zinc) and allied compounds for steel and cupronickel in bullet jackets was found to lessen bore erosion and metal fouling Later, during World War II. when copper was scarce, the United States turned to the use of steel jackets coated nith a thin deposit of copper or gilding metal.

Most early 20th-century rifle cartridges produced chamber pressures betneen 35.000 and 50 000 Ib. per square inch and muzzle velocities betneen 2 000 and 2.800 ft. per second. They fired bullets that were a little more than one inch long and weighed between 135 and 244 gr. Their powder charges normally ranged between 30 and 50 gr. Cartridges varied in calibre from 6 mm. (.236 in.) in the U S. navy's Lee rifle to 8 mm. (.315 in.) in the French Lebel, and in over-all length from about 2.50 in. to 3.35 in. Fired from a firm support at a target 200 yd. distant, the best ammunition nould group ten shots within a circle about five inches in diameter. Using U.S. Springfield?, expert riflemen could consistently hit a 20-in bull's-eye at 600 yd.

2. Chargers **and** Clips.—The introduction of magazine rifles in all armies put an end to the older method of feeding from a tube in the butt or under the barrel, and the use of chargers or clips for loading became standard practice. These terms are often used loosely and interchangeably, but. for the sake of historical accuracy, a distinction is best observed. A clip was originally a light metal openwork box in which a small number of cartridges, usually between five and ten. were placed, one on top of the other, against a spring at the bottom. They all faced the same way and their bullet ends were exposed. The entire clip filled with cartridges was slipped into the magazine, the so-called *en* bloc system of loading. It remained there until all its cartridges were fired, then dropped out at the bottom or, on some models, popped out at the top. In contrast. a charger was merely a flat strip of metal nith its edges curled slightly to hook over the rims or extractor grooves of a row of cartridges, usually five. To load a rifle, the bolt was drawn back, the charger holding a row of cartridges was slipped into position above the receiver, and the cartridges were pushed down into the magazine against a spring-supported follower. The empty charger was then discarded. The Garand rifle was loaded with a double-row, eight-round clip; the Springfield and other Mauser-type rifles were loaded from five-round chargers.

3. Types of Cartridges— Three types of central-fire cartridges —rimmed, semirimmed and rimless—deserve some explanation. The first was the type developed on the pattern of the earlier rimfire case but operated on a differentprinciple. It was a central-fire case and its rim mas a flange at the base that could be gripped by the extractor hook to remove the spent case from the chamber after firing. The rimless type had no protruding flange but had instead an annular groove just forward of the base into which the extractor could fit; the groove thus served the same purpose as the rim. The semirimmed case was essentially rimless. but its base section had a somewhat greater diameter than the main body of the case, thus giving it some of the characteristics of both the rimmed and rimless types. The widely used Mauser family of rifles fired rimless cartridges, as did the U.S. Springfield. British, French and Russian rifles fired rimmed ammunition.

Another feature of most modern cartridge cases is their bottleneck shape. As bullets of smaller calibre came into use at the end of the 19th century, ordnance designers had to narrow the mouths of cartridge cases and fit the bullets into them like corks in bottles. Retaining the standard size for the main body of the cartridge case provided room for a large powder charge nithout resorting to use of a much longer and narrow case. Most 20th-century military rifle cases assumed the bottleneck shape, but that for the U.S. carbine did not, nor did ammunition for pistols and submachine guns.

Three years after adoption of the Springfield rifle the U.S. army standardized the calibre-.30 M1906 cartridge, familiarly known as the .30-'06. It had a rimless case and fired a 150-gr. flat-based bullet. After World War I this cartridge was replaced by a more powerful type, with a 172-gr. boat-tailed bullet, known as M1. It had an extreme range of 3.500 yd.. or nearly two miles. Its lead core was hardened with antimony and its jacket was of gilding metal rather than cupronickel. As noted above, the M1 cartridge was supplanted by a lighter (152-gr.) flat-based round, known as M2, in the late 1930s when the Garand semiautomatic rifle came into use. It remained the basic rifle round of the U.S. army until the 1950s when its replacement by the 7.62-mm. NATO cartridge began (*see* above).

During the second quarter of the 20th century another major advance in small-arms ammunition came with the introduction of noncorrosive primers. In the early 1920s manufacturers of sporting ammunition had brought forth cartridges containing no potassium chlorate, a substance that left a moisture-attracting residue in the bore and caused rusting if the weapon were not cleaned promptly after firing. U.S. military authorities were reluctant to accept new primer compositions without exhaustive testing, particularly in view of their problems with defective primers during World War I. The first large-scale production of noncorrosive military primers in the United States came during World War II when commercial firms manufacturing carbine ammunition employed their own primers with good success. Germany made extensive use of noncorrosive primers during World War II for 9-mm. and 7.92-mm. ammunition. In 1949 the U.S. army standardized a noncorrosive styphnate mixture for small-arms primers.

4. **Types** of Ammunition.— The most noteworthy trend in small-arms ammunition development in the 1910–60 period was the appearance of many different types of ammunition to serve special purposes. The impetus for this development came largely from the employment of machine guns for aircraft and antiaircraft fire. In addition to the familiar type known as ball ammunition there were added others known as armour-piercing. incendiary, tracer, armour-piercing-incendiary and special types for launching rifle grenades. Whatever the type. the term cartridge was used to designate the complete round, including cartridge case, propellant, primer and bullet.

Ball ammunition is most closely akin to the lead spheres of an earlier age and is chiefly an antipersonnel round. Its core is of lead alloy or common steel. Despite its name, the bullet fired by a round of ball rifle ammunition is not actually ball-shaped; it more nearly resembles a short cigar, with the front end pointed (but not sharply pointed) and the other end flat or slightly tapered. The bullet of the calibre-.45 ball cartridge for pistols, revolvers and submachine guns is more nearly ball-shaped, with rounded nose and flat base.

Armour-piercing (AP) cartridges assumed great importance during and after World War I as a means of attacking tanks, planes and other armoured vehicles. In the U.S. army there was a strong tendency during and after World War II to use AP ammunition for all purposes and do away with ball ammunition. The bullets of AP cartridges normally consist of a hardened steel core, gilding metal jacket and a small amount of lead to fill the space between the point of the core and the point of the jacket.

Tracer cartridges contain a chemical agent that emits light or smoke to enable the shooter to see where his shots are going. Such ammunition proved to be of special value in adjusting the aim of machine guns in aerial combat and, to a lesser extent, in setting fire to gasoline tanks of enemy planes.

Incendiary cartridges contain a chemical agent that ignites upon striking the target. They are highly effective against aircraft with light armour protection carrying heavy loads of fuel.

Grenade cartridges are designed to propel grenades (*q.v.*) from rifles and, in some cases, from carbines. They have no bullet but contain a powder charge that propels the grenade from a launcher fitted to the muzzle.

Efforts to improve rifle ammunition during the decades following World War I were directed toward reducing barrel erosion, eliminating muzzle flash and attaining improved ballistic performance. One of the most notable developments was a propellant known as ball powder that was widely used in British ammunition and in U.S. carbine ammunition during the 1940s and in many other types in later years. Brass remained the preferred metal for cartridge cases in spite of extensive experiments with steel, aluminum and plastics. Brass was strong, nonrusting and could easily be worked into the desired shape; it was also sufficiently elastic to expand slightly under the pressure of firing and then to contract for easy extraction.

SMALLEY, GEORGE WASHBURN (1833–1916), U.S. journalist and war correspondent, was born at Franklin, Mass., on June 2, 1833. He was educated at Yale university. where he received a master of arts degree in 1853. and Harvard lam school. After practising law in Boston, he served as a correspondent for the *New York Tribune* from Nov. 1861 to Oct. 1862 in the Shenandoah Valley campaigns of the American Civil War and with the army of the Potomac. He is credited with assisting the Union forces by carrying orders in the field at the battle of Antietam (Sept, 17, 1862). Two days later his account of the battle appeared in the *New York Tribune;* it was the first newspaper story on Antietam and a notable achievement for the time.

In 1866 Smalley went to Europe to report the Seven Weeks' War between Prussia and Austria. He thereafter organized a *Tribune* European bureau in London and was head of European correspondence for the paper until 1895. During the period he won wide acclaim for his dispatches on the Franco-German War.

In 1895 Smalley returned to the United States, where for ten years he was U.S. correspondent for the *Times* (London). He later settled in London, and died on April 4, 1916. Smalley had married in Dec. 1862 the adopted daughter of the U.S. reformer Wendell Phillips, with whom Smalley was associated in Boston before he became a *Tribune* correspondent.

Smalley's books, largely collections of his letters to the *Tribune,* include *A Review of Mr. Bright's Speeches* (1868); *London Letters,* 2 vol. (1891); *Studies of Men* (1895); and *Anglo-American Memories* (first series, 1911; second series, 1912). He also wrote *The Life of Sir Sydney H. Waterlow, Bart.* (1909).

SMALL HOLDINGS. The term small holdings covers several categories of relatively small farm tracts. Throughout the world, the essential characteristics of small holdings include recognized rights to operate the land, a high ratio of labour to land with the labour furnished mainly by the operator and his family, and relatively low levels of farm production and income. In most parts of the world, the labour is mainly by hand with the assistance of one or two horses, oxen or cows and simple tools.

This article outlines the characteristics and traces the history of small holdings after the breakdown of feudalism and indicates their prevalence in the second half of the 20th century. Separate sections deal with farm ownership in the United States and discuss some of the economic aspects of small holdings. For additional information on the trend to larger holdings in the United States *see* FARM MANAGEMENT: *Production Resources. See* also AGRICULTURE; FARM TENANCY; LAND REFORMS; LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS.

Included in the commonly accepted meaning are the subsistence tracts of the peasant farmer and garden tracts and part-time farms as well as small family farms. The mechanized family farm, of substantial size in commercial agricultural areas, usually is excluded. Certainly excluded are the plantation, the estate, the collective farm and the factory-in-the-field farm. Many ranches, even if family operated, would not commonly be thought of as small holdings, for the size is an important, though not by any means the only, determinant. The United Kingdom Small Holdings act of 1892 and the Small Holdings and Allotment act of 1926 provided examples of legal applications of the term. In other countries somewhat the same results were accomplished by legislation not so exactly named.

The bulk of the world's population lives on farms and perhaps three-fourths of the world's farmers live on small holdings. The farm population constitutes about 1,500,000,000 people or about 60% of the estimated total world population. Small holdings are most prevalent in Asia and other underdeveloped parts of the world, but are also numerous in other countries. Population pressure on the land is sufficient in much of the world to reduce the average size of farms well within the small-holding limits. In most countries small holdings also are used by labourers and other part-time farmers for housing, subsistence and incidental agricultural production.

History of **the** Small Holding.—In Denmark, England and other countries of western Europe. governmental interest in small holdings was aroused by the breakdown of feudalism. The object of governmental programs was to provide holdings for labourers and tenants who were being dispossessed. As early as 1682, 20 years before serfdom was abolished, it was decreed in Denmark that no farms that were large enough to support a family should be combined with other farms. This was an anticonsolidation rule aimed at landlords who had discovered that the prevailing three-field system was not very efficient and might be profitably replaced by improved rotation methods. thereby consolidating some of the peasant-cultivated land. But that would have meant less taxes and fewer soldiers for the crown—hence the rule that meant in practice that no tenant could be dispossessed. In the same country, as early as 1781–82, many of the agricultural labourers were by law given ownership of four to six acres of land to keep the individual available to work the lord's land. Comprehensive legislation after 1899 furthered the establishment of small holdings averaging five to seven acres, the government lending the prospective holder nine-tenths of the purchase price of land and buildings.

Later emphasis was on having a farm large enough to keep the farmer fully employed and provide a living for the family; hence 12½ ac. of land were set as a minimum goal for all farms. Still later government measures were directed at obtaining land for small holdings or to add to small holdings, as equitably as possible, from entailed estates and from the higher valued, more extensive holdings.

In England small independent holdings existed under the feudal system, their numbers being greater in some manors than in others. For centuries, through the modification and disappearance of the feudal system, the number of small holdings or family farms increased until they became the predominant form of land occupancy. This trend continued up to the last great enclosure movement beginning in the latter part of the 18th century.

The enclosure movement contributed greatly to a reduction in the number of small holdings and to an increase in the number of farm labourers.

The success of large numbers of small holdings was dependent on the common for pasture. When the common was enclosed an allotment was made to the commoner in proportion to his interest. These allotments were of little value to many small holders, however, because they were often far from the allottee's cottage and because he was obliged to fence them. Consequently many small holders sold their land to larger landowners and became labourers.

With the reaction to the materialism of the Industrial Revolution, the social and economic consequences of the decline of small holdings aroused the attention of the English government. The weight of arguments for small holdings resulted in reform legislation beginning with the Allotments acts of 1887 and 1890. The Small Holdings act of 1892 authorized county councils to create small holdings on a self-supporting basis where a need was proved to exist. Small holdings were legally defined in the Small Holdings act of 1892 as holdings of less than 50 ac. in extent or under £50 in annual rental value. In 1926 the limit of annual rental value was raised to £100. If an applicant could not purchase land he could obtain a holding on lease. The results of the act of 1892 were negligible largely because it was only permissive, and it was amended by the Small Holdings act of 1908, a much more comprehensive enactment, particularly in introducing the principle of central initiative and authority. This act instructed county councils to provide small holdings in response to the demand. In case the council failed to carry out its obligations the ministry of agriculture was given power to develop a plan. If a loss was actually incurred the ministry was authorized to bear one-half the loss.

Operations under the act of 1908 mere suspended during World War I. Legislation following World War I had the main objective of providing small holdings under particularly favourable terms for ex-servicemen.

The Small Holdings and Allotments act, 1926, renewed the powers of county councils to provide small holdings. In the event that holdings could not be provided without loss, the ministry of agriculture would contribute 75% of the estimated annual loss. Under this series of enactments a total of 28,700 small holdings were established from 467,000 ac. of land. Only a small part of this land was held by councils on lease.

In 1947 small-holding policy was made the subject of part iv of the 1947 Agricultural act. The objective emphasized in this act was the use of small holdings as a step in the agricultural "ladder" for farm families with little capital. Permitted sizes of holdings were increased to 75 ac. or £150 rental value. In 1958 a Small Farmers scheme was introduced providing grants to eligible small farmers for the purpose of carrying out approved plans for improving the farm business.

During the early 1900s small-holdings programs were established in many other countries, including Germany, Rumania, Hungary and parts of Russia immediately following the Revolution. The collectivization of agriculture greatly reduced numbers of small holdings in many Communist countries. However, in 1954 Yugoslavia instituted a policy permitting decollectivization of agriculture. Beginning about 1930, attention in France, Switzerland, Germany and other countries was focused on the consolidation of fragmented holdings and enlargement of excessively small holdings. After World War II land reforms favourable to small holdings were undertaken in Japan, Italy, Egypt, Mexico and other countries.

Prevalence of Small Holdings.—In England and Wales in the 1950s, 22% of the holdings of over 1 ac. were from 1 to 5 ac., 24% were from 5 to 20 ac. and only 36% of the holdings were of 50 ac. or more. The number of units under 50 ac. provides a rough measure of the importance of small holdings in Great Britain. They vary considerably in size, in returns and in types of products grown. Many of the holdings under five acres are cottage gardens or allotments. Some occupy small acreages with specialization in intensive enterprises such as growing vegetables or producing eggs. Others are larger and more diversified. Probably most of the holdings from 20 to 50 ac. are commercial units producing mainly for sale. In Ireland, long after the period commonly considered as the reform period, very small holdings continued to increase both in number and in per cent of total, though average size remained fairly constant. Three-fourths of the holdings in Ireland are under 50 ac. In Germany and other countries of western Europe considerable permanent hired labour is used on farms of 20 ha. (hectare = 2.47 ac.) and over.

Data from selected countries show that the size distribution of holdings is highly variable from country to country, but small holdings greatly predominate. Moreover, allotments made as a part of land reform, as in Italy, are small—only one to five hectares per holder. The numbers of holdings reporting less than one hectare vary widely, largely because of the varying farm definitions used in various countries.

In eastern Europe small units were prevalent prior to collectivization. In Bulgaria in 1934 only 1% of the holdings were larger than 49 ac. Less than 3% of those of Yugoslavia in 1931 were more than 49 ac. Even in Hungary, with its large pre-World War II estates, 70% of all holdings in 193j were in tracts of 7 ac. or less. It may be significant that in some of these countries members of the new state co-operative farms were permitted to retain small plots—of 0.5 to 1.2 ac. in Bulgaria and Rumania, up to 2.j ac. in Yugoslavia and about 2 ac. in Hungary.

In Egypt, where 95% of those who own land have j ac. or less, expropriated land was to be distributed in units varying in size, according to quality, from a minimum of 2 feddans to a maximum of j feddans (about 2 to 5 ac.). In Iran units of 14.5 to 21 ac. each were distributed. In Iraq settlement after 1946 appeared to recognize that tracts could be too small; the Dujail project involved allocation of $62\frac{1}{2}$ ac. per family from a tract of 75,000 ac. of newly irrigated, formerly desert land.

In the orient, holdings are extremely small and tend toward further reduction under the pressure of population. More than 90% of Japanese farmers work less than 2.0 ha. After World War II Japan instituted a comprehensive system of land reform. Under these laws strict upper limits were set on farm size. Numbers of small farms increased substantially but net productivity of labour apparently rose with increased savings and capital formulation. Very small farms are also characteristic of India and China. More than half the farms in India are under 2.0 ha. In the late 1950s considerable emphasis was placed on the formation of co-operative and collective farms in China.

In Africa small native holdings greatly predominate even in areas such as Nigeria, producing export crops of cocoa and peanuts for the world market. Ninety per cent of the non-European farms in Southern Rhodesia also are in holdings of under 14 ac. Cultivation in these countries is by plow or hand hoe.

There is appreciable variation in the size of holdings in Central and South America. Chile, with 2.5 ac. of cropland per capita, has about 20 cultivated acres per person engaged in agriculture. On the other hand, in Guatemala more than one-fifth of all agricultural holdings are leas than 0.7 ha. and more than 75% are less than 3.5 ha. Over half of the holdings in Puerto Rico are under 3.5 ha. in size. Even in Uruguay, which is still accepting settlers, 42% of the holdings are less than 20 ha. in size.

United States.—In the United States, even during the period of abundant land, relatively small holdings were generally favoured. In 1820 the minimum unit of sale of government land was lowered to 80 ac. Limitation of acreage of public land that could be acquired by one individual was early recognized. The Pre-emption act of 1841, as amended, provided that a settler could legally enter upon public land and establish a claim for not more than 160 ac.; he could not make more than one such entry, and such a claim could not be made by anyone owning as much as 320 ac. The Homestead act of 1862, under which something like 285,000,000 ac. were patented, provided that a qualified individual might acquire title to land, not to exceed 160 ac., by five years of residence thereon with improvements, or by six months of residence plus payment of $1.25 per acre.

*U.S. Farms by Categories, 1929–54**
(in 000)

Class of farm	value of sales (1954 prices)	1929	1939	1949	1954
Part-time and residential.	Cnder $2,500		1,181	1,670	1,507
Small-scale	Under $2,500				1,174
Medium and large . .	2 0 0 and over				2,101
All farms	—	6,203	5,950	5,382	4,782

*Excludes farms listed in 1940 and 1930 censuses that could not meet minimum criteria used in censuses of 1950 and 1954 Adapted from J. V. McElveen, "Family Farms in a Changing Economy," A.I.B. 171, U.S. Dept. of Agriculture (March 1957).

In 1954 the United States census of agriculture classified 4,782,000 holdings as farms. A postenumerative survey indicated that about 419,000 additional places that would have qualified mere missed by census enumerators; most of the latter were small holdings. About 35% of the 4,782,000 farms enumerated operated less than 50 ac., and more than 50% were under 100 ac.

Because of the wide variation in productivity, acreage is not a very satisfactory measure of size of farms in the United States. In terms of value of products for sale, farms in the United States can be separated into three major groups, two with value of sales under $2,500 and one with value of sales $2,500 and over. (See table.) Medium to large farms accounted for about 44% of the farms in the United States in 1954. Their numbers increased with the growing commercialization of agriculture. Most of them are mechanized family farms (see also FARM MANAGEMENT). Less than 2% of the farms in the United States would be classified as large-scale units primarily dependent on hired labour. Nearly one-third of the farms are part-time and residential units, most of them classed as small holdings, with farm production for sale of less than $2,500. Over four-fifths of these had sales of less than $1,200 in 1954. Nearly one-fourth of the farms in the United States can be classified as small-scale units primarily dependent on farming for a living. While the number of small-scale farms was decreasing, they remained a substantial segment of U.S. agriculture, characterized by low levels of mechanization, relatively small acreages and underemployment of operator and family labour. A substantial number of the operators were 55 years of age or over.

Beginning in the 1930s the problem of the small farmer was approached in a modest way by the Farmers Home administration of the U.S. department of agriculture with a program of supervised credit and individual guidance for the development and enlargement of land resources and working capital. In 1955 a rural development program was initiated by the U.S. department of agriculture in several counties in areas where farm incomes were low. Approximately 100 counties came to participate in this program.

Some Economic Aspects of Small Holdings.—Developments in machinery. equipment and modem aids and techniques focused attention on the fragmentation of holdings in some areas and on the uneconomic sizes of fields and lack of the opportunity to make efficient use of modern agricultural machinery.

This situation suggested consolidation of small and scattered holdings and the injection of capital to mechanize the consolidated units to give at least part of the reorganized population more income per hour worked and turn part of the population to other work. The difficulty of attaining efficient production with a small land unit (except for a few types of intensive specialization) led to attempts to overturn the small-holding pattern in some countries.

Another aspect of the problem is what is called the underemployment of farm labour. It has been argued that many small holders value leisure and the satisfactions of self-employment more highly than the advantages they might gain from fuller or more productive employment. Furthermore, a high percentage of families on small holdings have some off-the-farm employment. In these cases the small tract can serve to provide a form of security plus some food and space for family living. But for many families more productive use of labour involves farm enlargement, occupational adjustments and the development of nearby non-farm industries.

SMALL ISLES, a parish of islands of the Inner Hebrides, Inverness-shire, Scot. Pop. (1951) 215. It consists of the islands of Canna, Sanday, Rum, Eigg and Muck, lying in the order named, like a crescent with a trend from northwest to southeast, Canna being the most northerly and Muck the most southerly. They are separated from Skye by Cuillin sound and from the mainland by the Sound of Ardnamurchan. The surface is moorland, pasture and mountain (exceeding 2,500 ft. on Rum). The islands are rich in seafowl and Rum contains red deer and wildcats. The fisheries include cod, ling and herring. Steamers call at Eigg, Rum and Canna.

Antiquarian remains at Canna include a weather-worn sculptured stone cross and the ruins of a chapel of St. Columba. On the northeast coast of Eigg is a cave with a narrow mouth, opening into a hollow a j5 ft. long. In it Macleod of Skye, toward the end of the 16th century ordered 200 Macdonalds to be suffocated: their bones were found long afterward.

SMALLPOX or **VARIOLA** is an acute infectious disease characterized by fever and, beginning about two days later, an eruption which after passing through the stages of papule, vesicle and pustule, dries up, leaving more or less distinct scars.

The characteristic eruption may be so profuse as to be confluent, especially on the face, or so scanty that the lesions are missed altogether. The lesions are commonly more deeply seated in the skin than are the lesions of chicken pox (varicella) and the scars are therefore more permanent than those of chicken pox, but mild forms of smallpox may also have comparatively superficial pocks, with correspondingly less tendency toward pustulation and less scarring.

These modifications, both toward fewer lesions and toward their being more superficial, may occur either naturally or as the result of a vaccination not recent enough to give complete protection. Nearly complete vaccinal protection commonly gives few lesions, but even if the vaccination has been a score or more years before, smaller and more superficial lesions are the rule where an unvaccinated person would have a severe attack. Such superficial lesions are also characteristic of the naturally occurring mild strains of the disease, called "variola minor." or in some countries '(alastrim" or "amaas." Even with strains of full severity. called "variola major." there may be much variation as regards severity from individual to individual among the unprotected.

Besides the characteristic focal eruptions (papule to vesicle to pustule to scab to scar) there may sometimes be seen a toxic eruption during the initial fever. These toxic rashes may be diffuse blushes on trunk or limbs somewhat suggestive of scarlet fever or measles; they may on the other hand be deeper red, with small haemorrhages like flea bites or larger blotches in the skin. They are unusual enough to be of not much importance except for the fact that the deeper red eruptions have often disguised the diagnosis so that smallpox is not thought of until the contagion has spread over a hospital or farther. Cases with such a haemorrhagic eruption are likely to be the most severe, even fatal before the characteristic focal eruption appears, and can carry an intense contagion.

Diagnosis. — Prompt diagnosis is of the highest importance in combating smallpox. one of the world's most dreaded plagues. Though general vaccination helps, there is no community anywhere so efficiently vaccinated as to prevent smallpox from getting a temporary toe hold on occasion. The mechanical refrigerator was largely responsible for the scarcity of the disease in the United States: vaccine is kept very cold constantly so that a screen of recently and successfully vaccinated individuals can be thrown promptly around any cases which might occur. Better refrigeration, quicker transportation, safer and more regularly potent vaccine and more enlightened sanitary practices also caused marked reductions elsewhere in the world. Smallpox rates and infant mortality rates are two of the best indexes of living standards. The scarcity of the disease, however, brought about a considerable dulling of a former accustomed keenness in diagnosis.

The course of a typical case is the surest criterion for diagnosis: fever beginning 7–21 days after effective exposure to a preceding case. then papules (pimples) appearing after 1–5 days of fever and becoming vesicles (blisters) in 1–4 days, pustules in another 1–4 days and crusting over (scabbing) in 2–6 days. The scabs fall off in 10–40 days after the beginning of the eruption, leaving pink scars which become white after months or years. Unfortunately this is too slow a method for efficient diagnosis. Complete isolation of the patient. search for persons who may have been in contact with him and vaccination of those who might be exposed should be begun nithin hours, not days. after the first trace of a case. For this reason the distribution of the eruption, which can be used at any stage after it appears, is the best guide.

The eruption of smallpox, nhether scanty or profuse, has more lesions on the parts of the body exposed to irritation than elsewhere, more on the face than on the abdomen dnd chest, more on the forearms and wrists than on the upper arms, more on the arms than on the trunk. more on back of the arms and hands than on the front. more on the shoulders than across the loins, more on the chest than on the abdomen, more on the limbs than on the trunk and more on the back than on 'the abdomen. Protected places such as the depression of the eyelid or back of the ear (unless irritated by wearing glasses) are relatively spared.

Cause. — The cause of smallpox is a virus whose particles can be visualized by the electron microscope and can pass through a filter which holds back most bacteria but are larger than the particles of such a virus as that which causes poliomyelitis. Elementary particles are also visible, after staining, in an oil-immersion microscope.

This virus can be cultivated in a developing chicken embryo in a fertilized egg, as well as on some other living animal tissues with a higher percentage of failures. Cultural, microscopic and serological identification of the virus may be a help in diagnosis but somewhat slow for effective handling of a case.

Method of Spread. — Each case of smallpox arises from contact, direct or indirect, with a preceding case of the disease. There are no natural animal carriers or natural propagation of the virus outside the human body, and the virus ordinarily does not live very long outside the body nor is it ordinarily carried more than a few feet through the air. Nevertheless all articles which may have been contaminated from a smallpox patient should be thoroughly disinfected by heat before they come in contact with unprotected persons. Smallpox is one of the few diseases in which terminal disinfection (as by formaldehyde) of living quarters is specified after removal or death of the patient. The virus may be carried passively by a third person, himself immune, from a sick person or from a corpse. The disease is presumably contracted by inhalation of particles bearing the virus, therefore thorough masking as well as the wearing of gowns should be carried out for necessary contact with the sick; isolation must be much more rigid than with the other contagious diseases.

Although smallpox is counted among the most contagious of diseases, its failure to spread to nonimmunes in spite of ample opportunity is no adequate evidence against diagnosis of the disease. Repeatedly persons with full-blown smallpox of virulent strains, which are usually more contagious than the milder strains, have come into contact with many nonimmunes without thus spreading the disease.

It can be similarly seen that failure to take the disease after exposure is no proof that one's vaccinal immunity is perfect. Though ordinarily once in five or ten years is often enough to be vaccinated, for medical and nursing personnel subject to exposure at any time. or for those living in contact with native families of a smallpox-infested region, vaccination with fully potent vaccine every one or two years should be the rule. There is always the chance that the tube of vaccine used was not of full potency, unless preceding immunity had decreased enough to permit a reaction approaching that of a first vaccination. This points to the wisdom of not counting on vaccination scars or statements of the patient's having been vaccinated to dismiss the possibility of smallpox in diagnosis.

History and Prevalence. — The Persian physician Rhazes about A.D. 900 wrote the first known account separating smallpox from measles, although Eusebius mentioned a Syrian epidemic in A.D. 302 and the term "variola" was used by Bishop Marius of the disease in France and Italy in 570. About 1200, Gilbert of England first referred to smallpox as a contagious disease but even this was continually contradicted — even by Thomas Sydenham (1675) who described the disease better than anyone before him.

Smallpox was pandemic in Europe in 1614, epidemic in England during 1666–75, and there mere scattered outbreaks in New England all through the 17th century. On account of their habits during sickness. the American Indians were severely stricken, and students have asssigned smallpox as one of the chief reasons for the conquest of the land by the white men. Of course there were many mistakes in diagnosis, and smallpox was confused with the great pox (syphilis). William Heberden in 1767 first clearly distinguished chicken pox from smallpox, but even in the 19th century the great skin physician. Ferdinand von Hebra of Vienna. Aus., denied the difference. It nould be difficult to assign to any one man credit for showing that variola virus can, by repeated transfer to the skin of animals, be attenuated and become vaccinia virus (cowpox); the cumulative evidence is convincing. One corollary to this is the danger of making vaccine virus too penetrating if the harvesting from the calf's skin is too deep or perhaps if the various layers of the chicken embryo are used as a source.

After the turn of the 20th century the predominance in some localities of very mild types gave rise to the thought that the mild type was a disease different from smallpox, but tests for immunity indicated that these are merely different forms of the same disease, each form generally breeding true to its type.

Statistics as to prevalence of smallpox must be accepted with some caution. Confusion with severe chicken pox and vice versa is easy. and reporting and diagnosis are likely to be imperfect in the very regions where vaccination is imperfect; in some places in the United States mild forms seem to have slumbered unrecognized for months or years. Eastern Asia has been a breeding ground for outbreaks of the severe form of the disease in Europe and the United States, although some outbreaks have arisen from travellers from Mexico.

Mild smallpox has been well established in the central and western United States but the reduction was so phenomenal that the elimination of the disease in the U.S., as far as indigenous cases are concerned, became a distinct possibility. Rapid air travel however, brought a need for fresh vaccination of all international travellers.

In 1921 there were 89,357 cases and 481 deaths from smallpox reported in the Cnited States; in 1924, 45,25j cases and 814 deaths; in 1939, 9.877 cases and 41 deaths; in 1945, 346 cases and 12 deaths; in 1950 only 42 cases. In 1949 there were reported in French West Africa 1.889 cases and 181 deaths; in the Belgian Congo 2,261 cases and 9 deaths; in Egypt 3 cases and 1 death (11,194 cases and 1,016 deaths in 1944); in Nigeria 14,790 cases and 2,224 deaths; in the Union of South Africa 1.461 cases and 115 deaths; in Argentina 500 cases and 3 deaths; in Brazil 598 cases and 6 deaths; in Canada. Australia and New Zealand none; in Mexico 1,030 cases and 293 deaths; in Peru 5,907 cases; in Burma 3.456 cases and 1,051 deaths; in China 237 cases and 80 deaths (reported. but 20,562 cases and 2,593 deaths reported in 1946, 20 574 cases in South Korea in 1946); in Formosa 188 cases and 20 deaths (5,250 and 1,718 in 1947); in India 74.178 cases and 17,740 deaths (304.062 cases and 216,538 deaths in 1944); in Indonesia 13 442 cases and 1,913 deaths; in Indochina 2,570 cases and 932 deaths; in Iraq 702 cases and 102 deaths; in Japan 124 cases and 13 deaths; in Pakistan 4.806 cases and 1,471 deaths; in Turkey 73 cases and 14 deaths. Two cases each were reported from France and Italy (2.831 in Italy in 1945), 11 from Portugal and 17 from England and Wales.

Treatment. — At mid-century, no specific treatment was yet known for the disease. Secondary infection during the pustular stage may be diminished by the sulfonamides or antibiotics which thus may make the disease milder. Prevention is by means of isolation and vaccination. Of all widely prevalent diseases, this is the most completely preventable by public health measures.

BIBLIOGRAPHY. — The literature on smallpox is enormous. In sorting and evaluating it, statistical soundness is not so important as thorough, accurate observation, which is rare. For this reason, some of the older literature, when opportunities for observation were more frequent, is more valuable than some having the advantage of more modern methods. The 295-page article on "Variola" by H. Immermann of Basle, Switz., in *Nothnagel's Specielle Pathologic und Therapie*, vol. 4, no. 4 (Vienna, 1896) gives the older views well. Diagnosis was put on the firmest basis so far achieved by the publication of *The Diagnosis oj Smallpox by T. F.* Ricketts and J. B. Byles (London, 1908): Ricketts, as medical superintendent of the London Smallpox Hospital and Ambulance Service in the epidemics of 1893 and 1902, had probably the richest experience in smallpox which had fallen to the lot of one man. *Blattern und Schutzpockenimpfung* by the Reich Board of Health (Berlin, 1925) gives the German point of view; *Epidemiology of Smallpox,* De Lamar Lecture, by J. P. Leake (1929), a U.S. view; and "Smallpox." by C. O. Stallybrass, *Public Health,* 60:77-79 (Jan. 1947), a British view. *Questions and Answers on Smallpox and Vaccination by J.* P. Leake was first printed in the Public *Health Reports* of the U.S. Public Health Service (Jan. 28, 1927): the last revision was that of 1946 issued as reprint no. 1137 from the Government Printing Office, Washington, D.C. Current data on the prevalence of smallpox are found in the monthly *Epidemiological and Vital Statistics Reports* of the World Health Organization, Geneva, Switz. (J. P. L.)

SMALRIDGE, GEORGE (1663–1719), English bishop, son of Thomas Smalridge, was born at Lichfield where he received his early education. After attending Westminster school, he entered Christ Church, Oxford, in 1682.

His political opinions were largely modelled on those of his friend Francis Atterbury, with whom he was associated at Oxford and elsewhere.

After being a tutor at Christ Church, he was minister of two chapels in London, and for six or seven years he acted as deputy for William Jane, the regius professor of divinity at Oxford; his Jacobite opinions, however. prevented him from securing this position when, upon Jane's death, it fell vacant in 1707. In 1711 he mas made dean of Carlisle and canon of Christ Church, and in 1713 he succeeded Atterbury as bishop of Bristol, but retained his deanery.

In 171j Smalridge, along with his friend Atterbury, refused to sign the declaration against the pretender, James Edward, defending his action in his *Reasons For Not Signing the Declaration.* His political principles had. apparently. undergone no decisive change since 1701 when he had announced in a sermon that "whosoever did not abhor the execution of Charles I mas so ill a man that no good man could converse with him."

In other ways also he showed animus against the house of Hanover. but his only punishment was his removal from the post of lord almoner to the king.

The bishop was esteemed by Jonathan Swift, Sir Richard Steele, William Whiston and other famous men of his day, while Samuel Johnson declared his sermons to be of the highest class.

Smalridge died on Sept. 27, 1719, and was buried in Christ Church cathedral. In 1726 his widow Mary collected and published his *Sixty Sermons, Preached on Several Occasions, Published From the Originals;* other editions appeared in 1827, 1832, 1853 and 1862. Selections from correspondence between Smalridge and Arthur Charlett, Walter Gough and several other figures of that time may be found in Nichol's *Literary Illustrations.* In Christ Church hall, Oxford, there was placed a portrait of Smalridge, painted by Sir Godfrey Kneller. Smalridge left two daughters and one son, Philip, who, like his father, was educated at Westminster and then at Christ Church.

SMALTITE, a mineral with the general composition cobalt nickel arsenide, $(Co,Ni)As_3$. In smaltite, cobalt exceeds nickel; while in chloanthite, nickel predominates. Both smaltite and chloanthite are deficient in arsenic, with the actual composition about $(Co,Ni)As_{2-2.5}$. Crystals are usually zoned. with the outer portion richer in arsenic. Considerable iron may be present.

Cubic and octahedral crystals are rare; smaltite is usually found as compact or granular masses. The colour is tin white to silver gray with a bright metallic lustre. The hardness is j.j to 6 and the specific gravity 6.5. It occurs with other cobalt and nickel minerals, associated with ores of silver and copper at Cobalt, Ont. (L. S. RL.)

SMART, CHRISTOPHER (1722–1771), English poet, mas born at Shipbourne, Kent, on April 11, 1722. His father was steward for the Kentish estates of William, Viscount Vane, younger son of Lord Barnard of Raby castle, Durham. Christopher Smart went to school at Maidstone and at the Durham grammar school of Durham. He spent part of his vacations at Raby castle, and his gifts as a poet gained him the patronage of the Vane family. Henrietta, duchess of Cleveland, allowed him a pension of £40 which was paid until her death in 1742. At Cambridge. where he was entered at Pembroke college in 1739, he spent much of his time in taverns and got badly into debt, but in spite of his irregularities he became fellow of his college, praelector in philosophy and keeper of the common chest in 1745. In Nov. 1747 he was compelled to remain in his rooms for fear of creditors. About 1752 he left Cambridge for London, though he kept his name on the college books. He wrote in London under the pseudonyms of "Mary Midnight" rind "Pentweazle."

Smart had a hand in many journalistic undertakings, and he completed a prose translation of Horace. Some criticisms made by "Sir" John Hill on his *Poems on Several Occasions* (1752) provoked his satire of the *Hilliad* (1753), noteworthy as providing the model for the *Rolliad.*

In 1751 Smart had shown symptoms of mental aberration. which developed into religious mania. and between 1; j6 and 1758 he was in an asylum. where he was visited by Samuel Johnson. who thought him sane. The poem written by him in the asylum. "A Song to David." is his only famous work, and has been compared by some critics to the work of Blake. After his release Smart produced other religious poems, but none of them shows the same inspiration. For some time before his death. which took place on May 21, 1771, he lived in the rules of King's Bench. and was supported by small subscriptions raised by Burney and other friends.

From the *Poems of the Late Christopher Smart* (1791) "A Song to David" (pr. 1763) was excluded. It was reprinted in 1819, and in an abridged form is included in T. H. Ward's *English Poets,* vol. iii; it was reprinted in 1895, and in 1901 with an introduction by R. A. Streatfeild.

SMART, SIR GEORGE THOMAS (1776–1867), English musician. was born in London. his father being a music seller. He was a choirboy at the Chapel Royal, and became violinist. organist, teacher of singing and conductor. From 1811 onward Sir George Smart was one of the chief musical leaders and organizers in England. conducting at the Philharmonic. Covent Garden. the provincial festivals. etc.. and in 1838 he was appointed composer to the Chapel Royal. He mas a master of the Handelian traditions. was personally acquainted with Beethoven and a close friend of Carl Maria von Weber. who died in his house. Much of his church music is still heard in the churches. He died in London on Feb. 23. 1867.

SMART, JOHN (*c.* 1742–1811), one of the foremost English miniature painters. the place and exact date of whose birth are not known. In his youth he won a series of prizes from the Society of Arts. He exhibited with the Society of Artists from 1762 and became president of that body in 1778. Smart spent ten successful years in India from 178j till 1795, becoming miniature painter to the nawab of Arcot. After his return to England he exhibited fairly regularly with the Royal Academy. Smart's first wife left him for William Pars. the water-colour painter, and he married once, and possibly twice. again. He died in London on Nay 1. 1811.

In an age prolific in miniature painters of the front rank. Smart's achievement is regarded as highly as that of his rival and contemporary. Richard Cosway. He employed entirely different methods. His brushwork was meticulous and his finish highly wrought; he used body colour to render the rich costume of the late 18th century. Though not acute analyses of character, his miniatures have great finesse and charm. Throughout his life Smart made a practice of dating as well as signing his works; on those he painted in India he added the letter I to his signature J. S.

See B. S. Long. *British Miniaturists* (1929); A. Jaffé, *The Art Quarterly,* vol. xvii, pp. 242–254 (1954). (G. Rs.)

SMEATON, JOHN (1724–1792), English civil engineer, builder of Eddystone lighthouse and founder of the civil engineering profession in Britain, was born at Austhorpe, Yorkshire. on June 8, 1724. He learned mathematical instrument making in London and, through contributing scientific papers to the Royal society, was elected a fellow in 1753. A tour of the Low Countries during 1755, studying canals. harbours and mills, was the turning point in his career. In 1756–59 he built the third lighthouse on Eddystone reef. opposite Plymouth, with dovetailed blocks of portland stone, and this established his reputation. In 1882 the upper portion was re-erected on Plymouth Hoe as a memorial. He also constructed the Forth and Clyde canal, built arched bridges at Perth, Banff and Coldstream, and completed the harbour at Ramsgate.

In 1754 Smeaton introduced cast-iron shafts and gearing into wind- and water mills, and received the Royal society's Copley medal for *An Experimental Enquiry Concerning the Natural Powers of Water and Wind to Turn Mills* (1759). He constructed a boring mill at Carron ironworks and, due to his improved designs, the Newcomen engine achieved its maximum performance. He designed large atmospheric pumping engines for Long Benton colliery, Northumberland, Chacewater mine. Cornwall, and Kronstadt docks, Russia. Smeaton was an original member of the Society of Engineers, founded in 1771, and in 1791 wrote his *Narrative of the Building . . . of the Eddystone Lighthouse.* He died at Austhorpe on Oct. 28, 1792, and was buried in Whitkirk parish church.

BIBLIOGRAPHY.—S. Smiles, *Lives of the Engineers,* vol. ii, rev. ed. (1874); Smeaton's *Reports,* 3 vol. (1812), *Papers* (1814); *John Smeaton's Diary of His Journey to the Low Countries, 1755,* with introduction by Arthur Titley (1938). (AR. S.)

SMEDEREVO (Ger. SEMENDRIA), an important commercial town, and capital of the Podunavski district of Serbia, Yugos. Pop (1953) 18.328. It is a walled town on the Danube. There is a good quay. and grapes, white wine. oils, livestock, pigs and cereals are exported. The only manufacture is that of railway trucks.

Smederevo is believed to stand on the site of the Roman settlement *Mons aureus,* and there is a tradition that its famous vineyards were planted by the Roman emperor Probus (A.D 276–282). In the 15th century when the Serbian prince George Brankovich became lord of Tokay in Hungary, he planted vines from Smederevo on his estates there, and from these came the famous white wine of Tokay. Close to the river is a medieval castle, with 19 square toners, built by George Brankovich in 1430, with a large cross built in, in red bricks. Under the surface of the walls are representations of three heads showing only the eyes, nose and mouth, and probably connected with the sacrificial practice of entombing individuals during the building. Smederevo was the capital of Serbia from 1430, when Belgrade was captured by the Turks, to 1459. Kara George, the leader of the first Serbo-Turkish rising, was murdered there in 1817, and the town was bombarded in World War I. It was occupied by German troops in World War II.

SMELL AND TASTE. Food flavour is man's commonest and most familiar smell and taste experience. Flavour, commonly misnamed "taste," is a composite of pressure, touch, temperature. common chemical sensitivity and smell, as well as taste. Sight and sound also contribute to the perception that delights the gourmet's senses. The smell component in flavour can be demonstrated by pinching shut the nostrils and trying to distinguish foods by taste alone: a slice of raw potato becomes indistinguishable from an apple; cinnamon yields only mild sweetness (a true taste) in addition to texture. Perfumes, on the other hand, excite primarily the sense of smell, although some may have slight taste or tactual components.

It is not possible to predict with certainty the sensation that an entirely new synthetic chemical will arouse until it has been tasted or smelled. The exact chemistry of odour and taste is still unknown in spite of the many empirical relations between chemical constitution and odour or taste that have been uncovered.

The common chemical sense, often classed with taste and smell as the "chemical senses," depends upon undifferentiated free nerve endings in the moist mucous membranes of the mouth, upper respiratory passages or other orifices of the body. Typical of the common chemical sense is the mild pain of pepper or other irritant spices, whereas taste is characterized by sensation qualities of salty, sour, bitter or sweet, and odour by foul, fruity, burnt, fragrant, etc. The common chemical sense, taste and smell form a hierarchy, respectively, from the simple to the more complex in structure, from the least to the most sensitive and from the least to the most differentiated in quality of sensation. In lower forms, especially water-inhabiting organisms, the distinctiveness of the three senses may not always be obvious because irritant, odour and taste stimuli are all transported in the fluid medium; on land, odours or irritating vapours are largely air-borne, whereas taste stimuli are in solution and stimulate by direct contact between solution and taste bud. In fishes the presence of distinct olfactory pits or of taste buds on barbels and other portions of the external body surface aid in identifying the senses.

No special account of the common chemical sensitivity will be given here. Taste and smell, having a relatively simpler morphology than vision or hearing, are often classified as lower senses Furthermore, the chemical senses have particular significance for the behaviour of lower organisms in the selection and acceptance of foods, the avoidance of noxious agents and the detection and attraction of sexual mates. Civilized man, more dependent upon his higher senses, finds in his lower senses the flavour and spice of life.

SENSE OF TASTE

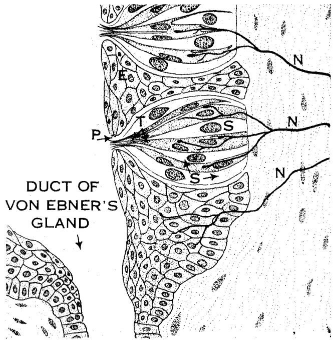

FIG. 1.— SCHEMATIC MICROSCOPIC SECTION OF TASTE BUDS OF CIRCUMVALLATE PAPILLA

(P) Gustatory pore with protruding filaments; (T) taste cells; (S) sustentacular cells; (N) nerve fibres; (E) stratified epithelium

The sense organs of taste are the taste buds, goblet-shaped clusters of cells that open by a small pore to the mouth cavity. The buds contain two types of cell, the thicker supporting cells and the more slender gustatory cells with a fine terminal hair projecting into the taste pore (fig. 1). In man and other mammals, taste buds are located primarily in the fungiform, foliate and circumvallate papillae of the tongue (*q.v.*) or in adjacent structures of the throat. Sensory nerve fibres entering the taste buds entuine about and make contact with one or more taste cells. When the nerves to the tongue are cut. these fibres and the whole taste bud degenerate. When the nerve fibres regenerate, the taste buds are reconstituted from the surrounding cells of the epithelium.

In invertebrates, the clearest distinction between taste and smell can be made in insects, although there is ample evidence that worms. gastropods and other forms reject bitter substances but accept sugars added to the substrate upon which they are feeding. In insects, contact chemoreceptors are located on certain hairs of the legs and mouth parts. Localized stimulation of these hairs by small droplets of sugar solution produce a definite proboscis extension. This response may be inhibited by adding salt to the sugar solution. In flies, the labellar hairs contain three nerve fibres, only two of which appear to extend to the chemoreceptive tip region. It is possible to record electrical discharges in these nerve fibres folloning chemical stimulation. Similar receptors may be found occasionally on the proboscis or antennae, but the latter are more commonly major olfactory organs.

Innervation. — There is no single sensory nerve for taste in vertebrates In man. the anterior tno-thirds of the tongue is supplied by the lingual nerve. the back of the tongue by the glossopharyngeal nerve and the throat and larynx by certain branches of the vagus nerve, all of which subserve touch, temperature and pain sensitivity to the tongue as well as taste. The taste fibres of the anterior tongue branch from the lingual nerve to form a slender nerve, the chorda tympani, which traverses the eardrum en route to the brain stem. When the chorda tympani is cut or damaged. as in the removal of the eardrum. taste buds disappear and taste sensitivity is lost on the anterior two-thirds of the tongue on the same side. The taste fibres from all the sensory nerves from the mouth run together in the tractus solitarius and its associated nucleus of the medulla oblongata. At this and all levels of the brain. taste fibres seem to be closely associated with touch and temperature sensory neurons for the tongue. From the medulla the fibres ascend by a pathway, not entirely delineated. to a small cluster of cells in the medial part of the sensory nucleus of the thalamus. From here fibres proceed to the anterior cerebral cortex where the taste fibres, still in close association with those for touch and temperature, project to the sensory receiving area for the mouth. No one part of the cerebrum appears to be exclusively devoted to taste.

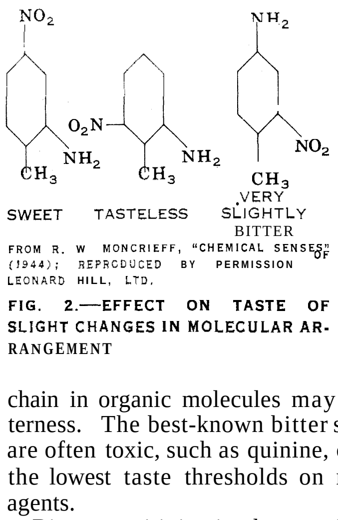
There is no simple relation between chemical composition and taste quality except in the case of acids. The taste qualities of inorganic salts are complex, only sodium chloride yielding the purely saline taste. Sweet and bitter tastes occur in many different chemical classes.

The tongue surface is not entirely sensitive. The middle surface is insensitive to taste, but salt sensitivity occurs around all edges, sweet sensitivity primarily at the tip, sour at the sides and bitter at the back. For many years it was believed that there were only four basic types of taste receptors, one each for salt, sour, bitter and sweet. Electrophysiological recording of sensory impulses in the taste nerves shows that this simple schema does not hold, at least in animal preparations. Individual nerve fibres from the tongue possess mixed sensitivity, in many cases responding to more than one of the basic taste stimuli. as acid plus salt, acid plus salt plus sugar. etc. Records from the individual taste cells show the same multiple sensitivity. The taste buds, therefore, appear to possess different clusters or patterns of sensit'vity. In some species, certain taste receptors may be activate by water but inhibited by sodium chloride. Thus, the taste impulse pattern to the brain may be increased or decreased by taste stimulation. The perception of taste depends upon the interpretation of such impulse patterns by the brain.

Sour. — The hydrogen ions of acids are largely responsible for the sour taste, and sourness increases with increase in hydrogen ion concentration. but this factor alone does not determine sourness. Weak organic acids such as the acetic acid of vinegar are more sour than would be predicted from hydrogen ion concentration alone.

Salt. — Although the salty taste is often associated with soluble salts, most chemical salts, except sodium chloride, have complex tastes such as bitter-salt, sour-salt, etc. Salts of low molecular weight are predominantly salty while those of higher molecular weight are bitter. The salts of heavy metals such as mercury have a metallic taste, although some of the salts of lead (especially lead acetate) and beryllium are sweet. Both the anion and cation contribute to taste quality and to stimulating efficiency. In man the following series for degree of saltiness, in decreasing order, is known: ammonium, potassium, calcium, sodium, lithium, magnesium salts. The seriation varies with species.

Sweet. — Except in the case of certain inorganic salts of lead or beryllium, the sweet taste is associated largely with organic compounds such as the alcohols, glycols, sugars and sugar derivatives. The complex relation between chemical structure and sweet taste is not readily explained by present-day systemizations. This is particularly apparent for synthetic sweeteners such as saccharin and Dulcin. Sensitivity for these synthetic substances is especially remarkable; at threshold saccharin is 700 times more dilute than cane sugar. Furthermore, the spatial arrangement of atoms in the taste molecule is strikingly important, so that slight changes in arrangement within a sweet molecule mill make it tasteless (fig. 2).



FROM R. W MONCRIEFF, "CHEMICAL SENSES" (1944); REPRODUCED BY PERMISSION OF LEONARD HILL, LTD.

FIG. 2.—EFFECT ON TASTE OF SLIGHT CHANGES IN MOLECULAR ARRANGEMENT

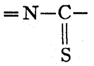
Bitter. — Bitter, like sweet, is elicited by many chemical classes and is often found in association with sweet and other taste qualities. An increase in molecular weight of inorganic salts or an increase in length of the carbon chain in organic molecules may be associated with increased bitterness. The best-known bitter substances are the alkaloids, which are often toxic, such as quinine, caffeine! strychnine: etc. Some of the lowest taste thresholds on record are found in this class of agents.

Bitter sensitivity is characterized by the unique defect known as taste blindness, an inability to detect such chemicals as PTC (phenyl thio carbamide) or the other substances with the chemical grouping

$$=N-\underset{\underset{S}{\|}}{C}-$$

in the molecule. Taste blindness appears to be genetically determined, a Mendelian recessive character such that about one-third of Caucasians cannot taste PTC, but this proportion varies in the different races of man. Evidence for taste blindness has been observed only in primates, human and subhuman, and not in lower forms.

The gene responsible for the defect apparently appeared at a relatively late stage of evolution. Taste blindness for



is not correlated with insensitivity to other bitter stimuli. There exists no definitive explanation for this defect.

Factors Affecting Taste Sensitivity. — It has long been known that fluids of extreme temperature, especially extreme cold, may cause temporary taste insensitivity. The optimum range for taste in general appears to be around or slightly below body temperature. The effect of temperature is often difficult to assess because the temperature of both the taste solution in the mouth and the mouth itself change. In more exact studies the tongue and mouth are first adapted to the temperature of the taste solution. In this case, sugar sensitivity increases with temperature rise, salt and quinine sensitivity decrease and acid sensitivity is relatively unchanged. It is quite clear that sense of taste does not behave like a chemical system with a simple temperature coefficient; otheraise all taste sensitivity should improve at the higher temperatures. Taste adaptation (*i.e.,* partial or complete disappearance of taste) may occur if a solution is held in the mouth for a period of time. In some cases, cross adaptation will occur; that is, adaptation by acid may adapt the sour taste for all other acids. Adaptation also may be followed by contrast; *e.g.,* distilled water tastes sweet following exposure to weak acid. Taste masking by mixtures of other tastes is well known from everyday experience. The bitterness of tea and coffee or the sourness of lemonade are masked or suppressed by sugar or saccharin.

The difference threshold or percentage increase in taste stimulus required for a just noticeable difference in intensity is approximately one-fifth, or a 20% increase in concentration. At very weak intensities, however, sensitivity is poorer, so that as much as a 100% increase in concentration may be required for a detectable difference.

Food Choice. — The sense of taste is intimately concerned with eating or the rejection of noxious agents. One of the earliest reflex responses of the infant, that of sucking, can be controlled by taste stimuli. Sweet solutions are sucked more readily than is plain water; bitter, salty or sour stimuli will stop the sucking reflex. Palatability and acceptability of food are due in good measure to taste. In children and lower organisms many food preferences or rejections appear to be directly related to taste. In the case of invertebrates, the very specific feeding reaction, proboscis extension, is so automatic a response that it is widely used as an index of taste stimulation. If a fly is fixed to a stylus by wax it can be held relatively immobile so that different parts of the mouth, legs and body may be stimulated by a drop of solution. Sugar solution will cause proboscis extension when applied to the legs or mouth parts. A fly that has been starved will show a positive response to a weak sugar solution that ordinarily would not affect a satiated one. Addition of salt or acid to the solution inhibits this response.

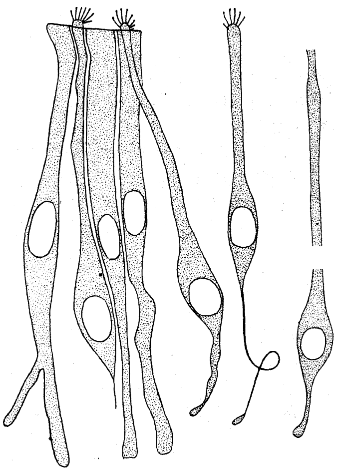
In lower mammals such as the rat, dramatic examples of beneficial self-selection behaviour can be cited. The laboratory rat, when given a free choice of pure carbohydrates, proteins, vitamins and minerals in separate containers, will show a consistent pattern of choice that may be modified by certain physiological stresses and strains. A rat rendered salt-deficient by removal of the adrenal glands, for example, will increase its intake of sodium chloride sufficiently to maintain health and growth; normally, adrenalectomy is fatal in the absence of salt-replacement therapy. Case histories of similar effects have been reported in human beings, one dramatic case being that of a child with adrenal pathology who kept himself alive by satisfying an intense salt craving. In adult man such responses may be less automatic. Adult eating habits are very much influenced by past experience and may even run counter to those most necessary to physiological well-being. Food habits and food fads, cultural conditioning, social usage and other complex psychological factors play a significant role in eating behaviour.

Toxic substances are often rejected by taste alone because of their bitterness, but not all toxic agents have a taste. The rat poison alpha-naphthyl thiourea (ANTU) was developed from a relatively insoluble and therefore tasteless form of highly toxic chemical; the soluble forms had all been rejected by the animal, but not the insoluble ANTU.

Unfortunately, not all toxic agents have the bitter taste. Lead salts are toxic but sweet. Lead acetate, sometimes called sugar of lead, was once used as a sweetening agent with disastrous results before its true action was appreciated. Other synthetic sweeteners or palatable taste stimuli may have toxic effects, so that taste alone is not a sure guide to safety.

SENSE OF SMELL

In mammals the olfactory receptors are located in the upper part of the nasal cavity. (See also OLFACTORY SYSTEM) In man, the yellow pigmented olfactory membrane measures about 2.5 sq.cm. in each nasal cavity. The olfactory sense organ is a long thin cell ending in several delicate hairs that project into and through the mucus covering the nasal epithelium (fig. 3). Electron microscope photographs show from 6 to 12 olfactory hairs per cell. The central end narrows to a fine nerve fibre which, in company with many other such fibres, enters the olfactory bulb of the brain through a fine channel in the bony roof of the nasal cavity. The olfactory area of the rabbit contains about 100,000,000 receptor cells, uhich, with their olfactory hairs, provide a total surface area equal to that of the total skin surface of the young rabbit.



FROM G H PARKER, "SMELL, TASTE AND ALLIED SENSES REPRODUCED BY PERMISSION OF J B. LIPPINCOTT CO

FIG. 3 — SEPARATED SECTION OF OLFACTORY MUCOSA SHOWING SENSE CELLS WITH OLFACTORY HAIRS AND SUPPORTING CELLS

Nerve endings of the trigeminal nerve fibres subserving common chemical sensitivity are widely distributed throughout the nasal cavity and olfactory region. Relatively mild odorants such as orange oil as well as the more obvious irritants such as ammonia stimulate such free nerve endings as well as the olfactory endings.

Odorous molecules may be carried to the olfactory region by slight eddy currents during quiet respiration, but vigorous sniffing produces a surge into the olfactory region. Odour sensitivity therefore may be impaired by blocking the nasal passages mechanically, as when membranes are congested by infection.

It is generally agreed that in insects the antennae are the principal olfactory sites, but such other appendages as the maxillary and labial palpi of the head may also bear olfactory endings (fig. 4). The olfactory sensilla of the honeybee appear to be the pore plates (fig. 5), but in some beetles, housefly larvae and *Drosophila* the sensilla are peglike hair derivatives. The cuticle of such pegs is less than one micron in thickness and the majority are innervated by a group of bipolar sensory cells. The stimulus, therefore, is separated from the neural elements by a nonliving cuticle with no detectable mucous or other secretion. This observation is often cited as evidence that odour molecules stimulate sense cells directly without prior solution in a liquid covering. Other authorities believe that in vertebrates olfactory stimulation occurs only after the odour molecule is dissolved in the mucus covering the olfactory epithelium. In spite of the obvious biological gap between man and the invertebrates, a number of studies seem to show that odour sensitivity of man and insect are very similar. Evidence from insect studies might be directly applicable to man.

In vertebrates the olfactory nerve fibres enter the olfactory bulb to end in a series of intricate basket-like terminations or clusters called glomeruli. Each glomerulus receives impulses from about 26,000 receptors and sends them on through 24 mitral cells and 68 tufted cells, showing a high degree of neural convergence. Most mitral-cell axons pass into the lateral olfactory tract en route to the higher olfactory centres at the base of the brain. Most tufted cells cross over to the olfactory bulb of the opposite side. Electrical activity in the primary olfactory nerves, the olfactory bulb, lateral olfactory tracts and pyriform lobe of the brain have been recorded following odour stimulation. It is known that when the olfactory bulb itself is removed by surgery, the ability to discriminate odours is lost, but the details of the higher neural centres for olfaction are still unclear.

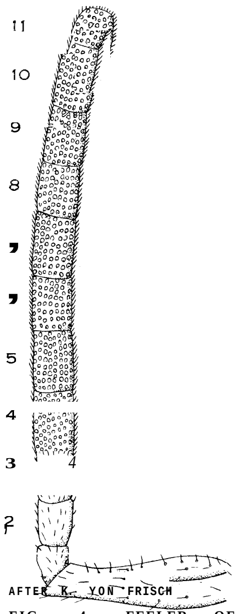


FIG. 4.— FEELER OF WORKER BEE: JOINTS 4 THROUGH 11 BEAR OLFACTORY ORGANS

Olfactory Qualities. — The vocabulary of odour is rich with words attempting to describe the great variety of olfactory qualities. Most odour names. however, are object names, and most attempts at classification of odour are largely psychological. One of the best known is that of H. Henning, who tested over 400 different scents on human observers. On the basis of the apparent similarities of perceived odour quality or confusions in naming, he concluded that there were six main odour qualities: fruity, flowery, resinous, spicy, foul and burnt. Their interrelations could be systematized by a diagram, the smell prism (fig. 6), which schematized only sensation qualities, not odorants or even the basic odour receptors.

Studies utilizing electrophysiological methods have been very revealing of the sensory mechanism underlying the different odour qualities. Electrical activity in the olfactory bulb can be detected readily by fine insulated wire electrodes inserted into the bulb itself. Two forms of activity have been observed: (1) a wave-like response that may be recorded from the surface of the bulb and (2) impulse activity that reflects discharges in the mitral cells following stimulation. Those portions of the bulb toward the anterior or oral region in the rabbit were found to be more sensitive to water-soluble substances, whereas the more posterior or aboral parts of the olfactory bulb were more sensitive to fat-soluble substances. In addition, when very fine electrodes mere used so that one unit could be identified, different mitral cells were found to be sensitive to different groups of chemicals. However, evidence for the existence of only a few primary receptors did not emerge from such studies; a variety of different combinations of sensitivity were found. Recordings from the primary receptor nerve fibres similarly reveal different patterns of sensitivity. Electrical recording of this type also shows that olfactory sensitivity can be enhanced by discharges in the sympathetic nerves to the nasal mucosa instigated by a painful stimulus or a pinch on the foot of the experimental animal. This appears to be a reflex to improve the detection of dangerous odours in the natural environment.

Odorous Substances. — To be odorous, a substance must be slightly volatile so that the molecules can be given off and carried into the nostrils by air currents. Fat and water solubility have also been thought to be necessary, and chemicals that possess both water and fat solubility are often strong odorants: but manv water- and fat-soluble substances are inodorous. The unique chemical or physical property that causes odour remains to be defined.

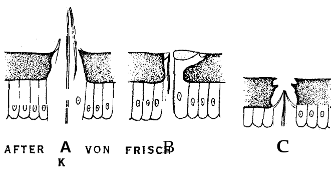

FIG. 5.—CROSS SECTION OF OLFACTORY ORGANS ON FEELERS OF INSECTS (A) OLFACTORY PEG. (B) PORE PLATE. (C) PIT PEG

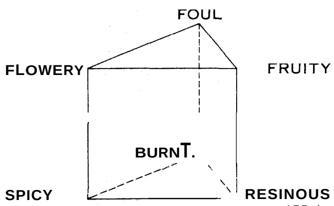
Of the elements, only seven are odorous: fluorine, chlorine, bromine, iodine, oxygen as ozone, phosphorus and arsenic. Most odorous substances are organic compounds in which both the arrangement and structure of the molecule as well as the presence of particular chemical groups within the molecule influence odour. Stereoisomers (*i.e.*, different arrangements of the same molecular components) may have different odours. On the other hand, a series of benzene derivatives all have a similar odour. It is of historic interest that the first natural compounds with the benzenoid structure were found in association with pleasant-smelling substances such as oil of wintergreen or oil of anise and so were labeled aromatic to distinguish them from fatty substances.

The natural scent of flowers and roots depends upon the presence of minute quantities of highly odorous essential oils. Although the major odour constituents can be identified by chemical analysis, naturally occurring essences are so complex that their odours can be duplicated only by including small amounts of the natural product in the synthetic formulation.

Odour Sensitivity. — In spite of the relative inaccessibility of the olfactory end organs, odour stimuli can be detected at extremely low concentrations. Olfaction is said to be 10,000 times more sensitive than taste. A threshold value for such a well-known odorant as ethyl mercaptan has been cited in the range of 4×10^{-8} mg. per litre of air. A just noticeable difference in odour intensity may be apparent by a 20% increase in odorant strength, but at low concentrations as much as 100% increase in concentration may be required. Temperature influences the strength of an odour by affecting the volatility and hence the emission of odorous particles from the source Humidity also affects odour for the same reasons. Following a spoor or odour trail is easier during high humidity since evaporation and dissipation of the odour are retarded. In perfumes, fixatives having the prime function of retarding evaporation are used to fix the more volatile constituents of the blend. The temporary anosmia, or absence of sense of smell, following nasal infection may be complete or partial; in the latter case only the odours of certain substances are affected. Paranosmia, or change in perceived odour quality, also may occur in some instances. Changes in sensitivity are said to occur during the menstrual cycle, particularly with certain odorants related to steroids and sex hormones. Olfactory acuity also is said to become more acute during hunger.



AFTER H. HENNING, S. S. STEVENS (ED), "HANDBOOK OF EXPERIMENTAL PSYCHOLOGY" (1951), REPRODUCED BY PERMISSION OF JOHN WILEY & SONS. INC.

FIG. 6 — SMELL PRISM (SEE TEXT)

Adaptation to odours is a striking olfactory phenomenon. The stench of the slaughterhouse or chemical laboratory ceases to be a nuisance after a few minutes have passed. Adaptation measured by the threshold rise is greater with stronger odours. Cross adaptation between different odours may take place; thus eucalyptole may be difficult to detect after adaptation by camphor but will be little affected by benzaldehyde. Adaptation long was regarded as the result of changes in the receptor, but later experiments with the electrophysiological method showed that the peripheral receptor does not seem to adapt. Rhythmic discharges continue in the olfactory bulb locg after the experimenter fails to detect the odour that is stimulating the experimental animal. Hence. it appears that olfactory adaptation may be Iocated partially in the brain, as well as in the sense organ.

Odour Blending and Flavour. — The ancient art of perfumery and the modern science of odour control attest to the realities of odour mixing and blending. When two different odours are presented at the same time they both may be readily identifiable. The more they resemble each other, the greater will be the tendency to blend, yet the trained chemist usually is able to discriminate the component notes of a successfully blended perfume. When the intensity of one odour is substantially greater than that of a second, masking often occurs. Chemical neutralization is the commonest basis for odour control. Nonchemical, purely physiological or psychological neutralization, although reported by some workers, has not been generally accepted. Odour blending and compounding is in good measure largely the art of the perfumer and is not a science.

FIG 7—OLFACTORY ORGANS OF CRUSTACEA. FIRST ANTENNA OF (LEFT) CRANGON (MALE), (RIGHT) UROLYCHUS NITIDUS (FEMALE)

The distinctive and unique flavours of food are due largely to the sense of smell. Flavour is the composite of many senses, but the aroma of roast beef and the delicate bouquet of wine are largely olfactory in origin. Flavour technology assumes an ever-increasing place in the food industry; it has become common practice to make use of flavour panels of four to eight members concerned with the detection of fine differences between a standard and a modified or experimental product. Such a panel may be asked to give a description or rating of the flavour components present or to give an over-all rating of flavour quality. With careful training and controlled psychophysical methods with adequate statistical control, such panels are found to yield highly reliable results. Their ability to detect differences is often more delicate than that achieved by physical or chemical methods. Though the exact physical basis for a particular flavour quality may be unknown, the human nose and palate can note its presence.

Such analytical panels are to be distinguished from large consumer panels used in surveys of flavour preferences or likes and dislikes. In these the emphasis is on acceptability, often a hedonic or emotional reaction to the product. Such reactions are more unstable and may vary among individuals because of idiosyncrasy or differences in experience. The strong cheese odour so palatable to the gourmet produces only revulsion in the uninitiated.

Effects on **Behaviour.**—Control of behaviour by olfactory stimuli is striking and obvious in lower animals. Recognition of friend or foe by social insects may depend upon olfactory cues: certain ants attack their own kind furiously if deprived of the sense of smell by amputation of their antennae; bees entering a strange hive are put to death because the scent of a foreign hive clings to them. In addition, bees possess a scent organ on the end of the abdomen by which they can mark by scent a newly discovered food source to guide foraging workers in the final stages of their search. The very existence of natural scents in flowers attests to the evolutionary importance of odour; insects attracted by odour to the nectar of flowers are the agents of pollination.

The effect of odours on sexual behaviour of invertebrates is legendary; a female moth was observed to attract more than 100 males during relatively brief observation periods of $6\frac{1}{2}$ hours. The remarkable difference in antennal development between the male and the female moth is shown in fig. 7. Mammals in the wild state appear to utilize their odour glands for sexual attraction. Even the domesticated laboratory rat will show a preference for the arm of a maze containing the odour of an oestrous female over one that contains the odour of a dioestrous female. That some rudiments of these effects may be found in man seems likely. The most sexually provocative perfumes have a high proportion of musk or musklike "odour notes." Genuine musk, of course, is derived from the sexual glands of the musk deer; chemically it is related to certain of the sex hormones, and the fact that odour sensitivity varies with the menstrual or ovarian cycle has been mentioned. Further study of the nature and extent of these effects in man is needed to place on a scientific basis what may be known in the folklore. The behaviour of civilized man, molded and shaped by custom and culture though it is, has many of its roots in his basic sensual appetites. *See* also SENSATION; PSYCHOPHYSICAL METHODS.

SMELLIE, WILLIAM (1697–1763), "the master of British midwifery," was born at Lanark in 1697. In 1739 he went to London. where in 1741 he began to teach midwifery by lecture-demonstrations for midwives and medical students. One reason for his success was that he attended poor women free of charge on condition that his students were allowed to watch. He thus broke the female monopoly in midwifery, and medical men (men midwives) began to be called in to attend childbirth.

Smellie invented (simultaneously with A. Levret of Paris) the "long" obstetric forceps, but his immortal contribution was his discovery and lucid description of "the mechanism of labour" (*i.e.*, the way in which the child's head adapts itself to the changes in shape and dimensions of the bony pelvic canal during birth). He retired to Lanark and died there on March 5, 1763.

Smellie's teaching was embodied in his *Treatise on the Theory and Practice of Midwifery*, 3 vol. (1752–64), and *A Set of Anatomical Tables* (1754).

BIBLIOGRAPHY.—Smellie's *Treatise*, ed. with a memoir by A. H. McClintock, New Sydenham Society, 3 vol (1876–78); J. Glaister, *Dr. William Smellie and His Contemporaries* (1894); R. W. Johnstone, *William Smellie. the Master of British Midwifery* (1952). (R. W. Jo.)

SMELT, in general, small, delicate fishes of the family Osmeridae, particularly certain species of *Osmerus*. The smelts, slender. silvery fishes, are closely related to the salmons and trouts; like the trouts, they have two dorsal fins, of which the second is small, fleshy and lacking rays; the ventral fins are attached below the first dorsal fins. They are chiefly cold-water fishes confined to the northern hemisphere. The American smelt (*Osmerus mordax)* ranges along the shores from Virginia to eastern Labrador and has become naturally landlocked in many lakes and ponds of the northeastern U.S. and Canada. They were introduced in 1912 into Crystal lake, Mich., from where they spread throughout the Great Lakes, becoming an important commercial species. Whether smelt are marine or landlocked, they come in to shore in late winter and spring and run for short distances upstream to spawn. The small, sticky eggs cluster and adhere to any object which they touch; they hatch in 8 to 30 days. The American smelt may grow to be 14 to 15 in. long, but most adults are usually smaller. The European smelt (*O. eperlanus*), ranging from Scandinavia to the English channel, is similar in appearance and habits to the American form.

Several closely related species occur in the north Pacific region. These include the rainbow herring (*Osmerus dentex*), the surf smelt (*Hypomesus pretiosus),* the Kodiak smelt (*Thaleichthys albatrossis)* and the eulachon or candlefish *(Thaleichthys pacificus*). A number of unrelated small fishes somewhat resembling osmerids externally are also called smelt in various parts of the world.

In the United States commercial fishermen take almost 11,000,000 lb. of smelts annually, and amateurs take an unknown but large additional quantity. More than 70% of the total is from the Great Lakes, a large part of the remainder from the Pacific coast, and about 1% from New England. *See* also Index references under "Smelt" in the Index volume. (L A. WD.)

SMELTING: *see* METALLURGY.

SMERDIS, the younger son of Cyrus the Great, who, according to the historian Ctesias, was appointed governor of the eastern provinces by his father on his deathbed. Before Smerdis' elder brother Cambyses set out to conquer Egypt, he secretly caused his brother to be murdered, being afraid that Smerdis might attempt a rebellion during his absence. His death was not known to the people, and so in the spring of 522 a usurper pretended to be Smerdis and proclaimed himself king on a mountain near the Persian town Pishiyauvada. Because of the despotic rule of Cambyses and his long absence in Egypt, "the whole people, Persians, Medes and all the other nations," acknowledged the usurper, especially as he granted a remission of taxes for three years. Cambyses began to march against him, but seeing that his cause was hopeless, killed himself (but *see* further CAMBYSES). The real name of the usurper was, as Darius tells us, Gaumata, a Magian priest from Media; this name has been preserved by Justin i. 9 (from Charon of Lampsacus?), but given to his brother (called by Herodotus

Patizeithes), who is said to have been the real promoter of the intrigue; the true name of the usurper is here given as Oropastes; by Ctesias as Sphendadates.

The history of the false Smerdis is narrated by Herodotus and Ctesias according to official traditions; Cambyses before his death confessed to the murder of his brother, and in public explained the whole fraud. But, as Darius said, nobody had the courage to oppose the new king, who ruled for seven months over the whole empire. Contracts dating from his reign have been found in Babylonia.

He transferred the seat of government to Media; and there in a castle in the district of Nisaya he was surprised and killed by Darius.

In the next year, another pseudo-Smerdis, named Vahyazdata, rose against Darius in eastern Persia and met with great success. But he was finally defeated, taken prisoner and executed.

See DARIUS (I) and PERSIA: History. (ED. M.)

SMET, PIERRE JEAN DE (1801–1873), Belgian Jesuit, known throughout the western United States as the Indians' truest friend, was born at Termonde, Belg., in 1801. He sailed to the United States in 1821 to enter the Society of Jesus, and was ordained priesr in 1827 at St. Louis university in Missouri, his headquarters for life. During 40 years he crossed the Atlantic 19 times, visiting European cities and courts to beg funds, equipment and recruits for the university and Indian missions. He founded his first mission in Iowa (1838). In negotiating peace between the Sioux and Potawatomi his unusual power over Indians was revealed. For 30 years, having their complete confidence, he mas welcomed among all tribes. He helped pacify the Plains Indians in 1841; in 1863, when he went alone to avert a Sioux attack; and in 1868, when he induced Sitting Bull to negotiate. He arranged peace in the Pacific northwest in 1851 and, as United States commissioner with Gen. William S. Harney, again in 1858. Ever outspoken for Indian rights and against punitive expeditions, De Smet won ready consent to establish Christian missions and send teachers. Between sea voyages and western travels totaling 180,000 mi., he published three books in four languages. His vigorous and winning personality made friends of statesmen, pioneers, traders and soldiers. He died in St. Louis, May 23, 1873.

See Hiram Martin Chittenden and Alfred Talbot Richardson, *Life, Letters, and Travels of Father Pierre-Jean De Smet, S.J.*, 4 vol. (1905). (J. V. J.)

SMETANA, BEDRICK (FREDERICK) (1824–1884), Czech composer, was born at Litomysl, southeast Bohemia, on March 2, 1824. He showed musical talent at an early age, appearing in public as a pianist when only six years old. At the Gymnasium of Prague, where he went to school in 1839, he neglected his studies for music to such an extent that his father removed him to a similar establishment at Plzen where he could be under the eye of a relative. There he met Katharina Kollar, a young pianist who was to become his wife ten years later. Overcoming parental opposition, Smetana went to Prague in 1844 to study composition under Josef Proksch, barely managing to live on the pittance allowed him by his father. He secured a post as music master to the family of Count Leopold Thun in his second year at Prague and eventually, with the generous help of Liszt, he started a private music school. Political troubles made life in German-dominated Prague difficult and, like many other Czechs Smetana sought greater opportunities abroad, becoming in 1856 director of music at Goteborg, Swed. During his five years' stay there he composed three symphonic poems — Richard *III, Wallenstein's* Camp and Hakon Jarl — in which the influence of Liszt is very apparent. His wife found the northern climate trying and died on her way home in 1859. His second wife, whom he married a year later, grew so homesick in Goteborg that Smetana resigned his post in 1861. He was also influenced in this decision by the better prospects opening up in his country for the development of a national art, a task to which he was to devote the rest of his life.

While waiting for the production (1866) of his first patriotic opera *Branibori* v Cechach (*The Brandenburgers in Bohemia*), Smetana composed the only opera in this form that was to prove a world-wide success — Prodana Nevesta (The Bartered Bride). His next two operas, Dalibor and *Libuse,* both serious works based on legends, disappointed the public who wanted another Bartered Bride, and brought from the critics renewed charges of Wagnerism. In World War II *Libuse,* long accepted as a masterpiece, became a symbol of Czech defiance of the German occupation.

Early in 1874 symptoms of total deafness began seriously to threaten Smetana and complete deafness came suddenly in October of that year. He nevertheless managed to compose the great series of six tone poems known as Ma *Vlast* (*My* Country), two delightful light operas, Hubicka (The Kiss) and *Tajemstvi* (The Secret), and the E-minor string quartet, Z *meho zivota* (*From* My Life) in which he wryly alludes to the tragedy of his deafness. A few more works came from his pen, but in 1884 his mind began to give way. He was unable to attend the celebrations at Prague in honour of his 60th birthday and died in a mental hospital on May 12 of that year. His tomb, in the famous cemetery on the Vysehrad, became a place of pilgrimage to the Czechs. Smetana, as a great patriotic figure and as a composer, is much more highly regarded in Czechoslovakia than Dvorak. Paul Stefan writes of him as "the hero of Czech music, not only its great founder, but its guardian spirit and its great architect." (AC. R.)

SMETHWICK, a municipal, county and parliamentary borough, Staffordshire, Eng., adjoining Birmingham 33 mi. N.W. Pop. (1951) 76,407. Area 3.9 sq.mi. The borough was incorporated in 1899, became a county borough in 1907 and a parliamentary borough in 1918. It returns one member. It was mentioned in Domesday Book as "Smedewich." The historic inventions of Matthew Boulton, James Watt and William Murdock (*qq.v.*) had their origin in the Soho foundry at Handsworth which was partly removed to Smethmick in 1848. The town has since become renowned for its glass works, the manufacture of lighthouse apparatus, iron and steel, rolling stock, industrial furnaces, weighing machines, aluminum castings, cycles, nuts, bolts, screws and metal windows.

SMETONA, ANTANAS (1874–1944), Lithuanian statesman and journalist, was born on Aug. 10, 1874, in the Ukmerge district, Lithuania, and made his law studies at St. Petersburg graduating in 1902. Smetona edited the first Lithuanian daily, Vilniaus *Zinios* ("Wilno news"), and the democratic party organ, *Lietuvos* Ukininkas. In 1905 he was elected a member of the presidium of the Vilnius (Wilno) diet, which proclaimed Lithuanian autonomy. On the convocation of the tautos taryba ("national council,") during the German military occupation of the country, he was unanimously elected its president, and from 1919–20 served as first president of the newly proclaimed independent state of Lithuania. In 1921 Smetona served as chairman of the Lithuanian delegation at Riga during the negotiations on the settlement of the Latvian-Lithuanian boundary dispute. Early in 1923, when the insurrection broke out in the Memel territory against the German directorate, Smetona was requested by the Lithuanian government to compose the trouble in co-operation with the Allied representatives. In the same year he became lecturer on philosophy in the newly established university. After the military *coup d'état* at Kaunas (Nov. 16–17, 1926), Smetona was elected (Dec. 17) president of the republic. He was re-elected in 1932 and in 1938, but in 1940, when Lithuania became a part of the Soviet Union, Smetona fled. arriving in the United States in March 1941. He died in a fire at Cleveland, O., Jan. 9, 1944.

SMIBERT (SMYBERT), **JOHN** (1688–1751), British-American portrait painter, one of the first well-trained artists to work in the American colonies, was born in Edinburgh, March 24, 1688, and apprenticed to a house painter. He went to London about 1709 to study art and worked there, except for a three-year visit to Italy, until 1728. In that year he accompanied George Berkeley (*q.v.*) to Rhode Island as prospective professor of fine arts in the college which Berkeley hoped to establish in Bermuda. When this project failed, he went in 1730 to Boston, Mass., where he married and spent the rest of his life. He painted many prominent Bostonians, but had to supplement his income by keeping a shop, where he sold art supplies and prints. His collection of copies from the "old masters" was unique in colonial America and influenced the development of several later artists, notably Copiey and Allston. In 1742 he drew the plans for Faneuil hall, Boston. He died in Boston, April 2, 1751. His best-known work is "Bishop Berkeley, Family and Friends" (1729, Yale university), which contains a self-portrait of the artist. Many of his single portraits are exhibited in American museums and historical societies.

(D. H. W.)

SMILES, SAMUEL (1812–1904), Scottish author, was born at Haddington, Scot.. on Dec. 23, 1812. He was the eldest of 11 children left, on their father's death, to be supported by their mother on slender means. To her spirit and example must be attributed some of the enthusiasm for self-reliance and self-education, that was later embodied in Smiles's writings and led to their popularity and influence. He qualified in medicine at Edinburgh, but early abandoned his medical practice for journalism.

From 1838 until 1844 he edited the weekly *Leeds Times;* 1845 until 1854 he was secretary of the Leeds and Thirsk railway, and from 1854 until 1866 of the South Eastern railway. At Leeds he came in contact with George Stephenson, whose *Life* by him, published in 1857, passed through five editions in its first year and was the precursor of a long series of biographies of leaders in the world of industry. In 1859 had appeared his most successful book, *Self-Help.*

The book's success suggested others of similar purpose, *Character* (1871), *Thrift* (1875), *Duty* (1880).

Smiles died in Kensington on April 16, 1904.

SMILLIE, the name of a family of U.S. painters, engravers and etchers.

JAMES SMILLIE (1807–1885), engraver, was born in Edinburgh, Scot., on Nov. 23, 1807, and emigrated to New York in 1829. He was a landscape line engraver of some distinction, the best known of his numerous works being a series of large plates after Thomas Cole's "The Voyage of Life." After 1861 he devoted his time to the engraving of bank notes. He died on Dec. 4, 1885.

JAMES DAVID SMILLIE (1833–1909), his eldest son, an engraver, etcher and painter, was born on Jan. 16, 1833, in New York city. He studied with his father and at the National Academy of Design. His work includes engraved steel vignettes for bank notes and some illustrations, notably F. O. C. Darley's pictures for Dickens' and Cooper's novels. He was elected an associate of the National academy in 1865—the year after he first began painting—and an academician in 1876, and was a founder (1866) of the American Water Color society and of the New York Etching club. Smillie's most significant works are his etchings, dry points and aquatints, which show complete technical mastery. He died on Sept. 14, 1909.

GEORGE HENRY SMILLIE (1840–1921), younger son of James Smillie, was a landscape painter. Like his brother, he first studied with his father; later he was a pupil of James MacDougal Hart. He, too, was a member of the National Academy of Design and of the American Water Color society. Smillie's best-known work probably is the "Lake in the Woods," first shown at the National academy in 1872. He died Nov. 10, 1921.

SMITH, ADAM (1723–1790), Scottish political economist and philosopher, whose book *The Wealth of Nations* exerted the greatest influence on subsequent economic and political theory and practice, was the son of the comptroller of the customs at Kirkcaldy. Fife, Scot. The exact date of his birth is unknown, but he was baptized at Kirkcaldy on June 5, 1723, his father having died some six months previously. In 1737 he proceeded to Glasgow university, studying moral philosophy under "the never-to-be-forgotten" Francis Hutcheson (as Smith called him). In 1740 he entered Balliol college, Oxford, but as William Robert Scott has said, "the Oxford of his time gave little if any help towards what was to be his lifework," and he relinquished his exhibition in 1746. In 1748 he began delivering public lectures in Edinburgh under the patronage of Lord Kames. Some of these dealt with rhetoric and belles-lettres, but later he took up the subject of "the progress of opulence," and it was then, in his middle or late 20s, that he first expounded the economic philosophy of "the obvious and simple system of natural liberty" which he was later to proclaim to the world in his *Inquiry into the Nature and Causes of the Wealth of Nations.* About 1750 he met David Hume, who became one of the closest of his many friends.

In 1751 Smith was appointed professor of logic at Glasgow university, transferring in 1752 to the chair of moral philosophy. His lectures covered the field of ethics, rhetoric, jurisprudence and political economy. or "police and revenue." In 1759 he published his *Theory of Moral Sentiments,* embodying some of his Glasgow lectures. This work, which established Smith's reputation in his own day, is concerned with the explanation of moral approval and disapproval. His capacity for fluent, persuasive, if rather rhetorical argument is much in evidence. He bases his explanation, not as the third Lord Shaftesbury and Hutcheson had done, on a special "moral sense," nor, like Hume, to any decisive extent on utility. but on sympathy. There has been considerable controversy as to how far there is contradiction or contrast between Smith's emphasis in the *Moral Sentiments* on sympathy as a fundamental human motive, and, on the other hand, the key role of self-interest in *The Wealth of Nations.* In the former he seems to put more emphasis on the general harmony of human motives and activities under a beneficent Providence, while in the latter, in spite of the general theme of "the invisible hand" promoting the harmony of interests, Smith finds many more occasions for pointing out cases of conflict and of the narrow selfishness of human motives.

Smith now began to give more attention to jurisprudence and political economy in his lectures and less to his theories of morals. An impression can be obtained as to the development of his ideas on political economy from the notes of his lectures taken down by a student in about 1763 which were later edited by E. Cannan (*Lectures on Justice, Police, Revenue and Arms,* 1896), and from what Scott, its discoverer and publisher, describes as "An Early Draft of Part of *The Wealth of Nations,*" which he dates about 1763.

At the end of 1763 Smith obtained a lucrative post as tutor to the young duke of Buccleuch and resigned his professorship. From 1764–66 he traveled with his pupil, mostly in France, where he came to know such intellectual leaders as Turgot, D'Alembert, André Morellet, Helvétius and, in particular, François Quesnay, the head of the Physiocratic school (*q.v.*) whose work he much respected. On returning home to Kirkcaldy he devoted much of the next ten years to his magnum opus, which appeared in 1776. In 1778 he was appointed to a comfortable post as commissioner of customs in Scotland and went to live with his mother in Edinburgh. He died there on July 17, 1790, after a painful illness. He had apparently devoted a considerable part of his income to numerous secret acts of charity.

Shortly before his death Smith had nearly all his manuscripts destroyed. In his last years he seems to have been planning two major treatises, one on the theory and history of law and one on the sciences and arts. The posthumously published *Essays on Philosoplzical Subjects* (1795) probably contain parts of what would have been the latter treatise.

The Wealth of Nations — It is on *The Wealth of Nations* that Smith's renown securely rests. This work, in the first place, with those of Sir William Petty, Richard Cantillon, Quesnay and Turgot, did most to create the subject of political economy and develop it into an autonomous systematic discipline; and secondly, in the western world, it is the most influential book on the subject ever published. In the plan of Smith's lifework, however, it seems that *The Wealth of Nations* had represented only one section of a comprehensive system of moral or social philosophy, in which he had intended to survey and explain the progress of society in all its aspects.

Controversial views have been expressed as to the extent of Smith's originality in *The Wealth of Nations.* However. it seems justifiable to regard him neither as the original and almost unique creator or founder of political economy, nor, on the other hand, as a completely unoriginal systematizer, deeply indebted in particular to Turgot and Quesnay. A survey of the influences on, or ingredients of. Smith's work would almost amount to a history of the economic thought of the century or more before his time. In his general philosophical approach Smith continued the tradition of the "natural law" school of Hugo Grotius and Samuel von

Pufendorf, and in the broad layout of his ideas started from his Glasgow predecessors Gershom Carmichael and, above all, Francis Hutcheson. Hume must have helped in strengthening and developing his liberal ideas, and Montesquieu his historical approach. His English predecessors, Petty, John Locke, Bernard Mandeville, Joseph Harris and Sir James Steuart, must also have been of some help.

The Wealth of Nations is a work of much wider sweep than its 19th-century successors, much wider even than *The Principles of Political Economy* by John Stuart Mill. Above all, it is marvelously rich in learning about earlier periods as well as acute in its observation of the contemporary scene. It is also a great work of political philosophy, most eloquently and persuasively delivered. As regards the economic analysis and theorizing, this provides a fairly loose and slender thread, not usually at all rigorously worked out and occurring mostly in the first two books. Nevertheless, *The Wealth of Nations,* rambling and prolix though it often is. did systematize its subject, with enormous gains to its public influence. Its five books are surveyed below:

Book I: The Division of Labour, Value and Distribution.— "The annual labour of every nation is the fund which originally supplies it with all the necessaries and conveniences of life" is Smith's opening sentence, and it enunciates, with its primary emphasis on the "real" productivity of labour, one of the leading themes of the work. Increasing the productivity of labour requires, above all, its specialization or "division," on which Smith places extreme emphasis as the key to economic progress. The division of labour is limited by the extent of the market, but, as exchanges multiply and ramify, money as a medium of exchange is required, and there arise the problems of the values and prices of goods and services. In these opening five chapters Smith pursues a now well-worn sequence of ideas, than which there is no more lucid or logical way of leading into the central problems of economics or social economy.

Smith begins his treatment of value with the distinction between value in exchange and value in use, or "utility," and drives this distinction so far as to proclaim that value in use is not necessary even for "the greatest value in exchange." After setting out, without keeping clearly separate, the concepts of the labour commanded by a good, the toil and trouble of commanding a good, and the labour contained in it, and having laid down labour as a measure or standard of value, he settles for an explanation of "natural" prices in terms of cost of production, made up of wages, profit and rent. Smith's distinction between "natural" and "market" prices established a pattern of analysis followed out by the main 19th-century theories of value and price. Natural price is the "long-run" competitive equilibrium price determined by cost of production, while market price is the "short-run" price, determined by supply and demand. Natural price consists of wages, rent and profits at their "natural" levels. As regards wages, these will tend in a stationary economy to a subsistence level, though they will remain above subsistence in a progressive economy. Smith emphasizes the stronger bargaining position of combinations of employers as against the workers, and also suggests the idea behind the later "wages fund" doctrine that wages are an advance by the employer to maintain the worker while his product is ripening. He distinguishes profit as a separate income by marking it off from wages of "inspection and direction," and he notes the element of compensation for risk. He argues that through increasing competition the rate of profit will tend to fall as an economy progresses toward the stationary state. On rent Smith's position is rather ambiguous, and his chapter on the subject includes a vast digression on variations in the value of silver. His explanation mentions the element of monopoly, as well as the productivity of land, and he argues that rent enters into price "in a different way from wages and profit," since "high or low wages and profit are the causes of high or low price; high or low rent is the effect of it"— thus anticipating David Ricardo's theory. Book I ends with an analysis of the effects of economic progress on wages, profits and rents—the incomes, that is, of the "three great, original and constituent orders of every civilized society, from whose revenue that of every other order is ultimately derived." Smith's analysis provided the pattern for subsequent important attempts on this subject, though the precise logic of his model is not entirely clear.

Book 11: Capital, Saving and Investment.—The title of the second book is "Of the Nature. Accumulation, and Employment of Stock," the term "stock" including consumers' capital, as well as producers' capital, which latter is capital in Smith's sense. He classifies capital into fixed and circulating, each with four sub-branches. He includes money as a part of the circulating capital of society, but not explicitly the means of subsistence advanced to productive labourers. In a long chapter on money, "the great wheel of circulation, the great instrument of commerce," he explains the saving to the economy which arises from the development of banking and paper money in place of the precious metals.

Smith comes next to his definitions of "productive" and "unproductive" labour, in which he is attempting to adapt the peculiar definition of the Physiocrats according to which only agricultural labour was "productive." Smith's distinction seems little more helpful for modern analysis, since he defines services—though not retailing—as unproductive, "how honourable, how useful, or how necessary soever" they may be. There follows Smith's theory of saving and investment, or that saving *is* investment. This lays unqualified emphasis on the universal and inevitable beneficence of "parsimony," or private voluntary saving, as "the immediate cause of the increase of capital," since, for any income-receiver, "that portion which he annually saves, as, for the sake of the profit, it is immediately employed as a capital, is consumed in the same manner" as what he spends on his consumption. Hence "every frugal man is a public benefactor," since, apparently, for every individual decision to save there is a corresponding decision to invest.

Joseph Schumpeter has pointed out the immense influence over the next century and a half of this analysis. It is very similar to that of Turgot's published ten years previously in his *Réflexions,* though Smith elaborates its implications, especially for policy, much more emphatically. The Turgot-Smith theory swept away the rudimentary analysis of effective demand of their predecessors as well as Quesnay's reservations regarding the inevitable beneficence of saving.

Smith's analysis of saving and investment, implying the utilization of all income for consumption or investment spending, formed the basis for important parts of his attack (notably in the first chapter of book iv) on what, following Physiocratic usage, he called "the mercantile system," for its preoccupation with monetary policies and "the popular notion that wealth consists in money." There Smith argues that "it is not for its own sake that men demand money" which "can serve no other purpose besides purchasing goods." Complaints of a general scarcity of money are wrongheaded, for "though a particular merchant, with abundance of goods in his warehouse, may sometimes be ruined by not being able to sell them in time, a nation or country is not liable to the same accident . . . It might, indeed, suffer some loss and inconveniency, and be forced upon some of those expedients which are necessary for supplying the place of money. The annual produce of its land and labour would be the same or very nearly the same."

Smith's theory of saving and investment is also an essential part of his general campaign for reliance on the invisible hand of the individualist profit motive as against state action. For, as he argues when discussing tariffs, "no regulation of commerce can increase the quantity of industry in any society beyond what its capital can maintain. It can only direct a part of it into a direction which it might not have gone." The same system of ideas pervades, also, his final chapter of book iv, "Of Public Debts," with its underlying assumption that all government expenditure is "unproductive." However, perhaps in contrast with his extremely emphatic and influential analysis of saving and investment, Smith favoured a legal maximum rate of interest rather than complete freedom. Nevertheless, what John Maynard Keynes was to call "the classical system of ideas" first emerged fully developed in *The Wealth of Nations.* The "law of markets" of Mill and Jean Baptiste Say, and what came to be known in Great Britain in the 1920s and 1930s as "the Treasury view," that government expenditure could do little or nothing to raise the level of employment, are traceable, above all, to Adam Smith.

Book *III:* "Of the *Different* Progress of *Opulence* in Different Nations."—This is probably the oldest part of the work, deriving from Smith's Edinburgh lectures. It forms an interlude on the course of economic development as it proceeds by the exchange of goods and services between town and country or manufacturing and agriculture, and it is illustrated by a selective survey of European economic history. Smith argues for a "natural course of things," according to which "the capital of every growing society is. first, directed to agriculture, then to manufacture, and lastly to foreign commerce." Any other order is "unnatural and retrograde." Indeed, it is in agriculture that the investment of a given capital is most advantageous to society. Over much of Europe. though fortunately not to the same extent in Britain, pernicious legislation with regard to land tenure and primogeniture. and internal obstructions and export prohibitions on the corn trade, have distorted the natural order and prevented the invisible hand from harmonizing the private and social gains from investment.

Book *IV:* "Of Systems of Political Economy". —This is devoted to Smith's attack on "the mercantile system" in the framework of a general review of commercial policies. It concludes with a critical but friendly chapter on "the agricultural system" of the Physiocrats. Smith's most definitely identifiable target was the existing mass of restrictive regulations and monopolistic institutions, practices and privileges, in fact, all those "systems either of preference or of restraint" which "being thus completely taken away, the obvious and simple system of natural liberty establishes itself of its own accord." He has already argued for free choice of occupations by the removal of apprenticeship restrictions and settlement laws, and for free trade in land by the abolition of primogeniture and entails. In book iv he calls, of course, for internal free trade, which he recognizes as a vital factor in the economic progress of Britain as contrasted with France. Most important are his weighty and detailed case for freedom in international trade and his attacks on duties, bounties and the monopolistic privileges of the chartered companies. However, he makes certain concessions regarding restrictions in special circumstances on the export of corn, a moderate export tax on wool and moderate import duties on manufactures where these might yield "a considerable advantage" to a country's own industries, though he will give no protection to infant industries as such. Smith argues for gradualness or "a good deal of reserve and circumspection" in the removal of restrictions, where considerable unemployment might be caused, and says that to expect that complete free trade should ever be established in Great Britain is Utopian.

It is in book iv that Smith introduces several of his most famous passages advocating the free play of self-interest: "As every individual, therefore, endeavours as much as he can both to employ his capital in the support of domestic industry, and so to direct that industry that its produce may be of the greatest value; every individual necessarily labours to render the annual revenue of the society as great as he can. 'He generally, indeed, neither intends to promote the public interest, nor knows how much he is promoting it. By preferring the support of domestic to that of foreign industry, he intends only his own security; and by directing that industry in such a manner as its produce may be of the greatest value, he intends only his own gain, and he is in this. as in many other cases, led by an invisible hand to promote an end which was no part of his intention. Nor is it always the worse for the society that it was no part of it. By pursuing his own interest he frequently promotes that of the society more effectually than when he really intends to promote it."

In his very striking chapter "Of Colonies" Smith campaigns against all nationalistic and monopolistic restrictions on colonial trade, claiming that these benefit only a small minority and not the broad masses of the nation. Because of the burden of defense "under the present system of management, therefore, Great Britain derives nothing but loss from the dominion which she assumes over her colonies." After a searching discussion of political relationships he suggests the vision of a free-trade association of politically independent partners, in which the mother country and its colonies would become "faithful, affectionate, and generous allies."

Book V: *"Of* the Revenue of the Sovereign or *Commonwealth."* —This deals with the expenditure (or functions) of the state and with taxation and public debts. Smith confines the role of the state to three heads: (1) defense (which in a famous aside approving the Navigation acts he had declared to be "much more important than . . . opulence"); (2) justice and civil government, particularly "the defence of the rich against the poor"; and (3) that of "erecting and maintaining those public institutions and those public works, which, though they may be in the highest degree advantageous to a great society, are, however, of such a nature, that the profit could never repay the expense to any individual or small number of individuals." This third heading could, of course, be a most capacious one. Smith specifically mentions the provision of roads, bridges, canals. harbours and, to some extent, education as duties of the state. He discusses further possibilities such as banks, his main criterion being that any state enterprise should pay its way. He emphasizes that what the state may beneficially take on is relative to the efficiency and standards of the government of the day, and he expresses a low view of the capacities of the contemporary British government; however, he has an equally unfavourable opinion of the efficiency of most joint stock companies. Previously he had enunciated as a principle (which might legitimatize an almost indefinite extension of governmental intervention) that "those exertions of the natural liberty of a few individuals which might endanger the security of the whole society, are, and ought to be, restrained by the lams of all governments." As regards taxation. Smith favours proportionality, along with certainty, convenience and economy, though later he claims that "it is not very unreasonable that the rich should contribute to the public expense, not only in proportion to their revenue. but something more than in that proportion."

Though Smith's main treatment of the functions of government comes in book v, various suggestions for beneficent state action are scattered throughout *The Wealth* of Nations. As J. Viner has pointed out. Smith never collected his full program together and, indeed, probably omitted to mention some kinds of state activity which he would heartily have favoured, such as some sort of provision for the destitute or unemployed. So state action emerges as an exception, which is to be assumed guilty until proved innocent or beneficent. while private initiative is to be assumed beneficent until proved guilty. Taken together, his considerable exceptions might build up into a very large role for the state, though, unlike his predecessors and his successors since Keynes, he held rigidly that the state neither could nor should seek to control the aggregate level of activity and employment. Indeed it mas the sweep and force of Smith's advocacy of the simple system of natural liberty which gave The Wealth *of Nations* its revolutionary influence and which constituted its great message for succeeding generations: "All systems either of preference or of restraint, therefore. being thus completely taken away, the obvious and simple system of natural liberty establishes itself of its own accord. Every man, as long as he does not violate the laws of justice. is left perfectly free to pursue his omn interest his own way, and to bring both his industry and capital into competition with those of any other man, or order of men. The sovereign is completely discharged from a duty, in the attempting to perform which he must always be exposed to innumerable delusions, and for the proper performance of which no human nisdom or knowledge could ever be sufficient; the duty of superintending the industry of private people, and of directing it towards the employments most suitable to the interest of the society." At the same time The *Wealth* of Nations provided a first great survey of economic life in all its interdependence, and a framework for the development of political economy as a separate discipline.

SMITH, ALFRED EMANUEL (1873–1944), U.S. politician and governor of New York state, was born in New York city on Dec. 30, 1873, in the Old Fourth ward under the Brooklyn bridge, of poor but respectable parents. Upon the death of his father, who had been a rather unsuccessful truckman, in 1886, Smith's education at St. James's parochial school, near his home, was interrupted. Forced to help support his mother and sister, the boy held a variety of jobs and finally became a checker at the Fulton fish market, where he remained for seven years. Even as a small boy Smith had given indications of talent in elocution and amateur dramatics, and, despite long hours at work, he continued his interest in theatricals and at one time considered a stage career.

Smith's political career began in 1895 when the Tammany district leader made him an investigator in the office of the city commissioner of jurors, with a salary of $800 a year. In the autumn of 1903 he was elected to the New York state assembly on the Democratic ticket. He went to Albany, N.Y., with little formal education but with an alert mind and an intimate knowledge of the city district he represented. He served continuously from 1904 to 1915. By 1913 he had become speaker of the assembly, an office second only to that of governor in power. During his first ten years in the legislature Smith gave small indication of the political independence he was to show later as governor. Industrious and intelligent, he was nevertheless a routine politician who obeyed the orders of Charles F. Murphy, the Tammany Hall "boss." After 1911, however, his viewpoint was broadened through his appointment to a commission which investigated factory conditions. In 1915 he was sent as a delegate to the constitutional convention held at Albany to revise the state's fundamental law.

Tammany Hall rewarded Smith in 1915 by making him sheriff of New York county. In 1917 he was elected president of the board of aldermen of Greater New York. The following year he resigned to run for governor against Charles S. Whitman. Although it was generally believed that he did not have a chance, he won by the narrow margin of 14,000 votes. He served four terms as governor, the first man in the history of the state to have this honour.

"Al" Smith, as he was affectionately known, showed extraordinary ability as a vote-getter. In 1920, when he ran against Nathan L. Miller, he was defeated in the Republican presidential landslide, but polled 1.000.000 more votes in his state than did the Democratic presidential nominee. He then became head of the United States Trucking corporation, but in 1922 was drafted to run for governor again. This time he defeated Miller, seeking re-election, 1,397,633 to 1,011,725—at that time the largest majority ever given a gubernatorial candidate in New York. In 1924 he defeated Theodore Roosevelt, Jr., and in 1926 defeated Ogden L. Mills. As governor, Smith fought for adequate housing, improved factory laws, proper care of the insane, child welfare and state parks. He effected a reorganization of the state government on a consolidated, businesslike basis. He repeatedly demonstrated his gubernatorial leadership by forcing Republican legislatures to accept his recommendations.

Smith was the first Roman Catholic to receive serious consideration as a presidential candidate in the United States. His religion, combined with his long record as an opponent of prohibition, resulted in a prolonged deadlock at the Democratic national convention of 1924. His nomination was opposed by the Protestant "dry" faction led by William G. McAdoo. On the 103rd ballot a compromise candidate, John W. Davis, was nominated.

In 1928, Smith was the leading candidate for the Democratic presidential nomination. At the Houston (Tex.) convention of the party on June 28 he was again placed in nomination by Franklin D. Roosevelt. The first ballot gave him the necessary two-thirds vote of the delegates, and Sen. Joseph T. Robinson was later nominated for vice-president. Though the western and southern Democratic delegates managed to bury the hatchet at the convention they could not persuade the voters to do so in the election. The opposition to Smith in the rural districts of closely contested states in the west and south contributed to his defeat in the election.

Smith carried on an aggressive campaign, making several extended speaking tours into the south and west. Hailed by Roosevelt as the "happy warrior," he was a picturesque figure who made his brown derby, cigar and colourful speech his trademarks and "The Sidewalks of New York" his theme song. But when the electoral votes were counted it was found that he had lost to Herbert Hoover, 444 to 87. Smith lost his own state as well as five southern states that had not gone Republican since the reconstruction era. The popular vote was much closer, 21,391,000 to 15,016.000. Smith polled the largest popular vote ever given to a Democrat up to that time.

The remaining years of Smith's life were embittered by the financial difficulties of the Empire State building, of which he became president, and by a bitter conflict with Franklin D. Roosevelt. Smith lost contact with his old following and supported the Republican presidential candidates in 1936 and 1940. He died on Oct. 4, 1944.

SMITH, CHARLOTTE (1749–1806), English novelist and poet, once famous for her sonnets and her romances, was born in London, May 4, 1749, the daughter of Nicholas Turner, a man of property. Her husband, Benjamin Smith, whom she married in 1765, was imprisoned for debt from Dec. 1783 to July 1784 and then fled to France to avoid creditors. There his wife joined him until, by her efforts, he could return to England (1785). Two years later she left him and turned to writing to support her children (she had 12, of whom 6 survived her). She had already published *Elegiac Sonnets* (1784) but, although these were well received, her free translations of *Manon Lescaut* (1785) and part of *Les Causes Célèbres (The Romance of Real Life*, 1786) promised higher financial reward for novels: hence *Emmeline, or the Orphan of the Castle* (1788), *Ethelinde, or the Recluse of the Lake* (1789), which Fanney Burney enjoyed, etc. *Desmond* (1792), based on the innocent love of a man for a married woman, was accused of immorality, and its political ideas, inspired by the French Revolution also caused some talk. Mrs. Smith began *The Old Manor House* (1793), generally considered her best novel, when, with Cowper and Romney, she was the guest of William Hayley (*q.v.*); she read a chapter to the company each evening. Scott praised "her invention. . . . her knowledge of the human bosom, her power of natural description, her wit and her satire"; but in spite of her Cowperlike attitude to nature and her radical ideas her novels, with their rather stilted dialogue and occasional Gothic effects, belong essentially to the large derivative group of 18th-century women novelists.

Toward the end of her life she turned to palatably instructive books for children, the best being *Conversations Introducing Poetry* (1804). She died at Tilford, near Farnham, Surrey, on Oct. 28, 1806.

See F. M. A. Hilbish, *Charlotte Smith* (1941).

SMITH, EDMUND KIRBY (1824–1893), Confederate general in the American Civil War, the son of Col. Joseph Lee Smith (1776–1846), an American lawyer and soldier, who served in the War of 1812, was born at St. Augustine (Fla.), on May 16, 1824. He graduated at West Point in 1845, being assigned to the infantry. In the Mexican War he was breveted first lieutenant, and captain for gallantry. He was assistant professor of mathematics at West Point from 1849 to 1852 and was later engaged in Indian warfare on the Texas frontier. In 1861 he attained the rank of major.

When Florida seceded he resigned his army commission and entered the Confederate service as a lieutenant-colonel. He was made a brigadier general on June 17, 1861, and was wounded at the battle of Bull Run (*q.v.*). In command of the Confederate forces in the Cumherland gap region, he took part in Gen. Bragg's invasion of Kentucky (1862), and inflicted upon the .Federal forces a severe defeat at Richmond (Ky.), on Aug. 30. From Feb. 1863 to the fall of the Confederacy he was in command of the trans-Mississippi department, and was successful in making this section of the Confederacy self-supporting. He instituted a regular system of blockade-running, and met and defeated the Red river expedition under Gen. N. P. Banks in 1864.

Kirby Smith and his troops surrendered in May 1865, being the last armed forces of the Confederate states to do so. After the war, he was president of the Atlantic and Pacific Telegraph company, president of the Western Military academy, chancellor of the University of Nashville, and from 1875 to his death professor of mathematics at the University of the South, Sewanee (Tenn.).

Smith died at Sewanee on March 28. 1893.

SMITH, GEORGE (1 840-1876), English Assyriologist was born on March 26,1840, at Chelsea, London. Through the interest of Sir Henry Rawlinson, Smith, who was a bank-note engraver by trade, was appointed assistant in the Assyriology department of the British Museum, and the earliest of his successes was the discovery of two inscriptions, one fixing the date of the total eclipse of the sun in the month Sivan in May 763 B.C., and the other the date of an invasion of Babylonia by the Elamites in 2280 B.C. In 1872 Smith achieved world-wide fame by his translation of the Chaldaean account of the Deluge. In the following January the *Daily Telegraph* arranged with Smith that he should go to Nineveh and carry out excavations with a view to finding the missing fragments of the Deluge story. This journey resulted in the discovery of the missing tablets, and of fragments which recorded the succession and duration of the Babylonian dynasties. In 1874 Smith again left England for Nineveh, this time at the expense of the Museum, and continued his excavations at Kouyunjik. In March 1876 the trustees of the British Museum despatched Smith once more to excavate the rest of Assur-banipal's library. He died at Aleppo Aug. 19, 1876.

SMITH, SIR GEORGE ADAM (I 856-1942), Scottish divine, mas born in Calcutta on Oct. 19, 1856, uhere his father, George Smith, C.I.E., was then principal of the Doveton college. He was educated at Edinburgh in the Royal high school, the university and New college. After studying at Tiibingen and Leipzig and travelling in Egypt and Syria, he entered the ministry of the Free Church of Scotland and was appointed professor of Old Testament subjects in the Free Church college at Glasgow, 1892. He was principal and vice-chancellor of Aberdeen university from 1909 to 1935 and moderator of the general assembly of the United Free Church of Scotland, 1916–17. He was knighted in 1916. In 1933 he was appointed chaplain to the king in Scotland He died March 3, 1942.

Among his works are *The Book of Isaiah* (2 vols. 1888–90); The *Book of the Twelve Prophets* (2 vols., 1896–97); *Historical Geography of the Holy Land* (1894); *Life of Henry Drummond* (1898); *Modern Criticism and the Preaching of the O. T.* (3rd Edn., 1902); *Jerusalem* (2 vols., 1908); *The Early Poetry of Israel* (1912); *Atlas of the His?. Geog. of the Holy Land* (1915); *Jeremiah* (1923).

SMITH, GERRIT (1797–1874), American reformer and philanthropist, was born in Utica (N.Y.), on March 6, 1797. About 1828 he became an active worker in the cause of temperance, and in his home village, Peterboro, he built one of the first temperance hotels in the country. He became an abolitionist in 1835, after seeing an anti-slavery meeting at Utica broken up by a mob. In 1840 he took a leading part in the organization of the Liberty Party, and in 1848 and 1852 he was nominated for the Presidency by the remnant of this organization that had not been absorbed by the Free Soil Party. An "Industrial Congress" at Philadelphia also nominated him for the Presidency in 1848, and the "Land Reformers" in 1856. In 1840 and in 1858 he was a candidate for the governorship of New York on an anti-slavery platform. In 1853 he was elected to the U.S. House of Representatives as an independent. At the end of the first session he resigned his seat. After becoming an opponent of land monopoly, he gave numerous farms of 50 ac. each to indigent families, and also attempted to colonize tracts in northern New York with free negroes; but this experiment was a failure. Peterboro became a station on the "underground railroad"; and after 1850 Smith furnished money for the legal expenses of persons charged with infractions of the fugitive slave law. With John Brown, to whom he gave a farm in Essex county (N.Y.), he became very intimate, and from time to time supplied him with funds, though it seems without knowing that any of the money would be employed in an attempt to incite a slave insurrection. Under the excitement following the raid on Harper's Ferry, he became temporarily insane, and for several weeks was confined in an asylum in Utica. He favoured a vigorous prosecution of the Civil War, but at its close advocated a mild policy toward the late Confederate States, declaring that part of the guilt of slavery lay upon the North. He even became one of the securities for Jefferson Davis, thereby incurring the resentment of Northern Radical leaders. He died on Dec. 28, 1874, while on a visit to relatives in New York city.

See O. B. Frothingham, *Gerrit Smith: a Biography (1879).*

SMITH, GOLDWIN (1823–1910), British historian and publicist, was born at Reading on Aug. 13,1823. He was educated at Eton and Magdalen college, Oxford, and became a fellow of University college. He was assistant secretary to the royal commission on the subject of university reform in 1850, and secretary to the commissioner appointed by the act of 1854. In 1868, when the question of reform at Oxford was again growing acute, he published a brilliant pamphlet, entitled *The Reorganization of the University of Oxford.* His aspiration that colonists and Americans should be attracted to Oxford has been realized by Mr. Rhodes's will. His principal historical writings—*The United Kingdom: a Political History* (1899), and *The United States: an Outline of Political History* (1893)—make no claim to original research, but are remarkable examples of terse and brilliant narrative.

The outbreak of the American Civil War proved a turning-point in his life. He warmly championed the cause of the North, and his pamphlets, especially one entitled *Does the Bible sanction American Slavery?* (1863), played a prominent part in converting English opinion. Visiting America on a lecture tour in 1864, he received an enthusiastic welcome, and was entertained at a public banquet in New York. In 1868 he threw up his career in England and settled in the United States, where he held the professorship of English and Constitutional History at Cornell University till 1871. In that year he removed to Toronto, where he edited the *Canadian Monthly*, and subsequently founded the *Week* and the *Bystander*.

He did not, however, cease to take an active interest in English politics. He stated that "if he ever had a political leader, his leader was John Bright, not Mr. Gladstone." Speaking in 1886, he referred to his "standing by the side of John Bright against the dismemberment of the great Anglo-Saxon community of the West, as I now stand against the dismemberment of the great Anglo-Saxon community of the East." These words form the key to his views of the future of the British Empire. He always maintained that Canada, separated by great barriers, running north and south, into four zones, each having unimpeded communication with the adjoining portions of the United States, was destined by its natural configuration to enter into a commercial union with them, which would result in her breaking away from the British empire, and in the union of the Anglo-Saxons of the American continent into one great nation. These views are most fully stated in his *Canada and the Canadian Question* (1891).

Goldwin Smith died at his residence, The Grange, Toronto, on June 7, 1910.

See Arnold Haultain, *Goldwin Smith, his Life and Opinions* (1913), which includes Smith's journal during his first visit to America in 1864.

SMITH, SIR HENRY GEORGE WAKELYN, BART. (1787–1860), British general, son of John Smith, surgeon, of Whittlesey, Cambridgeshire, was born at that place on June 28, 1787. Harry Smith (as he consistently preferred to be called throughout his life) was educated privately and entered the army in 1805. His first active service was in South America in 1806, and he subsequently served through the Peninsular War from the concentration at Salamanca in Nov. 1808 to the battle of Toulouse on April 10, 1814. He married in 1812 a young Spanish girl, Juana Maria de Los Dolores de Leon, who remained with him throughout the rest of the war, accompanying the baggage train, sleeping in the open on the field of battle, riding freely among the troops, and sharing all the privations of campaigning. "Juanita" was idolized by the soldiers. At the close of the war Harry Smith volunteered for service in the United States. where he was present at the battle of Bladensburg (Xug. 24, 1814), and witnessed the burning of the capitol at Washington, which, as he said, "horrified us. coming fresh from the duke's humane warfare in the south of France." Returning to Europe he was brigade major at Waterloo; and in 1828 was ordered to the Cape of Good Hope. where he commanded a division in the Kaffir War of 1834–36. In 1835 he accomplished the feat of riding from Capetown to Grahamstown, a distance of 600 mi., in less than six days; and was appointed governor of the new province of Queen Adelaide, where he gained unbounded influence over the native tribes. But though supported by Sir Benjamin D'Urban, the high commissioner, the ministry in London reversed his policy and—to quote Smith's own words—"directed the province of Queen Adelaide to be restored to barbarism." Smith himself was removed from his command, his departure being deplored alike by the Kaffirs and the Dutch: and numbers of the latter, largely in consequence of this policy of Lord Glenelg, began the migration to the interior known as "the great trek."

Harry Smith was now appointed deputy adjutant general of the forces in India, where he took part in the Gwalior campaign of 1843 (for which he received a K.C.B.) and the Sikh War of 1845–46. He was in command of a division under Sir Hugh Gough at the battles of Moodkee and Ferozeshah. where he conspicuously distinguished himself, but was insufficiently supported by the commander-in chief. After the second of these actions Smith was appointed to an independent command, and on Jan. 28, 1846, he infiicted a crushing defeat on the Sikhs at Aliwal on the Sutlej. At Sobraon on Feb. 10 he again commanded a division under Gough. For the great victory of Aliwal he was awarded the thanks of parliament. and was created a baronet. In 1847 he returned to South Africa as governor of Cape Colony and high commissioner, to grapple with the difficulties he had foreseen 11 years before *(see* CAPE OF GOOD HOPE: *History)*. He took command of an expedition to deal with the disaffected Boers in the Orange River Sovereignty, and fought the action of Boomplaats on Aug. 29, 1848. In Dec. 1850 war broke out with the Kaffirs; Smith was insufficiently supplied with troops from England; and Lord Grey recalled him in 1852 before the Kaffirs had been completely subdued. He protested strongly against the abandonment of the Orange River Sovereignty to the Boers, which was carried out two years after his departure, and he actively furthered the granting of responsible government to Cape Colony. His Spanish wife was his constant companion in his second as in his earlier sojourn in South Africa, where her memory is recalled by the town of Ladysmith in Natal, as is that of her husband by Harrismith in the Orange Free State; while Aliwal North, founded in 1849 and named after his great Indian victory, further commemorates Smith. On his return to England he held a military appointment for some years, and died in London on Oct. 12, 1860. Juana, Lady Smith, survived till 1872.

SMITH, HENRY JOHN STEPHEN (1826–1883), British mathematician who specialized in the theory of numbers, was born in Dublin, Ire., on Nov. 2, 1826. When he was two years old his father died and his mother left Ireland for England. After being privately educated he entered Rugby in 1841 and Ealliol college, Oxford, in 1844. He was elected a fellow of Balliol in 1850 and Savilian professor of geometry in 1861. He was elected a fellow of the Royal society in 1861, served on various royal commissions and from 1877 was chairman of the managing body of the meteorological office. He died at Oxford on Feb. 9. 1883.

Smith published a few papers on geometry and then began a study of the existing work on the theory of numbers. The results of his researches are contained in his *Report on the Theory of Numbers*, which appeared in the British association volumes from 1859 to 1865. His further original researches on the subject were communicated to the Royal society in two memoirs. "Systems of Linear Indeterminate Equations and Congruences" and the "Orders and Genera of Ternary Quadratic Forms" *(Phil. Trans.*, 1861 and 1867). After 1864 he devoted himself chiefly to elliptic functions. His *Collected Papers*, prefaced by several biographical notices. were edited by J. W. L. Glaisher (1894). (O. OE.)

SMITH, HOLLAND McTYEIRE (1882–), U.S. marine corps officer who in World War II exemplified the fighting tradition established by men like Philip Sheridan and "Stonewall" Jackson, was born April 20, 1882. in Seale, Ala.. and graduated from Alabama Polytechnic institute, at Auburn, in 1901, receiving a law degree from the University of Alabama. Tuscaloosa. two years later. He practised law for one year and then entered the marine corps. During World War I Smith saw combat service in France, 1917–18. He specialized in amphibious warfare and trained marines and soldiers for the amphibious forces in World War II. Later he commanded the 5th amphibious corps, with the rank of lieutenant general, in successful operations in the Gilbert and Marshall Islands, on Saipan, Guam and Tinian and at Iwo Jima. His initials "H. M." and his insistence on thoroughness in training brought him the nickname "Howlin' Mad." Smith was retired for age May 15, 1946. and promoted to general. His autobiography, *Coral and Brass*, was published in 1949. (J. B. HN.)

SMITH, JAMES (1775–1839) and **HORACE** (1779–1849), authors of the *Kejected Addresses*, sons of a London solicitor, were born, the former on Feb. 10, 177j. and the latter on Dec. 31, 1779, both in London. In 1812 the managers of the Drury Lane theatre offered a prize of £50 for an address to be recited at the reopening of the rebuilt theatre in October. The brothers Smith had the idea of making the most pnpular poets of the time figure as competitors and issuing a volume of unsuccessful addresses in parody of their various styles. They divided the task between them. James took Wordsworth, Southey, Coleridge and Crabbe, while Moore, Scott and Bowles were assigned to Horace. Both had a hand in Byron. Seven editions were called for within three months. *Rejected Addresses* is a classic in the literature of parody. The only other undertaking of the two brothers was *Horace in London* (1813). James Smith made another hit in writing *Country Cousins, A Trip to Paris, A Trip to America* and other lively skits for Charles Mathews who said he was "the only man who can write clever nonsense." James was reputed one of the best of talkers in an age when the art was studied. and it was remarked that he held his own without falling into the great error of wits—sarcasm. But in his old age the irreverent *Fraser's* put him in its gallery of living portraits as a gouty and elderly but painstaking joker. He died in London on Dec. 24. 1839.

After making a fortune as a stockbroker, Horace Smith wrote about a score of historical novels—*Brambletye House* (1826), *Tor Hill* (1826), *Reuben Apsley* (1827). *Zillah* (1828), *The New Forest* (1829), *Walter Colyton* (1830), etc. But he was more of an essayist than a storyteller. Three volumes of *Gaieties and Gravities*, published by him in 1826, contain many witty essays both in prose and in verse. but the only single piece that has taken a permanent place is the "Address to the Mummy in Belzoni's Exhibition." Shelley said of Horace: "Is it not odd that the only truly generous person I ever knew who had money enough to he generous with should be a stockbroker? He writes poetry and pastoral dramas and yet knows how to make money. and does make it, and is still generous." Horace Smith died at Tunbridge Wells on July 12. 1849.

SMITH, JEREMIAH, JUNIOR (1870–1935), American lawyer and economist. was born at Dover. N.H., on Jan. 14, 1870. He graduated at Harvard university in 1892 and the Harvard law school in 1895. In 1895 he became secretary to Justice Gray of the C.S. supreme court. but in 1896 started the practice of law in Boston. He was a captain in the quartermaster corps, A.E.F.. in France in 1918. At the conclusion of hostilities he was appointed counsel to the treasury department in Europe and was associated in that capacity with the U.S. peace commission, acting also as an adviser in financial matters. After the signature of the Treaty of Versailles he resumed practice in Boston. During 1924–26 he was commissioner general of the League of Nations in Hungary, being successful in stabilizing the currency and placing Hungarian finance on a sound basis. On the completion of his work, July, 1926, he returned to practice in Boston. He generously refused to accept any remuneration except his expenses; and the sum of approximately $60,000 thus saved was designated by the Government as a scholarship fund for sending Hungarian students to the United States.

SMITH, JOHN (1579–1631), the best known of the early settlers of Virginia, was born of excellent parentage at Willoughby, in Lincolnshire. England. He attended school but was an unwilling scholar, the call of the sea making itself heard in his consciousness. Hence when about 16 years of age he started on his adventures. These he pursued on land and sea, with a short interruption, for ten years, and to his lot fell a great number of unusual experiences and hairbreadth escapes.

It is unfortunate that our main source of information in reference to this period of Smith's life is the testimony of Smith himself, but where it has been possible to check his narrative it has been found substantially correct. Hence, argue his friends, why not accept his credibility as a whole? It is a notable fact that probably the closest student of Smith's works, Edward Arber, who in 1884 edited John Smith's works for the *English Scholar's Library,* gives his adherence unreservedly to this credibility. Professor Arber's hope, however, to establish Smith's reputation beyond dispute was vain, for very shortly after the appearance of Arber's edition hfr. Alexander Brown brought out his two books, *The First Republic in America* and *The Genesis of the United States*, in both of which Smith is heavily attacked. His animus against Smith arose from the fact that an exaltation of Smith appeared to him to carry with it a belittling of those engaged with Smith in the effort to establish a settlement at Jamestown, an effort engaged in by many leading Englishmen of the time, and of such importance as to merit disassociation from it of the idea that its success was at any time dependent on any one man.

When Smith finally returned to England in 1605, he was only twenty-six years of age, but his varied experiences had matured him early, and he had graduated from the ranks of the mere fighter and entered those of the pioneer and the colonizer. He threw himself with energy into colonization schemes. He embarked heart and soul in the London Company enterprise—first in securing the charter and then in securing colonists. Not only did he go himself, but he spent his money in getting others to go. It is a great compliment to Smith that the Council of the company in London chose him to be a member of the Council in Virginia. His selection shows that, though young, he was already a man of mark.

The colonists set out from England Dec. 19, 1606, and did not reach Virginia till April 26, 1607 When the box containing the names of the members of the Council was opened, and it was found to contain Smith's, he was not permitted to take his seat, being under arrest on a charge of conspiracy on the trip over. Later, however. he was cleared, and his principal accuser fined £200. He was admitted a member of the Council June 26, 1607.

The actual landing of the colonists at Jamestown was made on May 14, and on May 22 Captain Newport with a party including Captain Smith made explorations up the James River, reaching the site of Richmond at the falls. Beyond this he desired to march inland but mas dissuaded by the Indian chief whose town was at the falls. Reaching Jamestown on the return on May 27, the party found that the Indians had the day before made an attack on the English when they were busy planting their corn, unsuspicious and unprepared. It was by means of the guns of the three ships lying close inshore that the enemy was forced to retire. In this fight was disclosed at least one of the advantages of Jamestown as the place of settlement, whatever points there may have been in its disfavour. The channel of the river there runs very close to the shore. Moreover, Jamestown Island was at that time a peninsula with a narrow, easily defensible neck, which was later, when Smith became president, protected by a block house.

On June 21 Captain Newport sailed away to England leaving 105 people at Jamestown with provisions for thirteen or fourteen weeks, under the command of the Council, with Edward Maria Wingfield as president, elected by the Council itself. Now a serious defect of organization soon become apparent. It was the Council that had the authority, not the president, who, however, presided at the deliberations of that body and had an additional vote in case of a tie This form of government was absolutely bad. Too much time was taken up in wrangling in the Council, too much feeling was engendered between individual councillors. The situation—scanty provisions and sickness within the stockade among inexperienced and largely unsuitable colonists and, without, lurking and hostile savages—called for concentration and not dispersion of power. The strong hand was needed.

It fell to Smith's lot to trade with the Indians for provisions that were to keep the settlers alive till the return of Captain Newport. These difficult and dangerous trading expeditions he conducted with success. He always returned to Jamestown safe and with good supplies. Others, all too frequently, when these duties later devolved on them. either returned not at all or with empty baskets Smith, no doubt, used all means in these expeditions—professions of friendship, cajolery, force, fraud, as well as fair trading. Several of these expeditions he made up the Chickahominy. On Dec. 10 he started out to discover the source of the Chickahominy, for it was thought that probably this source was in a ridge whose westerly flowing streams might have their outlet in the South Sea It was on this trip that he was captured by the Indians and the best-known incident of his life occurred, namely, his rescue by Pocahontas, who when, according to the orders of Powhatan, her father, the great chief of a confederacy of Indians, he was led forth to execution in retaliation for the killing by him of an Indian in the fight in which he was captured. threw herself upon him and by her entreaties prevailed with her father to spare his hfe. This was the act of a kindhearted, simple little Indian maiden of twelve or thirteen years of age who had been entertained by Smith with stories and sights of marvels in the time he had been at her father's residence before the execution had been decided on. He was then adopted as a member of the tribe. Later he was permitted to return to Jamestown. He faced another danger, however, when he returned. His enemy Gabriel Archer, who had in his absence been made a member of the Council, promptly charged him under the Levitical law with the death of his companions. On this absurd charge he was actually tried and sentenced to be hanged. But the hanging was averted by the arrival of Captain Newport from England. When Newport with his "First Supply" arrived on the 9th of Jan. 1608, only 38 of the colonists remained of the original 105. When Newport again left the colony on April 10, he took with him Captains Wingfield and Archer. On April 20 arrived the "Phoenix," Captain Francis Nelson, the consort of Newport's ship of the "First Supply." Newport's ship and Nelson's ship had brought 120 colonists.

In the early summer of 1608 Smith set out on his famous exploration of the Chesapeake Bay and its tributaries. He explored both sides of the bay far up to its head and went up the Potomac River as far as the site of the present city of Washington and up the Rappahannock as far as the site of Fredericksburg. At one time he uas so violently hurt by a stingray that he found it necessary to return to Jamestown to be treated by a surgeon. On this trip—or two trips—the party travelled three thousand miles in an open boat and met many adventures. One hardly knows which more to admire, the determined endurance of Smith and his men or the careful collection of data which went later into a narrative of the expedition and into a truly remarkable map

When Smith returned from Stingray Point to get his surgeon, he found the colonists clamouring that Ratcliffe should be deposed from the presidency and Smith put in his place. This was accordingly done by the Council, but Smith asked his friend Scrivener to act for a time, and he resumed his explorations He remained in Jamestown only from the 21st to the 24th of July. He returned from the second voyage on Sept. 7, 1608. and three days later assumed the duties of president. His activities were incessant. In October came Captain Newport with the "Second Supply" consisting of seventy colonists. The population of Jamestown now numbered about 200, of whom, owing to improved conduct of affairs, no more than six or seven succumbed to disease before the arrival of the "Third Supply" the following year.

Newport's instructions from the Council in London, impatient for quick returns on the company's investment, were to find gold, discover the passage to the South Sea, search for Raleigh's missing colonists, crown Powhatan (in order to gain his favour), and to employ certain Poles and Dutchmen in making pitch, tar, glass, and soap-ashes. Smith was opposed to these objects, with a varying degree of intensity, as diverting energy which should be expended in making the colony self-supporting, first and foremost in the matter of the food supply. As for Powhatan, he knew that his favour and support were important, that trade with the Indians for supplies was essential, but he was opposed to the use of any great amount of flattery. It was only another case, however, in which a distant and imperfectly informed higher authority had to be obeyed by the able administrator on the spot. Hence Smith bent his energies toward carrying out the instructions. But when Newport returned to England, Smith sent, with his celebrated map already referred to, a letter to the Council setting forth plainly his views as to these instructions and as to all questions affecting the good of the colony. His letter is most important, stressing the necessity of sending over competent toilers to make the colony self-supporting.

During the winter Smith found it necessary to make several expeditions among the Indians to obtain corn to stave off famine and was always successful, though it was sometimes necessary for him to force the Indians to trade. He had many narrow escapes from disaster. His courage, his resourcefulness, and his knowledge of Indian character, however, brought him through. After his return from the last expedition, with what seemed to be enough corn to last for a long time, he compelled the lazy among the colonists to do their share of work, and many necessary things were done in Jamestown and the vicinity. Forty acres of corn were planted. Now the rats at Jamestown, however, ate up large quantities of the precious corn, and Smith experimented by sending parties oil to live on oysters and fish, and even billeted some among the friendly Indians in the neighbourhood of Jamestown. Despite ever>-thing untoward that had happened and the shortage of food, Smith could feel in the spring and summer of 1609 that a solid foundation was being laid for the future wellbeing of the colony. His authority was now supreme because all the other members of the Council had died or returned to England.

On July 10, 1609, there arrived a ship under Captain Samuel Argall, to fish for sturgeon and to trade, and Captain Smith found it advisable to commandeer the provisions brought out, with the understanding, of course, that they would be paid for by the company. The ship brought out letters much less welcome to Smith than the supplies. In them he was much criticized for what the Council was pleased to think his harsh treatment of the Indian; and for failure to send back to England more valuable cargoes. Smith bridled at the injustice. His letter to the Council sent by Newport the preceding November had had little effect. News was also brought that the London Company had obtained a new charter, providing for a reorganization of the plan of government of the colony. There was to be a governor-general, who was, or whose deputy was, to be in real control. Lord De la Warr was to be this governor; nine supply ships were coming over. Smith understood, of course, that this change in the government was wise, but he did not relish being set aside, and he honestly thought that he with his experience, especially with his knowledge of the Indians, was the best man that could be found for the position. And almost certainly he was correct, though it may be argued that Smith had by his overhearing and impatient manner with his equals—though not with his inferiors—in station made so many enemies among influential members of the company and colony that the time had come for a new man to be put in control, who would be sure, however, to profit by the experience of his predecessor.

Lord De la Warr did not at first intend to come to Virginia himself till much later but to remain in England and there give attention to its affairs. He was to be represented in Virginia by Sir Thomas Gates, lieutenant-governor. The "Sea Venture," carrying Sir Thomas Gates, lieutenant-governor, Sir George Somers, admiral, Sir Thomas Dale, high marshal, and Captain Christopher Newport, vice-admiral, was wrecked on one of the Bermuda Islands, and the arrival in Virginia of these high officials was much delayed. This vessel also carried instructions. The other ships were dispersed and much distressed by the same storm that wrecked the "Sea Venture," but four of them sailed up the James on August 11 and others came in later, all in a very dilapidated condition. These ships brought Ratcliffe, Martin and Archer, former members of the Council in Virginia. When these demanded that Smith give up his office, he refused, since neither the new governor nor the lieutenant-governor was at hand, nor had he been officially informed of the changes made. He chose, however, to recognize Martin as a member of the Council, though maintaining that the other two were not now legally members, and a few days before his year's term as president was to expire on Sept. 10, he named Martin as his successor, who immediately, however, resigned in favour of Smith. Smith now sent Martin to make a settlement among the Nansemond Indians and he himself went to inspect a settlement he had previously sent Captain West to make at the falls of the James. He found affairs going badly. When he was returning to Jamestown, he was dangerously burned by an explosion of gunpowder and his return to England was necessitated. With him went charges drawn up by his enemies in Virginia, which, however, were not pressed. But Smith was never employed again by the London Company. He had made too many enemies.

When he left, the harvest was newly gathered and the colony was otherwise in a sufficiently stable condition to ensure its steady growth if only a competent administrator had been in charge. We cannot, however, go further into the history of the colony except to say that things at once went to pieces. The winter of 1609–10 is known as the "starving time." The colony was only saved from extinction by the arrival in the spring of Sir Thomas Gates and a little later of Lord De la Warr.

Though Captain Smith saw no more service with the Virginia Company of London, he, when he recovered his health, carried on his work in the interests of colonization and in the establishment of fisheries. With two ships he made a fishing and exploring voyage in 1614, and, as he had done in the case of the Chesapeake Bay country, mdde a surprisingly accurate map of the New England coast from the Penobscot to Cape Cod. He called the country "New England" and he assigned the name "Plymouth" to the mainland opposite Cape Cod.

Smith gained the favour of Sir Ferdinando Gorges, one of the principal members of the Virginia Company of Bristol. Under his patronage he made in 1615 two attempts to reach New England for purposes of settlement, the first of which failed on account of stress of weather, and the next attempt was frustrated by his being captured by pirates. In 1617 he made another unsuccessful attempt. He had been given by the Virginia Company of Bristol the vain title of admiral of New England. In 1618 he endeavoured without success to enlist the support of Lord Bacon for his colonization plans. In 1619 he offered to pilot the Pilgrim Fathers to North Virginia, that is, New England, but the offer was not accepted. After this he was mainly engaged in producing pamphlets, books, and maps, the design of which was to excite an interest in the colonization of America and now especially that part of it he had named New England. He died in June, 1631. He was buried in St. Sepulchre's Church, London.

Smith's principal writings, the titles being given in modern spelling and abbreviated form and in the order of their publication, are as follows: *A True Relation* (1608); *A Map of Virginia* (1612); *A Description of New England* (1616); *New England's Trials* (1620); *The General History of Virginia, New England, and the Summer Isles* (1624); *An Accidence for All Young Seamen* (1626); the same work recast and enlarged and given the title

A Sea Grammar (1627); *The True Travels* (1630); *Advertisements for the Unexperienced Planters* (1631).

The best edition of Smith's works is that edited by Edward Arber, and published in Birmingham. Eng., in 1884. In this are also printed most of the pamphlets of his contemporaries, including those unfriendly to Smith. A later biography is by E. K. Chatterton. This was published in 1927 as one of the *Golden Hind Series*, which contains the biographies of the great Elizabethan seamen and explorers who gave lustre to that age. This book contains a full bibliography of Smith's own writings, and a very extensive list of the writings in reference to him. An engraving was made of Captain John Smith from life by Simon van der Pass, which has been reproduced many times. There is in the Virginia state library a portrait of an Englishman dressed in Turkish costume, which experts pronounce an original portrait of Captain Smith. (H. R. McI.)

SMITH, JOHN RAPHAEL (1752–1812), English painter and mezzotint engraver, a master particularly of the latter art, was the son of Thomas Smith, called Smith of Derby, a landscape painter. Some of the younger Smith's reproductions of Reynolds' works rank among the masterpieces of the art of mezzotint, the prints being delicate, excellent in drawing and finely expressive of colour. Smith also had an extensive connection as a print dealer and publisher, and his small full-lengths in crayons and his portraits support his claim to be a successful draftsman and painter. He died at Doncaster, Yorkshire, on March 2, 1812.

SMITH, JOSEPH (1790–1877), U.S. naval officer whose outstanding service during the Civil War as chief of the bureau of navy yards and docks, in the navy department, won the praise of Secretary Welles and President Lincoln. He was born in Hanover, Mass., March 30. 1790, and became a midshipman in 1809. He received a silver medal from congress for gallantry in the battle of Lake Champlain. After commanding the ship of the line "Ohio!" he was commodore of the Mediterranean squadron. 1843–45. Smith became chief of the bureau of navy yards and docks in 1846, serving until 1869. He was made a rear admiral on the retired list when that rank was established in 1862. He died in Washington, D.C., Jan. 17, 1877. His son, JOSEPH BRYANT SMITH. was killed while in command of the U.S.S. "Congress" during her battle with the "Merrimac" on March 8, 1862. (J. B. HN.)

SMITH, JOSEPH (1805–1844), U.S. founder of the Mormon religion, was born at Sharon, Vt., Dec. 23, 1805, the third son of Joseph and Lucy Mack Smirh. His early career is shrouded in controversy. Neighbours in Palmyra, N.Y., described him as a romancer and diviner who dug for buried treasure, and their stories can be largely verified by court records, early newspaper accounts and the autobiography of his mother. In his own history, written after 1838, Smith described himself as an unschooled, pious boy who had a vision of God and Jesus Christ at the age of 14. At 17, he said, an angel directed him to buried golden plates containing a history of the American Indians, which described them as descendants of Hebrens who had centuries earlier sailed to America by way of the Pacific. This *Book of Mormon* he translated from "reformed Egyptian" with the aid of magic stones he called the Urim and Thummim.

By most objective scholars the book is regarded as a potpourri of local Indian origin legends, fragments of autobiography, and the current religious and political controversies, particularly Anti-masonry, all transformed with remarkable ingenuity into a religious saga of quasi-biblical authority. After its publication in 1830, Smith offered it as scientific evidence of his divine calling, and claimed that his new church, organized April 6, 1830, was a restoration of the ancient, primitive Christian religion

Converts in ever-increasing numbers followed Smith from New York to Ohio, then to Missouri and on to Illinois, despite great suffering. The young prophet governed his people with the help of revelations, which dealt with such divergent matters as the anthropomorphic nature of God, the communistic United Order and the size, location and financing of a hotel. He taught that the heavens are peopled with many gods, and that every man can aspire in time to be a god himself.

Joseph Smith was a man of commanding presence, athletic grace and prodigious personal charm. A genius at improvisation, he managed to combine Jewish and Christian mysticism with the goal of perpetual prosperity, and to establish the tradition of Mormonism as a complete "way of life." Although his revelation on polygamy was not made public (by Brigham Young) until 1852, four years after Smith's death, and though it is not supported by the *Book of Mormon,* there is evidence that he may have married as many as 50 wives. He publicly acknowledged only his first, Emma Hale Smith, who bore him nine children.

When a handful of dissenting Mormons attacked him in their newspaper, Smith had their press destroyed. For this he was imprisoned, with his brother Hyrum. On June 27, 1844, an anti-Mormon mob stormed the jail at Carthage, Ill., and shot both men. The church split into pieces, but the majority followed Brigham Young (*q.v.*), a sagacious administrator and colonizer, who led the Mormon exodus to Great Salt lake. A smaller group, led by the eldest of Smith's four surviving sons, who denied that their father had practised polygamy, settled in Independence, Mo. (*See* also LATTER-DAY SAINTS, CHURCH OF JESUS CHKIST OF.)

Joseph Smith's writings include, in addition to *The Book of Mormon* (1830), *A Book of Commandments for the Government of the Church of Christ* (1833); *Doctrine and Covenants of the Church of The Latter Day Saints* (1835).

Brodie, *No Man Knows My History, the Life of Joseph Smith, the Mormon Prophet* (1945); Thomas O'Dea, *The Mormons* (1957); Lucy Mack Smith, *Biographical Sketches of Joseph Smith the Prophet and His Progenitors for Many Generations (1853);* B. H. Roberts (ed.), *History of the Church of Jesus Christ of Latteu-Day Saints,* 6 vol. (1902–12) (F. M. B.)

SMITH, SIR KEITH MACPHERSON (1890–) and **SIR ROSS MACPHERSON** (1892–1922), brothers, Australian pioneer aviators, were born at Adelaide, S. Austr., on Dec. 20, 1890. and Dec. 4. 1892, respectively. They were both educated at Queen's school, Adelaide, and at Warriston school, Moffat. Scotland. During World M'ar I, Keith served in the Royal Flying Corps and Royal Air Force as a pilot, 1917–19, while Ross served with the Australian Light Horse in Gallipoli and Sinai. In 1916 he learned to fly in Egypt and spent the last two years of the war in the Australian flying corps in Palestine. He made the first flight from Cairo to Calcutta in 1918. In Nov.–Dec. 1919, Ross as first and Keith as second pilot, in a Vickers Vimy twin-engined biplane with Rolls Royce 375 h.p. engines, accompanied by Sgts. J. M. Bennett and W. H. Shiers as mechanics, made the first flight from England to Australia, landing at Darwin, Northern territory, on Dec 10, 1919. For this flight the brothers received knighthoods and the prize of £10,000. Three years later they began preparations for a pioneer round-the-world flight in a Vickers pusher-amphibian aircraft, but Ross was killed, together with Bennett, while testing the aircraft at Brooklands, Eng., on April 13, 1922. Keith went into business in Sydney, Austr. (D. CR.)

SMITH, ROBERT (1757–1842), U.S. statesman, was U.S. secretary of the navy, 1802–09, under Jefferson; also secretary of state, 1809–11, under Madison. In the last mentioned post he entered into an agreement with David M. Erskine, the British minister at Washington, D.C., which was promptly repudiated by George Canning, the British foreign secretary; and, when Canning sent the insolent Francis James Jackson to take Erskine's place at Washington, it became necessary for Secretary Smith to break off all relations with the British minister.

Smith was much maligned by his enemies, the chief of whom was Albert Gallatin, uho had been kept out of the office of secretary of state; and the reputation of Smith has subsequently suffered at the hands of historians. But a later writer pointed out that as a member of the Maryland legislature, and as secretary of the navy under Jefferson, Smith appeared eminently successful; and this writer has also shown that his work as secretary of state was of a high order, that Gallatin's charges against him (the mishandling of government funds) broke down completely. and that Gallatin, by threatening to resign as secretary of the treasury, prompted Madison to call for the resignation of Smith.

After his retirement Smith reviewed his career as secretary of state in an *Address to the People of the United States* (June 1811).

Thereafter he served in various positions in Maryland, and died on Nov. 26. 1842. the last survivor of the electoral college of 1789, which elected George Washington first president of the United States.

See Charles C. Tansill, "Robert Smith, Secretary of State," in Samuel Flagg Bemis (ed.), *The American Secretaries of State and Their Diplomacy*, iii, 151–200 (1927).

SMITH, SEBA (MAJOR JACK DOWNING) (1792–1868), U.S. editor and humorist, creator of Major Jack Downing, a rustic Yankee whose horse sense and wise saws as the purported counselor and friend of Andrew Jackson brought laughs that swept the country, mas born in Buckfield. Me., on Sept. 14. 1792. A graduate of Bowdoin college. Brunswick, Me.. Smith in 1829 founded the *Portland Courier,* where the Major's fictional letters first appeared in Jan. 1830, continuing later in the *National Intelligencer* until July 1853. Major Jack was a common man magnified as oracle; yet there was irony in his role of threadbare office seeker exposing follies in a mobocracy. As adviser to President Jackson, Jack was in the heyday of his popularity; this led to shameless counterfeiting of Smith's invention and to his collection of the letters in book form. the last volume being published in 1859 under the title of *My Thirty Years Out of the Senate*. In the Downing letters Smith is intent on the portrayal of New England character, an aim more completely carried out in his *Way Down East* (1854). Smith's title to distinction comes from his hitting upon something new in humour that has become a part of American tradition. Practically forgotten himself. he numbers among his followers in satire James Russell Lowell's Hosea Biglow, Artemus Ward and Will Rogers.

Smith died July 28, 1868. in Patchogue, N.Y.

See Mary A. Wyman, *Two American Pioneers, Seha Smith and Elizabeth Oakes Smith* (1927); Constance Rourke, *American Humor* (1931). (M. A. WN.)

SMITH, SYDNEY (1771–1845), English writer and Anglican priest, son of Robert Smith, was born at Woodford, Essex. on June 3, 1771, the son of a wealthy and eccentric landowner. Sydney was the second of a family of four brothers and one sister, all remarkable for their talents. While two of the brothers, Robert Percy. known as "Bobus," afterward advocate general of Bengal, and Cecil. were sent to Eton. Sydney was sent with the youngest to Winchester, where he rose to be captain of the school. In 1789 he had become a scholar of New college. Oxford; he received a fellowship after two years' residence, took his degree in 1792 and proceeded M.A. in 1796. He was ordained priest at Oxford in 1796. and became a curate in the small village of Nether Avon, near Xmesbury. in the midst of Salisbury plain. The squire of the parish, Michael Hicks-Beach, engaged him after a time as tutor to his eldest son. It was arranged that they should proceed to the University of Weimar, but before they reached their destination Germany was disturbed by war and "in stress of politics," said Smith, "we put into Edinburgh." This was in 1798. While his pupil attended lectures, Smith was not idle. He studied moral philosophy under Dugald Stewart, and devoted much time to medicine and chemistry. He also preached in the Episcopal chapel, where his practical brilliant discourses attracted many hearers.

In 1800 he published his first book. *Six Sermons, Preached in Charlotte Street Chapel, Edinburgh,* and in the same year married, against the wishes of her friends, Catharine Amelia Pybus. They settled at no. 46 George street. Edinburgh. Toward the end of his five-year residence in Edinburgh, in Jeffrey's flat in Buccleuch place, Sydney Smith proposed the setting up of a review as an organ for young malcontents. "I was appointed editor." he says in the preface to the collection of his contributions. "and remained long enough in Edinburgh to edit the first number" (Oct. 1802) of the *Edinburgh Review*. He continued to write for the *Review* for the next quarter of a century, and his brilliant articles were a main element in its success.

Life in London.—He left Edinburgh for good in 1803, when the education of his pupils was completed, and settled in London, where he was morning preacher at Berkeley chapel. Mayfair, and "alternate evening preacher" at the Foundling hospital. He lectured on moral philosophy at the Royal institution for three seasons, from 1804 to 1806, when the London world crowded to Albemarle street to hear him. With the brilliant reputation that Sydney Smith had acquired in the course of a few seasons in London, he would probably have obtained some good preferment had he been on the powerful side in politics. Sydney Smith's elder brother "Bobus" had married Caroline Vernon, aunt of the 3rd Lord Holland. and he was always a welcome visitor at Holland house. His Whig friends came into office for a short time in 1806, and presented him with the living of Foston-le-Clay in Yorkshire. He shrank from this banishment for a time, and discharged his parish duties through a curate; but Spencer Perceval's Residence act was passed in 1808, and after trying in vain to negotiate an exchange, he moved his household to Yorkshire in 1809.

"Peter Plymley."—The ministry of "all the talents" was driven out of office in 1807 in favour of a "no popery" party, and in that year appeared the first installment of Sydney Smith's most famous production, *Peter Plymley's Letters,* on the subject of Catholic emancipation, ridiculing the opposition of the country clergy. Its full title was A *Letter on the Subject of the Catholics to My Brother Abraham Who Lives in the Country, by Peter Plymley*. Nine other letters followed before the end of 1808, when they appeared in collected form. Rumours of Peter Plymley's identity got abroad. Lord Holland wrote to him expressing his own opinion and Grenville's, that there had been nothing like it since the days of Swift (*Memoir,* i, 151). He also pointed out that Swift had lost a bishopric for his wittiest performance. Smith won the hearts of his Yorkshire parishioners as quickly as he had conquered a wider world. There had been no resident clergyman in his parish for 150 years; he had a farm of 300 ac. to keep in order; a rectory had to be built. All these things were attended to besides his contributions to the *Edinburgh Review*. He continued to serve the cause of toleration by ardent speeches in favour of Catholic emancipation. "I defy Dr. Duigenan[1]," he pleaded, addressing a meeting of clergy in 1823, "in the full vigour of his incapacity, in the strongest access of that Protestant epilepsy with which he was so often convulsed, to have added a single security to the security of that oath." At this time appeared one of his most vigorous and effective polemics, *A Letter to the Electors Upon the Catholic Question* (1826).

Later Years.—After 20 years' service in Yorkshire, he obtained preferment at last from a Tory minister, Lord Lyndhurst. who presented him with a prebend in Bristol cathedral in 1828, and two livings in the neighbourhood. From this time he discontinued writing for the *Edinburgh Review* on the ground that it was more becoming in a dignitary of the church to put his name to what he wrote. It was expected that when the Whigs came into power Sydney Smith would be made a bishop. But though he was not without warm friends at headquarters, the opposition was too strong for them. One of the first things that Lord Grey said on entering Downing street was, "Now I shall be able to do something for Sydney Smith"; but he was not able to do more than appoint him in 1831 to a residentiary canonry at St. Paul's in exchange for the prebendal stall he held at Bristol. He was as eager a champion of parliamentary reform as he had been of Catholic emancipation, and one of his best fighting speeches was delivered at Taunton in Oct. 1831 when he made his well-known comparison of the house of lords, who had just thrown out the Reform bill, with Mrs. Partington of Sidmouth, setting out with mop and pattens to stem the Atlantic in a storm.

On the death of his brother Courtenay he inherited £50,000, which put him out of the reach of poverty. He died at his house in Green street, London, on Feb. 22, 1845, and was buried at Kensal Green.

Sydney Smith's other publications include: *Sermons,* 2 vol. (1809); *The Ballot* (1839); *Works,* 3 vol. (1839), including the *Peter Plymley* and the *Singleton Letters* and many articles from the *Edznburgh Review;* A *Fragment on the Irish Roman Catholic Church* (1845); *Sermons at St. Paul's* ... (1846); and some other pamphlets and sermons. Lady Holland said (*Memoir,* i. 190) that her father left an unpublished manuscript. compiled from docu-

[1]Patrick Duigenan, M.P. for the city of Armagh, a Protestant agitator.

mentary evidence, to exhibit the history of English misrule in Ireland, but had hesitated to publish it. This mas suppressed by his widow in deference to the opinion of Lord Macaulay.

BIBLIOGRAPHY.—*A Memoir of the Reverend Sydney Smith by His Daughter, Lady Holland, With a Selection From his Letters Edited by Mrs.* [*Sarah*] *Austin,* 2 vol. (1855); Stuart J. Reid, *A Sketch of the Life and Times of . . . Sydney Smith* (1884); "Sydney Smith" in Lord Houghton, *Monographs Social and Personal (1813)*; A. Chevrillon, *Sydney Smith et la renaissance des idees libérales en Angleterre au XIX^e siècle* (1894); and especially the monograph, with a full description of his writings, by G. W. E Russell in *Sydney Smith,* "English Men of Letters Series" (1905). There are numerous references to Smith in contemporary correspondence and journals.

SMITH, THEOBALD (1859–1934), U.S. pathologist, a pioneer in the comparative etiology and immunology of infectious and parasitic diseases, was born in Albany, N.Y., July 31, 1859. He earned baccalaureate and medical degrees at Cornell university, Ithaca, N.Y. (1881), and Albany Medical college (1883). From 1884 to 1895 Smith was director of the pathological laboratory of the bureau of animal industry in Washington, D.C., where he was also professor of bacteriology at Columbian university (later George Washington university). He served also as director of the pathological laboratory of the Massachusetts state board of health (1895–1915); as professor of comparative pathology at Harvard university (1896–1915); and as director of the department of animal pathology of the Rockefeller Institute for Medical Research (1915–29). Some of his most valuable research included the role of ticks in transmitting Texas or southern cattle fever (1888); his differentiation of bovine from human tubercle bacilli (1898), which was of value to Robert Koch in his later work; and the demonstration that killed cultures of bacteria may produce immunity. He died on Dec. 10, 1934.

See Hans Zinsser, "Biographical Memoir of T. Smith," *Biographical Memoirs of National Academy of Science* (1937–38), with bibliography. (W. F. N.)

SMITH, WALTER BEDELL (1895–1961), U.S. army officer and diplomat, was born in Indianapolis, Ind., Oct. 5, 1895. He began his military career as an enlisted man in the Indiana national guard, 1910–15, and in 1917 mas commissioned second lieutenant of infantry in the U.S. army. In Feb. 1942. during World War II, Smith was appointed secretary of the joint chiefs of staff and U.S. secretary of the combined chiefs of staff, with the rank of brigadier general. The following September he became chief of staff, European theatre of operations, and chief of staff to Gen. Dwight D. Eisenhower, serving in those posts until Eisenhower's departure from Europe after the war. Smith negotiated and accepted for the Allies the surrender of Italy in 1943 and that of Germany in 1945.

On his return to the United States in 1945 Smith became chief of the operations and planning division of the mar department general staff. Shortly thereafter he was appointed U.S. ambassador to the Soviet Union, holding the post from 1946 to 1949. Later he commanded the U.S. 1st army, 1949–50, mas director of the Central Intelligence agency, 1950–53 (having been promoted full general in 1951), and on Jan. 31, 1953, retired from active military service to become undersecretary of state. In Oct. 1954 he resigned from government service and entered private business. He died in Washington, D.C.. on Aug. 9, 1961. General Smith was the author of *My Three Years in Moscow* (1950) and *Eisenhower's Six Great Decisions* (1956). (F. C. PE.)

SMITH, WILLIAM (1769–1839), English geologist, called the father of English geology and known as "Strata Smith," was born at Churchill in Oxfordshire on March 23, 1769. At 18 he became assistant to a surveyor, Edward Webb, of Stow-on-the-Wold, and traversed the Oolitic lands of Oxfordshire and Gloucestershire, the Lias clays and red marls of Warwickshire and other districts, studying their varieties of strata and soils. In 1791 his observations at Stowey and High Littleton in Somersetshire first impressed him with the regularity of the strata. In 1793 he executed the surveys and levelings for the line of the Somerset coal canal, in the course of which he confirmed his supposition, that the strata above the coal were not horizontal. but inclined in one direction —to the east—so as to terminate successively at the surface.

On being appointed engineer to the canal in 1794 he made a tour with regard to inland navigation. He carefully examined the geological structure of England, and corroborated his generalization of a settled order of succession in the strata. In 1794 he coloured his first geological map—that of the vicinity of Bath—showing the ranges of the different strata across England.

In 1799 Smith dictated his first table of British Strata, (presented to the Geological society of London in 1831). It was headed *Order of the Strata, and Their Imbedded Organic Remains, in the Neighbourhood of Bath; Examined and Proved Prior to 1799.* In 1813 Joseph Townsend published, with acknowledgment, much information on the English strata communicated by William Smith, in a work entitled *The Character of Moses Established for Veracity as an Historian, Recording Events From the Creation to the Deluge*. Meanwhile Smith was completing and arranging the data for his large *Geological Map of England and Wales, With Part of Scotland* (15 sheets, 1815). The map—of great significance in the development of modern geology—was reduced to smaller form in 1819; and from this date to 1822, 21 separate county geological maps and several sheets of sections were published in successive years, constituting a *Geological Atlas of England and Wales.*

Smith's collection of fossils was purchased in 1816–18 by the British museum. In 1817 a portion of the descriptive catalogue, *Stratigraphical System of Organized Fossils,* was published. In 1816 he had commenced the publication of *Strata Identified* by *Organized Fossils,* with figures printed on paper to correspond in some degree with the natural hue of the strata. In this work (of which only four parts were published, 1816–19) is exemplified the principle he established of the identification of strata by their included organic remains, which changed the whole conception of paleontology. In 1831 the Geological society of London conferred on Smith the first Wollaston medal; and from the government he received a life pension of £100 per annum. The last years of his life were spent at Hackness (of which he made a good geological map), near Scarborough; and in the latter town. He died at Northampton on Aug. 28, 1839.

Smith's *Memoirs,* edited by his nephew, John Phillips, appeared in 1844.

See C. L. and M. A. Fenton, *Giants of Geology,* rev. ed., pp. 70–83 (1952).

SMITH, WILLIAM FARRAR (1824–1903), U.S. general, was born at St. Albans, Vt.. on Feb. 17, 1824, and graduated from West Point in 1845, being assigned to the engineer branch of the army. In Aug. 1861 he became brigadier general of volunteers, and in July 1862 he received promotion to the rank of major general, U.S. Volunteers. Smith led with conspicuous valour at Antietam and later was placed at the head of the 6th corps of the army of the Potomac, which he led at the disastrous battle of Fredericksburg (*q.v.*). The recriminations which followed led to a general order in which Smith and several other senior officers of the army were dismissed and suspended by Gen. Burnside. As a brigadier general Smith commanded troops in Pennsylvania during the critical days of the Gettysburg campaign. Later, in 1863, as chief engineer of the army of the Cumberland, he conducted the engineer operations which reopened the "cracker-line" from Chattanooga (*q.v.*) to the base of supplies. For the Virginian campaign of 1864 Smith was specially assigned by Grant to command the 18th corps, army of the James, and he took part in the battle of Cold Harbor and the first operations against Petersburg, after which, while absent on leave, he was suddenly deprived of his command by Grant. He resigned from the Volunteers in 1865 and from the U.S. army in 1867. After 1881 he was engaged in civil engineering work.

Smith died at Philadelphia on Feb. 28, 1903.

SMITH, WILLIAM HENRY (1825–1891), English man of business and statesman, was born in London on June 24, 1825. His father was the founder of the distributing firm of W. H. Smith & Son, in the Strand, and at an early age he became a partner and devoted himself to the business. In 1865 he contested Westminster in the Conservative interest against John Stuart Mill. He failed, but he won the seat in 1868. He was secretary to the treasury (1874), first lord of the admiralty (1877) secretary for war (1885), chief secretary for Ireland (1885), secretary for war (1886), and in the end of that year first lord of the treasury and leader of the House of Commons. He was no orator, and made no pretence to genius, but his success in these high offices was complete, and was due to the universal respect which was gained by his patience, good temper, zeal for the public service, and thorough kindness of heart. He died at Walmer Castle (which he occupied as Warden of the Cinque Ports) on Oct. 6, 1891. In recognition of his services a peerage in her own right was conferred on his widow, with the title of Viscountess Hambleden.

SMITH, WILLIAM ROBERTSON (1846–1894), Scottish philologist, physicist, archaeologist, Biblical critic, and editor, from 1881, of the 9th edition of this *Encyclopædia,* was born on Nov. 8, 1846, at Keig in Aberdeenshire, where his father was Free Church minister. He was educated at home and at Aberdeen University, where he won, among other honours, the Ferguson mathematical scholarship. In 1866 he entered the Free Church college at Edinburgh as a student of theology. During two summer sessions he studied philosophy and theology at Bonn and Göttingen. From 1868 to 1870 he acted as assistant to the professor of natural philosophy in Edinburgh University. During this period he produced much original work in the experimental and mathematical treatment of electricity. In 1870 he was appointed and ordained to the office of professor of Oriental languages and Old Testament exegesis at the Free Church college, Aberdeen. He was the pupil and personal friend of many leaders of the higher criticism in Germany, and from the first he advocated views which, though now widely accepted, were then regarded with apprehension. The articles on Biblical subjects which he contributed to the 9th edition of the *Encyclopædia Britannica* distressed and alarmed the authorities of the Free Church. In 1876 a committee of the General Assembly of that Church reported on them so adversely that Smith demanded a formal trial, in the course of which he defended himself with consummate ability and eloquence. The indictment dropped, but a vote of want of confidence was passed, and in 1881 Smith was removed from his chair. At the end of the trial he was probably the most popular man in Scotland. Marks of sympathy were showered on him from all sides.

In 1875 he was appointed one of the Old Testament revisers; in 1880–1882 he delivered by invitation, to very large audiences in Edinburgh and Glasgow, two courses of lectures on the criticism of the Old Testament, which he afterwards published *(The Old Testament in the Jewish Church,* first edition 1881, second edition 1892, and *The Prophets of Israel,* 1882, which also passed through two editions); and soon after his dismissal from his chair he joined Professor Baynes in the editorship of the *Encyclopedia Britannica,* and after Professor Baynes's death remained in supreme editorial control till the work was completed. His versatility, firmness combined with tact, width of view, and painstaking struggle for accuracy were largely responsible for the maintenance of its high standard. But he did not let his other duties interfere with his Semitic studies. He visited Arabia, Egypt, Syria, Palestine, Tunis and southern Spain, and had an intimate knowledge of, and personal acquaintance with, not only the literature, but the life of the East. His early friendship with J. F. McLennan, that most original student of primitive marriage, had a great influence on Smith's studies, and his attention was always strongly attracted to the comparative study of primitive customs and their meaning. His chief contributions to this branch of learning were a section of the article "Sacrifice" in the 9th edition of the *Encyclopædia Britannica,* his *Kinship and Marriage in Early Arabia* (Cambridge, 1885), and his *Lectures on the Religion of the Semites* (1st ed. 1889, 2nd ed. 1894). His originality and grasp of mind enabled him to seize the essential among masses of details, and he had in a marked degree the power of carrying a subject farther than his predecessors.

In 1883 Robertson Smith was appointed Lord Almoner's Professor of Arabic at Cambridge, which henceforth became his home. He occupied rooms in Trinity college till 1885, when he was elected to a professorial fellowship at Christ's college. In 1886 he became university librarian, and in 1889 Adams professor of Arabic. In 1888–1891 he delivered, as Burnett lecturer, three courses of lectures at Aberdeen on the primitive religion of the Semites. Early in 1890 grave symptoms of constitutional disease manifested themselves, and the last years of his life were full of suffering, which he bore with the utmost courage and patience. He never ceased to work, and when near his end was actively engaged in planning the *Encyclopaedia Biblica,* which he had hoped to edit. He died at Cambridge on March 31, 1894, and was buried at Keig. Small and slight in person and never robust in health, Robertson Smith was yet a man of ceaseless and fiery energy; of an intellect extraordinarily alert and quick, and as sagacious in practical matters as it was keen and piercing in speculation; of an erudition astonishing both in its range and in its readiness; of a temper susceptible of the highest enthusiasm for worthy ends, and able to inspire others with its own ardour; endowed with the warmest affections, and with the kindest and most generous disposition, but impatient of stupidity and ready to blaze out at whatever savoured of wrong and injustice. The sweetness and purity of his nature combined with his brilliant conversational powers to render him the most delightful of friends.

See the *Life* by J. S. Black and G. W. Chrystal (1912); *see* also James Bryce, *Studies in Contemporary Biography* (1903).

SMITH, SIR WILLIAM SIDNEY (1764–1840), English admiral, was born at Westminster on July 21, 1764, and entered the navy. In Jan. 1780 he was appointed lieutenant of the "Alcide" (74) after serving at Cape St. Vincent under Rodney; and in May 1782 was made commander of the "Fury" sloop, and promoted captain. He was knighted for his services (1790–92) in advising the king of Sweden during the war with Russia. In 1793 he assisted Lord Hood in the attempt to burn the enemy's ships at Toulon. In 1796 he was captured while hunting French privateers in the Channel, and imprisoned in Paris, whence he made his escape in 1798. In 1799 he left Constantinople, where he was plenipotentiary jointly with his brother, and hastened to the relief of St. Jean d'Acre, compelling Napoleon to raise the siege in May. For this exploit he received an annuity of £1,000. Smith co-operated with Abercromby in Egypt, and was wounded at Aboukir. Promoted rear-admiral of the blue in 1805, he was sent in 1806 to Sicily and Naples, and relieved Gaeta and captured Capri. Proceeding to Malta in 1807, he destroyed the Turkish fleet off Abydos, and in the following November blockaded the Tagus and assisted the Portuguese royal family to embark for Rio de Janeiro. Recalled from Rio de Janeiro, where he had been sent as commander-in-chief (1808), owing to his quarrel with the British minister, he was made a vice-admiral of the blue (1810) and in 1812 was sent to the Mediterranean, as second in command under Sir Edward Pellew. Made K.C.B. in 1815, and admiral in 1821, he died on May 26, 1840, at Paris. His self-assertion brought him into conflict with many of his contemporaries, including Nelson and Sir John Moore, but he was a daring and ingenious officer.

See Barrow, *Life of Admiral Sir W. S. Smith* (2 vols., 1848).

SMITH, WINCHELL (1871–1933), U.S. playwright, directed and wrote, usually with others, a number of popular successes. Born in Hartford, Conn., on April 5, 1871, he attended school there. He was an actor in New York city from 1892 and in 1904 began to produce, with Arnold Daly, plays by George Bernard Shaw. In 1906 he dramatized, with Byron Ongley, Barr McCutcheon's *Brewster's Millions,* the story of a man who had to spend $1,000,000 within a year. Smith's legendary actor "George Spelvin" (a second name given to a member of the cast who played two parts) first "appeared" in that play. His comedy *Lightnin'* (1918), written with Frank Bacon who starred in it, ran for 1,291 performances, a new record.

Smith's other plays included *The Fortune Hunter* (1909), in which John Barrymore appeared, and *The Only Son.*

He died on June 10, 1933.

SMITH COLLEGE, an institution for the higher education of women at Northampton, Mass. It was founded under the will of Sophia Smith (1796–1870) of Hatfield, who chose the neighbouring town of Northampton as the site of the college and selected the first trustees. The college was chartered in 1871 and opened in 1875. It became the largest independent college for women in the United States.

The equipment of the college consists of a campus of more than 200 ac., including about 30 ac. for athletics, dormitory units, the Neilson library, the Hillyer and Tryon Art galleries, Sage hall for music, the Lyman plant houses and a botanic garden, a swimming pool, an infirmary, a students' building containing a theatre, a student centre, an auditorium seating more than 2,000, gymnasiums and boat houses.

All students enter by the examinations of the college entrance examination board. The undergraduate courses, which are chiefly elective, lead to the degree of bachelor of arts. About 20% of the students in the junior and senior (third- and fourth-year) classes follow honours programs which allow a maximum amount of flexibility and give opportunities for individual work. Graduate courses lead to master's degrees in arts, education, physical education and, more rarely, to the degree of doctor of philosophy.

The Smith college school for social work, which established an eight weeks' summer session and programs of supervision in field work in various cities in winter, trains psychiatric social workers and prepares students for the degree of master of social science. Scholarships and fellowships are offered annually. From 1925 the college sent groups of students abroad, each under the direction of a member of the faculty, for study in the junior year, groups of Smith college juniors being established in Paris, Fr., Geneva, Switz., Florence, It., and Madrid, Sp. The college also made an exchange arrangement with the University of Toronto and sent students to the Wayne university junior-year in Munich. The department of education conducts a nursery school and a day school.

The college publishes the Smith College Studies in history, classics, modern languages and social work.

The college is governed by a board of 15 trustees, 4 of whom are nominated by the alumnae and serve for eight years, the others, with the exception of the president, serving for ten years and retiring in rotation. (W. A. N.; B. F. W.)

SMITH-DORRIEN, SIR HORACE LOCKWOOD (1858–1930), British general, was born on May 26, 1858. He joined the army in 1876, took part in the Zulu War and in the Egyptian campaign of 1882 and, attached to the Egyptian army, served at Suakim in 1884 and on the Nile in 1885–86. He took part in the Tirah campaign of 1897–98, in the final advance to Khartum in 1885 and later in South Africa. After being adjutant-general in India, he held the Aldershot command until 1912, when he was transferred to the Southern command.

On the death of Sir James Grierson in Aug. 1914, Sir H. Smith-Dorrien was appointed commander of the II. Army Corps. His troops received the brunt of the enemy's onset at Mons, and, although his action in giving battle at Le Cateau was criticized, it was subsequently recognized that it saved the British army from disaster. Afterward he commanded his corps at the battle of the Marne, on the Aisne, and during the severe fighting in Flanders in October and November. On the splitting-up of the expeditionary forces into two armies he was appointed to the command of the 2nd. Difficulties with the commander in chief led, in April 1915, to his return to England where he was placed in charge of one of the home defense armies. In the following November he was chosen to take charge of the operations against German East Africa, but he fell ill on the voyage out, and had to return home. From 1918–23 he was governor and commander in chief of Gibraltar. After his retirement in 1923 he published (1925) Memories of 48 Years' Service. He died Aug. 12, 1930.

SMITHSON, HENRIETTA CONSTANCE (1800–1854), Irish actress, the daughter of a theatrical manager, made her first stage appearance in 1815 at the Crow Street theatre, Dublin, as Albina Mandeville in Reynolds' Will. Three years later she appeared at Drury Lane, London, as Letitia Hardy. She had no particular success in England; but in Paris, in 1828 and 1832, where she first went with Macready, she aroused immense enthusiasm as Desdemnna, Virginia, Juliet and Jane Shore. She died on March 3, 1854.

SMITHSON, JAMES (1765–1829), English scientist and founder of the Smithsonian institution at Washington, D.C., was the natural son of Hugh Smithson Percy, first duke of Northumberland of the third creation. The duke's family name was Smithson. James Smithson's mother, Elizabeth Keate Macie, was a gentlewoman of large fortune, who had been twice married before James Smithson was born. She was a lineal descendant of King Henry VII. Most of Smithson's large fortune came from his mother's family but some also came from his father's relatives. He was educated at Pembroke college, Oxford, and is said to have been the best chemist and mineralogist of his year. He later became well known for his important work in these fields. The carbonate of zinc is named smithsonite (*q.v.*) in his honour. At the age of 22 he was admitted into membership in the Royal society on the recommendation of the great physicist Henry Cavendish, among others. He had a great regard for original research and publication. He wrote: "Every man is a valuable member of society who by his observations, researches, and experiments procures knowledge for men."

Smithson never married. Much of his life was spent on the continent, where he was well acquainted with the scientific leaders of the period. He died in Genoa, Italy, on June 27, 1829. The founding of the Smithsonian institution in Washington, D.C., was the result of a provision of Smithson's will. During his life Smithson never visited America, but in 1904 his remains were brought to the U.S. and are now interred in the original building of his institution in Washington. See also SMITHSONIAN INSTITUTION.

(L. CAR.)

SMITHSONIAN INSTITUTION, an institution of learning in Washington, D.C., founded by the bequest of an English scientist, James Smithson (*q.v.*). His estate was left to a nephew, Henry James Hungerford, with the stipulation that, should Hungerford die without issue, or should his issue die intestate or under 21, the whole estate should go "to the United States of America, to found at Washington, under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge among men." Hungerford died without issue in 1835. There was much opposition in the U.S. to the acceptance of Smithson's bequest, especially by John C. Calhoun and others, who held that congress had no power under the constitution to accept such a gift, but it was accepted, largely through the efforts of John Quincy Adams.

Establishment. — In Sept. 1838 £104.960 in gold sovereigns was delivered from the clipper "Mediator" to the Philadelphia mint, where it was recoined into U.S. money to the amount of $508,318.46. In 1867, after the death of Hungerford's mother, a residuary legacy of $26,210 was received and the fund then amounted to $650,000. By savings of interest and by other gifts the fund was increased.

After 10 years of debate congress in 1846 accepted the trust and created by enactment an "establishment" called the Smithsonian institution, consisting of the president of the United States, the vice-president. the chief justice and the members of the president's cabinet. The institution has a secretary who is its executive officer. Smithson's money, a great fortune in that day, was lent to the U.S. treasury, the government agreeing to pay perpetually 6% interest upon it. The act of congress that created the institution provided that it should be governed by a board of regents composed of the vice-president and chief justice, three members of the senate, three members of the house of representatives and six private citizens. The act also provided for a library and for a museum to contain "objects of art and of foreign and curious research, and objects of natural history, etc.," belonging to the United States. The museum was later designated the United States National museum but remains under the direction of the Smithsonian institution.

The regents met for the first time on Sept. 7, 1816, and in the autumn of the same year they elected as secretary Joseph Henry (*q.v.*), then a professor at Princeton university, known for his experiments on the electromagnet and other subjects relating to electricity. Under his guidance the institution took shape. Henry seized the unique opportunity offered by the opening up of the great western areas of the United States to make collections of vegetation and wildlife and to study the Indian tribes. A principal feature of his administration was the establishment of international exchanges of scientific literature.

The diffusion of knowledge was promoted by publishing a series of periodical reports on the progress of different branches of knowledge, occasional separate treatises on subjects of general interest and monographs on special subjects investigated by experts. The Smithsonian was probably the first establishment in the United States to have a staff of full-time research scientists in a broad series of fields. In 1846 a plan was presented for the unification and systematization of weather observation under the institution. In Dec. 1847 an appropriation was made by the board for such meteorological research; in 1849 telegraphic transmission of meteorological intelligence collected by the institution mas begun; weather maps were successfully made in 1856. In 1870 the meteorological work of the institution was incorporated with the U.S. army signal corps. Still later the U.S. weather bureau was established by act of congress. After 1854 Henry's annual reports contained a general appendix with reports of lectures, such as were held under the auspices of the institution until 1865, summaries of correspondence, special papers, etc.

National Museum. — Spencer F. Baird (*q.v.*), Henry's successor, incorporated in the general appendix annual reports on the progress of the sciences. He also perfected Henry's system of international exchanges under which the institution, through agents in the principal cities of the world, exchanges its own publications, those of other departments of the U.S. government and those of learned societies for foreign publications. Baird had been at the head of the US. National museum, a branch of the institution, before he became secretary of the institution, and the museum particularly was developed during his administration. It was built up around the collections of the U.S. patent office, which were turned over to it in 1858, and those of the National institute, transferred to the Smithsonian in 1861 when the institute was dissolved. A part of the collection (including Smithson's collection) was destroyed by fire in 1865. The museum gained much valuable archaeological and ethnological material from the exploring parties sent out under John Wesley Powell (*q.v.*). It obtained excellent ichthyological specimens through Baird's position as U.S. fish commissioner, and acquired general collections from the Centennial exhibition of 1576. Its great collection of plants is known as the National herbarium. The museum had a phenomenal growth. In 1960 it occupied parts of three Smithsonian buildings and its catalogued objects totaled more than 54,000,000, distributed among its eight departments (anthropology, botany, geology zoology, science and technology, arts and manufactures, civil history and armed forces history).

The Bureau of American Ethnology was established as a branch of the institution in 1879, when the various organizations doing survey work in the west united as the U.S. geological survey, and anthropological and ethnological research was transferred to the Smithsonian institution. The bureau carried on studies of the American Indians and published monographs and reports of its researches. The river basin surveys became an active program of the bureau in 1945 when a unit was organized to salvage and preserve archaeological materials in the path of national flood-control, irrigation, hydroelectric and navigation projects.

Astrophysical Observatory. — In 1887 Samuel P. Langley (*q.v.*) was appointed as assistant secretary of the institution, and succeeded as secretary upon Baird's death in the same year. In 1890 Langley established the Smithsonian Astrophysical observatory to carry on research on the physical aspects of the heavenly bodies, particularly the sun. Its early research concerned especially the measurement of the intensity and characteristics of the infrared solar rays. Langley developed the bolometer, an instrument capable of recording one-millionth of a degree of temperature. After 1900 the research concentrated on measuring the quantity and quality of the sun's radiation as it is found in free space at the earth's mean diameter. Field stations for solar observation mere operated at several points in Africa, South America and the United States. In 1955 the observatory moved its scientific headquarters to Cambridge, Mass. Its activities encompassed the study of meteorites and the optical tracking of artificial earth satellites.

National Zoological Park. — By acts of congress of March 2, 1889, and April 30, 1890. the National Zoological park mas established under the institution. In a wooded area of 175 ac. in the valley of Rock creek in Washington, D.C.. the institution installed a small collection of animals that later grew to be one of the foremost collections of its kind in the United States.

Art Collections. — Upon her death in 1903, Mrs. Harriet Lane Johnston left her art collection to a national gallery of art, when such a gallery should be established. In 1906 the supreme court of the District of Columbia decreed that the art collection of the Smithsonian institution was a national gallery, and turned the bequeathed collection over to it. It was later renamed the National Collection of Fine Arts. Housed in the Smithsonian's natural history building. the gallery attracted gifts of great interest and value, including the Ralph Cross Johnson collection of old masters the William T. Evans collection of paintings of American artists and the John Gellatly collection of paintings, glass, jewels and antiques. The gallery also directs a Smithsonian traveling exhibition service.

In 1907 Charles Doolittle Walcott (*q.v.*), eminent geologist and paleontologist, was elected secretary. During his administration of almost exactly 20 years the outstanding event for the Smithsonian was the receipt of the gift by Charles L. Freer of Detroit, Mich., of the Freer Gallery of Art, together with a large testamentary endowment. The Freer gift comprised more than 9.000 pieces, including works of American artists, especially James McNeill Whistler, Dwight W. Tryon, Abbott H. Thayer and T. W. Dewing, and of Japanese and Chinese masters, including precious screens ceramics and bronzes.

A major event of the 1930s was the establishment of the National Gallery of Art, the gift of Andrew W. Mellon (*q.v.*) to the American people, as a bureau of the Smithsonian.

Further Developments. — In 1928 Charles Greeley Abbot, astrophysicist and assistant secretary of the Smithsonian from 1918. was elected secretary. He continued the researches begun by Langley on the variation of the sun's radiation, improving instruments and methods and establishing three solar observatories in aidely separated regions of the earth.

Abbot was succeeded in 1945 by Alexander Wetmore, eminent ornithologist, whose administration was marked by the addition of two bureaus to the Smithsonian organization, both in 1946—the National Air museum, created by congress to collect, preserve and display aeronautical equipment of historical interest and significance; and the Canal Zone Biological area, a 3,000-ac. jungle-covered reserve on Barro Colorado Island, C.Z., where a wide variety of biological studies are conducted.

Leonard Carmichael, psychologist. became secretary in 1953. Under his leadership two Smithsonian programs mere notably advanced—an extensive project of renovating and modernizing museum exhibits; and a long-term program to provide new buildings for the growing institution. The total number of visitors to the Smithsonian, including all its buildings, exceeds 12,000,000 each year.

The Smithsonian park occupies an area in Washington, D.C., equivalent to about 12 city blocks. The oldest building. that of the institution proper. was erected in 1847–55. It is of Seneca brownstone in a mingled Gothic and Romanesque style, designed by James Renmick (*q.v.*), and is located in the southwestern part of the grounds. Southeast of it is the arts and industries building, erected in 1881; on the north side of the park is the natural history building (1911). Southwest of the original Smithsonian building is the Freer Gallery of Art (1921). The monumental National Gallery of Art building (1941) faces on the Mall and Constitution avenue, between Fourth and Seventh streets, N.W. In 1959 construction of a new building for a museum of history and technology was begun directly west of the natural history building. On the grounds is a bronze statue of Joseph Henry by W. W. Story.

Publications. — The institution conducts an extensive publication program and has issued and distributed throughout the morld about 10,000 scientific books and monographs. in the following series: Annual *Reports* (1846 *et seq.)*, in which the *Reports* of the

National museum were included until 1884, after which the museum *Reports* appeared as separate volumes; *Smithsonian Contributions to Knowledge* (1848–1916); *Smithsonian Miscellaneous Collections* (1862 *et seq.*); *Proceedings of the United States National Museum* (1878 *et seq.*); *Bulletins of the United States National Museum* (1875 *et seq.*), containing larger monographs than those printed in the *Proceedings,* and including *Contributions From the United States National Herbarium* (1890); *Annual Reports of the Bureau of American Ethnology* (1880 *et seq.*); *Bulletins of the Bureau of American Ethnology* (1886 *et seq.*); *Annals of the Astrophysical Observatory* (1900 *et seq.*); *Smithsonian Contributions to Astrophysics* (1956 *et seq.*); *Catalogues of the National Collection of Fine Arts* (1922 *et seq.*); *Oriental Studies of the Freer Gallery of Art* (1933 *et seq.*); *Freer Gallery of Art Occasional Papers* (1951 *et seq.*); and *Ars Orientalis* (1954 *et seq.*), sponsored jointly by the Smithsonian institution and the University of Michigan.

SMITHSONITE, a mineral consisting of zinc carbonate, an ore of zinc which was formerly, until sphalerite (*q.v.*) began to be used in the 1880s, the principle source of all zinc produced (*see* also ZINC). In England smithsonite is known as calamine (*q.v.*). The formula of smithsonite is $ZnCO_3$. It crystallizes in the hexagonal system and is a member of the calcite group. Crystals are rare; it occurs usually in crusts or botryoidal masses. A porous variety is called dry-bone ore. The hardness is 4 to 4.5, and the specific gravity is 4.43 for the pure material, but varies with isomorphous replacement of the zinc by iron, manganese, calcium and magnesium. The colour of the pure mineral is white, but it is more often brownish and sometimes green or blue; a bright yellow variety containing some cadmium sulfide has been found in Arkansas and is known as "turkey-fat" ore. It is a secondary mineral, formed by the action of ground water containing carbon dioxide on primary zinc minerals. It is frequently associated with hemimorphite, sphalerite and galena.

Smithsonite occurs in Silesia and the Rhineland (Germany); Sardinia (Italy); Laurium, Greece (a translucent blue-green variety); Santander, Spain; Missouri, New Mexico, Utah, Colorado, Montana and other localities in the United States; and in Algeria, Tunisia, Northern Rhodesia and Tsumeb, South-West Africa. The mineral was named after James Smithson, the founder of the Smithsonian institution. (L. S. RL.)

SMOG: *see* SMOKE AND SMOKE PREVENTION; FOG; DUST.

SMOHALLA (SHMOQULA; *i.e.,* "preacher"), a religious prophet of the North American Indians and founder of the sect called Dreamers, was born in the Columbia river valley about 1820 and became chief of the Wanapum tribe in Washington state. On one occasion after a tribal fray he was left for dead, but recovered and journeyed through California, Mexico, Arizona and Nevada back to his home on the upper Columbia, where he announced that he had been in the spirit world and had returned with a new revelation. This consisted in a return to primitive Indian customs, and a ritual combining genuine Indian features with what he remembered of Roman Catholic ceremonies. Smohalla had frequent trances and his influence extended over most of the tribes of eastern Washington and Oregon and western Idaho. The sect gave much trouble from 1870 to 1885 by refusing to come under reservation restrictions. A church was established at Priest Rapids on the upper Columbia, and one at Union Gap on the Yakima reservation. Smohalla died about 1908 but his religion continued to be influential.

See J. Mooney, "The Ghost-Dance Religion," in *14th Annual Report,* Bureau of Ethnology (1896).

SMOKE: IN WARFARE. While smoke has been one of the symbols and signs of warfare from earliest times, it was usually fire—rather than its by-product, smoke—that was dreaded by ancient armies in the field. Among primitive warriors, the American Indians had learned to employ smoke as an adjunct to military activity. They developed a visual signaling system of ascending smoke puffs that could be seen and interpreted by friendly tribesmen at considerable distances. Up until World War I, however, the use of smoke for tactical purposes was confined to special situations and was produced by improvised methods. It was during World War I that smoke and other chemical munitions had their inception on a standardized basis on the battlefields of Belgium and France. Later the employment of smoke munitions in warfare became recognized doctrine in all armies. In military operations smoke is used to advantage by ground, air and naval forces either on the offensive or on the defensive. Its main purposes are (1) screening and (2) signaling.

Screening Smokes.—For tactical and strategic purposes, smoke clouds are formed by firing smoke shells, dropping smoke bombs, burning smoke pots or operating mechanical smoke generators. These clouds are made up of masses of tiny particles that remain suspended in the air and hence produce an obscuring curtain. The behaviour of the smoke is dependent on wind and other natural factors, but the mechanical agencies that are used to create the clouds give them certain initial characteristics. Smoke created by a bursting shell, for instance, is released instantaneously and quickly forms into an expanding, rising puff. Smoke pouring from a continuing source, such as smoke pots, generators and burning-type shells, on the other hand, rises in a long, unbroken stream and remains effective for much greater periods of time. In deciding on the use of smoke under a given tactical situation, the commander must be thoroughly familiar with the prevailing natural conditions of the area in which the target is located and know the possibilities and limitations of the smoke munitions immediately available to him. Otherwise, the employment of smoke might revert to the advantage of the hostile forces.

While the direction and the velocity of prevailing winds exert the major effect on released smoke, humidity and the nature of the terrain also have a bearing on its behaviour. As might be expected, the obscuring power and effective duration of smoke is enhanced under conditions of high humidity. Ordinary ranges of temperature encountered in the field, however, have no perceptible effect. Level and unbroken terrain is reflected in a more evenly spread obscuring cloud above it, whereas smoke over hilly and broken terrain is less predictable because of the prevalence of inconsistent and erratic wind directions and speeds in such areas. In wooded regions smoke clouds persist longer and tend to cling to the treetops. Ordinarily smoke will follow ravines and defiles that crease the terrain in target sectors. A variety of chemical shells produce smoke of varying properties that help overcome, or at least minimize, many of the screening handicaps inherent in the prevailing natural conditions of the battleground. Whenever smoke is used there is need for adequate observation and close co-ordination so that gaps and bare spaces that occur in the curtain can be readily repaired by directing artillery to fire smoke-producing munitions to the proper sectors of the target.

Individual soldiers and military units of all sizes have some means at their disposal for producing smoke. Smoke-producing munitions include the hand grenade and rifle grenade designed for the use of the individual soldier. Shells are made for firing from mortars, howitzers and guns. In the U.S. army, they range in size from those fired by 4.2 in. mortars up to the big 155 mm. guns and howitzers used by the ground forces. Airplanes use either smoke generators or bombs when assigned to screening missions. Generator-produced smoke establishes long, low-hanging, persistent curtains and can be used over water as well as land areas. Naval vessels are equipped with smoke generators to provide smoke curtains for self-concealment. In amphibious operations, guns mounted on ships of war fire gas shells at enemy installations. Under certain circumstances, smoke pots which will float on the surface of the water can be launched.

The most widely used chemical agent in smoke-producing artillery shells is white phosphorus. This chemical is inert when sealed in airtight jackets but burns and produces billows of dense white smoke when the shell bursts and the contents are exposed to the atmosphere. Special petroleum oils, heated and mixed with steam, are the smoke-producing agents used in mechanical smoke generators.

In tactical situations, smoke has many purposes that result in reducing casualties. saving matériel and speeding up operations in favour of the using forces. Its most important functions are to (1) blind hostile observation; (2) reduce effectiveness of enemy fire power: (3) hamper and confuse enemy operations; and (4) deceive the foe regarding the user's tactical preparations. Field tests and combat experience prove that the fire from troops enveloped by smoke is tremendously less effective than that from troops aiming into it. As a consequence. an attacking force can develop an advantage by firing smoke shells directly on hostile defensive positions both before and during an assault. This will not only minimize enemy fire power but will cause confusion among his troops. At the same time smoke conceals from enemy observation the size, deployment pattern. armament and movement of the, advancing forces so that they achieve a certain degree of surprise in the attack. This is particularly important in assaults on strong points such as caves, dugouts. bunkers, pillboxes and machine gun emplacements where success is dependent upon getting close enough to the target so that flame throwers or hand grenades can be used effectively. Before the introduction of modern smoke munitions, attacking forces were obliged to rely on the natural concealment of night and early dawn to create similar advantages.

In the rear areas as well as in the combat zones smoke screens are used to conceal vital targets from observation and air attack Troop concentrations, supply dumps, ports. communication centres, towns and industrial areas can be given this screening security in both daylight and darkness. If the strategic situation indicates the need. smoke curtains can be maintained continuously in friendly locations over periods of weeks or even months by the use of mechanical generators. Smoke screens are sometimes used for deceptive purposes. Spread over strategically valueless areas they divert enemy attention from real targets and tend to draw wasted fire or useless bombing.

Signal Smokes. — Smoke munitions used for signaling or marking purposes contain organic dyes mixed with the basic burning chemicals which produce coloured smoke clouds. These clouds are visible for miles in good weather. Smoke-signal munitions come in a variety of colours. each having its own significance By using different colours or combinations of colours. almost any type of information concerning objectives can be conveyed to friendly forces deployed over wide areas. Coloured smokes are most frequently used to mark targets, to signal the need of specialized attack on specific objectives, to announce the time for attack and to call for artillery fire. Artillerymen often use signal-smoke shells for registering fire on targets. Smoke signals are also used to indicate rallying points and assist members of units in getting oriented in difficult terrain during the heat of battle. In joint air and ground operations, troops use coloured smoke signals to identify themselves and their positions to friendly aircraft. For the use of the individual soldier. coloured smoke chemicals are contained in hand and rifle grenades. They are also used in various sizes of artillery shells as well as in smoke pots.

See also CHEMICAL WARFARE. (M. B. H.)

SMOKE AND SMOKE PREVENTION. The character of smoke varies according to its source, but the smoke that is produced in far the largest quantities and has the most injurious effects is caused by using raw bituminous coal as a fuel.

Most fuels consist of carbon, hydrogen, oxygen and nitrogen, with usually a little sulfur also, while in solid fuels there is also incombustible mineral ash. If complete combustion were attained no fuel would emit smoke. the final products being limited merely to carbon dioxide. water vapour and free nitrogen, all quite innocuous gases. But, if sulfur is present, small quantities of sulfur dioxide are also given off; and this, although not visible, has a pungent smell and, in contact with air and moisture, tends rapidly to be converted into a corrosive acid.

For complete combustion a fuel must be brought into contact with enough air for full oxidation while maintained at a sufficiently high temperature. These conditions are by no means easy to fulfill, and in practice fuels always elude complete combustion. The unburned products vary widely both in amount and in composition according to the nature of a fuel and the way in which it is used. They are moreover, not necessarily in the form of smoke, since with insufficient air carbonaceous materials may emit gaseous intermediate products such as carbon monoxide and unsaturated hydrocarbons: but whether or not smoke is produced, imperfect combustion is always indicative of thermal loss

Gaseous fuels in properly constructed and properly adjusted burners produce neither smoke nor other unburned products in appreciable quantity. An inadequate air supply, however, or the chilling or smothering of the flames, may result in unburned gaseous products, including carbon monoxide and oxides of nitrogen. both highly poisonous; or in extreme cases may even cause the deposition of soot.

Smoke From Solid Fuels. — Because of their relatively high density, the problem of bringing solid fuels into contact with sufficient air for complete oxidation is greatly intensified. and, even with an air supply far in excess of that theoretically required perfect combustion is not feasible. Anthracite, however. which is naturally nearly free from volatile matter, or coke, from nhich the volatile matter of the original coal has been artificially extracted, can be burned, if not completely, at least without emitting smoke. With bituminous coals. on the other hand, some smoke is practically unavoidable; for such coals decompose at temperatures belon the ignition point, evolving combustible gases and condensable tarry vapours. Coal smoke consists of unconsumed distillation products. in association with carbon and tarry matter condensed by premature chilling of flame, together nith dust and ash entrained by the upward rush of hot air and gases from the grate Some of this settles on the walls of the flue as soot; the remainder is carried out through the chimney into the atmosphere with the excess air and gaseous products of combustion, both burned and unburned.

The total home consumption of coal in Great Britain in the second half of the 20th century averaged more than 215,000,000 tons annually. Of this over 60,000.000 tons have gone to meet domestic requirements, the remainder being used industrially, largely for steam raising and for making gas and electricity. Coals of relatively low volatile content are used for steam raising; and nhen due attention is paid to furnace design. stoking procedure and draft control these coals can be burned without much smoke and nith remarkably high efficiencies of steam generation. On the other hand, in certain metallurgical furnaces, etc , it is claimed that a smoky atmosphere is essential. Other sources of industrial pollution are collieries railways, shipping, power stations. coke ovens and gasnorks the clay industries, etc.

Most of the British domestic coal supplies are drawn from highly bituminous seams, and, since they are burned in a very haphazard and careless manner, with little possibility of proper air regulation, it is not surprising to learn that the domestic chimney is on the whole responsible for far more than its proportionate share of smoke and soot. In London, two-thirds of the total smoke is domestic but in centres of iron. steel or pottery manufacture, or in the immediate vicinity of large works, industrial smoke may obviously preponderate. Apart from considerations of its quantity, hen-ever, domestic smoke is in character far more objectionable than factory smoke, as it contains relatively high proportions of tar. nhile boiler smoke consists largely of ash and dust. The sticky nature of tarry soot causes it to adhere tenaciously to anything with which it comes into contact and, since it usually contains free sulfur acids in addition to ammonium sulfate, it has a destructive action upon stone, fabrics, metals and vegetation.

In 1912, under the auspices of the Coal Smoke Abatement society, a voluntary committee was appointed for the investigation of atmospheric pollution. This later became an advisory committee of the meteorological office, but in 1927 was transferred to the department of scientific and industrial research as the atmospheric pollution research committee. Annual reports are published by

H.M. stationery office. The chief aim throughout has been the compilation and collation of systematic information respecting the nature and amount of atmospheric pollution in various localities, as carried out in co-operation with various local authorities.

Town air contains large numbers of suspended solid particles, which of course are not derived exclusively from smoke but include also dust, vegetable matter, etc. These tend gradually to settle down under the force of gravity. The impurities so deposited can be caught in a suitable receptacle and analyzed and, collected under similar conditions in different places, afford material for interesting comparisons. The lowest deposits, measured in the smaller towns or in suburban districts, amount annually to 75–100 tons per square mile; the highest deposits, measured in the heart of large industrial areas, reach ten times these amounts. Altogether, in Great Britain. about 3,000,000 tons of solid matter and about 5,000,000 tons of sulfur dioxide are emitted into the atmosphere every year.

One of the most interesting features is the gradual alteration shown in the composition of the deposit from town to country, particularly in regard to carbonaceous matter and sulfates. In the heaviest deposits the proportion of carbonaceous and tarry matter is relatively high, usually 20%–25% of the total, but in the lightest deposits it may fall as low as 10%. On the other hand sulfates. which (as sulfur trioxide) in city deposits account for only 5%–15% of the total. may rise to 20% in country districts. In London the impurity suspended in the atmosphere is at its minimum between midnight and 6 A.M., subsequently rising rapidly, on the lighting of fires, to a maximum at 9 or 10 A.M.. after which it gradually falls again; pollution is naturally less in summer than in winter, and Sundays are on the whole the cleanest days.

Evil Effects of Smoke.—Smoke damages health, property and vegetation and causes greatly increased expense in general maintenance. washing, cleaning and artificial lighting It is also indicative of a loss of fuel, which in soot alone probably amounts to at least 2,000 000 tons annually in Great Britain, while unburned gaseous products of combustion are responsible for still more serious thermal losses.

The duration of sunshine in such towns as Leeds, Sheffield and Manchester is in the winter months less than half that in outlying districts. In summer the deficiency is less marked but the intensity is at all times impaired. particularly in respect of the ultraviolet rays, which are now recognized as being so essential to health.

Were it not for the action of the nind in spreading smoke and its tendency to rise to the upper layers of the atmosphere, which normally are cooler than those beloa, fog would be an everyday occurrence in thickly populated districts. Still weather, indeed, is in winter usually accompanied by more or less dense smoke fog. or haze, especially since on cold. clear nights radiation to space chills the surface layers of air and is liable to produce in the atmosphere a "temperature inversion," or increase of temperature with height, which checks the upward drift of chimney products. Smoke also contains hygroscopic particles which act as nuclei for the condensation of water vapour and tend to produce wet fogs in chilled air. As might be expected, not only the number of carbon particles but also the amounts of carbonic and sulfurous acid rapidly increase during fog.

The depressing effects of dirt and gloom perhaps scarcely need be insisted upon, but the exact relation between smoke and physical welfare is impossible to assess. because of the large number of other contributory factors. Smoky fog is certainly the signal for an increase in the number of deaths from pulmonary and cardiac diseases. but since such fogs are associated nith special types of weather they are not necessarily its sole cause.

The sulfur acids in soot or rain attack and destroy building materials, particularly limestones, slates and zinc; but sandstones are not so badly affected.

The contrast between town and country gardens makes sufficiently apparent the detrimental effects of smoke upon vegetation. A deposit of soot, apart from the corrosive action of its acid constituents, not only impedes the transpiration of plants but also acts as a screen to sunlight. Acid rain is also directly harmful to plant life. The vitality of any type of vegetation usually suffers progressively as an industrial centre or large town is neared; crops diminish and reproductive powers are enfeebled, while some plants refuse altogether to grow in urban districts.

Prevention of Smoke.—To speak broadly, the prevention of smoke is to be sought both in improved methods of burning raw coal and in pretreatment of coal for the production of potentially smokeless alternative fuels, such as gas and coke.

There are grounds for regarding hopefully the prospects of industrial smoke abatement. The observation of scientific principles in furnace design and air regulation coupled with the adoption of continuous mechanical stoking has made possible the almost smokeless operation of modern large-scale boilers, even when working on bituminous coals; but smoke is less easy to prevent in small hand-fired boiler furnaces.

Nevertheless there is ample evidence to prove that coke is a convenient and efficient boiler fuel, capable of giving results not inferior to those obtainable with coal. Its bulkiness. however, is a disadvantage. There is also taking place, especially in small-scale furnaces, a gradual development of the use of gas and oil. The use of pulverized fuel has also increased, especially in big power stations. In this form solid fuel can be burned completely, but the sulfur products are of course not reduced, and unless special precautions are taken a large proportion of the ash may be carried into the atmosphere as a gritty dust. Gas firing is being successfully adopted in certain branches of the pottery industry, and both gas and electrical furnaces are making headway in formerly smoky metallurgical processes; while for power production the use of electricity is steadily developing. The work of the ministry of fuel and power on fuel economy was expected to react against industrial smoke-emission.

There is little hope of burning bituminous coal smokelessly in domestic appliances despite improvements in the design of grates and other appliances. The Egerton report on the heating and ventilation of dnellings (1945) and the Simon report on domestic fuel policy (1946) dealt exhaustively with this important subject. For certain purposes, such as cooking and intermittent heating, gas or electricity may compare favourably with coal even in running cost; but unfortunately the complete elimination of solid fuel was not immediately practicable in Great Britain in the middle of the 20th century. Gas coke and anthracite suggest themselves as alternatives to coal, but both are somewhat difficult to ignite and, although suitable for use in independent boilers or special grates, they are not altogether convenient in ordinary grates. The coke from low-temperature carbonization is a good household fuel, but is made only in small quantities.

British Legislation Against Smoke.—As early as 1306 a royal proclamation was issued, forbidding the use of coal in London, followed by a commission to punish miscreants "for the first offence with great fines and ransoms, and upon the second offence to destroy their furnaces" A further proclamation issued in Elizabeth I's reign made illegal the burning of coal during the periods when parliament was sitting. Nevertheless its use continued, for the great forests were dwindling before the agricultural needs of an increasing population, and wood was becoming both scarce and dear. In 1648 Londoners unsuccessfully petitioned parliament to prohibit the importation of coal from Newcastle on account of the injury suffered from smoke.

The extraordinary industrial activity of the 19th century gave the coal industry further impetus, and by 1819 the smoke nuisance had become so conspicuous that parliament appointed a committee to enquire how far persons using steam engines and furnaces could erect them in a manner less prejudicial to public health and comfort: but although it was reported that evidence bore out the practicability of smoke prevention, no active steps were taken. Select committees in 1843 and 1845 achieved some practical result: sections were inserted in the Railway Clauses act of 1845 requiring locomotives and in the Town Improvement Clause act of 1817 requiring factory furnaces to consume their own smoke.

Between 1875 and 1926 English law relating to the excessive emission of smoke from industrial chimneys, with the exception of London. was administered under clauses in the Public Health act, 1875. London was covered by very similar but somewhat more severe provisions in its own Public Health (London) act, 1891, while certain modifications of the general clauses of the act of 1875 were introduced in local acts. Scotland also had separate legislation. By mid-20th century legislation was still based on the act of 1875, modified by the Public Health (Smoke Abatement) act, 1926, which was largely the outcome of the work of a departmental committee on smoke abatement. Domestic grates were exempted, but power was given to make bylaws requiring the provision in new buildings other than private dwelling houses of such arrangements for heating and cooking as might be calculated to prevent or reduce smoke emission.

Under some of the subsequent local acts, several towns made plans for establishing "smokeless zones" in which all emission of smoke would be prohibited; and one local authority was planning to subsidize the installation of modern domestic appliances.

The Clean Air act, 1956. went into force (1958), dark smoke emission or lack of dirt and grit-arresting equipment being made offenses. The local authorities could declare smoke control areas in which smoke emission was an offense.

U.S. PRACTICE

St. Louis. Mo., at mid-19th century passed an ordinance regulating the height of chimneys, and the first smoke case on record in any U.S. court occurred in that city in 1864, when one Whalen was awarded $50 damages in the local court, which declared smoke to be a nuisance. The case was appealed to the Missouri supreme court. which upheld the lower court's decision.

Until the early part of the 20th century, anthracite from the mines of eastern Pennsylvania was the prevailing fuel used in New England and along the northern Atlantic seaboard. Even until World War I, New York city. Philadelphia and Boston were cited as examples of smokeless cities. From western Pennsylvania to the Rockies. the prevailing fuel was high volatile (more than 30%) bituminous coal. Large deposits of such fuel were readily available. For these reasons, agitation about smoke began mostly in midwestern communities.

Chicago began to be concerned about smoke as early as 1874, when a citizens' association interested itself in the problem. The first smoke ordinance in the United States was adopted by the Chicago city council. April 1881, to take effect May 1, 1881. It declared that "the emission of dense smoke from the smokestack of any boat or locomotive or from any chimney anywhere within the city shall be . . . a public nuisance." The penalty for violation was not less than $5 and not over $50. Cincinnati. O., adopted a somewhat similar ordinance a few months later. Within a few years, smoke ordinances were adopted by several midwestern cities. including Pittsburgh, Pa., Cleveland. O.. St. Louis and St. Paul. Minn.

An interesting case which reached the U.S. supreme court originated in Des Moines. Ia.. in 1915. The city of Des Moines had prosecuted a laundry plant for violation of the city smoke ordinance. which became effective September 6, 1911. After conviction. the laundry filed in the U.S. district court, southern district of Iowa, a bill to enjoin the enforcement of the Des Moines smoke ordinance. After receiving an unfavourable decision, the laundry appealed to the U.S. supreme court, which affirmed the district court's decision.

Early in the 20th century the Mellon institute made a comprehensive investigation of the damage caused by smoke in Pittsburgh and its costs to the people. The report showed that the actual cost of smoke to the residents of Pittsburgh amounted to $15–$20 per capita per annum. These costs included waste of fuel, extra cost of laundry and cleaning, damage to clothing, furnishings and structures, damage to merchandise in stores, cost of extra artificial lighting, replacement of metalwork on buildings, cost of cleaning exteriors of buildings, etc. Various later estimates of the cost of smoke to the American people ran as high as $2,500,000,000 annually.

Much of the physical damage caused by smoke is due to the burning of the sulfur in the fuel. The sulfur dioxide formed in the combustion process is a gas. When discharged from a stack, this gas quickly picks up moisture in the atmosphere. The moisture combines with the sulfur gases, together with free oxygen in the air. forming sulfuric acid, a highly corrosive substance. Any soot or dust particles accompanying the combustion gases. act as mechanical carriers of the acid. When deposited on structures, furnishings, clothing, etc., actual damage often results.

For many years, the U.S. bureau of mines acted as a clearinghouse for smoke prevention activities. In 1924 the bureau, in co-operation with the national engineering societies, drew up a standard smoke ordinance as a guide for lawmaking bodies. In the late 1920s and in the 1930s there was agitation for more strict smoke legislation and some standard on dust concentration to combat the increase in emissions of soot, fly ash and cinders. Late in 1939, the American Society of Mechanical Engineers appointed its model smoke law committee, to recommend a standard or model ordinance. This committee was composed of leading fuel and combustion engineers. After many years' work by the committee, the "Example Sections of a Smoke Regulation Ordinance" was adopted by the A.S.M.E. and published in 1949. These sections were used as a guide in writing or revising more than 100 ordinances.

At Donora, Pa., in Oct. 1948 a 5-day smog resulted in the death of 20 persons and the illness of nearly 6,000—43% of the population. This disaster resulted in greatly increased interest in prevention of smoke all over the United States. Agitation for preventive measures was voiced in scores of communities. Many municipalities adopted smoke ordinances or made existing ones more strict. Chicago, in 1907, was the first city to provide that there could be no construction of new fuel-burning plants or reconstruction of old ones without a city permit as to design. This ordinance proved satisfactory and came to be used almost universally. In 1938, Chicago established annual inspections to assure that plants were properly maintained.

Budgets for enforcing smoke regulations vary from about 2 cents to more than 20 cents per capita annually. In general, faster progress is made by those communities with the larger budgets.

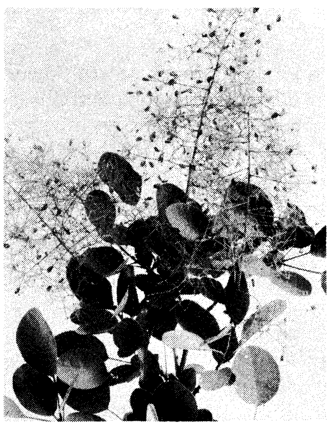
SMOKELESS POWDER: *see* EXPLOSIVES.

SMOKE TREE (*Cotinus coggygria*, formerly *Rhus cotinus*), a spreading shrub, sometimes 15 ft. high, of the cashew family (Anacardiaceae), native to southern Europe and eastward to central China, and widely planted for its feathery flower clusters and attractive foliage. The very similar American smoke tree (*C. americanus*), a tree sometimes 40 ft. high, is found from Kentucky and Missouri southward to Texas. The indigo bush (*Dalea spinosa*, family Leguminosae), sometimes 25 ft. high, native to the deserts of southeastern California adjacent to Arizona and Mexico, is also called smoke tree.



J. HORACE MCFARLAND CO.

COMMON SMOKE TREE (COTINUS COGGYGRIA)

SMOKY HILL RIVER, U.S. river that rises in extreme eastern Colorado, then flows east across the High plains. Blue hills and Smoky hills uplands of Kansas to join the Republican and become the Kansas river at Junction City, Kan. Like most western Kansas streams it carries relatively little water, fluctuates markedly in flow during the year and from year to year and has a normal peak from May to July. At Junction City the average flow is 861 cu.ft. per second. It is 540 mi. long, drains an area of 20,480 sq.mi. and has a valley floor from 1 to 9 mi. wide.

In sections of western Kansas it has eroded highly coloured Cretaceous beds into badlands. Much of the basin has annual rainfall below 20 in., and agriculture depends mainly on wheat, cattle and sorghum. Significant oil fields straddle its middle course. In the early 1960s four flood-control, irrigation and recreation reservoirs were in use: two at Kanopolis and Cedar Bluff and two on the Solomon (tributary) at Webster and Kirwin. (D. S. St.)

SMOLENSK, an *oblast* of the central region, Russian Soviet Federated Socialist Republic, U.S.S.R., having an area of 19,266 sq.mi. Population (1956 est.) 1,166,000 (urban 331,000, rural 835,000). It is bounded on the north by the Pskov and Kalinin *oblasts,* on the west by the Byelorussian Soviet Socialist Republic, on the south by the Orel *oblast* and on the east by the Moscow *oblast.* The central Russian plateau occupies much of the *oblast.*

The Vazuza and Gzhat, tributaries of the Volga, have cut a deep valley opening northward toward Rzhev, but most of the river valleys open toward the western plain. The Dnieper and its tributaries the Vop, Vyazma, Sozh and Desna have their source here but are not navigable, though timber is floated on them. The Kasplya and Mezha, flowing into the Dvina, and some of their affluents, are navigable for small boats. The Ugra, flowing eastward into the Oka, also forms a channel for floating timber.

The plateau region is composed of Carboniferous limestone, the western plain mainly of Tertiary sands, marls and ferruginous clays, covered with boulder clay. Post-Tertiary sands cover some areas, and the marshy depressions, which are a marked feature of this morainic region, and which are a source of malaria, are filled with peat bogs. These are a potential source of wealth in view of the increasing use of peat as fuel in electricity generating stations. There are patches of forest everywhere, most dense in the northwest and north, and thinning out to the southwest. The soil is of a clayey or sandy forest type, which is not favourable to agriculture.

The climate is somewhat modified by proximity to the western oceanic régime; average January temperature at Smolensk 13.5° F., average July temperature 67.2° F., rainfall about 20 in. per annum.

In spite of the poor soil, agriculture is the main occupation, the chief crops being rye, oats, potatoes and flax, with smaller quantities of buckwheat, barley, hemp and makhorka tobacco. Sheep, cattle, pigs and horses are bred. There is also a dairy and poultry industry. The improvement of agricultural methods began before 1917 and was actively carried on afterward.

Industries include flour milling, sawmilling, oil pressing and leather works. There are textile industries at Sychevka and Yartsevo. Apart from Roslavl, which has a population of 25,494, there is no large town other than Smolensk. Every variety of work dependent on the abundant timber supply is carried out, including the preparation of tar and pitch.

The *oblast* was important in early times as a link on the commercial route between Constantinople and the north. Later its position on the west made it the arena of struggles between Lithuania, Russia and Poland. The region suffered severely during the French invasion of 1812, and the peasants afterward remained in dire poverty, partly because of the unequal distribution of pasture. Proximity to the disorders of the western front in 1914–20 added to the distress.

SMOLENSK, a town of the R.S.F.S.R., U.S.S.R., the administrative centre of the *oblast* of Smolensk, situated on the Dnieper river, in 54° 50′ N., 32° 5′ E., at a point where the plateau is deeply entrenched and approaches the river both on the north and south. The ancient *kreml* or fortress was built on high crags on the left bank during the reign of Boris Godunov (1598–1605), but is now in ruins. The town developed owing to its position as a railway junction for five lines. Its industries include copper and iron smelting, the making of machinery for the textile industries, sawmilling, the manufacture of wooden goods, brick and pottery making and brewing. Pop. (1959) 146,000. After the revolution a university was created in the town. Its cathedral was built in 1676–1772. A monument commemorates the Russian composer M. I. Glinka (1885).

Smolensk is one of the oldest towns of Russia, and is mentioned in Nestor's *Chronicle* as the chief town of the Slav tribe of the Krivichis, situated on the great commercial route "from the Varyaghs to the Greeks." It maintained a lively traffic with Constantinople down to the 11th century, when the principality of Smolensk included Vitebsk, Moscow, Kaluga and parts of the present government of Pskov. The princes of Kiev were often recognized as military chiefs by the *vyeche* (council) of Smolensk, who mostly preferred Mstislav and his descendants, and Rostislav, son of Mstislav, became the ancestor of a series of nearly independent princes of Smolensk. From the 14th century these fell under the influence of the Lithuanian rulers, and in 1408 Smolensk was annexed to Lithuania. In 1449 the Moscow princes renounced their claims upon Smolensk, nevertheless this important city, with nearly 100,000 inhabitants, was a constant source of contention between Moscow and Lithuania. In 1514 it fell under Russian dominion; but during the disturbance of 1611 it was taken by Sigismund III of Poland, and it remained under Polish rule until 1654, when the Russians retook it. In 1686 it was definitely annexed to Russia. In the 18th century it played an important part as a basis for the military operations of Peter the Great during his wars with Sweden. In 1812 it was fortified; but the French, after a two days' battle, defeated the Russians here and took the city. Taken by the Germans in World War II in July-August of 1941, it became the central battlefield in the unsuccessful German drive towards Moscow in the autumn of 1941. It was liberated during the Russian advance of 1942–43.

SMOLLETT, TOBIAS GEORGE (1721–1771), British novelist, was born in Dalquhurn, Dumbartonshire. His father Archibald (youngest son of Sir James, the laird of Bonhill, a zealous Whig judge and promoter of the Union of 1707) died in 1723.

Tobias was sent to Dumbarton school, and, after qualifying for a learned profession at Glasgow university, was apprenticed in 1736 to a surgeon in that city. At the age of 18 he crossed the border to conquer England with a tragedy, *The Regicide,* based on Buchanan's description of the death of James I.

The story of the journey is told in the early chapters of *Roderick Random.* The failure of the play—certainly the worst thing he ever wrote—became the stock grievance of Smollett's life. No one would read it, and he would have starved had he not secured a position as surgeon's mate on H.M.S. "Cumberland," and served during the whole of the siege of Cartagena in 1741. The fleet returned to Jamaica, where Smollett fell in love with the daughter of a planter, Nancy Lascelles, whom he married on returning to England. He set up as a surgeon in Downing street, but with little success, and he soon began to devote his attention to writing fiction. His first novel *Roderick Random* (1748) recounts a life of varied adventure in the company of a servant. The author draws on his adventures on the English highway and in the cockpit of a king's ship, revealing the seaman to such purpose that, as Scott says, every one who has written about the navy since seems to have copied more from Smollett than from nature. There was no author's name on the title of the two small volumes of *Random;* it was actually translated into French as being by Fielding. But Smollett went to Paris to ratify his fame, and published his derelict play as "by the author of *Roderick Random.*"

Smollett still designed to combine medicine with authorship, for in June 1750 he obtained the degree of M.D.; and after a visit to Paris published in 1751 his second novel, *The Adventures of Peregrine Pickle,* which was a resounding success, both in England and France. It is no exaggeration to say that the tideway of subsequent fiction is strewn on every hand with the *dissecta membra* of Smollett's happy phrases and farcical inventions; but this novel is marred to an even greater extent by interpolations and personal attacks than its predecessor. His third novel, *Ferdinand Count Fathom*, appeared in 1753, by which time the author, after a final trial at Bath, had abandoned medicine for letters, and had settled down at Monmouth house, Chelsea. The squalor and irony of the piece repel the reader, but it is Smollett's greatest feat of invention, and was the model of all the mystery and terror school of fiction commencing with Radcliffe and Lewis. It was not particularly remunerative, and his expenses seem always to have been profuse. He was a great frequenter of taverns and entertained largely.

To sustain these expenses Smollett organized big and saleable "standard" works for the booksellers, contracting them out to his "myrmidons." He edited *Don Quixote*, a new literary periodical the *Critical* (Feb. 1756) by way of corrective to Griffith's *Monthly Review*, and organized a standard library *History of England*, and a seven-volume compendium of *Voyages*, for which he wrote a special narrative of the siege of Cartagena. In 1758 he projected and partly wrote a vast *Universal History*, and in Jan. 1760 he brought out the first number of a new sixpenny magazine, the *British*, to which he contributed a serial, the mediocre *Adventures of Sir Launcelot Greaves*. By these Herculean labours as a compiler Smollett must have amassed a considerable sum. For the extravaganza, *The Reprisal, or the Tars of Old England* he received £200. In 1762 Smollett edited the *Briton*. He had already been ridiculed, insulted, fined and imprisoned in the Marshalsea. He was now to support the North British favourite of George III in the press, not, we may reasonably suppose, without substantial reward. Yet after incurring all this unpopularity, Smollett was thrown over by his chief, Lord Bute, on the ground that his paper did more to invite attack than to repel it.

The *Briton* expired in Feb. 1763, and again Smollett undertook such tasks as a universal gazetteer and a translation of Voltaire in 38 volumes. In April, however, his only daughter died at the age of 15, and, over-wrought from sedentary strain, he followed the advice of his wife and made a two-years' sojourn abroad, mainly on the Riviera, which Smollett turned to such excellent purpose in his *Travels* (1766), remarkable alike for their acidity and for their insight. On his arrival from Italy, where he had provided material for Sterne's portrait of the distressful "Smelfungus," Smollett seemed to be getting over his pulmonic complaint. But his health was undermined, and a neglected ulcer helped to sap his strength. He resolved on a summer journey to Scotland, and when he proceeded to Bath in 1766 his complaint took a turn for the better. In 1768 he was again in London, and with a return of his vital energy came a recrudescence of the old savagery. *The History* and *Adventures of an Atom* is a clever, but coarse Rabelaisian satire upon the conduct of public affairs in England from the Seven Years' War to the date of publication. He lashes out on all sides without fear or favour. In 1769 he settled at Pisa and then near Antignano, near Leghorn, where during the autumn of 1770, he wrote ***Humphry Clinker***, in the form of itinerant letters. The character drawing, though still caustic, seems riper and more matured. He died at Leghorn Sept. 17, 1771, and was buried there in the old English cemetery.

The chief collective editions are as follows: 6 vols., Edinburgh, 1790; 6 vols., London, 1796, with R. Anderson's Memoir; *Works*, ed. J. Moore, 1797 (re-edited J. P. Browne, 8 vols., 1872); *Works*, ed. Henley and Seccombe (12 vols., 1899–1902); to which must be added a one-volume *Miscellaneous Works*, ed. Thomas Roscoe (1841); *Selected Works* (with a life by David Herbert) (Edinburgh, 1870); Ballantyne's edition of the Novels with Scott's memoir (2 vols., 1821); and G. Saintsbury's edition of the Novels (12 vols., 1895). There are Lives by Robert Chambers (1867), David Hannay (1887) and O. Smeaton (1897). Additional information will be found in the article on Smollett in the *Dict. Nat. Biog.*, Masson's *British Novelists*, H. Graham's *Scottish Men of Letters in the Eighteenth Century*, *Blackwood's Mag.* for May 1900; and the introduction to Smollett's *Travels Through France and Italy* (World's Classics, 1907). *See* also H. S. Buck, *A Study in Smollett, Chiefly Peregrine Pickle* (New Haven, 1925); L. Melville. *Life and Letters of Tobias Smollett, 1721–71* (1926); H. S. Buck, *Smollett as Poet* (1927).

SMOOT, REED (1862–1941), U.S. senator, was born at Salt Lake City, Utah, on Jan. 10, 1862. He was educated at Deseret university and at the Brigham Young academy. Provo Utah. He amassed considerable wealth as a banker and woolen manufacturer. In 1895 he was appointed one of the president6 of the Utah stake of the Church of Jesus Christ of Latter-day Saints (Mormon), and in 1900 was made an apostle. He was elected to the U.S. senate from Utah in 1902. Attempts were made to prevent his entering the senate because of his connection with the Mormon Church, and on the charge that he personally favoured polygamy and was a polygamist. He was allowed to take his seat; but the matter was referred to the senate committee on privileges and elections for investigation.

In June 1906 the committee, by a vote of seven to five, recommended that he be unseated; but, as the personal charges against him had not been proved, the senate in Feb. 1907, by a vote of 42 to 23, refused to remove him. He was re-elected in 1908, 1914, 1920 and 1926. In 1919 Smoot opposed participation by the United States in the League of Nations. Later he served as chairman of the finance committee of the senate, was a member of the World War foreign debt commission, a regent of the Smithsonian institution, an elector of the New York Hall of Fame, and chairman of the public buildings commission, directing the government building program at Washington, D.C., begun in 1927. He served in the senate until 1933.

SMUGGLING, a breach of the revenue laws either by the importation or the exportation of prohibited goods or by the evasion of customs duties on goods liable to duty. Legislation on the subject in England was very prolific from the 14th century downwards. In the reign of Edward III the illicit introduction of base coin from abroad led to the provision of the Statute of Treasons, 1351, making it treason to import counterfeit money as the money called "lushburg." Such importation is still an offense, though no longer treason. After the Statute of Treasons a vast number of acts dealing with smuggling were passed, most of which will be found recited in the repealing act of 1825. The smuggler of the 18th century finds an apologist in Adam Smith, who writes of him as "a person who, though no doubt highly blamable for violating the laws of his country, is frequently incapable of violating those of natural justice, and would have been in every respect an excellent citizen had not the laws of his country made that a crime which nature never meant to be so." The gradual reduction of duties (begun by Pitt) brought smuggling in the United Kingdom into insignificance until the revival of import duties after World War I led to frequent offense. Most of the existing legislation on the subject of smuggling is contained in the Customs Consolidation act, 1876.

The main provisions are as follows. Vessels engaged in smuggling are liable to forfeiture, and their owners and masters to a penalty not exceeding £500. Smuggled and prohibited goods are liable to forfeiture. Officers of customs have a right of search of vessels and persons. Fraudulent evasion or attempted evasion of customs duties renders the offender subject to forfeit either treble the value of the goods or £100 at the election of the commissioners of customs. Heavy penalties are incurred by resistance to officers of customs, rescue of persons or goods, assembling to run goods, signaling smuggling vessels, shooting at vessels, boats or officers of the naval or revenue service, cutting adrift customs vessels, offering goods for sale under pretense of being smuggled, etc. Penalties may be recovered either by action or information in the superior courts or by summary proceedings. In criminal proceedings the defendant is competent and compellable to give evidence. The Merchant Shipping act, 1894, makes any seaman or apprentice, after conviction for smuggling whereby loss or damage is caused to the master or owner of a ship, liable to pay to such master or owner such a sum as is sufficient to reimburse the master or owner for such loss or damage. and the whole or a proportional part of his wages may be retained in satisfaction of this liability. Additional provisions as to smuggling are also contained in the Customs and Inland Revenue act, 1879, and the Customs and Inland Revenue act, 1881. A smuggling contract is generally illegal, but it may be valid; and the vendor may recover the price of goods, even though he knew the buyer intended them to be smuggled, unless he actually aids in the smuggling so as to become *particeps criminis* Contracts to defraud the revenue of a foreign state are, 'according to English decisions, not illegal. There is a German decision, more consonant with international morality, to the opposite effect. The penalties for smuggling in the United States will be found mainly in tit. xxxiv, ch. 10 of the revised statutes. The seaman guilty of smuggling is liable to the same penalty as in England, and in addition to imprisonment for 12 months (sec. 4596) *See* also COAST GUARD.

SMUT AND BUNT, in botany and agriculture, the names given to certain parasitic fungus diseases of various flowering plants, especially cereals and other grasses. Smuts and bunts comprise the order Ustilaginales of the class Basidiomycetes. The name smut refers to the black or brownish powderlike masses of fungus spores which commonly appear in the flowers or heads, but in some cases on the stems, leaves or even roots of host plants. The smut fungi usually give little if any evidence of their presence in the host prior to spore formation. In some cases the fungus mycelium causes hyperplasia (increase in cell division) or hypertrophy (abnormal enlargement of existing cells) of the host, resulting in galls or tumours as exemplified in corn smut. The smuts in general are best typified by the genus *Ustilago,* species of which attack oats, barley, wheat, corn, etc. The loose and covered smuts (in the former the membrane enclosing the infected grain ruptures; in the latter it does not) which destroy the inflorescence of cereals are among the best known of the *Ustilago* types.

Bunt indicates a special group of the inflorescence smuts, caused by species of *Tilletia.* The bunts, or stinking smuts. so called because of their characteristic and unpleasant odour of decaying fish, are best exemplified by the bunt of wheat (Tilletia *caries* and *T foetida).* a classical disease of plant pathology. The bunt fungi invade the host when the latter is in the seedling stage. Their mycelia ramify and grow harmoniously with the host plant to its maturity. At this point the presence of the fungus is detected as it sporulates in the wheat head and completely replaces the grain with powdery masses of black spores.

The principal means for controlling most smuts is by seed treatment, either with chemicals or heat. Soil treatment, the use of resistant varieties and the adoption of certain cultural practices are other important control measures. Seedling-infecring smuts usually are controlled by various chemical seed treatments. The embryo-infecting loose smuts of wheat and barley may be checked by the hot-water or water-soak treatment of seed or by the use of certified smut-free seed.

The economic importance of smut fungi becomes apparent when it is realized that cereals constitute 73% of the total food consumed by man, and that smuts are one of the most important and uidely studied groups of cereal diseases. In the Pacific northwest region of the U.S., where wheat bunt has always been a serious problem, the average annual loss attributed to bunt in the five-year period 1951–55 was $4.500,000. The loose and covered smuts of barley, wheat and oats constantly threaten these cereal crops, especially where they are grown in the more humid or irrigated regions of the world.

Annual losses attributable to corn smut in the U.S. have run as high as 55,000,000 bu.

See FUNGI: *Basidiomycetes* (Club *Fungi*).

A bibliography pertaining to the smut fungi may be found in G. W. Fischcr and C. S. Holton, Biology and Control *of the Smut Fungi* (1957). (E. L. KE.)

SMUTS, JAN CHRISTIAAN (1870–1950), South African statesman and general, was born on May 24, 1870, near Riebeek West, Malmesbury district, Cape Colony, the son of J. A. Smuts and Catharina de Vries. In 1886 he commenced his studies at Stellenbosch, and in 1891 went to Cambridge, where his career was brilliant. In 1895 he was admitted to the Cape Town bar. In Oct. 1895 his first political speech was delivered at Kimberley, where. as a result of the understanding between Jan Hofmeyr and Rhodes, he defended the latter's policy. The Jameson raid (Jan. 1896) changed the whole complexion of South African politics. Smuts ranged himself on the side of the Transvaal, and shortly afterwards joined the Bar at Johannesburg. In 1898, though two years under the legal age, he was made state attorney by President Kruger, and took part in the negotiations with the British agent at Pretoria on the franchise. He accompanied Kruger to the abortive conference with Milner at Bloemfontein in July 1899.

In the early stages of the Boer War, Smuts was employed in legal and organising work, but on the occupation of Pretoria, in 1900, he joined the Boer field forces. From the Eastern Transvaal, where his Government was hard pushed, he made his way to the West, where he fought under De la Rey. Subsequently he acted as commander-in-chief of the Boer and Cape rebel commandoes in the Cape. He was besieging a mining camp in Namaqualand, when Botha sent for him to take part in the peace negotiations at Vereeniging (1902). He threw in his weight on the side of those who urged a compromise, as against the intransigent commandants.

After peace, Smuts became a strong and active protagonist of Botha's policy—loyalty to the new order, and racial conciliation. Practising as a barrister at Pretoria, he spent a good deal of time in the reconstruction of the remnants of the Boer nation and together with Botha and other leaders he met Joseph Chamberlain at Pretoria. The Boers, supported by part of the British population, strongly opposed several points in Milner's policy, *e.g.,* the importation of Chinese coolies for the gold mines, and Smuts was among those who refused Milner's offer of seats in the nominated Legislative Council.

Het Volk.—In 1904 Botha and Smuts founded the political organisation open to both races known as "Het Volk." Early in 1906 Smuts visited London, where he worked for fully responsible government in the Transvaal and Orange Free State, which was granted in 2906. Early in 1907 elections for the Assembly were held. Smuts took a prominent part and was returned unopposed for Wonderboom (Pretoria). As colonial secretary, under Botha, he became the driving force of the Cabinet. In May 1908 Smuts openly declared for the union of the South African colonies. In October of that year, the National Convention, which eventually produced the South African Act, began its work. Smuts was one of the makers of the Act. In May 1910 Union was consummated. Smuts was elected member of the legislative assembly for Pretoria West, and became minister of the interior, mines and defence. In 1911 the South African party was founded at Bloemfontein, where Smuts foreshadowed the political difficulties ahead. Early in 1912 he introduced his Defence bill, which powerfully affected the future of South Africa. A little later Smuts took over the treasury, retaining the portfolio of defence. During the Hertzog crisis, at the end of 1912, he did his utmost to prevent a split, but once the fateful step had been taken, he resolutely supported Botha. In July 1913 a revolutionary strike shook the Rand to its foundations. Botha and Smuts, at great personal risk (and unescorted) saved the situation at Johannesburg, after Lord Gladstone had sanctioned the use of Imperial troops to quell disturbances. In Jan. 1914 an attempted general strike was nipped in the bud by Smuts, who in record time rushed up the commandoes but recently organised under his Defence Act. The deportation of nine strike leaders on the S S. "Umgeni," though authorised by the Cabinet, was chiefly debited to Smuts by his opponents. A double Indemnity bill, covering the tno revolts, led to a violent and protracted parliamentary debate.

World War I.—The outbreak of World War I shifted the South African centre of gravity to Smuts' office. In Sept. 1914, when Beyers resigned as Commandant-General in the midst of the preparations for a campaign against the Germans in South-West Africa. Smuts assumed his functions. The rebellion of De Wet, Maritz. Beyers and others followed. This was suppressed by Botha, acting in the closest collaboration with Smuts at headquarters. In 1915, after a visit to Botha's forces in South-West Africa, Smuts took the leading part in the general election, which was marked by extreme bitterness. He was re-elected for Pretoria West by a narrow majority. Early in 1916 he refused the command offered him in East Africa by the Imperial Government, but shortly afterwards yielded to representations and proved successful in his operations against the German general Lettow-Vorbeck.

Work in London.—In March 1917 Smuts arrived in London to represent South Africa at the Imperial War conference, and was sworn as a privy councillor. After the conference, at a dinner given by members of both Houses of Parliament, he made his famous declaration embodying the concept of a British Commonwealth of Nations. He accepted a seat in the War Cabinet, taking a deep interest in the flying services, and his proposals for their unification were accepted by the Cabinet. Incidentally, he supervised London's air defences. He suggested, and became chairman of, the War Priorities Committee, which settled priority of claims among departments concerned in the war, and allocsted manpower and other resources. Occasionally he visited the Western front, where he conferred with commanders. In Dec. 1917 Smuts met Count Mensdorff at Geneva, and explored the possibility of a separate peace with Austria; but was finally convinced that it was not possible. The following Feb. he spent with Allenby in Palestine, working out plans for a great advance.

After the Armistice, Smuts wrote his Memorandum on the League of Nations, The League of Nations: *A* Practical *Suggestzon* (1918), which received the support of both President Wilson and Mr. Lloyd George. With Botha, he represented South Africa at the Peace Conference, where he was mainly concerned with the Covenant and Dominion status.

South African Politics.—After the conference, he returned to South Africa. In Aug. 1919 he became prime minister of the Union (in succession to Botha). During this period he twice attended the Imperial Conference. In **1921** his visit was notable for the part he played in securing peace in Ireland. During the Conference of 1923 (held while the Ruhr crisis was at its worst), he advocated a fresh attempt to settle the European situation. The suggestion was generally approved, and it helped to prepare the may for the Danes Commission.

In **1920,** repeated attempts to reunite the South African party and the Nationalists failed. The Unionists, under Sir Thomas William Smartt, decided to dissolve their organisation and to join the South African party. The consequences of this fusion lost Smuts a certain amount of support among both English and Dutch. A general election, held on that issue, left him, however, with a working majority, and the combined party did fairly well in Par. liament. In **1922,** however, another workers' revolt on the Rand (which was suppressed by the military and burghers) led to a junction of forces between advanced Nationalists and the Labour element.

In 1924 Gen. Smuts dissolved Parliament, realising that the people were dissatisfied with him. Although he lost Pretoria West, he was elected unopposed for Standerton, Botha's old constituency.

For the next decade Smuts was politically inactive, taking occasion to travel and lecture, while indulging his fondness for philosophy and botany. During this time he published Holism *and Evolution,* a philosophical treatise **(1926)** and *Africa* and *Some* World *Problems* (1930). In 1933 a new Union government came into being under Gen. James Hertzog and Smuts became minister of justice. This post he held until 1939 when Britain's declaration of war against Germany brought him back as prime minister. On Sept. **6** Smuts formed a war cabinet, and the Union proclaimed a state of war with Germany. He was made a field marshal in the British army in 1941. In 1945 Smuts attended the sessions of the United Nations conference in San Francisco, Calif., as a delegate of the Union of South Africa, and he authored the preamble to the U.N. charter. In **1948** he was defeated in the general elections and resigned as prime minister, retaining a seat in the assembly for Pretoria East.

He retired from leadership of his party in June 1950 and died at Irene. near Pretoria, Sept. 11, 1950.

(N. Le, X.)

SMYRNA (*Izmir*), in ancient times one of the most important and now the greatest of the cities of Asia hfinor, Turkey, has preserved an unbroken continuity of record and identity of name from the dawn of history to the present time.

The Ancient City.—It is said to hare been a Lelegian city before the Greek colonists settled in Asia Minor. The name, nhich is said to be derived from an Amazon called Smyrna, is indubitably Anatolian, having been applied also to a quarter of Ephesus, and (under the cognate form Myrina) to a city of Aeolis, and to a tumulus in the Troad. The Aeolic settlers of Lesbos and Cyme, pushing eastwards by Larissa and Neonteichos and over the Hermus, seized the valley of Smyrna. It was the frontier city between Aeolis on the north and Ionia on the south, and was more accessible on the south and east than on the north and west. By virtue of its situation it was necessarily a commercial city, like the Ionian colonies. It is therefore not surprising that the Aeolic element grew weaker; strangers or refugees from the Ionian Colophon settled in the city, and finally Smyrna passed into the hands of the Colophonians and became the thirteenth of the Ionian states. The change had taken place before **683,** when the Ionian Onomastus of Smyrna won the boxing prize at Olympia, but it was probably then a recent event. The Colophonian conquest is mentioned by Mimnermus (before **600** B.C.), who counts himself equally a Colophonian and a Smyrnaean. The Aeolic form of the name, Σμύρνα, was retained even in the Attic dialect, and the epithet "Aeolian Smyrna" remained long after the conquest. The situation of Smyrna on the path of commerce between Lydia and the west raised it during the 7th century to the height of power and splendour. It lay at the head of an arm of the sea, which reached far inland and admitted the Greek trading ships into the heart of Lydia. One of the great trade routes which cross Anatolia descends the Hermus valley past Sardis, and then diverging from the valley passes south of Mt. Sipylus and crosses a low pass into the little valley, about 7 m. long and **2** broad, where Smyrna lies between the mountains and the sea.

When the Mermnad kings raised the Lydian power and aggressiveness Smyrna was one of the first points of attack. Gyges (c. 687–652) was, however, defeated on the banks of the Hermus; the situation of the battlefield shows that the power of Smyrna extended far to the east and probably included the valley of Nymphi (Nif). A strong fortress, the ruins of whose ancient and massive walls are still imposing, on a hill in the pass between Smyrna and Nymphi, was probably built by the Smyrnaean Ionians to command the valley of Nymphi. According to Theognis (about 500 B.C.), "pride destroyed Smyrna." Mimnermus laments the degeneracy of the citizens of his day, who could no longer stem the Lydian advance. Finally, Alyattes III. (609–560) conquered the city, and Smyrna for **300** years lost its place in the list of Greek cities. It did not cease to exist, but the Greek life and political unity were destroyed, and the Smyrnaean state was organized on the village system (ῴκεῖτο κωμηδόν.) It is mentioned in a fragment of Pindar, about 500 B.C., and in an inscription of **388** B.C. A small fortification of early style, rudely but massively built, on the lowest slope of a hill N. of Burnabat, is perhaps a fortified village of this period. Alexander the Great conceived the idea of restoring the Greek city; the two Nemeses who were worshipped at Smyrna are said to have suggested the idea to him in a dream. The scheme was, according to Strabo, carried out by Antigonus (316–301), and Lysimachus enlarged and fortified the city (301–281). The acropolis of the ancient city had been on a steep peak about 1,250 ft. high, which overhangs the north-east extremity of the gulf; its ruins still exist, probably in much the same condition as they were left by Alyattes. The later city was founded on the modern site partly on the slopes of a rounded hill called Pagus near the south-east end of the gulf, partly on the low ground between the hill and the sea.

The "crown of Smyrna" seems to have been an epithet applied to the acropolis with its circle of buildings. Smyrna is shut in on the west by a hill now called Deirmen Tepe, with the ruins of a temple on the summit. The walls of Lysimachus crossed the summit of this hill, and the acropolis occupied the top of Pagus. Between the two the road from Ephesus entered the city by the "Ephesian gate," near which was a gymnasium. Closer to the acropolis the outline of the stadium is still visible, and the theatre was situated on the north slopes of Pagus. The line of the walls on the east side is unknown; but they certainly embraced a greater area than is included by the Byzantine wall, which ascends the castle hill (Pagus) from the Basmakhanē railway station. Smyrna possessed two harbours—the outer, which was simply the open roadstead of the gulf, and the inner, which was a small basin, with a narrow entrance closed by a rope in case of need, about the place now occupied by bazaars. The inner harbour was partially filled up by Timur in 1402, but it had not entirely disappeared till the beginning of the 19th century. The modern quay has encroached considerably on the sea, and the coast-line of the Greek time was about go yd. farther south. The streets were broad, well paved and laid out at right angles; many were named after temples: the main street, called the Golden, ran across the city from west to east, beginning probably from the temple of Zeus Akraios on the west side of Pagus, and running round the lower slopes of Pagus (like a necklace on the statue, to use the favourite terms of Aristides the orator) towards Tepejik outside the city on the east. where probably the temple of Cybele, the Metroön, stood. Cybele, worshipped under the name of Meter Sipylene, from Mt. Sipylus, which bounds the Smyrna valley on the north, was the tutelar goddess of the city. The plain towards the sea was too low to be properly drained and hence in rainy weather the streets were deep with mud and water.

The river Meles, which flowed by Smyrna, is famous in literature and was worshipped in the valley. The most common and consistent tradition connects Homer with the valley of Smyrna and the banks of the Meles; his figure was one of the stock types on Smyrnaean coins, one class of which was called Homerian; the epithet "Melesigenes" was applied to him; the cave where he was wont to compose his poems was shown near the source of the river; his temple, the Homereum, stood on its banks. The steady equable flow of the Meles, alike in summer and winter, and its short course, beginning and ending near the city, are celebrated by Aristides and Himerius. The description applies admirably to the stream which rises from abundant fountains, now known as Diana's bath, east of the city, and flows into the south-east extremity of the gulf. The belief that the torrent, almost dry except after rains, which flows by Caravan bridge, is the ancient Meles, flatly contradicts the ancient descriptions.

In the Roman period Smyrna was the seat of a *conventus* which included south Aeolis and a great part of the Hermus valley. It vied with Ephesus and Pergamum for the title "First (city) of Asia." A Christian church existed here from a very early time, having its origin in the considerable Jewish colony. Polycarp was bishop of Smyrna and was martyred there A.D. 155. The bishops of Smyrna were originally subject to the metropolitan of Ephesus; afterwards they became independent (**αὐτοκέφαλοι**), and finally were honoured with metropolitan rank.

When Constantinople became the seat of government the trade between Anatolia and the west lost in importance, and Smyrna declined apace. A Turkish freebooter named Tsacha seized Smyrna in 1084, but it was recovered by the generals of Alexius Comnenus. The city was several times ravaged by the Turks, and had become quite ruinous when the emperor John Ducas Vatatzes about 1222 rebuilt it. But Ibn Batuta found it still in great part a ruin when the famous chieftain Aidin had conquered it about 1330 and made his son Amur governor. It became the port of the Aidin amirate. Soon afterwards the Knights of Saint John established themselves in the town, but failed to conquer the citadel. In 1402 Timur stormed the town and massacred almost all the inhabitants. The Mongol conquest was only temporary, but Smyrna was resumed by the Seljuks of Aidin and has remained till the present day in Mohammedan hands. Until the reign of Abdul Mejid it was included for administrative purposes in the *eyalet* of Jezair (the Isles) and not in that of Anatolia. The representative of the Capitan Pasha, who governed that *eyalet*, was, however, less influential in the city than the head of the Kara Osman Oglu's of Manisa. *(See* MANISA.) From the early 17th century till 1825, Smyrna was the chief provincial factory of the British Turkey Company, as well as of French, Dutch and other trading corporations. (W. M. RA.; D. G. H)

For general authorities *see Bibliographzes* under ASIA MINOR. Also B. F. Slaars, *Etude sur Smyrne (1868)*; and W. M. Ramsay, *Letters to the Seven Chuvches* (1904) and article in Hastings's *Dict. of the Bible* (1902).

Developments After World **War** I.—At the peace conference which was held in 1919 Greece put forward a claim to the Smyrna area, assigned it was understood to Italy by the agreement of St. Jean de Maurienne (April 17, 191;)—an agreement which remained unratified owing to Russian objections. Venizelos argued on the Greek claim before the Council of Ten on Feb. 3–4, 1919. The final decision of the Council of Three, authorizing the Greeks to occupy Smyrna. was taken apparently without the knowledge of the Italians. who had withdrawn temporarily from the conference; or of the U.S. expert advisers to President Wilson. The occupation was in theory an Allied occupation. but was generally taken to mean acceptance of the Greek claims. Greek troops occupied Smyrna on May 15, 1919. The first entry of the Greeks was marked by atrocities against the Turkish population.

Under the Treaty of Sèvres, Aug. 10, 1920, it was stipulated that the town of Smyrna and the Ionian hinterland were to be under Greek administration for five years. The Greek claim was based on ethnographical grounds. Reliable population statistics for the area were not available, but U.S. computation of 1914 gave the total population as 1,057,000, including 509,000 Turks, 470,000 Greeks and 78,000 others.

Turkish forces under Mustafa Kemal and the Greeks were soon engaged in hostilities, in which at first the Greeks were successful. Mustafa Kemal, however, continued to consolidate his position in Turkey, while the fall of Venizelos (Nov. 1920) and the return of King Constantine to Greece *(see* GREECE) weakened the sympathies which Greece had enjoyed in Great Britain, its chief supporter among the Allied powers. Negotiations at the London and Paris conferences (1921 and 1922) having failed. the Kemalists drove back the Greek army, which with many thousands of Greek refugees from all parts of Asia Minor embarked hurriedly and left Smyrna, which the Turks entered on Sept. 9. 1922. Under the Treaty of Lausanne (July 24, 1923) Smyrna and the surrounding zone reverted under full Turkish sovereignty.

Meanwhile, the town and district had suffered frightfully under the atrocities of both belligerents, and these sufferings culminated when, a few days after the Turkish entry into the town. fire broke out in the Armenian quarter. Only the wretched Turkish quarter on Mount Pagus was untouched, and more than three-fifths of the city was destroyed, including all the banks, business houses and consulates in the European quarter on the quay. The loss of life was impossible to compute. In April 1928 Smyrna again suffered serious damage by earthquake.

For the modern city, *see* IZMIR.

SMYTH, DAME ETHEL MARY (1858–1944), D.B.E. (1922), British composer, was born in London April 23. 1858, the daughter of Gen. J. H. Smyth. She studied music at Leipzig under Heinrich von Herzogenberg. She produced her first opera *Fantasio* at Weimar in 1898, others being given at Leipzig. Prague and Vienna. Her first opera to be produced in London was *Der Wald,* given at Covent Garden in 1902 which was followed by *The Wreckers* (1909), a vividly romantic work. Her Mass in D. first performed in 1893, was revived 30 years later. *The Boatswain's Mate,* a comic opera, was produced in 1916. She took a prominent part in the suffragist movement, and composed *The March of the Women* (1911). Her compositions include *Fête Galante* (1923) and *Entente Cordiale* (1924) both operas; also chamber music, choruses and songs, all characterised by energy of invention, exuberant vitality and clever workmanship. *See* her brilliant memoirs *Impressions That Remained* (1919); *Streaks of Life* (1921); *A Three-Legged Tour in Greece* (1927); *A Final Burning of Boats* (1928); *As Time Went On* (1935); *What Happened Next* (1940). She died May 8, 1944.

SMYTH, HERBERT WEIR (1857–1937). U.S. philologist, perhaps the foremost Greek scholar of his time in the U.S., was born at Wilmington, Del.. on Aug. 8, 1857. He was educated at Swarthmore (A.B., 1876). Harvard (A.B., 1878), and Gottingen (Ph.D., 1884). During 1884–85 he was instructor in Greek and Sanskrit at Williams college, and then for two years was reader in

Greek at Johns Hopkins university. From 1888 to 1901 he was professor of Greek at Bryn Mawr. In 1901 he was appointed professor of Greek literature at Harvard (later Eliot professor), becoming emeritus in 1925. During 1899–1900 he was professor at the American Classical school at Athens, Gr. From 1889 to 1904 he was secretary of the American Philological association and editor of its Transactions, and in 1904 was elected president. His works include a treatise on the Ionic dialect (1894); Greek *Melic* Poets (1900); Greek *Grammar* for Colleges (1916, 2nd ed., 1957); *Aeschylus,* text and translation (1922–26), in the "Loeb Classical Library"; and Aeschylean Tragedy (1924).

Smyth turned from the linguistic and grammatical studies of his youth more and more to criticism and interpretation. He regarded the diminished influence of Greek studies almost a national misfortune. He died July 16. 1937, at Bar Harbor, Me.

See E. K. Rand in *Yearbook of the American Philosophical Society,* pp. 398–408 (1937). (X.; J. Wh.)

SMYTH (Smith), **JOHN** (c. 1570–1612), English nonconformist divine. commonly called the Se-baptist, was born about 1570, and was educated at Christ's college, Cambridge, where he proceeded M.A. in 1593. He was probably vicar of Hutton Cranswicke in the East Riding of Yorkshire from 1593 to 1600, when he was elected lecturer or preacher of the city of Lincoln. an office of which he was deprived in Oct. 1602. Becoming connected with the Separatist movement he joined the Gainsborough church. and became its pastor[1]. With Thomas Helwys, John Murton (or Morton) and others. he migrated to Amsterdam at the end of 1607 to escape' religious persecution. and in that city practised as a physician, and became the leader of "the second English church." (See Congregationalism.) Under Mennonite influence he became a Baptist (see Baptists). But he and his company were then faced by the dilemma that their own infant baptism did not count, and Smyth solved the problem by first baptizing himself (hence the name Se-Baptist), probably by affusion. and then administering the rite to Helwys and the others. Afterward they decided to join the Mennonites, who were suspicious of a man who had never held one position for long, and demanded a statement of doctrines. which he gave them in 20 articles written in Latin, and in The Last Book of John *Smyth,* culled the Retractation of his Errors, together with a confession of faith in 100 Propositions. Smyth himself died of consumption in Xug. 1612. Helwys and Morton returned to England, and established the first English Baptist churches.

See J. H. Shakespeare, *Baptist and Congregational Pioneers* (London, 1906); H. M. Dexter, *The England and Holland of the Pilgrims* (London and Boston, 1906). (A. J. *G.*; X.)

SMYTH (or Smiti-i), **WILLIAM** (c. 1460–1514), bishop of Lincoln, was a Lancashire man by birth, and probably passed some of his early days at Knowsley under the roof of Margaret, countess of Richmond and Derby, the mother of Henry VII. He appears to have been a member of Lincoln college, Oxford, and in 1485, just after the battle of Bosworth, he was made keeper of the hanaper of the chancery. Two of Edward IV's daughters were entrusted to his keeping; he was a member of the royal council and he obtained many rich preferments. In 1493 he became bishop of Coventry and Lichfield. The bishop was a member of Prince Arthur's council in the marches of Wales: and in 1501, five years after he had been translated to the bishopric of Lincoln. he became lord president of Wales. About 1507 he and Sir Richard Sutton (d. 1524) set to work to found a new college in Oxford. They rebuilt Brasenose hall, added other existing halls to it, and having obtained a charter in 1512, called it The King's *haule* and college of Brasennose. Smyth, who was one of the executors of Henry VII's will, retired from public life just after this king's death; he was, however, president of Wales until his death at Buckden in Huntingdonshire on Jan. 2, 1514. In addition to his liberal gifts to Brasenose college he gave money or land to Lincoln and to Oriel colleges; he founded a school at Farnworth, Lancashire, and he refounded the hospital of St. John at Lichfield. From 1500 to 1503 he was chancellor of Oxford university.

[1]He was never vicar of Gainsborough, and must not be confused with the John Smyth who was imprisoned in the Marshalsea in 1592.

SMYTHE (Smith), **SIR THOMAS** (1558?–1625), English entrepreneur, was pre-eminently instrumental in launching, financing and administering pioneer English joint-stock enterprises in overseas trade, colonial settlement and exploration during the first two decades of the 17th century. A member of the London Haberdashers' and Skinners' companies from 1580. he accumulated a considerable fortune from commerce. Besides holding other official posts, he was incorporator and for some years governor of the East India company, treasurer of the Virginia and Somers Islands (Bermuda) companies, governor of the Muscovy and French companies and ambassador to the tsar (1604–05). He was a prime initiator of voyages to discover a Northwest passage. Smythe's efforts and a good part of his fortune were consistently and selflessly devoted to experiments that underlay England's subsequent imperial and commercial greatness. Although there was some controversy as to his management of the Virginia company, his fame as the entrepreneur and supporter of outstanding ventures is secure. Smythe died at Sutton-at-Hone, Kent, on Sept. 4, 1625.

SNAIL, the name usually given to land molluscs of the class Gastropoda which have spiral shells, such as the common snail (Helix aspersa) and the wood snail (*Cepaea* nemoralis). In Scotland both shell-bearing and shell-less land molluscs are known as "snails." Marine gastropod molluscs are sometimes called "sea snails" and the freshwater gastropods (*Viviparus,* Lymnaea, etc.) are known as "pond snails" and "river snails." The shell-bearing Gastropoda ("snails" in the wide sense) are a very large class of animals, embracing some 40,000 living and extinct species, with a world-wide distribution.

Perhaps the most striking feature in the structure of snails is their shell. In the majority this is spiral and consists of several whorls which have a right-handed (dextral) coil. A left-handed (sinistral) coil is found in certain forms, either as an occasional variation of normally dextral forms (*Lymnaea peregra* and *Neptunea antiqua*) or as a fixed generic characteristic (Physa, *Clausilia*). Sometimes the shell is cup-shaped (Patella, the common limpet), tubular (*Coecum*) or plate-like (Scutum). In many land and marine gastropods it becomes internal and degenerate or is eventually lost entirely, and a sluglike form is attained. The land snails belong, with some exceptions, to the order Pulmonata and a very large proportion of them are placed in the family Helicidae, which is one of the largest groups of land invertebrates. They are mainly animals of retiring habits living on green plants or on decaying vegetable debris, though a few (e.g., *Glandina, Streptaxis*) are carnivorous. As a rule, they are more frequently found upon calcareous soils and are certainly rare on "acid" formations. They usually live during the daytime buried out of sight under leaves and, as a certain amount of moisture is necessary for their well-being, they aestivate in hot and sunny weather in crevices or under ground, from which protection they emerge at night or during rain.

Including the "snail-slugs" (Testacella), there may be said to be 125 species of land and fresh, or brackish, water snails in the British Isles. The largest family (indeed, the largest in the phylum Mollusca) is the Helicidae, of which there are 22 species in Great Britain. Among the commonest forms are Helix aspersa, the common or speckled snail, Cepaea nemoralis and *hortensis,* the wood and garden snails and *Lymnaea* peregra, the common pond snail. Certain species (e.g., *Belgrandia marginata*), which are still living in continental Europe, are found in a fossil state in the British Isles. *Paludestrina jenkinsi,* the only mollusc at present known to reproduce itself parthenogenetically (without fertilization), is found very plentifully in Great Britain.

In North America there are numerous species of fresh-water and land snails. Among representatives of the former are about 6j species of Lymnaea and 25 of *Planorbis.* Of the land snails important families are the Pupillidae, with 50 species; the Zonitidae, with 65; and the exceedingly numerous Polygyridae. of which 9 genera and 256 species and subspecies are recognized. Concerning the use of snails by man, *see* GASTROPODA. *See* also Index references under "Snail" in vol. 24.

SNAKEBIRD (DARTER. AHINGA or WATER TURKEY), a bird belonging to the same order as the cormorant (*q.v.*), which it resembles both outwardly and in habits. The snakebirds, however. are slenderer in form and have an elongated neck and tail. The pointed bill has its edges beset with backwardly directed "teeth."

A. W. AMBLER FROM NATIONAL AUDUBON SOCIETY

AMERICAN SNAKEBIRD (ANHINGA ANHINGA) SHOWING CHARACTERISTIC WING PATCHES OF THE MALE

There is only one genus of snakebirds, *Anhinga,* with four species occurring (one each) in the Americas. Africa, southern Asia and Australia. The male of the American species. *A. anhinga,* often called the water turkey, has a black plumage. glossed with green. with a white line on the neck; the bare skin of the head is both green and orange, and there are white patches on the wings and tail. The bird haunts large rivers and lakes, frequently perching on overhanging branches or snags. It feeds on fish, which it chases and spears with its dagger-like bill; its agility under water is amazing. It often swims with only its head above water. The bird has been observed to play at catch with small twigs. The nest is built in a tree close to the water and is a large structure of sticks. The four eggs have white, chalky shells.

All four species are characterized by the structure of the neck; the first seven neck vertebrae form a curve with its concavity forward; but the eighth articulates with the seventh nearly at right angles; the ninth is directed abruptly downward and the rest form a gentle forward convexity. This mechanism permits great flexibility.

SNAKE FLY, the name given to insects of the order Neuroptera (*q.v.*) of the superfamily Raphidoidea, closely allied to the alder flies, remarkable for the elongation of the head and prothorax to form a neck and for the presence in the female of a long ovipositor. The larva is active, carnivorous and terrestrial, and lives under loose bark of various trees. These insects occur chiefly in the northern hemisphere.

SNAKE RIVER, one of the most important streams in the Pacific northwest of the United States, is the largest tributary of the Columbia river. Its drainage basin of 109.000 sq mi is 30% greater than the total area of Idaho and contains one-half the entire area of the Columbia river basin in the United States. Runoff from Wyoming, Utah, Nevada. Idaho, Oregon and Washington combine in this stream. From elevations of 10.000 ft. the river descends to an elevation of 300 ft. and contributes 36,820,000 ac.ft. of water annually to the Columbia.

The river rises in high, rugged mountains of the continental divide near the southeast corner of Yellowstone National park in Wyoming. It flows south along the eastern base of the Teton mountains, and swings northwest near the mouth of Greys river and enters Idaho. Near Heise. the river leaves the mountains and crosses southern Idaho in a huge, southwesterly curving arc that terminates near the junction of the Boise and Snake rivers on the western edge of Idaho. Turning north, it forms the Oregon-Idaho boundary for 216 mi. From the northeast corner of Oregon it forms the Washington-Idaho boundary to Lewiston, Ida.. and then turns west to join the Columbia near Pasco, Wash. Its total length is 1,038 mi.

The upper Snake river, above King Hill, Ida., is used to irrigate over 1,500.000 ac. of land and to generate electric energy. The main stem is regulated by Jackson lake. Palisades, American Falls, Minidoka and Milner reservoirs. Principal tributaries below Heise are Henrys Fork (the largest). Blackfoot, Portneuf. Raft. Little Wood and Big Wood rivers. The last two and Henrys Fork enter the river from the north. Other north side streams sink into Snake river plains and become part of an immense underground reservoir. Numerous large springs—outpourings of the underground water body—emerge from the canyon walls in Hagerman valley. Twin falls and Shoshone falls, with drops of 125 and 195 ft., respectively, are located downstream from Milner dam.

The central Snake river, from King Hill to Weiser, Ida., is used primarily for hydroelectric generation. Over 1,000,000 ac. of land are irrigated in this section, primarily from tributary streams. Principal reservoirs and their associated rivers are Lucky Peak. Arrowrock and Anderson Ranch on the Boise; Cascade, Deadwood and Black Canyon on the Payette; Owyhee on the Owyhee; and Warm Springs and Agency on the Malheur.

The lover Snake river, from Weiser to the mouth, flows through a 1 mi.-deep gorge known as Hells canyon, one of the deepest river gorges in North America. Salmon river, largest tributary and most important wildlife area of the river system, joins the main stem near the downstream end of the canyon section. (G. V. SK.)

SNAKEROOT. In most countries where snakes abound some root or herb is used by the natives as an antidote for the bites of venomous species, and many herbs have consequently received the name of snakeroot. Botanically speaking, the name properly belongs to *Ophiorrhiza mungos,* a plant of the family Rubiaceae. used in Indonesia for the purpose above indicated. In medicine, however, the roots of *Aristolochia serpentaria, Polygala senega* and *Cimicifuga racemosa* were understood by this name, being distinguished as the Virginian, seneca and black snakeroots. The root of *Aristolochia reticulata* is known in the United States as Red river or Texan snakeroot.

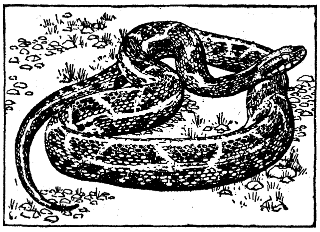
JOHN H. GERARD

WHITE SNAKEROOT (EUPATORIUM RUGOSUM)

The roots or rhizome of *Liatris spicata, Eryngium aquaticum* and *Eupatorium rugosum* have all been used in North America for snake bites, the first two being known as button snakeroot and the last as white snakeroot. The rhizome of *Asarum canadense* passes under the name of Canadian snakeroot. All of these contain acrid or aromatic principles which, when a warm decoction of the drug is taken, exercise a powerfully diaphoretic or, in some cases, diuretic action, to which the benefit, if any, derived from their use may be attributed.

SNAKES, an order (Serpentes) in the class of REPTILES (*q.v.*). They are elongate animals without limbs, or with claw-like vestiges of the hinder pair; without eyelids or external ears, with pointed recurved teeth fused to the supporting bones, with a forked slender tongue which can be withdrawn into a sheath at its base, and with the two halves of the lower jaw not fused but joined by an elastic ligament. Like the lizards, with which they have many affinities, they are one of the dominant groups of reptiles of the present day and at least 2,000 different species are known. Their distribution is cosmopolitan with the exception of New Zealand, Ireland and some of the more recent, completely isolated, oceanic islands such as the Azores and most of Polynesia; as in other groups of terrestrial, cold-blooded animals, the area of permanently frozen subsoil limits their northern and southern range, and the greatest profusion of species and individuals is to be found in the tropics.

In the loss of limbs and the absence of well-differentiated neck, body and tail they may be regarded as degenerate and, by analogy with certain groups of limbless lizards, it seems probable that this type of bodily form arose in correlation with a habitat amongst dense vegetation; under these conditions limbs do not appear to be such efficient organs for motion as the lateral undulations that form the basis of serpentiform locomotion. Contrary to the idea expressed in the conventional representations of snakes, the body is not undulated vertically but laterally, and locomotion is effected by the passage of a series of "waves" from before backwards, each wave in its progress pressing against the surrounding medium and forcing the animal forwards. Such a system is efficacious only when the surrounding medium is sufficiently dense to offer an appreciable resistance to the passage of the waves and the majority of terrestrial snakes possess an additional mechanism. The scales of the lower surface are enlarged to form transverse, overlapping plates, whose free edge is directed backwards, and to each of these plates is attached a pair of movable ribs. When the ribs are moved forwards they carry the scute with them, and as this is smooth and has its leading edge protected by the one in front of it, it slips easily over any irregularities of the surface. But, when the scute is moved backwards its free, hinder edge catches on the slightest projection and so enables the snake to push itself forward. As there may be as many as 300 of these ventral shields, each of which can utilise any slight irregularity, progress is possible over almost any surface.



THE FER-DE-LANCE OF THE WEST INDIES AND SOUTH AMERICA

Probably also correlated with the ancestral habitat is the development of a hard transparent covering over the eye to protect the delicate cornea; in many lizards a transparent covering is developed from the lower eyelid, but in snakes the analogous covering is probably the modified nictitating membrane. In most snakes the outer horny covering of the scales is shed in one piece; sloughing commences at the lips and by vigorous rubbing movements the slough is turned back on itself and the animal works its way out, the old skin being turned inside out in the process. Though the sense of sight is well-developed, hearing must be of a different nature from that of most vertebrates, as there is no external ear or ear-drum; the *columella auris,* which normally transmits vibrations from the ear-drum to the inner ear, in snakes rests with its outer end on the quadrate, the bone which supports the lower jaw; possibly the ear is sensitive, not to air-borne vibrations, but to vibrations transmitted through the substratum on which the animal rests. The sense of smell is well-developed but a snake's most important sensory organ is its tongue; exactly what sense is centred here is not known, but the constant play of this organ makes it evident that the sensations registered by the tongue are of paramount importance in determining the animal's reactions to external conditions.

Snakes are carnivorous or insectivorous and the prey, which under natural conditions must be captured alive, is swallowed whole, the conical re-curved teeth and the divided lower jaw being adaptations to this method of feeding. The prey may be killed by poison or constriction or swallowed alive; it is worked round until the head is in the snake's mouth and then commences the laborious swallowing process. The bones supporting the lower jaw are movable on the skull so that the gape of the mouth is tremendous and this, assisted by the stretching of the elastic ligament between the halves of the lower jaw, permits the swallowing of masses of considerably greater diameter than the snake itself; the teeth of one side of the mouth are hooked into the victim and then, with this as a fulcrum. the other side is pushed forwards a short distance, the teeth engaged and the same action repeated with the opposite side The hooked shape of the teeth permits of their being pushed forward but not easily drawn back, and in this way the snake literally draws itself over its food. Teeth are frequently broken off by the victim's struggles, but by the side of each functional tooth is a series of new teeth, in different stages of development, lying within a special fold of the lining of the mouth, the *vagina dentis;* as soon as a tooth is lost one of the successional series moves into its place and becomes fused to the jaw-bone. Teeth are also the means by which the venom of poisonous species is injected; these "poison fangs" are always situated in the upper jaw either at the front or the hind end and the channel for the venom is either a simple groove or a groove whose edges have met and so produced a tube with openings at the base and the tip of the fang. The venom itself is the product of a modified salivary gland and is a clear straw-coloured liquid containing certain poisonous proteins, the proportions in which each is present varying according to the type of snake. The two principal constituents are a "haemolytic" agent which breaks up the blood corpuscles and attacks the lining of the blood vessels and a "neurotoxic" agent which attacks the nerve centres, causing paralysis, and having a special affinity for the nerves supplying the respiratory apparatus; the predominance of one or other of these two bodies determines the nature of the symptoms of snake-bite. If neurotoxic agents predominate, paralysis, general prostration and difficulty in breathing are the most dangerous symptoms, but if the patient survives this stage, recovery is rapid and there are few severe local symptoms at the site of the bite; when, on the other hand, "haemolysins" are the principal constituents of the venom there is no paralysis, though there are severe constitutional symptoms and prostration, but even if this is not fatal, local symptoms follow with local extravasation of blood and much swelling of the bitten parts, which may suppurate and become gangrenous.

The first aid to be given is the application of a light ligature above the location of the bite, followed by active sucking. It has been found by direct experiment that the application of potassium permanganate to the wound is harmful rather than helpful. It is essential that the patient should not run, and difficult as the advice may be to follow, he should not become excited. Administration of large quantities of stimulants is useless, but small repeated doses may be given if the patient is on the verge of collapse.

"Anti-venins" are now manufactured in most countries where snake-bite is at all common. They are prepared by immunising horses against a particular venom by increasing, regulated doses; the blood serum of the horses is then sterilised and made up into doses ready for inoculation. It has not yet been found possible to prepare a serum that is really efficacious against the venoms of more than one or two snakes, so that. to ensure treatment with the correct anti-venin, an attempt should be made to identify the one responsible for the accident.

Since the reaction to large doses of horse serum may itself be a Severe one, it is essential that anti-venin be administered only under medical supervision.

In serious cases of bite from vipers or pit-vipers, blood transfusions may save the patient.

No snakes have a larynx or vocal chords and, in consequence, none have a true voice; they are all, however, capable of hissing and some of the larger, heavy-bodied species, with a large lung capacity, can do so loudly enough to be heard at some little distance; a few forms have a special piece of cartilage in front of the epiglottis and, when a blast of air is emitted, the vibration of this cartilage produces a sound which has been compared with that of a gently struck tuning fork. Rattlesnakes (*q.v.*) have a special sound-producing apparatus and some vipers can make a swishing noise by the movement of the scales one over the other.

The majority of snakes lay eggs; these are elongate with a parchment-like shell, and are usually deposited in a situation exposed to moist heat. In some groups, however, they are retained inside the body of the mother until the young are fully developed.

The various families, based largely on characters of the skull, may best be considered separately.

1. *Typhlopidae.*—Small, harmless, burrowing, worm-like snakes, with the eyes hidden beneath the scales of the head, with a very short, blunt tail, with small, shiny over-lapping scales, no enlarged scutes across the belly and with teeth only in the upper

jaw; inhabitants of almost all tropical countries. These snakes form burrows in loose soil, and to assist in this operation many have a short spine at the tip of the tail which is dug into the ground to obtain a purchase while the rounded head is thrust forward, or retracted, by a looping movement of the body; insect pupae and larvae, ants and earth-worms, seem to form the staple diet. The commonest colouring is brownish or flesh colour, but a few, for instance the common *Typhlops punctatus* of tropical Africa, are irregularly marked with black and yellow.

2. *Leptotyphlopidae.*—Another family of blind, burrowing snakes very similar to the Typhlopidae from which they differ in having teeth in the lower, but not in the upper jaw; they are found in Africa, southwestern Asia and America. The usual colours are browns or blacks but in *Leptotyphlops* albifrons, the common species of tropical America and the lesser Antilles, the forehead and tip of the tail are white. As the head and tail are also similar in shape, the colouring may be of the "directive mark" type designed, apparently, to enhance the resemblance of the two for the confusion of any would-be attacker.

3. *Anilidae.*—Harmless burrowing snakes, without any distinct neck but with the cylindrical body tapering slightly at either end, with a pair of claw-like vestiges of hind limbs visible on either side of the vent and with slightly enlarged scales on the belly; teeth are present in both jaws. The few members of this family are larger than most burrowing snakes, attaining a size of 2½ to 3 ft.; they seldom appear above ground but take readily to water, and their food seems to consist principally of other snakes and eels; all, so far as is known, are ovoviviparous. *Anilius scytale,* of tropical South America, coloured a beautiful coral-red with more or less complete black rings, superficially resembles some true coral snakes (*Micrurus*); as the latter are all venomous this is often regarded as an instance of mimicry. *Cylindrophis rufus* of Burma, the Malayan region and the East Indies also exhibits what appears to be mimicry, but of a different kind; the upper surfaces are brown or black, with, as a rule, light cross-bars, the belly is white with transverse black bands, and the tail bright red beneath. When the snake is brought above ground the tail is bent sharply upwards exhibiting the brilliant lower surface and if the animal is touched the tail snaps round in the manner of a striking head. Precisely the same tail colour and actions occur also in another burrowing snake of the same regions, *Doliophis intestinalis*, but this animal is venomous, with the largest poison glands of any elapid snake.

4. *Uropeltidae.*—Harmless burrowing snakes similar to those of the preceding family, but without any vestiges of hind limbs and with the tail ending in an enlarged scale which is either rugose or produced into two short points. The "earth-snakes" of Ceylon and the hills of southern India are all burrowers in loose earth in damp, forested regions and feed almost exclusively upon earthworms; those whose breeding habits are known are all ovoviviparous.

5. *Xenopeltidae.*—This family contains but a single species, *Xenopeltis* unicolor of southeastern Asia, a handsome snake with highly iridescent black or dark brown scales, each of which has a lighter edge; the head is small, not sharply marked off from the rest of the body and covered with enlarged shields; there are no traces of hind limbs, teeth are present in both jaws, the tail is short and the belly is covered with transversely enlarged scutes; total length about 3 ft.

6. *Boidae.*—Non-poisonous, often large, snakes with clam-like rudiments of hind-limbs visible on either side of the vent, enlarged scutes on the belly and teeth in both jaws. This family differs from the following in the absence of an extra bone (the supraorbital) in the skull, and in being viviparous.

The majority of boas are arboreal or semi-arboreal, and correlated with this habit the tail is usually more or less prehensile; all kill their prey (chiefly small mammals and birds) by constriction, and all those whose breeding habits are known are ovoviviparous, in contrast with the pythons which usually lay eggs. Though the name "Boa Constrictor" is frequently used to designate any large snake it is strictly applicable only to a single South American species, Constrictor constrictor, which is not particularly large, attaining a total length of only about 11 ft. The genus Boa contains a number of species in tropical America, including the West Indies, and two in Madagascar; *Corallus,* another very similar genus, has a similar distribution. The largest species is the anaconda (Eunectes *murinus*), which inhabits the forests of the Amazon basin and is said to reach a length of 30 ft., though actually, specimens of even 25 ft. seem to be very rare. The animal is largely aquatic and is usually found along the banks of rivers or in swampy regions; it is dark green in colour with numerous, sharply defined, round, black spots and is highly iridescent. In the old world, Enygrus occurs in the islands around New Guinea and on those of Polynesia as far east as Fiji; all the species have prehensile tails. Eryx, with about seven species, is an assemblage of small, sand-loving forms in north Africa, southeast Europe and southwest Asia; none of them greatly exceed 3 ft. in length and all have small heads, merging imperceptibly into their bodies, and short, scarcely prehensile tails.

7. *Pythonidae.*—The giant snakes of the old world mostly belong to the genus Python, the largest being the East Indian Python reticulafus, the reticulated python, in which very large individuals may exceed 30 ft. in iength. The females of the python family, as far as known, brood their eggs. There are various East Indian genera, among which *Chondropython* viridis forms a striking analogue is body form and colouring to Boa canina of South America. The only American python is *Loxocemus* of western Mexico. (See PYTHON.)

8. *Colubridae.*—This family comprises the great majority of snakes and its members show great diversity of habits and adaptations. In the restricted sense in which the name is here used the family may be defined as follows:—typical snakes, without any rudiments of limbs, with the head usually covered by enlarged scales, with enlarged ventral scutes, with teeth in both jaws and poison fangs, if present, situated on the hinder end of the upper jaw and preceded by smaller, solid teeth; distributed over all the temperate and tropical regions. Every kind of terrain is tenanted, from dense tropical forests to deserts and high mountains, and so uniform are the modifications connected with their different habits that, from its appearance alone, it is possible to draw a fairly safe conclusion as to a snake's mode of life. Burrowing forms are invariably small with relatively short tails, with small heads merging imperceptibly into the body and with greatly reduced eyes; desert dwellers are usually rough-scaled, with pallid or sombre colouring; terrestrial species have cylindrical bodies, a distinct neck and moderately long tails; arboreal snakes are greatly elongate with whip-like tails, long, pointed snouts, very large eyes and a more or less compressed body; thoroughly aquatic forms have the nostrils on the top of the snout and fitted with valves which can be closed while the animal is under water and, as a rule, the enlarged ventral scutes, so necessary for locomotion on land, are reduced. Two familiar, but perhaps artificial groups of colubrids can be recognised thus:—

Aglypha, without any grooved teeth.

Opisthoglypha, with one or more enlarged, grooved, poison fangs at the rear of the upper jaw.

These two groups, the one harmless, the other venomous, but, on account of the position of the poison fangs, rarely dangerous to man, almost grade into one another, a few species being known in which the posterior teeth are only slightly enlarged and sometimes grooved and sometimes not. The following classification into subfamilies is still essentially a provisional one. The Colubridae are sub-divisible into six "subfamilies."

(a) *Dipsadinae.*—Arboreal forms with the anterior teeth in both jaws enlarged and without a groove beneath the chin. This groove, present in almost all other colubrids, is part of the mechanism which allows of the two halves of the lower jaw being pushed apart in swallowing bulky objects and its absence in the dipsads is connected with the feeding habits of the group; they appear to feed exclusively on slugs. *Amblycephalus* and *Haplopeltura* occur in southeast Asia and the Malay Archipelago and *Dipsas* and its allies are confined to Central and tropical South America. Aglyphous.

(b) *Acrochordinae.*—Aquatic snakes with valvular nostrils on the upper surface of the snout; they are heavy-bodied animals frequenting fresh-waters and estuaries in southeast Asia and Central America, and feeding on fishes. The enlarged ventral scales are scarcely distinguishable and the common Indo-Malayan *Chersydrus* has the body laterally compressed and equipped with a fold along the lower surface; this fold, simulating a median fin, the compressed body and the absence of ventral shields bespeak an existence spent wholly in water. The less specialised forms with cylindrical bodies and retaining the ventral scutes are still capable of rapid movement on land. Aglyphous.

(c) *Xenoderminae.*—In the scale characters of the body the snakes of this subfamily link the very distinct Achrochordinae, which are entirely aquatic, with the typical colubrid land snakes. They are confined to southeastern Asia and the East Indies. The most remarkable genus, *Xenodermus*, has small scales with three series of much enlarged tubercles. Aglyphous.

(d) *Colubrinae.*—Typical snakes, with well-developed teeth in both jaws, with a dental groove and with, as a rule, lateral nostrils. Aglyphorous. This subfamily is cosmopolitan and its members may be more or less aquatic. arboreal, terrestrial or cryptozoic; as a rule they are oviparous, but some produce fully developed young. Perhaps the most thoroughly aquatic species is *Glypholycus* bicolor which inhabits Lake Tanganyika and in the general shape and the position of the nostrils superficially resembles the Acrochordinae. The common English grass snake (Natrix natrix) is a member of a widely distributed genus whose members are decidedly aquatic, and whose food consists principally of frogs and fishes; N. natrix, widely distributed through northern Europe, is very variable in colour, but is usually a grayish-green with some black markings on the back, traces of an incomplete yellow or orange collar on the neck and chequered black and white beneath; it frequents damp and marshy localities and feeds principally on frogs. Its European relative N. *viperinus*, very common in Spain and Portugal, is more aquatic still and feeds almost exclusively on fishes and the Indian keel backs (N. *piscator*) and the North American moccasins (N. fasciatus) have similar habits. Allied to *Natrix* are the N. American garter snakes (*Thamnophis*), a group of likewise semi-aquatic species. The strictly terrestrial genera, very numerous throughout most of the world except the Australian region, feed chiefly on small mammals, birds, toads and lizards. The rat snakes or racers of Europe and N. America (*Coluber*) the chicken snakes (*Elaphe*) and the Indian rat snakes (Ptyas) are all externally of very similar build and either kill their prey by constriction or eat it alive. Coronella, another similar genus. is represented in Britain by the smooth snake (*C. austriaca*), a species frequently confused with the viper but readily distinguished by its smooth scales and the enlarged plates on the top of the head; the species of this genus feed largely upon lizards, and the distribution of the smooth snake in England corresponds exactly with that of the sand lizard. Other terrestrial genera with specialised feeding habits are the king snakes (*Lam*propelfis) of N. America, and the African Lycophidion. The species of the first-mentioned genus live almost exclusively on other snakes, poisonous or harmless, the victim being killed by constriction; some "mimic" coral snakes in their colour pattern which consists of broad reddish bands edged with black and separated by narrower yellowish or buff interspaces. *Lycophidion* is characterised by enlarged teeth on the front of both jaws, the "canine" teeth being also directed outwards, and this is probably an adaptation to enable them to hold the smooth, hard-scaled skinks that form their principal diet. The American hog-nosed snakes (Heterodon) are remarkable for their superficial similarity to vipers, due to the broad, flat head and stout body; if annoyed they puff themselves up and hiss in true viperine manner. but if this fails to intimidate the enemy they roll over on their backs and "sham dead." Tree-snakes are greatly elongate, slender creatures and are represented by such genera as Dendrophis of southeast Asia and Australia and *Leptophis* of South America; they feed principally on lizards and young birds. Aglyphous.

(e) *Homalopsinae.*—Aquatic snakes with valvular nostrils situated on the top of the snout, and often with the ventral scales much reduced. They are confined to the fresh waters and estuaries of southeast Asia, Papua and North Australia and are all ovoviviparous. Opisthoglyphous.

(f) *Boiginae.*—This subfamily parallels the Colubrinae; its members are cosmopolitan and adapted to the same types of habitats, though in this group arboreal forms predominate. Among these may be mentioned a few which are remarkable for their habits or appearance; the slender, bodily form and elongate head is exaggerated in some, such as *Dryophis mycterizans* of the Indian Region or *Langaha* of Madagascar, by the production of the tip of the snout into a pointed or leaf-like dermal appendage. Many of these tree-snakes are brilliantly green to match the foliage, others brown to harmonise with the branches, but some show brilliant colour patterns which, though conspicuous when removed from their natural surroundings, are almost invisible in the dappled light and shade of the bushes which the animals frequent. *Chrysopelea* ornata of India and Malaya is often black with yellow dots on the centre of each scale and a series of red-centred yellow, tetra-petalous flowers along the back. This species is also famous as the flying snake, a name it has earned by its ability to "glide" to a limited extent; to accomplish this feat the body is held straight and rigid, the ribs pushed outwards to their full extent and the belly drawn in so that a considerable concave surface is produced which checks the fall of the animal and enables it, in an emergency, to descend with safety from a considerable height. Some members of the group, for instance the boomslang (*Dispholidus* typus) of South Africa, have the peculiar habit of expanding the neck to form a vertical "hood" when annoyed. Unlike the horizontal hood of the cobras, which is produced by an outward pressure of the ribs, this vertical "hood" is brought about by inflation of the mind-pipe. In snakes the cartilaginous rings of the trachea are incomplete along the side nearest the backbone, and a strip of tissue between their free ends is very distensible, so that, when air from the lungs is forced into the wind-pipe, this elastic tissue stretches and the neck is inflated.

Terrestrial genera are represented in Europe by *Malpolon*, one of the largest snakes of the continent, in the Mediterranean countries. *Erythrolamprus aesculapii* of tropical America is a very variable species whose many colour varieties mimic coral snakes; sometimes the groove on the fangs may be absent. Africa has many terrestrial forms, of which the commonest are the sand snakes (*Psammophis*), and also several burrowing genera, e.g., *Miodon* of West Africa and *Aparallactus* from the east and south. Some burrowing forms, notably *Apostolepis* in South America. exhibit "directive mark" coloration; the body is yellow, sometimes with longitudinal black stripes, and the head and stumpy tail are black with a few lighter dots, so that the similarity of the two ends is remarkable.

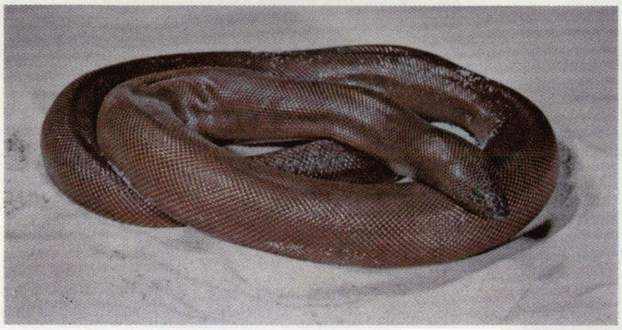
Only a few opisthoglyphs can be considered as dangerous to man; the situation of the fangs renders it difficult for any but the very large species to bring them into play except on the smallest objects. Should, however. a wound be inflicted by one of the larger species, such as the boomslang, the consequences are apt to be dangerous; the venom is largely haemolytic in its action and resembles that of the vipers rather than that of the cobras and their allies. Opisthoglyphous.

9. *Dasypeltidae.*—Terrestrial snakes highly modified for egg eating. A series of neck vertebrae have downwardly projecting processes that pierce the oesophagus to form an egg-shell cutting apparatus. The mouth and neck are enormously distensible and the egg is swallowed whole. When it reaches the "oesophageal teeth," compression of the neck muscles and a back and forth sawing motion cuts the shell, the contents of the egg being forced into the stomach. The shell is then rejected. The teeth are greatly reduced in number in the African genus *Dasypeltis*, which may explain the absence of grooved fangs, present in the Indian Elachistodon.

10. *Elapidae.*—Sometimes regarded as colubrids, these snakes are "proteroglyphous," *i.e.*, have fixed poison fangs in the front of the upper jaw and they always have well-developed ventral shields. Apart from the cobras (*q.v.*), this family contains other genera in the same regions, the true coral snakes of the Americas, and a great variety of forms in Australia. Some of the best

Reticulated python (*Python reticulatus*), one of the largest of all snakes, may reach a length of more than 30 ft. Found in southeast Asia and the Philippines

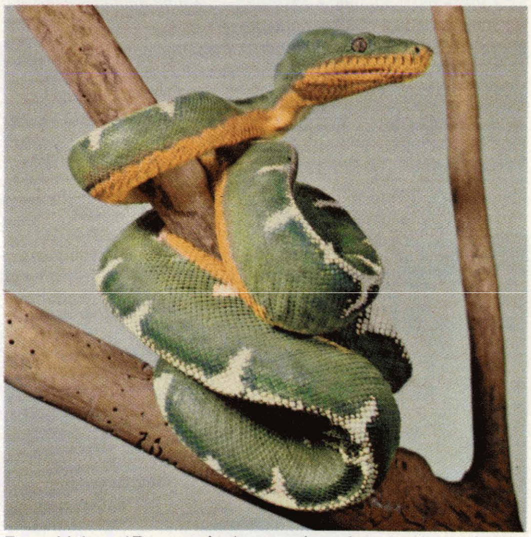
Diamond snake or carpet python (*Morelia argus*) of Australia and New Guinea



Sand boa (*Eryx johni*), a small burrowing snake that lives in sandy regions from north and central Africa to India and central Asia

White Indian python (*Python molurus*), a rare colour freak, not albino, caused by domination of white pigment cells over those of normal coloration

Boa constrictor (*Constrictor constrictor*), widely distributed in South America and found north, along the coasts of Mexico, almost to the U.S. border



Emerald boa (*Boa canina*), an arboreal snake found in the tropical jungles of South America

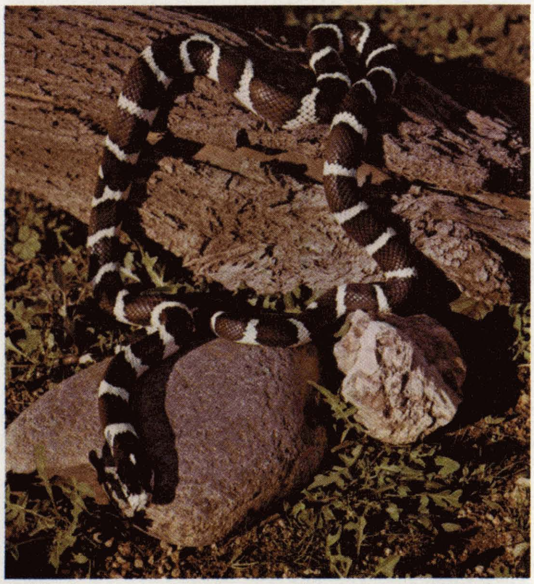
PYTHONS AND BOAS

PHOTOGRAPHS, (TOP LEFT, BOTTOM LEFT) JOHN H. GERARD, (TOP RIGHT, CENTRE RIGHT) CY LA TOUR AND (TOP RIGHT) BROOKFIELD ZOO, (CENTRE LEFT) NATHAN W. COHEN, (BOTTOM RIGHT) EDWARD VAN BAERLE

Eastern hognose snakes (*Heterodon platyrhinos*), showing two of the several oolour variations that are characteristic of this species. Found in sandy areas of most of the eastern and central U.S.

Yellow rat, or chicken, snake (Elaphe obsoleta *quadrivittata*), an arboreal species of the south Atlantic coastal U.S.

Texas rat snake (*Elaphe obsoleta lindheimeri*), found in Texas and western Louisiana. LIke most other obsoleta varieties, it is a large snake and may reaah a length of 7 ft.



California king snare (*Lampropeltis getulus californiae*), one of many *Lampropeltis* species widely distributed in the U.S.

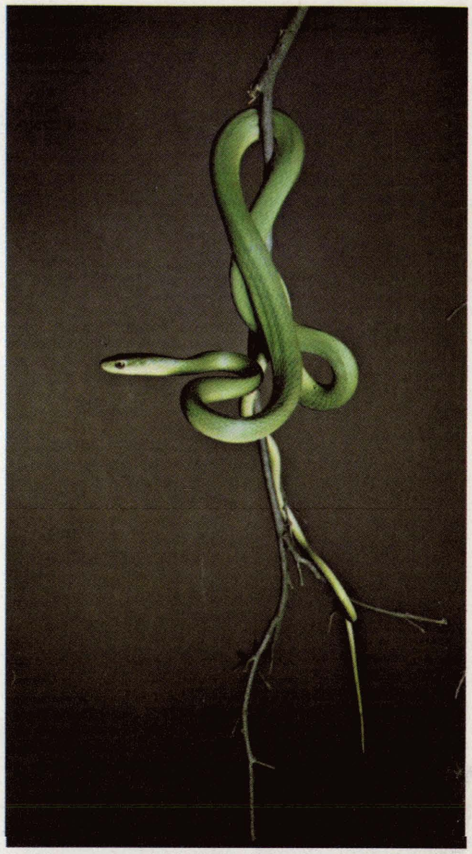
Red milk snake (tarnpropeltis *doliata syspila*). Banded pattern of the harmless milk makes, or king makes, is slmllar to that of some of the venomous coral snakes (Elapidae). Central U.S.

Aesoulaplan snake (Elaphe *longissima*), a chicken snake found in Europe and Asia Minor

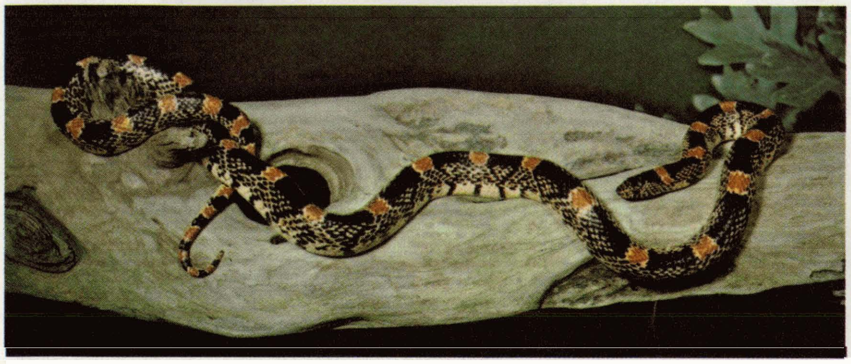
KING, RAT AND HOGNOSE SNAKES

PHOTOGRAPHS, (TOP LEFT, TOP RIGHT, CENTRE LEFT, BOTTOM LEFT) JOHN H. GERARD, (CENTRE RIGHT) WILLIS PETERSON, (BOTTOM RIGHT) JOHN MARKHAM

Eastern yellow-bellied racer (*Coluber constrictor flaviventris*), an extremely fast-moving, smooth snake found chiefly in the Middle West, north of the Ohio valley to the Great Lakes

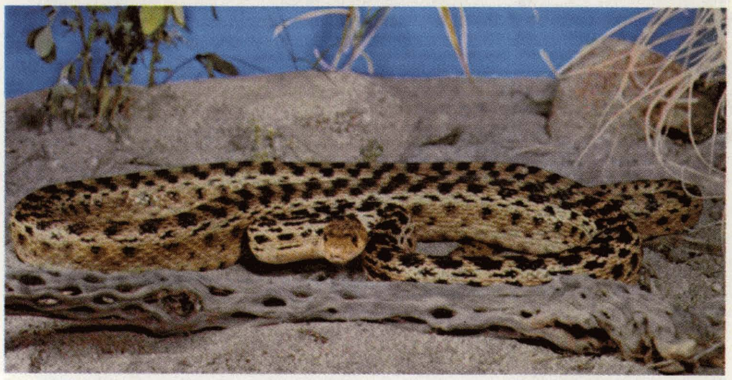


Rough green snake (*Opheodrys aestivus*), a long, slim arboreal species seen in south central and Atlantic coastal states



Texas long-nosed snake (***Rhinocheilus lecontei tessellatus***), a **speckled,** burrowing **snake** found in arid regions of the extreme southwest and northern **Mexico**

Western worm snake (Carphophis ***amoenus vermis***), a small **terrestrial** snake usually found hidden beneath moist **foliage,** rocks or logs



Sonora gopher snake (***Pituophis catenifer affinis***), a **large western bull snake known** for the loud **hissing it makes** when **attacked** or frightened

Western ribbon snake (Thamnophis ***sauritus proximus***), a slender garter snake found In most of the middle western states west of the Mississippi river

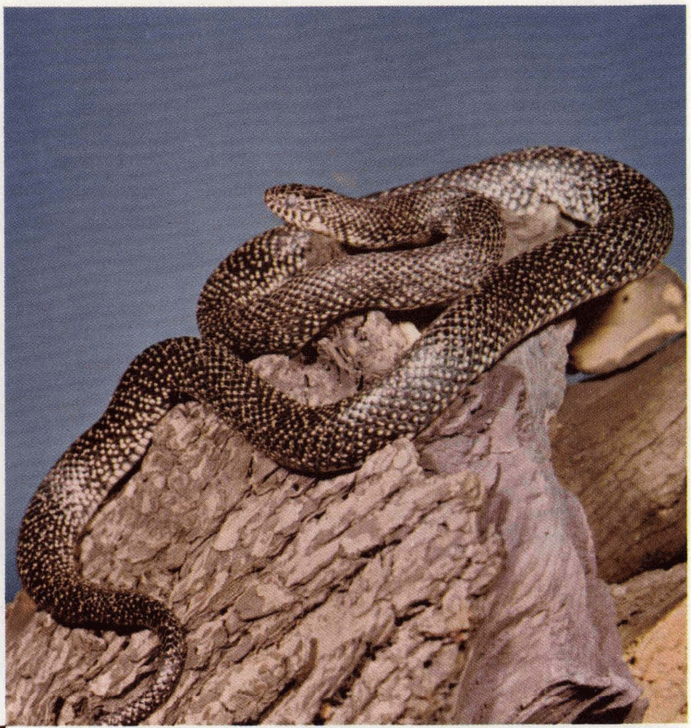
Eastern garter snake (Thamnophis ***sirtalus sirtalus***), a very common snake of the entire eastern half of the U.S. and southeastern Canada

COLUBRIDS: HARMLESS SNAKES OF THE U.S.

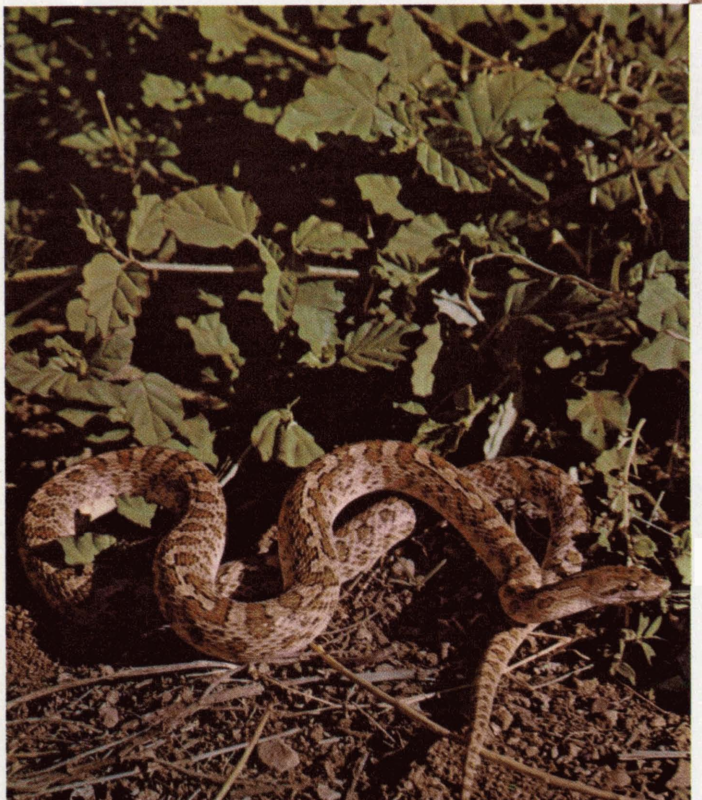
PHOTOGRAPHS, JOHN H. GERARD EXCEPT (CENTRE RIGHT) CY LA TOUR

SNAKE

Sonora king snake (*Lampropeltis getulus splendida*), a largely nocturnal species found In the southwest and north central Mexico. It constricts Its prey, often other snakes

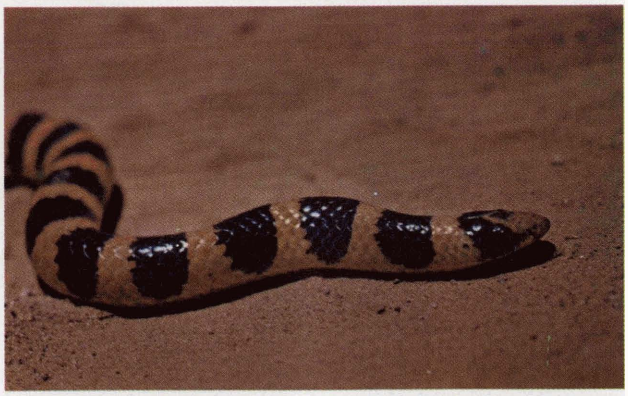


Speckled king snake (*Lampropeltis getulus holbrooki*), another of the snake-eating snakes. Found In the prairie and south central states



Glossy snake (Arizona *elegans*), a burrowing snake usually found in sandy areas of the southwest and northern Mexico

Northern black-headed, or flat-headed, snake (*Tantilla gracilis hallowelli*), a small, secretive species of the middle western states

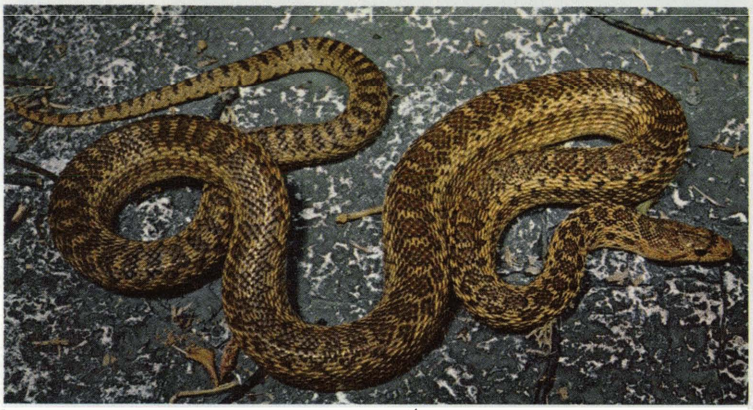


Banded sand snake (*Chilomeniscus cinctus*), a small snake whose snout Is adapted for rapid burrowing into sand. Found chiefly in Arizona and Baja California

COLUBRID SNAKES OF THE U.S.

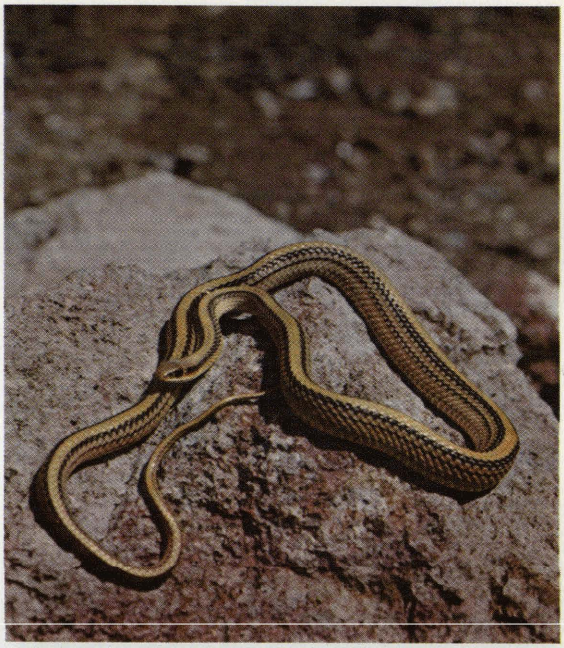
PHOTOGRAPHS, (TOP LEFT, CENTRE RIGHT) JOHN H. GERARD, (TOP RIGHT) JOHN MARKHAM, (BOTTOM LEFT) WILLIS PETERSON, (BOTTOM RIGHT) HYMEN MARX

Western ringneck snake (***Diadophis amabilis***) in its defense posture, coiled with the underside of its tail exposed. Found chiefly on the Pacific coast



Pacific gopher snake (***Pituophis catenifer catenifer***), a constricting bull snake found on the west coast

Eastern indigo snake (***Drymarchon corais couperi***), a relative of the racers, may reach a length of about 8 ft. Found chiefly in Florida. Georgia and Alabama



Texas patch-nosed snake (***Salvadora lineata***), a slender species found most often in rocky terrain in northern Mexico, Texas and Oklahoma

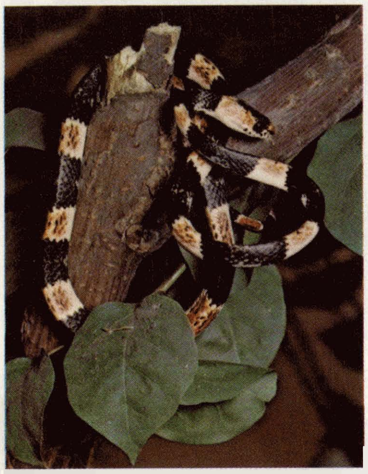
Graham's water snake (***Natrix grahami***), found in streams and quiet water west of the Mississippi river to Texas and north to Illinois

Bull snake (***Pituophis melanoleucus sayi***), a large prairie-dwelling species that will strike when alarmed but is not dangerous to man

HARMLESS SNAKES OF THE U.S.

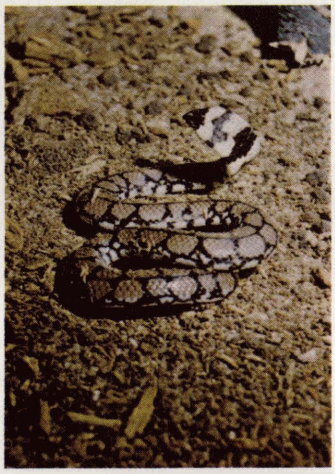
PHOTOGRAPHS. (TOP LEFT) NATHAN W. COHEN, (TOP RIGHT) WILLIS PETERSON, (OTHERS) JOHN H. GERARD

Mangrove snake (***Boiga dendrophila***), a rear-fanged arboreal species found in tropical Asia



Blunt-headed tree snake (***Imantodes cenchoa***), native to Central and South America

Elephant trunk, or wart, snake (***Acrochordus javanicus***), a **loose-skinned aquatic snake—the** only **living** member of **its** family **(Acrochordidae)—found** in southeast Asia



An **anilid snake**, ***Cylindrophis maculatus***, in **its defense** position with **head** hidden and tail curled. Asian

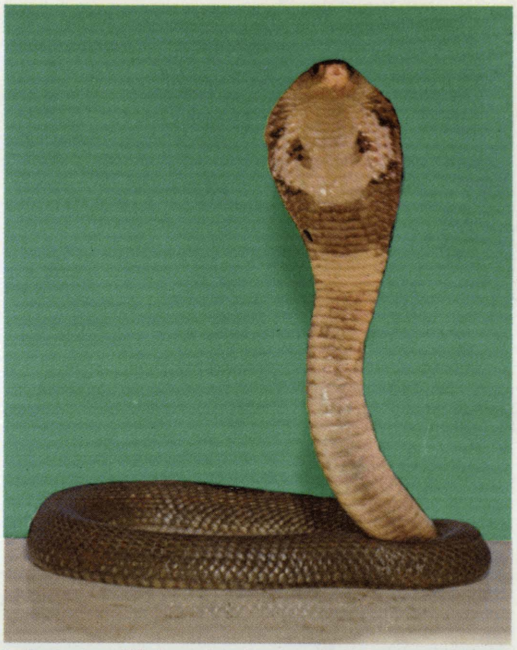
Common water snake of North America (*Natrix sipedon*), very widely distributed throughout the central and northeastern U.S.

Common water, or grass, snake of **Europe** (***Natrix natrix***), another **successful,** widely distributed **species** of **this** genus

COLUBRID WATER SNAKES AND SNAKES OF SMALLER FAMILY GROUPS

PHOTOGRAPHS, (TOP, BOTTOM RIGHT) JOHN MARKHAM, (CENTRE LEFT) CY LA TOUR, (CENTRE) HYMEN MARX (CENTRE RIGHT) G. B. RABB—BROOKFIELD ZOO, (BOTTOM LEFT) JOHN H. GERARD

East Indian coral snake, *Matacora* (formerly *Doliophis*) *bivirgata,* shown exposing the vivid underside of its tall, a defensive maneuver



Indian cobra (*Naja naja*) in characteristic pose, with its neck muscles (hood) extended (front view). Found in Asia and Africa

Head of a black mamba (*Dendroaspis polylepis*), a large, aggressive and extremely venomous African elapid

Vermicella calonota, a small, weakly venomous cobra (harmless to [redacted]) of western Australia

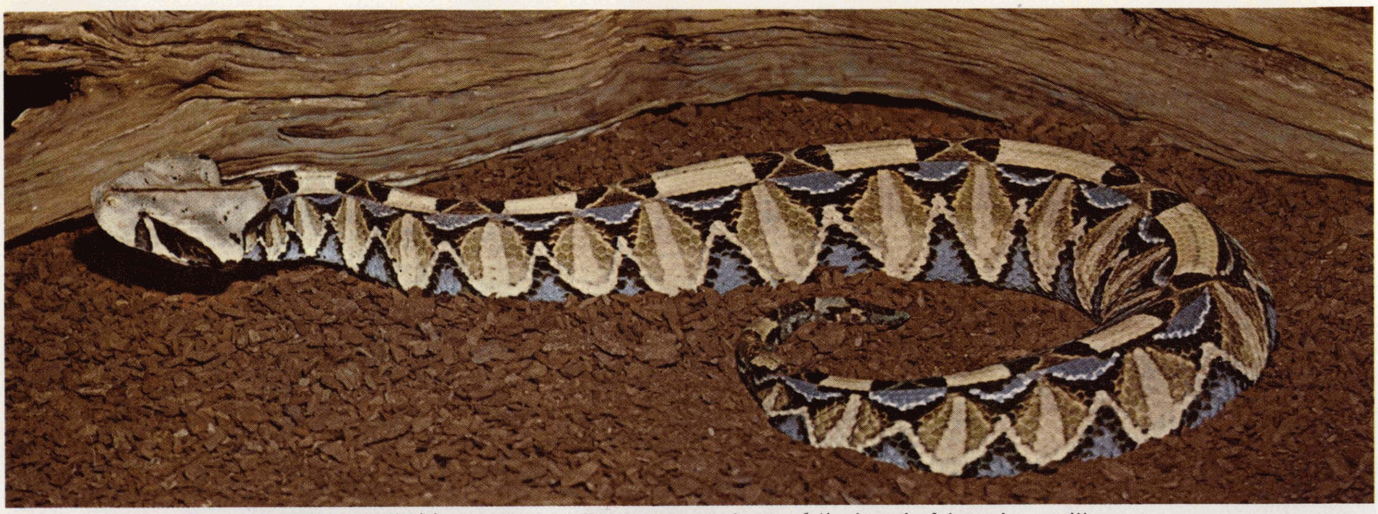
Krait (*Bungarus fasciatus*), found in India and southeast Asia. Large and strongly venomous

Eastern coral snake (*Micrurus fulvius*), found in the southeastern section of the U.S.

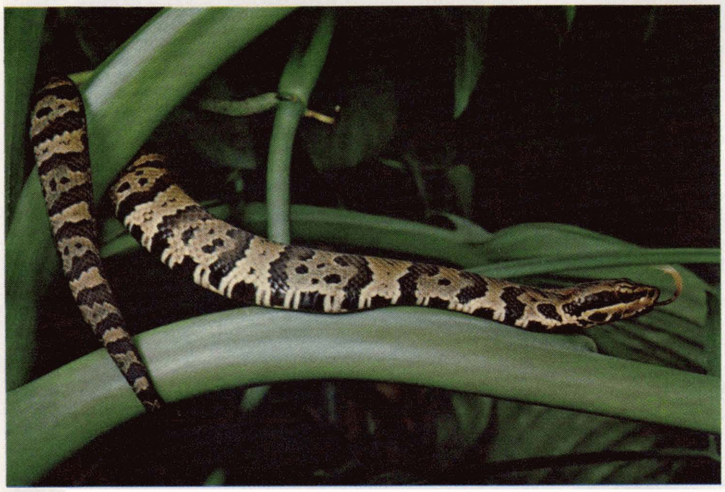
VENOMOUS SNAKES: COBRAS, CORALS AND OTHER ELAPIDS

PHOTOGRAPHS, (TOP LEFT) D. DWIGHT DAVIS, (TOP RIGHT, BOTTOM LEFT) CY LA TOUR AND (BOTTOM LEFT) DETROIT ZOO, (CENTRE LEFT) JOHN MARKHAM, (CENTRE RIGHT) R. MERTENS, (BOTTOM RIGHT) ALLEN D. CRUICKSHANK FROM THE NATIONAL AUDUBON SOCIETY

SNAKE



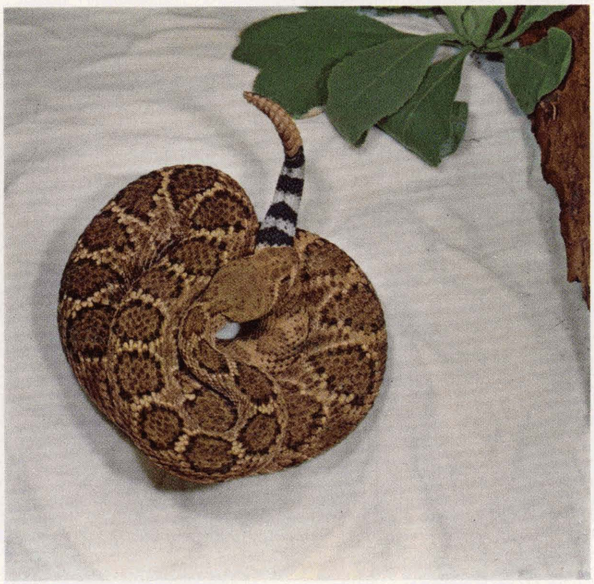
Gaboon viper (***Bitis gabonica***), **strikingly coloured,** is one *of* the **largest** of true **vipers, with** a **length up** to 6 ft. and a diameter of 6 in. **It** is unaggressive but **extremely venomous.** Found in **Africa**



Water **moccasin** or **cottonmouth** (***Agkistrodon*** [or ***Ancistrodon***] ***piscivorous***), a dangerous **aquatic** pit **viper** of the southeastern U.S.

Common **viper** (***Vipera berus***), **known as the adder in England, is** the most widely **distributed poisonous** snake of **Europe, England, Scotland** and Wales

Copperhead (***Agkistrodon*** **[or *Ancistrodon*]** ***concortrix***), one of four varieties that are found In most of the eastern, southern and southwestern **U.S.** Its bite is rarely fatal to man



Western diamondback rattlesnake (***Crotalus*** atrox) showing the **dis-**tinctive tail of the rattlesnakes. The western diamondback is one of the largest and most dangerous of its **type**

VENOMOUS SNAKES: VIPERS AND PIT VIPERS

PHOTOGRAPHS, (TOP) CY LA TOUR AND THE ST. LOUIS ZOO, (CENTRE LEFT, BOTTOM LEFT, BOTTOM RIGHT) JOHN H. GERARD, (CENTRE RIGHT) JOHN MARKHAM known of the latter are the Australian black snake (Pseudechis), which reaches a length of 6 ft. and has a small distensible hood, the tiger snake (Notechis), and the death adder (*Acanthophis*), in which the broad head, with small scales, and the stocky body produce the most viper-like of the elapids. In the Indian region the common hooded cobra and the king cobra are accompanied by other genera, especially the kraits (Bungaras). The large and active mambas of Africa (Dendraspis), whose venom appears to be extremely potent, are both arboreal and terrestrial. The coral snakes (*Micruroides, Micrurus* and *Leptomicrurus*) are the only American representatives. The genus *Elaps,* from which the family takes its name, is a South African snake with black and white rings.

The East Indian *Doliophis* is notable for the enormous development of the glands, which extend backward through the anterior third of the body. The species of Doliophis are brilliantly coloured, and have the further interesting habit of raising the tail when annoyed, to expose its brilliant red undersurface.

The larger snakes of this family are all highly dangerous to man; the venom is chiefly neurotoxic in its action, as compared with the more haemolytic venom of the rear-fanged snakes and of the vipers and pit-vipers.

11. Hydrophidue.—Sea snakes well adapted to aquatic life, with valvular nostrils on the top of the snout, vertically flattened tails, and the ventral shields greatly reduced (subfamily Laticaudinae) or absent (subfamily Hydrophinae). There are about 55 species all told. The snakes of the former subfamily, mainly of the Australian region, come ashore to lay eggs, while the more advanced Hydrophinae, mainly Malayan, produce living young. One of these, the pelagic *Pelamis platurus,* ranges from Madagascar to Panama. It has a striking coloration, with a brown or black back sharply set off from the yellow belly.

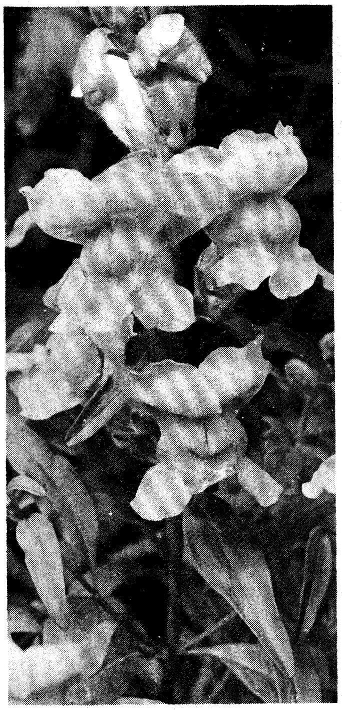
All of the sea snakes are venomous, but the majority are entirely docile, and fishermen, who in some places throw them out of the nets with their bare hands, are rarely bitten. Most of the species are moderate in size, reaching lengths of three or four ft.; the giants of the family may be as much as 8 ft. in length (*Hydrophis cyanocinctus,* for example). Only one species, *Hydrophis semperi* of Lake Taal on Luzon, inhabits fresh water.

12. *Viperidae.*—This family and the following are characterized by large poison fangs situated at the front of the upper jaw, the only teeth on the maxillary bone being the fangs. The maxillary is movable so that the fangs can be erected for use or folded back on the roof of the mouth. In both families the venom is powerful and usually strongly haemolytic in action. The family Viperidae is confined to the old world. The primitive genera *Causus* and *Azemiops* have the large shields on the head of the typical snakes. The African *Atractaspis,* with very large fangs, has a narrow rounded head and cylindrical body. Certain arboreal African forms have a prehensile tail. The puff adder and its relatives, *Bitis* and the true vipers *Vipera,* have much enlarged poison glands, broadened heads, and have lost the normal head shields (see VIPER).

13. *Crotalidae.*—This family is distinguished by the presence of a curious sense organ on the face between the eye and nostril, the "pit," hence the name pit vipers. It includes the moccasin and copperhead of North America with related species in Asia (*Agkistrodon*); the fer-de-lance group (*Trimeresurus*) also American and Asiatic; the bushmaster (Lachesis); and the numerous species of rattlesnakes of the genera *Crotalus* and *Sistrurus.* See also PIT VIPER and RATTLESNAKE. (H. W. P.; K. P. S.)

SNAPDRAGON (ANTIRRHINUM), any herbaceous plant of the genus *Antirrhinum,* of the snapdragon or figwort family (Scrophulariaceae), of which there are over 40 species, scattered over the north temperate zone, especially in the western states of the U.S. The common garden snapdragon, *A. majus,* much grown for its handsome flowers, is a perennial from the Mediterranean region, usually grown as a summer annual; growers for the florist trade, however, force it for winter bloom. It is a stout plant 12–25 in. high, producing pouchlike, irregular flowers in a showy terminal cluster (raceme).

Another species is the beautiful chaparral snapdragon, *A.* coulterianum of California, with purple or white flowers that have conspicuous yellow hairs in the throat of the corolla.



A. W. KERR

A VARIETY OF SNAPDRAGON. ANTIRRHINUM MAJUS

Scores of showy garden varieties have replaced the typical *A.* majus. They are dwarfs (6–9 in. high), intermediates (10–20 in. high) and talls (20–40 in. high).

For outdoor culture seeds are shallowly sown in Aug. or Sept. and wintered in cold frames for transplanting the following spring. In all cold regions this must be done annually, for snapdragons are not frost hardy. When forced for winter bloom, seed is sown in June, and the potted seedlings are transferred to a cool greenhouse in September for blooming in Dec.–Jan., or later if successive sowings are made.

Snapdragon is also the somewhat inappropriate name of *Galvesia speciosa,* closely related to *Antirrhinum,* an evergreen shrub with showy scarlet flowers, found on the islands off the coast of California. (N. TR.)

SNEEK, a town in the province of Friesland, Netherlands. west of Sneek lake, 14 mi. by rail S.S.W. of Leeuwarden, with which it is also connected by canal. Pop. (1957 est.) 19,881 (mun.). One of the former city gates (1615) remains, and in one of the churches is the tomb of the naval hero of the 16th century, Lange, or Groote Pier (Long or Great Peter).

Sneek is one of the great butter and cheese markets of the province.

SNEEZING, a violent expiration of air from the nose and mouth. an involuntary reflex respiratory act caused by irritation of the nerve endings of the mucous membrane of the nose or by stimulation of the optic nerve by a bright light. The irritation may be due to: swelling of the nasal mucous membrane, sneezing often accompanying nasal catarrh; foreign bodies in the nose, as by inhalation of snuff; or allergy. The spray emitted may carry infection to others.

Sometimes spasms of sneezing occur. A venerable and widespread belief survives in the custom of saying "God bless you" when a person sneezes. (F. L. A.)

SNELL, HANNAH (1723–1792), English "female soldier," was born at Worcester, Eng., on April 23, 1723, the daughter of a hosier. In order to seek her husband, who had ill-treated and abandoned her, in 1745, she donned man's attire and enlisted as a soldier in Guise's foot regiment, but soon deserted; she then shipped on board the sloop "Swallow," took part in the siege of Pondicherry and was wounded. Her adventures were told in *The Female Soldier,* or the Surprising Adventures of Hannah Snell (1750).

Hannah Snell died insane in London, Feb. 8, 1792.

SNELL (VAN ROIGEN), **WILLEBRORD** (1591–1626), commonly known as SNELLIUS, Dutch astronomer and mathematician, the discoverer of the law of refraction, was born at Leiden. In 1613 he succeeded his father, Rudolph Snell (1546–1613), as professor of mathematics in the Gniversity of Leiden. In his Eratosthenes *Batavus* (1617), he describes his method of measuring the earth, and gives as the result of his operations between Alkmaar and Bergen-op-Zoom a degree of the meridian equal to 55,100 toises (= 117,449 yd.). His discovery (1621) of the law of refraction was of significance fbr the study of the nature of light (see LIGHT: History).

Snell died at Leiden, Oct. 30, 1626.

SNIPE, a name for certain shore birds of the sandpiper family Scolopacidae. much sought after as game birds. The common snipe, *Capella gallinago* of Europe and America, is 11 in. long with a long ($2\frac{1}{2}$–3 in.) bill, eye placed far back in the head, rather short legs, but long toes, a very short tail, and a complicated pattern of brown, buffs and black on its upper parts. It lives in bogs and wet meadows where it probes for worms.

Secretive, it flushes from the grass with a hoarse cry and zigzags rapidly away. The birds, though usually solitary, sometimes feed and travel in loose flocks. They winter south to Africa, Java and South America. In the spring the male gives a flight song, the pair lines a hollow in the ground for a nest; four spotted eggs are laid and incubated by the female; and the active downy young are cared for by both parents.

There are other, related species in Europe. Asia (some of which migrate to Australia). Africa and South America. A more different species, the jacksnipe, *Lymnocryptes minimus* of Europe, is only seven and one-half inches long. In Europe, dowitchers are also called snipe.

The species of painted snipes, one of Africa and the area of southern Asia and Australia, the other of South America, form a related iamily. Rostratulidae, in which the birds are more brightly coloured: in this family the female is larger and brighter than the male, and takes the initiative in courtship, while the male incubates the eggs. (A. L. RD.)

SNOILSKY, CARL JOHAN GUSTAF, COUNT (1841–1903), Swedish poet, the most notable of a group of early poetic realists, was born in Stockholm on Sept. 8. 1841. At Uppsala university Snoilsky made himself known by his great poetic talent. He went to Italy in 1864 and wrote poems praising the joy and beauty of the Mediterranean landscape. After several years as a diplomatist and civil servant he gave up his career in 1879 and lived abroad, devoting himself to poetry. Deeply affected by social problems, he favoured the breaking down of class barriers and expressed his social anguish and humane liberalism in important poems. From these years also dates his well-known series on figures and episodes from Swedish history. *Svenska bilder* (1886). In 1890 Snoilsky returned to Stockholm, where he died on May 19, 1903.

Snoilsky's poetry is clear and elegant and has, though rather traditional in form, a strong note of realism.

SNORRI STURLUSON (1179–1241), the celebrated Icelandic historian, the youngest son of a chief in the Vestfirðir (western fiords), was brought up by a powerful chief. Jon Loptsson, in Odda, who seems first to have awakened in him an interest for history and poetry. His career begins with his marriage, which made him a wealthy man; in 1206 he settled at Reykjaholt. where he constructed magnificent buildings and a bath of hewn stones, preserved to the present day, to mhich water was conducted from a neighbouring hot spring. He early made himself known as a poet, especially by glorifying the exploits of the contemporary Norse kings and earls; at the same time he was a learned lawyer, and from 1215 became the *lögsögumaðr,* or president of the legislative assembly and supreme court of Iceland. The prominent features of his character seem to have been cunning, ambition and avarice, combined with want of courage and aversion from effort. By royal invitation he went in 1218 to Norway, nhere he remained a long time with the young king Haakon and his tutor Earl Skuli. When, owing to disputes betneen Icelandic and Norwegian merchants, Skuli thought of a military expedition to Iceland, Snorri promised to make the inhabitants submit to Haakon of their own free will. Snorri himself became the *lendrmaðr,* vassal or baron, of the king of Normay, and held his lands as a fief under him. On his return home Snorri sent his son to the king as a hostage, and made peace between Norway and Iceland, but his power and influence were used more for his own enrichment and aggrandizement (he was *lögsögumaðr* again from 1222 to 1232) than for the advantage of the king. Haakon, therefore, stirred up strife between Snorri's kinsman Sturla and Snorri, who had to fly from Reykjaholt in 1236; and in 1237 he left the country and went back to Norway. Here he joined the party of Skuli. who was meditating a revolt. Learning that his cousin Sturla in Iceland had fallen in battle against Gissur, Snorri's son-in-law, Snorri, although expressly forbidden by his liege lord, returned to Iceland in 1239 and once more took possession of his property. Meanwhile. Haakon, who had vanquished Skuli in 1240, sent orders to Gissur to punish Snorri for his disobedience either by capturing him and sending him back to Norway or by putting him to death. Gissur took the latter course, attacked Snorri at his residence, Reykjaholt, and slew him on Sept. 22, 1241.

Snorri is the author of the great prose *Edda (see* EDDA), and of the *Heimskringla or Sagas of the Norwegian Kings,* a connected series of biographies of the kings of Norway down to Sverri in 1177. Snorri's sources were partly succinct histories of the realm, such as the chronological sketch of Ari: partly more voluminous early collections of traditions, as the *Noregs Konungatal (Fagrskinna)* and the Jarlasaga, partly legendary biographies of the two Olafs; and, in addition to these, studies and collections which he himself made during his journeys in Norway. His critical principles are explained in the preface. where he dwells on the necessity of starting as much as possible from trustworthy contemporary sources, or at least from those nearest to antiquity—the touchstone by which verbal traditions can be tested being contemporary poems. He inclines to rationalism, rejecting the marvelous and recasting legends containing it in a more historical spirit; but he makes an exception in the accounts of the introduction of Christianity into Norway and of the national saint, St Olaf Besides his principal work. he elaborated in a separate form its better and larger part, the *History oj St. Olaf* (the great *Olaf's Saga).* In the preface to this he gives a brief extract of the earlier history, and, as an appendix, a short account of St. Olaf's miracles after his death. *See* further ICELANDIC LITERATCRE. and EDDA.

SNOW is the solid form of water which grows while floating, rising or falling in the free air of the atmosphere. It often takes the form of beautiful crystals generally having a hexagonal pattern Snow crystals sometimes come from a cloudless sky since they may form spontaneously or in the presence of suitable sublimation nuclei before there is enough water vapour present in the air to form the common water droplet cloud.

Snow has attracted the attention and admiration of many from ancient times. The word crystal is of Greek origin and is derived from *kryllos,* the word for frost. One of the first indications of man's early awareness that there was more to snow than cold, hunger. trouble, and restricted travel is the biblical reference to the "storehouses of the snow" in the Book of Job xxxviii, 22.

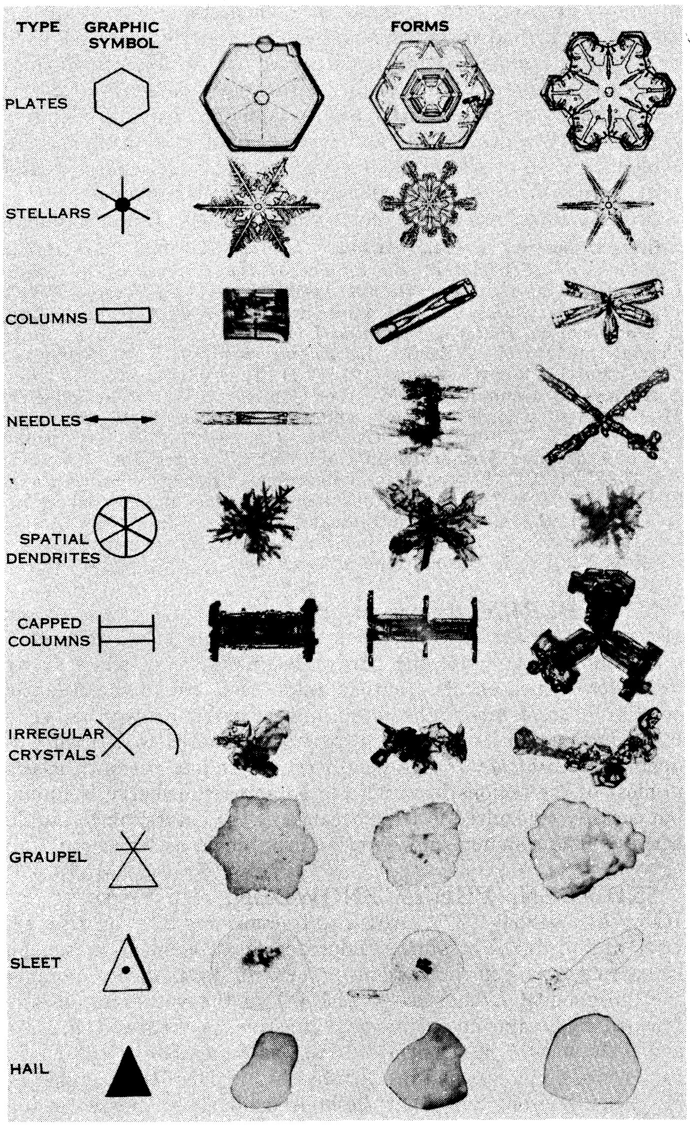
One of the first recorded instances showing recognition of the hexagonal symmetry of snow crystals is ascribed to Olaus hlagnus, archbishop of Uppsala in Sweden who depicted the crystal form in a book on natural phenomena published in Rome in 1555. The development of the microscope increased this knowledge. Robert Hooke of England studied the snow crystal structure and published illustrations of some of the beauty and symmetry he saw in his fascinating book, *Micrographia,* published in 1665. During the middle of the 19th century. poetry and prose mere written about snow and snow crystals. An extremely interesting book of this period entitled *Cloud Crystals* written by "A Lady" and published in 1864 contains scientific fact, poetic fancy and excellent wood cuts shoning some of the basic forms of snow.

Snow Crystals.—It has been said that no two snow crystals are the same. This statement is true in the sense that it is quite unlikely that among all the countless myriads that fall from the sky there are ever two identical in shape, size and absolute number and distribution of water molecules.

Honever, it is no problem during a particular storm to observe two crystals mhich to the unaided eye or even at low power magnification are similar in outline and general structure. The main point to observe in this relation is that there is a bewildering variety of size. shape and pattern. They range from simple, solid triangles and hexagons to the exquisite fernlike dendrites, with all manner of complicated three-dimensional formations.

In an attempt to simplify the task of the research scientist concerned with reaching a better understanding of the fundamental science related to the formation of snow and ice, a classification of solid precipitation was developed in 1951 for international usage. This is shown in fig. 1 which illustrates the typical forms of ten types of frozen precipitation. It is quite feasible to subdivide any one of these ten types into subtypes and for special purposes this is being done. For all practical purposes. however, the types illustrated can be used to describe the precipitation of snow, ice and hail storms.

A considerable amount of the popular interest in snow crystals stems from the pioneer and classic photographic work done by



FROM "ARTIFICIAL STIMULATION OF RAIN,' (1957); REPRODUCED BY PERMISSION OF PERGAMON PRESS, INC.

FIG. 1. — CLASSIFICATION OF FROZEN PRECIPITATION

Wilson W. Bentley, farmer-meteorologist of Jericho, Vt. Bentley became enthralled by the beauty of snow crystals and spent many winters with his camera, recording the varieties and symmetry of the crystals that are such a common feature in the vicinity of his northern Vermont home. Of the more than 5,000 photomicrographs prepared by him. nearly half have been perpetuated in *Snow* Crystals, published in 1931. His persistent efforts. careful observations and beautiful photographs did much to arouse the interest of scientists in snom crystals.

In Europe a similar effort was expended by **A.** B. Dobrowolska of Poland who wrote many scientific articles on this subject. In Japan, the classic work in the study of snow by U. Nakaya of the University of Hokkaido, culminated in his book **Snow** Crystals (1954).

The relationship of snom to ice and the peculiar underwater snow storms caused by frazil ice formations have been studied for many years and are of much economic importance.

The bewildering variations and modifications occurring in snow after it has reached the ground are a specialized study that still continues. The early studies have been uell summarized by G. Seligman. The modern work increases in complexity with much of it in North America under the leadership of the Snow, Ice and Permafrost establishment of the U S. army corps of engineers.

There are many factors controlling the size and shape of snow crystals. One of these—probably the most important—is the supply of water molecules in the air. If the air contains a rich supply of moisture. the snow crystals will grow fast and is likely to have dendritic or fernlike arms. will be large and may clump together with others to form a snowflake. Snowflakes may have 50 or more crystals interlocked nith each other. If a stellar-type crystal forms or falls into a cloud containing a high density of subcooled cloud droplets, it may sweep up some of them which freeze upon contact and cover the crystal until it looks like a miniature snonball. Such particles are called soft hail (*q.v.*) or snow pellets but are most commonly called by the German name *graupel*.

The temperature of the air is another condition controlling the form of the snow crystal. If the air is colder than about −30° C. it contains very little water vapour so that any crystals developing grow very slowly and are likely to be tiny. dense and compact in shape and crystal form. This is the condition nhich produces the crystals of the filmy cirrus clouds that form in the high levels of the atmosphere often at altitudes of five to eight miles over the middle and low latitudes. In the polar regions, cirruslike clouds may be close to the ground due to the intense cold.

At temperatures close to −40° C. (−40' F.) which commonly occur in the polar regions and at levels in the sky above 30,000 ft., ice crystals form spontaneously whenever a sufficient concentration of water molecules exceeds the amount that can exist in vapour form. This is called homogeneous nucleation phenomenon. At all temperatures warmer than −40° and colder than 0° C. (32° F.), heterogeneous nucleation occurs. In this range, special type microscopic or submicroscopic particles floating in the air serve as nuclei for ice crystal formation. Particles in the size range of 0.01 to 10 μ (0.0000025 to 0.0025 in. in diameter) consisting of such materials as volcanic dust, loess, certain types of clays, silver iodide and a special form of copper sulfide serve as effective ice nuclei. Except for the silver iodide and copper sulfide, which become active at temperatures colder than −4° C. most ice nucleating substances are effective in the temperature range of −12° to −25' C. There is much still to be learned about the behaviour and characteristics of such particles.

Effects of Snow.—Like so many of the small things in nature, a snow crystal, when considered as a single particle, is at once beautiful or at least interesting in structural form and seemingly ineffectual as an element of force or destruction. It is only when they occur in quantity—nearly countless numbers—that their presence causes wonder, interest. concern or terror.

Floating in the rare air of the high atmosphere, the tiny, pointed or flat-ended hexagonal columns and thickened hexagonal plates form the coloured halos. pillars, arcs and circles surrounding the sun in orderly array. Formed in the upper parts of turbulent clouds, the reactions between crystals and subcooled water cause the development of electrical charges often manifested as cloud-to-cloud or cloud-to-ground lightning and radio static and lesser degrees of atmospheric electricity. Sweeping over and smashing on airplane wings and fuselage, the snow crystal causes electrification which may appear as St. Elmo's fire on leading surfaces and may illuminate the trailing edges of the wing tips.

Much of the moderate to heavy rain in the middle latitudes starts as snow in the high reaches of the sky and thus is responsible for the precipitation on which most life as we know it is primarily dependent. Snow packs represent a form of water storage that is very useful to man. The heavy winter snows in the higher elevations remain as a slonly melting snow pack long into the summer which feeds the mountain streams flouing into the drier valleys. The interior valleys of California and Oregon, plains of Utah, Colorado, New Mexico, Arizona, parts of Spain north Africa and a number of similar areas which have insufficient precipitation to support crops. are made into fertile agricultural regions by means of irrigation water from nearby massive mountains.

At times snon may become so deep and unstable on the mountain slope as to form a terrifying avalanche or it may become consolidated to form massive layers of turquoise green-blue glacial ice to flow down the mountain as a river of ice *(see* AVALANCHE; GLACIER).

It would not be proper to end the discussion of the massive effects of snow without reference to the beauty of snow and the sport of skiing. With the rapid development in the second half of the 20th century of ski centres and ski lifts of all kinds, and the equipment demanded by the skier, the importance of snow as a valuable commodity in certain areas assumed such value that it became economically profitable to generate snow on cold nights from high pressure air and cold water.

For an account of the history of this sport and description of its development *see* SKIING. *See* also SLEIGH; SNOWSHOES; WINTER SPORTS.

Snow Crystals and Cloud **Modification.**—When the droplets in clouds cool below 0" C. (32° F.), they do not normally freeze but remain in liquid form. These subcooled droplets may cool to −30° C. or colder before they freeze, depending on whether or not they contain freezing nuclei or float near ice crystals. Whenever water subcools, it becomes unstable, so that an ice crystal alongside a liquid droplet will grow at the expense of the droplet. If nuclei suitable for ice crystal nucleation enter a cloud, they grow rapidly and either transform the entire cloud to snow or grow until large enough to overcome rising currents in the air and thus fall out of the cloud.

Since. as shown by V. J. Schaefer in 1946, it is feasible to produce local concentrations of ice nuclei in greater numbers than occur under natural conditions and having a nucleating activity better than naturally occurring particles, scientists aye able to carry out experiments using clouds in the atmosphere for their

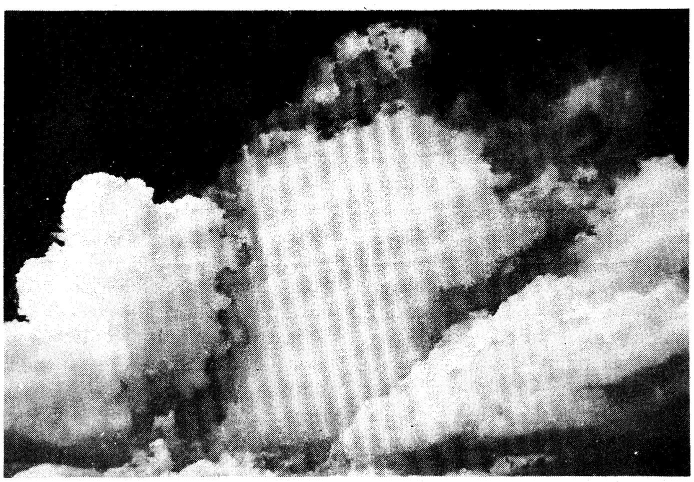


FIG. 2.— PRODUCING SNOW CLOUD (CENTRE) BY SILVER IODIDE SEEDING. UNSEEDED CLOUDS AT LEFT AND RIGHT

subjects. Efforts are being made to take advantage of these opportunities. to prevent damaging hailstorms. to modify lightning storms, to increase snow deposits in the high mountains, to increase rainfall and to moderate or prevent the development of disastrous storms

These local efforts may eventually lead the way to large-scale weather control. Although some evidence has been found that other methods may be useful to modify clouds, the ice nucleus and the snow particle uhich grows on it seem likely to remain of great importance in the science of experimental atmospheric physics.

Snow Crystal Replicas.—The form and appearance of the fragile and evanescent snow crystal may be preserved in minute detail by an extremely simple and effective process of replication. A dilute 0.5 to 3% solution of polyvinyl formal (a plastic) dissolved in ethylene dichloride (a common solvent) is required to make the replica. The solution must be cooled a few degrees below 0° C. (32° F.) before using. A small amount of the replica solution is poured onto a piece of black cardboard. sheet glass or similar material that also has been cooled below 0° C. The wet surface is then placed so that snow falls into it. When the desired number of crystals have fallen into the solution, it is placed in a cold, well ventilated place until the solvent evaporates. This ordinarily requires 5 to 10 minutes. When the sample is dry, it may be warmed up and examined. When properly prepared. each crystal is encased in a thin plastic shell whose inner surface is an exact negative copy of the original crystal. When the crystal melts, the water passes through this thin film. leaving behind a hollow cavity which reflects and scatters light in a manner quite similar to that of the original crystal. Frost, fallen snow and related substances may be replicated in a similar manner.

SNOWBERRY, the common name for several species of the genus *Symphoricarpos* of the honeysuckle family (Caprifoliaceae; *q.v.*), but especially for the hardy, deciduous, snow-white fruits of *S. albus* which occurs from Colorado eastward to the Atlantic coast. *S. occidentalis,* the western snowberry or wolfberry, is more northern in its range and extends westward to British Columbia. *S. orbiculatus,* the coralberry or Indian-currant, occurs in most of the regions in which the common snowberry is found, but is easily recognized in fruit because of the coral-pink to purple berries. The common snowberry is also known as waxberry. (J. M. BL.)

SNOWDEN, PHILIP SNOWDEN, 1ST VISCOUNT, of Ickornshaw (1864–1937), British statesman, was born on July 18, 1864, at Cowling, Yorkshire. Educated at an elementary school, he became a clerk in the customs and excise department. Joining the Independent Labour party (I.L.P.) in the year after it was founded. he became one of its most effective speakers and. in 1903 and again in 1917. its chairman. He was a member of the I.L.P. for 34 years, but resigned his membership in Dec. 1927, giving as his reason his conviction that the body ought to be merged in the Labour party and that its continued separate existence was neither desirable nor necessary. His first parliamentary attempts, for Keighley and Blackburn. failed. but in 1906 he was returned for Blackburn as Labour M.P. In the house he at once made his mark, notably on financial matters. When war broke out in 1914 he was in Australia. On his return he at once ranged himself with J. R. MacDonald and shared much of the latter's unpopularity. Defeated in the 1918 election, he won Colne valley for Labour in 1922, and held the seat with increased majorities in 1923 and 1924. His appointment as chancellor of the exchequer in MacDonald's cabinet was a matter of course.

In his budget, introduced in April 1924, while limited by the commitments of his predecessor. Snowden endeavoured to relieve the burden of taxation on the poor by his reduction in the food duties, and by making provision, in his contingent Old Age Pensions act, for the removal of the oppressive features of the thrift disqualification. At the same time, he stood fast by his free-trade principles and repealed the McKenna duties on imported motor-cars. clocks, musical instruments. etc.

At the London conference in July–August 1924. Snomden took charge of the discussions with the bankers which ended in the successful flotation of the German loan in October of that year. He was chancellor of the exchequer again from 1929 to 1931, when he was created a viscount.

Snowden warmly espoused the cause of Ramsay MacDonald when he consented to form a national government with the Conservatives and Liberals to solve the exchange and financial crisis of 1931. In the election of 1931 he hit very hard at his former friends of the Labour party who opposed the new government. This was deeply resented and he became for a time as unpopular with official Socialists as he had once been admired. With characteristic independence he left the government with Sir Herbert Samuel and the Free Trade Liberals in 1932 and for the rest of his life was a lonely figure. In perspective his service to British socialism will probably be regarded as of cardinal importance in spite of the later break.

He was the author of various books, among them A Socialist Budget (1907); A Living Wage (1912); *Socialism* and Syndicalism (London, 1913); *Wages* and Prices (1920); *Labour and National* Finance (London, 1920); *Labour* and the *New* World (1924); *Autobiography* (1934).

SNOWDON (Welsh, Y *Wyddfa*, "view place"; Eryri for the whole range, which modern scholars translate as "high land," the Welsh eryr, "eagle," being of the same root), the highest peak (3,561 ft.) in Wales, situated in Caernarvonshire. Snowdon is the name usually given to the mountain mass, occupying most of the triangle between Llarberis. Pen-y-Gwryd and Beddgelert, culminating in the Wyddfa, the dominating feature of the area: which is easily climbed. The region as a whole, which contains several peaks rising above 3.000 ft.. is called Snowdonia. Formed principally of Ordovician volcanic rocks, slates and grits, Snowdon consists of five sharply ascending ridges converging on the summit, with cirques containing small lakes between them. Surrounding the lakes are the three celebrated passes of Llanberis. Aberglaslyn and Rhyd-ddu. A rack-and-pinion railway (opened 1897) ascends to the Wyddfa summit ($4\frac{3}{4}$ mi.) where there is a hotel, open in summer.

The area is noted for alpine flora. Some of the finest scenery in Great Britain is contained in the 32,282 ac. of Caernarvonshire owned by the National Trust (1955). It includes Carnedd Dafydd (3,427 ft.). the sombre Llyn Idwal (a lake 1,223 ft. above the sea), the head of the pass of Nant Ffrancon, and also the rugged peaks of Tryfan (3,010 ft.), Glyder Fawr (3,279 ft.) and Glyder Fach (3.262 ft.).

See F. J. North, B. Campbell and R. Scott, Snowdonia (London, New York, 1949), for description of area and bibliography.

(J. C. G. J.)

SNOWDROP, any plant of *Galanthus,* a small old world genus of the amaryllis family (Amaryllidaceae). All the plants of the genus have bulbs. linear basal leaves and erect flower stalks about one foot tall. bearing at the top, a solitary, pendulous. bell-shaped white flower. Most especially, the term snowdrop indicates *G. nivalis,* the common snotvdrop widely cultivated in the U.S. and England, often in naturalized masses in the lawn. Other distinct species are the Crimean snowdrop, G. *plicatus,* with broad leaves folded like a fan, and G. *elwesi,* the giant snowdrop, a native of eastern Mediterranean, with large ($1\frac{1}{4}$ in. long) flowers.

ROCHE

SNOWDROP (GALANTHUS NIVALIS), ONE OF THE EARLIEST SPRING FLOWERS

All species thrive in almost any soil or position. The bulbs should be planted in autumn, 3 in. deep and about 3 in. apart, preferably by the hundreds if sheets of early white bloom—often before the winter snow disappears—are desired. (N. TR.)

SNOW LEOPARD: see OUNCE.

SNOW LINE, a line above which snow accumulates, temporarily (seasonal snow line) or perennially. Two types of perennial snow lines are recognized, orographic and regional. The orographic snow line passes through the lowest limit of perennial snow masses lying in protected spots. The regional snow line marks the lowest limit of an essentially continuous snow mantle, and its altitude depends primarily upon temperature and precipitation.

The regional snow line rises from near sea level in polar regions to 20,000–21,000 ft. in the horse latitudes (*q.v.*) and descends to 15,000–18,000 ft in equatorial regions. The orographic snow line may be 2.000–3,000 ft. lower. (R. P. SP.)

SNOW PLANT (Sarcodes sanguinea), a North American saprophytic herb of the family Pyrolaceae, so named because it often blooms in moist places in the vicinity of melting snow. It is closely allied to the Indian pipe (*q.v.*) and, by reason of its bright red or crimson colour throughout, presents a striking appearance.

Snow plant grows in pine woods on mountain slopes from southern Oregon to Lower California and eastward to Nevada. The single. fleshy, scaly stem. 6 to 15 in. high, rises from a ball of brittle roots and bears at its summit a cylindrical cluster of nodding. bell-shaped crimson flowers.

SNOWPLOW. A device for clearing snow from streets, highways, railroad tracks. airfields and the like. There are three general types of snowplows, known as rotary. V and single-blade.

The rotary plow in railroad use is mounted on a carriage that is pushed by one or more locomotives. It consists of several large biades attached to a horizontal shaft powered by an engine mounted on the carriage. A housing is provided for the protection of the engine. the rotary controls and the operating personnel. The plow is forced into deep drifts or slides while the blades are rotating. The snow is sliced from the face of the drift and discharged to one side of the track. The rotary is generally used to remove snow in depths which cannot be handled with the V-plow.

Under some conditions flangers are used to remove snow from the inside of the top of the rail to avoid the formation of ice that might cause derailments.

The rotary plow for highway use is of similar design but is built into a self-propelled truck unit. In some cases pusher trucks may be used for additional power. An adaption of the rotary plow is a unit consisting of two or more augers which feed the snow from the left and from the right to a centre collecting point from which a high-speed rotor discharges the snow to one side of the right-of-way. This unit is frequently mounted on the front of a standard motor grader or special heavy truck.

The V-plow consists of two concave surfaces fastened to a common centre line and sloping upward and to the rear, one to the right and one to the left. The V-plow forces the snow to either side and is used in areas of heavy snow, deep drifts or slides. For clearing railroad tracks the V-plow is mounted on a carriage pushed by one or more locomotives. In some mountainous areas the plows are mounted directly on the front of steam locomotives. The V-plow for highway clearance may be mounted on a heavy-duty truck, motor grader or tractor.

The single-blade plow may consist of a concave surface of varying depth or a straight blade. The former moves the snow in one direction only; the straight-blade type is reversible and may be set to move the snow to the right or to the left. The single-blade plow mounted on a heavy-duty truck is commonly used on highways and airports. The trucks operate at relatively high speed in order to throw the snow well off the travel way. A wing may be attached back of and above the single-blade plow. It may be adjusted to direct the snow well away from the plowed way.

(F. W. ST.)

SNOW SCORPION FLY: see SCORPION FLY.

SNOWSHOES, a form of footgear devised for traveling over snow. Nearly every American Indian tribe has its own particular shape of shoe, the simplest and most primitive being those of the far north. The Eskimos possess two styles, one being triangular in shape and about 18 in. in length, and the other almost circular. Southward the shoe becomes gradually narrower and longer, the largest being the hunting snowshoe of the Crees, which is nearly 6 ft. long and turned up at the toe.

Typical snowshoes worn by lumbermen are about 34 ft. long and broad in proportion, while the tracker's shoe is over 5 ft. long and very narrow.

Snowshoes may be made of a single strip of some tough wood, usually hickory, curved round and fastened together at the ends and supported in the middle by a light crossbar. the space within the frame thus made being filled with a close webbing of dressed caribou or neat's-hide strips, leaving a small opening just behind the crossbar for the toe of the moccasined foot. They are fastened to the moccasin by leather thongs, sometimes by buckles. The method of walking is to lift the shoes slightly and slide the overlapping inner edges over each other, thus avoiding the unnatural and fatiguing "straddle gait" that would otherwise be necessary. Snowshoe racing is common in the Canadian snowshoe clubs, and one of the events is a hurdle race over hurdles 3 ft. 6 in. high. In the thick forests of America, the snowshoe was found more suitable for use than the Norwegian ski (see SKIING). (X.)

Compared with the snowshoe clubs of Canada. the United States interest in snowshoeing is more casual. Still the colleges in the snow belt conduct snowshoe cross-country races, obstacle races and snowshoe hikes. Practically every winter carnival held in the United States includes snowshoe competitions. The Intercollegiate Winter Sports union includes snowshoe dashes and similar races in its programs. (F. K. B.; X.)

SNUFF, a powdered preparation of tobacco (*q.v.*) used by inhalation or by "dipping"; *i.e.,* rubbing on the teeth and gums. The practice of inhaling snuff became common in England around the 17th century, and throughout the 18th century it was universal.

At first each quantity was fresh grated (Fr. *râper,* whence coarser kinds were later known as "rappee"). This entailed the snuff taker's carrying with him a grater; early 18th-century graters made of ivory and other material are in existence. The art and craft of the miniature painter, the enameler, jeweler and gold- and silversmith were bestowed upon the box. Humbler snuff takers were content with boxes of silver, brass or other metal, horn, tortoise shell or wood.

The mull, a silver-mounted ram's head, is a large table snuffbox.

Snuff manufacture, which requires 18 to 20 months, involves grinding the tobacco and subjecting it to repeated fermentations. Snuffs are scented with attar of roses, lavendar, cloves, jasmine, etc.

SNYDERS, FRANS (1579–1657), Flemish painter of animals and still life, was born at Antwerp, where he was baptized on Nov. 11, 1579. He studied under Pieter Brueghel the younger, and afterward under Hendrick van Balen, the first master of Van Dyck. He visited Italy in 1608. On Oct. 23, 1611. he married Margaretha de Vos, the sister of the painters Cornelis and Paul de Vos. He died on Aug. 19. 1657.

Snyders originally devoted himself to painting flowers, fruit and subjects of still life, later turning to animal painting and executing with the greatest skill and spirit hunting pieces and combats of wild animals. His composition is rich and varied, his drawing correct and vigorous, his touch bold and thoroughly expressive of the different textures of furs and skins. Rubens frequently employed him to paint animals, fruit and still life in his own pictures. and he assisted Jordaens similarly. In the lion and boar hunis that bear the name of Snyders the hand of Rubens sometimes appears. Snyders was appointed principal painter to the archduke Albert. governor of the Low Countries, for n-hom he executed some of his finest works. One of these. a "Stag Hunt." was presented to Philip III, who commissioned the artist to paint several subjects of the chase. The Prado museum. Madrid, is rich in the works of Snyders. Others may be seen at the Museum of Fine Arts, Boston, Mass. ("Boar Hunt"); the California Palace of the Legion of Honor. San Francisco ("The Monkey and the Gander"); the Kaiser Friedrich museum, Berlin ("Bear Hunt"): and at many other public galleries.

SOANE, SIR JOHN (1753–1837), English architect, one of the most original architects of his time in Europe. aas born at Goring-on-Thames. Sept. 10, 1753, son of a bricklayer. In 1768 he entered the office of George Dance the younger. surveyor to the City of London. whom in later life he referred to as his "revered master"; in 1772 he went to Henry Holland (*q.v.*) as an assistant; and from 1771 he attended the Royal Academy schools. winning the gold medal in 1776. In 1778 the king's traveling studentship took him to Italy. He cut short his studies abroad because of magnificent promises of employment made to him by Frederick Hervey, bishop of Derry. These were not kept. and he was an only moderately successful country house architect until in 1788 he was appointed. thanks to William Pitt, surveyor to the Bank of England. Various government appointments followed and in 1806 he succeeded Dance as professor of architecture at the Royal Academy; he was knighted in 1831 The list of his works is a long one: some of the finest. which helped establish his reputation, included his rebuilding of the Bank of England (since rebuilt again), his own house at 13 Lincoln's Inn Fields, London (left by him to the nation as a museum) and the Duluich college art gallery, Kent His style is characterized by a tendency to strip classical elements of design down to their structural essentials, the substitution of linear for modeled ornamentation, frequent use of shallow domes and top lighting and an ingenious and often highly imaginative handling of interior space. Soane died on Jan. 20. 1837. in London.

BIBLIOGRAPHY.—A T. Bolton, *The Portrait of Sir John Soane, R.A.* (1927); John Summerson, *Sir John Soane 1753–1837* (1952); H. M. Colvin, *A Biographical Dictionary of English Architects 1660–1840* (1954) (Ms. W.)

SOAP may be defined as a chemical compound or mixture of chemical compounds resulting from the interaction of fatty oils and iats with alkali: *i.e.,* the salts of fatty acids. Functionally, soap is a substance possessing the characteristic "soaplike" properties of sudsing. detergency, surface tension lowering. wetting and emulsifying power, curd and gel formation. Modern research has led to the view that these properties may be attained by inserting strongly polar (water-soluble) groups into a wide variety of long-chain molecules. Since 1930 many such long-chain substances. some of them bearing no relation to the fats, have been developed, and some of them (*e.g.,* sulfated alcohols; sulfonates. etc.) are of commercial importance in the field of soaps. The functional consideration of soap brings within its scope these synthetic detetgents (see below) and at the same time excludes the water-insoluble compounds of fatty acids with bases of calcium, iron, aluminum, etc. These latter are better termed "metallic soaps."

Soap appears first to have been made by boiling goat's tallow and causticized wood ashes. as described by Pliny. The resulting soft potash soap was converted into hard soda soap by treating the paste repeatedly with salt. In the 13th century the industry was introduced from Italy and Germany into France. and in the 14th century into England. In America soapmaking was a household art, with few industrial developments until after about 1800.

The processes and extent of the manufacture of soap were revolutionized during the first half of the 19th century as a result of M. E. Chevreul's classical researches on the constitution of oils and fats, and by the introduction of the Leblanc process (invented in 1791) for the manufacture of soda from brine. Large-scale manufacturing operations developed. and the industry rapidly became able to process individual kettles of soap containing from 100,000 lb. to 1,000,000 lb. per charge.

Chemistry of Soap.—All fatty oils and fats are mixtures of glycerides: *i.e.,* compounds (esters) of the trihydric alcohol glycerol (glycerin) and some fatty acid such as palmitic acid. etc. The important investigations of Chevreul (1811–23) established this fact and led to an understanding of the chemical nature of soap. The chemistry involved in soap manufacture may be expressed in the following equation:

$$C_3H_5(OCOC_{15}H_{31})_3 + 3NaOH = 3NaOCOC_{15}H_{31} + C_3H_5(OH)_3$$
$$\underset{\text{(fat)}}{\text{palmitin}} + \text{caustic soda} = \underset{\text{(sodium palmitate)}}{\text{soap}} + \text{glycerin}$$

The reaction of the fat with the aqueous caustic solution is termkd saponification. (The term may also refer to the action of water on a fat to produce fatty acid.) It will be observed that the saponification reaction produces both soap and glycerin. As discussed below, the usual method of manufacture of soap requires a further series of operations to separate the glycerin from the soap and bring the soap to the correct physical form (or phase).

Commercial soap products are essentially soap-water systems, the properties, form and appearance of the product depending in great degree on the proportion of soap to water present. Strictly anhydrous or water-free soap has none of the usual soaplike properties and is not met with in practice.

At room temperature for most of the potash soaps: and at more elevated temperatures for the soda soaps, soap-water systems exhibit a variety of physical forms or phases. These different phases, described below, are the materials with which the soapmaker works and from which his products are derived. For example. true soap solutions (called nigre phase) occur when the proportion of soap to water is under about 30% (varying from soap to soap). In potash soaps the solutions, with some modification with glycerin or alcohol. form the liquid soaps of commerce. (Special compositions of soap solutions containing electrolytes constitute the nigres of the soap kettle.) When the soap-water system contains about 40%–50% water a different phase or form of soap results. This phase is called *middle* soap or gum soap, and when derived from potash is sometimes sold as a soft soap. Middle soap is stiff and viscous. much more so than either more dilute or more concentrated systems. At concentrations approximating 70% soap–30% water a form of soap called neat soap occurs. Neat soap when cooled and solidified is converted into unmilled bar soap. It is the starting material for the vast majority of toilet, laundry and household soaps. since it is produced as the final product of the soap kettle and hydrolyzer, and is then further processed as occasion requires (see below). When neat soap is diluted with water. instead of becoming less viscous, as is the usual rule, it becomes more viscous due to formation of middle soap.

When the soap concentration is raised to a value of about 85% (15% water), under some conditions a waxy form of soap occurs. At lower moisture contents. the now almost anhydrous soap exists in fibre or crystalline form (*curd* phase), and it is in this composition range that most of the beads, powders and flakes are made. The moisture content at which the various forms are obtained depends on the fat stock used in making the soap, on the temperature and on the presence of builders or electrolytes.

Since the great bulk of commercial soap products is derived from saponification with a soda base, it is sufficient to consider further the soda soaps alone. Dilute solutions of the order of 0.1% to 0.5% are used in laundry and dishwashing. Such solutions (nigre phase) are relatively thin and fluid. but more concentrated hot solutions when cooled are either opaque jellies or semisolid masses. The frothing or sudsing of soaps occurs only in the solution (nigre) state. Neat, middle, waxy and solid forms do not foam or suds until water is added to transform them. at least partially, to nigre. Thus while soaps are ordinarily manufactured and sold in one of the concentrated phases. their usefulness in cleansing comes about after their conversion to the nigre or solution state by means of water.

Neat and middle soap are anisotropic, liquid crystalline phases. Nigre is an isotropic. colloidal solution. The solid. crystalline forms of soap are called alpha, beta, delta and omega. each of the latter three contributing its distinctive properties when present in bars. powders and pastes.

The peculiar colloidal and electrical properties of the solution or nigre form of soap have led to the classification of soap as a colloidal electrolyte. At very low concentrations (of the order of .001%) the dissolved soap is hydrolyzed to a degree by the water to form free fatty acid and small amounts of iree alkali. At slightly higher concentrations. acid soap (*e.g.,* sodium hydrogen palmitate) precipitates. and is the cause of much of the cloudiness seen in dilute soap solutions and liquid soaps. The molecules of dissolved soap and soap ions in solutions of the order of 1% concentration begin to clump together to form "neutral colloid" and colloidal "ionic micelle." which may be hydrated. The colloidal ionic micelle (which may be thought of as an electrically charged colloidal particle) and other ions give the solution pronounced electrical conductivity in contradistinction to ordinary colloids.

The behaviour of a pure, single, anhydrous soap when heated is very complex and has led in the past to much confusion about the melting points of soaps. The solid soap when heated is converted in turn at definite transition temperatures to subwaxy soap, waxy soap, superwaxy soap. subneat soap, neat soap and finally to nigre.

Only the compounds prepared from fatty acids of between about 10 and 18 carbon atoms in chain length can be considered soaplike under usual conditions. Indeed, sodium stearate (18 carbon atoms) possesses practically no soaplike properties at room temperature; it is only at temperatures approaching the boiling point of water that this compound behaves as a soap.

Detergent Power.—The washing or detergent power of soap was formerly attributed to the alkalinity produced by hydrolysis of the soap. Though this explanation has been abandoned. no comprehensive substitute explanation based on adequate experimental data has yet been established in its place. The detergent action of soap is an intricate phenomenon in which wetting power. emulsification, grease dissolving, etc., all play a role. A widely held and plausible hypothesis has considered that washing is dependent on an unsymmetrical structure inherent in the soap molecule, one end (polar) being water soluble and the other being insoluble in water and soluble in oil. Such molecules tend to form a concentrated film at the interface between the water and the dirt, each molecule attaching itself at one end to the dirt and at the other end to the water. and hence tending to pull the dirt into solution.

There is much evidence that the micellar (colloidal electrolyte) form of soap must be present for good washing. For example. sodium stearate is a poor washing agent at l o temperatures, being too insoluble to form significant amounts of colloidal electrolyte. When the solution is heated, enough of the soap dissolves to allow formation of the micellar form. On the other hand. sodium laurate is so soluble at ordinary washing temperatures that it exists predominantly as the unaggregated soap ion. having little tendency to aggregate into the micelle. At lower temperatures its solubility is reduced, much more aggregation results and its washing power is increased.

Soap Materials.—Almost any fat can be utilized in the manufacture of soap, but the principal requisite for a successful commercial product is an economical and proper balance of stocks to yield a soap that will exhibit the necessary soaplike properties over the range of conditions likely to be met with. In the section on the *Chemistry of Soap* it was pointed out that the soap properties of a given soap (*e.g.,* sodium stearate) are evident only under certain conditions. This characteristic behaviour necessitates the "blending" of fats to produce a widely applicable product. Thus. tallow is a much used stock in making soap, but tallow alone will not yield a toilet soap that will give a copious lather over a wide range of temperatures in either soft or hard water. Therefore the tallow is commonly blended n-ith a proportion of coconut oil. although palm kernel oil may be substituted. Various blends of oils and fats are used for laundry soaps, and it is safe to say that almost every knon-n fatty oil at one time or another has found its way into soap manuiacture.

The most generally used stocks are, of the animal oils. tallow and grease; of the vegetable oils, coconut, cottonseed, corn, soya, palm. palm kernel and olive. Fish and whale oil were used in soapmaking in increased quantities after the process of hydrogenation (*q.v.*) enabled them to be hardened (and largely deodorized) to proper consistency for soapmaking. Rosin (in saponified form) is an ingredient of yellow laundry soaps. Certain alkaline materials called builders are almost universally present in laundry soaps. The most important are sodium silicate (water glass), sodium carbonate (soda ash) and various phosphates. These materials give increased detergent action for conditions of usage. and are not to be thought of simply as fillers such as starch and barites which are added to cheapen the soap. For saponification of the fats, large quantities of caustic soda are required by the industry. together with lesser quantities of caustic potash for soft soap manufacture. Ammonia. tri-ethanolamine and various organic bases are used to make special soaps.

Manufacturing Processes.—Soap is manufactured by (1) the boiling process; (2) the hydrolyzer process; or (3) semiboiling, in small lots in the household or on the farm.

Boiling Process.—The object of the boiling process is to produce neat soap in purified condition free from glycerin. Neat soap (a special composition of which is called kettle soap) constitutes the starting material for making bars, flakes, beads and powders. The process is conducted in a series of steps called changes, and all the changes occur in the same piece of apparatus; *i.e.*, the kettle, or as it is termed in Great Britain, the pan. The soap kettle is one of the largest pieces of processing equipment used by any chemical industry.

The first step begins with the introduction of the melted fats into the kettle together with some excess of caustic (soda) solution, which is added gradually. The whole mass is boiled with open steam from perforated coils within the kettle. A gradual emulsification occurs. the caustic reacting with the fat (saponification) to form soap and glycerin.

In order to separate the glycerin from the soap, the pasty boiling mass is treated with brine or salt. The contents of the kettle "salt out" or separate into two layers. The upper layer is a curdy mass of impure soap. while the lower layer is an aqueous salt solution containing the glycerin dissolved in it. The basis of glycerin removal thus is the solubility of glycerin and the insolubility of soap in salt solution. The slightly alkaline salt solution, termed "spent lye." is run off from the bottom of the pan or kettle and subsequently treated for glycerin recovery.

The grainy. curdy mass of soap remaining in the kettle after the spent lye has been removed contains any (usually traces of) unsaponified fat which escaped reaction during saponification, and also dirt and colouring matter present in the original oils. The "strong change" is calculated to remove the last traces of free fat, and is carried out by adding strong caustic solution and boiling for several hours.

The final stage (pitching and settling) in the process has for its purpose the transformation of the soap into the neat form and the final removal of dirt and colouring matter. The soap, after the strong change, may be given one or more salt water washes to remove free alkali, or it may be pitched directly following the strong change. In any case the open soap is partially "smoothed" by boiling with addition of water (or open steam condensation) until the correct concentration is attained to cause the kettle contents to separate into two, or sometimes three. layers. The upper layer is neat soap (kettle soap) of an almost constant composition for a soap from a given fat (approximately 70% soap–30% water); the lower layer is a nigre, whose composition varies between about 15% and 40% soap depending on the "closeness" of the pitch. Since colouring matter and dirt generally (also salt, alkali and metal soaps) are soluble in nigre but relatively insoluble in neat soap, and because most of the impurities are dense and tend to settle, the nigre layer removes these impurities from the neat soap. The kettle boiling process requires from 4 to 11 days from the time the saponification starts until the neat soap is ready to be drawn off. Even today the complicated stages of the boiling process are usually conducted by the soap boiler with appearance and taste of the soap as criteria for judging its condition. The utilization of the finished neat or kettle soap in making the final commercial product is described below under Soap Products.

Hydrolyzer Process.—The boiling process requires that individual batches of fat be treated in separate units (kettles). By 1956 continuous processes had replaced the older batch process to the extent of 50% to 75%. Where, in the kettle, alkali was used for saponification, in the hydrolyzer process the fat is "split" into fatty acids and glycerin by means of water at high temperature and pressure in the presence of a catalyst (zinc soap). The splitting reaction

$$\underset{\text{fat}}{(RCOO)_3C_3H_5} + \underset{\text{water}}{3HOH} \rightleftarrows \underset{\text{fatty acid}}{3RCOOH} + \underset{\text{glycerin}}{C_3H_5(OH)_3}$$

is carried on countercurrently, usually in a vertical column 50 ft. or more in height. The molten fat and water are introduced continuously into opposite ends of the column, while the fatty acids and glycerin are withdrawn continuously. The water, almost insoluble in fat at low temperatures, becomes soluble to the extent of 10%–25% at 400°–480° F., the reaction being greatly speeded up by the solubility effect.

In about one hour a given unit of fat passes through the column and is 99% converted to fatty acids. which. as drawn off, are continuously distilled under vacuum to effect purification. They are then neutralized with caustic (NaOH or KOH) containing the proper amount of water to yield neat soap phase. Just as in the boiling process, this phase constitutes the base material for further processing into bars, flakes, powders, pastes or other products.

The operations necessary to obtain final products can be combined sequentially with the hydrolyzer to give a continuous flow from the original fat to the final marketable product, the whole sequence occurring in a matter of hours as contrasted with the 4–11 days required when the boiling process is used. The by-product glycerin is purified and concentrated synchronously with the fatty acid production.

Economy considerations of time, less factory space, improved quality and better control of product characteristics contributed to the introduction of this process into the industry in Europe and the United States.

Semiboiling Process.—The semiboiling process may be thought of as ending when the saponification change is completed. The fat is saponified, usually in small quantities. as completely as possible by boiling with caustic. The saponified mass, containing the glycerin, is run into frames for cooling and solidifying or, in the case of soft (potash) soap. is packed directly into containers. This process has the advantage of allowing. by water adjustment, the direct production of either neat soap, middle soap or in some instances nigre (liquid) soap.

Soap Products.—Hot neat soap phase from either the boiling or hydrolyzer process forms the starting material for a wide variety of products.

Framed Soaps.—These are usually made by pumping molten neat soap into molds or "frames" to cool. The solidified soap is then cut and stamped into cakes. Such soaps contain about 70% soap–30% water. For laundry purposes, builders such as water glass, phosphate, etc., are "crutched" or mixed in before solidification.

Floating Soaps.—Formerly, most of these were made by crutching air into the neat soap before cooling. By 1950, rapid chilling or "freezer" processes were in use in the United States. The molten neat soap was either aerated and then rapidly chilled, or chilled to a semisolid condition and then aerated. The two procedures give bars of somewhat different lather and other characteristics.

Milled Soaps.—Most toilet soaps of the better quality are made by the milling process. Originally developed in France as a way of allowing the cold incorporation of fine perfumes which could not withstand the heat of the crutcher, the milling process is now applied to the bulk of toilet soap manufacture. It produces a glossy, waxy bar of characteristically smooth feel, having more pronounced qualities of lather and solubility thanunmilled soap.

The most widely applied milling process requires that the hot neat soap first be reduced to ribbon or flake form. This is accomplished by allowing the molten soap.to flow between two hollow, rotating metal rolls. The warm roll spreads the soap into a thin film which solidifies and adheres to the cold roll. The film is removed in ribbons. These are dried in an oven to about 12%–16% moisture.

After the dried, cooled ribbons have been broken into flakes they pass into an amalgamator, where perfume, dye and any special ingredients are mixed into them. The amalgamated soap is milled by passing between successive polished metal (sometimes marble) rolls. The perfume and any other added ingredient is thus intimately and evenly pressed into the soap. The sheet of soap from the final milling roll is cut into ribbons and flakes and then subjected to pressure in a "plodder." This is a screw device operating in a cylinder. which forces the flakes together and cements them into a continuously extruded bar or cylinder of soap. The soap coming from the plodder is cut into lengths, which are then stamped into bar or tablet form and wrapped.

Flaked or *Chipped* Soaps.—Soap flakes are ribbons of dried soap broken into short lengths. The development of packaged soap flakes came about mainly between 1920 and 1930. and in the United States was concomitant with the introduction of small-scale household, power washing machines, which created a great demand for soaps that were more soluble than the old bar soaps or chips cut from bars. By 1939 flakes were produced whose thickness was only about 0.002 in. as compared with early products, which were of the order of 0.1 in.

Seat soap forms the basis for soap flakes. The crutched soap, containing builder if desired. to give increased washing effects, is run onto the rolls isee section on *Milled* Soaps). spread into a film or sheet and removed in the form of ribbons. These are then dried to proper moisture (usually 5% to 15%). broken into flakes and packaged. By proper controi of moisture, fat stocks and pressure, an increased transparency is sometimes given the flakes.

Granulated Soaps, Beads and *Powders*.—While flake soaps were a long step in the direction of a product of increased effectiveness in use! there arose about 1926 in this field a new development. involving the application of spray drying methods to neat soap. Early powders and granulated products were made by grinding flakes to the desired fineness: but such products were either slowly soluble when coarse. or lumped and "balled" in water when fine. When hot neat soap is sprayed into a current of heated air, the atomized soap particles dry and puff into expanded bead or bubble form. The puffed particles, of spongy texture. exhibit a very high rate of solution and do not have the dusty quality of other types of powdered soap. Denser, unpuffed particles may also be made by spray drying at lower temperatures.

Medicated Soaps.—Soap itself has germicidal power against some organisms. and many of the cationic synthetic detergents are strongly germicidal. Soap is used as an enema and as an emetic. Substances such as hexachlorophene are sometimes used in soap to suppress the formation of the odorous compounds of perspiration.

Textile Soaps.—In the preparation of wool fabrics soap is required in three stages: scouring of raw wool to remove wool grease, scouring the yarns and cloth after oiling, in fulling or milling. Soap is used for degumming raw silk, for cleansing rayon, silk and cotton before and after dyeing, in the dye bath and in printing. For all these purposes ready solubility is required, and hence soda soaps of low titre (*e.g.*, red oil. olive, corn) and potash soaps are preferred. Synthetic detergents have entered widely into the textile field because of their stability toward acid and hardness in water. They are used in scouring both cotton and synthetic fibres.

Shaving Creams.—Shaving creams are usually mixtures of potash and soda soaps of tallow and coconut oil. The cream is prepared by semiboiling methods. Bar shaving soaps and powders are of similar composition except for water content. which is kept at a minimum. Latherless or brushless shaving creams are not strictly soap at all, but are modifications of vanishing or cold cream formulas. In any type of lather, the water is the principal beard-softening ingredient.

Metallic Soaps.—The term metallic soap refers to the fatty soaps of the alkaline earths and heavy metals. Their chief common characteristic is insolubility in water. hence their application (copper soap, aluminum soap, etc.) as waterproofing agents. The lubricating grease industry uses large quantities of calcium, aluminum and other soaps to produce greases of various types, since another important characteristic of the metal soaps is their ability to gel in mineral oils. The demand for extreme pressure lubricants brought about the development of transparent or clear greases which are usually prepared by addition of aluminum soap. alone or in combination with other soap, to oil of the desired character.

Synthetic Detergents— This term is applied somewhat loosely to water-soluble, surface-active substances with pronounced ability to wash and clean but differing from the true soaps in the important respect of not precipitating in hard water. They differ chemically from the soaps.

Even the casual user of soap notices the scum or precipitate that forms in hard water. leaving a ring around the bathtub, a whitish residue on glassware and a sticky curd in the rinse water of the laundry tub. Not so easily perceived is the relation of this "hard-water scum" and a dull. lustreless condition of the hair after shampooing. yellow spots on laundry after ironing, and heavy usage of soap in the household. All these effects point to a serious defect of the true soaps. namely their reaction to give a precipitate with the calcium and other metal salts constituting the hardness of water. The true soaps also react with traces of acidic compounds to form a precipitate.

The introduction into commercial use of the synthetic detergents was based on their ability to transcend and overcome the hard-water behaviour of soap. In general, the synthetic detergents are unaffected. or very little affected. by hardness or acids; for although they may react chemically with them. the resulting compounds are either soluble or remain dispersed in colloidal form in the solution. Certain other unique and useful properties of the synthetics. such as cold-water solubility and flexibility of formulation, also contributed to their rapid replacement of soap products. By 1957 the synthetic detergents made up more than 70% of the tonnage of soaplike products sold as washing agents in the United States.

From the view of physical chemistry the synthetic detergents fall into three main groups. the anionic, cationic and nonionic types.

Anionic Type.—In the anionic group the long chain part of the molecule when dissolved in water becomes the negative ion or anion. The anionics are by far the most important synthetic detergents for use in washing or laundry products. Many hundreds of different anionic compounds have been suggested, but the most widely exploited have been the sodium alkyl sulfates ($ROSO_3Na$) and the sodium alkyl benzene sulfonates ($RC_6H_4SO_3Na$) (R = hydrocarbon chains containing 8 to 18 carbon atoms).

The production of any single synthetic detergent involves its own specialized chemistry. For example. in production of the sodium alkyl sulfates the raw material may consist of fats such as coconut oil and tallow which are converted to fatty acids by, say, hydrolysis. The fatty acids (or their esters) may then be catalytically reduced by hydrogenation (or by sodium) to the corresponding alcohols. The alcohols are then sulfated with concentrated sulfuric acid, followed by neutralization with caustic to yield the sodium alkyl sulfate together with sodium sulfate, which usually is left in the product. Just as with the true soaps, the product at this stage is a colloidal system of water, salt (Na_2SO_4 or NaCl) and synthetic. Many of the same types of phases exist in the synthetic systems as in soap systems. It is from the manipulation of these phases that the final bars, pastes, powders and liquids are developed.

For reasons of economy, for higher or heavy-duty detergency under widely varying conditions of use, and for desirable product form and appearance, it has been customary to combine the synthetic with builders. Thus the most widely marketed synthetic detergents in granule form contain as little as 15% to 40% of the synthetic combined with phosphate builder in amounts ranging up to 50% of the product. The builder is usually, sodium tripolyphosphate or sodium pyrophosphate, although borates. silicates and other complex phosphates are sometimes substituted. The remainder of the product consists largely of water, salts and in some instances smallquantities of suds builders (such as ethanolamide), brighteners (fluorescent, substantive dyes to give residual whiteness to the fabric), soil redeposition inhibitors (*e.g.*, carboxymethyl cellulose) and perhaps corrosion or tarnish inhibitors.

Synthetic detergents for light duty in fine fabric cleaning. dishwashing, etc.. may contain little or no builder. It is possible with the synthetics to formulate compositions with wide varieties of special properties and to make liquid, powder or bar products designed to produce highly specialized results as to detergency, wetting power, emulsification, sudsing, etc.

Cationic Type.—In this type, when dissolved in water, the long chain part of the molecule is the positive ion or catidn. Such compounds are sometimes called "inverted" soaps, because the long chain ion is opposite in sign of electric charge to that of the true soaps. 4 s with the anionics, many hundreds of compounds have been suggested. An example of a typical cationic is $C_{18}H_{37}NH_3Cl$, called octadecyl ammonium chloride. Although possessing valuable related characteristics, the cationics have been of relatively little importance in detergent products.

Nonionic Type.—In this group the molecule as a whole is surface active, but no ions form when the substance is placed in water. The most widely used nonionics in detergent formulations are the polyoxyethylene derivatives; for example, $RC_6H_4(OC_2H_4)_xOH$.

The use of automatic washing machines led to the development of what are sometimes called low sudsing detergents, since some of these machines wash less effectively when large volumes of suds build up and cushion the agitation effect. Nonionics are useful in such formulations because they give detergent action with production of little and in some instances practically no suds. For this same purpose anionic types of high sudsing ability are sometimes combined with suds inhibitors, or they may be combined with the true soaps to produce less suds and to give other desired properties such as a "soapy" feel to lather.

SOAPBARK, the inner bark of *Quillaja saponaria*, a small tree of the rose family (Rosaceae), which grows in Chile. Reduced to powder, it is employed as a substitute for soap, since it forms a lather with water because of the presence of a glucoside saponin, which has a marked surface tension action. The same, or a closely similar substance, is found in soapwort (*Saponaria officinalis*), in senega root (Polygala senega) and in sarsaparilla.

The saponins are poisonous, having a marked hemolytic (blood-destroying) action.

SOAPBERRY, the common name for the species of the genus *Sapindus* of the Sapindaceae (*q.v.*) family, comprising about 15 species of trees and shrubs bearing pinnate leaves. numerous small, greenish or whitish flowers in large terminal panicles or racemes, and fleshy or somewhat leathery berries containing saponin, a soap-like substance that is used for cleansing by the natives of certain tropical countries. At least three species occur in the United States.

S. drummondi, the western soapberry, is native to the south central and southwestern United States, and *S. marginatus* and S. saponaria are native to Florida and tropical America.

(J. M. BL.)

SOAP PLANTS, the name given to numerous herbs, shrubs and trees which contain the poisonous glucoside saponin. Various parts of such plants form a lather in water and may be used for cleansing purposes, as the soapbark (*q.v.*). Other examples are the soapwort (*q.v.*) or bouncing Bet and the cowherb (Saponaria vaccaria).

In the southwestern United States various plants called *amole* by the Indians are similarly utilized, especially the small agave (Agave heteracantha) and the soaproot (Chlorogalum *pomerid*ianum). Other soap plants of the western United States are the zygadenus and the sand lily (*qq.v.*).

SOAPWORT (*Saponaria officinalis*), a perennial herb of the pink family, Caryophyllaceae (*q.v.*), called also bouncing Bet, widely naturalized in North America, native to Europe and western Asia, common in Great Britain and often planted in borders and rockeries.

It is a stout, smooth, sparingly branched perennial, two to three feet high, with lance-shaped leaves and pink or whitish flowers. borne in dense clusters. The leaves and roots contain saponin, which makes a froth with water, and can be used for washing delicate fabrics. *See* SOAP PLANTS.

SOBAT, a river of north-east Africa. the most southerly of the great eastern affluents of the Nile It is formed by the junction of various streams which rise in the south-west of the Abyssinian highlands and north-west of Lake Rudolf. The length of the Sobat. reckoning from the source of the Baro, the chief upper stream, to the confluence with the Nile is 215 mi. The Baro rises in about 36° 10' E., 7° 50' N. at an altitude of some 7,000 ft. The Baro descends the escarpment of the plateau between great walls of rock, dropping 3.000 ft. in 45 miles. It then flows through a narrow gorge at an altitude of about 2.000 ft., the mountains on either side towering 3.000 to 4.000 ft. above the river bed. Just east of 35" E. the Birbir joins the Baro. Some 40 mi. lower down the hills are left behind and the river flows west across a vast plain. From Gambela, a town on its north bank 20 mi. below the Birbir junction, the river is navigable by steamers during flood time (June–December) to the point of confluence with the White Nile. In about 33" 20' E . 8° 30' N., it is joined by the Pibor. This river issues from the swamp region east of Bor on the Bahr-el-Jebel stretch of the Nile. It is joined from the east and south by various streams from the Kaffa plateau. Of these the chief are the Gelo—which breaks through a gap in the mountains in a series of magnificent cascades—and the Akobo. The Akobo rises in about 6° 30' A'.. 35° 30' E. The whole region of the loner Pibor and Baro is one of swamps, caused by the rivers overflowing their banks in the rainy season. At its junction with the Baro the Pibor is over 100 yd. wide, with a depth of 8 ft. and a speed of 2.3 ft. per second.

Below the confluence of the Pibor and Baro the united stream, now known as the Sobat, takes a decided north-west trend, passing for some distance through a region of swamps. Just beyond the swamps and some 40 mi. below the confluence, is the fortified post of Nasser. From Nasser to the junction of the Sobat with the Nile the river has a course of about 180 miles. As it approaches the Nile the Sobat flows in a well-defined channel cut in the alluvial plains through which it passes. The banks become steep, the slope rapid and the current strong. The Sobat enters the Nile almost at right angles in 9° 22' N., 31° 31' E. It is 400 ft. wide at its mouth and has a depth of 18 to 20 ft. at low water and of 30 ft. when in flood. The colour of the water when in moderate flood is that of milk, and it is from this circumstance that the Nile gets its name of Bahr-el-Abiad, *i.e.,* White river. In full flcod the colour of the Sobat is a pale brick red. The amount of alluvium brought down is considerable. The average volume of water discharged varies from 100 cu.m. per second at low stage in April to 770 in October and November when it is in full flood. For the part played by the Sobat in the annual rise of the Nile see NILE.

The Sobat was ascended for some distance in 1841 by the Egyptian expedition despatched in the previous year to explore the upper Nile. The post of Nasser was founded in 1874 by General C. G. Gordon when governor of the equatorial provinces of Egypt, and it was visited in 1876 by Dr. W. Junker, the German explorer. The exploration of the river system above Nasser was carried out in the last decade of the 19th century by the Italian explorer V. Bottego; by Colonel (then Captain) Marchand, of the French army, who, on his way from Fashoda to France, navigated the Baro up to the foot of the mountains; and by Captain M. S. Wellby, Majors H. H. Austin and R. G. T. Bright, of the British army, and others. By the agreement of May 15, 1902, between Great Britain and Abyssinia the lower courses of the Pibor and Baro rivers to their point of confluence form the frontier between the Anglo-Egyptian Sudan and Abyssinia. (See ETHIOPIA; NILE.)

SOBRAON, a decisive battle in the first Sikh War (see SIKH WARS). It was fought on Feb. 10, 1846, between the British (15,-000) under Sir Hugh Gough and the Sikhs (20,000) under Tej Singh and Lal Singh. The Sikhs had fortified themselves in a bend on the left bank of the Sutlej, with the river in their rear, The battle began with a two-hour artillery duel, in which the Sikh guns were the more powerful and the British heavy guns expended their ammunition. Then the infantry advanced nith the bayonet and after a fierce struggle took the Sikh entrenchments. The Sikh losses were estimated at from 5,000 to 8,000. This battle ended the first Sikh War.

SOCAGE, a species of feudal land ownership whereby a freeman held a fee simple estate as tenant of a lord in return for his rendering periodic services of an agricultural or economic kind to the lord. With the decline of feudalism and the rise of a money economy "free and common socage" became the most desirable form of land tenure because its economic burdens were less onerous and on the restoration of Charles II in 1660 almost all species of tenure were converted by statute into socage tenure. (*See* LAWS OF REAL PROPERTY AND CONVEYANCING.) Free and common socage was also the most common tenure by which the king granted lands in the North American colonies Since tenure has no modern significance in land ownership anywhere in the Anglo-American legal world, socage tenure is no longer important and if its semblances are retained, it is for nonlegal reasons.

Although socage developed under Norman feudalism in England, it is Anglo-Saxon in origin. The term is derived from the Old English word *soc* or soke and is frequently associated with sac, in an alliterative jingle ("sac and soc"). The precise meaning of both terms is uncertain, but they refer to the district in which a lord may hold court, to the right of a tenant to make suit in such a court and to his duty to use the court. The "sokemen" or persons holding by socage tenure nere a class of tenants midway between the military or chivalrous class and the bond tenants or villeins. While personally freemen they performed many agricultural services similar to those performed by the villeins.

If a freeman had to onn land under the theory of feudal tenure, socage was the least objectionable form. Minors inheriting socage lands were not. as in military tenure, wards of the lord of nhom the land was held. but came under guardianship of the nearest relative who could not inherit the lands, and this guardian, unlike the lord in a wardship, could not keep the profits during minority, but had to account to the heir for them Neither, under socage, could the lord or guardian "sell" the minor heir in marriage for his own personal profit.

As in the case of military tenure, honever, the death of the owner required the heir to pay to the lord a relief to claim his inheritance.

At an early time the services that had to be rendered to the lord were commuted into money payments fixed in amount At the time they were fixed, these "quitrents" as they were called, no doubt. represented the economic value of the land The long continuous fall in the value of money meant that in course of time, they became so insignificant as not to be worth the trouble of collection. Sometimes the services nere purely nominal as the result of gifts to younger members of the family, or to friends or as the result of a sale for a capital sum with a nominal quitrent reserved to preserve the form of the tenure.

The 1681 charter of Maryland granted to Lord Baltimore lands to be held in free and common socage yielding to the king as lord, "two Indian arrows of those parts to be delivered every year on Tuesday in Easter week." The feudal service attached to the grant of Pennsylvania was the delivery to the king of two beaver skins annually.

In some American colonies. now part of the United States the king permitted the grantee in socnge to establish his onn manor, that is to regrant portions of the land to tenants in return for an annual rent, although this could not be done in England after 1290.

Thus it is today that some property owners in Pennsylvania render to the present members of the Penn family a red rose at midsummer. The continuation of this service is now ior ceremonial and not for legal reasons. In New Tork and some other parts of the North American colonies, those holding grants from the king sought to impose substantial quitrents on their grantees. Thus even after the Revolution the Van Rensselaer family granted lands on the upper Hudson to a settler "forever" upon a yearly rental of a certain number of bushels of wheat. So distasteful was this feudal concept that these quitrents contributed to rebellions such as Bacon's rebellion in Virginia in 1676, and some major antirent disturbances in New York in the mid-19th century.

(A. DM.)

SOCCER, the name given in the United States and Canada to the game called, with a few minor exceptions, football or association football in all other parts of the world. For a description of the game as played outside America, see FOOTBALL: Association Football (Soccer).

Many different stories are current about where the first games of soccer were played in America. A marker on the Common in Boston, Mass., refers to the fact that the game was played there. There is little doubt that the first intercollegiate "football" game between Princeton and Rutgers mas actually a version of soccer, and it has been fairly well established that the game was introduced into the United States by the British.

Like American football, soccer is played by two teams of 11 men each. employing a round leather- or rubber-covered inflated rubber bladder slightly larger than a volleyball and slightly smaller than a regulation basketball. It is called the booting game for good reason: only the goalkeeper is permitted to touch the ball with his hands while it is in play.

The main propulsion of the ball is given by a player's foot, although he can use any part of his body except his hands and arms to trap, deflect or project the ball. Heading the ball is considered a major movement in the game.

Should a player other than the goalkeeper handle the ball deliberately or unintentionally, a penalty is called against him and the opposing team is permitted a free kick. When the infraction occurs in the penalty area of the defending team, the attackers are allowed a penalty kick from a point 12 yd. out and directly in front of the goal.

A regulation game in soccer consists of two halves of 45 minutes' duration each. In the event that a 90-min. game cannot be played for a specific reason, the time may be shortened, but the halves still must be equal. Some college conferences and scholastic leagues play their games in equal quarters rather than halves, but no regular games last longer than 90 min. unless there is a provision for overtime play in order to determine a winner.

Play.—The maximum length of a soccer field or pitch, as it is known, is 130 yd., with the minimum set at 100 yd.; the maximum width is 100 yd. with the minimum 50 yd. The markings of the pitch include two touch lines (the length of the field) and two goal lines (the width of the field) to make a rectangle. In addition there is a midfield line across the width of the field with the centre kickoff circle (10 yd. in diameter). Before each goal is a penalty area 18 yd. long by 44 yd. wide. Inside the penalty area and also before each goal is a goal area 6 yd. in length and 20 yd. in width. The two goal posts are 8 yd. apart supporting a crossbar 8 ft. off the ground. Normally nets are required to be attached to the goal posts and crossbar and extending behind the goal.

The penalty kick area is denoted by a small (solid) circle directly in front of and 12 yd. from the goal. Quarter circles of 1-yd. radius are marked at each corner for the corner kick. which is given when the defending team last touches the ball before it goes over the defending team's goal line outside the goal. Corner flags, preferably of some bright colour, are placed in the four corners of the field.

To score a goal, the whole ball must pass over the goal line between the two goal posts and under the crossbar, either on the ground or in the air, without being carried, thrown or motivated by arm or hand of an attacking player. If a defending player accidentally kicks or deflects the ball into his own goal, it counts as a goal for the opposing side.

Three types of kicks are awarded for rule infractions including penalty kick and direct free kick from which goals can be scored directly. In order to score on an indirect free kick the ball must be played by another player before entering the goal.

When a ball goes over the touchline. it is awarded to the opponent of the team that last touched the ball before it went out of bounds. A throw-in is taken at the point where the ball went over the touchline. It is the sole instance during a game when a player other than the goalkeeper is allowed to handle the ball. The colleges have amended the throw-in rule to make it a kick-in.

The offside rule is an important rule of the game. A player is offside when there are not two defending players nearer the goal than himself at the time the ball is passed to him, with the following exceptions: from a goal kick; a corner kick; a throw-in; when he is behind the ball when the pass is given; when the ball comes from an opponent; when he is in his own half of the field.

One of the American deviations from international rules is that substitution of players is permitted in American soccer. However, the different governing bodies and sectional leagues have varying limits on substitutions. On the whole, the deviations from the international rules are rather few, which is one of the reasons why soccer lends itself easily to international contest.

Competition and Organization.— Soccer is a relatively simple game to understand, the basic rules being neither complicated nor difficult. It is also an exciting game, with play going on continuously in the open. Compared with American football it is inexpensive to support, and there are no special physical requirements for the participant, hence wide participation is possible. While the popularity of soccer in America has not always been great, it is still expanding in schools and colleges, where it is a seasonal sport, played for about three months in the autumn.

The season of amateur and professional soccer runs for approximately ten months with a layoff during the summer. In certain areas competition is halted during the winter because of poor field conditions.

In addition to the various league and state competitions, three major national tournaments attract entries. The National Challenge cup competition for the DeWar trophy is the open tourney in which professional and amateur teams compete. The event was first held in the 1913–14 season and regularly thereafter. In the 1923–24 season, entries for the National Challenge cup became so numerous that it was decided to inaugurate the National Amateur cup competition to be restricted to amateur teams and amateur players. The National Junior Challenge cup: limited to junior teams, began in the 1934–35 season, but the final game between eastern and western sectional champions is not always played.

The United States Soccer Football association (U.S.S.F.A.), organized in 1913 and successor to other predecessor groups, is the governing body of the sport in America. This includes amateurs and professionals, who are allowed to play side by side on the same teams without any change in status. College and school groups have their own organizations and are merely associate members of the U.S.S.F.A. Leagues and state associations of amateur and professional groups are direct affiliates of the U.S.S.F.A.

Only one organized professional league is recognized, the American Soccer league, which operates chiefly along the eastern coast and includes New York, Newark and Elizabeth. N.J., Philadelphia and Baltimore. In 1960, the International Soccer league was formed to include visiting foreign teams and a New York side.

In the late 1920s and early 1930s, a professional soccer player was able to earn money enough so that he could devote full time to the game. Currently, however, even the highest paid professional cannot support his family by playing. Whereas European players devote regular days and hours each week to practice, few teams in the Cnited States hold regular drills. A team designated to represent the United States in international competition usually has opportunity for no more than one or two practice games, which is reflected in the poor showing of United States teams in such competition. Further, few clubs: leagues or associations have the personnel to conduct programs to promote development of young players.

Soccer in the United States is an amateur rather than a professional sport. Few soccer teams have their own stadiums; most of the big international games are played in baseball parks or municipal or school stadiums. For the most part, however, regular games are played in parks or on open fields. (M. Mi.)

SOCIAL ANTHROPOLOGY. Social anthropology is one of the social sciences engaged in the comparative study of human societies. It is closely related to sociology, which shares the same aim. Many social anthropologists indeed regard themselves as sociologists of a specialized kind. The separation between social anthropology and sociology is on two grounds—of content and of technique. In its content social anthropology has concerned itself primarily with what are known as the simpler, the primitive, the preliterate peoples, while sociology has studied at first hand mainly the more advanced peoples. This division has to some extent disappeared under modern conditions, however, as social anthropologists have begun to investigate advanced oriental and western societies (see *Studies* in *Literate Societies,* below). These studies are usually of small communities such as villages or special groups in factories, or camps of displaced persons, or of special aspects of social life such as kinship. But social anthropology shares with and helps to contribute to sociology a theoretical framework for the study of social life and social systems as wholes. In technique, social anthropology uses above all an intensive type of inquiry which ordinarily involves living among the people to be studied, learning their language as the most effective medium of communication, and observing closely their behaviour in their day-to-day activities. The social anthropologist is interested in what people do, as well as in what they say, and say they do. Such divergencies between word and act are often of great importance to him. So closely may he become associated with the activities of the people whom he studies that he may engage in "participant observation." That is, he co-operates with the people by engaging in their activities himself—going on a fishing expedition, taking part in a religious rite, keeping their tabus, exchanging property with them as if he were a member of the society.

"Social anthropology" is a term formerly used largely to describe British studies, especially of social structures of primitive peoples. It must be distinguished from ethnography, studies of a purely descriptive order, though many works contain material of both kinds. The subject has owed much to the theoretical analyses of sociologists including the European writers E. Durkheim, M. Mauss, M. Weber and V. Pareto, and the later Americans—K. Davis. R. Merton and T. Parsons. Certain branches of the study, particularly in the theory of kinship, were also affected by the work of S. Freud. The major development of social anthropology in the British field has been associated particularly with the names of W. H. R. Rivers. B. Malinowski and A. R. Radcliffe-Brown. Among later contributors of general works are E. E. Evans-Pritchard, R. Firth, C. D. Forde, S. F. Nadel, R. Piddington; and of analyses of particular structures or aspects, A. P. Elkin, M. Fortes, P. Kaberry, M. Gluckman, H. I. Hogbin, E. R. Leach, A. I. Richards, I. Schapera and M. Wilson. European work in the subject during the first half of the 20th century was not so great, but significant contributions were made, for example, by R. Thurnwald, J. P. B. de Josselin de Jong and C. Lévi-Strauss. But essentially the same types of investigation were carried out by Americans and other scholars, usually as part of the studies labelled "cultural anthropology." In the United States the foundations of the subject had been laid by A. Goldenweiser, A. L. Kroeber, R. Linton, R. H. Lowie, P. Radin, R. Redfield and E. Sapir, and studies of a general theoretical order by R. Benedict, F. Eggan, M. J. Herskovits, G. C. Homans, C. Kluckhohn, M. Mead and G. P. Murdock also had contributed to this end. There, comparative work and special analyses of importance had come from many writers, including G. Bateson, J. Dollard, C. du Bois, J. Gillin, A. I. Hallowell, F. M. Keesing, D. G. Mandelbaum, M. Opler, H. Powdermaker, L. Spier, J. Steward. S. Tax, W. L. Warner and L. White. From the orient there had been as yet little development of social anthropology, though A. Aiyappan, H. T. Fei, F. L. K. Hsü and M. N. Srinivas need mention.

It had increasingly come to be recognized by the 1950s that the terms "society" and "culture" refer to different aspects of the same basic material, the actions and relations of human beings in social living. "Society" and "social anthropology" lay more emphasis on the human element—the interpersonal and intergroup relations of men. "Culture" and "cultural anthropology" lay more emphasis on the creative achievement, the objects and ideas nhich are brought into being and transmitted from one generation to another by the acts of men in society. Where the studies differ, cultural anthropology tends to be the wider, embracing, for instance, simple technology and linguistics as well as ethnography and investigation of social structures. But the different emphases shade into one another and there is a large area of common ground. Anthropological opinion was still not unanimous on this point in the 1950s. But the essential unity of the studies in their major fields of interest is shown, for example, by use of the conjoint term "cultural/social anthropology" in an international symposium.

Social Structure and Social Organization. — The basic data for social anthropology are usually defined as social relations. Man as an animal living in society acts in relation to his fellows in pursuing both individual and common ends. These social relations are not haphazard; they have regularities or patterns shown by repetition — as when a man plays with his children every evening after he comes home from work. These social relations also tend to compose a system, those of one kind being linked with, and to some degree determined by, those of other kinds. So a man's regular relations with his children in play are tied in with his relations with them at meals and in the house generally, and depend in large part on his marital relations with their mother. But they may also depend on his economic relations — as when he is forced to go away from home on a job — or on his legal relations — as when a court awards him custody of his children at divorce. The main elements in the interdependent system of social relations, looked at somewhat abstractly, form the social structure.

Social structures are sometimes stated, as by E. R. Leach and C. Lévi-Strauss, to be models representing the main principles of a society or social system in respect of their ideal or formal qualities. Another way of looking at social structures is to regard them less formally as comprising the more permanent groups and other continuing features of the social system (E. E. Evans-Pritchard) or even the network of social relations of the system (A. R. Radcliffe-Brown). These, however, are all linked concepts, since the regularity and permanence of social relations depend largely on the ideal type laid down by the society. and perception of all this involves considerable abstraction of formal qualities by the observer.

The social structure is like the anatomy of the society — it provides its major shape. But the conduct of individuals varies; some follow the rules laid down and others do not; there are choices to be made between various courses of action and decisions to be taken. Not every man abides by the legal and moral rules of marriage in society — nor does every man or woman marry. Some fathers make generous provision for the education of their children and try to guide their social development. Others allow them to fend for themselves. In all fields of social action such different arrangements by individuals occur as the result of the choices they make between alternatives to social action. The total body of such arrangements can be termed social organization.

Linked with these concepts also is the notion of social values, the system of preferences that govern action in any society (see *Values*, below). It is by adhering to the conceptions and principles embodied in the system of social values that the members of the society are enabled to maintain their social structure.

Social Structure of Primitive Societies. — The most obvious difference of a primitive society from our own is in size — it may consist of only a few hundred or a few thousand people, very rarely of hundreds of thousands. But though demographic studies have been shown to be important for structural analysis by M. Fortes and others, size alone is not the most important factor in the structure of a primitive society.

In such a society almost all interpersonal relations are face to face — except where western influence has recently introduced written communication. Rloreover, partly for technical, partly for social reasons, people are apt to move about much less. Hence, any one person is apt to have relationships with fewer people than in our own society and those relationships are likely to be more permanent. Almost every relationship, too, is between people already acquainted; the impersonal day-to-day contacts of western society — as with a sales assistant or a government official — do not occur.

This factor of proximity — expressed formally in terms of neighbourhood associations and local groupings — is extremely important as an element in social relations. The units of household, homestead, hamlet, village, urban ward vary greatly in different societies. But not only do they serve as basis for economic and other co-operation; they may also tend to determine the character of kin grouping by virtue of the property and other rights usually associated with them. In a primitive society, the range of occupations and special social activities is much less than in our society; there is far less differentiation of roles. For example, most of the people are primarily engaged in food getting with fairly similar technical equipment. This means that the types of relationship possible for a given person are far fewer. But the people with whom one is in contact may play several roles. Relationships are many-stranded. The same person may be father, war leader, judge, economic boss, teacher and priest.

This many-stranded quality of relationships in primitive society means that the social anthropologist is faced with a problem of disentangling for analysis. sometimes arbitrarily, various categories of relationship such as economic, political, legal and ritual relatibns. The overlapping of these types or aspects of relationship leads the anthropologist to emphasize the interdependence of their different fields, that is, to seek the function of the relationships in any one field in maintaining the total pattern of the society.

In any society, people arrange themselves in groups — families, villages, clans, professional associations, age sets. In a primitive society, groups tend to be closed rather than open — that is, most groups recruit through birth, and membership is compulsory. But a primitive man does not normally belong to groups having quite different, voluntary membership, as we may belong, say, to a factory. a tennis club and a church congregation. Everyone in a primitive society is compelled to belong to a certain number of groups, and a larger sector of behaviour has to do with group membership than in our own society. The principles of age, sex, neighbourhood and kinship are the common bases of group formation, since there are fewer differences of skill and interest. Since a primitive man or woman is both more dependent on the groups in which he or she has membership, and at the same time less able to withdraw, to change membership, conformity to wishes and standards of other people in one's immediate environment is to a much greater extent a condition of well-being, even of survival, of the individual than in the more advanced societies.

The rate of social change, barring outside influences such as natural disasters or conquest, is slow. though it is by no means true that all primitive societies are static, as has sometimes been assumed. (See Social Change, below.)

Sex and Age Grouping. — All societies make use of the physiological differences of sex and age. The basic division of duties between man and woman seems to be universal — a woman is primarily responsible for young children and for most specifically domestic tasks, while tougher jobs which involve heavier work, greater distances from home or violence — hunting and fighting — are male tasks. The formal control both of internal group affairs and of relations with other groups is almost entirely in male hands — though women may exercise great informal power. The queens or female chiefs who are found among the Lovedu and in a few other societies are not direct exceptions. Either they lack real power or else they are in some way symbolically equated with men. This universal division of function is invariably backed up by a more specific division oi labour between the sexes which varies greatly from society to society. These divisions are felt to be right and natural. Violation of the rules may cause mirth or abhorrence, and very often the tasks of one sex are ritually forbidden to the other. Invariably, as in our own society, the difference of sex is symbolized in differences of dress and etiquette. Sexual differences are emphasized in ritual and in dogma, and the sexual dualism is often carried over into theological and cosmological notions, as among Australian aborigines and as it was in classical antiquity.

The principle of seniority and juniority is equally used for social distinctions. In a few societies old people are regarded as a burden. But almost invariably old age is highly respected.

Where there is no writing, and where the skills and cultural heritage alter little through the generations, the old men are the obvious repositories of wisdom and experience. In its extreme form, the respect for the aged becomes gerontocracy — the rule of the old men. In such societies, old men keep for themselves special privileges, often including rights to marry younger women. thus forcing up the average age of male marriage. Their position is often backed by magical knowledge and ritual respect. Sometimes the age principle is formalized in a system of grades. The change in status from child to adult is marked by a ceremony of initiation (usually including an ordeal). Those initiated together form a special group, an age set, with special rights and obligations. Ritual occasions may mark the movement of a group of agemates from one status to the next.

Among the Australian aborigines a man's advance toward old age is marked by successive initiations into the totemic mysteries, which are fully known only to the old. In some east African societies. as the Nandi. the grade of warriors ritually takes over the status of elders and its members replace their seniors in the direction of tribal affairs. Even where no age sets exist, the principle of seniority is of vital importance. Elder brothers usually exercise authority over younger brothers, and the principle is so important that in many societies words for "elder" and for "younger" are found, but no one word for brother.

Kinship. — Kinship is the social recognition of real or putative biological ties formed by procreation and marriage. The continuity of any society must be ensured by the procreation and training of new members. The family provides legitimacy for the procreation of children and a social unit to undertake their care and training and place them in a defined position in society.

The minimum social unit which is necessary to carry out these functions is the elementary (nuclear, individual) family, consisting of father, mother and children. Almost every person who achieves adulthood is a member of two such families, called by R. Linton the family of orientation, that into which he is born or adopted, and the family of procreation, that in which he or she becomes a parent. The interlocking of these families creates a complex framework of relationships, consisting of consanguineal ties (by blood) and of affinal ties (by marriage). Adoption is the simulation of consanguineal ties. Most human societies make great use of the kinship principle in the ordering of social life. It provides channels for organization of economic, political, judicial and ritual affairs.

The concept of a kinship unit should be separated from that of a domestic unit, though these units overlap in fact. Statistically the elementary family is frequently the norm in residential terms, occupying a single separate dwelling. But in many societies, as in Malaya, a young couple begin married life in one of the parental households rather than in a new home of their own (this latter being called neolocal residence). Where a young couple live with the groom's family. the marriage is termed patrilocal or more correctly virilocal. Where they settle with the bride's family, the term is matrilocal or uxorilocal.

A domestic unit of such kin is referred to as an extended family (expanded family). Where a household consists of two or more siblings, their spouses and children, they may be termed a joint family — fraternal or sororal as the case may be. In some societies, such as rural Turkey, the two types of structure often merge into one another by the death of the parental head. Where a man has more than one wife, they usually live in separate huts or rooms.

A man or woman is born — or adopted — not only into a family, but also into a wider kin group, a descent group. For the purpose of defining this group both parents may be held relevant or only one of them. Where descent is reckoned always through one parent only. the principle is called unilineal, and the group so constituted is a lineage. A patrilineal lineage (patrilineage) consists of the male descendants through males of a common ancestor, together nith their sisters and daughters. Conversely. a matrilineage consists of the female descendants of an ancestress through females, together nith their brothers and sons. A lineage may comprise any number of generations. Even an extended family may be regarded as an incipient lineage. But commonly descent is traced to an ancestor from five to ten generations back. Often the genealogical connections of a large lineage may be invented, or even inconsistent. Lineage structure may be regarded as the result of a branching process. Hence, two or three small lineages whose founding ancestors are brothers will comprise a single larger lineage. From the point of view of a larger lineage, the smaller ones are segments and the whole society is of segmentary structure.

In many unilineal societies, the lineage is exogamous, that is, a man cannot marry a woman of his own lineage. Marriages will then always set up reiationships between lineages. The structure of a society with patrilineages, where a man belongs to the group of his father, is markedly different from that of a society having matrilineages, where a man belongs to the group of his mother's brother.

The prevalent pattern of residence in a society greatly affects the operation of the unilineal principle. Among the Tallensi of the Gold Coast, a patrilineal virilocal people, the pattern on the ground corresponds closely to the lineage structure. Households under brothers or brothers' sons are usually adjacent; households in one area will belong to a larger lineage segment; and so on. Among the Nuer of the south Sudan, the fiction of localized lineages is found, although in fact men often live with matrilateral or affinal kin. In matrilineal societies the problem is more complex. If all the men of a lineage live together, then the children born in the group will belong not to that group but to the various lineages of their mothers. In the Trobriands, this difficulty is met by the sons of a man leaving him to rejoin their mother's brothers on adolescence. If, on the other hand, all the women of a lineage live together, no man of the lineage may be present to direct affairs — unless, as among the Hopi, brother and sister normally live in the same village. Among the Yao of Nyasaland, this problem is met by allowing the eldest brother of each set of sisters to take his own wife to live with his sisters, so that he can take charge of their affairs. In Dobu, a Melanesian island, married couples alternate residence between the lineage of the husband and that of the wife. Among the Nayars of south India, an aristocratic people of high caste, husbands only visit their wives and the joint households contain brothers, sisters and the sisters' children by their visiting husbands. In this case, as often, lineages larger than the joint family do not live adjacently, yet they maintain coherence through common rights and duties, rituals and symbols.

In some societies, both matrilineal and patrilineal descent are recognized for different social purposes. This is known as double unilineal descent. Thus among the Yako of southeastern Nigeria, as C. D. Forde showed, the household and the farming group are based on patrilineages, while matrilineal groups, although not residential, are of great importance in the ritual and political system. With new demands and attractions resulting from western influences, larger kin groups often tend to break up, as more individual rights are asserted. As A. I. Richards and M. Fortes showed for Bemba and Ashanti. in matrilineal systems fathers tend to take over functions traditionally performed by mother's brothers.

Often no very specific descent groups are found but all kin on both sides are recognized equally. This system of kinship is called bilateral. The people recognized as kin are different for each set of full siblings. ("Sibling" means brother or sister — from Old English, *sib*, related by blood or descent.) Though not forming a distinct group for any other purpose, such a body of kin may be responsible for their common kinsman, and be liable if he commits wrong. In other societies. as among the Maori, a person normally belongs to only one specific group, but this may be his father's or his mother's according to his pattern of residence and his interest in land rights.

The word "clan" is widely used in anthropology, often in the older literature in a vague and unsatisfactory way. In fact, it is necessary to define it in relation to the social organization of a particular society. Usually the term clan is used for a group of people claiming unilineal descent from a common ancestor but unable to give a precise genealogy. In the past the clan has been described as an exogamous unit (as it often is) but this strict definition is unnecessary. On the other hand, the word is now confined to unilineal groups, although the Scottish prototype is bilateral.

Descent should be distinguished from inheritance of property and succession to office. Though these may follow the main lines of descent, they do not necessarily do so. Thus certain kinds of property may pass patrilineally in a matrilineal society, or a sister's son may succeed to an office in a patrilineal society. In societies with bilateral descent, succession and inheritance often have a patrilineal bias.

Though in many societies one side of the family is far more emphasized in determining group membership, inheritance and succession than the other, yet it does not follow that in these societies only one side of the family is recognized. Close ties are invariably maintained and keen interest taken in the welfare of all who marry out of a group, and in their offspring. Among the Coorgs of south India, a strongly patrilineal people, a proverb urges a diver for pearls to see that his mother's brother holds the rope. Within any body of kin the principles of generation — or, less ambiguously, of kinship grade — of solidarity of the sibling group and of equivalence of siblings are important regulators of behaviour.

The study of kinship in anthropology began with the study of kinship terminologies by Lewis H. Morgan. Morgan and his contemporaries were interested in classifying systems of kinship terminology into "stages" of human evolution, and equated types of kinship terminology with levels of political and technological evolutionary development. Where they thought that kinship terminology was inconsistent with existing social structure. they supposed a previous state of society which would fit such a terminology. A. L. Kroeber criticized the historical soundness of these arguments, which had gained wide currency. It was particularly A. R. Radcliffe-Brown and B. Malinowski who attacked this whole evolutionary approach and insisted on analysis and comparison of contemporary societies, with the aim of establishing general principles. Speculation about early origins of human institutions, which formerly provided the main drive for the beginning of anthropology, was later abandoned as unprofitable by social anthropologists.

Much attention was given to the study of terminologies. But it is now generally recognized that kin terms cannot be understood without reference to the total pattern of kin behaviour. Nevertheless, the study of terminologies provides us with important clues to the structure of a society. A terminology reveals the way in which people in a society classify their kin, reflects the system of descent groups and provides linguistic symbols for much social behaviour.

Marriage. — All societies recognize the distinction between casual sexual relations, or cohabitation, and a formal union of a man and a woman with the approval of society, for the purpose of establishing a family. Several forms of union are often recognized in one society and no universal definition of marriage can be given.

Marriage necessitates a definite realignment of social relations. A permanent relationship is set up between the two groups involved, through common interest in the partners and in the offspring of the match. There are accordingly rules determining with whom it shall be arranged. Very often such a relationship between families is felt to be inappropriate within a fairly large group, a clan. lineage or village. Such a group is then called exogamous. Exogamy, by ensuring social intercourse between potentially hostile groups, performs an extremely important integrating function. Conversely, rules may exist which bar marriage between groups. The extreme case is that in which marriage outside a specific group is forbidden. The term endogamy is used in these cases, and also more loosely, for a tendency to marriage within a group. Endogamy is apt to be characteristic of religious and ethnic minorities in civilized societies. In India, every small subcaste tends to be endogamous, on ritual grounds.

In primitive societies. strict endogamy is rare. On the other hand, rules specifying the group from which a man must or preferably should choose his wife are extremely common. It is often felt that an affinal tie between two groups should be preserved generation after generation. In unilineal societies this is done by a rule of cross-cousin marriage, by which a man takes his wife either from the group to which his father's sister went or from the group from which his mother came. Such a rule also reduces the disturbance of domestic relationships, since the girl is going to kinsfolk, and they are receiving someone they already know.

In all societies, the formal beginning of a new marriage is marked by ceremony. Exchange of gifts always takes place, even if only of food. In many societies, where groups of men are handing over women, a bride price is paid, that is, the groom's side gives far more than the bride's side. Sometimes the reverse is the case, and dowry is paid, as in the matrilineal Trobriands, where a man is said to be compensated for his services in caring for the children of his wife's lineage.

Monogamy is common in all types of society, and polygamy is normally the exception, even where it is the ideal. But many societies permit a man to have more than one wife—polygyny—and a few permit a woman to have more than one husband — polyandry. Each separate relationship is then usually a separate marriage, though sometimes within a minimum of ceremony. In traditional Mandan society when a man married, he was entitled to marry his wife's younger sisters, as they came of age simply by giving them horses. In polyandry the cohusbands are usually brothers, as in parts of Tibet, or else do not reside with their wife, as among the matrilineal Nayars of south India, who practised both polygyny and polyandry.

In all societies, unregulated extramarital intercourse with a married woman is felt to be wrong — or at least a wrong to the husband. The reaction to adultery varies from a mild claim for damages or divorce to killing both parties. But spmetimes certain kinsmen— a husband's unmarried younger brother or, as in the Trobriands, a brother's son — are privileged. or special licence is allowed on ritual occasions. Premarital intercourse is quite commonly condoned. But premarital pregnancy is always a serious matter, since it threatens to create an illegitimate member of society with no defined position.

Most societies recognize divorce, though in some societies it is almost unknown. Plausible attempts have been made to relate divorce rates to the structure of the household and to the amount of bride price, but no adequate theory has been found. Problems of the definition of marriage and of divorce make comparison of the stability of marriage very difficult.

Rules against incest are found in all known societies. Earlier, incest prohibitions were confused with exogamy, but it is clear that a rule against marriage within a specific group is not the same as a universal rule against sexual intercourse with certain close kindred. Incest is always a sin, that is, it is thought to carry supernatural penalties, and sometimes, as in Tikopia, these are almost the only penalties.

Status and Stratification. — Status is the position which an individual occupies in the social structure, with its attendant rights and duties. The word carries an implication of stratification, position on a vertical scale. This spatial analogy, which is found in most languages as a way of symbolizing social rank. covers several meanings. A man may be said to occupy a "high" position because he is able to control, by order or by influence, other people's conduct; or because, in Kingsley Davis' terms. he derives prestige from holding an important office; or because by his conduct he has earned the esteem of his fellows. Relative status is one of the major factors determining the behaviour of people toward each other.

Moreover, competition for status seems to be one of the main human drives. A man's status is made up of a number of different factors, or it might be said he occupies different status in different social contexts. For example, the position of a man in his kin group helps to determine his position in the community. Among the Hopi. as F. Eggan showed, the lineage. although unnamed, contains the mechanism for transmitting rights to land, houses and ceremonial knowledge and is thus vital for a personal status. Among the Tallensi, M. Fortes stated, a mere lad who, having lost his father, is head of a household, counts as an elder, while a middle-aged man who is still under his father's roof is still formally a child Sometimes status is governed by primarily occupational considerations. Thus in Negro Africa blacksmiths commonly form a separate group of low status.

Status is closely correlated with conformity to the etiquette and morality of the society. In many societies the liberal use of wealth is important in conferring status. C. du Bois stated. for the Alorese, that the manipulation of the wealth-status system often demands great individual effort as well as aggression, chicanery and an excellent memory.

Social classes are social groups arranged in a clearly hierarchical status system, whose members interact on this account mainly within their own group and to a lesser degree with groups of higher or lower status. They are rare in primitive societies. But many primitive societies have some kind of stratification. Even an age-grade system where, as in many East African societies, it plays an important part in directing social interaction, resembles in some ways a class structure. In some unilineal societies, clans may be ranked, from royal clans from which the ruler is chosen to clans which, for some special reason such as slave origin or lowly occupation, rank below the majority.

True class systems obtain in the West African emirates: with urban capitals from which a ruling class. different in dress, speech, etiquette and morality, dominates a semipagan peasantry. One of the most striking class systems in the world is the Indian caste system. Hindu villages are divided into a number of small endogamous groups or subcastes based on traditional occupations, arranged in a hierarchy from Brahmans to Untouchables, though the exact order of the middle subcastes is not always agreed on by all parties concerned. Contact with a lower caste, such as eating or drinking from their hands. bodily contact and so on, pollutes a member of a higher caste and necessitates ritual purification. Escape from caste is thus almost impossible and the whole system is still highly immobile, though western influences have tended to loosen some of the rules.

The concept of status and the concept of class should not be confused. One might say that no two persons in any society are exactly equal in status. and that it is therefore a central concept for anthropology. On the other hand, comparatively few studies of social class had been made by anthropologists by the mid-1950s.

Economic Relations. — Economic relations have to do with the choices men make in matching means to ends. These choices are socially conditioned. So while the members of every society must provide themselves with food and shelter, with other material goods and with services of many kinds including ritual services, in all societies the nature of the goods and services varies. There are two main sets of problems here for social anthropology: What is the system of relations involved in the production, distribution, exchange of these goods and services? In what ways do the economic relations affect the social relations?

In a primitive society economic relations have a more personalized character than in an industrial society. Ordinary western categories of employer. employed, wage earner, capitalist often do not apply. Economic services are contributed not simply to earn a living but as part of a much wider system of social obligations.

In almost all nonindustrial societies the main economic unit is the family or household rather than the individual. All able-bodied members share, under the direction of the head of the household, the routine tasks of getting and preparing food and satisfying other recurring wants, according to recognized patterns of division of work by age and sex. Some tasks require a wider basis of co-operation than the household—a rice transplanting team, a canoe crew or a hunting band. The co-ordination of work may then depend on the rights and duties of kinship, on a central authority in the community or on ritual and magic. B. Malinowski showed this in his analysis of the importance of the gardening magician and his rites in the organization of village agriculture in the Trobriand Islands. When large working parties are assembled, the person whose work is done will offer food or perhaps (as in Africa) beer. He may also make gifts, but these do not usually reflect any precise measure of the service rendered. Later, he will return the service by working for others. Technological specialists generally receive some additional payment, but this is apt to be traditionally fixed.

Property in any society is a bundle of rights against other people. In primitive society the variety of these "bundles" is very great, varying from more or less unconditional ownership of some material objects to highly complex relationships to such things as land, ritual apparatus or magic.

The most important resource to any primitive society is land, and the problems of land tenure are often complex to a western observer. Most peoples, even nomads, have a definite territory to which they have a prior right. In purely hunting and gathering societies, such communal rights possessed by kin groups and local groups are the only rights to land.

In cultivating systems, unless fertile land is available in abundance, rights to exploit a particular piece of land usually vest in kin groups such as lineages or families. But the variety of possible arrangements makes it clear how misleading a naive application of our own notions of ownership may be. Some rights may inhere in other members of the community. Thus in Tikopia, until a land shortage became acute, anyone could cultivate a piece of fallow land, without prior permission of the owner, so long as he gave a nominal gift of the produce to the owner at the harvest. Other rights may belong to the ruler. Among the Lozi, the paramount chief "owns" all the land. In many cases a chief holds it from him, a headman holds it from the chief and the cultivator holds it from the headman. Each "owns" the land in a different sense. In fact, this is as much a political as an economic arrangement — the holding of land is inextricably bound up with political dependence, and a man loses his land if he changes his residence, that is, his political allegiance. Sometimes more definite concepts of ownership may be found. Rights to territory, and also rights of individuals to special plots, are often validated by myth and ritual. It may be unthinkable to part with the land where one's ancestors emerged from the ground or where one's fathers and grandfathers are buried. Other kinds of property are generally owned in a way more familiar to us. Property in food may be personal or household property. The house itself will belong to the head of it, subject to the rights therein of the other members. Tools and implements are usually personally owned. Not only material objects, but titles. songs and dances, magical spells or medicines may be owned, personally or by a group, and many of these can be sold or exchanged

Although in primitive societies, where most essential skills are possessed by most adults. the amount of exchange of goods and services is very much less than in our own. goods still constantly change hands and services are continually rendered to other people. The word "prestation" is a useful one to cover all such goods given and services rendered to others. In most primitive societies, prestations are not normally valued or paid for in the precise way to which we are accustomed. But the account is balanced in the end; indeed. the principle of reciprocity, or basic compensation, was strongly emphasized in the theories of M. Mauss. B. Malinowski. R. Firth and other social anthropologists. A prestation is normally part of an already established relationship between two people. If the parties are of roughly equal status. a return of equal value will be made, directly or indirectly. A voluntary prestation unreturned indicates that the giver is of higher status than the receiver; the basic compensation in this case is prestige.

The exchange or consumption of wealth may not thus have primarily utilitarian motives but be symbolic statements of status or a set of social relationships. Such are the *kula* ceremonial exchanges of the Massim of New Guinea and the pctlatch of the northwest coast Indians. The more valued the objects a man handles. the higher his status in his own community. At the same time, in these exchanges a man may seek to score over his partners by giving them gifts the value of which they cannot equal in return, or returning a gift more valuable than they have received.

These and other exchanges of goods and services may also serve more practical ends. Australian ceremonial exchange systems provide a channel for the distribution of the products of the special local skills over wide areas. In the Trobriands. men of coastal and inland villages exchange fish for yams both ceremonially and by process of barter in an ordinary commercial way. Some primitive societies derive much of their income from trade. Thus the

Manus, a canoe people who live in the Admiralty Islands off the north coast of New Guinea, inhabit unfertile islands which provide them only with fish. and they rely for daily dietary needs on trade, which consists basically of the exchange of fish for sago. In West Africa many people trade extensively, and a money economy is now completely established in many parts. So far does the trading concept go that among the Nupe, S. F. Nadel reported, a man sometimes pays his wife for her duty of marketing the household grain surplus.

Among primitive societies the exchange of goods is often made, easier by the use of certain articles as mediums of exchange. Coconuts, blankets, dogs' teeth, shells have all been used to fulfil some of the functions of a currency. Usually the range of goods and services which can be exchanged against such so-called "primitive currencies" is limited, and the occasions of their use ceremonially prescribed. None of them become the full equivalent of money, that is. a general measure and repository of economic value.

Political Relations. — Political relations are those concerned with preservation of order and the conduct of affairs of public concern within a community or society, and with relations between communities or societies. Political relations are always concerned with the power to control some aspect of other people's behaviour.

Many primitive societies lack any form of legislative or judicial machinery or any group leadership above the level of the village or camp. Since in such societies both internal and external affairs are usually conducted in an orderly fashion, the anthropologist is forced to extend the use of the word "politics" beyond the field of instituted government. But attempts to classify primitive political systems have not proved satisfactory because of their very great variety. In Africa alone they range from societies like the Tonga of Northern Rhodesia, where the village, based on kinship, is an autonomous unit, to the large states such as the Nupe kingdom of Nigeria or the Baganda kingdom of Uganda.

In the political systems of village type, kinship and neighbourhood provide the necessary institutions for the organization of power and authority. But in some societies much larger political groups exist. still without any formal government. These societies make use of the unilineal principle of organization, described above under ***Kinship.*** E. E. Evans-Pritchard's work on the Nuer provides an excellent example. Territorial divisions are called by the names of the branches of the lineage system, although they do not exactly correspond to them. There is no specific authority over the various segments of the lineage. In cases of dispute no one official can order a group to accept compensation and make peace. But an elder with special powers, called by E. E. Evans-Pritchard the leopard-skin chief, is usually able to persuade them to do so. Thus among this independent and quarrelsome people, group relations are ordered according to well-established moral principles.

In many parts of the world chiefs are the heads of governments. The paramount chief of the Bemba of Northern Rhodesia rules over a considerable territory. He has under him advisers, councillors and ritual officers, besides a whole range of courtiers and messengers, and resides in a capital considerably larger than a normal village.

Members of the royal clan rule as lesser chiefs over sections of his territory, with capitals and courts similar to his own. Beneath these are headmen, responsible to the chiefs. In this case, a large number of people, larger than could ever form a single clan, are united in one political society. The extent in area and numbers of such a state depends only on the strength and efficiency of the administration which it devises.

Relations between autonomous groups naturally vary with the size and organization of the group, and with ecological conditions. In primitive conditions, the normal attitude to other autonomous groups is often one of hostility. Even within one political system where there is some specific tie of friendship, intermarriage, common ritual or common opposition to a larger enemy. the constituent groups will express mutual antagonism as well as mutual solidarity.

Wars between primitive communities are conducted according to specific rules. They vary greatly in aim and in ferocity. Between neighbouring groups who are kin to one another, as among the Andaman islanders, killing in such fights may be rare. Women and land, as the Maori used to say, are probably the commonest causes of such fights. Habitual cattle raiding and slave raiding used to be common in many parts of Africa, without any notion of conquest. Wars of conquest are obviously impossible unless the conquerors have a state organization to control their subjects. Great rulers like Shaka (or Chaka), the powerful Zulu king of the 19th century, are rare in primitive society.

Primitive military leadership and organization are often ad *hoc* and informal, though sometimes the war leader may be identical with the chief. Many societies have or had special war leaders with no other political tasks, as among many Amerindian peoples. In eastern and southern Africa warrior regiments often existed, based on an age-grade organization. It was by his reorganization of age regiments and maintenance of them in royal barracks that Shaka was able to gain power and military success.

The maintenance of authority in any nonliterate society must depend on personal contact between ruler and ruled, directly or vicariously. Moreover, all rules and ordinances must be remembered and transmitted orally. A great deal of ceremonial behaviour and story-telling serves this end. The society looks to the past for validation of rules and values, and explicit legislation is very rare. On the other hand, verbal transmission leaves room for continual adjustments of which the society may not be clearly aware.

Informal arbitration is found in all societies, but in many no sanction of force supports a decision, though public opinion may be a strong influence. In some Amerindian societies, as R. H. Lowie showed, the persuasion of an arbitrator can be exercised only by a man who is not a war leader. In more complex societies, a political hierarchy coincides with a hierarchy of courts, with right of appeal to the paramount. In Africa many societies have a constituted court and litigation is common.

At all levels of society, even where, as in Polynesian societies, the thief is treated with very great deference, the political system provides for checks and balances. Sometimes there is provision for an assembly of the whole people, as among certain of the Southern Bantu. Sometimes the chief, as among the Tikopia, has to pass orders through subordinates who, in practice, if supported by public opinion, can tactfully evade these orders. Sometimes, as among the Bemba, the chief depends on the co-operalion of ritual functionaries who can, if necessary, refuse their help. Only when a ruler is able to monopolize force is he able to set up a tyranny, that is, when a fairly complex political and military organization exists. Ritual sanctions behind a ruler may be very strong, but they will equally impose on him strict rules of conduct and limit the free use oi his power.

The cohesion of any group of people depends on their thinking of themselves as a unit. This is only possible through a symbol of their unity. The more powerful the emotional charge, so to speak, of the symbol, the greatei their loyalty to the group. A common and effective symbol of unity is a human symbol, a chief who becomes also a symbol of the society's well-being and fertility. The chief is thus sacred and acquires important ritual functions. In extreme cases he may be thought of as an incarnation of a divine being. Sometimes, as among the Shilluk, his own personal vigour is associated with the weal of the society, and in former times when he was ailing or old he was put to death Alternatively, the religious head of the society and the ruler may be distinct but interdependent persons

Religious rites map also be of great importance in group relations Among the Tallensi there were no chiefs with secular authority, but only ritual leaders. Once a year they all took part in a great ritual festival involving a number oi autonomous clans, who were required during this period to settle all quairels and refrain trom hostile acts. Such arrangements are common among less politically developed peoples.

In all societies, political organization is linked with ritual and symbolism. In primitive societies this aspect of political relations is perhaps the most striking one.

Ritual Relations. — Rites form an important sector of human behaviour. "Rites" may be loosely defined as routine acts or series of acts which are not technically related to immediate purposes, but which are symbolic in character though often believed to have validity in themselves They are usually closely related to a set of myths and dogmas, which explain and help to validate the rites and which they in turn symbolize and keep alive. Ritual behaviour ranges from the worship of God to the concocting of medicines against witchcraft or incantations to render a spear more deadly. Attempts to divide this field have met with difficulties. Many authors have sought to apply the distinction current in our own society between religion and magic. J. G. Frazer suggested that religion is characterized by prayer to a personal power, magic by command to an impersonal force. E. Durkheim identified religion with public and obligatory, magic with private and optional rites. B. Malinowski held that magic is done for immediate practical ends, religion being concerned with general well-being. But each of these criteria would force us to class as magic some rites which are normally called religious, and vice versa. Moreover, as R. H. Lowie, P. Radin, G. Reichard, R. Piddington and many others showed, there are too many borderline cases between prayer and command, between obligatory and optional, between practical and general purposes, for these to be final criteria. The general meanings of "religion" and "magic" therefore remain vague, though more precise classification is possible for particular societies.

All known societies have beliefs in a spirit world. In most primitive societies, their gods and spirits are thought of as belonging to the particular society, and symbolize its unity. Often dead ancestors are important among the spirits, and belief in their pomers thus reinforces lineage or other kinship systems. The myths and dogmas about the spirit world are thought to explain the universe, give an account of man's place in nature and validate the moral law. They also often provide a charter for existing rights and obligations between peoples, and between kinship and local groups, in such matters as the possession of lands or ritual co-operation.

Public rites may be performed simply as worship, or they may have explicit aims such as the fertility and well-being of human society, the fecundity of animals and of vegetable foods or control of the weather. The passage of an individual from one status to another—birth, initiation, marriage, death—are marked by *rites de passage*, rituals which, as the classic work of A. van Gennep showed, have important functions in social integration. Rites may also be important to the social structure in symbolizing social distance, uniting potential enemies, enforcing the cessation of feuds or mars.

The forms which rites may take are too various for description but as examples magic, shamanism and totemism may be mentioned.

Magical rites were analyzed by B. Malinomski into three elements, though not all are always present. The performer, who must be in the correct ritual state, uses certain specified apparatus or medicines; he performs certain routine actions and he recites a spell. In the Pacific area the correctness of the spell is usually vital to success. In Africa more emphasis is laid upon the virtues of medicines. As J. G. Frazer early pointed out, magical rites often symbolize directly the end they'aim to compass.

Communication with the spirit world is important in all primitive religions. Among its many forms is shamanism, a widespread phenomenon with rites of mediumship and divination—the term is derived from a Siberian word for a "master of spirits." Usually in trance state, the shaman diagnoses causes of illness and expels the evil from the patient by spirit means. His technical and ritual practices often appear to give some relief to the sick person. The role of shaman also seems to provide an occupation and status for aberrant personalities in the society.

Frequently spirits are either identified with animals or even plants or are thought to have special connections with them. In this way, man puts himself in a social relationship with his natural environment. The most striking form of this type of belief is totemism. A clan, lineage or other social group has a special ritual relationship with one or more species of animal or plant or, more rarely, a natural phenomenon such as rain, with which there is an ancestral identification in some form. Many of the Australian tribes have highly developed myths and rituals connected in this way with the fertility of natural species. Following the earlier work of B. Spencer, J. Gillin and C. Strehlow, the intricate relationships involved have been analyzed by A. R. Radcliffe-Brown, A. P. Elkin, W. L. Warner, P. Kaherry, W. E. H. Stanner and R. and C. Berndt and others.

Ritual prohibition or tabu, a word borrowed from Polynesia, has been much discussed by anthropologists. A man's totem is often tabu, in the sense that hc may not kill or eat it. Tabus are often associated with a notion of sacredness—it is dangerous, for example, for a commoner to touch a Polynesian chief—or with pollution. Corpses, excrement, menstruation, for instance, are often polluting agencies which require those affected to perform special purification ceremonies. The concept of sacredness and the concept of pollution are related, as W. Robertson Smith pointed out—in fact, in some societies they appear to be indistinguishable.

Belief in witchcraft or sorcery is common. Sometimes a man or woman is believed to achieve power to harm or kill others simply by rites; somtimes he is believed to inherit or acquire special malignant pomers of a supernatural order. E. E. Evans-Pritchard distinguished these as sorcery and witchcraft. B. Malinowski shomed how sorcery may have para-legal functions, in the form of magic against thieves, for example, or vengeance magic supporting the pomers of a chief. Most personal misfortunes, especially sickness and death, which are not attributed to the action of spirits, are diagnosed as witchcraft or sorcery and the diagnosis is frequently backed by oracles. The system of thought is self-validating and constantly borne out by events since, though no one normally admits to sorcery or witchcraft, some kind oi evidence can always be found to give colour to the accusation. Witchcraft accusations are found to occur at certain points of tension in the social structure. So, as C. Kluckhohn and others showed, witchcraft beliefs canalize and provide a cathartic for anxiety and hostility. They also provide a strong sanction against deviant, especially malicious, behaviour.

From an individual point of view, ritual and belief clearly provide people with important means of adjusting to their environment. Here the inherent variability of the religious systems is of great importance. Religious dogma and mythology is a society's form of metaphysics and theology. It should not be assumed that. it is inflexible. Scepticism, reflection, unconscious modifications in transmission and even trial and error with ritual procedure are reported from many societies. But the system of belief provides a limiting framework within which speculation is necessarily confined.

Social Control.—Social order consists in the conformity of the individual members of a society to a set of rules of conduct. People act in conformity with rules for two main reasons. Most oiten, they wish to do so or are conditioned to do so without conscious choice. But where deviation from the rules offers immediate or personal advantages, then such a course of action must involve also outweighing penalties if conformity is to be preserved. Social control, therefore, involves both the training of members of society and the system of rewards and punishments which operate to produce conformity in behaviour.

Education of a formal sort is rare outside civilized, literate societies. In most primitive societies, a child learns by constant imitation, by participation in activity and by correction when it does wrong and praise when it does right. Many U.S. anthropologists such as R. Linton, M. Mead, J. W. Whiting, C. du Bois, came to concentrate from various points of view on the theory of child training, seeking to describe the growth in each society of a "basic" personality which both summarizes and explains the types of behaviour current in that society.

Ritual forms one of the major ways in which strong reactions of approval and disapproval are inculcated into and maintained in the members of a society. Thus *rites de passage* (see *Ritual Relations*, above) serve to emphasize moral rules, always through symbolism and oiten through explicit instruction. In initiation ceremonies, the solemnity of the occasion may be heightened by the infliction of pain—circumcision or scarification.

The expected reaction of a group or part of a group, directly or through its representatives, to unusual conduct is called a sanction. Where the conduct is specially approved of, the sanction may be called a premial sanction, and where, as is more often the case, the conduct is disapproved of, the sanction is called repressive.

Sanctions are sometimes formal, that is, carried out by recognized officers of the community according to recognized procedures—through police and law courts or through a church. More often they are either informal—the unplanned result of individual reactions—or an organized but informal penalty such as the singing of songs of ridicule, or ostracism.

Most control over conduct is unplanned. If a person deviates from the conduct expected of him by those with whom he has relationships, then these relationships will change and the deviator will suffer. Thus, if a Trobriander fails in his part in an exchange relationship, he not only loses the co-operation of his partner, but mill be unable to establish a new partner relationship. It is plain that in a small community, where everyone's behaviour is well known and most relationships are lifelong, this kind of informal sanction can be very strong. Failure to conform, apart from material consequences, means loss of esteem and status in a person's immediate group.

Even formal sanctions do not necessarily involve judicial procedure. Action by a chief, by a secret society, by a professional body or by a religious leader may be taken without any formal weighing of evidence or statement of law.

Conduct is often controlled by expectations of a different sort—the expectation that a certain action mill produce undesirable consequences apart from any human agency. Such actions are tabu. The belief in dire consequences is probably less a deterrent than a symbolic expression of strong social disapproval. More generally, divine punishment is often said to follow some or all kinds of moral or ritual lapses, that is, sins. Sin may also be directly punished by society, especially if it is believed to endanger the well-being of the whole community.

The moral rules of any community are usually supported directly or indirectly by its cosmology and by its religious myths and dogmas; the moral order of human society has its validation in the moral order of the universe.

Social control is thus seen to be imbedded in the social system, a by-product, as it were, of kinship, economic, political and ritual relations. It is only in the field of law as such that social control has its own institutions.

R. Thurnwald and A. R. Radcliffe-Brown suggested the limiting of the use of the word "law" to societies where some kind of court exists, with control of organized force to back up its decisions. It follows from this definition that many societies have no law at all. On these grounds B. Malinowski, H. I. Hogbin and others objected to it, and R. H. Lowie, following K. N. Llewellyn and E. A. Hoebel, defined law in terms of action by a person against breach of a norm with communal approval or sanction. But, as I. Schapera showed, if such a broad definition of law be adopted, to include all binding custom, there is still need to separate out those aspects where formal judicial procedures obtain.

Law may be divided into two kinds: public action by the society or its representatives to punish an act regarded as a threat to the whole society, corresponding to modern criminal law; and the settlement of private disputes, corresponding to modern civil law. In primitive societies the first is rare and is often confined to serious ritual offenses endangering the whole society, especially incest, and witchcraft or sorcery. On the other hand, private disputes cover much that in our society is criminal behaviour—homicide and theft, for example.

Specific legislation in a primitive society is rare. Where courts are found, the conduct of cases differs greatly from our own. Although most cases are in the form of private disputes, the court will not hesitate to lecture both sides on their moral responsibilities—the law coincides closely with the ethical notions and public opinion oi the society. Oaths and ordeals are used to establish evidence, and hearsay evidence is admissible. Professional pleaders are unusual. In punishment, fining is common but imprisonment rare. Banishment or exile from the society is often the most severe penalty.

Oral Tradition.—By oral tradition is meant the body of stories, including folk tale, legend and myth, which are transmitted by word of mouth from one generation to another and kept mainly in memory, not in writing. Great collections oi such traditional material have been made from almost every area of the world. The stories have been analyzed for style, character, incident and plot. As the result of the work of many writers—to mention only F. Boas, A. Aarne, Stith Thompson, R. B. Dixon, K. Luomala—a great deal is known about the classification, distribution and spread of the leading themes and about the way in which such stories are used.

The earlier view of such verbal material was that it has two primary functions. One is its quality as art, a series of imaginative constructs giving rein to fantasy, to narrative interest and to sense of dramatic form. From this aesthetic point of view these stories have been described as "oral literature." The other function is that of providing a history. It mas thought that by pruning away of incidents clearly belonging to the realm of the marvellous or of the irrelevant, a main stem of fact would be left, embodying in either descriptive or figurative form events of significance in the past of the people concerned.

The modern interpretation of oral tradition by social anthropologists emphasizes other functions. In particular, stress is laid upon its current meaning for the society which remembers it, rather than upon its retrospective interest. The traditions are kept alive because they embody claims to status, to land, to ritual and political privileges. Various people in the society, often the heads of kinship groups, regard themselves as the owners of particular traditions, the only persons entitled to recite them or allow them to be recited or to say whether a version is correct or not. They quote these stories, or incidents in them, to settle disputed points of precedence or to back up their arguments. From this point of view it is seen to be important for the anthropologist not so much to try and establish any single version of a tradition as "accurate," and still less to try and combine versions to get a synoptic "historical" account, but to study each version in context. To understand the significance of a tale it is necessary to know the social position of the person telling it and the social circumstances in which the tale is regarded as relevant by the people concerned.

Oral tradition can then be a powerful social force. The appeal to the past is not merely to explain the present, but also to validate it. This is especially so in myths, the stories which are regarded as sacred and which in all societies provide a basis ior social and ritual organization and moral rules. As B. Malinowski and others showed, an important aspect of the functions of myth is in endowing social action with greater value either by tracing it back to a higher, better, more supernatural reality of initial events, as in a "golden age," or by contrasting it with a past in which customs were the moral reverse of the present. Even the explanatory or aetiological myths of protophilosophical character examined by P. Radin have a sociological significance. They help to buttress the status of a kinship group by providing it with an unimpeachable genealogy going right back to the very origin of the land itself. M. J. Herskovits suggested that while Polynesian mythology which deals with creation and an orderly development of nature may be related to the stress these people lay on a hierarchy of rank, the lack of any such evolutionary concepts by North American tribes may be linked with their more democratic classless structure.

The emphasis on the sociological context of tradition was developed by E. E: Evans-Pritchard and M. Fortes in their studies of time perspective in segmentary social structures. They show how there is a direct correlation between time perspective recognized by the society and the structure of the social units. Genealogies are telescoped, and past events are placed in relations of structural relevance rather than on a scale of historical time, so fitting the lineage relations.

Values.—The study of social relations necessarily means taking account of the values of the people concerned. Social anthropologists have always paid some attention to values, usually under the head of beliefs, ideas or institutions. A. R. Radcliffe-Brown in 1922 described what he termed the "social values" of the Andamanese by considering the effects on their social organization of their interest in certain kinds of objects. The social value of fire to them, ior instance, is illustrated by the ceremonies in which they pay respect to it and recognize its importance in their social life. But the precise definition of what is meant by values had not pet been generally agreed upon in the 1950s. In a broad sense they may be described as the preference qualities assigned to objects and actions in social contexts, having regard to relationships between means and ends. More narrowly, following C. Kluckhohn, they may be defined as conceptions of the desirable which influence the selection from available modes, means and ends of action.

Some values are explicit, that is, they can be formulated in words. In many Oceanic societies a sister's child has special value for its mother's brother, who is expected by the social code to give particular attention to such nephews and nieces, care for their welfare, make them gifts and take charge of them in crises of life. This set of values can be stated by the people in moral rules and opinions. But some values are implicit, tacit premises implied in action. Thus the Navaho have as an implicit value the conception of harmony or balance among the various parts of the universe—a value expressed in much Navaho behaviour but expressed in words only rarely, and by singers, who are the intellectuals of the society.

Problems in value study—such as the relation of values to behaviour, the conformity and nonconformity of individuals to the predominant values of their society, the relation between explicit and implicit values, the processes whereby values change—were receiving much more attention from anthropologists by the middle of the 20th century than before. One of the most ambitious and important of these studies in the field was the Rimrock project undertaken by C. Kluckhohn and associates—a comparative study of the values of five neighbouring societies in New Mexico.

A iurther problem of theoretical and practical interest, which R. Redfield and S. F. Nadel in particular discussed, is the degree to which anthropologists are influenced in their observations and interpretations by their own personal values. (For practical implications of this see ANTHROPOLOGY, APPLIED.)

Studies in Literate Societies.—The methods of intensive field research and systematic analysis of social relations developed by social anthropology proved so strikingly successful in bringing a new understanding of primitive or preliterate societies that some anthropologists applied them to the study of civilized or literate societies. In fact, the earlier anthropologists, who saw themselves as historians oi human institutions, had already made free use of materials from the ancient civilizations, especially Greece and Rome. Moreover, the transition from primitive to civilized was made easier by the rapid spread of literacy and western influences in general in Africa, Oceania and other parts of the formerly primitive world.

Studies by social anthropologists of rural communities of the "folk culture" type—to use R. Redfield's term—were pioneered by Redfield in Middle America, C. M. Arensberg in Ireland, J. Embree in Japan, H. T. Fei, Li An-Che and F. L. K. Hsü in China, A. Aiyappan in south India, R. Firth in Malaya, E. E. Evans-Pritchard in Cprenaica. In urban communities the problems of isolation of field of study have been more acute, and the approach to conventional sociological methods has been closer. But urban anthropological studies have been carried out, some with special attention to the industrial problems raised through the work of Elton Mayo, by W. L. Warner and associates, J. West, H. Powdermaker, E. D. Chapple and others. Urban African problems have been studied by E. Hellman, M. Hunter, G. Wilson and C. Mitchell. Among the special problems, within a primarily urban field, which are of interest to the social anthropologist are those of family organization, child training and child care, to which much stimulating work was contributed by W. H. R. Rivers and C. G. Seligman earlier, and later by R. Benedict, E. Sapir, M. Mead, C. Kluckhohn, I. A. Hallowell, R. Linton, J. Gillin, M. Opler, D. M. Schneider. (For summary by W. Caudill see Anthropology Today, edited by A. L. Kroeber I A particular type of study, related in various ways to the others, is the anthropological investigation of American Negro and other special ethnic groups, as by M. J. Herskovits, R. Landes, J. Dollard, H. Powdermaker, A. Davis, K. L. Little, S. Patterson, M. Freedman, as part of a wider interest in racial relations.

Social Change.—But it is not only in studying civilized societies that the anthropologist is facing new problems. In his own traditional field, practically no societies remain within possible reach which have not been influenced by western civilization. The social anthropologist has accordingly included in his range of interest studies called culture contact or, later, social change.

Social change takes place in all societies at all times. But when *a* small primitive society comes into contact with western civilization, the changes are bound to be rapid and may be catastrophic. New techniques alter patterns of work and co-operation, the arrival of money greatly accelerates exchange, providing a universal measure of value and rendering wealth storable. New avenues of employment open up. Missions and many kinds of government and other developmental agencies increasingly introduce new values and affect the institutional life of the native people. Some degree of social disintegration is oiten the result, and social controls lose their force. In extreme cases, such as African shanty towns, crime and disease increase greatly. On the other hand, some societies make a relatively successful adjustment, raising the material levels of living of their members and increasing the scale and complexity of their economic and political organization without any radical alteration in morale. But in every case the new social situation is not simply a mixture of primitive and civilized ways but a fresh social phenomenon demanding special study. Techniques have to be devised to handle a much greater range of data, a greater variation in social action than is usually included in an anthropological monograph. New social forms, such as the so-called nativistic cults or "cargo cults," may demand more subtle interpretation.

Nowadays most social anthropologists include data on social change in their studies. But while the static theory of social systems is fairly well worked out, in general framework, by social anthropology, an adequate dynamic theory is still largely lacking.

SOCIAL CONTRACT, in political philosophy, a term applied to certain theories of political obligation. Although similar ideas can be traced back as far as the Greek Sophists, social contract theories had their greatest currency in the 17th and 18th centuries. and are associated with such names as Thomas Hobbes, John Locke and Jean Jacques Rousseau (*qq.v.*). What distinguished these theories from other doctrines of the period was their attempt to justify political authority on grounds of individual self-interest and rational consent. The method used was to demonstrate the value and purposes of organized government by comparing the advantages of civil society with the disadvantages of the state of nature, a hypothetical condition characterized by a complete absence of governmental authority. The purpose of this comparison was to show why and under what conditions government is useful, and ought therefore to be accepted by all reasonable men as a voluntary obligation. These conclusions were then reduced to the form of a social contract, from which it was supposed that all the essential rights and duties of citizens could be logically deduced.

Although social contract theorists were agreed as to method. the conclusions they drew from it were widely different. According to Hobbes (*Leviathan*, 1651), the state of nature was one in which there were no enforceable criteria of right and wrong Each person took for himself all that he could; man's life was "solitary, poor, nasty, brutish and short." The state of nature was therefore a state of mar, which could be ended only if men agreed to give their liberty into the hands of a sovereign. who was thenceforward absolute. on the sole condition that the lives of the citizens were safeguarded by his power. Locke (the second of two *Treatises on Civil Government*, 1690) differed from Hobbes insofar as he described the state of nature as one in which the rights of life and property were generally recognized under natural law, the inconveniences of the situation arising from insecurity in the enforcement of those rights. He therefore argued that the obligation to obey civil government under the social contract was conditional upon the protection not only of the person but also of private property. Rousseau (*Du contrat social*, 1762) held that in the state of nature man was unwarlike and even timid, and that his rational powers were too little developed to enable him to have any conception of rights and duties. Laws resulted from the combination of men nho agreed for mutual protection to surrender individual freedom of action, and thereby acquired for the first time a sense of moral and civic obligation. In order to retain its essentially moral character, government must therefore rest on the consent of the governed, the *volonté générale* ("general will"). Other social contract theorists provided yet other interpretations of the common theme.

These theories are historically important for the part they played in the development of modern ideas of government especially the idea of government by popular consent. Toward the end of the 18th century, however with the rise of modern historicism they became increasingly unacceptable, not so much because of their content as because of the abstractly rationalistic terms in which they were formulated. The more perceptive social contract theorists, including Hobbes had always recognized that their concepts of the social contract and the state of nature mere unhistorical. and could be justified only as hypotheses useful for the clarification of timeless political problems David Hume, in particular. is absolutely explicit on this point. But as people grew increasingly interested in history, and tried to understand political problems in terms of the historical origins and growth of specific institutions, the earlier types of abstract analysis seemed ever less relevant. Thus the term social contract fell gradually into disuse, and ceased to play a significant part in the vocabulary of modern politics (F M W)

SOCIAL HYGIENE is a term usually restricted to imply hygiene with respect to sex problems alone. Many branches of medicine. economics and government are concerned intimately with sex problems, but these, as such. are not included in social hygiene. Nor do the different attitudes taken toward sex problems in different parts of the world enter into the question, though obviously such points merit consideration. To a large extent social hygiene is a product of civilization, yet in many ancient civilizations of high order social hygiene was but little prosecuted. Rather it is a product of the health and morality which are functions of certain types of civilization. Thus in the Mosaic code, social hygiene in its modern sense is evident to a far greater extent than it was in Athenian civilization.

The measures employed in the program of social hygiene are educational. legal and protective and medical. Educational measures aim to promote understanding of sex problems and of the best methods in dealing with them; to promote sex education; and to promote the training of teachers, leaders of religious and social agencies and parents. Legal and protective measures are concerned with the repression of prostitution and with promction of sound legislation. effective law enforcement and improvements in the police departments, courts and institutiqns caring for sex offenders. Medical measures aim at the prevention and cure of venereal disease, through education, provision of facilities for diagnosis and treatment, follow-up casework. research and training of practitioners of medicine.

SOCIAL INSECTS. True social insects are those that live in populations exhibiting division of labour for various functions among mature individuals separated into reproductive and sterile castes. Societal organization has evolved independently in several groups of insects. Best known are the social wasps (*see* WASP), social bees (*see* BEE; BEEKEEPING) and ants (*see* ANT) of the order Hymenoptera and termites (*see* TERMITE) of the order Isoptera. In each of these groups, the reproductive caste (males. females, kings. queens, imagoes) is structurally and functionally distinct from the sterile castes (workers, soldiers) with vestigial reproductive organs. The mechanisms of integration are analogous and not homologous (*see* HOMOLOGY) in each of these separately evolved societal systems. Both sexes are represented in the various castes of termites. but the sterile castes of the social wasps, bees and ants are composed wholly of nonreproductive females developed from fertilized eggs while the functional male develops parthenogenetically from an unfertilized egg.

SUBSOCIAL INSECTS

The true social insects arose from subsocial insects that in each case have sexual and familial adjustments with a division of labour between adults and young, but do not have a division of labour between adults of the same sex. The social wasps emerged from the predatory solitary wasps related to *Eumenes* and *Odynerus* (subfamily Eumeninae of the family Vespidae) that store food or progressively feed paralyzed caterpillars to their larvae in burrows or constructed nests. The social bees arose from solitary bees and these in turn from solitary wasps close to the family Sphecidae. The ants form a family, Formicidae, all members of nhich are social. They are related to the solitary vespoid wasps, but there is no living family from which the ants evolved. Bethylid wasps of the genus *Scleroderma* exhibit subsocial behaviour nith either winged or wingless adults. although winged males and wingless females are most common. The termites arose from roaches. probably in early Mesozoic times. Subsocial behaviour is found among nood-eating roaches of the genus *Cryptocercus* that live in integrated families and harbour nood-digesting flagellate protozoa belonging to related groups that serve the same function in the primitive termites.

A number of other subsocial insects are known nith various elaborations of group and family organization, but these have not evolved into true social systems. Among the best known are earwigs (order Dermaptera). webspinners (order Embioptera). true bugs (order Hemiptera: Heteroptera), tent caterpillars (order Lepidoptera) and several families of beetles (order Coleoptera) including the Carabidae. Cucujidae. Staphylinidae, Platypodidae. Scolytidae, Tenebrionidae. Passalidae. Scarabaeidae and Silphidae. A chronological sequence of forms with somewhat different functions occurs in the aphids (suborder Homoptera), but these are not classified as social or subsocial because of the temporal separation of morphological types. A possible sequence from the solitary insect through family organization to the truly social system was outlined by C. D. Michener and M. H. Michener (1951): (1) the mother drops her eggs at random wherever she finds herself, with no regard for the needs of the young; (2) the mother places her eggs in, on or at least near suitable food for the young; (3) the mother places her eggs in a specially constructed nest provided with a supply of food; (4) the mother remains with her eggs, often appearing to protect them from enemies; (5) the mother remains with her offspring as well as with her eggs so that a family group results; (6) the mother remains with her eggs and young, feeding the progeny with especially collected food; (7) the mother remains with her eggs and then feeds her young which. on maturity, co-operate with her in caring for additional broods. Although all of these relations of mother to the eggs and young are to be found among various living insects, there is no question that the examples are often unrelated and that the behaviour has evolved convergently. It is possible that some of the social

Hymenoptera actually evolved through most of these stages, but in the roach to termite evolution, the male and female remain together and the mother is not the exclusive parent in the resultant families and societies. Also great social differences occur when the food is wood and cellulose in contrast to the diet of the predatory solitary wasps and the primitive social types that arose from them.

A theory of the origin of termite society was suggested by the studies of L. R. Cleveland (1934). The American wood-eating roach. *Cryptocercus punctulatus,* harbours a number of species of cellulose-digesting flagellate protozoa in its highly adapted hind intestine The roach is dependent upon the protozoa for its major food supply while most of the protozoa are dependent upon their roach hosts for their restricted habitat and for their food of wood particles. Once the protozoa are acquired by the roach they are never lost entirely and the individual then can live alone for its entire life: However, protozoa can only be transferred in fecal pellets to a recently hatched nymph from infected molting nymphs. Sexually mature adults do not molt and could not reinfect the recently hatched young. It is apparently necessary for the adults, recently hatched nymphs and molting nymphs to live together in an integrated family organization. Sexually mature adults cannot found a new colony alone, but new colonies can arise by a budding process from pre-existing colonies. This particular roach does not have unnecessary wings in the adult stage of either sex. The termites arose from a primitive type of roach that possessed four membranous wings. The adult termites can found a new colony without accompanying nymphs because the protozoa can be passed by means of liquid feces from the nonmolting adults to the recently hatched nymphs or to the recently molted nymphs that have lost their protozoa. At the same time, adults must live with their young and the young with each other to facilitate the transmission of the protozoa upon which they are dependent for the digestion of their principal food. Termite protozoa, in contrast to roach protozoa, never encyst but are also anaerobic and cannot live for long outside the bodies of their hosts. All species of termites in the four primitive families (Mastotermitidae. Hodotermitidae, Kalotermitidae and Rhinotermitidae) are dependent upon protozoa, but the highest family (Termitidae), which contains about three-fourths of all species of termites, does not harbour cellulose-digesting protozoa and has acquired other methods of cellulose digestion not yet fully understood.

A study of the subsocial insects shows that dependence of the young upon the adults and upon each other has resulted in the natural selection of group integration and specialization of function. The unit of selection is the group, rather than the individual alone, and further selection has guided evolution to a high degree of social co-ordination in several independent branches of the evolutionary tree.

TRUE SOCIAL INSECTS

Social Wasps.—The social wasps include more than 1,000 species, all members of the family Vespidae. The true social wasps belong to three subfamilies, the Polybiinae, Polistinae and Vespinae. They are primarily predaceous. They may also feed on nectar. fruit and other sweet substances. The new world genus *Brachygastra* (=*hTectarina)* stores honey in its paper cells. Social wasps in general construct paper nests composed of chewed dry wood mixed with saliva. These nests usually consist of combs in one or more layers, rarely of vertical strings of cells. The cells are generally hexagonal in shape and the layers may be covered with an outside envelope of a paper or cardboard consistency. Nests may be found in cavities in the soil or vegetation, or hanging from leaves, branches or the eaves of buildings. Eggs, larvae and pupae are found in the brood cells.

Some of the tropical stenogastrin wasps construct a vertical series of single cells attached to a leaf by a strand. The oriental genus *Stenogaster* has a few primitive social species that construct small nests with a few horizontally attached cells. The female progressively feeds the larvae which eventually pupate in sealed cells, and the daughter wasps remain with the mother after emergence. The primitive African genus *Belonogaster* has larger colonies with a small degree of division of labour between older egg-laying females and younger foraging and nest-building females without differentiation into a distinctive worker caste. True sterile workers appear in *Polybia* and new colonies are founded by the swarming of several queens with many workers—a type of colony establishment found only in tropical wasps.

The most familiar social wasps are the temperate species of *Polistes* (Polistinae) and the vespine genera *Vespa, Vespula* and *Dolichovespula.* These temperate wasps and hornets have colonies lasting only through a single season. and colony founding occurs only in the spring by an ovenvintering fertilized queen. A few more primitive species have polygynous colonies with several reproducing females. but by far the majority are monogynous with a single queen and a large number of workers. New fertile females appear only in the fall when males are also produced. The entire colony perishes in the fall except for the over intering mated females. each of whom may became the queen of a new colony in the spring. The *Polistes* queen builds a few cells attached to a single stalk hanging downward in a sheltered place. often under the overhanging eaves of a house or shed. As the workers appear, new cells are added horizontally until a fairly large comb with as many as 500 hexagonal cells is formed. The comb of *Polistes* is naked, without a paper envelope. *Vespa* and *Vespula* found their colonies in the same manner as *Polistes,* but their nests usually consist of several combs in storied layers, the whole covered by a paper envelope that is destroyed and rebuilt as the population grows. The nests may be built in animal burrows, in hollow branches or trunks of trees or hanging from branches or houses. The brood cells open below as is characteristic of both primitive and highly social wasps. The queen cements an egg to the upper end of each cell. The larva hangs downward in each cell and is progressively fed with chewed up portions of insects caught by the queen or the later developed workers. The mature larva spins a cocoon and caps its cell before pupation. The adult emerges from four to six weeks after the egg is laid, and with numerous workers present the queen may devote herself entirely to egg laying.

The young grubs stimulate nursing activity from the adult queen or workers by emitting secretions from their mouths. Social facilitation through the exchange of nutrient substances or through tactile and chemical stimulation is termed trophallaxis and is characteristic of social insects in general.

Socially parasitic wasps have evolved from their social ancestors in both *Polistes* and *Vespula.* Social parasitism has appeared independently many times among the major groups of social Hymenoptera. The so-called cuckoo wasps have lost the worker caste. The cuckoo queen first invades an established host colony and during the ensuing battle many of the host workers are killed. Ultimately the host queen is also killed. A parasitized colony will not develop host males and fertile females in the late summer, but the cuckoo brood will be fed by the surviving host workers and will ultimately develop fertile males and females of the social parasite.

L. H. Taylor (1939) postulated the stages in the evolution of social parasitism among wasps as follows: (1) intraspecific, facultative temporary parasitism in which queenless nests are invaded by queens of the same species; (2) interspecific, facultative temporary parasitism in which queenless nests are invaded by queens of different, but closely allied, species with gradual replacement of the host workers; (3) interspecific, obligatory temporary parasitism in which the invading queen has lost her ability to found her own nest, but develops her own brood of workers; (4) interspecific, obligatory permanent parasitism in which the worker caste is lost.

Social Bees.—Truly social bees constitute about 5% of the total of well over 10.000 species, and there is little question that the social adaptations are an evolutionary specialization. The functional adaptations of the mouth parts, hairs and leg structures for nectar and pollen transportation and feeding evolved long before the origin of the worker caste, but many specializations of the species and genera of workers evolved subsequent to the origin of social behaviour. Short-tongued bees are ancestral to long-tongued bees, burrowing and simple architecture is ancestral to the use of wax and complicated architecture, and the storage of honey in special cells evolved later than the storage of a paste of pollen and nectar.

The Bombidae or bumblebees are probably the most primitive of the true social bees. About 300 species are found in the north temperate and arctic regions and a few extend into the tropics. As is the case with the temperate social wasps, the fertilized female of *Bombus* overwinters in a sheltered niche and seeks a favourable site for a nest in the spring. Most species of *Bombus* find empty mouse nests or animal burrows in the soil or in fallen logs, but a few may construct nests on the surface in thick vegetation. After the nest site is selected, the solitary queen gathers pollen and nectar, mixes them into a paste and builds a circular wall of wax around the lump of paste placed on the floor of the nest cavity. Wax is produced from both dorsal and ventral abdominal glands. She lays several eggs on the lump of paste and closes over the wax cell with her jaws. Soon after the first batch of eggs is laid, the queen builds a large "honey pot" of wax at the entrance to the nest, and in this she stores honey for her own use. The eggs hatch in about four days and the larvae soon eat the paste. The queen opens the end of the cell and progrersively feeds the growing larvae with a liquid mixture of pollen and honey. The waxen cover over the larvae is enlarged as the young grow, and around the 11th day the full-grown larvae spin separate cocoons. While the first brood is developing, the queen not only feeds and guards the larvae, but also warms them with her body heat. The adult norkers that emerge with the help of the queen from the first cocoons are always smaller than the queen, but vary considerably in their size range. They soon relieve their mother of her foraging role, enlarge the nest, build new cells, store honey in newly constructed cells or old cocoons and tend the young larvae. The workers may lay eggs, but these only develop into males because the workers never mate. In the late summer, abundantly fed larvae develop into fertile females and ovenvinter after mating. At the height of the population in the late summer, the whole colony may number from 100 to 600 bees. All die in the fall with the exception of the impregnated females. In the tropics, bumblebees form perennial colonies and s arming occurs.

Socially parasitic bumblebees belonging to the genus *Psithyrus* lack the worker caste and also lack the pollen-collecting apparatus on the legs. Each species has a single host species or a favourite species of *Bombus* with which it lives. *Psithyrus* seems to have evolved from *Bombus,* and some species of *Bombus* have queens that on occasion invade the nests of their own species rather than found independent colonies of their own. The European species of *Psithyrus* resemble the host species of *Bombzrs* in colour and size, but the North American *Psithyrus* do not exhibit the same degree of resemblance. The queen of *Psithyrus* kills the *Bombus* queen and usurps her place in the *Bombus* colony. The *Bombus* workers tend the eggs of the *Psithyrus* queen until they develop into overwintering *Psithyrus* queens.

The stingless bees of the family Meliponidae are tropical and subtropical. The genus *Melipona* is confined to the new world while the large genus *Trigona* is found in all of the tropical regions of the world. Although without a defensive sting. these bees can be very annoying by swarming over the intruder, buzzing, and biting exposed areas of the skin. The worker caste is distinct from the queen, not only in the loss of egg-laying capacity, but also in the possession of functional pollen-gathering structures on the legs. The colonies are monogynous until virgin daughter queens are developed, and new colonies are formed by the young impregnated queen accompanied by a swarm of workers. In *Melipona* the cell containing a developing queen cannot be differentiated from those containing young workers or males, while in *Trigona* the queen cell is distinct from the others (H. F. Schwarz, 1948). The nests are usually found in cavities in trunks or branches of trees. and more rarely the nest cavity may be subterranean. Commonly ground nests and arboreal nests of termites serve as shelters for a stingless bee nest, and the constructions of other animals may also be used. The bees typically seal off the nest cavity from the surrounding material by mud or waxen partitions Wax is produced from dorsal abdominal glands. The entrance to the nest may be simple or an elaborate funnel constructed by the bees. Brood combs may be in clusters or in layered stories. Honey and pollen is stored in globular clusters of pots, and in a few species the pots with honey differ from those containing pollen. The adult bee population varies among species from a few hundred to as many as 80,000. The meliponid bees in general store the larval food in brood cells that are soon sealed and the developing larvae are not fed progressively as they are in other social bees. Meliponid bees have evolved a robber species that regularly steals food from other bees.

W. E. Kerr (1950) gave evidence of the genetic distinction of workers compared to queens in the genus *Melipona.* All other social bees including the genus *Trigona* have trophogenic determination (determination by food) of the female castes. Because of the phylogenetic position of these somewhat advanced bees, it may be assumed that genetic infiltration occurred during evolution and triggered the original physiological mechanisms of caste determination.

Social life among bees reaches its highest development in the honeybees or domestic hive bees of the genus *Apis. Apis* contains only four species and all except the domestic honeybee *(Apis mellifica)* are found only in the tropical orient. The family Apidae contains only this one genus and the other social bees already discussed are included in separate families, which together with the solitary bees constitute the superfamily Apoidea. The common honeybee has been introduced into almost all countries of the world and it is occasionally established in the natural habitat where it successfully competes with native social bees. Colonies of honeybees were brought to the new world by the Jamestown colonists in 1607.

The castes are distinct and easily distinguished. The drone (male) differs from the female castes by its blunter abdomen and its large eyes that almost touch at the top of the head. The queen can be recognized by her large abdomen which extends beyond the closed wings, and by the reduction of the pollen-transporting structures on her legs. She is capable of laying over 3,000 eggs in a single day. The reproductive organs of the workers are usually rudimentary and the occasional egg laid by a worker is never fertilized and can only produce a drone.

The colonies are perennial and established by a large swarm of workers accompanying a queen. The population of a thriving colony may contain 50,000 to 80,000 workers. The combs are composed of wax secreted from ventral abdominal glands. Each comb contains many hexagonal cells arranged in two series back to back, and many combs may hang vertically with sufficient space between them to enable the bees to move freely. Honey is stored in combs separate from the brood cells; the brood cells are of three types—small ones for worker brood. slightly larger ones for drone brood, and very large cells constructed for the larvae of new queens. The queen cells are few in number, ovoid and irregular in form, and are only constructed by the workers when needed. In addition to wax, the bees collect propolis—a sticky substance exuding from buds of trees—which is used for filling up crevices and for gluing the combs to their base. The queen lays an egg in each brood cell previously constructed by the workers. A fertilized egg is laid in each worker cell or queen cell and an unfertilized egg is laid in each drone cell. Probably some stimulus from the size of the cell wall opens or closes the passage from the spermatheca where the sperms are stored and thus enables or prevents sperms from entering the oviduct through which the eggs pass from the ovaries. Eggs hatch in about 3 days, workers develop in about 21 days, drones in 24 days and the queen in about 16 days. Young larvae, irrespective of caste, are fed a secretion from the salivary glands of the workers that is rich in protein and other substances. This so-called "royal jelly" is progressively fed queen larvae until they pupate, but the drone and worker larvae are nourished, after the third or fourth day, only with "bee bread," a mixture of pollen and honey.

The trophogenic determination of female castes in the honeybee is better known and more distinctive than for the other social insects, but, with modifications and gradations, it is probably the basic mechanism of caste determination except for the genetic determination already noted in the genus *Melipona.* The queen lives from five to eight years and performs no other functions than reproduction and colony founding as an essential part of the swarm. She may lay as many as 2,000,000 eggs during her lifetime. Soon after emergence a new queen takes her nuptial flight accompanied by a number of drones. Mating usually takes place in the air and the fertilized queen returns to the nest of her origin. At the time of the first swarm, it is usually the old queen that accompanies the swarm to the new colony site. but if a second swarm occurs during the season, it is usually headed by a new queen.

At the end of swarming and nectar gathering, the honeybee colony exterminates the drones by depriving them of food, ejecting them from the hive and occasionally killing them directly. Drone elimination also occurs among the Meliponidae. This control over population numbers of drones is a most remarkable social phenomenon. After emergence, the worker bee shows a temporal succession of activities. The first stage of about two weeks is that of a nurse bee attending and feeding the brood and building the comb. The second period of about ten days is occupied with household activities, receiving and ripening the nectar, storing the honey, cleaning the hive, guarding the entrance and secreting wax. In the last period the functions are those of a field bee for 20 to 30 days during which it forages for pollen and nectar. In case of need, a worker in the early period of field foraging may return to its preceding activities as a nurse or house bee, so the temporal division of labour is not strictly rigid in sequence. Summer-hatched workers live for about one to two months, but those harched in autumn live through the winter on stored honey and resume their work in the spring.

In most social insects, trophallaxis, or the exchange of nourishment, facilitates social interaction and is probably a major stimulus for mutual attraction, particularly between young and adults. Young wasps, ants and termites give off secretions which their nurses avidly lick. and the nurses in turn feed the young with collected food: secretions and sometimes even excretions. The larval honeybees do not secrete liquids that attract their nurses, so far as is known. However, the nurse workers progressively feed the young with collected food somewhat modified when regurgitated in the form of honey and predigested pollen. The salivary secretion or "royal jelly" fed to all larvae soon after hatching is rich in proteins, fats and carbohydrates. T. C. Schneirla (1946) included the exchange of olfactory and tactile stimuli in the concept of trophallaxis. and there is little doubt that the sense organs of taste, smell and touch are used for interaction in all social insects including the relations between nurses and larval honeybees.

A remarkable system of communication was discovered among honeybees by K. von Frisch (1950, 1955). A scout field worker may learn to associate food with colour in a range from ultraviolet to, but not including, scarlet red. The bees that have discovered a rich source of food also attract other bees by an odour emitted from a scent gland on the abdomen. After returning to the hive, the scout bee tnay be accompanied by a number of workers back to the food source. Odour of the food is also imparted to the hive bees. The scout may communicate the distance, direction and amount of food by means of a food dance on the comb, even though the scout is experimentally removed following the dance. If the food is 50 m. or less from the hive, the scout performs a turning dance, first in one direction and then in the other direction. If the distance is between 50 and 100 m., the dance includes a short straight run between the turns and the abdomen is wagged during this straight run. At distances greater than 100 m., the number of turns decreases per unit of time while the wagging motions increase in intensity. The time or the effort needed to reach the food seems to be the basis for the bees' estimation of distance and the dance varies with head winds, tail winds or hills rather than with absolute distance. If the food is toward the sun, the straight run is vertically upward on the comb. A downward run indicates a direction away from the sun. A deviation of 10° to the right of the vertical indicates the direction of the food 10° to the right of the sun. Any angle to the right or left of the vertical corresponds to the angle to the right or left of the sun. If the comb is on its side, the straight run of the dance is in the direction of the iood. If the sun is shaded by clouds. the bees are capable of orientation in relation to the position of the sun by means of their sensitivity to polarized light intensities. The amount of food is indicated by the vigour of the dance. Small amounts or dilute food do not stimulate dancing behaviour, while larger amounts or sweeter concentration produce more energetic dances that stimulate a isrger number of hive bees to seek the food. The hive bees that react to the dance of the scout follow the dancer with their antennae and heads and at intervals between dances the scout may feed the followers with a little nectar. Although this type of communication has been called the "language" of the bees, and it demonstrates learning by association, there is no learning of symbols comparable to human communication. Both the dance and the response to the dance are unlearned and instinctive. implying hereditary behaviour.

Ants.—Social life among the Hyinenoptera attains its highest level in the ants. All ants are social, but varying degrees from relatively simple to relatively specialized may be found in the phylogenetic series of subfamilies. genera and more than 5,000 species. Nearly 600 species and subspecies are recorded from the United States (W. S. Creighton, 1950). The nests of ants are commonly found in excavated galleries in the soil or fallen logs, but many ants are moundbuilders on the surface of the ground, or are arboreal, with nests in natural or prepared cavities of plants or constructed of paperlike carton composed of plant materials chewed and mixed with salivary secretions. Ants may become highly adapted to plants with natural cavities in their leaf petioles, thorns. twigs, trunks or roots. Such plants that regularly attract ants are known as ant plants. Evolutionary adaptation, however, seems to be largely in the ants rather than in the plants. The ants of the genus Oecophylla in tropical Africa and the orient construct their arboreal nests of leaves attached by means of silk spun from the salivary glands of the larvae. Some workers hold the leaf edges together while other workers holding larvae in their jaws weave the silk-secreting larvae back and forth from one leaf to the other. Ant nests on the whole are more loosely organized than the cells and combs of social wasps and bees.

Eggs are laid by the queens and gathered by the workers in masses, often in nursery chambers in the nests. The eggs hatch into legless larvae or grubs with proportionately small heads (in general. characteristic of the higher Hymenoptera) but often with specialized "pockets" in which iood pellets are placed by their nurses or with specialized glands that secrete attractive substances licked by their nurses. Larvae are transported to favourable temperature and moisture conditions in the nest and may be sorted according to size and stage of development.

The sterile caste of primitive ants is composed of wingless workers of one size (monomorphic). In the ponerine ants, the worker is structurally close to the queen, but lacks simple eyes, wings and well-developed ovaries. Occasionally workers may lay eggs that invariably develop parthenogenetically into males. The more advanced ants in all of the subfamilies, including a few ponerines, may have workers of different sizes (polymorphic) and in some genera nutritive and protective functions may be somewhat divided in structurally specialized worker and soldier castes. Some species retain only one or two of the worker types found in their polymorphic ancestors. Large soldiers may retain many worker roles or they may specialize for protection only. In two unrelated genera in different subfamilies (*Colobopsis* and *Cryptocerus*) the soldier plugs the doorway of the nest with its truncated head, allowing the workers of the colony to pass in and out but rejecting all foreigners. The factors that cause differential development of the various female castes are not clearly understood, but it may be presumed that either quantity or quality of food may be involved. The potentiality for the special types of polymorphism must have a genetic basis, because rhe caste types are characteristic of species, genera and groups of genera.
